- Assess for bleeding or drainage from the affected ear. *Infection and hemorrhage are possible complications.*
- Administer antiemetics as ordered to prevent vomiting. *Vomiting may increase the pressure in the middle ear, disrupting the surgical site.*
- Elevate the head of bed and position the patient on the unaffected side. *This position minimizes the pressure in the middle ear.*
- Assess for vertigo or dizziness, especially with ambulation or movement in bed. Avoid unnecessary movements such as turning. Take measures to ensure safety during ambulation. *Surgery on the ear may disrupt equilibrium, increasing the risk of falling.*
- Assess hearing postoperatively. Stand on the unaffected side to communicate and use other measures such as written messages as needed for effective communication with the patient with impaired hearing. Reassure the patient that decreased hearing acuity immediately after surgery is expected. *Hearing improvement, if an expected result of the ear surgery, typically does not occur until earplugs are removed and edema and drainage at the operative site have resolved. If no reconstruction of the middle ear is done or the cochlea is involved, permanent hearing loss in the affected ear may be an expected result.*
- Remind to avoid coughing, sneezing, or blowing the nose. *These increase pressure in the middle ear.*

Health Education for the Patient and Family

- Provide instructions for home care:
  a. To prevent contamination of the ear canal, avoid showers, shampooing, and immersing the head until the physician says you can do so.
  b. Keep the outer earplug clean and dry, changing it as needed. Do not remove inner ear dressing until instructed to do so by the physician.
  c. Avoid blowing the nose; if you need to cough or sneeze, keep the mouth open.
  d. Do not swim or dive without physician approval. Check with your doctor regarding air travel.
  e. Meclizine hydrochloride (Antivert) or other antiemetic/antihistamine medication may be necessary for up to 1 month following surgery.
  f. Fever, bleeding, increased drainage, increased dizziness, or decreased hearing after discharge may indicate a complication. Notify the physician if any of these occur.

THE PATIENT WITH OTOSCLEROSIS

Otosclerosis is a common cause of conductive hearing loss. Abnormal bone formation in the osseous labyrinth of the temporal bone causes the footplate of the stapes to become fixed or immobile in the oval window. The result is a conductive hearing loss.

Otosclerosis is a hereditary disorder with an autosomal dominant pattern of inheritance. It occurs most commonly in Caucasians and in females. The progressive hearing loss typically begins in adolescence or early adulthood and seems to be accelerated by pregnancy. Although both ears are affected, the rate of hearing loss is asymmetric. Because bone conduction of sound is retained, the patient may be able to use the telephone but have difficulty conversing in person. Tinnitus may also be associated with otosclerosis.

On examination, a reddish or pinkish-orange tympanic membrane may be noted because of increased vascularity of the middle ear. The Rinne test shows bone sound conduction to be equal to or greater than air conduction, an abnormal finding.

Patients with otosclerosis may choose conservative treatment, relying on a hearing aid to improve their ability to hear and interact with others. Sodium fluoride may be prescribed to slow bone resorption and overgrowth. Surgical treatment involves a stapedectomy and middle ear reconstruction or a stapedotomy. A *stapedectomy* is a microsurgical technique for removing the diseased stapes. A metallic prosthesis is then inserted, with one end connected to the incus and the other inserted into the oval window. *Stapedotomy* involves creation of a small hole in the footplate of the stapes and insertion of a wire or platinum ribbon prosthesis. An argon, KTP, or CO_2 laser may be used for surgery. Surgery usually restores hearing for the patient with otosclerosis.

Education and referral of the patient to appropriate community agencies are important nursing care priorities for the patient with otosclerosis. For the patient who chooses surgical treatment, nursing care is similar to that for other patients undergoing ear surgery. The following nursing diagnoses may be appropriate:

- *Risk for Injury* related to hearing loss or postoperative vertigo
- *Impaired Hearing* related to bony sclerosis of the stapes
- *Impaired Verbal Communication* related to hearing loss
- *Anxiety* related to concern about transmission of a genetic disorder to children.

THE PATIENT WITH AN INNER EAR DISORDER

Disorders affecting the inner ear are much less common than disorders of the outer or middle ear. Inner ear disorders affect equilibrium and may also affect sensorineural hearing, the perception of sound. Labyrinthitis and Ménière's disease are the most common diseases of the inner ear. Vertigo may be a disorder of the inner ear itself or a manifestation of other disorders.

Pathophysiology and Manifestations

The inner ear (also called the *labyrinth*) contains the cochlea and the semicircular canals. The hair cells and neurons that allow sound perception and transmission to the auditory center of the brain are in the cochlea. The semicircular canals filled with endolymph are the primary organs involved in maintaining equilibrium. Disruption of this portion of the ear by an inflammatory process or excess endolymph not only affects balance but may also result in permanent hearing loss.

VERTIGO

Normally, the integration of input from the labyrinths, eyes, muscles, joints, and neural centers maintains balance and posture. This input and integration can be affected by disorders of the labyrinth, vestibular nerve or nuclei, eyes, cerebellum, brainstem, or cerebral cortex, causing vertigo. Vertigo, the sensation of movement when there is none, is a disorder of equilibrium. The sensation of whirling, rotation, or movement is described as either subjective or objective.

Patients with subjective vertigo report the sensation of being in motion in a stable environment. This is not always a sense of spinning; the patient may have a sense of tumbling or falling forward or backward. The sensation is reversed in objective vertigo; patients report a sensation of stability in a moving environment. This motion may be perceived as the room spinning around the patient or the ground rocking beneath the patient's feet. Dizziness, which may be mistaken for vertigo, is a sensation of unsteadiness, lack of balance, light-headedness, or movement within the head. The person who is dizzy does not have the rotational sensation felt with vertigo.

Vertigo may be disabling, resulting in falls, injury, and difficulty walking. Attacks of vertigo are often accompanied by nausea and vomiting, nystagmus, and autonomic symptoms such as pallor, sweating, hypotension, and salivation.

LABYRINTHITIS

Labyrinthitis, also called otitis interna, is inflammation of the inner ear. It is an uncommon disorder, because the bony protection of the membranous labyrinth makes it difficult for organisms to enter the inner ear. However, bacteria, viruses, and other organisms may enter and infect the inner ear through the oval window during acute otitis media, through the cochlear aqueduct during meningitis, or through the blood. Viral labyrinthitis is suspected when the patient has a sudden onset of symptoms after an upper respiratory infection or when there is no evidence of concurrent otitis media. Labyrinthitis also may result from an autoimmune process of unknown etiology.

MANIFESTATIONS Inflammation of the labyrinth typically causes vertigo, sensorineural hearing deficit, and **nystagmus** (rapid involuntary eye movements).

Vertigo is the hallmark manifestation of inner ear disorders. The vertigo of labyrinthitis is severe and often accompanied by nausea and vomiting. Any movement can aggravate the vertigo, and falling is a significant risk if the patient attempts to stand. Vertigo lasts days to weeks in labyrinthitis, making patient education a vital component of care.

Hearing loss in the ear affected by labyrinthitis may be temporary or permanent. If inflammation destroys tissue of the membranous labyrinth, the hearing loss may be complete and permanent.

The involuntary rhythmic eye movements of nystagmus may not be present in all patients with labyrinthitis. When present, the eye movement is typically horizontal. Applying positive or negative pressure to the tympanic membrane of the affected ear may stimulate nystagmus, as will caloric testing (irrigating the ear canal with warm or cool water). Although nystagmus may also be a symptom of brainstem or cerebellar dysfunction, vertigo and hearing loss are not typically associated with those disorders.

MÉNIÈRE'S DISEASE

Ménière's disease, also known as endolymphatic hydrops, is a chronic disorder characterized by recurrent attacks of vertigo with tinnitus and a progressive unilateral hearing loss. This disorder affects men and women equally, with adults between the ages of 35 and 60 at highest risk. The cause of Ménière's disease is unclear, although the most common form of the disease is thought to result from viral injury to the fluid transport system of the inner ear. Other factors that may increase the risk for Ménière's disease include trauma, bacterial infection, autoimmune processes, and selected drugs and toxins (Grossman & Porth, 2014). A family history of the disease increases risk, suggesting a possible genetic link in some patients.

Ménière's disease results from an excess of endolymph, the fluid in the membranous labyrinth of the inner ear. Although the precise pathophysiologic mechanism leading to accumulation of endolymph is unclear, it is thought to result from impaired filtration and excretion of the fluid by the endolymphatic sac (Grossman & Porth, 2014). Excessive pressure resulting from the increased fluid volume causes neural organs of the cochlea to degenerate.

COURSE AND MANIFESTATIONS The onset of Ménière's disease may be gradual or sudden. It is characterized by recurrent attacks of vertigo, gradual loss of hearing, and tinnitus. Attacks may be preceded by a feeling of fullness in the ears, and a roaring or ringing sensation. The sensorineural hearing loss and tinnitus are usually unilateral but can become bilateral. Attacks of severe rotary vertigo occur abruptly and often unpredictably, lasting from minutes to hours. An attack may be linked to increased sodium intake, stress, allergies, vasoconstriction, or premenstrual fluid retention. As the disease continues, hearing loss progresses and the vertigo can be severe enough to cause immobility, nausea, and vomiting. Attacks are often accompanied by hypotension, sweating, and nystagmus.

●○● INTERPROFESSIONAL CARE

The manifestations associated with inner ear disorders are similar, making testing necessary to establish a diagnosis. Once the diagnosis is determined, collaborative care is directed toward managing symptoms and preventing permanent hearing loss. Patients with labyrinthitis or an acute attack of Ménière's disease may require hospitalization to manage the vertigo and its effects.

DIAGNOSIS

The following diagnostic studies may be ordered:

- *Electronystagmography (caloric testing)* evaluates the vestibulo-ocular reflex by identifying eye movements (nystagmus) in response to changes in head position or instillation of warm or cool water into the ear canal. In patients with impaired vestibular function, the normal nystagmus response is blunted or absent. This portion of the test is contraindicated in patients who have a perforated tympanic membrane.
- *Rinne* and *Weber tests* of hearing show decreased air and bone conduction on the affected side if a sensorineural hearing loss is present. In Ménière's disease, audiology shows sensorineural hearing loss involving the low tones.
- *X-rays* and *CT scans* of the petrous bones are used to evaluate the internal auditory canal. In patients with Ménière's disease, the vestibular aqueducts may be shorter and straighter than normal.
- A *glycerol test* is conducted by giving the patient oral glycerol to decrease fluid pressure in the inner ear. An acute temporary hearing improvement is considered diagnostic for Ménière's disease.

MEDICATIONS

In Ménière's disease, a diuretic such as acetazolamide (Diamox) or hydrochlorothiazide may be prescribed to reduce endolymphatic pressure. A central nervous system depressant such as diazepam (Valium) or lorazepam (Ativan) may halt an attack of vertigo. Parenteral droperidol (Inapsine) provides both a sedative and antiemetic effect, making it a useful drug for acute attacks. Antivertigo/antiemetic medications such as meclizine (Antivert), prochlorperazine (Compazine), or hydroxyzine hydrochloride (Vistaril) are prescribed to reduce the whirling sensation and nausea. Intratympanic gentamicin, injected through the tympanic membrane into the middle ear, has been shown to be effective in reducing the vertigo of Ménière's disease. The gentamicin damages vestibular hair cells, effectively reducing attacks of vertigo while causing less hearing loss than traditional surgical approaches (De Beer et al., 2007).

TREATMENTS

Bed rest in a quiet, darkened room with minimal sensory stimuli and minimal movement provides the most comfort for the patient experiencing an acute attack of vertigo.

Between acute attacks, management of the patient with Ménière's disease is directed at preventing future attacks and preserving hearing. A low-sodium diet (2 g/day) helps reduce labyrinthine pressure. A very low salt diet (1 g) may be prescribed if moderate sodium restriction is ineffective in controlling attacks. Patients should avoid tobacco, which causes vasoconstriction and can precipitate an attack, along with alcohol and caffeine.

SURGERY

When episodes of vertigo cannot be controlled through medical interventions, surgery may be necessary. Surgical *endolymphatic decompression* relieves the excess pressure in the labyrinth; a shunt is then inserted between the membranous labyrinth and the subarachnoid space to drain excess fluid away from the labyrinths and maintain lower pressure. This procedure preserves hearing for most patients. Vertigo is relieved in approximately 70% of patients, but about half of patients undergoing this procedure continue to experience sensations of fullness and tinnitus.

Destruction of a portion of the acoustic nerve is an alternative to shunting procedures. In a *vestibular neurectomy*, the portion of cranial nerve VIII that controls balance and sensations of vertigo is severed. This procedure relieves vertigo for up to 90% of patients. Although there is a risk of damage to the cochlear portion of the nerve and resultant hearing loss, for most patients hearing loss stabilizes after neurectomy, even improving for some.

The surgery of last resort for Ménière's disease is a *labyrinthectomy*. The labyrinth is completely removed, destroying cochlear function. This procedure is used only when hearing loss is nearly complete and vertigo is persistent. Although labyrinthectomy relieves vertigo in nearly all cases, the patient may remain unsteady and have continued problems with balance.

After surgery on the inner ear, the patient is positioned to minimize ear pressure and vertigo. Movement is restricted, and assistance is provided when the patient gets up. Antiemetics and antivertigo

medications are used to manage symptoms resulting from disruption of the inner ear. Complications include infection and leakage of cerebrospinal fluid.

●○● NURSING CARE

The patient with an inner ear disorder has multiple nursing care needs related to the manifestations of the disorder.

Health Promotion

Health promotion focuses on identifying patients with potential inner ear disorders. Persistent episodes of dizziness, ringing in the ears, balance problems, or loss of hearing should be reported to a healthcare provider. Patients diagnosed early may have a lower risk for injury and can be taught strategies for maintaining as near normal as possible their work and social lives.

Assessment

In addition to the following, assess the older patient for other medical causes of imbalance and dizziness, such as neurologic dysfunction, musculoskeletal and cardiovascular disorders, and endocrine problems.

- *Health history:* medication use; presence of vertigo, tinnitus, nausea and vomiting, and hearing loss; balance problems; frequency and duration of symptoms, precipitating factors for an attack
- *Physical assessment:* vital signs, general health; hearing, nystagmus, balance.

Priorities of Care

Maintaining safety is the priority of care for patients with inner ear disorders. Attacks of vertigo may occur without warning and can be so severe that the patient is unable to remain upright.

Diagnoses, Outcomes, and Interventions

The risk for trauma due to attacks of vertigo in patients with inner ear disorders is great. If frequent attacks are accompanied by nausea, nutrition may be compromised. Constant or intermittent tinnitus can interfere with sleep and rest. Finally, because nearly all inner ear disorders are associated with some degree of hearing loss, which may be progressive, the patient has significant psychosocial needs.

Risk for Trauma

Because of the unpredictable nature of attacks, the patient with vertigo due to an inner ear disorder needs to learn strategies for dealing with an acute episode. Because vertigo tends to be chronic except in acute labyrinthitis, the emphasis is on helping the patient develop strategies to reduce the frequency of attacks and the risk of injury.

Expected Outcome: Patient will remain free of injury.

- Monitor for vertigo, nystagmus, nausea, vomiting, and hearing loss. *Monitoring is important to determine the severity of impairment, the duration of attacks, and the patient's ability to predict an impending attack.*
- Instruct to not get up without assistance during episodes of vertigo. *During attacks of vertigo, assistance reduces the risk of falling.*

SAFETY ALERT

During an acute attack of vertigo, keep on bed rest with the side rails raised and the call light readily accessible.

- Teach to avoid sudden head movements or position changes. *Sudden movement may precipitate an attack of vertigo.*
- Administer prescribed medications as ordered, including antiemetics, diuretics, and sedatives. *These medications may reduce the frequency, severity, and duration of vertigo attacks.*
- Instruct to take the prescribed medication and lie down in a quiet, darkened room when an impending attack is sensed. *These measures help protect the patient from injury and may shorten the duration and reduce the severity of the attack.*
- Advise to pull to the side of the road and wait for the symptoms to subside if an attack occurs while driving. *Perception and judgment necessary for safe driving may be impaired during an acute attack; pulling off the road is vital to protect the safety of the patient and others.*
- Discuss the effect of unilateral hearing loss on the ability to identify the direction of sounds. To ensure safety, encourage the patient to use other senses (e.g., when crossing the street). *Just as depth perception changes when vision is lost in one eye, sound perception and differentiation of direction change when hearing is lost unilaterally.*

Disturbed Sleep Pattern

The tinnitus often associated with inner ear disorders may be loud and continuous, interfering with the patient's ability to concentrate, relax, and sleep. It may be perceived as a continuous high-pitched whine, buzzing, ringing, or a humming sound. In some patients, it may have a pulsatile quality.

Expected Outcome: Patient will identify and use strategies to achieve restful sleep.

- Refer for a complete hearing and ear examination if one has not been done. *Although most tinnitus is associated with hearing loss, often due to noise exposure, it may also be associated with treatable conditions such as impacted cerumen, hypertension, cerebrovascular disorders, and other conditions.*
- Discuss options for masking tinnitus to promote concentration and sleep:
  - Ambient noise from a radio or sound system
  - Masking device or white-noise machine
  - Hearing aid that produces a tone to mask the tinnitus
  - Hearing aid that amplifies ambient sound.

  These techniques or devices help mask the subjective perception of tinnitus, allowing the patient to focus on something other than the sound.
- Discuss the possible risks and benefits of medications to treat tinnitus. *Many medications have been used to treat tinnitus; oral antidepressants such as nortriptyline (Aventyl, Pamelor) taken at bedtime have been shown to be most effective.*

Continuity of Care

Because disorders of the inner ear disrupt balance, safety is a primary focus of teaching. Assist the patient to identify possible hazards in the home environment. Discuss the following points during the teaching session:

- Change positions slowly, especially when ambulating.
- Turn the whole body rather than just the head.

- Sit down immediately with the onset of vertigo and lie down if possible.
- Take prescribed antiemetic and antivertigo medications.
- Wear medical alert identification.
- If appropriate, discuss the surgical procedure, the immediate postoperative period, and the long-term effects of the surgery.
- Discuss alternative communication techniques as needed.
- Suggest the following resources: the Better Hearing Institute and Self-Help for Hard of Hearing People.

THE PATIENT WITH A VESTIBULAR SCHWANNOMA

A vestibular schwannoma (or acoustic neuroma) is a benign tumor of the vestibular portion of cranial nerve VIII. It typically occurs in adults between the ages of 40 and 50. Vestibular schwannomas are common, accounting for about 9% of primary brain tumors. Although usually unilateral, people with neurofibromatosis type 2, a genetic disorder, frequently develop bilateral schwannomas (DeAngelis & Wen, 2012).

These tumors usually occur in the internal auditory meatus, compressing the auditory nerve where it exits the skull to the inner ear. If allowed to grow, the tumor eventually destroys the labyrinth, including the cochlea and vestibular apparatus. As the tumor expands, it erodes the wall of the internal auditory meatus. The tumor may eventually impinge on the brainstem and cerebellum, with development of obstructive hydrocephalus. Cranial nerves VII (facial) and V (trigeminal) are often affected by the expanding tumor; the tumor frequently wraps around the facial nerve.

Early manifestations of vestibular schwannoma are those associated with disorders of the inner ear: tinnitus, unilateral hearing loss, and nystagmus. Dizziness or vertigo may occur. As the tumor expands and occupies increasing amounts of space in the closed cranium, the patient experiences neurologic signs related to the area of the brain affected.

The presence of the tumor can generally be identified on CT or MRI scans. X-ray films of the petrous pyramid of the temporal bone may show erosion caused by the tumor. The treatment of choice for vestibular schwannoma is surgical excision using microsurgery techniques or destruction of the tumor via stereotactic radiotherapy. Bevacizumab (Avastin), a drug that blocks blood vessel growth within tumors, may be beneficial in patients with neurofibromatosis type 2 (Lustig & Schindler, 2012).

Postoperative nursing care focuses on preserving cerebral function. Position the patient to minimize cerebral edema and monitor frequently for signs of increased intracranial pressure. Because the gag reflex may be affected, assess the patient carefully before food and fluids are allowed by mouth. Speech therapy is often prescribed for the patient after surgery. Because deficits may not resolve for a long time after surgery, education and support are vital components of nursing care for the patient. (See Chapter 42 for care of the patient undergoing craniotomy.)

THE PATIENT WITH HEARING LOSS

Hearing loss is a significant problem, affecting an estimated 17% of adults in the United States. The problem of hearing loss is particularly significant in older adults, affecting about 30% of people between the ages of 65 and 74, and 47% of those over age 75 (National Institute on Deafness and Other Communication Disorders [NIDCD], 2010). As many as 70% of nursing home residents have impaired hearing.

Hearing loss impairs the ability to communicate in a world filled with sound and hearing individuals. A hearing deficit can be partial or total, congenital or acquired. It may affect one or both ears. In some types of hearing loss, the ability to perceive sound at specific frequencies is lost. In others, hearing is diminished across all frequencies.

Patients with hearing loss often display signs that caregivers can recognize. The voice volume of the patient with impaired hearing frequently increases, and the patient positions the head with the better ear toward the speaker. The patient frequently may ask people to repeat what they have said or respond inappropriately to questions or statements. A question may elicit a blank look if the patient has not heard or understood its content.

Pathophysiology and Manifestations

Lesions in the outer ear, middle ear, inner ear, or central auditory pathways can result in hearing loss. The process of aging also can affect the structures of the ear and hearing. Hearing loss is classified as conductive, sensorineural, or mixed, depending on what portion of the auditory system is affected. Profound deafness is often a congenital condition.

CONDUCTIVE HEARING LOSS

Anything that disrupts the transmission of sound from the external auditory meatus to the inner ear results in a conductive hearing loss. The most common cause of conductive hearing loss is obstruction of the external ear canal. Impacted cerumen, edema of the canal lining, stenosis, and neoplasms all may lead to canal obstruction. Other causes of conductive loss include a perforated tympanic membrane, disruption or fixation of the ossicles of the middle ear, fluid, scarring, or tumors of the middle ear.

With conductive hearing loss, there is an equal loss of hearing at all sound frequencies. If the level of sound is greater than the threshold for hearing, speech discrimination is good. Because of this, the patient with a conductive hearing loss benefits from amplification by a hearing aid.

SENSORINEURAL HEARING LOSS

Disorders that affect the inner ear, the auditory nerve, or the auditory pathways of the brain may lead to a sensorineural hearing loss. In this type of hearing loss, sound waves are effectively transmitted to the inner ear. In the inner ear, however, lost or damaged receptor cells, changes in the cochlear apparatus, or auditory nerve abnormalities decrease or distort the ability to receive and interpret stimuli.

A significant cause of sensorineural hearing deficit is damage to the hair cells of the organ of Corti. In the United States, noise exposure is the major cause, resulting in high-frequency hearing loss in about 26 million Americans between ages 20 and 69 (NIDCD, 2010). Damage may result from either loud impulse noise (e.g., an explosion) or loud continuous noise (e.g., machinery). Exposure to a high level of noise (e.g., standing close to the stage or speakers at a concert) on an intermittent or continuing basis damages the hair and supporting cells of the organ of Corti. Ototoxic drugs also damage the hair cells; when combined with high noise levels, the damage is greater and resultant hearing loss more profound. Ototoxic drugs include aspirin, furosemide (Lasix), aminoglycosides, streptomycin, vancomycin (Vancocin), antimalarial drugs, and chemotherapy drugs such as

cisplatin (Platinol). Other potential causes of sensorineural hearing loss include prenatal exposure to rubella, viral infections, meningitis, trauma, Ménière's disease, and aging.

Tumors such as vestibular schwannomas (acoustic neuromas), vascular disorders, demyelinating or degenerative diseases, infections (bacterial meningitis in particular), or trauma may affect the central auditory pathways and produce a neural hearing loss.

Sensorineural hearing losses typically affect the ability to hear high-frequency tones more than low-frequency tones. This loss makes speech discrimination difficult, especially in a noisy environment. Hearing aids may not be useful, because they amplify both speech and background noise. The increased sound intensity may actually cause discomfort for the patient.

PRESBYCUSIS

With aging, the hair cells of the cochlea degenerate, producing a progressive sensorineural hearing loss. In **presbycusis**, gradual hearing loss associated with aging, hearing acuity begins to decrease in early adulthood and progresses as long as the individual lives. Higher-pitched tones and conversational speech are lost initially. Hearing aids and other amplification devices are useful for most patients with presbycusis.

Because the hearing loss of presbycusis is gradual, the patient and family may not realize the extent of the deficit. The individual with impaired hearing may be described as unsociable or paranoid. The family may worry that the person is becoming increasingly forgetful, absentminded, or perhaps "senile." Depression, confusion, inattentiveness, tension, and negativism have been noted in older adults with hearing impairments. Functional problems such as poor general health, reduced mobility, and impaired interpersonal communication are also associated with hearing loss. Caregivers need to be alert for signs of impaired hearing such as cupping an ear, difficulty understanding verbal communication when the person cannot see the speaker's face, difficulty following conversation in a large group, and withdrawal from social activities.

TINNITUS

Tinnitus is the perception of sound or noise in the ears without stimulus from the environment. The sound may be steady, intermittent, or pulsatile and is often described as a buzzing, roaring, or ringing.

Tinnitus is usually associated with hearing loss (conductive or sensorineural); however, the mechanism producing the sound is poorly understood. It is often an early symptom of noise-induced hearing damage and drug-related ototoxicity. Tinnitus is especially associated with salicylate, quinine, or quinidine toxicity. Other etiologies include obstruction of the auditory meatus, presbycusis, middle or inner ear inflammations and infections, otosclerosis, and Ménière's disease. Most tinnitus, however, is chronic and has no pathologic importance.

Tinnitus that is intermittent or slight enough to be masked by environmental sounds is often well tolerated. When it is loud, continuous, and not responsive to treatment, tinnitus can be a significant stressor. It can interfere with ADLs, sleep, and rest.

●○● INTERPROFESSIONAL CARE

The best treatment for hearing loss is prevention. Patients need to know the risk for hearing damage and how to prevent it. Awareness of the effects of noise exposure, especially when combined with the ototoxic effects of aspirin or other drugs, is important to prevent sensorineural hearing loss.

DIAGNOSIS

Hearing evaluation includes gross tests of hearing (such as the whisper test), the Rinne and Weber tests, and audiometry.

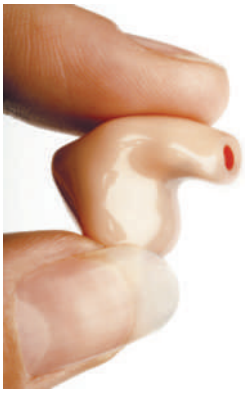
- *Rinne* and *Weber tests* compare air and bone sound conduction. When bone conduction of sound is better than air conduction, the hearing deficit is a conductive loss. The Rinne test can identify even mild conductive hearing losses. If both air and bone conduction are impaired, a sensorineural loss is indicated.
- *Audiometry* identifies the type and pattern of hearing loss. Specific sound frequencies are presented to each ear by either air or bone conduction.
- *Speech audiometry* identifies the intensity at which speech can be recognized and interpreted. *Speech discrimination* evaluates the ability to discriminate among various speech sounds.
- *Tympanometry* is an indirect measurement of the compliance and impedance of the middle ear to sound transmission. The external auditory meatus is subjected to neutral, positive, and negative air pressure while the resultant sound energy flow is monitored.
- *Acoustic reflex testing* uses a tone presented at various intensities to evaluate movement of the structures of the middle ear.

AMPLIFICATION

A hearing aid or other amplification device can help many patients with hearing deficits. These assistive devices do nothing to prevent, minimize, or treat the hearing loss itself. They amplify the sound presented to the hearing apparatus of the ear, which may bring the level of sound above the hearing threshold, allowing more accurate perception and interpretation of its meaning. When sound perception is distorted, a hearing aid may be less helpful, because it simply amplifies the distorted sound.

Unfortunately, less than one-fifth of older patients with a hearing deficit have or use a hearing aid. Denial of the deficit, other health problems, poor visual acuity, decreased manual dexterity, and cost all contribute to this low usage. Hearing aids must be individually prescribed by an audiologist. Proper design, proper fit, and regular maintenance are necessary for their effectiveness.

All hearing aids include a microphone, amplifier, speaker, earpiece, and volume control. Most allow volume control, reduce background noise, and can be adjusted for the patient's pattern of hearing loss. Behind the ear and in-ear aids often include a telecoil, which amplifies sound from the telephone without feedback. These models also may allow direct audio input (e.g., from an MP3 player) or include Bluetooth capability for hands-free telephone use. Hearing aids are available in a variety of styles, each with advantages and disadvantages, as summarized in Table 46–4.



With both the in-canal and in-ear styles, cleaning is important. Small portals may become plugged with cerumen, interfering with sound transmission.

Patients with tinnitus may find a white-noise masking device helpful to promote concentration and rest. These devices conduct a pleasant sound to the affected ear, allowing the patient to block out the abnormal sound.

SURGERY

Reconstructive surgeries of the middle ear, such as a stapedectomy or tympanoplasty, may help restore hearing with a conductive hearing loss. Stapedectomy is the removal and replacement of the stapes. This procedure is used to treat hearing loss related to otosclerosis.

TABLE 46–4 Types of Hearing Aids

Type	Uses	Advantages	Disadvantages
Completely in canal	Mild to moderately severe hearing loss	• Nearly invisible • Allows telephone use • Can be worn during exercise	• Require good manual dexterity to insert, clean, and replace batteries
In the canal 	Mild to moderately severe hearing loss	• Barely visible • Allows telephone use • May be worn during exercise • May include directional microphone depending on size of ear canal	• Short battery life • Ear canal may feel plugged, causing discomfort • Too small for directional microphone • Vulnerable to wax and moisture
In the ear 	Mild to severe hearing loss	• Allows greater amplification than canal hearing aids • Size allows features such as telecoil, directional microphone, and volume control • May be more comfortable than in-canal aids	• More visible • May be difficult to manipulate for less dexterous individuals • Vulnerable to wax and moisture
Behind the ear with earmold 	Mild to profound hearing loss	• Most versatile and reliable • Allows finer amplification level adjustments • Easier to manipulate • Can be incorporated into temple of eyeglasses	• Most visible • Earmold is vulnerable to wax and moisture • Earmold can cause canal to feel plugged and uncomfortable
Behind the ear open-fit	Mild to profound hearing loss	• Comfortable, less visible • Works well in loud social settings • Less likely to be damaged by wax or cause ear canal to feel plugged	• Manual controls are limited
Assistive listening device	Mild to profound hearing loss	• May be used alone or with hearing aids or cochlear implants • Does not require a prescription • Helps separate speech from background noise or facilitate hearing when speaker is further away • Can be used with telecoil, headphones, or earbuds	• Requires separate amplifier unit

In a tympanoplasty, the structures of the middle ear are reconstructed to improve conductive hearing deficits. Chronic otitis media with necrosis and scarring of the middle ear is a common indication for this type of surgery.

A device to strengthen sound vibrations is surgically attached to one of the ossicles in a middle ear implant. An external audio processor worn behind the ear transmits signals directly to the implant, bypassing the ear canal and tympanic membrane.

For the patient with a sensorineural hearing loss, a *cochlear implant* may be the only hope for restoring sound perception. The cochlear implant consists of a microphone, speech processor, transmitter, receiver/stimulator, and electrodes (Figure 46–19 ■). Its function is more similar to the way the ear normally receives and processes sounds than it is to a hearing aid. The microphone picks up sounds, sending them to the speech processor, which selects and processes useful sounds. The transmitter and receiver/stimulator receive signals from the speech processor, convert them to electrical impulses, and send these impulses to the electrodes for transmission to the brain.

Cochlear implants provide sound perception but not normal hearing. The patient is able to recognize warning sounds such as automobiles, sirens, telephones, and doors opening or closing. The implants also receive stimuli to alert them to incoming communication so they can focus on the person speaking. Many patients learn to interpret perceived sounds as words, especially when the hearing loss is acquired as an adult.

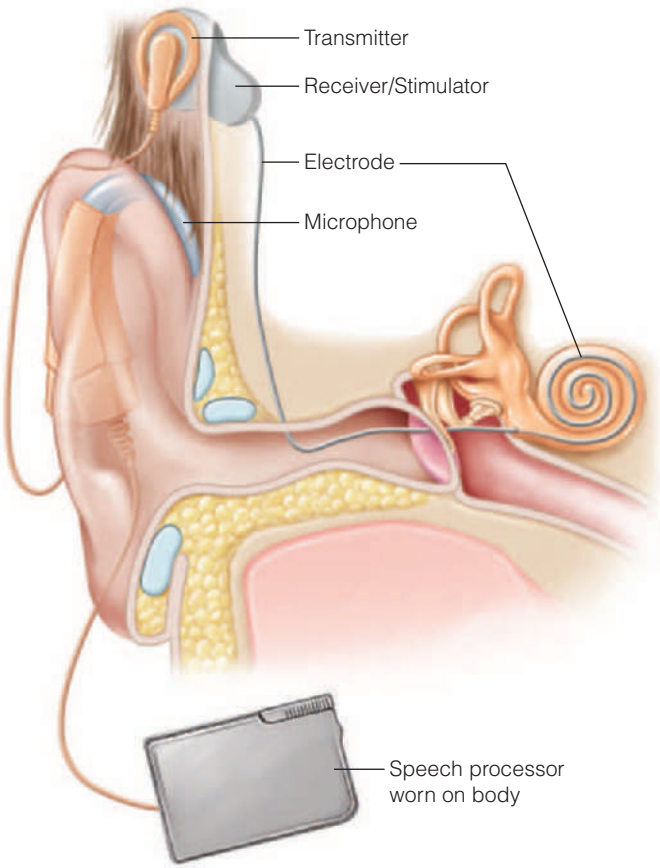


Figure 46–19 ■ A cochlear implant for hearing loss.

●○● NURSING CARE

In planning and implementing nursing care for the patient with a hearing deficit, the type and extent of hearing loss, the patient's adaptation to the loss, and the availability of assistive hearing devices are considered, as well as the patient's ability and willingness to use assistive devices.

Health Promotion

Healthcare personnel can be instrumental in the early identification of hearing loss (see the accompanying Moving Evidence into Action box) and in preventing hearing loss through education. It is important to promote environmental noise control and the use of ear protection. The Occupational Safety and Health Administration requires ear protection for work environments that consistently exceed 85 decibels. Teaching for primary prevention focuses on the following:

- Care of the ears and ear canals, including cleaning and treatment of infection
- Not placing objects into the ear canal
- Use of plugs to protect the ears during swimming or diving
- Avoiding intermittent or frequent exposure to loud noise
- Monitoring for side effects with ototoxic medications
- Hearing evaluation when hearing difficulty is present.

Assessment

- *Health history:* perceived ability to hear; effect of hearing loss on function and lifestyle; risk factors such as use of ototoxic medications, upper respiratory or ear infections, or noise exposure; presence of vertigo, tinnitus, unsteadiness, or imbalance.
- *Physical assessment:* apparent perception of normal speech; inspection of external ear, tympanic membrane; whisper, Rinne, and Weber tests; tests of balance and cranial nerve function.

Priorities of Care

In addition to health promotion activities to reduce the risk of hearing loss, the nurse's focus for the patient with a hearing impairment includes problems associated with the hearing deficit, impaired communication, and social isolation.

Diagnoses, Outcomes, and Interventions

Impaired Hearing

Whether the patient's hearing deficit is partial or total, impaired sound perception is the primary problem. The patient needs to understand what causes the deficit and what to expect for the future. Nursing interventions focus on maximizing available hearing and preventing further deterioration to the extent possible.

Expected Outcome: Patient will verbalize understanding of hearing loss, its evaluation, and management.

- Encourage discussion about the hearing loss and its effect on activities of daily living. *Hearing loss affects each individual in a different way. The patient may be denying the extent of the deficit or grieving the loss. Listening and providing support encourage the patient to develop coping strategies.*
- Provide information about the type of hearing loss. Refer to an audiologist for evaluation of the hearing loss and possible

Moving Evidence into Action

Hearing Loss

Hearing loss is recognized as a significant problem, affecting more than 30% of older adults. Hearing loss can lead to negative outcomes such as isolation, depression, and possibly declining cognition. Central auditory processing declines with aging; this decline likely is augmented when peripheral auditory sensory input is lacking (Pryce, 2011). Despite these widely recognized statistics and consequences, nurse researchers found that 85% of study participants with documented hearing loss and clear recall reported that their primary care provider had never proactively asked about or screened for hearing loss (Wallhagen & Pettengill, 2008). Furthermore, some participants reported lack of concern or affirmative action when asking the physician about their perceived hearing loss.

Implications for Nursing

This study suggests that hearing loss among older adults is underaddressed and even discounted by many healthcare providers. Nurses are in a position to overcome this healthcare disparity and promote health by initiating hearing screening and providing information about hearing loss and its treatment. Initial screening can be as simple as asking the patient about hearing loss or difficulty hearing. It is important to avoid assuming that a patient with hearing loss has undergone hearing evaluation and chosen to "live with it." Including screening for hearing loss as a regular part of nursing assessment of older adults can prevent or reduce negative effects of untreated hearing loss (Wallhagen & Pettengill, 2008).

Moving Knowledge into Action

1. Several participants in this study reported that their concerns about hearing loss were discounted by the primary care provider with statements such as "it was just normal for me to lose my hearing a little bit." Identify more appropriate possible responses to a patient's concerns about hearing loss.
2. Depression and cognitive decline are identified as potential negative outcomes of untreated hearing loss. How does hearing loss contribute to these problems in the older adult?
3. A patient who admits to some hearing loss is reluctant to undergo a hearing screening. How would you approach the patient to identify and address his or her concerns?

exploration of amplification devices. *With improved understanding of the deficit, the patient can plan ways to compensate.*

- Replace batteries in hearing aids regularly and as needed. *Hearing aid batteries last approximately 1 week. If a battery is old or has been improperly stored, the life may be reduced further.*
- If the hearing aid has a toggle switch for microphone/telephone, be sure it is in the appropriate position. *This ensures proper amplification with the hearing aid.*

PRACTICE ALERT!

Check hearing aids for patency, cleaning out cerumen as necessary.

Impaired Verbal Communication

A hearing deficit impairs the patient's ability to receive and interpret verbal communication. A hearing loss affects the patient's ability to follow conversations, use the telephone, and enjoy television or other forms of entertainment.

Expected Outcome: Patient will interact appropriately and express understanding of caregiver instructions.

- Use the following techniques to improve communication:
  - Wave the hand or tap the shoulder before beginning to speak.
  - If the patient wears corrective lenses, ensure that they are clean, and encourage the patient to wear them.
  - When speaking, face your patient and keep your hands away from your face.
  - Keep your face in full light.
  - Reduce the noise in the environment before speaking.
  - Use a low voice pitch with normal loudness.
  - Use short sentences and pause at the end of each sentence.
  - Speak at a normal rate, and do not overarticulate.
  - Use facial expressions or gestures.
  - Provide a magic slate for written communication.

  Individuals with hearing impairments often lip-read, making good visibility of the speaker's face necessary. Excessive environmental noise interferes with the ability to perceive the message. Higher tones are typically lost with presbycusis and other types of hearing loss. Using short sentences and pausing give the patient time to interpret the message. Overarticulating makes it more difficult to follow the flow and to lip-read. Nonverbal cues and written messages enhance the patient's understanding.
- Be sure hearing aid is properly placed, is turned on, and has fresh batteries. *The patient may not be aware that the hearing aid is not functioning well.*
- Do not place intravenous catheters in the dominant hand. *The patient may need to use that hand to write.*
- Rephrase sentences when there is difficulty understanding. *Hearing losses may affect different sound tones, making some words more difficult to comprehend. Using alternative words and phrases may increase the patient's ability to perceive the message.*
- Repeat important information. *The nurse makes sure that the patient understands the information.*

Evidence for Nursing Care

The Patient with Impaired Hearing

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Demers, K. (2013). Hearing screening in older adults. *Try This: Best Practices in Nursing Care to Older Adults, Issue 12.* New York, NY: Hartford Institute for Geriatric Nursing, New York University College of Nursing. Retrieved from http://www.hartfordign.org
- Harkin, H., & Kelleher, C. (2011). Caring for older adults with hearing loss. *Nursing Older People*, *23*(9), 22–28.
- U.S. Preventive Services Task Force. (2012). Screening for hearing loss in older adults: U.S. Preventive Services Task Force recommendation statement. *Annals of Internal Medicine*, *157*(9), 655–661.

- Inform other staff about the patient's hearing deficit and effective strategies for communication. *Consistent use of effective strategies for communication decreases the patient's frustration.*

Social Isolation

The patient with impaired hearing often becomes socially isolated. This isolation may be self-imposed because of difficulty communicating, especially in a group. Often, however, the isolation comes about gradually and without intention. The patient finds social settings such as family dinners or community gatherings increasingly difficult. Friends and family become frustrated trying to communicate with someone who has a hearing impairment, and invitations to participate in social activities dwindle.

Expected Outcome: Patient will engage appropriately in social activities.

- Identify the extent and cause of the social isolation. Help to differentiate the reality of the isolation and its cause from the patient's perception of isolation. *Patients with impaired hearing may be unaware that they are isolated. Identifying factors that contribute to isolation may provide the needed impetus to remedy the hearing loss. Patients may also experience paranoid thinking as a result of impaired communication and believe that friends and family have purposely begun to avoid interactions.*
- Encourage to interact with friends and family on a one-to-one basis in quiet settings. *Patients with impaired hearing are more successful in understanding conversations that take place in small groups and quiet settings.*
- Treat with dignity and remind friends and family that a hearing deficit does not indicate loss of mental faculties. *Inappropriate responses due to a hearing deficit can cause others to perceive the patient as "stupid" or demented.*
- Involve in activities that do not require acute hearing, such as checkers and chess. *The patient has an opportunity to interact socially without the stress of straining to hear.*
- Obtain a pocket talker or encourage the patient and family to do so.
- Refer the patient to an audiologist for evaluation and possible hearing aid fitting.
- Refer to resources such as support groups and senior citizen centers. *These groups provide new social outlets.*

Continuity of Care

Teaching for home and community-based care for the patient with hearing loss focuses on managing the deficit and developing coping strategies. Referral to an audiologist for evaluation of the deficit and the usefulness of a hearing aid may be appropriate. In addition, discuss the following topics as appropriate for each patient:

- Use, care, and maintenance of a hearing aid
- Strategies for coping with the hearing deficit
- Voicing a preference for individual visits and small group interactions rather than large social functions
- Helpful resources include the following:
  - American Academy of Audiology
  - American Speech-Language-Hearing Association
  - House Ear Institute
  - National Institute on Deafness and Other Communication Disorders
  - National Deaf Education Center
  - Self-Help for Hard of Hearing People.

CHAPTER HIGHLIGHTS

- **Structures of the external eye are vulnerable to trauma and infection. Although usually minor, these problems can cause significant pain, scarring and clouding of the cornea, and loss or impairment of vision.**
- **Cataracts, glaucoma, age-related macular degeneration, and diabetic retinopathy are leading causes of visual impairment in the United States. Although these conditions cannot, in most cases, be prevented, they often can be treated or their progress slowed, preserving vision.**
- Age, smoking, diabetes, radiation (sun exposure), and long-term use of certain drugs are risk factors for cataract development. Removal of the clouded lens with insertion of an intraocular lens is the treatment of choice for cataracts. Surgery is elective, performed only when the cataract significantly impairs the ability to maintain ADLs and recreational activities.
- Glaucoma is progressive loss of visual fields associated with increased intraocular pressure and impaired aqueous humor drainage. Open-angle or chronic glaucoma, the predominant form of the disorder, has few symptoms, making regular vision exams an important factor to preserve vision. It can be controlled using medications and, as needed, laser surgery to promote aqueous humor drainage.
- Angle-closure glaucoma is a medical emergency requiring immediate treatment to lower intraocular pressure to preserve vision. Angle-closure glaucoma usually affects only one eye; however, the patient is at risk for future attacks affecting the other eye.
- Age-related macular degeneration, a leading cause of blindness, cannot be effectively treated, although its progress may be slowed or halted through use of high-dose antioxidant vitamins and zinc if it is identified early. Macular degeneration affects the macula, the area of high-acuity central vision.
- Diabetic retinopathy eventually affects nearly all people with diabetes. It is a disease of the small blood vessels of the retina, leading to formation of aneurysms, retinal ischemia, and growth of fragile

new vessels (neovascularization) that easily rupture, leading to hemorrhage. It is treated with laser surgery to seal fragile vessels.

- **Disruption of the integrity of any portion of the auditory pathway from the external ear through neural transmission to auditory centers of the brain can impact an individual's ability to hear and interpret sounds. Health promotion activities and prompt treatment of disorders are important measures to preserve hearing.**
- Otitis media is related to auditory tube dysfunction, with impaired pressure equalization of the middle ear. Otitis media may be either serous (sterile) or infectious. Both cause acute discomfort with diminished hearing, snapping, popping, and possible vertigo and systemic symptoms. The risk of complications, including rupture of the tympanic membrane, damage to structures of the middle ear, and spread of infection to surrounding tissues, is greater with acute otitis media.
- Potential complications of acute otitis media include mastoiditis, chronic otitis media with tympanic membrane perforation, and cholesteatoma formation. Hearing loss in the affected ear is a possibility with these disorders. The primary treatment is prevention through adequate treatment of acute otitis media.
- **Inner ear disorders can affect the perception of sound as well as equilibrium. When balance is affected, the patient is at significant risk for injury, making safety a nursing care priority.**
- The primary manifestations of disorders of the inner ear are vertigo and possible hearing loss. Severe vertigo can interfere with safety, nutrition, and the patient's ability to maintain ADLs and life roles.
- **Hearing loss affects people of all ages, although older adults are disproportionately affected. Impaired hearing significantly affects the ability to communicate, making it a major public health problem. Despite its prevalence, impaired hearing often is undiagnosed and untreated.**
- The two major types of hearing loss are conductive and sensorineural. Presbycusis, hearing loss associated with aging, is a type of sensorineural hearing loss. Hearing loss may be accompanied by tinnitus, the perception of sound without an environmental stimulus. Amplification devices (hearing aids) are the primary treatment for hearing loss.

TEST YOURSELF NCLEX-RN® REVIEW

1. The nurse is caring for a group of residents in a long-term care facility, all of whom have moderate to severe hearing or vision impairment. What should the nurse identify as the highest priority of care for these residents?
   1. maintaining resident safety
   2. encouraging social interaction
   3. promoting family relationships
   4. preventing sensory deprivation
2. The nurse is teaching a patient with newly diagnosed glaucoma about the disease process. What should the nurse emphasize when teaching this patient?
   1. Contact the physician if further decline in vision is noticed.
   2. Use the prescribed eyedrops as directed on a continuing basis.
   3. Avoid coughing, sneezing, or straining to have a bowel movement.
   4. Turn the head side to side to compensate for impaired peripheral vision.
3. A patient with a history of heart failure is prescribed medication for glaucoma. Which medication should the nurse question before providing to the patient?
   1. timolol (Timoptic)
   2. latanoprost (Xalatan)
   3. dorzolamide (Trusopt)
   4. brimonidine (Alphagan)
4. The nurse is instructing a patient with Ménière's disease on ways to prevent attacks of vertigo and tinnitus. What should the nurse include in this teaching? (Select all that apply.)
   1. Stop smoking.
   2. Follow a low-sodium diet.
   3. Avoid caffeine and alcohol.
   4. Sit down when an attack develops.
   5. Take prescribed antiemetic medications.
5. A patient is brought to the recovery room after having cataract surgery. Which action should the nurse immediately perform for this patient?
   1. Place the patient in a private room.
   2. Position the patient on the affected side.
   3. Place the patient in semi-Fowler's position.
   4. Ensure the patient is in proximity to the nurses' station.
6. A patient is experiencing bright flashing lights throughout the field of vision. What is the most appropriate response by the nurse?
   1. Initiate immediate referral to an ophthalmologist.
   2. Advise to make an appointment to have blood pressure checked.
   3. Recommend the patient lie down until the sensation has passed.
   4. Reassure that this is not unusual and should resolve without treatment.
7. A patient is experiencing right ear pain. What should be included in the physical assessment of this patient? (Select all that apply.)
   1. vital signs with temperature
   2. manipulation of the ear pinna
   3. inspection of the oral pharynx
   4. palpation of cervical lymph nodes
   5. inspection of the retina and cornea
8. An older patient is experiencing head stuffiness and ringing in the ears. What should the nurse do to help this patient?
   1. Notify the primary care physician.
   2. Inspect the ear canals for patency.
   3. Refer for evaluation by an audiologist.
   4. Provide nonprescription eardrops for daily use.

9. The nurse is caring for a patient with a severe hearing deficit. Which would be an appropriate goal to improve the patient's social interaction?
1. Attend religious services of choice.
2. Plan to have dinner with one or two friends weekly.
3. Engage in activities such as card tournaments and dancing.
4. Participate in senior center communal lunches at least twice per week.

10. During an assessment the nurse notes an absence of the red reflex in the patient's right eye. When questioned the patient responds that cataracts have been diagnosed and asks when they should be removed. How should the nurse respond?
1. "It appears that the right eye is due for surgery."
2. "Cataracts can be removed any time that it is convenient for you."
3. "Are you having difficulty reading or doing activities you enjoy?"
4. "Are you starting to experience pain in your right eye or frequent headaches?"

See Test Yourself answers in Appendix B.

UNIT

12 Building Clinical Competencies

Responses to Altered Sensory Function

CLINICAL SCENARIO

Directions: *Read the following clinical scenarios and answer the questions that follow. To complete this exercise successfully, you will not only use knowledge of the content in this unit, but also principles related to priority setting and maintaining patient safety.*

You have been assigned to work with the following four patients for the 0700 shift on a medical-surgical unit. Significant data obtained during report is as follows:

- Andrew Hardy is a 50-year-old with type 1 diabetes admitted with a blood glucose of 600 and hypertension during the night shift. Upon assessment the patient reveals that he has been seeing black spot floaters and flashing lights at times. He is now complaining of blurred vision.
- Gladys Harvey is an 84-year-old who had right eye cataract surgery yesterday under general anesthesia. Her vital signs have been stable since surgery. She has begun complaining of itching and slight discomfort in the right eye.
- Georgia Stanley is a 45-year-old admitted with complaints of feeling like she is spinning or falling, and ringing and a fullness feeling in her left ear. Her vital signs are temperature 37°C (98.6°F), pulse 78 bpm, respirations 16/min, and blood pressure 102/68 mmHg. She is diaphoretic and complains of nausea. She is scheduled for x-rays and a CT scan of her head at 0800.
- Kenneth Koch, a 30-year-old, is a postoperative patient who had a right ear tympanoplasty yesterday because of hearing loss due to chronic otitis media. Vital signs are temperature 37.6°C (99.6°F), pulse 90 bpm, respirations 20/min, and blood pressure 136/86 mmHg. The patient is requesting pain medication for ear pain. Pain is rated as 9 out of 10 on a scale of 1 to 10, with 10 being the highest.

CLINICAL REASONING

1. Ms. Stanley is to be evaluated for Ménière's disease. The nurse anticipates that which of the following diagnostic tests will be ordered? (Select all that apply.)
- A. caloric testing
- B. Rinne and Weber tests
- C. troponin
- D. complete blood count
- E. glycerol test
- F. blood glucose level

Priority Setting

2. In what order would you visit these patients after report?
- A. _____
- B. _____
- C. _____
- D. _____

Health Promotion

3. What instruction should Mr. Hardy be given about controlling his risk factors for vision loss?

4. Which is the appropriate primary prevention to teach Mr. Koch to prevent hearing loss?
- A. Cleanse the ear with ear swabs to prevent earwax buildup.
- B. Avoid getting water in the ears when showering.
- C. Monitor for ringing in the ears when taking acetaminophen (Tylenol).
- D. Wear ear protectors when exposed to loud noises.

Nursing Process

5. After cataract surgery, Ms. Harvey is placed in which position to reduce intraocular pressure?
- A. Sims' position on the unaffected side
- B. semi-Fowler's position on the unaffected side
- C. supine with the head elevated 10 degrees
- D. prone position on the affected side

6. A low-sodium diet is ordered for Ms. Stanley with Ménière's disease. The patient understands this diet when she selects which meal plan?
- A. hot dog on a roll with ketchup and mustard
- B. ham and cheese sandwich with potato salad
- C. grilled chicken sandwich with lettuce and tomato
- D. hamburger on a roll with potato chips

Communication

7. Which techniques may improve communication with the patient who has a hearing impairment? (Select all that apply.)
- A. Speak loudly to enhance hearing.
- B. Speak at a normal rate and avoid overarticulating.
- C. Stand in front of a window so patient can see the face.
- D. Face the patient to enhance lip-reading.
- E. Turn down the television or radio.
- F. Use short sentences and pause frequently.

Delegation

8. For each patient, what interventions can be delegated to the unlicensed assistive personnel (UAP)?

A. _____
B. _____
C. _____
D. _____

Interprofessional Care

9. The nurse should collaborate with the healthcare provider for relief of which of Ms. Stanley's symptoms until diagnosis is confirmed?

A. tinnitus
B. nausea
C. fullness feeling in the left ear
D. blood pressure of 102/68 mmHg

Continuity of Care

10. Which of the following discharge instructions related to the patient's eye surgery should be provided to Ms. Harvey?

A. Avoid lifting more than 15 pounds.
B. Avoid coughing or sneezing.
C. Lie on the affected side.
D. Remove the eye patch when sleeping.

Safety

11. Which of the following strategies is most aimed at error prevention?

A. scanning the barcode on Ms. Harvey's eyedrops and her identification bracelet prior to instillation
B. providing pain medication to Mr. Koch
C. discontinuing Ms. Stanley's IV to avoid sending the medication pump to CT scan
D. typing Mr. Hardy's medical record number from memory into the glucose monitoring device

Quality Improvement

12. Describe a quality improvement project aimed at reducing the incidence of diabetic retinopathy.

Informatics

13. In reporting Mr. Hardy's visual changes to the physician, in what section of the EMR would the nurse document the conversation?

A. medication administration record
B. vital sign flow sheet
C. progress note
D. electronic order entry

UNIT

13

Responses to Altered Reproductive Function

47 Assessing the Male and Female Reproductive Systems 1537

48 Nursing Care of Men with Reproductive System and Breast Disorders 1555

49 Nursing Care of Women with Reproductive System and Breast Disorders 1581

50 Nursing Care of Patients with Sexually Transmitted Infections 1621

Sexuality–Reproductive Pattern

Disorders affecting the reproductive systems of men or women pose a risk to sexuality, fertility, body image, and self-concept.

47 Assessing the Male and Female Reproductive Systems

LEARNING OUTCOMES

1. Describe the anatomy, physiology, and functions of the male and female reproductive systems, including the breasts.
2. Identify specific topics for consideration during a health history interview of the patient with health problems of the reproductive system and breasts.
3. Give examples of genetic disorders of the male and female reproductive systems and breasts.
4. Describe normal variations in reproductive assessment findings for the older adult.
5. Identify manifestations of impairment in the male and female reproductive systems and breasts.

CLINICAL COMPETENCIES

1. Assess male and female reproductive health status including physical comfort, values, preferences, and expressed needs.
2. Identify, report, and document normal, abnormal, and unexpected assessments of the male and female reproductive systems.

MAJOR CHAPTER CONCEPTS

- Male and female reproductive organs provide sexual pleasure and produce offspring. Physical health, psychosocial health, self-care habits, family, culture, and the environment impact reproductive functioning.
- Physical assessment of the male reproductive system includes inspection and palpation of external genitalia, palpation of internal reproductive organs, transillumination of the testes, assessment of inguinal areas, and assessment of the perianal area and rectum. Abnormal findings in the male reproductive system include lesions, disorders of the penis or scrotum, and inguinal hernias.
- The female reproductive system undergoes cyclic changes in response to estrogen and progesterone levels. The female reproductive system manufactures ova for fertilization, transports fertilized ova for implantation, regulates production and secretion of hormones, and provides sexual stimulation and pleasure. Abnormal findings in the female reproductive system include inflammatory processes and problems with the external genitalia, the cervix, and the vagina.
- Psychosocial factors including stress, anxiety, and grief influence sexual functioning. Sensitivity to cultural differences in discussions of reproductive function is important.

KEY TERMS

androgens, *1538*
anorgasmia, *1548*
dyspareunia, *1548*
estrogens, *1544*
gynecomastia, *1541*
impotence, *1540*
menstrual cycle, *1544*
menstruation, *1543*
phimosis, *1541*
progesterone, *1544*
semen, *1538*
testosterone, *1538*

EQUIPMENT NEEDED

- Disposable gloves
- Water-soluble lubricant
- A good light source
- Sterile cotton swabs (for culture)
- Culture media (for culture)
- A spatula, cotton swab or endocervical brush, slides, and cytologic fixative (for Pap smear)
- Vaginal speculum of appropriate size

The reproductive organs in men and women share the functions of enabling sexual pleasure and reproduction. The reproductive organs, in conjunction with the neuroendocrine system, produce hormones important in biologic development and sexual behavior. Parts of the reproductive organs in men enclose and are integral to the function of the urinary system. The assessment of the reproductive system may be difficult for both the nurse and the patient and requires sensitivity on the part of the nurse when asking questions about topics that the patient may be hesitant to talk about. Skill in conducting physical examinations of an area of the body usually considered private is also required.

Anatomy, Physiology, and Functions of the Male Reproductive System

The male reproductive system consists of the paired testes, the scrotum, ducts, glands, and penis (Figure 47–1 ■). The breasts are also part of the male reproductive system.

The Breasts

The male breast is comprised primarily of an areola (circular pigmented area) and a small nipple. These lie over a thin disk of undeveloped breast tissue that may not be overtly different from surrounding tissue. Approximately one in three men have a firm area of breast tissue 2 cm or larger; the limits of normal size of this area have not been established. Some men have overdeveloped breasts, a condition called gynecomastia.

The Penis

The penis is the genital organ that encloses the urethra. It is homologous to the clitoris of the female. The penis is composed of a shaft and a tip called the glans, which is covered in the uncircumcised man by the foreskin (or prepuce). Erection of the penis occurs when erectile tissue is filled with blood in response to a reflex that triggers the parasympathetic nervous system to stimulate arteriolar vasodilation. The erection reflex may be initiated by touch, pressure, sights, sounds, smells, or thoughts of a sexual encounter. After ejaculation, the arterioles vasoconstrict, and the penis becomes flaccid.

The Scrotum

The scrotum hangs at the base of the penis, anterior to the anus, and regulates the temperature of the testes. The optimum temperature for sperm production is about 2 to 3 degrees below body temperature. When the testicular temperature is too low, the scrotum contracts to bring the testes up against the body. When the testicular temperature is too high, the scrotum relaxes to allow the testes to lie further away from the body.

The Testes

The testes develop in the abdominal cavity of the fetus and then descend through the inguinal canal into the scrotum just before birth.

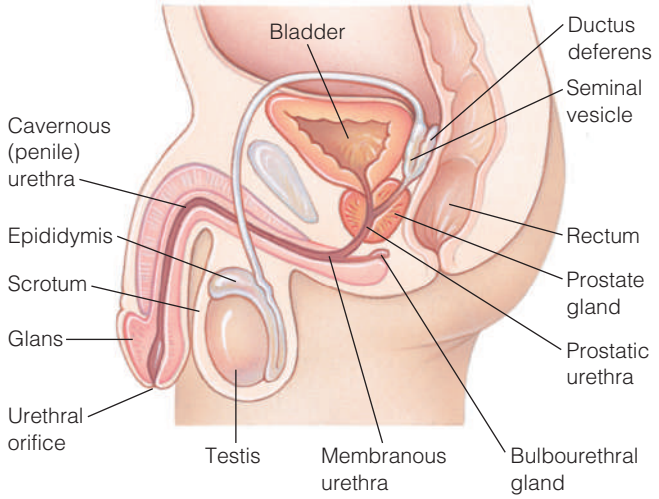

Figure 47–1 ■ The male reproductive system.

They are homologous to the ovaries in females. These paired organs are each about 4 cm (1.5 in.) long and 2.5 cm (1 in.) in diameter. Each testis is divided into 250 to 300 lobules, with each lobule containing one to four seminiferous tubules. The testes produce sperm and testosterone. The seminiferous tubules are responsible for sperm production. Leydig's cells (or interstitial cells) lie in the connective tissue surrounding the seminiferous tubules and produce testosterone. It is not unusual for one testes to be lower than the other.

The Ducts and Semen

The seminiferous tubules lead into the efferent ducts and become the rete testis. From the rete testis, 10,000 to 20,000 efferent ducts join the epididymis, a long coiled tube that lies over the outer surface of each testis. The epididymis is the final area for the storage and maturation of sperm. When a man is sexually excited, the epididymis contracts to propel the sperm through the vas deferens to the ampulla, where the sperm are stored until ejaculation.

The seminal vesicles produce most of the volume of seminal fluid. Seminal fluid is also made of secretions from the accessory sex organs, the epididymis, the prostate gland, and Cowper's glands. Seminal fluid nourishes the sperm, provides bulk, and increases its alkalinity. An alkaline pH is essential to mobilize the sperm and ensure fertilization of the ova. Sperm mixed with this fluid is called **semen**. Each seminal vesicle joins its corresponding vas deferens to form an ejaculatory duct, which enters the prostatic urethra. During ejaculation, seminal fluid mixes with sperm at the ejaculatory duct and enters the urethra for expulsion. The total amount of semen ejaculated is 2 to 6 mL, although the amount varies. The total ejaculate of a healthy male contains from 20 million to 150 million sperm per milliliter (Vorvick, 2012).

The Prostate Gland

The prostate gland is about the size of a walnut. It encircles the urethra just below the urinary bladder and is surrounded by smooth muscle. Secretions of the prostate gland make up about one-third of the volume of the semen. These secretions enter the urethra through several ducts during ejaculation. Prostatic fluid helps activate sperm and has antibiotic properties thought to help prevent urinary tract infections in men.

Male Sex Hormones

The male sex hormones are called **androgens**. Most androgens are produced in the testes, although the adrenal cortex also produces a small amount. **Testosterone**, the primary androgen produced by the testes, is essential for the development and maintenance of sexual organs and secondary sex characteristics, and for spermatogenesis. It also promotes metabolism, growth of muscles and bone, and libido (sexual desire).

ASSESSING THE MALE REPRODUCTIVE SYSTEM

The structures and functions of the male reproductive system are assessed by findings from diagnostic tests, a health assessment interview to collect subjective data, and a physical assessment to collect objective data.

Diagnostic Tests

The results of diagnostic tests of the structures and functions of the male reproductive system are used to support the diagnosis of a specific sexual problem, injury, or disease; to provide information to identify or modify the appropriate medications or treatments used to treat the disease; and to help nurses monitor the man's responses to treatment and nursing interventions. Diagnostic tests used to assess the male reproductive system are described in the Diagnostic Tests table. More information is included in the discussion of specific health problems or diseases in Chapter 48.

DIAGNOSTIC TESTS of the Male Reproductive System

Name of Test	Purpose and Description	Related Nursing Interventions
Biopsy of the prostate	A biopsy of the prostate is conducted to help determine the cause of an elevated prostate-specific antigen (PSA) level and to diagnose cancer if a lump is found in the prostate. Various routes may be used to insert a biopsy needle into the prostate, through the rectum (transrectal), through the urethra (transurethral), or through the perineum. Transrectal ultrasound (TRUS) is often used to guide the placement of the needle during the procedure. The biopsy may be done in a physician's office, in an outpatient surgery unit or clinic, or in a hospital operating room.	Assess for a history of bleeding problems, allergies to medications, and if taking any anticoagulant medications (such as warfarin [Coumadin], heparin, enoxaparin [Lovenox], aspirin, or NSAIDs). If the biopsy is done with a local anesthetic, no other preparation is needed. If the biopsy is done transrectally, the patient may need an enema before the procedure. If the biopsy is done with general anesthesia, tell the patient he will be unable to eat or drink fluids for 8–12 h before the procedure, and that he may be given antibiotics. After the biopsy, advise the man to avoid strenuous activity for 4 hours. Explain that there may be some discomfort in the biopsy area for 1–2 days, there may be some blood in the urine or from the rectum, and semen may appear dark. Following a transurethral biopsy, a urinary catheter may remain in place for a few hours after the procedure. Excess bleeding, pain, inability to urinate, or signs of infection should be reported to the physician.
Gonorrhea culture	A culture is performed to evaluate for gonorrhea. A swab is used to collect a sample of discharge from the infected area (urethra, penis, anus, or throat), smeared on a slide, and a Gram stain is conducted to identify the organism (*N. gonorrhoeae*). A urine sample is used in some tests.	No special preparation is needed. If test is positive, request referral to an STI testing center or clinic and emphasize need for treatment to eradicate the infection.
Prostate-specific antigen (PSA)	A blood test used to screen for prostate cancer and to monitor treatment of prostate cancer. The American Cancer Society recommends that the decision to undergo routine prostate screening should be determined on an individual basis by the informed man and his physician. Normal value: 0–4.0 ng/mL	Inform the patient that transient increases in PSA occur following prostate palpation or rectal examinations; these procedures as well as prostate surgery should not be scheduled for 3 days before the PSA is done.
Prostate ultrasound (transrectal)	Transrectal ultrasound (TRUS) is conducted to evaluate prostate enlargement. Ultrasound also is used to identify testicular torsion or masses. Uses high-frequency sound waves, passed through tissues of various densities, to produce a visual graphic of tissue being examined.	Tell the patient to administer a Fleet enema about 1 h before the procedure (if ordered). Ask the patient to void and remove clothing from the waist down prior to the procedure. The patient may also be asked to avoid anticoagulants and antiplatelets, such as aspirin, before the procedure.
Semen analysis	Done to assess volume, motility and sperm count, and percent of abnormal sperm. Normal values: Volume: 1.5-5 mL Sperm count: 60-150 million/mL Motility: >60% motile Normal forms: >70%	Instruct the patient to refrain from use of alcohol for 24 hours and to abstain from intercourse for 3 days prior to the test. The patient is asked to bring in a fresh specimen (usually in a condom) within 2 h of ejaculation.
Syphilis screening tests • Venereal Disease Research Laboratory (VDRL) • Rapid plasma reagin (RPR) • Fluorescent treponemal antibody absorption (FTA-ABS)	These blood tests are conducted to screen for syphilis. Positive findings can be made within 1–2 weeks after primary lesion appears or 1–4 months after the initial infection. The FTA-ABS test is considered the most accurate, and is often used if findings from the VDRL or RPR are questionable.	No special preparation is needed. If test is positive, request referral to an STI testing center or clinic and emphasize need for treatment to eradicate the infection.

Regardless of the type of diagnostic test, the nurse is responsible for explaining the procedure and any special preparation needed, for assessing any medication use that might affect the outcome of the tests, for supporting the man during the examination as necessary, for ensuring the consent form is signed (if required), and for monitoring the results of the tests. The nurse is also responsible for postprocedure care and patient teaching for self-care at home.

Genetic Considerations

When conducting a health assessment interview and a physical assessment, it is important for the nurse to consider genetic influences on health of the adult. Several diseases of the male reproductive system have a genetic component. During the health assessment interview, it is especially important to ask about a family history of testicular or prostate cancer. During the physical assessment, assess for any manifestations that might indicate a genetic disorder (see the accompanying Genetic Considerations box). If data are found to indicate genetic risk factors or alterations, ask about genetic testing and refer for appropriate genetic counseling and evaluation. Chapter 8 provides further information about genetics in medical-surgical nursing.

Health Assessment Interview

A health assessment interview to determine problems with the male reproductive system may be conducted during a health screening, may focus on a chief complaint (such as a discharge from the penis), or may be part of a total health assessment. Men may be embarrassed to discuss health problems or concerns involving their reproductive organs; it is important for the nurse to ask questions in a nonthreatening, matter-of-fact manner. Consider the psychologic, social, and cultural factors that affect sexuality and sexual activity. Use words that the man can understand, and do not be embarrassed or offended by the words he uses. The man may perceive the interview as less threatening if the discussion begins with more general questions and then progresses to specific questions, and if questions are asked in a way that gives him permission to describe behaviors and manifestations. For example, rather than asking a man if he has difficulty achieving or maintaining an erection, ask him to describe any changes he has noticed in his erections.

If the man has a reproductive health problem, analyze its onset, characteristics and course, severity, precipitating and relieving factors, and any associated symptoms, noting the timing and circumstances. For example, you may ask the man the following questions:

- When did you first notice that you were having difficulty urinating?
- Did you use a different brand of condoms before you noticed the rash on your penis?
- Describe the changes that occurred in your ability to have an erection after you started taking medicine for high blood pressure.

In questioning the man about past medical history, ask about chronic illnesses such as diabetes, chronic kidney disease, cardiovascular disease, multiple sclerosis, spinal cord tumors or trauma, or thyroid disease. The effects of these illnesses as well as the treatment of the illnesses may cause **impotence** (inability to achieve or maintain an erection). The following drugs may cause erectile dysfunction: antihypertensives, antidepressants, antispasmodics, beta-blockers, tranquilizers, sedatives, and histamine$_2$-receptor antagonists. Psychosocial stressors also may contribute to impotence.

If the man was born to a woman treated during pregnancy with diethylstilbestrol (DES), a drug used in the 1940s and 1950s to prevent miscarriage, he may have congenital deformities of the urinary tract as well as decreased semen levels. If the man had mumps as a child, sterility is possible. The risk for testicular cancer is greatest in men who have a history of an undescended testicle, an inguinal hernia, testicular swelling with mumps, a history of maternal use of DES or oral contraceptives, and a family history of testicular cancer.

Explore the lifestyle and social history of the man; the use of alcohol, cigarettes, or street drugs may affect sexual function. Unprotected sexual intercourse increases the potential for sexually transmitted infections (STIs) including HIV infection. Ask about sexual preference. Sexual intercourse with same-sex partners further increases the risk for HIV infection. Other questions about sexuality may include number of sexual partners; history of premature ejaculation, impotence, or other sexual problems; any history of sexual trauma; use of condoms or other contraceptives; and current level of sexual satisfaction.

Physical Assessment

Physical assessment of the male reproductive system may be performed as part of a total assessment or separately for men with known or suspected problems. If conducted as part of a total physical assessment, this is usually the final system to be assessed. Problems of the male reproductive system may involve the urinary system, making an assessment of both systems important (refer to Chapter 26 for assessment of the urinary system). The nurse must feel comfortable with the examination of patients of the opposite gender. If either the nurse or the patient is not comfortable, a nurse of the same gender should be asked to conduct this part of the assessment. Normal age-related findings for the older man are summarized in the Nursing Care of the Older Adult box.

The male reproductive system is assessed by inspection and palpation. Explain the procedures for the examination thoroughly and in a matter-of-fact way to decrease anxiety and embarrassment. If the man is unfamiliar with his internal genitalia, charts may be used to demonstrate the parts that will be examined. Ask the man to empty his bladder, remove his clothing, and put on a gown or drape. The assessment may be done with the man sitting or standing. Expose only those body parts being examined to preserve modesty. Ensure that the examining room is warm and private. Put on gloves before beginning and wear them throughout the examination.

GENETIC CONSIDERATIONS

Examples of Male Reproductive System Disorders

- Although the exact genetic predisposition for some men to have prostate cancer is unknown, the findings of many studies have identified a family history as a major risk factor.
- A family history of testicular cancer is a risk factor for cancer of the testes. (Cryptorchidism can be a risk factor for testicular cancer.)
- Men who have XX chromosomes (instead of XY) often have altered testicular development because they are missing a gene called the sex-determining region Y gene (*SRY*), which is responsible for the development of secondary sex characteristics in men.

Male Reproductive System Assessments

Technique/Normal Findings	Abnormal Findings
Breast and Lymph Node Assessment	
Inspect and palpate both breasts, including areola and nipple. *Breast tissue should not be swollen, tender, or enlarged (although soft, fatty, and enlarged breast tissue does occur with obesity in men).*	• A smooth, firm, mobile, tender disk of breast tissue behind the areola indicates **gynecomastia**, abnormal enlargement of the breast(s) in men. Gynecomastia requires additional investigation to determine the cause. • A hard, irregular, fixed nodule in the nipple area suggests carcinoma.
Palpate the axillary and supraclavicular lymph nodes. *Lymph nodes should not be palpable.*	• Enlarged axillary nodes are common with infections of the hand or arm but may be caused by cancer. • Enlarged supraclavicular nodes may indicate metastasis.
External Genitalia Assessment	
Inspect and palpate the inguinal and femoral area for bulges. Ask the man to bear down or cough as you palpate (Figure 47–2 ■). *There should be no bulging with coughing or bearing down.*	• A bulge that increases with coughing or straining suggests a hernia.
Inspect the penis. If the man is uncircumcised, retract the foreskin or ask him to do so. *When nonerect, the penis is normally soft, flaccid, and nontender. The foreskin should be without lesions, of color equal with the penis, and should retract easily. The glans is normally free of lesions.*	• **Phimosis** (tightness of prepuce that prevents retraction of foreskin) may be congenital or due to recurrent balanoposthitis (generalized infection of glans penis and prepuce). • Narrow or inflamed foreskin can cause paraphimosis, retraction of the foreskin that causes painful swelling of the glans. • Balanitis (inflammation of the glans) is associated with bacterial or fungal infections. • Ulcers, vesicles, or warts suggest an STI. • Nodules or sores seen in uncircumcised men may be cancer.
Inspect the external urinary meatus. Press the glans between the thumb and forefinger (Figure 47–3 ■). Replace the foreskin if appropriate. *The external urinary meatus is normally in the center of the glans, without redness or discharge.*	• Erythema or discharge indicates inflammatory disease. Further assessment is required.
Inspect the skin on the shaft of the penis. *The skin on the shaft of the penis should be free of redness or lesions.*	• Excoriation or inflammation suggests lice or scabies.
Palpate the shaft of the penis. *The shaft of the penis should not be tender.*	• Induration with tenderness along the ventral surface suggests urethral stricture with inflammation.

Figure 47–2 ■ Palpating the male inguinal area for bulges.

Figure 47–3 ■ Inspecting the external urinary meatus of the male.

(*continued*)

Male Reproductive System Assessments (*continued*)

Technique/Normal Findings	Abnormal Findings
Inspect the scrotum. Further assess any swelling in the scrotum using transillumination: Darken the room and place a lighted flashlight against the skin of the scrotum. *The normal scrotum and epididymis appear as dark masses with regular borders.*	• A unilateral or bilateral poorly developed scrotum suggests cryptorchidism (failure of one or both testes to descend into the scrotum). • Swelling of the scrotum may indicate indirect inguinal hernia, hydrocele (accumulation of fluid in the scrotum), or scrotal edema. Swellings containing serous fluid will transilluminate. Swellings containing blood or tissue will not transilluminate.
Palpate each testis and epididymis. *The testes should not be tender or swollen.*	• Tender, painful scrotal swelling occurs in acute epididymitis, acute orchitis, torsion of the spermatic cord, and strangulated hernia. • A painless nodule in the testis is associated with testicular cancer.

Prostate Assessment

The prostate gland is assessed by digital rectal examination (DRE). Refer to Figure 21–19 for the technique used to palpate the prostrate through the rectal wall. This assessment is usually conducted by a physician or advanced practice nurse.

With a gloved index finger, palpate the posterior surface of the prostate gland. *The prostate is normally nontender, with two lateral lobes that are divided, smooth, and about 2.5 cm (1 in.) long.*	• Enlargement (1-cm protrusion into the rectum) with obliteration of the median sulcus suggests benign prostatic hypertrophy. • Enlargement with asymmetry and tenderness suggests prostatitis. • A hard irregular nodule is suspicious of carcinoma.

NURSING CARE OF THE OLDER ADULT

Age-Related Changes in the Male Reproductive System

Age-Related Change	Significance
PROSTATE GLAND	
• A significant number of older men have some degree of benign prostatic hyperplasia.	Although aging does not cause prostate cancer, its incidence does increase with age.
PENIS, TESTES, AND SCROTUM	
• Epithelial tissue and mucosa of seminal vesicles are thinner and have reduced capacity to hold fluid. • Sclerosis of penile arteries and veins may occur.	Although men may father children throughout life, the sperm count is reduced in some men. Changes in the vascular system of the penis may mean the aging man takes longer to achieve an erection and ejaculation, or may be impotent.

Anatomy, Physiology, and Functions of the Female Reproductive System

The female reproductive system consists of the external genitalia (mons pubis, labia, clitoris, vaginal and urethral openings, and glands) and the internal organs (vagina, cervix, uterus, fallopian tubes, and ovaries). The breasts are a part of the women's reproductive organs. In women, the urethra and urinary meatus are separated from the reproductive organs; however, they are so close to each other that a health problem with one often affects the other.

The Breasts

The breasts (or mammary glands) are located between the third and seventh ribs on the anterior chest wall. They are supported by the pectoral muscles and are richly supplied with nerves, blood, and lymph (Figure 47–4 ■). A pigmented area called the areola is located slightly below the center of each breast and contains sebaceous glands and a nipple. The nipple is usually protrusive and becomes erect in response to cold and stimulation. The breasts produce milk for the infant following delivery.

The breasts are made of adipose tissue, fibrous connective tissue, and glandular tissue. Cooper's ligaments support the breast and extend from the outer breast tissue to the nipple, dividing the breast into 15 to 25 lobes. Each lobe is made of alveolar glands connected by ducts that open to the nipple.

The External Genitalia

The external genitalia are collectively called the vulva. They include the mons pubis, the labia, the clitoris, the vaginal and urethral openings, and glands (Figure 47–5 ■).

The mons pubis is a pad of adipose (fat) tissue covered with skin and hair that lies anterior to the symphysis pubis. The labia are divided into two structures. The labia majora, outermost folds of skin and adipose tissue covered with hair, begin at the base of the mons pubis and end at the anus. The labia minora, usually light pink and hairless, are located between the clitoris and the base of the vagina, and are enclosed by the labia majora.

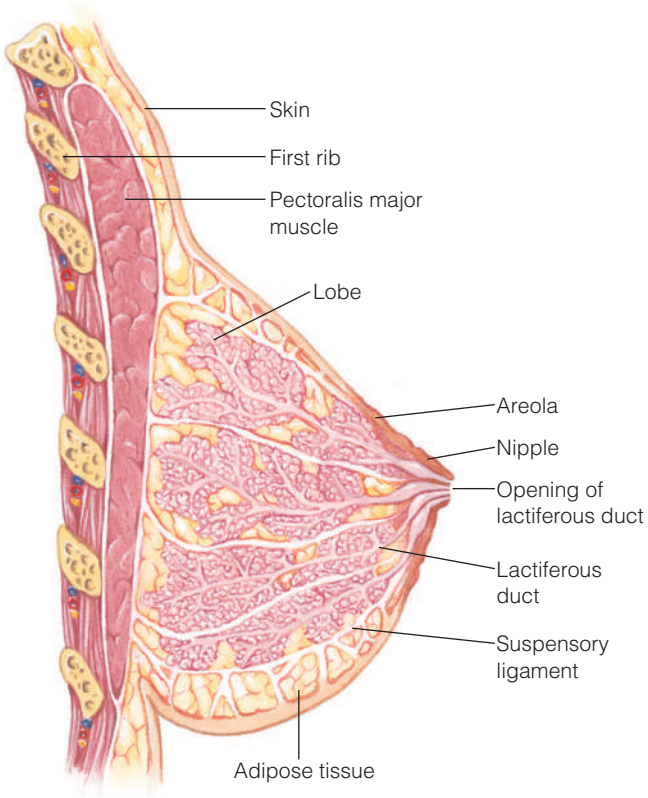

Figure 47–4 ■ Structure of the female breast.

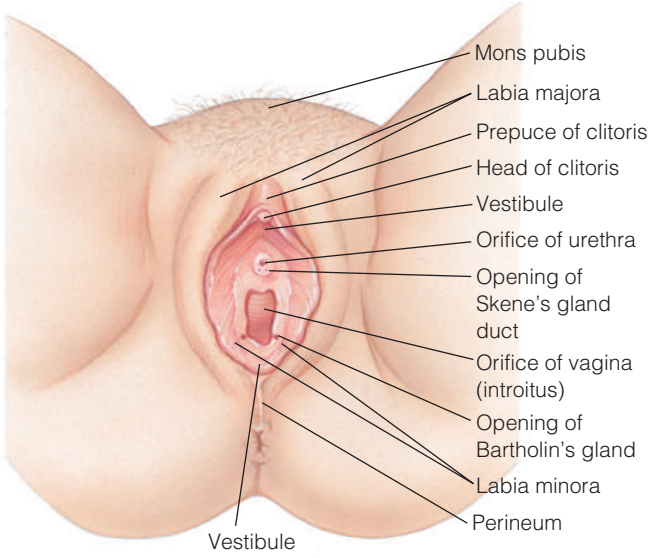

Figure 47–5 ■ The external organs of the female reproductive system.

The vestibule (the area between the labia) contains the openings for the vagina and the urethra as well as Bartholin's and Skene's glands. Prior to menopause, Bartholin's and Skene's glands secrete lubricating fluid during the sexual response cycle. The clitoris is an erectile organ analogous to the penis in the male. Like the penis, it is highly sensitive and distends during sexual arousal. The vaginal opening, called the introitus, is the opening between the internal and the external genitals. Prior to the first intercourse or trauma, the introitus is surrounded by a connective tissue membrane called the hymen. After menopause, Bartholin's and Skene's glands become dry because of the lack of estrogen.

The Internal Organs

The vagina, cervix, uterus, fallopian tubes, and ovaries are the internal organs of the female reproductive system (Figure 47–6 ■). The ovaries are the primary reproductive organs in women and also produce female sex hormones. The vagina, uterus, and fallopian tubes serve as accessory ducts for the ovaries and a developing fetus.

THE VAGINA AND CERVIX

The vagina is a fibromuscular tube about 8 to 10 cm (3 to 4 in.) in length located posterior to the bladder and urethra and anterior to the rectum. The upper end contains the uterine cervix in an area called the fornix. The vagina serves as a route for the excretion of secretions (including menstrual fluid), as an organ of sexual response, and as a passageway for the birth of an infant. The walls of the vagina are usually moist and maintain a pH ranging from 3.8 to 4.2. This pH is bacteriostatic and is maintained by the action of the hormone estrogen and normal vaginal flora. Estrogen stimulates the growth of vaginal mucosal cells so that they thicken and have increased glycogen content. The glycogen is fermented to lactic acid by Döderlein's bacilli (lactobacilli that normally inhabit the vagina), slightly acidifying the vaginal fluid. The cervix projects into the vagina and forms a pathway between the uterus and the vagina. The cervix is a firm structure, protected by mucus that changes consistency and quantity during the menstrual cycle and during pregnancy.

THE UTERUS

The uterus is a hollow pear-shaped muscular organ with thick walls located between the bladder and the rectum. It has three parts: the fundus, the body, and the cervix. It is supported in the abdominal cavity by the broad ligaments, the round ligaments, the uterosacral ligaments, and the transverse cervical ligaments. The uterus receives the fertilized ovum and provides a site for growth and development of the fetus.

The uterine wall has three layers. The perimetrium is the outer serous layer that merges with the peritoneum. The myometrium is the middle layer and makes up most of the uterine wall. This layer has muscle fibers that run in various directions, allowing contractions during **menstruation** (the periodic shedding of the uterine lining in a woman of childbearing age who is not pregnant) or childbirth, and expansion as the fetus grows. The endometrium lines the uterus; its outermost layer is shed during menstruation.

THE FALLOPIAN TUBES

The fallopian tubes are thin cylindrical structures about 10 cm (4 in.) long and 2.5 cm (1 in.) in diameter. They are attached to the uterus on one end and are supported by the broad ligaments. The lateral ends of the fallopian tubes are open and made of projections called fimbriae that drape over the ovary. The fimbriae pick up the ovum after it is discharged from the ovary. The fallopian tubes are made of smooth muscle and are lined with ciliated, mucus-producing epithelial cells. The movement of the cilia and contractions of the smooth muscle move the ovum through the tubes toward the uterus. Fertilization of the ovum by the sperm usually occurs in the outer portion of a fallopian tube.

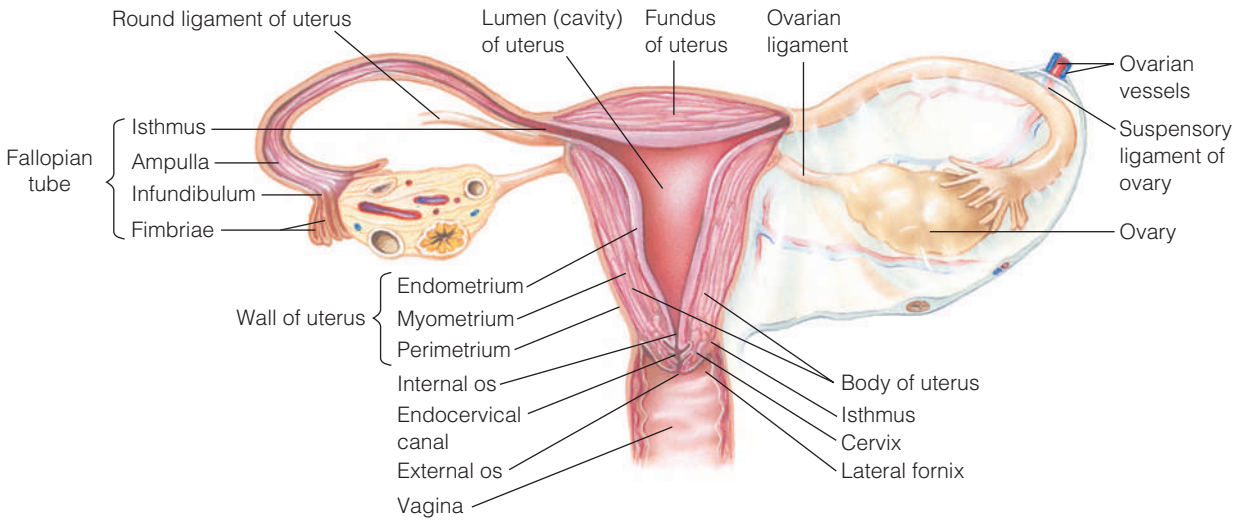

Figure 47–6 ■ The internal organs of the female reproductive system.

THE OVARIES

The ovaries are flat, almond-shaped structures located on either side of the uterus below the ends of the fallopian tubes. They are homologous to the male's testes. The ovaries store the female germ cells (ova) and produce the female hormones estrogen and progesterone. A woman's total number of ova is present at her birth.

Female Sex Hormones

The ovaries produce estrogens, progesterone, and androgens in a cyclic pattern. **Estrogens** are steroid hormones that occur naturally in three forms: estrone (E_1), estradiol (E_2), and estriol (E_3). Estradiol is the most potent and is the form secreted in greatest amount by the ovaries. Estrogens are essential for the development and maintenance of secondary sex characteristics. In conjunction with other hormones, they stimulate the female reproductive organs to prepare for growth of a fetus. Estrogens are responsible for the normal structure of skin and blood vessels. They also decrease the rate of bone resorption, promote increased high-density lipoproteins, reduce cholesterol levels, and enhance the clotting of blood. Estrogens also promote the retention of sodium and water.

Progesterone primarily affects the development of breast glandular tissue and the endometrium. During pregnancy, progesterone relaxes smooth muscle to decrease uterine contractions. It also increases body temperature. Androgens are responsible for normal hair growth patterns at puberty and may also have metabolic effects.

The Menstrual Cycle

The **menstrual cycle** begins with the menstrual phase, lasting from days 1 to 5. The inner endometrial (functionalis) layer detaches and is expelled as menstrual fluid (fluid and blood) for 3 to 5 days. As the maturing ovarian follicle begins to produce estrogen (days 6 to 14), the proliferative phase begins. In response, the functionalis layer is repaired and thickens, while spiral arteries increase in number and tubular glands form. Cervical mucus changes to a thin, crystalline substance, forming channels to help the sperm move up into the uterus.

The final phase, lasting from days 14 to 28, is the secretory phase. As the corpus luteum produces progesterone, the rising levels act on the endometrium, causing increased vascularity, changing the inner layer to secretory mucosa, stimulating the secretion of glycogen into the uterine cavity, and causing the cervical mucus again to become thick and block the internal os. If fertilization does not occur, hormone levels fall. Spasm of the spiral arteries causes hypoxia of the endometrial cells, which begin to degenerate and slough off as menstrual fluid.

ASSESSING THE FEMALE REPRODUCTIVE SYSTEM

The structures and functions of the female reproductive system are assessed by findings from diagnostic tests, a health assessment interview to collect subjective data, and a physical assessment to collect objective data. Information from the health assessment interview is used to individualize the questions that are asked; for example, the postmenopausal woman would not be asked specific questions about her menstrual cycle, but it would be important to ask about vaginal dryness. Sample documentation of an assessment of the female reproductive system is included following the physical assessment section.

Diagnostic Tests

The results of diagnostic tests of the structures and functions of the female reproductive system are used to monitor the health of female reproductive structures; to support the diagnosis of a specific sexual problem, injury, or disease; to provide information to identify or modify the appropriate medications or treatments used to treat the disease; and to help nurses monitor the woman's responses to treatment and nursing care interventions. Diagnostic tests to assess the female reproductive system are described in the accompanying Diagnostic Tests table. More information is included in the discussion of specific health problems or diseases in Chapter 49.

Regardless of the type of diagnostic test, the nurse is responsible for explaining the procedure and any special preparation needed, for assessing any medication use that might affect the outcome of the tests, for supporting the woman during the examination as necessary, for ensuring the consent form is signed (if appropriate), for documenting the procedures as appropriate, and for monitoring the

DIAGNOSTIC TESTS of the Female Reproductive System

Name of Test	Purpose and Description	Related Nursing Interventions
Breast biopsy • Fine-needle aspiration • Core needle biopsy • Vacuum-assisted mammotome • Large-core surgical biopsy • Open surgical biopsy	• A fine-needle aspiration is conducted to withdraw fluid from cysts, and may be used to sample cells from masses in the breast. A 22- to 25-gauge needle is used to collect five to six samples of fluid or cells. • A core needle biopsy is conducted to obtain a sample of tissue from a solid mass or calcium deposits in the breast. A 10-, 11-, or 12-gauge needle is used to collect five to six tissue samples. • A vacuum-assisted mammotome is primarily used to evaluate calcifications. An 11- or 14-gauge needle is inserted through a small (1/4-in.) incision and 8–10 samples are removed. • A large-core surgical biopsy is performed to evaluate breast masses or calcification identified with a mammogram but nonpalpable. An incision is made and a 5- to 20-mm cylinder of breast tissue (about the size of a wine cork) is removed. • An open surgical biopsy is performed to evaluate breast masses, hard-to-reach lesions, multiple lesions, and masses with calcifications. A 4- to 5-cm (1.5- to 2-in.) incision is made and a golf ball size (or larger) area of tissue is removed.	Explain that, depending on the physician, some procedures may be performed with or without a local anesthetic. Explain that a local anesthetic may be used, but no stitches are required for a fine-needle aspiration, a core needle biopsy, or mammotome. Explain that a local anesthetic will be administered and stitches will be used to close the incision for a large-core biopsy. For an open surgical biopsy, explain that a general anesthetic is usually used and that the incision will require stitches and leave a scar. For all types, wearing a bra, applying ice packs, and taking mild analgesics decrease discomfort postprocedure.
Breast cancer genetic testing (*BRCA1*, *BRCA2*)	This blood test is used to identify a predisposition to breast and ovarian cancers by mutations of the *BRCA1* and *BRCA2* genes. The genetic defect is passed to children by both the male and female parents.	Food and fluids are not restricted. Suggest the patient have genetic counseling, regardless of the test outcome. If a woman tests positive for this mutation, she may decide to have one or both breasts removed in an effort to prevent the development of cancer.
Breast ultrasound	This examination uses high-frequency sound waves passing through tissues to detect masses in the breast. It may be performed if lesions are identified by a mammogram.	Tell the woman not to apply ointment, body powder, or underarm deodorant prior to the test, or if present, to wash it off.
Chlamydia screening	This test is performed to screen for or diagnose chlamydial infections. A swab of cells from the infected area is taken and either smeared on a slide and analyzed or cultured. Although usually taken from the urethra, vagina, or cervix, cultures may also be taken from the throat and rectum.	Assess if the woman is pregnant or has enlargement of inguinal lymph nodes. Withhold antibiotics (if prescribed) until after obtaining the specimen. Instruct not to douche before the examination. If the test is positive, emphasize need for treatment to eradicate the infection.
Colposcopy	A colposcopy may be done if a Pap test detects cell changes. The procedure, done in the health provider's office, uses a small binocular microscope to visualize the cervix. Acetic acid is applied to the cervix and abnormal cells turn white. A biopsy of the cervix and/or cryosurgery (freezing) of abnormal cells may be done during the procedure.	Instruct the woman to abstain from douching and intercourse for 48 hours prior to the examination. Assess for pregnancy, which may alter the procedure. Postprocedure: Tell the woman there may be slight vaginal bleeding for several days after the procedure, to abstain from vaginal intercourse for 1–2 days, and to take NSAIDs for discomfort or cramping.
Conization, cervical biopsy • LEEP (loop electrosurgical excision procedure) • LETZ (loop electrosurgical excision of transformation zone)	Conization, cervical biopsy, LEEP, or LETZ is done if a Pap smear indicates abnormal cervical cells or cervical dysplasia. A cone-shaped portion of tissue surrounding the cervical os is removed for evaluation (most often for cervical cancer) or to treat cervical abnormalities. A thin wire electrode that transmits an electrical current is used to cut away the affected cervical tissue in LEEP and LETZ procedures; alternately, a cold knife or laser may be used. The procedure is usually done on an outpatient basis or at a surgery center.	Explain that an OTC analgesic may be recommended prior to the procedure or general, spinal, or epidural anesthesia may be required. If anesthesia is used, up to 4 h will be spent in recovery after the procedure before going home. Following the procedure, explain that the patient should not use tampons, douche, lift heavy objects, or have sexual intercourse for the recommended length of time, and that she should take showers (not tub baths). Explain that minor vaginal bleeding and discharge are expected for several days after the procedures and spotting may continue for about 3 weeks; perineal pads (not tampons) should be used. The physician should be called for bleeding heavier than a normal period, severe pain, fever, heavy vaginal discharge, or strong vaginal odor. OTC pain medication may be prescribed for pain and cramping.

(*continued*)

DIAGNOSTIC TESTS of the Female Reproductive System (*continued*)

Name of Test	Purpose and Description	Related Nursing Interventions
Cultures for bacteria, *Candida* (yeast), or *Trichomonas*	A culture is performed to identify vaginal organisms or blood cells. A specimen of vaginal discharge is obtained with a swab, placed in solution, and examined under the microscope immediately after it is collected (referred to as a wet-mount).	Request the patient not douche before the examination.
Endometrial biopsy	An endometrial biopsy is performed to identify endometrial hyperplasia or endometrial cancer. The cervix is cleaned and tissue is obtained transcervically from the endometrium either by curettage or vacuum aspiration.	Explain that the procedure is briefly painful, and causes vaginal bleeding for a few days. Advise to use perineal pads, and avoid tampons and sexual intercourse while bleeding.
Gonorrhea culture	A culture is performed to evaluate for gonorrhea. A swab is used to collect a sample of discharge from the infected area (cervix, urethra, anus, or throat), smeared on a slide, and a Gram stain is conducted to identify the organism (*N. gonorrhoeae*). A urine sample is used in some tests.	Instruct not to douche before the examination. If the test is positive, request referral to an STI testing center or clinic and emphasize need for treatment of the patient and her partner(s) to eradicate the infection.
HPV test (HPV DNA test, genital human papilloma test)	An HPV test is used as a screening tool for human papillomavirus (HPV) in women after the age of 30. It is usually conducted in conjunction with a pelvic examination and Pap smear. A finding of "low-grade changes" on the Pap smear with HPV indicates the likely presence of HPV and the need for further testing. A positive test for HPV indicates an increased risk for cancer, but does not specify which type of HPV is present; HPV 16 and 18 are highly carcinogenic, other strains may carry a low risk for cancer (Kee, 2014).	Explain that the test should be done during a time when the woman is not menstruating, and that she should not douche, use tampons, or use vaginal medications for at least 48 hours prior to the examination. Ask the woman to void prior to the examination. Explain that following the test there may be a small amount of vaginal bleeding or gray-green discharge; a panty liner may be used to avoid spotting clothing. Instruct her not to have intercourse until the healthcare provider says it is safe to do so.
Hysterosalpingogram	This test is conducted to diagnose causes of infertility and abnormalities of the uterus or fallopian tubes. A contrast medium is instilled through the cervix, through the uterus, and out the fallopian tubes while x-rays are taken. The test should be done on the seventh to the ninth day after the end of the menstrual period.	Assess for pregnancy, vaginal bleeding, or acute infection (all would contraindicate the test). Assess for allergy to seafood (iodine) or previous contrast media. A cleansing enema and douche may be ordered prior to the test. Inform the woman that there may be some bloody discharge for 3–4 days after the test; if it continues after that time, she should notify her healthcare provider.
Laparoscopy	This examination is conducted to visualize the organs in the peritoneal cavity (uterus, fallopian tubes, ovaries); and to perform a tubal ligation. A fiberoptic scope is inserted through small abdominal incisions and carbon dioxide is inserted into the peritoneal cavity for better visualization. It is performed in an ambulatory surgery center. A microlaparoscopy uses much smaller instruments and is considered only minimally invasive, resulting in less post-procedure discomfort.	Instruct the woman not to smoke, eat, or drink fluids after midnight the day of the procedure. Depending on protocol, the woman may be asked to take laxatives and/or enemas to empty the bowel. Ask the woman to shower or bathe and remove nail polish and make-up the evening before the procedure. Ask the woman to void prior to the examination and explain that a general anesthetic will be used. Following the procedure, the woman remains in the recovery room for about 1 h, and remains in the treatment center for 3–4 h. After voiding, the woman is discharged home. After the procedure, the woman will have medications for pain, and may experience watery, pink-tinged drainage from the small abdominal incisions (the drainage usually lasts less than 48 hours). Explain that shoulder pain is common after the procedure (referred pain from the retained carbon dioxide gas); that some vaginal bleeding may occur and the woman should use a perineal pad; and to report excess bleeding, pain, or signs of infection to the physician.

DIAGNOSTIC TESTS of the Female Reproductive System (*continued*)

Name of Test	Purpose and Description	Related Nursing Interventions
Mammogram	Used to detect tumors in the breast. Breasts are flattened in the mammography machine and low-dose x-rays are taken. The American Cancer Society (2014) recommends annual mammography for women starting at age 40; however, other groups recommend mammography every 2 years for women over the age of 50.	Ask the woman if she is pregnant; if so, the test is contraindicated. Tell the woman not to apply ointment, body powder, or underarm deodorant prior to the test, or if present, to wash it off. Women should discuss the recommended frequency of mammography with their healthcare provider.
Papanicolaou smear (Pap test)	This test is conducted to diagnose malignant and premalignant lesions of the cervix; to assess the effects of hormone replacement; identify viral, bacterial, fungal, and parasitic conditions; and to evaluate response to chemotherapy or radiation therapy to the cervix. Cells are obtained during a pelvic examination with a plastic spatula, a cotton swab, or an endocervical brush. The sample collected may be smeared on a glass slide or put into a special liquid preservative and then the cells in suspension are processed onto a slide. The cells are then stained and examined.	Explain that the test should be done during a time when the woman is not menstruating, and that she should not have intercourse, douche, or use vaginal medications for at least 24 hours, and preferably 48 hours prior to the examination. Ask about menstrual history, including any menstrual problems, last menstrual period, bleeding, and flow. Ask about vaginal discharge and vaginal itching. Assess medication use; vaginal antibiotics alter test results, so testing should be delayed if taking (Leeuwen, Poelhuis-Leth, & Bladh, 2011). Ask the woman to void prior to the examination.
Syphilis (dark-field examination)	See the Male Diagnostic Tests table.	
Syphilis screening tests • Venereal Disease Research Laboratory (VDRL) • Rapid plasma reagin (RPR) • Fluorescent treponemal antibody absorption (FTA-ABS)	See the Male Diagnostic Tests table.	
Ultrasound (abdominal, vaginal)	An ultrasound is used to detect the presence of space-occupying lesions, such as fibroid tumors, cysts, abscesses, and neoplasms. The abdomen is coated with transducing gel, and a graphic visualization is made. For a vaginal ultrasound, a transducer is covered with a condom or vinyl glove coated with transducer gel and then introduced into the vagina.	Explain the need to increase intake of fluids and tell the woman not to void until the test is completed to ensure a full bladder (this lifts the pelvic organs higher in the abdomen and improves visualization).

results of the tests. The nurse is also responsible for postprocedure care and patient teaching for self-care at home.

Genetic Considerations

When conducting a health assessment interview and a physical assessment, it is important for the nurse to consider genetic influences on the health of the adult. Several diseases of the female reproductive system have a genetic component. During the health assessment interview, it is especially important to ask about a family history of ovarian or breast cancer. During the physical assessment, assess for any manifestations that might indicate a genetic disorder (see the accompanying box). If data are found to indicate genetic risk factors or alterations, ask about genetic testing and refer for appropriate genetic counseling and evaluation. Chapter 8 provides further information about genetics in medical-surgical nursing.

GENETIC CONSIDERATIONS

Examples of Female Reproductive System Disorders

- There is a clear genetic link for some of the cases of both breast and ovarian cancer. Two breast cancer susceptibility genes have been identified: *BRCA1* and *BRCA2*. If a woman has either of these genes, she is at increased risk for having breast or ovarian cancer at some point in her life.
- A family history of endometrial, colon, or breast cancer increases a woman's risk for endometrial cancer.
- Turner syndrome is a disorder in a female caused by complete or partial absence of one of the two X chromosomes. The disorder is characterized by short stature, a webbed neck, and a lack of sexual development at puberty.

Health Assessment Interview

A health assessment interview to determine problems with the female reproductive system may be conducted during a health screening, may focus on a chief complaint (such as severe menstrual cramping), or may be part of a total health assessment. Women may be embarrassed to discuss health problems or concerns involving their reproductive organs; it is important for the nurse to ask questions in

a nonthreatening, matter-of-fact manner. Consider the psychologic, social, and cultural factors that affect sexuality and sexual activity. Use words that the woman can understand, and do not be embarrassed or offended by the words she uses. The woman may perceive the interview as less threatening if the discussion begins with more general questions and then progresses to specific questions, and if questions are asked in a way that gives the woman permission to describe behaviors and manifestations. For example, first ask a female patient about menstrual and childbirth histories before asking questions about STIs.

The focused interview for the female reproductive system is usually extensive. However, the questions may in many instances be tailored to the specific health problem of the woman. As with the assessment of other body systems, analyze and document the onset of the problem, its duration, frequency, precipitating and relieving factors, any associated symptoms, treatment, self-care, and outcome. For example, ask the woman the following questions:

- Have you noticed vaginal bleeding after intercourse?
- Does over-the-counter medication relieve the vaginal itching and discharge?
- Have you had any fever or abdominal pain with this vaginal infection?

Ask about menstrual history, sexual history, obstetric history, use of contraceptives, use of medications, and reproductive system examinations. Assess the use of condoms during intercourse; unprotected sexual intercourse increases the risk of STIs, including HIV infection. Ask about smoking; a history of smoking increases the risk of circulatory problems in the woman taking oral contraceptives and increases the risk for cancer of the cervix.

Chronic illnesses may affect the function of the female reproductive system. Diabetes mellitus increases the risk of vaginal infections and vaginal dryness, both of which interfere with sexual pleasure. Chronic heavy menstrual flow may result in anemia. Thyroid and adrenal disorders may affect secondary sex characteristics, the menstrual cycle, and the ability to become pregnant.

Obtaining any family history of cancer is important. The risk for endometrial cancer is higher in women with a family history of endometrial, breast, or colon cancer; the risk for ovarian cancer is higher in women with a family history of ovarian or breast cancer; and the risk for breast cancer is higher in women with a family history of breast cancer. Exposure to DES in utero increases the risk of cancer of the cervix and vagina. Exposure to asbestos poses a risk for cancer of the ovary. The risk for breast cancer is also greater if the woman has a history of fibrocystic disease.

Carefully explore any history of vaginal bleeding and vaginal discharge. Ask about the onset of vaginal bleeding, any related factors, the color (pink, red, dark red, brown), the character (thin, watery, presence of mucus, size and number of clots), the amount (spotting, how many pads or tampons in a specific amount of time), and relationship to menstrual cycle. Regarding vaginal discharge, ask about the onset, color (white, green, gray), character (thin, thick, curdlike), odor, itching, and rash.

Questions about sexuality may include sexual preference, number of sexual partners; history of **anorgasmia** (absence of orgasm), **dyspareunia** (painful intercourse), or other problems with intercourse; history of sexual trauma; use of condoms or other contraceptives; and current level of sexual satisfaction.

Physical Assessment

Physical assessment of the female reproductive system usually is conducted as part of a scheduled screening (e.g., for an annual Pap smear) or for a specific reproductive health problem. If conducted as part of a total physical assessment, this is usually the final system to be assessed. The nurse must feel comfortable with the examination of patients of the opposite gender; if either the nurse or the patient is not comfortable, or if cultural beliefs prohibit examination by a nurse of the opposite gender, a nurse of the same gender should be asked to conduct this part of the assessment.

The female reproductive system is assessed by inspection and palpation. Ask the woman to void before having the examination. Prior to the examination, collect all necessary equipment and explain the techniques to the woman to decrease anxiety. Put on disposable gloves before beginning the examination and wear them throughout the examination. Ask the woman to remove her clothing and put on a gown. Ensure that the examining room is private and warm.

Explain the procedures for the examination thoroughly and in a matter-of-fact way to decrease anxiety and embarrassment. If the woman is unfamiliar with her reproductive organs, charts may be used to demonstrate the parts that will be examined. Carefully explain the procedure for the examination, and show the speculum to the woman. The assessment may be done with the woman in the sitting or supine position to examine the breasts and in the lithotomy position to assess the external genitalia and internal organs. Expose only those body parts being examined to preserve modesty. Normal age-related findings for the older woman are summarized in the Nursing Care of the Older Adult feature.

The examination usually begins with examination of the breasts with the woman in the sitting and supine positions. The nurse then helps the woman move to the lithotomy position on the examining table, with the feet in the stirrups and the buttocks even with the foot of the table. Older or frail women may not be able to tolerate this position. In this case, the woman is examined in the supine position or the left lateral position. Although the entire examination is described here, the internal examination is only conducted by a nurse with advanced practice in the procedure. However, nurses are often asked to assist with the examination and should be able to explain the examination to a woman.

NURSING CARE OF THE OLDER ADULT

Age-Related Changes in the Female Reproductive System

Age-Related Change	Significance
BREASTS	
• Atrophy, with sagging of breast tissue • Linear strands may appear from shrinkage and fibrotic changes	Although aging does not cause breast cancer, the incidence rises in older women; age-related changes may make finding tumors more difficult.
EXTERNAL GENITALIA	
• Labia flatten, and vulvar adipose tissue and hair decrease. • ↓ collagen and adipose tissues in the vaginal canal, resulting in loss of rugae, and shortening and narrowing of vaginal canal. • ↓ vaginal lubrication; epithelium becomes thinner and avascular. • More alkaline pH of vagina. • Cervix becomes smaller.	Vagina is more easily irritated, increasing the risk of vaginal infections. Lubricants are necessary for comfortable intercourse.
INTERNAL ORGANS	
• Uterus shrinks. • Fallopian tubes shrink and shorten. • Ovaries are smaller and thicker. • With menopause, production of estrogen decreases. • Loss of estrogen may cause pelvic floor muscles to weaken. • Loss of estrogen causes changes throughout the body, including loss of skin tone (wrinkling) and growth of facial hair.	With the completion of menopause, the menstrual cycles end and the woman is infertile. Weakening of the pelvic floor muscles may contribute to involuntary incontinence with increased intra-abdominal pressure (as with coughing and sneezing). Skin is dry and thin.

Female Reproductive System Assessments

Technique/Normal Findings	Abnormal Findings
Breast Assessment	
Inspect both breasts simultaneously with the woman seated in the following positions: arms at sides, arms overhead, hands pressed on hips, leaning forward. Inspect breast size, symmetry, contour, skin color, texture, venous patterns, and lesions. Lift the breasts, and inspect the lower and lateral aspects. *Breasts normally vary slightly in size and shape, and one breast may normally be larger than the other. Color should be consistent with the skin tone and texture smooth. There should be no redness, swelling, prominent veins, or lesions.*	• Retractions, dimpling, and abnormal contours suggest lesions, and should be further evaluated for malignancy. • Thickened, dimpled skin with enlarged pores (called peau d'orange, orange peel, or pig skin) and unilateral venous patterns are associated with malignancy. • Redness may be seen with infection or carcinoma.
Inspect the areolae and nipples. *The color of the areolae should be consistent with the woman's skin color (ranging from dark pink to dark brown), and Montgomery tubercles may be present. The nipples should be equal bilaterally in size, centrally located in each breast, and free of lesions or discharge. Nipples are usually everted, but may normally be inverted or flat.*	• Peau d'orange may be noted first in the areola. • Recent unilateral inversion of the nipple or asymmetry in the directions in which the nipples point suggests cancer.
Palpate both breasts, axillae, and supraclavicular areas. Figure 47–7 ■ illustrates a possible pattern for breast palpation. Various palpation patterns may be used as long as every part of each breast is palpated, including the axillary tail (also called tail of Spence), which is the breast tissue that extends from the upper outer quadrant toward and into the axillae. Ask the woman to assume a supine position with a small pillow under the shoulder and the arm over the head, and repeat the systematic palpation sequence. Describe identified masses by location, size, shape, consistency, tenderness, mobility, and delineation of borders. *Breasts should feel smooth, firm, and elastic, without palpable masses. Prior to the menstrual cycle, there may be increased nodularity and tenderness.*	• Tenderness may be related to premenstrual fullness, fibrocystic disease, or inflammation. • Nodules in the tail of the breast may be enlarged lymph nodes. • Hard, irregular, fixed unilateral masses that are poorly delineated suggest carcinoma. • Bilateral, single or multiple, round, mobile, well-delineated masses are consistent with fibrocystic breast disease or fibroadenoma. • Swelling, tenderness, erythema, and heat may be seen with mastitis.

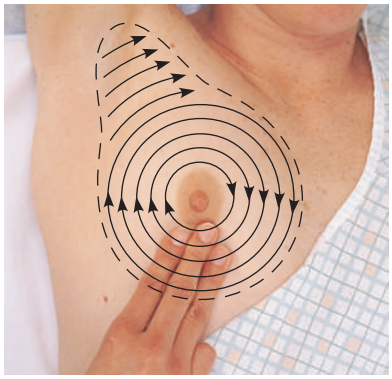

Figure 47–7 ■ Possible pattern for palpation of the breast.

(*continued*)

Female Reproductive System Assessments (*continued*)

Technique/Normal Findings	Abnormal Findings
Palpate the nipple, then compress it between the thumb and index finger. Note the color of any discharge. *Nipples should be firm and elastic, normally without discharge (although some women normally have a clear discharge, and a milky substance may be expressed during pregnancy and lactation).*	• Loss of nipple elasticity is seen in cancer. • Bloody or serous discharge is associated with intraductal papilloma. • Milky discharge not due to prior pregnancy and found on both sides suggests galactorrhea (lactation not associated with pregnancy or nursing), which is sometimes associated with a pituitary tumor. • Unilateral discharge from one or two ducts can be seen in fibrocystic breast disease, intraductal papilloma, or carcinoma.
Axillary Assessment	
Inspect and palpate the axillae. Palpate all sections of both axillae for palpable notes (Figure 47–8 ■). *There should be no redness, irritation, lesions, or enlarged lymph nodes on palpation.*	• Rash may be due to allergy or other causes. • Signs of inflammation and infection may be due to infection of the sweat glands. • Enlarged axillary nodes are most often due to infection of the hand or arm but can be caused by malignancy. • Enlarged supraclavicular nodes are associated with lymphatic metastases from abdominal or thoracic carcinoma.

Figure 47–8 ■ Palpating the axillary lymph nodes.

External Genitalia Assessment

Help the woman to the lithotomy position with the knees flexed and separated.

Inspect and palpate the labia majora. *The labia majora should be equal in size and free of lesions or bulging.*	• Excoriation, rashes, or lesions suggest inflammatory or infective processes. • Bulging of the labia that increases with straining suggests a hernia. • Varicosities may be present on the labia.
Inspect the labia minora. Separate the labia majora for better visualization. *The labia minora should be symmetrical, dark pink and moist, without redness or lesions.*	• Inflammation, irritation, excoriation, or caking of discharge in tissue folds suggests vaginal infection or poor hygiene. • Ulcers or vesicles may be manifestations of an STI.
Palpate the inside of the labia minora between thumb and forefinger. *There should be no nodules, ulcers, or lesions.*	• Small, firm, round cystic nodules in labia suggest sebaceous cysts. • Wartlike lesions suggest condylomata acuminata (genital warts). • Firm, painless ulcers suggest chancre of primary syphilis. • Shallow, painful ulcers suggest herpes infection. • Ulcerated or red raised lesions in older women suggest vulvar carcinoma.
Inspect the clitoris. *The clitoris is normally not enlarged.*	• Enlargement may be a symptom of a masculinizing condition.
Inspect the vaginal opening. *There should be no swelling, discoloration, lacerations, discharge, or lesions visible in the vaginal opening.*	• Swelling, discoloration, or lacerations may be caused by trauma. • Discharge or lesions may be symptoms of infection. • Fissures or fistulas may be related to injury, infection, growth of a malignancy, or trauma.
Palpate Skene's glands. Using the index finger, "milk" Skene's glands on both sides and over the urethra and inspect for possible discharge (Figure 47–9 ■). *There should be no discharge or tenderness present.*	• Discharge from Skene's glands and/or tenderness suggests infection.

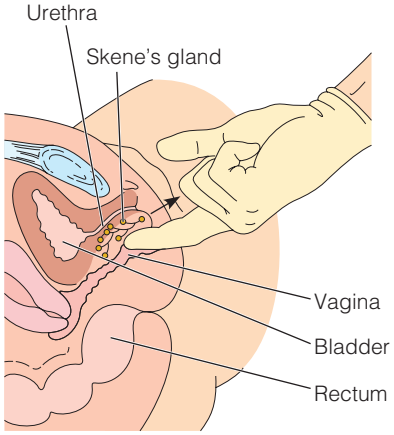

Figure 47–9 ■ Palpating Skene's glands.

Female Reproductive System Assessments (*continued*)

Technique/Normal Findings	Abnormal Findings
Palpate Bartholin's glands at the posterior labia majora (Figure 47–10 ■). *There should be no masses, redness, swelling, or tenderness on palpation.*	• A nontender mass in the posterolateral portion of the labia majora is indicative of a Bartholin's cyst. • Swelling, redness, or tenderness, especially if unilateral, may indicate abscess of Bartholin's glands.
Inspect the vaginal orifice for bulging and urinary incontinence. Ask the woman to strain or "bear down." *No bulging should be visible with straining.*	• Bulging of the anterior vaginal wall and urinary incontinence suggest a cystocele. • Bulging of the posterior wall suggests a rectocele. • Protrusion of the cervix or uterus into the vagina indicates uterine prolapse.
Inspect and palpate the perineum. *The perineum should be free of redness or lesions. Episiotomy scars are a normal finding.*	• Inflammation, lesions, and growths may be seen in infections or cancer. • Fistulas may be the result of injury, trauma, infection, or growth of a malignancy.

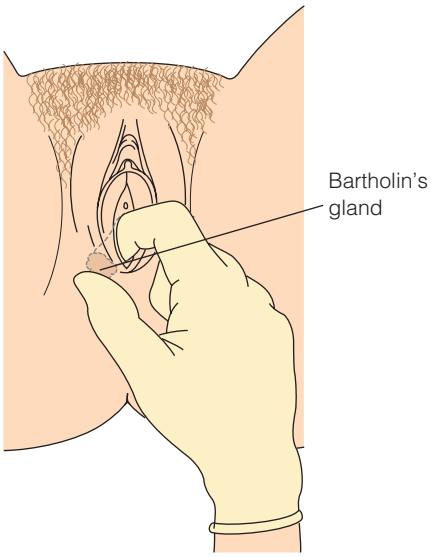

Figure 47–10 ■ Palpating Bartholin's glands.

Vaginal and Cervical Assessment

This assessment is primarily conducted by a physician or an advanced practice nurse.

Use a vaginal speculum to inspect the vaginal walls and cervix. See the guidelines in Box 47–1. *The vaginal opening varies, depending on age, sexual history, and vaginal births. Vaginal mucosa is normally pink and moist, without discharge or odor. There should be no bulging or loss of urine. The cervix is normally smooth and pink, without lesions and has a consistency similar to the tip of the nose.*	• Bluish color of the cervix and vaginal mucosa may be a sign of pregnancy. • A pale cervix is associated with anemia. • A cervix to the right or left of the midline may indicate a pelvic mass, uterine adhesions, or pregnancy. • Projection of the cervix more than 3 cm (about 1 in.) into the vaginal canal may indicate a pelvic or uterine mass. • Transverse or star-shaped cervical lacerations reflect trauma causing tearing of the cervix. • An enlarged cervix is associated with infection. • Nabothian cysts (small, white, or yellow raised, round areas on the cervix) are considered normal but may become infected. • Cervical polyps may be cervical or endometrial in origin.
Palpate the cervix, uterus, and ovaries. See the guidelines in Box 47–2. *The cervix can be moved slightly without discomfort. The uterus is normally at the level of the pubis, moves freely, and is nontender. The ovaries (about the size of a walnut) are firm, smooth, mobile, and slightly tender on palpation. The ovaries are not usually palpable 3–5 years after menopause. A small amount of clear drainage is normal.*	• The uterus may be retroverted (tilted backward) or retroflexed (angled backward). • Pain on movement of the cervix during manual examination suggests pelvic inflammatory disease (PID). • Softening of the uterine isthmus (Hegar's sign), softening of the cervix (Goodell's sign), and uterine enlargement may be objective signs of pregnancy. • Firm, irregular nodules that vary greatly with size and are continuous with the uterine surface are likely to be myomas (fibroids). • Unilateral or bilateral smooth, compressible adnexal masses are found in ovarian tumors. • Profuse menstrual bleeding is seen with endometrial polyps, dysfunctional uterine bleeding (DUB), and use of an intrauterine device. • Irregular bleeding may be associated with endometrial polyps, DUB, uterine or cervical carcinoma, or oral contraceptives. • Postmenopausal bleeding is seen with endometrial hyperplasia, estrogen therapy, and endometrial cancer.

BOX 47–1 Guidelines for Intravaginal Assessment and Use of the Vaginal Speculum

The size of the speculum that is used for an internal examination of the female reproductive system depends on the age of the woman and size of the vagina. Two types of specula are available. The Graves speculum is larger and used most often for examinations of adult women. The Pederson speculum, which is narrower, may be used to examine adolescents or adult woman who are virgins, have never had a baby, or who are postmenopausal with vaginal atrophy. The speculum should be warm. If cultures or smears are to be obtained, neither water nor gel should be used to warm or to lubricate the speculum.

If cells are to be taken for cytologic studies, the patient should not douche, use vaginal medications, or take a tub bath for 24 hours before the examination. Finally, the examination is usually deferred if the patient is menstruating or has a vaginal infection.

The general procedure is as follows:

1. Place the index and middle finger of one hand into the vagina, just inside the introitus, and press the fingers toward the rectum. Hold the speculum in the other hand.
2. Ask the patient to bear down, and insert the closed blades of the speculum into the vagina at an oblique angle until the ends of the blades reach the fingertips (see the accompanying figure). Withdraw the fingers and rotate the speculum to a transverse position.
3. Continue to insert the speculum until it reaches the end of the vagina. Depress the lever of the speculum to open the blades. When the cervix is in full view, fix the depressed lever to an open position.
4. Inspect the cervix. The normal cervix is pink and midline. Assess color, position, size, projection into the vagina, surface and shape, and any discharge.

If a Pap smear to collect cervical cells for cytologic studies is done, the following procedure may be used: To collect endocervical cells, place the groove of the spatula or synthetic endocervical brush snugly against the cervical os, and rotate it 360 degrees. In a single stroke, spread the material from both sides of the spatula on a slide, and immediately spray with fixative. If using a liquid method, place the brush or spatula in the liquid vial and swirl at least 10 times to thoroughly mix specimen in medium.

If a yeast or bacterial culture is indicated, a specimen can be obtained by a trained provider. A cotton-tipped applicator is used and the inside walls of the vagina are gently wiped to obtain the specimen. The applicator is then placed into the culture medium according to agency protocol.

At the end of the examination, loosen the lever control and slowly withdraw the speculum, closing the blades slowly and rotating the speculum while observing all areas of the vaginal wall. Assess the color of the mucosa and the color and appearance of any discharge.

BOX 47–2 Guidelines for Bimanual Pelvic Examination

The bimanual pelvic examination is done to palpate the cervix, uterus, and ovaries. The examiner's hand that will be used intravaginally is held with the index and middle fingers extended, the thumb abducted, and the fourth and fifth fingers folded on the palm of the hand. The extended fingers are lubricated.

The general procedure is as follows:

1. Spread the labia with the thumb and finger of the opposite hand and insert the lubricated fingers into the vagina with the palm upward.
2. Place the opposite hand on the abdomen; it is used to press on the abdomen and gently move the internal genitals toward the intravaginal fingers (see the accompanying figure).
3. Ask the patient to take deep breaths to relax the abdominal wall.
4. Palpate the cervix, assessing size, contour, position, surface, consistency, tenderness, and mobility. The cervix should be freely movable and nontender.
5. Palpate the uterus by pressing downward on the abdomen while placing the intravaginal fingers in the anterior fornix and gently lifting against the abdominal hand. Assess the size, shape, surface, consistency, position, mobility, and tenderness of the uterus. The normal uterus is freely movable and nontender.
6. Palpate the adnexal areas, which surround the uterus and contain the fallopian tubes and ovaries. Because these structures are small, palpation may not be possible. If the ovaries are palpable, they should be smooth and firm. The normal ovary is sensitive to touch, firm, and highly movable.
7. Withdraw the fingers. Provide tissues for the patient's use in wiping the genital area.

SAMPLE DOCUMENTATION

Assessment of the Female Reproductive System

A 32-year-old female, first visit to health department for problems with "burning and pain in my crotch area" and "It really hurts to urinate." Also states she had unprotected sex on a date about 2 weeks ago. Oral temperature 38.3°C (101°F). Vaginal examination findings of vesicles and red ulcerations on labia majora and vaginal mucosa. Inguinal lymph nodes enlarged and tender to palpation. Culture of discharge from ulcerations sent to lab.

CHAPTER HIGHLIGHTS

- **Male and female reproductive organs provide sexual pleasure and produce offspring. Physical health, psychosocial health, self-care habits, family, culture, and the environment impact reproductive functioning.**
- **Physical assessment of the male reproductive system includes inspection and palpation of external genitalia, palpation of internal reproductive organs, transillumination of the testes, assessment of inguinal areas, and assessment of the perianal area and rectum. Abnormal findings in the male reproductive system include lesions, disorders of the penis or scrotum, and inguinal hernias.**
- **The female reproductive system undergoes cyclic changes in response to estrogen and progesterone levels. The female reproductive system manufactures ova for fertilization, transports fertilized ova for implantation, regulates production and secretion of hormones, and provides sexual stimulation and pleasure. Abnormal findings in the female reproductive system include inflammatory processes and problems with the external genitalia, the cervix, and the vagina.**
- **Psychosocial factors including stress, anxiety, and grief influence sexual functioning. Sensitivity to cultural differences in discussions of reproductive function is important.**

TEST YOURSELF NCLEX-RN® REVIEW

1. While assessing a male patient who is obese, the nurse notes a normal change in the patient's breasts. What did the nurse most likely assess in this patient?
   1. phimosis
   2. absent areola
   3. gynecomastia
   4. enlarged axillary lymph nodes
2. The school nurse is preparing a lecture on the differences between the male and female reproductive anatomy. Which female structure should the nurse explain as being analogous to the penis in the male?
   1. ovary
   2. clitoris
   3. labia majora
   4. labia minora
3. An older male patient with prostate problems does not understand why this health problem causes a change in urination. What should the nurse say when beginning to respond to this patient's question?
   1. "The prostate gland presses on the bladder."
   2. "The prostate gland surrounds your urethra."
   3. "The prostate gland sits on top of the kidneys."
   4. "Your kidneys respond to prostate enlargement."
4. A male patient being treated for prostate cancer is scheduled for laboratory tests. Which blood test may be used to measure the success of prostate cancer treatment?
   1. PSA
   2. CBC
   3. WBC
   4. VDRL
5. The nurse is conducting a health history with a young male patient. Which questions would be appropriate to identify his health perception-health management? (Select all that apply.)
   1. "Do you smoke?"
   2. "Have you experienced dribbling of urine?"
   3. "Are you currently in a sexual relationship?
   4. "Have you ever noticed blood in your urine?"
   5. "Do you practice testicular self-examination?"
6. A female patient in menopause has a low estrogen level. Which should the nurse explain as potential changes that can occur with this low level of hormone? (Select all that apply.)
   1. loss of skin tone
   2. growth of facial hair
   3. cervix becomes smaller
   4. pelvic floor muscles weaken
   5. development of heart disease

7. A young female patient is experiencing cessation of menstruation. Which biologic event should the nurse investigate first?
   1. onset of puberty
   2. onset of menopause
   3. implantation of an embryo
   4. beginning spermatogenesis
8. A patient is scheduled for a diagnostic test to detect cervical cancer. For which test should the nurse prepare the patient?
   1. Pap smear
   2. colposcopy
   3. mammogram
   4. blood culture
9. The nurse is preparing to assess a female patient's breasts. Which assessment techniques should the nurse use to determine abnormalities of the breast? (Select all that apply.)
   1. palpation
   2. aspiration
   3. inspection
   4. percussion
   5. auscultation
10. A 72-year-old female patient reports suddenly having menstrual periods. What should the nurse respond to this patient?
    1. "Do you still have sexual activity?"
    2. "This is perfectly normal, even at your age."
    3. "Do you have menstrual cramps with the periods?"
    4. "You need to see your doctor, because you should not be having these."

See Test Yourself answers in Appendix B.

48 Nursing Care of Men with Reproductive System and Breast Disorders

LEARNING OUTCOMES

1. Explain the pathophysiology, manifestations, complications, interprofessional care, and nursing care of disorders of the male reproductive system, including disorders of sexual function, the penis, the testes and scrotum, the prostate gland, and the breast.
2. Compare and contrast the risk factors for cancer of the penis, testes, and prostate gland.
3. Discuss the purposes, nursing implications, and health education for medications and treatments used to treat disorders of sexual function, the penis, the testes and scrotum, the prostate gland, and the breast.
4. Describe the various surgical procedures used to treat disorders of the male reproductive system.

CLINICAL COMPETENCIES

1. Assess the functional health status of men with reproductive system and breast disorders and monitor, document, and report abnormal or unexpected manifestations and responses.
2. Use current evidence and patient preferences to plan and implement optimal nursing care for men with reproductive and breast disorders.
3. Prompt patient responses of values, preferences, and expressed needs as part of the clinical interview, implementation, and evaluation of care.
4. Function competently within own scope of practice as a member of the healthcare team caring for men with reproductive and breast disorders.
5. Apply quality measures, processes, and tools to improve outcomes for men with or at risk for reproductive and breast disorders.

MAJOR CHAPTER CONCEPTS

- Many different illnesses, medications, and surgical procedures can affect male sexual function. It is important for nurses to initiate a conversation regarding sexual concerns with male patients.
- Disorders of the male reproductive system including scrotal masses, testicular infections and cancer, prostate enlargement and cancer, phimosis and priapism may interfere with normal urination and sexual function.
- Breast enlargement (gynecomastia) and breast cancer can occur in men.
- Psychologic issues can result from alterations in a man's sexual function at any age. Nurses must recognize patient values and preferences and demonstrate a sensitivity to the patient's concerns.

KEY TERMS

benign prostatic hyperplasia (BPH), *1565*
epididymitis, *1561*
erectile dysfunction (ED), *1556*
gynecomastia, *1577*
hydrocele, *1560*
impotence, *1556*
libido, *1556*
orchitis, *1561*
phimosis, *1559*
premature ejaculation, *1559*
priapism, *1559*
prostatitis, *1564*
retrograde ejaculation, *1559*
spermatocele, *1560*
testicular torsion, *1562*
varicocele, *1560*

Men are subject to various disorders of the penis, scrotum and testes, prostate gland, and breast. These disorders may be inflammatory, structural, benign, or malignant. Young men are at increased risk for testicular cancer. Both benign and malignant conditions of the prostate gland become common as men age. Many of the disorders pose significant risk to the man's fertility and sexual and urinary function, and some are life threatening. This chapter discusses disorders of the male reproductive system, including disorders affecting sexual expression and the male breast. Because many of the treatments and disorders of the male reproductive system have the potential to affect erection and ejaculation, these problems are discussed first.

Disorders of Male Sexual Function

THE MAN WITH ERECTILE DYSFUNCTION

Erectile dysfunction (ED) is the inability of the male to attain and maintain an erection sufficient to permit satisfactory sexual intercourse. **Impotence**, a term often used synonymously with erectile dysfunction, may involve a total inability to achieve erection, an inconsistent ability to achieve erection, or the ability to sustain only brief erections. ED has many possible causes (Table 48–1), and may or may not be associated with a loss of **libido** (sexual desire).

The incidence of ED is difficult to estimate because many affected men may not report the disorder. It is estimated that as many as 30 million men in the United States have ED, and most are older than age 65 (National Kidney and Urologic Diseases Information Clearinghouse [NKUDIC], 2012a). The incidence of the problem increases rapidly after age 50. Most problems with erection are the result of a disease (with a three times greater incidence in men with diabetes mellitus), injury, or chemical substances (such as prescribed medications, alcohol, nicotine, cocaine, or marijuana) that affect nerve conduction or hormone levels or decrease blood flow in the penis (Cleveland Clinic, 2011). Clinical studies have also found a correlation between obesity and ED; a 40% higher risk has been found in men with obesity (Esposito & Giugliano, 2011). ED also occurs more often in men who smoke. Because impotence most often occurs in aging men, the discussion of pathophysiology focuses on this age group.

Pathophysiology

Age-related changes in sexual function involve cellular and tissue changes in the penis, decreased sensory activity, hypogonadism, and the effects of chronic illness. In the penis, a change from elastic collagen to a more rigid collagen results in decreased distensibility (a less rigid erection). This, in turn, interferes with the veno-occlusive mechanism, which prevents blood from prematurely leaking out of the penis into the general vasculature. Problems with this mechanism result in incomplete erections. Vibrotactile sensation over the skin of the penis declines with age: some older men require longer stimulation to achieve an erection. Hypogonadism, common in aging men, results in decreased testosterone levels. There may be a relationship between lower androgen levels and erectile function.

TABLE 48–1 Causes of Erectile Dysfunction

Major Pathologic Causes		Major Iatrogenic Causes	
		Medications	**Procedures and Infections**
NEUROGENIC	**ARTERIAL**	**ANTIHYPERTENSIVES**	**SURGERY**
Spinal cord injury	Atherosclerosis	Hydrochlorothiazide	Coronary artery bypass
Stroke	Hypertension	Spironolactone	Pelvic lymphadenectomy
Parkinson's disease	Aortic aneurysm	Methyldopa	Radical prostatectomy
Multiple sclerosis	Sickle cell disease	Clonidine	Radical cystectomy
ENDOCRINOLOGIC	**MECHANICAL**	Prazosin	Abdominal perineal resection
Diabetes mellitus	Decreased penile distensibility	Propranolol	Sympathectomy
Hypogonadism	Congenital disorders	Reserpine	Aortic aneurysm repair
Hypothyroidism	Morbid obesity	**PSYCHOTROPIC AGENTS**	Transplant surgeries
INFLAMMATORY	Hydrocele	Phenothiazines	**OTHER**
Prostatitis	Hip or pelvic fractures	Butyrophenones	Severe nosocomial infection
Cystitis	**PSYCHOGENIC**	Tricyclic antidepressants	Radiation therapy to pelvis
ACTIVITY INTOLERANCE	Depression	MAO inhibitors	
Pulmonary disease	Stress	Diazepam	
Anemias	Fatigue	Chlordiazepoxide	
Myocardial infarction	Fear of failure	**ENDOCRINOLOGIC AGENTS**	
Congestive heart failure	**COMPULSIVE FOOD DISORDERS**	LHRH agonists	
Hepatic diseases	Compulsive overeating	Estrogen compounds	
Renal failure	Anorexia nervosa	Progesterone	
SUBSTANCE DEPENDENCY	Bulimia	**OTHER**	
Alcohol		Antiparkinsonian agents	
Marijuana		Anticholinergic agents	
Narcotics		Immunosuppressive agents	
Sedatives		Antihistamines	
Tobacco			

Many illnesses affect erectile function. Damage to arteries, smooth muscles, and fibrous tissues are the most common causes of impotence. Diseases such as diabetes, kidney disease, chronic alcoholism, atherosclerosis, and vascular disease are responsible for organic ED. Innervation and blood flow to the penis may be damaged from disease processes such as Parkinson's disease and also during prostate surgery. Given the effects of aging on the vasculature of the penis, the increased incidence of chronic illness, and the multiple medications and treatments required to manage those illnesses, it is not surprising that many older men have problems with ED.

●○● INTERPROFESSIONAL CARE

The management of men with ED is growing in importance and scale because the population as a whole is aging, with the incidence increasing proportionately. Another factor is the positive change in the willingness of men and their partners to discuss sexual concerns. Although sexuality is still a very sensitive and private area for most people, the knowledge that help is available is causing men to seek answers. Many older men are coming to know that loss of erectile function is not an inevitable part of aging.

DIAGNOSIS

The diagnostic tests that may be ordered include laboratory studies, penile monitoring, and penile blood flow. Blood chemistry, complete blood count, lipid profile, urinalysis, testosterone, prolactin, thyroxin, and prostate-specific antigen (PSA) levels are measured to identify possible cardiovascular, metabolic, and endocrine problems that may be causing the dysfunction. Nocturnal penile tumescence and rigidity (NPTR) monitoring helps differentiate between psychogenic and organic causes. NPTR can be performed in a sleep laboratory, although home testing with portable devices is an alternative. The number and quality of erections occurring during REM sleep can be determined. Cavernosometry and cavernosography of the corpora are used to evaluate arterial inflow and venous outflow of blood in the penis.

MEDICATIONS

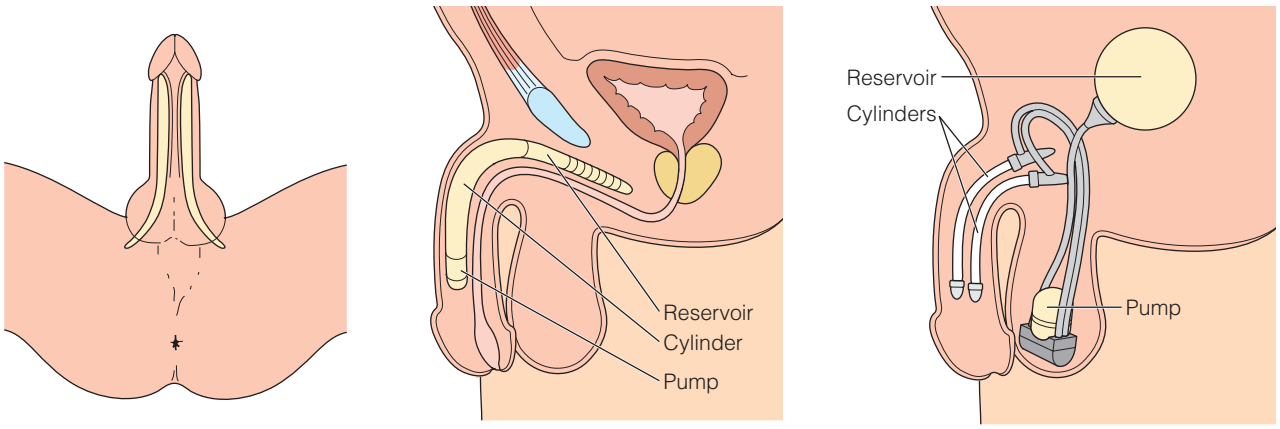
ED can be treated with medications taken orally, injected directly into the penis, or inserted into the urethra at the tip of the penis.

- *Oral medications:* The oral medications used to treat ED include sildenafil citrate (Viagra), vardenafil hydrochloride (Levitra), or tadalafil (Cialis). Viagra and Levitra are taken an hour before sexual activity and enhance the effects of nitrous oxide to facilitate relaxation of the smooth muscle in the penis during sexual stimulation to increase blood flow. Both drugs should be taken no more than once a day. They should not be taken by men who are also taking nitrate-based medications because this may result in severe hypotension or serious cardiac side effects. It is recommended that men taking alpha-blockers to treat hypertension and prostate enlargement should only use these drugs if the baseline blood pressure is at least 90/60 mmHg, other treatments have been unsuccessful, and the patient is monitored closely by a physician (Lee, 2011). Cialis is a selective phosphodiesterase type 5 inhibitor that allows smooth muscle relaxation to facilitate inflow of blood into the penis. Different forms of Cialis allow a single dose as a sustained-release medication that lasts for 36 hours or as a daily low-dose medication. In either case, an erection only occurs with sexual stimulation. Cialis should not be taken if the man is also taking nitrates, alpha-blockers, erythromycin or rifampicin (antibiotics), ketoconazole or itraconazole (antifungals), or protease inhibitors (for HIV). Men taking any of these medications should be told to call their healthcare provider for erections lasting more than 4 hours.
- *Injectable medications:* Hormone replacement therapy with testosterone injections or topical patches may be used for men with documented androgen deficiency and who do not have prostate cancer. Injectable medications, including papaverine and prostaglandin E injections, may be used. When injected directly into the penis, papaverine relaxes the arterioles and smooth muscles of the cavernosum, thus inducing tumescence (swelling). An erection usually develops that lasts from 30 minutes to 4 hours. Prostaglandin E functions much as papaverine does, but has fewer side effects. One problem with this treatment is its mode of delivery. There is a high attrition rate, and patients report dissatisfaction with lack of spontaneity, loss of interest in sex, physical limitations, cost, and, occasionally, pain. Alprostadil (Caverject) is another injectable medication that may be used to treat ED. It may be injected into the penis or placed in the urethra as a minisuppository.

MECHANICAL DEVICES

The vacuum constriction device (VCD) is a frequently prescribed mechanical device for ED. The VCD draws blood into the penis with a vacuum, trapping it there with a constricting band at the base of the penis. After the device is removed for intercourse, a single small band, often called an O-ring, is left at the base of the penis to maintain the erection. If the man can attain an erection but cannot maintain it, then an O-ring alone can be used.

SURGERY



Surgical treatment for ED involves either revascularization procedures or implantation of prosthetic devices. Venous or arterial procedures are generally not successful. The result is often temporary because the underlying cause of the vascular insufficiency is usually not corrected. Implantation of penile prostheses is now common (Figure 48–1 ■). Men are generally satisfied with their prostheses, and they rank the inflatable type highest. Partners are also more likely to report satisfaction with the penile implant, although not to the same degree as patients. Some partners report that the implanted penis is harder than a normal erect penis and therefore causes pain. Also, the man can have intercourse for a prolonged period of time, and some partners do not find prolonged penetration enjoyable. Patient and partner teaching is necessary to ensure proper use of and satisfaction with the device. Counseling by a sex therapist may be needed to facilitate adaptation to the implant.

LIFESTYLE CHANGES

Depending on the cause of the ED, changes in lifestyle may improve the condition or decrease the progression of the problem. Smoking cessation, eating a healthy diet, and regular exercise may improve overall health and cardiovascular functioning. If the man is overweight, a weight loss program as well as avoidance of alcohol and practicing stress-reducing activities may be beneficial.

●○● NURSING CARE

Nurses in any healthcare setting may encounter men with ED, either through routine examinations or through assessment of patients' conditions and treatments that may incidentally cause ED. Nurses employed in clinics, operating rooms, and surgical units with urologic

A Semirigid **B** Self-contained **C** Inflatable

Figure 48–1 ■ Types of penile implants. A, With semirigid rods implanted in the corpora cavernosa, the penis is always in a state of semi-erection, which may not be acceptable to the man. B, With a self-contained penile implant, the penis remains flaccid until the man compresses a pump at the head of the penis, which transfers fluid from a reservoir to a cylinder within the penis to achieve an erection. The man presses a release valve to return the fluid to the reservoir. C, With an inflatable penile implant, the penis remains flaccid until the man compresses a pump in the scrotum, which transfers fluid from an abdominal reservoir to cylinders in the corpora cavernosa to achieve an erection. Pressing a release valve returns the fluid to the reservoir.

services commonly encounter men being treated for ED. Nurses in a variety of settings, including long-term care, encounter men who have had surgical interventions, such as penile implants.

Diagnoses, Outcomes, and Interventions

Because nurses often complete a patient's health history, they are most likely to discover problems of ED. Once a problem is known, nurses are involved in providing information and emotional support, and referring patients to physicians or counselors. Although there are many possible nursing diagnoses, this section focuses on nursing care related to sexual dysfunction and self-esteem.

Sexual Dysfunction

Many men who lose erectile function are not aware of the cause. Not knowing causes anxiety and increased risk for depression. Often the man blames the loss on unrelated factors, such as age, a medication, a significant illness, or his sexual partner. Medications such as those used to treat hypertension (known to have ED as a side effect) may not be taken as prescribed if the man believes this is the cause of the ED.

Expected Outcome: Patient will demonstrate willingness to discuss changes to sexual function and adapt modes of sexual expression to accommodate age-, medication-, or illness-related changes.

- Assess for risk factors for ED. Be especially alert to men who have recently begun medications or had recent surgeries that could cause ED. *Awareness of risk factors helps the nurse prioritize care, although nurses must remember that almost all aging men have at least one risk factor for ED.*
- Assess for sexual dysfunction. Men have shown increasing willingness to discuss sexual concerns and expect nurses to be aware of the physiologic effects of their disease and side effects of treatment on all aspects of their health. *If a problem exists, information obtained in a sexual assessment guides the nurse in deciding if the next step should be patient teaching, referral, or both.*
- Conduct a detailed assessment of current sexual practices. *It is essential for healthcare providers to understand the patient and partner's sexual pattern in order to provide appropriate, individualized care.*
- Discuss previous methods of coping with ED. *Awareness of coping strategies can provide insight for the nurse and guide teaching.*
- Provide information about treatment options. *The man needs to know the details of the intervention, the chances for success, and the possible complications.*
- Encourage discussion of condition with partner. *It is not uncommon for men to withdraw from their partners, causing strain on the relationship and adding to the feelings of anxiety.*

PRACTICE ALERT!

Many men will not volunteer information about sexual function unless asked, but then are open about concerns and appreciate being asked.

Situational Low Self-Esteem

The man with ED often believes himself to be "less than a man." In addition, the insertion of a penile implant with a semirigid prosthesis may result in disturbances in body image related to changes in sexual activity as well as the appearance and embarrassment of a permanent semi-erection.

Expected Outcome: Patient will demonstrate self-esteem by use of effective coping strategies to deal with changes in body image.

- Collect data during the health history, in a nonjudgmental manner, about physiologic function, other chronic illnesses, and feelings of sexual inadequacy. *This information is necessary to establish the database for individualized interventions.*
- If the man has had a penile implant, teach him and his partner how to use the pump, including how to inflate and deflate the device. Suggest he practice inflation and deflation during the postoperative period. Suggest wearing snug-fitting underwear with the penis placed in an upright position on the abdomen and loose trousers. Provide information about length of healing, and that sexual activity may resume within 6 to 8 weeks following surgery. *Practicing use of the pump will maintain the pump position and promote tissue*

growth around the implant. The type of clothing worn can improve the ability to conceal a semirigid prosthesis and decrease embarrassment. Recovery from surgery is necessary before resuming sexual activity.

Continuity of Care

Many nurses find that men with ED and their partners have lived in isolation with the problem for many years. The partner may even be unaware of the problem, believing that the man is seeing someone else or that the man has lost his attraction to the partner. The man may have kept his problem a secret because an intense feeling of shame makes him unable to admit that he cannot perform sexually. Many men greet the information about the high incidence of ED with a sense of relief that they are not alone in having this problem. All men and their partners need to be aware of support services available to them. Referral sources include the Sexual Function Health Council, the American Urological Association, and the American Association of Sex Educators, Counselors, and Therapists.

THE MAN WITH EJACULATORY DYSFUNCTION

There are many types of ejaculatory dysfunction. **Retrograde ejaculation** (seminal fluid discharged into the bladder) may develop in aging men but is usually related to surgery of the prostate or for testicular cancer. **Premature ejaculation** is the most common form of sexual dysfunction in men and is thought to be psychogenic in origin, but some studies suggest alterations in serotonin regulation affect sexual function (Steggall, 2010). Comorbidities such as diabetes can cause the problem as well. Delayed ejaculation can be related to aging changes, such as decreased vibrotactile sensation over the penis or decreased libido secondary to hypogonadism. Delayed ejaculation and inability to ejaculate at all may be caused by certain medications, such as antihypertensives, antidepressants, anxiolytics, and narcotics.

Among these problems, premature ejaculation has proved most responsive to medical management. Medications such as selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants, and topical anesthetics are often prescribed. The man can also experiment with ways to decrease sensitivity (such as wearing condoms). Using relaxation and guided imagery can delay orgasm. Mechanical devices, such as constrictive rings around the base of the penis, can help the man delay ejaculation and sustain an erection.

Nursing care focuses on assessment of the problem and teaching for all types of ejaculatory dysfunction. The man's partner can be taught how to avoid excessive stimulation that would result in premature ejaculation. If the problem persists, the man should be referred to a specialist.

Disorders of the Penis

THE MAN WITH PHIMOSIS OR PRIAPISM

Two disorders of the penis are phimosis and priapism. Although uncommon, these disorders can cause problems with urination and sexual activity. In some cases, they are considered a medical emergency because decreased blood flow to the penis may result in tissue ischemia and necrosis.

Pathophysiology

Phimosis is constriction of the foreskin in uncircumcised men so that it cannot be retracted over the glans penis. Phimosis may be congenital, or it may be related to chronic infections under the foreskin, which lead to adhesions. The major problem with this condition is that it prevents adequate hygiene, which in turn may increase the risk of cancer of the penis. Phimosis also may interfere with urinary elimination and intercourse. In a related disorder, called paraphimosis, the foreskin is tight and constricted, and is not able to cover the glans penis. The glans becomes engorged and edematous, and is painful. Paraphimosis may result from long-term retraction of the foreskin, such as may occur in placement of an indwelling catheter in the uncircumcised male (Huether & McCance, 2012). The tight foreskin can result in ischemia of the glans.

Priapism is an involuntary, sustained, painful erection that is not associated with sexual arousal. The prolonged erection may result in ischemia and fibrosis of the erectile tissue with high risk of subsequent impotence (Huether & McCance, 2012). The disorder, classified as either primary or secondary, is caused by impaired blood flow in the corpora cavernosa. Primary priapism results from conditions such as tumors, infection, or trauma. Secondary priapism is caused by blood disorders (e.g., leukemia, sickle cell disease, and thrombocytopenia), neurologic disorders (e.g., spinal cord injury or stroke), renal failure, and some medications (e.g., papaverine, alcohol, marijuana, psychotropic drugs). Men who use intracavernous injection therapy or medications for ED are at risk for priapism.

●○● INTERPROFESSIONAL CARE

Severe phimosis or paraphimosis may require surgical circumcision. If infection is present, the appropriate antibiotic is administered.

Treatment of priapism varies, depending on the cause. Conservative measures include ice packs and analgesia. Under local or regional anesthesia, blood may be aspirated from the corpora cavernosa, followed by saline irrigation and intracavernous injection of phenylephrine, an α-receptor agonist. If necessary, surgery to create vascular shunts to maintain blood flow is performed. When priapism is prolonged, it increases the risk of subsequent ED.

●○● NURSING CARE

Nursing care for priapism focuses on assessing the penis, monitoring urinary output, and providing pain control. Assessment of the penis includes inspection for degree of erection and changes in color due to ischemia, and palpation of the penis for firmness and degree of rigidity. Monitor urine output, assessing for oliguria or signs of acute urinary retention. Pain is treated with analgesics.

The man usually has moderate to severe anxiety related to pain, the treatment, and the threat to his sexual function. The treatment

may sound bizarre and painful, especially since the area is already extremely sensitive. The man may be acutely embarrassed by the erection and needs reassurance that the nurse understands that the erection is not within his control.

THE MAN WITH CANCER OF THE PENIS

Cancer of the penis is a rare cancer in North America, occurring in approximately 1500 men per year (American Cancer Society [ACS], 2012b). The cause is unknown, although infection HPV-16 and 18 causes nearly 50% of penile cancer (National Cancer Institute, 2014). Age is a factor, and the greatest incidence is in men ages 60 and above. It is lower in populations in which routine circumcision is practiced, although the correlation between circumcision and this cancer is unclear. Phimosis and poor genital hygiene are risk factors, as are human papillomavirus (HPV) and HIV infections. Ultraviolet radiation exposure (such as that used to treat psoriasis) also may play a role (Shapiro et al., 2011).

Pathophysiology

Squamous cell carcinoma accounts for 95% of all penile cancers (Huether & McCance, 2012). The tumor usually develops as a nodular or wartlike growth or a red velvety lesion on the glans or foreskin. (Squamous cell carcinoma is illustrated in Chapter 16.) Penile cancer spreads to the superficial or deep inguinal nodes, and very late in the disease may spread to the bone, liver, or lungs. If the lesion is treated before inguinal node involvement, chances for a cure are good. Most of these lesions are painless but significant ulceration and bleeding may occur. Purulent, foul-smelling discharge may be evident under the foreskin. Occasionally, men with penile cancer may present with enlarged inguinal lymph nodes.

●○● INTERPROFESSIONAL CARE

Cancer of the penis is diagnosed by a biopsy of the lesion, including any suspicious inguinal lymph nodes. The cancer is staged according to the size of the tumor, extent of invasion, status of inguinal lymph nodes, and presence or absence of distant metastasis. Small, localized lesions may be treated with fluorouracil cream, external-beam radiation, laser therapy, or surgical excision. Larger lesions with superficial or deep infiltration of penile structures require partial or total amputation of the penis. Chemotherapy (discussed in Chapter 14) may be administered to men with distant metastasis.

●○● NURSING CARE

Education can help prevent this disease or provide early detection and cure. Advise parents and young men about recommendations for HPV vaccine (see Chapter 12 for more information about recommended immunizations). Teach men about genital hygiene (including retraction of the foreskin if uncircumcised and washing the glans penis while bathing or showering), the risks of unprotected sex, and the importance of using condoms. Instruct men to shield their genitals when having ultraviolet light therapy or using tanning salons. Discuss the importance of seeking prompt treatment for any lesion or abnormal drainage noted on the penis.

If the man has a penile amputation (penectomy), nurses can help in coping with the problems of a shortened or absent penis, including the potentially devastating effect on body image and self-concept. If a total penectomy is performed, the surgeon creates a perineal urethrostomy, preserving urinary continence. However, the man must void in the sitting position, reinforcing the feeling of loss. Dribbling of urine after voiding may be a problem for a few weeks. The man should be taught to perform careful perineal hygiene following surgery, using mild soap and water. Sitz baths may be helpful to relieve pain and to promote healing. If an inguinal lymph node dissection is performed, the man may experience persistent lymphedema of the lower extremities.

Radiation therapy may affect skin integrity and possibly cause irritation and stricture of the urethra. Radiation prior to surgery may impede incision healing. It is important to assess skin integrity and the man's ability to void. Leakage of urine from dribbling or catheters could also further irritate sensitive tissues.

Disorders of the Testis and Scrotum

THE MAN WITH A BENIGN SCROTAL MASS

Most scrotal masses are benign and can be managed in a manner that is satisfactory to the patient. The most common benign scrotal masses are hydroceles, spermatoceles, and varicoceles (Figure 48–2 ■).

Pathophysiology

A **hydrocele**, the most common cause of scrotal swelling, is a collection of fluid within the tunica vaginalis. The swelling ranges from slightly larger than the testicle to larger than a grapefruit. Hydroceles may occur secondary to trauma, infection, or a tumor. The cause of chronic hydrocele in men over the age of 40 years is an imbalance between production and reabsorption of fluid within the layers of the scrotum. A hydrocele may be differentiated from a solid mass by transillumination or ultrasound of the scrotum. If the hydrocele becomes large enough to cause embarrassment or significant pain, the fluid is aspirated and an agent is injected into the scrotal sac to sclerose the tunica vaginalis. Hydroceles are not associated with infertility.

A **spermatocele** is a mobile, usually painless mass that forms when efferent ducts in the epididymis dilate and form a cyst. It is thought to result from leakage of sperm due to trauma or infection. Treatment is usually not necessary. Spermatoceles are not associated with infertility.

A **varicocele** is an abnormal dilation of a vein within the spermatic cord. Incompetent or congenitally missing valves allow blood to pool in the spermatic cord veins. The dilated vein forms a soft mass

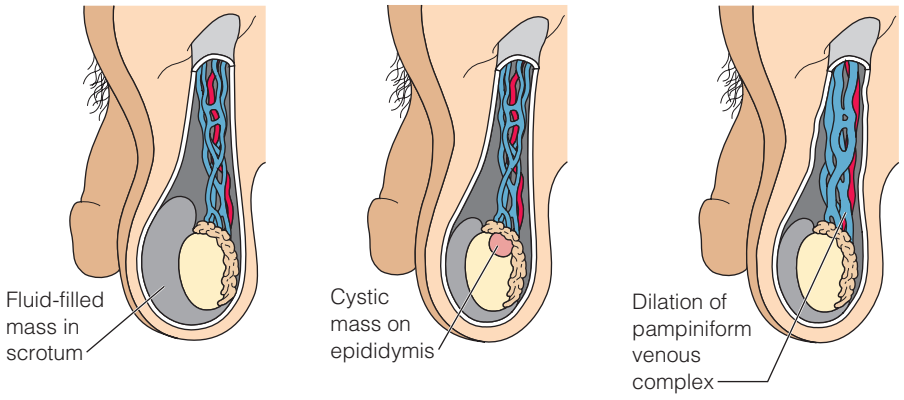


Figure 48–2 ■ Common disorders of the scrotum. Hydroceles and spermatoceles do not usually require treatment unless they become large and cause pain. Varicoceles are usually treated to prevent infertility.

that may be painful. Most varicoceles occur on the left side. A major concern with this condition is that it can decrease blood flow through the testis, interfere with spermatogenesis, and cause infertility. Varicoceles can be felt by scrotal palpation and most often disappear when the man is in the supine position. Sonography is frequently used for diagnosis. If infertility is a concern, the spermatic vein may be ligated or occluded with a sclerosing agent or balloon catheter. If the varicocele is small and infertility is not a concern, a scrotal support is recommended.

●○● NURSING CARE

Nursing care focuses on reducing anxiety and teaching about comfort measures. Almost all men are aware of the possible pain associated with scrotal manipulation. They need information and reassurance about pain management if surgical treatment is necessary. External bleeding is minimal after surgery; however, some men do develop scrotal hematomas, manifested by scrotal edema and a purple discoloration.

THE MAN WITH EPIDIDYMITIS

Epididymitis is an infection or inflammation of the epididymis, the structure that lies along the posterior border of the testis. This disorder is more often seen in sexually active men who are less than 35 years of age.

Sexually transmitted urethritis caused by *Chlamydia trachomatis* or *Neisseria gonorrhoeae* is the usual precipitating factor for epididymitis in younger men. Men who practice unprotected anal intercourse may acquire sexually transmitted epididymitis from *Escherichia coli*, *Haemophilus influenzae*, *Cryptococcus*, or tuberculosis. In men older than age 35, epididymitis is often associated with a urinary tract infection or prostatitis. Chemical epididymitis is associated with an inflammatory response to the reflux of urine into the ejaculatory ducts from urethral strictures, congenital structural anomalies, or increased abdominal pressure from excessive heavy lifting. This type is usually self-limiting and does not require treatment.

Infectious epididymis spreads by ascending the vas deferens from an already infected urethra or bladder. Early manifestations include pain and local edema, which can progress to erythema and edema of the entire scrotum, especially on the side of the involved epididymis. Complications of the disorder include abscess formation, infarction of the testis, and infertility.

●○● INTERPROFESSIONAL CARE

The infection is diagnosed with a specimen culture from a urethral swab or epididymal aspiration. Severe epididymitis may be treated with intravenous antibiotics and hospitalization. Less acute forms of the disease are treated with outpatient antibiotic therapy. The man's sexual partner should be treated with antibiotics if the causative organism is sexually transmitted.

●○● NURSING CARE

Nursing care involves symptomatic relief and teaching. Ice packs and a scrotal support may be applied to the scrotum to relieve pain. Ensure the man knows that complete resolution of the infection may take weeks to months, and that treatment should continue until the infection is gone. Provide information about the possibility of infertility, because the man may wish to seek evaluation for this problem at a later date. Instruction on sexually transmitted infection (STI) prevention may also be necessary if the epididymitis was caused by a sexually transmitted organism.

THE MAN WITH ORCHITIS

Orchitis is an acute inflammation or infection of the testes. It most commonly occurs from an extension of a genitourinary infection or as a complication of a systemic illness. Infection may reach the testes through the vas deferens and the lymphatic and vascular channels. Trauma, including vasectomy and other scrotal surgeries, may cause inflammation of the testes.

The most common systemic infectious cause of orchitis in postpubertal men is mumps. Other causes include scarlet fever or pneumonia. The manifestations have a sudden onset, usually within 3 to 4 days after the swelling of the parotid glands. Manifestations include a high fever, increased WBCs, and unilateral or bilateral scrotal redness, swelling, and pain. If both testes are involved, permanent sterility may result, but this is rare (Huether & McCance, 2012).

●○● INTERPROFESSIONAL CARE

Treatment is supportive and symptomatic, including antibiotic therapy if urine cultures are positive. Bed rest, scrotal support and elevation, hot or cold compresses, and analgesics for pain are prescribed. If a hydrocele occurs, it is aspirated. Nursing care is similar to that of the patient with epididymitis and other scrotal disorders.

THE MAN WITH TESTICULAR TORSION

Testicular torsion, twisting of the spermatic cord resulting in sudden onset of scrotal swelling, pain, and nausea and vomiting, is a potential medical emergency. The condition occurs most often between birth and age 20, but can occur at any age. Testicular torsion may occur spontaneously, or it may follow trauma or physical exertion. The torsion of the arteries and veins decreases or stops testicular circulation with resultant vascular engorgement and ischemia.

Testicular torsion is usually diagnosed by history and physical examination. It may be confused with epididymitis but is much more serious in nature, so accurate assessment and diagnosis are imperative for successful outcome of the patient. Testicular scanning may be used to determine if blood flow to the testicle is reduced, or a prostate ultrasound may be done to identify masses or torsion. Surgical treatment, which involves detorsion of the testicle and fixation to the scrotum, must begin as quickly as possible. If the testicle is necrotic or has sustained significant damage, an orchiectomy (surgical removal of a testes) is performed.

THE MAN WITH TESTICULAR CANCER

Testicular cancer accounts for only 1% of all cancers in men; however, it is the most common cancer in men between the ages of 13 and 35 and can occur from infancy through old age. Annually, more than 8600 new cases are diagnosed (ACS, 2014). Although the cause is unknown, White American men are five times more likely to develop testicular cancer than are men from other races (see the Focus on Cultural Diversity box). The incidence of testicular cancer has increased during the past several decades but survival from testicular cancer has improved dramatically as a result of treatment with effective combination chemotherapy. Testicular cancer is considered to be one of the most curable cancers, with a 95% 5-year survival rate for men living in the United States (ACS, 2012c).

The cause of testicular cancer is unknown, but both congenital and acquired factors have been associated with tumor development. About 5% develop in men with a history of undescended testicle (cryptorchidism). Testicular cancer is more common on the right side (Huether & McCance, 2012).

FOCUS ON CULTURAL DIVERSITY

Risk for Testicular Cancer

- White American men have about a five times greater risk of testicular cancer than do Black American men.
- White American men have more than three times the risk of Asian American and American Indian men.
- Hispanic men have a risk between that of Asians and non-Hispanic Whites.

Source: ACS, 2012c.

Risk Factors

Risk factors for testicular cancer follow:

- Age
- Cryptorchidism (undescended testicle)
- A family history of testicular cancer
- Cancer of the other testicle
- Other risk factors under investigation include occupational risks, presence of multiple atypical nevi, HIV infection, cancer *in situ*, and age (20% occur between the ages of 25 and 45) (ACS, 2012c).

Pathophysiology

Approximately 90% of testicular malignancies are germ cell tumors (Huether & McCance, 2012). Germ cell tumors are classified, depending on their origin and ability to differentiate, as seminomas and nonseminomas. Seminomas are the most common type, and are believed to arise from the seminiferous epithelium of the testes. Nonseminomas contain more than one cell type; they include embryonal carcinoma, teratoma, choriocarcinoma, and yolk cell carcinoma. Testicular cancer may also arise from specialized cells of the gonadal stroma. These tumors are named for the cells from which they originate: Leydig cell, Sertoli cell, granulosa cell, and theca cell tumors.

Manifestations

The first sign of testicular cancer may be a slight, painless enlargement of one testicle. The man may also have an abdominal ache and a feeling of heaviness in the scrotum. Local spread of the cancer to the epididymis or spermatic cord is inhibited by the outer covering of the testicles, the tunica albuginea. Therefore, spread by lymphatic and vascular channels to other organs often causes distant disease before large masses develop in the scrotum. Lymphatic dissemination usually leads to disease in retroperitoneal lymph nodes, whereas vascular dissemination can lead to metastasis in the lungs, bone, or liver. Bilateral testicular cancer is unusual. Manifestations of testicular cancer are summarized in the accompanying box. Manifestations of metastasis include lower extremity edema, back pain, cough, hemoptysis, or dizziness. HCG-producing tumors may cause breast enlargement (gynecomastia).

MANIFESTATIONS OF TESTICULAR CANCER

COMMON
- Painless swelling on one testicle

METASTATIC SYMPTOMS
- Neck mass
- Respiratory symptoms
- Gastrointestinal disturbance
- Lumbar back pain

OCCASIONAL
- Dull ache in pelvis or scrotum
- Painless nodule on one testicle

UNCOMMON
- Acute pain in scrotum

RARE
- Infertility
- Gynecomastia

●○● INTERPROFESSIONAL CARE

Care focuses on diagnosis, elimination of the cancer, and prevention or treatment of metastasis. Once testicular cancer is suspected, the man undergoes a number of screening tests to help identify the disease and its stage. If the disease is confined to the testicle, it is classified as stage I. Stage II disease is limited to the testicle and regional lymph nodes. Stage III disease involves metastasis above the diaphragm or extensive visceral involvement. Often, the man does not undergo biopsy before the beginning of treatment, but instead receives a definitive diagnosis after orchiectomy. Most men treated for testicular cancer will live a normal life span.

DIAGNOSIS

Diagnosis may be made by various laboratory tests. Serum studies are done to identify tumor markers. Germ cell tumors produce biochemical markers such as human chorionic gonadotropin (hCG) and alpha-fetoprotein (AFP) that can be measured using radioimmunoassay techniques. Elevated levels provide strong evidence of testicular cancer. These markers are also measured after surgery to help determine the presence of residual disease that remains undetected by other means. Persistent elevation may indicate the need for further therapy. Serum lactate dehydrogenase (LDH) levels are elevated in testicular cancer, and may be significantly elevated when metastatic disease is present. The LDH is a less specific indicator of testicular cancer than the hCG and AFP.

MEDICATIONS

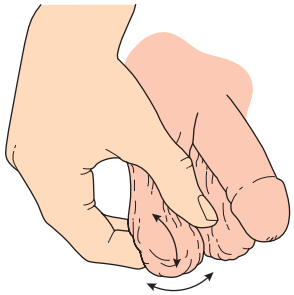
Progress in chemotherapy to treat testicular cancer is one of the chief reasons why curative rates are as high as 95% (Sachdeva et al., 2012). The patient with advanced disease receives platinum-based combination chemotherapy. Chemotherapy is discussed in Chapter 14.

SURGERY

Radical orchiectomy, which removes the affected testicle and spermatic cord, is the treatment used in all forms and stages of testicular cancer. A modified retroperitoneal lymph node dissection that preserves the nerves necessary for ejaculation often is performed at the same time.

RADIATION THERAPY

Radiation therapy is used for stage I seminoma to treat cancer in the retroperitoneal lymph nodes, the most frequent site for distant metastasis. The man may experience temporary diarrhea, nausea, or a decline in bone marrow function, such as thrombocytopenia or leukopenia. These problems are usually mild and respond well to symptomatic treatment or time. Damage to the contralateral testicle is minimized by careful shielding. Pretreatment and post-treatment analyses of sperm number and function are necessary. The most common long-term complication is dyspepsia or ulcer disease. Radiation therapy is discussed in Chapter 14.



●○● NURSING CARE

Health Promotion

Unfortunately, most men who develop testicular cancer do not have overt risk factors. Therefore, beginning at the age of 15, all men should perform monthly testicular self-examination, as described in Box 48–1.

BOX 48–1 Testicular Self-Examination

- Examine your testicles when you are taking a warm shower or bath, or just after if you prefer to use a mirror to compare size.
- The scrotum, testicles, and hands should be soapy to allow easy manipulation of the tissue.
- Gently roll each testicle between the thumb and fingers of each hand. If one testicle is substantially larger than the other, or if you feel any hard lumps, consult your physician immediately.
- Normal scrotal contents may be confusing. Just above and behind the testicle is the epididymis. It feels soft and tender overall, although parts of it may be rather firm. This is normal. The spermatic cord, a small, round, movable tube, extends up from the epididymis. It feels firm and smooth. Of greatest concern is any hard lump felt directly on the testicle, even if it is painless.
- Choose a day of each month on which to examine yourself. Most men choose an easy day to remember, such as the first or last day of the month. Star this day on your calendar to help you remember.

Diagnoses, Outcomes, and Interventions

Nursing care of the man with testicular cancer is complex. The nurse must consider the reactions to the diagnosis, the change in body image accompanying treatment, and sexual and reproductive issues. Although chances of a cure are excellent, the long-term effect on quality of life may be extensive, requiring a change in life goals.

Readiness for Enhanced Knowledge: Testicular Cancer Surgery

The nurse often initiates and reinforces teaching about what to expect after radical orchiectomy. The man's knowledge about surgery is assessed, and postoperative routines such as early ambulation are explained.

Expected Outcome: Patient will describe expected postoperative experience including pain management and surveillance for postoperative complications.

- Explain pain control methods. In addition to the usual analgesics used to control postoperative incisional pain, ice bags may be applied to the scrotum. A scrotal support provides relief, especially when the patient ambulates. *Surgery results in incisional pain, and the scrotum is tender and slightly swollen.*
- Teach the manifestations of complications. The incision is closed with Steri-Strips or staples, and, although rare, wound dehiscence is possible. If the incision gapes open, or if there is bleeding beyond slight oozing after 24 hours, the man should call the surgeon. Another rare complication is a hematoma in the scrotum

Evidence for Nursing Care

The Patient with Testicular Cancer

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Bradford, B. (2012). Chemotherapy-induced infertility in patients with testicular cancer. *Oncology Nursing Forum*, *39*(1), 27–30.
- Davis, J., Buchanan, K., Katz, R., & Green, B. (2012). Gender differences in cancer screening beliefs, behaviors, and willingness to participate: Implications for health promotion. *American Journal of Men's Health*, *6*(3), 211–217.
- Rovito, M., Gordon, T., Bass, S., & DuCette, J. (2011). Perceptions of testicular cancer and testicular self-examination among college men: A report on intention, vulnerability, and promotional material preferences. *American Journal of Men's Health*, *5*(6), 500–507.

caused by bleeding from the spermatic cord stump. Rapid onset of scrotal edema is a sign of this problem. *Because the man is usually discharged early, complications may not become apparent until he is at home.*

Risk for Sexual Dysfunction

The effect of testicular cancer and its treatment on sexual and reproductive function is varied. If the man has a retroperitoneal lymph node dissection, severing of the sympathetic plexus may result in retrograde ejaculation or failure to ejaculate. Infertility may be caused by ejaculation disorders, surgery, chemotherapy, or radiation therapy.

Expected Outcomes: Patient will demonstrate willingness to discuss changes to sexual function. Patient adapts modes of sexual expression to accommodate testicular cancer treatment-related changes.

- Assess the man's prediagnosis sexual function. To assess this area, the nurse must establish an atmosphere of openness and permission to discuss sexual concerns. After the initial shock of the diagnosis, men report intense concern about sexual and reproductive issues, which can be relieved only by information. *Knowledge of the man's usual sexual function is used to guide teaching.*
- Discuss the possibility of preserving sperm in a bank prior to treatment. *This option may help relieve the man's fears about his ability to father children in the future, but must be completed prior to initiating treatment with surgery, chemotherapy, or radiation therapy.*
- Help the patient cope with feelings about altered sexual function and appearance. Explain that testicular implants can be inserted to preserve appearance. *Many patients, regardless of whether they are in a significant relationship, deeply grieve the loss of the ability to father children. It is important to maintain body image despite disfiguring surgery.*

Continuity of Care

Families need to be included in teaching for a variety of reasons. If the man is of reproductive age, his partner will have significant anxiety and will require information. For a young single man, parents need information about the effect on sexual function and are often very involved in postoperative care. The man needs the support of the people he loves, and knowledgeable loved ones can give effective support.

Provide teaching and reinforcement of the need for follow-up, especially if the retroperitoneal lymph nodes were not surgically explored. For men with a risk for recurrence, surveillance with periodic physical examinations, chest x-ray films, tumor markers, and CT scans of the retroperitoneal nodes could continue for a minimum of 5 years and possibly 10 years after orchiectomy. Studies have found that men treated with chemotherapy are at an increased risk of developing cardiovascular disease and secondary malignancies. Men receiving both chemotherapy and radiation have an even higher rate of secondary malignancies. Educating men on the need to remain proactive in their healthcare throughout their lifetime is important (Zoltick, 2011).

Disorders of the Prostate Gland

THE MAN WITH PROSTATITIS

Prostatitis is a term used to refer to different types of inflammatory disorders of the prostate gland. Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS), previously known as prostatodynia, is a condition in which the patient experiences the symptoms of prostatitis but shows no evidence of inflammation or infection.

Pathophysiology and Manifestations

The National Institutes of Health (NKUDIC, 2012b) have defined four types of prostatitis: acute bacterial prostatitis, chronic bacterial prostatitis, CP/CPPS, and asymptomatic inflammatory prostatitis. Men with asymptomatic inflammatory prostatitis have no subjective manifestations, but are diagnosed when a biopsy or prostatic fluid examination is conducted. Manifestations of prostatitis and CP/CPPS are summarized in the accompanying box.

ACUTE BACTERIAL PROSTATITIS

Acute bacterial prostatitis is usually caused by an ascending infection from the urethra or reflux of infected urine into the ducts of the prostate gland. The organism most often responsible for the infection is *E. coli*; other causative organisms include *Pseudomonas*, *Klebsiella*, and *Chlamydia*.

Manifestations of acute bacterial prostatitis include fever, malaise, muscle and joint pain, painful ejaculation, urinary frequency and urgency, dysuria, and urethral discharge. The man often experiences dull, aching pain in the perineum, and/or pain in the prostate gland, rectum, or lower back. On rectal examination, the prostate is enlarged and painful.

CHRONIC BACTERIAL PROSTATITIS

Men with chronic bacterial prostatitis often present with a history of recurrent urinary tract infections. The causative organisms are most often *E. coli*, *Proteus*, or *Klebsiella*. Calculi may form in the prostate and contribute to the chronicity of the problem.

The manifestations of chronic bacterial prostatitis include urinary frequency and urgency, dysuria, low back pain, and perineal discomfort. Epididymitis may be associated with the prostatitis.

CHRONIC PROSTATITIS/CHRONIC PELVIC PAIN SYNDROME (CP/CPPS)

This type of prostatitis is both the most common and the least understood of the syndromes (NKUDIC, 2012b). It is being questioned whether the disorder has anything to do with the prostate gland or whether other etiologies such as pelvic wall pain or dysfunction of the pelvic floor musculature are the cause of the symptoms. This is primarily the reason the disorder is now named chronic pelvic pain syndrome (Watson, 2011). The two types (inflammatory and noninflammatory) are based on the presence or absence of white blood cells in the prostatic fluid.

- *Inflammatory prostatitis* is believed to be an autoimmune disorder, but the actual cause is unknown. Men with this type of prostatitis have low back pain; urinary manifestations; pain in the penis, testicles, scrotum, lower back, and rectum; decreased libido; and painful ejaculations. They do not have bacteria in their urine, but do have abnormal inflammatory cells in prostatic secretions.
- *Noninflammatory prostatitis* has manifestations similar to those of inflammatory prostatitis, but no evidence of urinary or prostatic infection or inflammation can be found. The cause is not known, but is believed to be the result of a problem outside the prostate gland, such as obstruction of the bladder neck.

MANIFESTATIONS OF PROSTATITIS

ACUTE BACTERIAL PROSTATITIS
- Onset (may be abrupt): obstruction, irritation, or pain upon voiding; frequency; and urgency
- Slow or small urinary stream
- Positive cultures of infectious organism
- Nonurinary symptoms: chills, fever, low back and pelvic floor pain

CHRONIC BACTERIAL PROSTATITIS
- Urinary symptoms may be similar to those of the acute form, except less sudden, less dramatic, or even absent
- Positive cultures of causative organism not always obtainable

CHRONIC PROSTATITIS
- Perineal, suprapubic, low back, or genital pain
- Irritation upon voiding
- Postejaculatory pain
- Negative cultures of organisms

CHRONIC PROSTATITIS/CHRONIC PELVIC PAIN SYNDROME
- Pelvic, low back, or perineal pain
- Irritation or obstruction upon voiding
- Evidence of prostate inflammation may or may not be present
- No urinary tract infection
- Normal prostatic secretions
- Pain when sitting

●○● INTERPROFESSIONAL CARE

DIAGNOSIS

It is often difficult to diagnose prostatitis. Urine and prostatic secretion examination and cultures are obtained to determine the presence and type of blood cells and bacteria. X-ray studies and ultrasound to visualize pelvic structures also may be useful.

MEDICATIONS

Bacterial prostatitis is treated with appropriate antibiotics. Men with the chronic form must take antibiotics for up to 4 months, and may still relapse as soon as the antibiotic is discontinued. Nonbacterial prostatitis and CP/CPPS do not usually respond satisfactorily to drug therapy, although relief from symptoms is possible. Nonsteroidal anti-inflammatory drugs are useful for pain, and anticholinergics may reduce voiding symptoms. Muscle relaxants and alpha-adrenergic blocking agents are also prescribed, depending on symptom severity. When pain is most severe, stress-reducing activities, warm baths, and avoidance of sitting have been reported to assist in pain reduction.

●○● NURSING CARE

Education is the focus of nursing care for the man with prostatitis. Teaching plans focus on symptom management. Men with acute and chronic bacterial prostatitis should be taught to increase fluid intake to around 3 L daily and to void often. These measures help decrease irritation when voiding. Increasing fiber intake to promote regular bowel movements helps ease the pain associated with defecation. Local heat, such as sitz baths, may be helpful to relieve pain and irritation. It is important to teach the man to finish the course of antibiotic therapy. Men with CP/CPPS need to know that the condition is not contagious (Mayo Clinic, 2011). Referral sources for information include the National Kidney and Urologic Diseases Information Clearinghouse, the American Foundation for Urologic Disease, and the Prostatitis Foundation.

THE MAN WITH BENIGN PROSTATIC HYPERPLASIA

Benign prostatic hyperplasia (BPH), an age-related, nonmalignant enlargement of the prostate gland, is a common disorder of the aging male. Benign hyperplasia (increased number of cells) begins at 40 to 45 years of age and continues slowly through the rest of life. It is estimated that more than one-half of all men over age 60 have BPH (Deters et al., 2011). Although the exact cause of BPH is unknown, risk factors include age, family history, race, and a diet high in meat and fats. The problem that brings men to a healthcare provider is the associated urinary dysfunction.

Pathophysiology

The two necessary preconditions for BPH are age of 48 or greater and the presence of testes. Men who are castrated before puberty do not develop BPH. The androgen that mediates prostatic growth at all ages is dihydrotestosterone (DHT), which is formed in the prostate from testosterone. Although androgen levels decrease in aging men, the aging prostate appears to become more sensitive to available DHT. Estrogen, produced in small amounts in men, appears to sensitize the prostate gland to the effects of DHT. Increasing estrogen levels associated with aging or a relative increase in estrogen related to testosterone levels may contribute to prostatic hyperplasia.

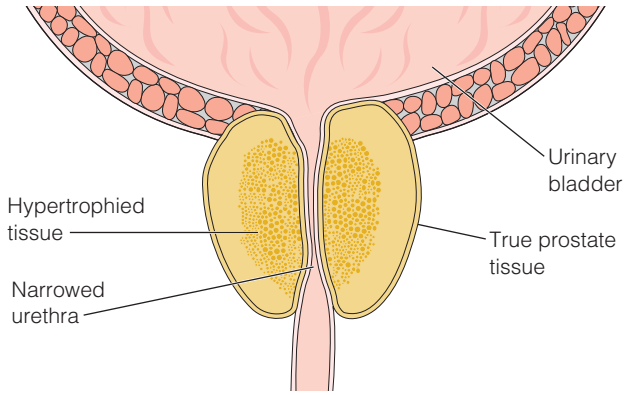


Figure 48–3 ■ Benign prostatic hyperplasia.

BPH begins as small nodules in the periurethral glands, which are the inner layers of the prostate. The prostate enlarges through formation and growth of nodules (hyperplasia) and enlargement of glandular cells (hypertrophy). Enlargement occurs in an inward fashion, gradually compressing the urethra and resulting in the urologic symptoms associated with BPH. These changes occur over a long period of time. The pathophysiologic effects result from a combination of factors, including urethral resistance to the effects of BPH, intravesical pressure during voiding, detrusor muscle strength, neurologic functioning, and general physical health.

Manifestations

The expanding prostatic tissue compresses the urethra (Figure 48–3 ■) and causes partial or complete obstruction of the outflow of urine from the urinary bladder. The detrusor muscles hypertrophy to compensate for increased resistance to urinary flow; however, eventually decreased bladder compliance and bladder instability occur. As a result, the man with BPH has manifestations from urinary obstruction and a decrease in bladder contractibility and compliance. Urinary retention may become chronic, resulting in overflow incontinence with any increase in intra-abdominal pressure. There is little correlation between the size of the prostate gland and the urinary manifestations. The linkage of the manifestations of BPH with the related pathophysiology are summarized in the Pathophysiology Linkage box.

Complications

Unless the enlarging mass is reduced, multiple complications may occur. As urine is retained in the bladder, increasing bladder distention occurs. Diverticula (outpouchings) on the bladder wall result from the distention. The distention may also obstruct the ureters. Infection, more common in retained urine and in diverticula, may ascend from the bladder to the kidneys. Hydroureter, hydronephrosis, and renal insufficiency are possible complications.

●○● INTERPROFESSIONAL CARE

Care of men with BPH focuses on diagnosing the disorder, correcting or minimizing the urinary obstruction, and preventing or treating complications. Treatment is often determined by the severity of the manifestations and the presence of complications. Mild cases are often monitored over time, and may remain stable or improve.

DIAGNOSIS

It is important for clinicians to determine the actual cause of manifestations, differentiating them from those of infections, stones, urinary strictures, cancer of the prostate or bladder, and side effects of certain medications such as antihistamines and decongestants. A diagnosis of BPH involves both physical examination and laboratory tests. A digital rectal examination (DRE) is done to examine the external surface of the prostate; in BPH it is asymmetrical and enlarged. Examination of the creatinine levels of the blood is conducted to assess for kidney damage.

The urine is examined for WBCs, RBCs, and bacteria. Urinary function is assessed by measuring residual urine (amount of urine remaining in the bladder after voiding) with ultrasonography or postvoiding catheterization (more than 100 mL is considered high), and through uroflowmetry, which measures urine flow rate; normal is greater than 14 mL/sec. A finding of less than 10 mL/sec indicates obstruction.

Prostate-specific antigen (PSA) levels are obtained to rule out prostate cancer. PSA is a glycoprotein produced only in the cytoplasm of benign and malignant prostate cells; the serum level corresponds with the volume of both benign and malignant prostate tissue. Further information is provided in the next section under diagnosis of prostate cancer.

In addition, the man's own subjective experiences with BPH are included in the diagnosis and treatment. For example, the International Prostate Symptom Score and the American Urologic Association BPH Symptom Score questionnaires use scales of 0 (not at all) to 5 (almost always) to collect data about areas such as feeling as though the bladder did not empty with urinating, need to urinate within 2 hours after urinating, starting and stopping the stream several times while urinating, and straining to urinate. These questionnaires also ask how many times during the night the man gets up to urinate and how the man feels about having the disorder.

MEDICATIONS

Treatment with medications is based on two considerations: The hyperplastic tissue is androgen dependent, and smooth muscle contraction within the prostate can exacerbate urinary obstruction. The first

PATHOPHYSIOLOGY LINKAGE

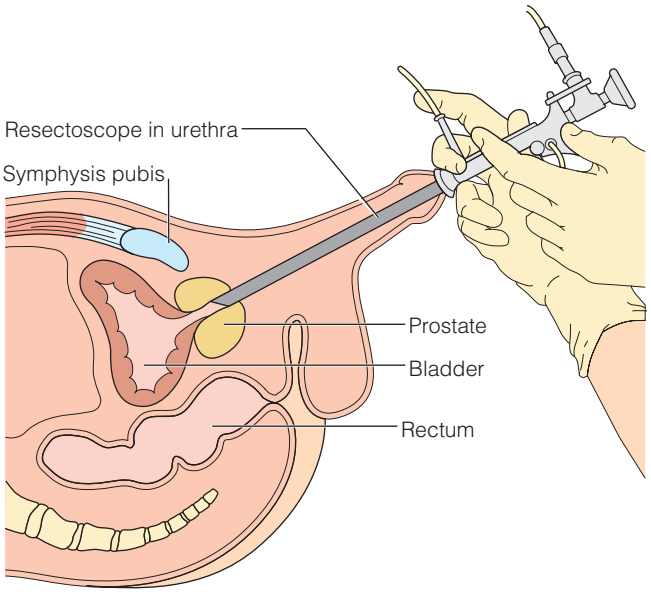
Benign Prostatic Hyperplasia

Manifestations	Related Pathophysiology
Urinary frequency, increased time to begin voiding, small urinary stream	As a result of the anatomic placement of the prostate at the bladder neck, an increase in the size of the prostate compresses the urethra and outflow of urine.
Dribbling of urine, increased time required to void, urgency, nocturia	Compression of the urethra and retention of urine in the bladder, coupled with impaired bladder contractibility and a decrease in bladder compliance.

consideration is usually addressed by treatment for mild prostate enlargement with finasteride (Proscar) or dutasteride (Avodart), antiandrogen agents that inhibit the conversion of testosterone to DHT and cause the enlarged prostate to shrink in size. These are usually only effective if the prostate is 40 mL or greater in size. They may cause impotence, decreased libido, and decreased volume of ejaculate. Patient and family education includes the information that crushed tablets should not be handled by pregnant women, because the drug may be absorbed through the skin and be harmful to a male fetus.

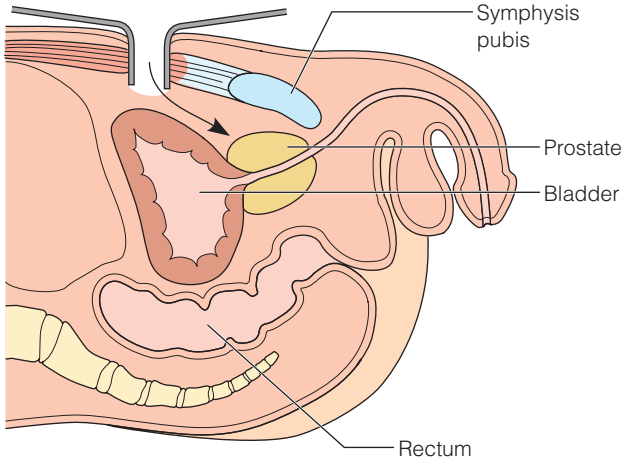
Excessive smooth muscle contraction in BPH may be blocked with the alpha-adrenergic antagonists such as terazosin (Hytrin), doxazosin (Cardura), tamsulosin (Flomax), and alfuzosin (Uroxatral). These medications relieve obstruction and increase the flow of urine. They may cause orthostatic hypotension. If they are taken with phosphodiesterase inhibitors to treat ED, orthostatic hypotension effects are increased. Studies have found that using finasteride and doxazosin together is more effective than using each alone to relieve manifestations and prevent the progression of BPH, but medication side effects are increased as well as the costs of the medication (Miller & Miller, 2011). Patient and family teaching includes advice about making position changes slowly to avoid dizziness and accidental falls, how to take and record blood pressure, and to check with the healthcare provider before taking any OTC medication for coughs, colds, or allergies (because these medications may contain an adrenergic agent).

SURGERY



Men who have urinary retention, recurrent urinary tract infection, hematuria, bladder stones, or renal insufficiency secondary to BPH are candidates for surgical intervention. Surgical treatment may be performed by minimally invasive surgery or through transurethral surgery, open surgery, or by laser surgery.

MINIMALLY INVASIVE SURGERY Because medications are not effective for all men, a number of procedures have been developed to relieve the manifestations of BPH.



Microwaves are used to heat and destroy excess prostate tissue in a procedure called transurethral microwave thermotherapy. During the procedure, a cooling system protects the urinary tract. The procedure takes about an hour and can be performed on an outpatient basis. Although microwave procedures do not cure BPH, they do reduce urinary manifestations. The procedures do not cause impotence or incontinence.

The transurethral needle ablation (TUNA) system uses heat produced by radio-frequency waves to burn away a region of the enlarged prostate. Shields protect the urethra. TUNA improves the flow of urine through the urethra. It does not cause impotence or incontinence. This technique is performed for men with large prostates who are not good candidates for more invasive surgical procedures.

TRANSURETHRAL SURGERY A transurethral resection of the prostate (TURP) is the surgical procedure used most often. Obstructing prostate tissue is removed using the wire loop of a resectoscope and electrocautery, inserted through the urethra (Figure 48–4A ■). No external incision is necessary. During the procedure the surgeon uses the resectoscope to remove obstructing tissue one piece at a time. The tissue is flushed into the bladder with fluid and then flushed out at the end of the operation. This surgery has potential risks, however, including postoperative hemorrhage or clot retention, inability to void, and urinary tract infection. Other possible complications are incontinence, impotence, and retrograde ejaculation.

A Transurethral resection of the prostate

B Retropubic prostatectomy

Figure 48–4 ■ A, In a transurethral resection of the prostate, a resectoscope inserted through the urethra is used to remove excess prostate tissue. B, In a retropubic prostatectomy, prostate tissue is removed through an abdominal incision.

In the transurethral incision of the prostate (TUIP) procedure, small incisions are made in the smooth muscle where the prostate is attached to the bladder. The gland is split to reduce pressure on the urethra. No tissue is removed, so this procedure is most appropriate for men with smaller prostate glands. TUIP can be done on an outpatient basis, and has the additional advantage of less risk of postoperative retrograde ejaculation than is associated with TURP or other prostatectomy procedures.

OPEN SURGERY When the prostate gland is very large, an open prostatectomy may be used. These procedures are discussed in the section on prostate cancer that follows. Nursing care for the patient having prostate surgery is outlined in an accompanying box.

NURSING CARE OF THE PATIENT

Having a Prostatectomy

PREOPERATIVE CARE

- Assess the man's and family's knowledge about the surgery. *Some men are confused about the surgical approach because there are several quite different methods.*
- Inform the man that he will have a urinary catheter when he returns from surgery, and he may have a drain(s) in his incision. He also will be wearing antiembolic stockings or sequential pneumatic compression stockings. *This knowledge can reduce anxiety postoperatively and increase cooperation with postoperative care.*
- Ensure that a signed consent form is in the chart and that all other preoperative tasks, as outlined in Chapter 4, are done.
- Bowel preparation with a 2% neomycin enema may be ordered. *This cleanses the bowel if a perineal approach will be used.*
- Communicate willingness to address any concerns or anxiety. *Men may be anxious about the outcome of their surgery and potential long-term effects of the surgery on their sexuality. When a prostatectomy is performed for prostate cancer, additional fears include the extent of the cancer and surgery, chances for cure, and possible end-of-life issues.*

POSTOPERATIVE CARE

- Maintain the usual postoperative assessments and follow aseptic techniques in urinary drainage and irrigation care. Monitor vital signs closely for the first 24 hours and regularly thereafter. *The man who has had prostate surgery is at risk for hemorrhage and infection. Vital sign changes may be early manifestations of complications.*
- Maintain accurate intake and output records, including amounts of irrigating solution used. Frequently assess patency of any catheters and drains. Monitor color and character of urine. *Catheters may become occluded by blood clots or kinks, interfering with urinary drainage and increasing the risk of hemorrhage.*
- Assess and manage pain. *The man may have at least three types of pain: incisional pain, bladder spasms, and abdominal cramps due to intestinal gas. Analgesics and nonsteroidal anti-inflammatory drugs (NSAIDs) are administered on a routine and prn basis to control incisional pain. Bladder spasms may be accompanied by strong urges to void and urine leakage around the catheter. Belladonna and opium (B&O) suppositories may be used to relieve bladder spasms.*
- Maintain antiembolic stockings or sequential compression stockings as prescribed, following agency protocol for assessments and times of removal. Assist with leg exercises and ambulation as ordered. *The man who has had prostate surgery is at risk for developing thromboemboli; these are important preventive measures.*
- Encourage the man to maintain a liberal fluid intake of 2 to 3 L a day. *Increased fluids reduce burning on urination after catheter removal and the risk of urinary tract infection.*

THE MAN WITH A TRANSURETHRAL RESECTION OF THE PROSTATE (TURP)

- For the first 24 to 48 hours, monitor for hemorrhage, evidenced by frankly bloody urinary output, presence of large blood clots, decreased urinary output, increasing bladder spasms, decreased hemoglobin and hematocrit, tachycardia, and hypotension. Notify the physician if any of these manifestations occur. *Postoperative hemorrhage may be either arterial or venous, and may be precipitated by movement, bladder spasms, or an obstructed urinary drainage system.*
- Instruct the man with a three-way indwelling catheter with traction to keep the leg straight while the traction is applied. *A No. 18- to 22-Fr three-way catheter with a 30- to 45-mL balloon usually is inserted following a TURP. The inflated balloon is pulled down into the prostatic fossa and the catheter tubing is pulled down and secured to the man's leg with a urinary catheter attachment device to apply pressure against the operative site, preventing bleeding.*
- Explain that the presence of a urinary catheter will cause the sensation of needing to void, but it is important not to strain to try to void around the catheter or when having a bowel movement. Explain that bladder spasms, experienced as lower abdominal pressure or pain and a desire to urinate, may occur and medications may help with this issue. *Pressure on the urethra by the large catheter and on the internal sphincter by the catheter's balloon stimulate the micturition reflex. Straining to void or to have a bowel movement may stimulate bladder spasms and increase pain; it also may increase the risk for bleeding. Administer pain medications at regular intervals.*
- If the man has a continuous bladder irrigation (CBI), assess the catheter and the drainage tubing at regular intervals. Maintain the rate of flow of irrigating fluid to keep the output light pink or colorless. Assess the urinary output every 1 to 2 hours for color, consistency, amount, and presence of blood clots; assess for bladder spasms. *CBI is used to prevent the formation of blood clots, which could obstruct urinary output. Bladder distention resulting from output obstruction increases the risk of bleeding. Irrigating fluids are continuously infused and drained at a rate to keep urine light pink or colorless. Urine that is frankly bloody, contains many blood clots, or is decreased in amount, as well as bladder spasms, are indicators of obstruction and bleeding.*
- Assess for fluid volume excess and hyponatremia, called TURP syndrome, which is manifested by hyponatremia, decreased hematocrit, hypertension, bradycardia, nausea, and confusion. If these manifestations occur, notify the physician. *TURP syndrome results from the absorption of irrigating fluids during and after surgery. Untreated, it may result in dysrhythmias, seizures, or both.*
- If the man does not have CBI, follow agency procedure and physician orders for irrigating the indwelling catheter (usually when the urine is frankly bloody or has numerous larger blood clots, or when bladder spasms increase). In most instances, using sterile technique, the catheter is gently irrigated with 50 mL of sterile irrigating solution at a time, until the obstruction is relieved or the urine is clear. Ensure equal input and output of irrigating fluid. *Intermittent irrigation may be used to prevent obstruction of urinary drainage.*
- Following catheter removal, assess the amount, color, and consistency of urine. Explain that the man may experience burning on urination, that dribbling after urination is a common experience, and that the urine may contain small blood clots after catheter removal. *The CBI and catheter usually are removed in the 24 to 48 hours following surgery. Urinary control may be improved by teaching the man to start and stop the urine stream several times during each voiding and by practicing Kegel exercises. Regaining full control may take up to 1 year.*

THE MAN WITH A RETROPUBIC PROSTATECTOMY

- Assess the abdominal incision (Figure 48–4B) for the presence of urine. *Because the bladder is not entered during a retropubic prostatectomy, no urine should be found on the dressing.*
- Assess the abdominal incision for increased or purulent drainage, and the man for an increased temperature and pain. *These manifestations indicate the presence of infection.*

THE MAN WITH A SUPRAPUBIC PROSTATECTOMY

- Assess urinary output from both the suprapubic and the urethral catheters. *The man with a suprapubic prostatectomy*

NURSING CARE OF THE PATIENT (*continued*)

often has two separate closed drainage systems: one from the suprapubic incision and one from a urethral catheter.
- Assess the abdominal dressing for urinary drainage, and change saturated dressings frequently. Consult with a skin care specialist if necessary. *Urine is highly irritating to the skin.*
- Following removal of the urethral catheter (usually 2 to 4 days after surgery) and based on physician orders, clamp the suprapubic catheter and encourage the man to void. Assess residual urine by unclamping the suprapubic catheter and measuring urinary output after voiding. *If residual urine is 75 mL or less with several voidings, the suprapubic catheter is removed.*

THE MAN WITH A PERINEAL PROSTATECTOMY
- Assess perineal incision for drainage and manifestations of infection. *Location of the incision in the perineum increases the risk of infection.*
- Do not take rectal temperatures or administer enemas. *Insertion of a thermometer or enema tubing into the rectum may precipitate bleeding.*
- Use a T-binder or padded scrotal support to hold the dressing in place. Following removal of the dressing and perineal sutures, heat lamps or sitz baths may be used. *The location of the dressing makes application difficult: Heat lamps or sitz baths provide heat and promote healing.*
- Teach the man to perform perineal irrigations with sterile normal saline as ordered and after each bowel movement. *Because of the proximity of the incision to the anus, special wound care is necessary to prevent infection.*

LASER SURGERY In laser surgery, the surgeon uses a cystoscope to pass the YAG laser fiber through the urethra into the prostate and then vaporizes obstructing prostate tissue with several short bursts of energy. An advantage of laser surgery is decreased blood loss and a more rapid recovery time. However, this method may not be as effective for larger prostates.

OTHER TREATMENTS

Other treatments for BPH include minimally invasive procedures such as balloon urethroplasty and placement of intraurethral stents to maintain patency of the urethra. Balloon urethroplasty is a simple procedure in which a balloon-tipped catheter is inserted into the narrowed portion of the urethra and inflated. Inflation of the balloon widens the urethra, relieving obstruction. These procedures can be done as outpatient surgery.

ALTERNATIVE AND COMPLEMENTARY THERAPIES

Phytotherapy is the use of plants or plant extracts for medical treatment. Several plant extracts have been used for years in Europe to treat BPH and are being used more often in the United States. Phytotherapy used includes saw palmetto berry, the bark of *Pygeum africanum*, the roots of *Echinacea purpurea* and *Hypoxis rooperi*, and the leaves of the trembling poplar. The mechanisms of action of these extracts are unknown. There are men who report effectiveness in relieving manifestations but recent studies have revealed no significant reduction in symptoms or growth of the prostate when used (Papadakis & McPhee, 2013).

●○● NURSING CARE

Most men are unsure of the function of the prostate gland and even the prostate's exact location, though its relationship to sexual and urinary function is at least generally known. This lack of knowledge, coupled with the growing number of treatment options, is confusing to many men. There are many similarities between the nursing care of men with BPH and that of men with prostate cancer (see the section that follows).

Diagnoses, Outcomes, and Interventions

This section provides interventions related to deficient knowledge, urinary retention, risk for infection, and risk for imbalanced fluid volume.

Readiness for Enhanced Knowledge: Benign Prostatic Hypertrophy

Expected Outcome: Patient will describe prostate anatomy and physiology and therapeutic options to treat BPH including medications and surgical options.

- Explain the anatomy and physiology of the prostate gland, as well as normal changes that occur with aging. *Men must know about their bodies in order to make accurate decisions about treatment.*
- Discuss treatment options, including information about effects on erectile function, ejaculation, and fertility. Counsel the man to discuss specific concerns with his urologist. *Many different treatment options are available; the choice should be a mutual decision between the man, his partner, and the urologist.*
- Discuss effects of prostate surgery, including urinary retention and urinary incontinence. *These common transient postoperative effects are related to the surgical procedure and the postoperative indwelling catheter.*
- Explain to the man having a TURP that a catheter will be placed into the bladder, with the tubing taped to his inner thigh, and that irrigation fluid may be infusing into and out of the catheter for the first 36 to 72 hours following surgery. *The catheter and irrigation are necessary to remove blood clots from the bladder and allow drainage of urine. Gentle traction is applied to the catheter to apply pressure to the operative site (prostatic fossa) and prevent excessive bleeding.*
- Explain that, following removal of the catheter, he will most likely have urinary frequency and urgency. He may also experience dribbling of urine after voiding. Stress the importance of increasing oral fluid intake and regular Kegel exercises. *Urinary manifestations are related to the surgical procedure and the indwelling catheter. Increased fluid intake helps decrease dysuria. Kegel exercises strengthen periurethral muscles and decrease postvoiding urine leakage.*

Urinary Retention

Expected Outcome: Patient will describe symptoms of urinary retention, medications, and actions to avoid development of urinary retention. Patient will demonstrate correct double-voiding technique to reduce urinary incontinence.

- Teach the manifestations of acute urinary retention: dysuria, overflow incontinence, bladder pain and distention, no urine output. *Acute urinary retention is a potential complication of BPH, requiring immediate medical attention.*

- Teach that the risk of developing urinary retention increases when the man with BPH takes OTC decongestant medications, or prescription medications such as antidepressants, anticholinergics, calcium channel blockers, antipsychotics, and medications to treat Parkinson's disease. *OTC decongestants may contain alpha-adrenergic agonists that increase smooth muscle tone of the prostate, bladder neck, and proximal urethra. The prescribed medications may relax detrusor muscle contractions. Both actions may increase the risk of urinary retention (Wilson et al., 2013).*
- Suggest avoiding intake of large volumes of liquid at any one time. *A single intake of a large volume of liquid results in rapid bladder filling and increases the risk of urinary retention.*
- Teach how to use the double-voiding technique: Urinate, then sit on the toilet for 3 to 5 minutes, then urinate again. *This technique may relieve mild to moderate urinary retention.*

PRACTICE ALERT!

In addition to avoiding a large amount of fluids at one time, it is also important to teach the man to limit liquids that stimulate voiding, such as coffee and alcoholic beverages.

Risk for Infection

Expected Outcome: Patient will describe symptoms of urinary tract infection and importance of early reporting of symptoms.

- Monitor WBC and vital signs. *Infection is indicated by an increase in WBCs, body temperature, and pulse rate.*
- Maintain sterile procedures when changing irrigation fluids and emptying Foley catheter draining bag. *Sterile procedures are necessary to prevent infection.*

Risk for Imbalanced Fluid Volume

A prostatectomy increases the risk for imbalanced fluid volume as a result of excessive bleeding from the operative site (prostatic fossa) as well as absorption of irrigating fluid. Report manifestations indicating hypovolemic shock, excess bleeding, and/or TURP syndrome immediately.

Expected Outcome: Patient will describe symptoms that require immediate reporting: drop in blood pressure, increase in pulse, increase in postoperative bleeding.

- Monitor pulse and blood pressure. *Manifestations of hypovolemic shock include an increasing pulse and a decreasing blood pressure.*
- Monitor color of drainage in urinary drainage bag (Table 48–2). *The appearance of urine and irrigation fluid in the urinary drainage bag is an excellent indicator of bleeding after a prostatectomy.*
- Monitor for manifestations of transurethral resection (TURP) syndrome: nausea and vomiting, confusion, hypertension, bradycardia, and visual disturbances. *The absorption of isotonic bladder irrigating fluids during and after surgery may cause this hypervolemic, hyponatremic state. Treatment includes diuresis and, in severe cases, hypertonic saline administration (Vijayan, 2011).*

Continuity of Care

Depending on the man's choice of treatment, the procedure may be performed on an outpatient basis. The man having a TURP, although hospitalized for the surgery, may be discharged within 2 days after surgery if there are no complications. Discharge instructions after

TABLE 48–2 Urine Characteristics after Prostatectomy with Related Nursing Implications

Urine Color	Nursing Implications
Light red to red	Normal day of surgery and first postoperative day.
Very dark red	May indicate increased venous bleeding or inadequate dilution. Catheter at risk for occlusion. Increase flow rate of irrigant. If urine does not clear, notify physician.
Bright red	May indicate arterial bleeding. Increase flow rate of irrigant, monitor vital signs, and notify physician.
Contains blood clots	Occasional blood clot normal. If clots are frequent, catheter may become obstructed. Increase flow rate of irrigant.
Clear to light pink	Normal throughout hospitalization.

Meeting Individualized Needs

Discharge Instructions after Prostate Surgery

ACTIVITY
The healing period lasts from 4 to 8 weeks. Avoid strenuous activity and heavy lifting. Do not drive for 2 weeks, except for short rides. Do not take long walks; take stairs slowly and carefully. Continue exercises that you did in the hospital to prevent blood clots in the legs. You can take showers; avoid tub baths while the catheter is in place.

BLEEDING
Bleeding can occur any time after surgery. It is fairly common after a bowel movement, coughing, or increased exercise. If you notice blood in the urine, increase fluids and rest until the urine is clear. If heavy bleeding obstructs urine flow, call the care provider immediately. Avoid aspirin and NSAIDs for at least 2 weeks.

BOWEL MOVEMENTS
Keep bowel movements regular and soft to avoid pressure on the prostate area. Drink fruit juices, increase fiber in the diet, and take mild laxatives or stool softeners if needed.

DIET
Resume your normal diet. Increase fluids to ten 8-oz glasses daily. Avoid alcohol unless otherwise approved by your physician.

SEXUAL INTERCOURSE
Do not have sex for 6 weeks after surgery to avoid bleeding. You may still have erections even with the catheter in place. When you resume sex, ejaculate may flow back into the bladder; if so, you will expel little or no semen when having an orgasm.

URINATION
After your catheter is removed, you may experience some burning, stinging, or leakage for several weeks, and you may pass small blood clots occasionally. These symptoms will disappear as the area heals. It is best to use pads to control leakage. Kegel exercises (see Box 27–3 on page 775) can help gain urinary control.

WORK
If work is not strenuous you may return in 4 weeks; otherwise, wait 6 to 8 weeks.

PLEASE CALL IMMEDIATELY IF THE FOLLOWING OCCURS:
- You are unable to urinate.
- Bleeding is not controlled by fluids and rest, or is excessive.
- You have chills and fever or severe abdominal pain.
- Your scrotum becomes swollen and tender.
- You have pain in one calf, chest pain, or difficulty breathing.

prostate surgery are provided in the Meeting Individualized Needs box. Home care often involves care of an indwelling urinary catheter. Teaching how to care for the catheter and drainage bag includes the following information:

- Change from the daytime leg drainage bag to a larger night drainage bag. A larger bag suspended from the bed frame at night permits gravity drainage of urine and prevents reflux of urine back into the bladder.
- Avoid strapping the leg bag on too tightly, which can decrease venous return and increase risk for thrombophlebitis and embolic complications such as pulmonary emboli.
- Place a soft cloth between the leg bag and thigh to decrease friction and absorb dampness under the bag, reducing the risk of skin irritation.
- Empty the leg bag every 3 to 4 hours during waking hours to prevent overfilling.
- Promptly report to the urologist any unexpected changes in urine color, consistency, or odor; hematuria; evidence of frank bleeding or large blood clots; or a lack of or significant decrease in urine output.

THE MAN WITH PROSTATE CANCER

Cancer of the prostate is the most common type of cancer and the second leading cause of cancer deaths among men in North America (American Society of Clinical Oncology [ASCO], 2012). The greatest risk factor for prostate cancer is age; 85% of men with prostate cancer are diagnosed after the age of 65. It is estimated that each year, more than 240,000 men will be diagnosed with prostate cancer and approximately 30,000 will die of it (ACS, 2012b). Even though prostate cancer death rates are decreasing, this cancer poses major health concerns for older men and implications for healthcare. Improved screening in the aging population has resulted in increasing numbers of men diagnosed. Treating this cancer often proves to be more harmful than the cancer itself and does not improve mortality rates. Prostate cancer treatments can affect quality of life, with urinary and sexual dysfunction as well as complications from surgery itself. There is growing consensus that for many men, careful monitoring is more appropriate than treatment. Still, for some men prostate cancer is more aggressive and ultimately contributes to their death. Because of these issues, debate exists concerning screening for prostate cancer. The American Cancer Society is recommending that screening be performed on an individual basis, dependent on risk factors and personal choice (ACS, 2012b).

Prostate cancer is usually curable if detected early. When the cancer is confined to the prostate at diagnosis, the 5-year survival rate is 100%. Even when the cancer has spread regionally, approximately 95% of patients are alive after 5 years and 91% reach 10 years (ASCO, 2012). Many men are found to have prostate cancer on autopsy; usually the cancer has produced no manifestations or complications. If, however, the cancer has metastasized outcomes are less positive and debilitation and death are a great possibility.

FOCUS ON CULTURAL DIVERSITY

Risk and Incidence of Prostate Cancer

- Prostate cancer occurs more often and at an earlier age in Black men than in men of other races.
- Blacks are more likely to be diagnosed later and to die of prostate cancer, with a mortality rate more than double that of other racial and ethnic groups.
- Asians and Native Americans have the lowest incidence of prostate cancer.

Source: ACS, 2012b.

Risk Factors

In addition to age, race is a significant risk factor for prostate cancer, although the cause is unknown (see the accompanying Focus on Cultural Diversity box). Other risk factors being investigated are as follows:

- Genetic and hereditary factors, with risk increased in men who have a family history of the disease. A father or brother having prostate cancer doubles a man's chances of developing it in his lifetime (Chapple & Steers, 2011).
- Having a vasectomy, believed to increase the levels of circulating free testosterone.
- Dietary factors, including a diet high in animal fat and excessive supplemental vitamin A.

Pathophysiology

The prostate gland consists primarily of glandular epithelial cells. The exact etiology of prostate cancer is unknown, although androgens are believed to have a role in its development. Almost all primary prostate cancers are adenocarcinomas, and they develop in the peripheral zones of the prostate gland. This location increases the risk of local spread to the prostatic capsule. Despite its proximity to the rectum, spread to the bowel is uncommon because a tough sheet of fascia acts as an effective physical barrier.

As the tumor enlarges, it may compress the urethra, obstructing urinary flow. The tumor may metastasize and involve the seminal vesicles or bladder by direct extension. Metastasis by lymph and venous channels is common.

Manifestations

Men with early-stage prostate cancer are often asymptomatic. Urinary manifestations depend on the size and location of the tumor and the stage of the malignancy. They are often much like manifestations of BPH: urgency, frequency, hesitancy, dysuria, and nocturia. The man may also notice hematuria or blood in the ejaculate. Pain from metastasis to bones may occur with advanced disease (Huether & McCance, 2012). Manifestations of prostate cancer are summarized in the accompanying box.

Complications

Death usually occurs secondary to debility caused by multiple sites of skeletal metastasis, especially to the vertebrae. The spinal cord may be compressed by tumors or by fractures of the spine, resulting in the possible loss of mobility and bowel and bladder function. Tumors may eventually involve bone marrow, resulting in severe anemias and impaired immune function.

●○● INTERPROFESSIONAL CARE

Care of the man with prostate cancer focuses on diagnosis, elimination or containment of the cancer, and prevention or treatment of

MANIFESTATIONS OF PROSTATE CANCER

GENITOURINARY
- Dysuria
- Frequency of urination
- Reduction in urinary stream
- Nocturia
- Hematuria
- Abnormal prostate on digital rectal examination

MUSCULOSKELETAL
- Bone or joint pain
- Migratory bone pain
- Back pain

NEUROLOGIC
- Nerve pain
- Bilateral lower extremity weakness
- Bowel or bladder dysfunction
- Muscle spasms

SYSTEMIC
- Weight loss
- Fatigue

complications. There are currently no clinical strategies to prevent the development of prostate cancer, although results of several large studies have demonstrated a reduced risk in men over age 55 who are treated with a 5α-reductase inhibitor such as finasteride (Propecia, Proscar) or dutasteride (Avodart). Education and early detection remain the major emphases for control of this disease.

The treatment of prostate cancer is complex and depends on the grade and stage of the cancer as well as the age, general health, and preference of the patient. In some cases, for example, when the patient with a slow-growing tumor is older or has a limited life expectancy, watchful waiting is the treatment of choice. Treatments for prostate cancer include surgery, radiation therapy, hormone manipulation, and chemotherapeutic agents.

DIAGNOSIS

Although an increasing number of patients are now diagnosed with asymptomatic prostate cancer, many patients with prostate cancer have either locally advanced cancer or distant metastasis at the time of diagnosis. The definitive diagnosis can be made only by biopsy; however, other tests may suggest the presence of prostate cancer.

A digital rectal examination (DRE) will find the prostate gland nodular and fixed in prostate cancer. PSA levels are used to diagnose and stage prostate cancer and to monitor response to treatment. Levels depend on age, and there is no specific normal or abnormal level. An increase over time is more significant than one reading. The PSA test is used with a DRE to screen for prostate cancer in men age 48 to 76 years.

Transrectal ultrasonography (TRUS) may be used when the DRE is abnormal or if the PSA is elevated. In this test, a small probe is inserted in the rectum. The probe gives off sound waves that are reflected off tissues to provide a picture of the prostate on a video screen. Guided by this picture, the physician inserts a narrow needle through the rectal wall into the prostate gland to remove a tissue sample for examination (biopsy). Other tests that may be ordered include a urinalysis or cystoscopy. Bone scan, MRI, or CT scans may be performed to determine the presence of tumor metastasis.

Grade and stage help to determine prognosis and guide treatment decisions. Grade (cancer cell differentiation) is determined by the pathologist. Prostate cancer is staged with a variety of tests. Table 48–3 outlines treatment options according to the stage of the cancer.

MEDICATIONS

Androgen deprivation therapy is used to treat advanced prostate cancer. Many cells in the growing tumor are androgen dependent and either cease to grow or die if deprived of androgens. Approximately 70-80% of men with advanced prostate cancer respond to androgen deprivation (Papadakis & McPhee, 2013). Strategies to

TABLE 48–3 Prostate Cancer Staging and Treatment

Stage	Description	Treatment
I	Confined to prostate; nonpalpable, focal involvement; well differentiated	Observation and follow-up Interstitial or external-beam radiation therapy Prostatectomy
II	Confined to prostate, palpable, involves one or both lobes; poorly differentiated	Careful observation in selected patients Prostatectomy Interstitial or external-beam radiation therapy Ultrasound-guided percutaneous cryosurgery
III	Extension of the tumor outside the prostate capsule, possible seminal vesicle involvement	External-beam radiation therapy Interstitial radiation Radical prostatectomy Adjunctive hormone therapy Palliative surgery (TURP)
IV	Extension of the tumor into surrounding tissues; lymph node involvement or distant metastasis	Hormone therapy External-beam radiation therapy Palliative treatment with radiation therapy and/or TURP Radical prostatectomy with orchiectomy Chemotherapy

TABLE 48–4 Surgical and Selected Hormone* Therapies for Androgen Deprivation

Treatment	Advantages	Disadvantages
Orchiectomy	Inexpensive Immediate effect (i.e., men report diminished pain from metastasis in the recovery room)	Body image problems due to loss of testicles
Estrogen compounds (diethylstilbestrol)	Inexpensive Effects reversible	Increased risk of cardiovascular problems More likely to cause gynecomastia, hypertrophy of breast tissue
Luteinizing hormone-releasing hormone (LHRH) agonist (leuprolide)	Effects reversible No cardiovascular risk Monthly administration	Very expensive Subcutaneous injection route Slow onset: up to 4 weeks
Steroidal antiandrogens (megestrol [Megace])	Effects reversible No cardiovascular risk Inexpensive	May not drop testosterone levels sufficiently Weight gain
Nonsteroidal antiandrogens (flutamide; often used in conjunction with LHRH)	Does not alter circulating androgens Blocks some side effects of LHRH May be effective if other methods fail	Very expensive

*All hormonal manipulations have the potential disadvantage of loss of libido, erectile dysfunction, hot flashes, and gynecomastia.

deplete androgen levels or block their effect vary from surgical orchiectomy (the most effective but least acceptable to the patient) to oral administration of hormonal agents (chemical castration). Table 48–4 compares surgical and hormone therapies to achieve androgen deprivation and the advantages and disadvantages of each.

Drugs such as degarelix (Firmagon), goserelin (Zoladex), and leuprolide (Lupron, others) are most commonly used to achieve androgen deprivation without orchiectomy. They may be administered orally or by depot injection. Hot flushes and ED are common adverse effects of these medications. Using these drugs in combination with an antiandrogen such as flutamide (Eulexin) or bicalutamide (Casodex) often reduces their adverse effects. Estrogens such as diethylstilbesterol (DES) may be used, but are associated with significant adverse effects (e.g., gynecomastia, hot flushes, ED) and a risk for thromboembolic disease.

Research is ongoing to demonstrate what mix of hormones is best and at what time in the perioperative period they are most effective. Hormonal therapy may also be used in conjunction with radiation therapy. Chemotherapy usually consists of cytotoxic agents (Alifrangis et al., 2011).

The biologic response modifier sipuleucel-T (Provenge) has been shown to improve survival rates for prostate cancer patients and received FDA approval in 2010. This drug is mixed with the patient's immune cells and administered by intravenous infusion to attack the tumor. Further studies of immunologic response drugs are currently in place to determine their effectiveness (Alifrangis et al., 2011).

SURGERY

Surgery for prostate cancer includes several types of prostatectomies. For very early disease in older men, cure may be achieved with a simple prostatectomy (such as TURP), discussed in the section on benign prostate hyperplasia. Following the surgery men usually experience erectile dysfunction for at least the first 3 months and return of sexual activity may take up to 2 years. Incontinence can also be a problem following prostatectomy surgery. Table 48–5 compares the potential complications associated with radical prostatectomy and radiation therapy to treat prostate cancer.

- *Radical prostatectomy* involves removal of the prostate, prostate capsule, seminal vesicles, and a portion of the bladder neck. In a laparoscopic radical prostatectomy (LRP), small incisions are made in the abdomen and a laparoscope is inserted and used to remove the prostate. Some surgeons use a robotic interface to perform this procedure. See the Moving Evidence into Action box for information about the experiences of men following laparoscopic prostate surgery.

The most common radical prostatectomy techniques are the following:

- *Retropubic prostatectomy* is currently the favored method and is being combined with nerve-sparing techniques to improve erectile and bladder dysfunction problems. This form of surgery (see Figure 48–4B) allows visualization of the prostate bed and bladder neck, and access to pelvic lymph nodes for biopsy (American Urological Association, 2010).
- *Perineal prostatectomy* is often preferred for older men or those who are poor surgical risks. This approach requires less time,

TABLE 48–5 Potential Complications of Prostate Cancer Treatment

Radical Prostatectomy	Radiation Therapy
Erectile dysfunction	Erectile dysfunction*
Urethral stricture	Urethral stricture
Fistula/rectal injury	Rectal/anal stricture*
Urinary incontinence	Cystitis
Surgical/anesthetic risk	Diarrhea
	Proctitis
	Rectal ulcer
	Bowel obstruction*
	Urinary incontinence

*Delayed complications; may appear months or years after completion of therapy.

Moving Evidence into Action

Improving Prostatectomy Teaching

Discharge following open or laparoscopic retropubic prostatectomy can occur as soon as 1.5 days postoperatively. Due to the limited length of stay, concern exists as to whether discharge teaching is adequate to address the many questions a patient may have concerning their care at home. The study conducted by Inman and colleagues (2011) examined whether providing postoperative educational efforts improved patient's knowledge and enhanced abilities to perform self-care practices as well as decreased utilization of healthcare services. The patients received a phone call from an experienced nurse 3 to 5 days postoperatively. They were questioned as to whether they understood their medications and how to manage their care. They were also asked if they had any questions. The men did have concerns over the urinary catheter, bladder spasms, and pain management. These patients also exhibited anxiety related to possible urinary and sexual side effects of the surgery. Analysis determined that the phone calls did improve knowledge even when patients had written information provided at discharge. It was also determined that this phone call improved the patient's satisfaction and decreased unexpected visits to clinics and emergency departments.

Implications for Nursing

Although the men who were subjects in the study had been provided information about the surgery, they were not prepared to totally care for self in relation to catheter care, bladder spasms, and pain management. Concerns over incontinence and erectile dysfunction also produced anxiety. Nurses should discuss the surgery and identify the expectations of the man prior to surgery as well as encourage organizations to consider follow-up programs to meet the needs of patients after discharge. If no follow-up program is offered, written information about available community resources should be provided.

Moving Knowledge into Action

1. You are caring for a 75-year-old man who has had a laparoscopic radical prostatectomy for prostate cancer. His wife tells you they have always had an active sex life and she hopes this surgery will not change that. What would you say to her?
2. Would the nursing diagnosis *Risk for Infection* be appropriate for a man following a radical laparoscopic prostatectomy? If so, what type of interventions would you suggest during discharge teaching to reduce this risk?
3. If you were developing a list of community resources for men following prostate surgery for cancer, what would you include? How would your list vary for the following situations?
   - A 64-year-old man with a wife and four married children who all live close
   - A 77-year-old man who lives alone and has no family
   - A 90-year-old man who will go to an assisted living facility after discharge from the hospital.

involves less bleeding and pain, and results in shorter hospital stays. A disadvantage to this approach is that lymph nodes cannot be accessed and require additional incisions to obtain.

- *Suprapubic prostatectomy* is rarely used, usually when problems with the bladder are expected. Control of bleeding is more difficult because the surgical approach is through the bladder.

For patients with stage III, locally advanced (beyond the prostatic capsule) cancer, surgery is controversial because of the likelihood of hidden lymph node metastasis and relapse. TURP is not performed as curative therapy but may be used to relieve urinary obstruction for men with advanced disease (stage III or IV).

Surgical intervention is now available for men with urinary sphincter insufficiency, which is the major cause of incontinence after prostatectomy. An artificial urinary sphincter is surgically implanted (Figure 48–5 ■). To be eligible, the man must be able to manipulate the pump placed in the scrotum and have adequate cognitive function to know when a problem with the appliance occurs.

RADIATION THERAPY

Radiation therapy may be used as a primary treatment for prostate cancer. Long-term problems of impotence and urinary incontinence occur less frequently, and survival rates often are comparable. Radiation may be delivered either by external beam or interstitial implants of radioactive seeds of iodine, gold, palladium, or iridium (brachytherapy). Interstitial radiation has a lower risk of impotence and rectal damage than external-beam radiation. Refer to Chapter 14 for nursing care of the patient receiving radiation therapy.

Radiation therapy has a palliative role for patients with metastatic prostate cancer, reducing the size of bone metastasis, controlling pain, and restoring function, such as continence or the ability to ambulate for patients with spinal cord compression.

●○● NURSING CARE

Nurses plan and provide interventions to help prevent prostate cancer and to facilitate a return to functional health status. Interventions may range from teaching to using knowledge and skill in physical care following a radical prostatectomy. See the Case Study & Nursing Care Plan for a man having a radical prostatectomy on page 1577.

Health Promotion

Nurses are in a unique position to increase public awareness about early detection of prostate cancer. Every encounter with men and their families—in clinics, hospital units, or in the home—is an opportunity to provide information about early detection and identify needs. Several studies have shown a positive correlation between increased awareness of and participation in prostate cancer screening procedures. The American Cancer Society provides free pamphlets about early detection of prostate cancer, which are useful in educating the public.

One risk factor that can be easily changed is diet. Men should know that they can lower their risk of prostate cancer by eating less red meat and fat. They should include fruits and vegetables as recommended in current USDA MyPlate guidelines; tomatoes, pink grapefruit, and watermelon are high in lycopenes that help prevent damage to DNA and may help lower prostate cancer risk.

All men should be given information about the limitations and benefits of testing for early detection and of treatment if diagnosed with prostate cancer, so they can make an informed decision. Men should be informed of the genetic predisposition in the development of prostate cancer. Men at high risk (men of African descent and those with a first-degree relative diagnosed at a younger age) should consider PSA testing.

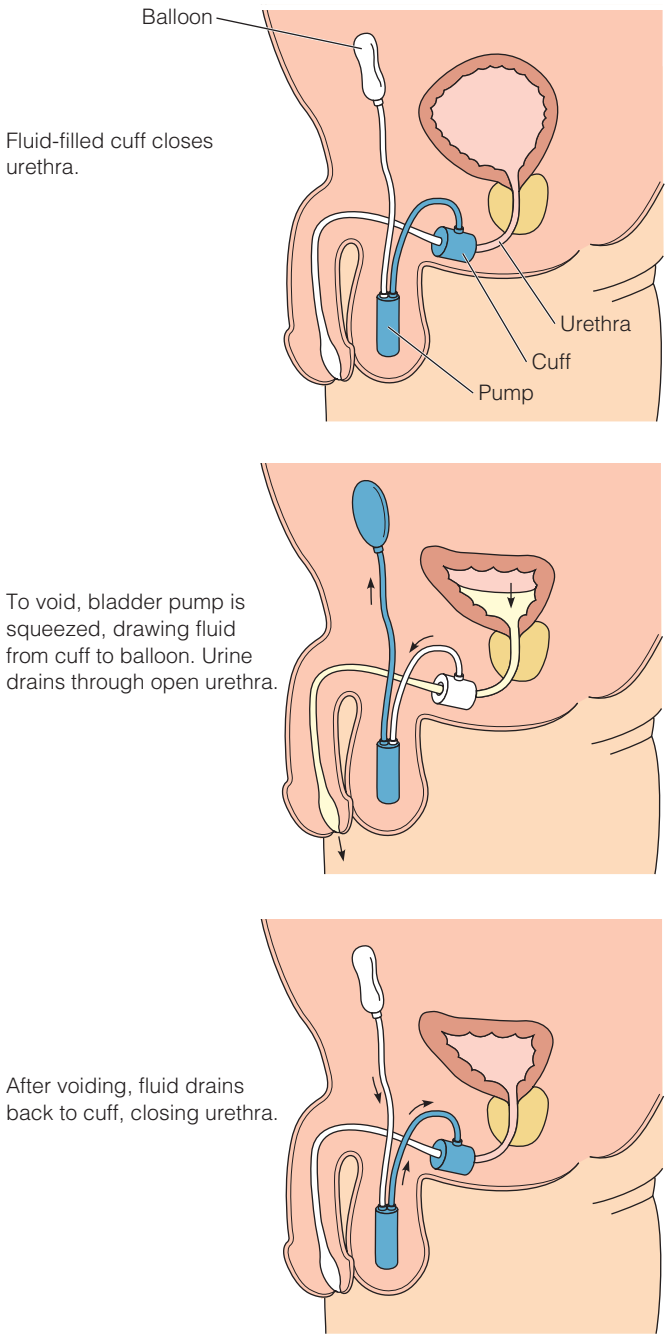


Figure 48–5 ■ Method of operation of an artificial urinary sphincter.

Assessment

Collect the following data through the health history and physical examination. Note that a digital rectal examination is an advanced nursing assessment.

- *Health history:* risk factors, urinary elimination patterns and manifestations, hematuria, pain
- *Physical assessment:* DRE to assess prostate size, symmetry, firmness, and nodules.

Nursing Care Priorities

Although the nursing care focus will differ depending on age of the man with prostate cancer, the stage of the disease, and the treatment plan, maintaining effective urinary elimination and helping the patient and family deal with the cancer diagnosis and treatment are priorities for nursing care.

Diagnoses, Outcomes, and Interventions

The nursing care of men with prostate cancer must be holistic, sensitive, and individualized. The nursing diagnoses discussed for the man with BPH may also be appropriate. This section focuses on problems with urinary incontinence, sexual function, and pain.

Urinary Incontinence (Reflex, Stress, Total)

Urinary incontinence is a disturbing complication following treatment for prostate cancer. Both radical prostatectomy and external-beam radiation therapy can cause incontinence, ranging from a drop or two when the patient lifts a heavy object (stress incontinence) to no control at all. Older men may experience urge incontinence, the involuntary passage of urine soon after a strong sense of urgency to void. Total and unpredictable loss of urine is classified as total incontinence. The man's reaction to incontinence may be significant even if the incontinence is not great. Many men have significant anxiety at the prospect of an incontinent episode in public, because they feel shame and often guilt about the loss of control.

Expected Outcome: Patient will demonstrate urinary continence by recognizing the urge to void, managing independent toileting, and maintaining a predictable pattern of voiding.

- Assess the degree of incontinence and its effects on lifestyle. *The nurse needs to determine previous urinary patterns and the type of incontinence currently being experienced to plan appropriate interventions.*
- Teach Kegel exercises to help restore continence. *Pelvic muscle or Kegel exercises can often either eliminate or improve stress incontinence.*
- Teach methods to control dampness and odor from stress incontinence as follows:
  - Do not attempt to prevent accidental voiding by restricting fluids. *Not only will the man continue to have incontinent episodes, but also his urine will become concentrated, exacerbating the problem with odor.*
  - Manage occasional episodes (one to three small-volume accidents per day) with absorbent pads worn inside the underwear and changed as needed. Most pads are made with a polymer gel that controls odor. *Appropriate measures help promote good hygiene, decrease anxiety, and increase comfort.*
- Refer to physical therapy or a continence specialist for additional measures to promote continence. *Special exercises, restricting some types of fluid, and other measures such as bladder training can help the patient deal with incontinence.*
- Explore options such as an external collection device (external catheter or Texas catheter) for the man with total incontinence. *This device may improve the man's self-esteem and allow resumption of social activities.*
- Encourage verbalizing feelings about the impact of incontinence on quality of life. *The degree of incontinence does not necessarily correlate with the perceived level of suffering. Listening to these concerns with sensitivity can help the man work through these feelings and may allow him to move toward a healthy adaptation to his disability.*

Sexual Dysfunction

Surgical treatment for prostate cancer may cause ED and changes in ejaculatory function. Hormone therapy for advanced prostate cancer lowers libido and may also cause ED. The diagnosis of cancer and body image changes caused by hormone therapy may lower self-esteem, which in turn can diminish sexual desire and willingness to interact sexually with a partner. Many older men are active sexually and fully capable of sustaining an erection. They are likely to fear the effect of treatment on their sexual health. They may allow this concern to guide their decision about the treatment course, or they may refuse all therapy because of this fear. Reactions vary greatly, and the nurse must maintain a nonjudgmental approach to education and support. It is also important to assess the spouse/partner's sexuality concerns because this will ultimately affect the man's decisions and well-being.

Expected Outcome: Patient will demonstrate willingness to discuss changes to sexual function and adapt modes of sexual expression to accommodate treatment-related changes.

- Assess the man's pretreatment sexual function. *Knowledge of previous sexual function is necessary to plan appropriate interventions.*
- Teach the man about the actual or potential effects of therapy on sexual function. *The incidence of ED varies with different therapies for prostate cancer.*
- Provide an opportunity for the man and his partner to discuss implications of and concerns about the diagnosis and treatment of sexual function. *The treatments for prostate cancer often affect the physiology of erection. The man and his partner need support and counseling during the period of adjustment.*

PRACTICE ALERT!

A therapeutic approach to assessing how the man feels is to use an opening statement such as "Some men are very concerned about the effects of (type of treatment) on their ability to have an erection. Tell me how you feel about it."

Evidence for Nursing Care

The Patient with Prostate Cancer

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Chapman, S. (2011). Assessment and management of patients with cancer pain. *Cancer Nursing Practice*, *10*(10), 28–36.
- Ferrante, J., Shaw, E., & Scott, J. (2011). Factors influencing men's decisions regarding prostate cancer screening: A qualitative study. *Journal of Community Health*, *36*, 839–844.
- Harrington, J. (2011). Implications of treatment on body image and quality of life. *Seminars in Oncology Nursing*, *27*(4), 290–299.
- Maliski, S., Connor, S., Oduro, C., & Litwin, M. (2011). Access to health care and quality of life for underserved men with prostate cancer. *Seminars in Oncology Nursing*, *27*(4), 267–277.
- Mirza, M., Griebling, T., & Kazer, M. (2011). Erectile dysfunction and urinary incontinence after prostate cancer treatment. *Seminars in Oncology Nursing*, *27*(4), 278–289.
- Turner, B., & Drudge-Coates, L. (2012). Management of patients with metastatic prostate cancer. *Nursing Standard*, *26*(27), 49–57.

- Discuss medical and surgical treatments for ED (see the first section of this chapter). *Many men are as devastated by the loss of erectile function as they are by the diagnosis of cancer. Information about achieving erection and maintaining sexual intimacy is essential to quality of life.*
- Refer for sexual counseling as appropriate. *The man and his partner may require therapy beyond that provided by nurses.*

Acute Pain/Chronic Pain

There are many causes of pain in men with advanced prostate cancer. It is not unusual for a patient to have three or four types of pain simultaneously, all from different sources. The most common cause of pain is metastasis to the spinal column, usually the thoracic spine. Other sources of pain include fractures, lymphedema of the lower extremities, and muscle spasms. Because most men with prostate cancer are over the age of 65, many also have pain associated with preexisting conditions, such as osteoarthritis, unrelated to the cancer.

Expected Outcome: Patient will demonstrate adequate pain management through use of prescribed pharmacologic and nonpharmacologic interventions for pain relief.

- Assess the intensity, location, and quality of the pain. *A cardinal rule of successful pain management is the importance of reducing or eliminating the cause of pain. Appropriate interventions are based on a careful assessment of the patient's pain.*
- Provide optimal pain relief with prescribed analgesics. *It is important for the man and his family to understand that pain medications should be used on a regular basis to maintain comfort and should not be delayed until pain is severe.*
- Teach the man and his family noninvasive methods of pain control. *Various modalities can be successful in alleviating pain or reducing its perception, thus enhancing the comfort of the patient* (refer to Chapter 9).

Continuity of Care

Depending on the type of treatment, the following topics should be addressed in preparing the patient and his family for home care:

- For the man having a surgical procedure: manifestations of infection and excessive bleeding, catheter care, wound care, pain management
- For the man receiving radiation therapy:
  - Risk of radiation damage to others (none for external beam radiation; if brachytherapy is used, sleep in a room alone for a week; avoid close contact with pregnant women, infants, and children)
  - Condom use during sexual contact (ejaculate may be discolored, distressing sexual partner)
- The importance of keeping appointments with healthcare providers and having PSA testing if recommended and agreed on by the man, along with rectal examinations
- If appropriate, community services, such as support groups, home health nurses, and hospice
- Helpful resources:
  - American Cancer Society
  - American Urological Association
  - National Cancer Institute

CASE STUDY & NURSING CARE PLAN A Man with Prostate Cancer

William Turner, a 71-year-old African American, lives with his wife in a small retirement community in Florida. His wife had a stroke 2 years ago, and Mr. Turner does all the cooking and housework. He has been in good health for most of his life, having only "a small touch" of osteoarthritis in his knees and hands. He has noticed a gradual onset of urinary urgency and frequency during the past 2 years, but has never had incontinence. During a routine checkup, the nurse practitioner at the local health clinic performs a digital rectal examination and palpates a hard nodule on the surface of Mr. Turner's prostate. After his PSA is found to be elevated, he is referred to a urologist, who diagnoses prostate cancer. Mr. Turner chooses to have surgery, and a radical retropubic prostatectomy and lymph node dissection are performed. The lymph nodes are negative for metastasis. Following surgery, his recovery is uncomplicated. However, the nurse caring for Mr. Turner is concerned about his ability to care for his indwelling catheter because of his arthritis and his wife's physical disabilities from the stroke. The nurse makes a referral to a home health agency to ensure Mr. Turner can manage his care at home. An initial home health assessment is scheduled for the day after Mr. Turner is discharged from the hospital.

ASSESSMENT

The home health nurse notes that the house is clean and neat. Mr. Turner is dressed, but still wearing his night urinary drainage bag, even though it is 1300. Mr. Turner tells the nurse that his main problem is going to get groceries, because he is embarrassed to be seen with the drainage bag. He says he has not been able to remove the drainage bag and attach the leg bag because of his arthritis. Physical assessment findings reveal the pelvic incision to be healing without signs of infection. There is no tenderness in his calves, chest pain, or shortness of breath. The urine is yellow, without odor. Mr. Turner does state that he sees no need for the pelvic exercises since he is no longer in the hospital. He also expresses the belief that he is cured of cancer and questions the need for follow-up care.

DIAGNOSES

- *Risk for Stress Urinary Incontinence* related to surgical procedure
- *Ineffective Health Maintenance* related to inability to care for the urinary drainage system, not understanding need for postoperative exercises, and questions about follow-up care

EXPECTED OUTCOMES

- Patient will regain urinary continence after catheter removal.
- Patient will change the urinary drainage bag with the appropriate assistance.
- Patient will verbalize the rationale for performing postoperative exercise.
- Patient will verbalize the need for continued follow-up care.

PLANNING AND IMPLEMENTATION

- Discuss the possibility of stress incontinence after the catheter is removed.
- Reinforce the need for Kegel exercises while the catheter is still in place.
- Explore Mr. Turner's support system to identify people who could assist him with catheter care, and arrange a teaching session with them.
- Teach Mr. Turner the importance of follow-up care, relating the care to the history of the disease.

EVALUATION

Good friends from Mr. Turner's church have assisted him with care of his drainage bag, and have reminded him to do his Kegel exercises several times a day while the catheter is in place. When the catheter is removed, Mr. Turner has only a small amount of leaking of urine after voiding. He understands that it may take several weeks for this to resolve. Efforts to help him understand the need for continued medical care are less successful. Mr. Turner continues to state that he is cured, his wife needs him, and he sees no need to go back to the doctor.

Clinical Reasoning in Patient Care

1. Outline a teaching plan for Mr. Turner for the *Risk for Impaired Skin Integrity* nursing diagnosis related to urinary incontinence.
2. As a result of Mr. Turner's refusal to have ongoing medical care, he might be labeled as noncompliant. Would you make this nursing diagnosis? Why or why not?
3. If you were the home health nurse making a home visit and found that Mr. Turner had no urinary drainage for 16 hours, what assessments would you make? How would you handle this problem?

See Evaluating Your Response in Appendix B.

Male Breast Disorders

THE MAN WITH GYNECOMASTIA

Gynecomastia, the abnormal enlargement of the male breast, is thought to result from a high ratio of estradiol to testosterone. It is common during puberty, affecting as many as 32% to 40% of adolescent males, but usually resolves within 3 to 4 months (Huether & McCance, 2012). Any condition that increases estrogen activity or decreases testosterone production can contribute to gynecomastia. Conditions that increase estrogen activity include obesity, testicular tumors, liver disease, and adrenal carcinoma; conditions that decrease testosterone production include chronic illness such as tuberculosis or Hodgkin's lymphoma, injury, and orchitis. Drugs such as digitalis, opiates, and chemotherapeutic agents are also associated with gynecomastia. Gynecomastia after adolescence is usually bilateral. If it is unilateral, biopsy may be necessary to rule out breast cancer.

No treatment is necessary for the transient gynecomastia of puberty. If the condition becomes chronic, however, creating psychologic discomfort, surgery may be necessary to remove the subcutaneous breast tissue. When related to an underlying disorder, treatment of that disorder is required. In severe cases, tamoxifen is given to decrease estrogen activity.

Nursing care for the patient with gynecomastia includes education about the cause and treatment of the condition, and emotional support for the psychosocial implications of this feminizing condition.

THE MAN WITH BREAST CANCER

Although male breast cancer is rare, accounting for about 1% of all breast cancer cases, it is as serious to the men who have it as it is to the women. It is estimated that about 2100 men in the United States are diagnosed with breast cancer each year, accounting for more than 400 deaths (ACS, 2012b). The etiology of male breast cancer is

unclear; hormonal and perhaps environmental factors appear to be important. Genetics play a role as well: men who inherit the BRCA-1 or BRCA-2 gene have an increased risk of developing breast cancer (Lippman, 2012).

Male breast cancer is clinically and histologically similar to female breast cancer, although lobular cancer is rare in males. Most tumors are estrogen-receptor positive. Because many men believe that breast cancer is only a woman's disease, they often delay seeking medical attention for manifestations and thus may present with advanced disease.

Treatment of male breast cancer is much like the treatment of female breast cancer, beginning with lumpectomy or mastectomy, node dissection, and staging to determine the therapeutic options. Radiation, chemotherapy, and hormonal therapy (usually tamoxifen) are the conventional adjuncts to surgery. Castration (surgical removal of the testes) was previously used but current treatments consist of antiandrogen therapy resulting in tumor regression and prolonging life (ACS, 2012a).

Nursing care for the man with breast cancer is essentially the same as for the woman with breast cancer (see Chapter 49). The nurse has an opportunity to help the man and his family cope with the psychosocial effects of having breast cancer. He may feel embarrassment or shame about his condition as well as fear about the life-threatening nature of the disease. His family may share those feelings. By listening with understanding and empathy, the nurse can help the patient and family resolve their feelings and move toward healing.

CHAPTER HIGHLIGHTS

- **Many different illnesses, medications, and surgical procedures can affect male sexual function. It is important for nurses to initiate a conversation regarding sexual concerns with male patients.**
- **Psychologic issues can result from alterations in a man's sexual function at any age. Nurses must recognize patient values and preferences and demonstrate a sensitivity to the patient's concerns.**
- Disorders of male sexual function include erectile dysfunction (ED) and ejaculatory dysfunction. Treatments include medications, mechanical devices, and surgical procedures. It is important for nurses to initiate a discussion of sexual concerns during assessments and to recognize that many male reproductive treatments and surgeries may result in sexual dysfunction.
- **Disorders of the male reproductive system including scrotal masses, testicular infections and cancer, prostate enlargement and cancer, phimosis and priapism may interfere with normal urination and sexual function.**
- Phimosis and priapism are disorders of the penis that can cause problems with urination and sexual activity and may in some cases be considered medical emergencies. The risk of cancer of the penis, although rare, is increased by phimosis, poor genital hygiene, and viral HPV and HIV infections.
- Benign scrotal masses include hydrocele, spermatocele, and varicocele. Epididymitis may be associated with a urinary tract infection, prostatitis, urethral strictures, or an STI.
- The testes may be infected (orchitis), twisted (testicular torsion), or develop cancer. Testicular cancer is the most common cancer in men between the ages of 15 and 40. Monthly testicular self-examination is critical to early detection and treatment of cancer.
- The prostate gland may be inflamed or infected (prostatitis), enlarged (benign prostatic hyperplasia), or may develop cancer. BPH is a common disorder of the aging male that causes problems with urination as the enlarging prostate gland constricts the urethra. Treatments include medications and various types of surgery, depending on the size of the prostate and the age and health status of the man.
- Cancer of the prostate is the most common type of cancer and the second leading cause of cancer deaths in American men. When diagnosed early, prostate cancer is curable. Diagnosis is often based on an increasing level of PSA and an abnormal DRE. The cancer is treated with surgery, radiation, or hormonal manipulation.
- **The male breast may become enlarged (gynecomastia) or develop cancer.**

TEST YOURSELF NCLEX-RN® REVIEW

1. The nurse is conducting a health history with a male patient. Which statement should the nurse use to gather information about the patient's sexual concerns?
   1. "Do you miss having sex?"
   2. "Why do you think you should be sexually active at your age?"
   3. "Following your prostate surgery, when did you first notice you had problems with sexual intercourse?"
   4. "Tell me about your experience with sexual function since you developed prostate enlargement."

2. The nurse is conducting a health teaching session for young men. Which information should the nurse include to reduce the risk of cancer of the penis? (Select all that apply.)
   1. Avoid tight pants and very hot showers.
   2. Wear a condom during sexual intercourse.
   3. Retract the foreskin of the penis when showering.
   4. Schedule diagnostic tests for HPV and HIV infections.
   5. Maintain a regular testicular self-examination schedule.

3. A male patient is diagnosed with gonorrhea. For which additional health problem should this patient be assessed?
   1. hydrocele
   2. epididymitis
   3. gynecomastia
   4. erectile dysfunction
4. The nurse is planning a teaching session on testicular cancer for high school students. Which information should the nurse include in this session?
   1. It rarely occurs in brothers.
   2. The incidence increases with age.
   3. Severe pain is the initial manifestation.
   4. It occurs most between ages 13 and 35.
5. The nurse is teaching a male patient with chronic prostatitis about self-care measures at home. What should the nurse teach the patient to decrease discomfort?
   1. Take cold showers and restrict oral fluids.
   2. Increase fiber intake and avoid sexual activity.
   3. Increase oral fluid intake to 3 L/day and void often.
   4. Wear a scrotal support and take anti-inflammatory drugs.
6. A male patient is being prepared for tests to diagnose prostate cancer. About which diagnostic tests should the nurse instruct the patient? (Select all that apply.)
   1. PSA level
   2. sperm count
   3. blood chemistry
   4. pelvic ultrasound
   5. digital rectal examination
7. During an assessment the nurse suspects a male patient is experiencing benign prostatic hyperplasia. On which body system is the patient experiencing symptoms that support the nurse's suspicions?
   1. skin integrity
   2. bowel elimination
   3. urinary elimination
   4. peripheral vascular function
8. The nurse is caring for a male patient recovering from a TURP. The urinary drainage bag is filled with dark red fluid with obvious clots and the patient is experiencing painful bladder spasms. What should the nurse do first?
   1. Assess intake and output since surgery.
   2. Report the assessments to the urologist.
   3. Nothing, because these are expected manifestations after a TURP.
   4. Administer pain medication in the form of a B&O suppository.
9. The nurse is preparing an educational seminar for a group of male community members on different types of neoplasms. What cancer should the nurse explain as being the most common malignancy in American men?
   1. lung cancer
   2. colon cancer
   3. prostate cancer
   4. testicular cancer
10. The nurse is participating on a community task force to reduce the risk of prostate cancer. What nutritional information should the nurse include to reduce the risk of this type of cancer?
    1. Increase fiber intake.
    2. Decrease lycopene intake.
    3. Avoid foods high in sodium.
    4. Decrease red meat and fat intake.

49 Nursing Care of Women with Reproductive System and Breast Disorders

LEARNING OUTCOMES

1. Explain the pathophysiology, manifestations, complications, interprofessional care, and nursing care of disorders of female sexual function, menstrual disorders, structural disorders, reproductive tissue disorders, and breast disorders.
2. Describe the physiologic process of the perimenopause.
3. Compare and contrast the incidence, risk factors, pathophysiology, manifestations, diagnosis, treatment, and nursing care for cancer of the cervix, endometrium, ovary, vulva, and breast.
4. Explain the purposes, nursing implications, and health education for women and their families for cancer screening, medications, and treatments for disorders of the reproductive system and breast.
5. Discuss alternative and complementary therapies used by women to relieve manifestations associated with menopause and menstrual disorders.
6. Describe the surgical procedures used to treat female reproductive system and breast disorders.

CLINICAL COMPETENCIES

1. Assess the functional health status of women with reproductive system and breast disorders, and monitor, document, and report abnormal manifestations and responses.
2. Use current evidence and patient preferences to plan and implement optimal nursing care for women with reproductive and breast disorders.
3. Prompt patient responses of values, preferences, and expressed needs as part of the clinical interview, implementation, and evaluation of care.
4. Function competently within own scope of practice as a member of the healthcare team caring for women with reproductive and breast disorders.
5. Apply quality measures, processes, and tools to improve outcomes for women with or at risk for reproductive and breast disorders.

MAJOR CHAPTER CONCEPTS

- Many different illnesses, medications, and surgical procedures can affect female sexual function. It is important for nurses to initiate a conversation regarding sexual concerns with female patients and respond in a caring, nonjudgmental manner.
- Disorders of the female reproductive system can include benign as well as malignant diagnoses. It is important to understand the emotional concerns of anxiety and fear of the diagnoses as well as the treatments.
- Menopause is a normal physiologic life event but often results in many changes in the woman's body that increase her risk for osteoporosis, fractures, and cardiovascular disease.
- Cervical and breast cancer are common forms of cancer in women. Cervical cancer is linked to HPV infection and can be prevented or diagnosed early with cervical exams and pap smears. Mammograms can detect breast cancer at an early stage. Education is necessary to encourage early diagnosis and prevention.

premenstrual syndrome (PMS), *1585*

Disorders of the female reproductive system range from menstrual cramps to life-threatening diseases such as cancer. Many of these disorders can occur at any point in a woman's adult life. They may affect her ability to bear children, her sexuality, and her sense of well-being as a woman. Women who experience reproductive system changes and disorders require a holistic approach to meet their physical, emotional, and educational needs. Because the ability to reproduce affects self-esteem, feelings of femininity, and general health, both sensitivity and understanding from caregivers are essential. Providing a medical and family history and undergoing diagnostic tests often require

women to disclose personal, intimate information and have invasive procedures, which they may find embarrassing and uncomfortable. When providing care, nurses must consider the woman within the context of her culture, socioeconomic and educational level, sexual orientation, and lifestyle.

This chapter discusses female perimenopause, sexual function, menstrual disorders, structural disorders, disorders of reproductive tissues, and disorders of the breast. Sexually transmitted infections (STIs), including vaginal infections and pelvic inflammatory disease, are discussed in Chapter 50. Many of the disorders discussed in this chapter result in actual or potential health problems requiring nursing care based on similar nursing diagnoses. To avoid repeating those diagnoses and interventions for each disorder, they have been divided among the nursing care discussions as appropriate. Treatment of cancer with chemotherapy and radiation is discussed in Chapter 14. Disorders of female sexual function may result from the physical or emotional effects of the disorders discussed in this chapter and thus are discussed first.

DISORDERS OF FEMALE SEXUAL FUNCTION

A female's body maintains the capacity for sexual activity for all of her life. In a typical sexual event, two physiologic sexual responses occur: vasocongestion and myotonia. Sexual stimulation results in vasocongestion of the blood vessels surrounding the vagina, causing engorgement, increased lubrication, and genital swelling and enlargement. Arousal, or myotonia, increases muscular tension, resulting in voluntary and involuntary muscle contraction.

The sexual response cycle has four phases: excitement, plateau, orgasm, and resolution. These phases always occur in the same sequence; however, the duration of each phase may vary. Sexual arousal typically ends in orgasm (climax), but sometimes fails to do so. A refractory period, or period in which the sexual organs are incapable of responding to stimulus, does not occur in the female. Multiple orgasms are physically possible in all women.

Although nurses may not conduct sexual counseling, they should be able to obtain a sexual history without embarrassment, discuss sexual concerns with women, and make appropriate referrals.

Pathophysiology

Disorders of sexual function include dyspareunia, inhibited sexual desire, and orgasmic dysfunction.

DYSPAREUNIA

The woman with **dyspareunia** (pain during intercourse) may find it difficult to express her feelings to her partner. This condition may manifest itself as decreased desire or inhibited orgasm. Physical conditions, such as imperforate hymen, vaginal scarring, or vaginismus, may cause dyspareunia. Vaginismus is a rare condition in which the vaginal muscles at the introitus contract so tightly that an erect penis cannot be inserted. The muscle contraction without penetration may be painful for the woman. An early traumatic event, such as sexual abuse, fear of men, or rape, may contribute to this disorder. However, it is estimated that most dyspareunia is psychogenic in origin. The woman develops an anxiety–fear–guilt cycle in which negative thoughts become associated with the act of vaginal penetration, initiating a conditioned involuntary reflex. Other sexual activity may be pleasurable.

INHIBITED SEXUAL DESIRE

Inhibited sexual desire may be a result of pathophysiologic processes or may be psychogenic in origin. Often, inhibited sexual desire is rooted deeply in childhood teaching or experiences that may be too painful to recall. Cultural and religious values can also affect the processing of sexual stimuli. Fear of pregnancy or STIs and depression also contribute to decreased libido.

ORGASMIC DYSFUNCTION

Inhibited female orgasm (**anorgasmia**) is a relatively common sexual problem among women. Primary anorgasmia, occurring in 10% to 15% of women, exists when a woman has never experienced an orgasm during the waking state, either through self-stimulation or intercourse. Secondary anorgasmia exists when a woman who previously experienced at least one orgasm in the past is no longer able to do so. Organic causes of anorgasmia include the presence of disease that results in general debilitation or that affects the sexual response cycle, and the use of drugs that depress the central nervous system (CNS).

●○● INTERPROFESSIONAL CARE

Although there is not currently a female version of Viagra, medications are being tested to treat female sexual-desire problems. These include tibolone, approved for use in Europe; yohimbine, a natural extract; and topical estrogens and testosterone creams (IsHak et al., 2010).

●○● NURSING CARE

Nursing care focuses on identifying the type of sexual dysfunction with a thorough history, including the onset, duration, frequency, and context or situation in which the problem occurs. Questioning the woman about medication use is important because many drugs can contribute to sexual dysfunction. Antidepressants, especially selective serotonin reuptake inhibitors (SSRIs), such as Celexa, Prozac, and Zoloft, contribute to lack of libido and delayed or absent orgasm (Schuiling & Likis, 2013). The woman's partner should be included in discussions when possible.

Teach the woman and her partner about varied normal sexual responses. The goal is to increase self-awareness and understanding of communication and their relationship to sexual desire. Explain the differences in the behaviors that men and women consider sexually stimulating. Sex therapists may provide training in autostimulation techniques (masturbation) after inhibitions against this practice are discussed. Group therapy may be encouraged to help the woman discuss her problem and to decrease the sense of isolation it gives her.

THE PERIMENOPAUSAL WOMAN

Menopause (referred to as *change of life)* is the permanent cessation of menses, a normal physiologic process as a woman ages. It is included here because it increases the risk of disorders of various aspects of women's health. In the United States, the average age of most women reaching menopause is age 50 (Huether & McCance, 2012). Menopause occurs as a result of aging, surgical removal of the ovaries, or chemotherapy (this discussion focuses on natural menopause). The climacteric, or perimenopausal, period denotes the time during which reproductive function gradually ceases. For most women, the

perimenopausal period lasts several years. It begins with a decline in the production of the hormone estrogen, includes the permanent cessation of menstruation due to loss of ovarian function, and extends for 1 year after the final menstrual period, at which time a woman is said to be postmenopausal. The average woman will live one-third of her life after menopause.

Many women welcome the freedom from monthly menstrual periods and have relatively minor physical effects from the estrogen depletion. However, the hormonal changes that occur can be accompanied by side effects (discussed later in this section). Early menopause (before the age of 40) can be familial, occur in women who smoke, or occur in women who have received chemotherapy drugs (Schuiling & Likis, 2013). Certain health risks increase after menopause, including heart disease, osteoporosis, macular degeneration, and breast cancer.

The Physiology of Menopause

The menopausal period marks the natural biologic end of reproductive ability. Surgical menopause occurs when the ovaries are removed in premenopausal women, dramatically reducing the production of estrogen and progestins. Chemical menopause often occurs during cancer chemotherapy, when cytotoxic drugs arrest ovarian function.

As ovarian function decreases, the production of estradiol (E_2), the most biologically active estrogen, decreases and is ultimately replaced by estrone as the major ovarian estrogen. Estrone is produced in small amounts and has only about one-tenth the biologic activity of estradiol. With decreased ovarian function, the second ovarian hormone, progesterone, which is produced during the luteal phase of the menstrual cycle, also is markedly reduced.

Manifestations

As estrogen decreases, various tissues are affected. There is a decrease in breast tissue, body hair, skin elasticity, and subcutaneous fat. The ovaries and uterus become smaller, and the cervix and vagina also decrease in size and become pale in color. These changes may result in problems with vaginal dryness, dyspareunia (painful intercourse), urinary stress incontinence, urinary tract infections (UTIs), and vaginitis. Vasomotor instability may cause hot flashes, palpitations, dizziness, and headaches. Other problems resulting from vasomotor instability include insomnia, frequent awakening, and perspiration (night sweats). The woman may experience mood and memory problems during the transition (Lentz et al., 2012).

Long-term estrogen deprivation results in an imbalance in bone remodeling and osteoporosis, leading to fractures and kyphosis. The risk for cardiovascular diseases increases in response to an increase in atherosclerosis (from an increase in the LDL-to-HDL cholesterol ratio). Manifestations of the perimenopausal period are listed in the accompanying Manifestations box. These manifestations vary widely. Some women experience severe symptoms, others experience moderate symptoms, and some women experience few or no symptoms.

MANIFESTATIONS OF THE PERIMENOPAUSAL PERIOD

- Menstrual cycles become erratic. Menstrual flow varies widely in amount and duration and eventually ceases.
- Vaginal, vulval, and urethral tissues begin to atrophy.
- Vaginal pH rises, predisposing the woman to vaginal infections.
- Vaginal lubrication decreases, and vaginal rugae decrease in number. This may result in dyspareunia, injury, and fungal infections.
- Vasomotor instability due to a decrease in estrogen may result in hot flashes and night sweats. A hot flash starts in the chest and moves upward toward the face and may last from seconds to several minutes.
- Psychologic symptoms may include moodiness, nervousness, insomnia, headaches, irritability, anxiety, inability to concentrate, and depression.

●○● INTERPROFESSIONAL CARE

Care of the woman experiencing menopausal symptoms focuses on relieving symptoms and minimizing postmenopausal health risks.

DIAGNOSIS

As estrogen secretion diminishes, levels of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) rise and remain elevated. A woman who has not menstruated for 1 full year or who has an increased FSH blood level is considered menopausal (Schuiling & Likis, 2013).

MEDICATIONS

Although controversial, menopause hormone replacement therapy (HRT) may be prescribed to alleviate severe manifestations of menopause, but only for a limited amount of time and only after a woman has been provided with known risks. HRT may include estrogen alone for women who have had a hysterectomy, or a combination of estrogen and progestin. The addition of progestin stimulates monthly shedding of the interuterine lining, decreasing the risk of uterine cancer. HRT relieves hot flashes and night sweats and decreases problems of vaginal dryness and urogenital tissue atrophy, which can lead to painful intercourse and urinary incontinence. Long-term HRT may increase the risk for breast cancer, ovarian cancer, stroke, heart attacks, and venous thrombosis. Recent trends in lowering dosages and eliminating the progesterone has been shown to decrease risks while limiting distressing menopausal manifestations (Lentz et al., 2012).

Selective estrogen receptor modulators (SERMs) such as raloxifene (Evista) and triphenylethylene (Tamoxifen) bind to estrogen receptors and exert site-specific effects in different target tissues. Tamoxifen and toremifene (a derivative of tamoxifen) have a beneficial effect on bone mineral density and serum lipids and decrease the risk of invasive breast cancer in women at high risk. They also provide an alternative to HRT for preventing osteoporosis.

Antidepressants may be prescribed as an off-label use for hot flashes and irritability. The SSRIs promote increased use of serotonin (a neurotransmitter) to in turn affect heat regulation in the body. Examples include fluoxetine (Prozac), paroxetine (Paxil), citalopram (Celexa), and sertraline (Zoloft). Possible side effects include headache, nausea, insomnia, anorexia, nightmares, diarrhea, and hypertension. Women over the age of 50 have an increased risk of bone fracture. Women should be told to discuss these medications with their physician prior to beginning or stopping use (Mayo Clinic, 2011).

ALTERNATIVE AND COMPLEMENTARY THERAPIES

As a result of the controversy surrounding the use of HRT, nontraditional or alternative therapies have become more popular. For example, phytoestrogens are estrogen-like substances found in some cereals, vegetables, legumes (including soy in tofu, tempeh, soymilk, and soy nuts) and herbs. Caution is recommended when using herbal therapies. The purity of the products is not assured and they may interact with traditional medications. Healthcare professionals need to assess for the use of these therapies because some plant products may be harmful when combined with other drugs. The following complementary therapies are examples of those used by menopausal women to reduce associated discomforts (Cleveland Clinic, 2010; Mayo Clinic, 2011; National Center for Complementary and Alternative Medicine, 2012):

- Acupuncture
- Biofeedback
- Massage
- Soy supplements and food
- Herbs: *Cimicifuga racemosa* (black cohosh), *Vitex agnus castus* (chaste tree), *Rehmannia*, ginseng, Kava, dong quai, golden seal, flaxseed, valerian, and evening primrose
- Meditation and yoga.

●○● NURSING CARE

Nursing care during and after the menopausal period focuses on minimizing the symptoms associated with hormonal changes; reducing the risk of cardiovascular disease, cancer, and osteoporosis; and educating the woman about lifestyle changes important to health and well-being.

Health Promotion

The American Cancer Society (ACS) recommends periodic cancer-related checkups (e.g., screening for cervical and breast cancer) beginning at age 20 or when the female becomes sexually active. Periodic mammography and colorectal cancer screening is initiated during perimenopause. Beginning at age 45, women should have periodic cholesterol and lipid profile tests. Women should undergo bone mineral density examination during perimenopause to establish a baseline. Refer to Table 3–5 on page 36 for health screening recommendations. Health counseling should also include information about alcohol and tobacco use, sun exposure, diet and nutrition, exercise, and risk factors. Information regarding a woman's sexual practice should be discussed (although pregnancy is not possible after menopause, the sexually active woman may still be at risk for STIs). It is important to discuss the benefits of rest and exercise, as well as a diet that includes fruits, vegetables, and fiber. In addition, suggest the following resources for further information: the National Institute on Aging, the North American Menopause Society, the Association of Reproductive Health Professionals, the Women's Health Initiative, and the National Women's Health Information Center.

Assessment

Collect the following data through the health history and physical examination. When assessing the older woman, be aware of normal changes with aging.

- *Health history:* problems with urinary frequency, urgency, or incontinence; menstrual history; sexual history; dyspareunia; use of alcohol, nicotine, and drugs; medications, sleep patterns, hot flashes, night sweats, changes in emotional responses
- *Physical assessment:* height and weight, posture, vital signs, breast examination, pelvic examination, abdominal assessment.

Priorities of Care

Because menopause is a normal event, providing information to facilitate this life transition and promote health is the nursing care priority.

Diagnoses, Outcomes, and Interventions

Although each nursing care plan must be individualized, interventions often focus on problems with lack of information, sexuality, self-esteem, and a disturbed body image.

Readiness for Enhanced Knowledge

Because menopausal manifestations vary widely, it is difficult to predict their effect on an individual woman. However, the well-informed woman is better prepared to deal with whatever symptoms she experiences.

Expected Outcome: Patient will describe menopausal changes and therapeutic options to treat menopausal symptoms including diet, exercise, and pharmacologic options.

- Discuss physiologic manifestations, such as hot flashes and night sweats. *The underlying cause of hot flashes is not known. Recent studies correlate the increased chance of vasomotor symptoms in women who have higher percentages of body fat (Schuiling & Likis, 2013). Many physiologic effects of menopause are amenable to nonpharmacologic methods of relief, such as lifestyle changes.*
- Provide information about dietary recommendations. The recommended daily intake of calcium for women over age 50 is 1200 mg. *Some women need to use calcium supplements or calcium-containing antacid tablets to meet this requirement.*
- Emphasize the importance of weight-bearing exercise. *Weight-bearing exercise reduces the rate of bone loss, helps maintain optimum weight, and reduces cardiovascular risk.*
- Provide information about the benefits and risks of HRT. Not every woman will need or want it. *Every woman needs to understand both the risks and the benefits before deciding whether to use HRT.*
- Encourage the woman to obtain yearly mammograms and clinical breast examinations, Pap tests as recommended, and to be familiar with the tissues and consistency of her breasts. The option of doing breast self-examination (BSE) should be discussed with the woman's healthcare provider and/or may be a personal choice. *The increased risk for cancer of the breast and pelvic reproductive organs makes healthcare provider screening during and after menopause even more important. There are benefits and limitations to BSE: the American Cancer Society (2012a) states that it is acceptable for women to choose or not choose to do BSE, but all women should be familiar with their own breasts in order to recognize abnormalities. If a woman chooses to do BSE, specific guidelines ("How to Perform a Breast Self-Exam") are published by the ACS based on an extensive review of the medical literature and input from an expert advisory panel.*

Risk for Sexual Dysfunction

Vaginal dryness and atrophy can interfere with sexual expression and satisfaction (see the Nursing Care of the Older Adult box on page 1586). Suggesting measures to help the woman and her partner cope with these changes can enable them to continue or resume a mutually satisfying sexual relationship.

Expected Outcome: Patient will demonstrate willingness to discuss changes to sexual function and treatment options and will adapt modes of sexual expression to accommodate menopausal-related changes.

- Encourage expression of feelings and concerns about how menopause is changing her sex life, if appropriate. *Midlife and older women may not be comfortable discussing their intimate sexual behavior.*
- Explain that as women age, it may take longer for vaginal lubrication and orgasm to occur. This information is important to prevent the woman from believing something is wrong with her, or her partner believing he or she is no longer interesting or sexually exciting. Suggest ways to increase vaginal lubrication, such as spending more time in foreplay and/or using water-soluble gels (e.g., Replens) or a vaginal HRT cream for vaginal lubrication. *A more leisurely approach to sexual activity can be mutually gratifying for both the woman and her partner. Use of water-soluble gels and vaginal HRT cream can prevent vaginal pain and irritation and improve the quality of the sexual experience.*

PRACTICE ALERT!

Plant estrogens, found in food such as brown rice, corn, green beans, lemon and orange peels, and tofu, are mildly estrogenic and may improve vaginal dryness.

Situational Low Self-Esteem

Each woman responds to the aging process in her own way, and most women have coping skills that adequately equip them to deal with the gradual changes associated with aging. Among the factors that may provoke a self-esteem disturbance are the loss of youth, a sense of emptiness as children leave home, and the need to redefine one's self-concept and roles as parenting becomes less important. Women who place a high value on their physical attractiveness may experience a painful psychologic response to the physical changes of menopause.

Expected Outcome: Patient will demonstrate self-esteem by use of effective coping strategies to deal with changes in body image and function.

- Encourage expression of fears and concerns related to changes in interpersonal and family functions. *Many women associate aging with uselessness and unattractiveness.*
- Suggest volunteer activities or employment for the woman who has extra time. *This enables the woman to feel that she is still a contributing member of society. Volunteering for activities involving young people can help reduce anxiety about the loss of reproductive ability or any late regrets about not having had children.*
- Discuss the importance of a healthy lifestyle in maintaining physical attractiveness. Identify risk factors and high-risk behaviors. *Lifestyle habits and behaviors affect many body systems and physical appearance. For example, cigarette smoking and overexposure to the sun make the skin age faster, contributing to wrinkles. Active women who exercise and eat a well-balanced diet look and feel better.*

Disturbed Body Image

As women progress through the perimenopausal period, changes in appearance and the loss of childbearing ability may combine to make the woman feel old, less attractive, and without purpose. Although this is far from the truth, it nevertheless is the perception of many women. The physical changes the woman often experiences include growth of facial hair, excessive perspiration and flushing of the face, and weight gain.

Expected Outcome: Patient will demonstrate appropriate adjustment to self-image by use of effective coping strategies to deal with changes in body image.

- Encourage the woman to describe her perceptions of her own body. *This information is necessary to obtain data to establish an individualized plan of care.*
- Encourage verbalization of feelings of concern, anger, anxiety, loss, and fear over body changes. *Expressing these emotions can facilitate the grieving process and acceptance of change.*
- Stress that certain physical characteristics of an individual cannot be changed; emphasize the importance of learning to recognize and appreciate one's own special strengths. *These help the woman gain acceptance and a realistic appraisal of self.*
- Refer, as appropriate, for dietary management, exercise, stress management, and cosmetic assistance (e.g., for aggravating facial hair). *These actions increase wellness and a positive sense of self.*

Menstrual Disorders

Monthly menstruation normally involves some minor discomfort, including breast tenderness, a feeling of heaviness and congestion in the pelvic area, uterine cramping, and lower backache. Many women, however, experience more serious effects, both physiologic and psychologic. This section discusses premenstrual syndrome, dysmenorrhea, and abnormal uterine bleeding.

THE WOMAN WITH PREMENSTRUAL SYNDROME

Premenstrual syndrome (PMS) is a complex of manifestations (e.g., mood swings, breast tenderness, fatigue, irritability, food cravings, and depression) that are limited to 3 to 14 days before menstruation and relieved by the onset of menses. It is estimated that up to 30% of all adult women experience moderate to severe symptoms and 3% to 8% have severe symptoms (Tschudin et al., 2010). For a small number of women, PMS is so disabling that it has the psychiatric label *premenstrual dysphoric disorder (PMDD).*

The syndrome is seen less frequently during the teens and 20s, reaching a peak in women in their mid-30s. Major life stressors, age greater than 30, and depression are risk factors associated with PMS. Premenstrual syndrome can be a factor in absenteeism at school or work, decreased productivity, interpersonal relationship difficulties, and lifestyle disruption.

NURSING CARE OF THE OLDER ADULT

Sexual Function in the Aging Woman

Myths, taboos, and stereotypes held by society may foster the belief that older women are no longer interested in expressing their sexuality. Two commonly held myths are that menopause is the death of a woman's sexuality and that hysterectomy results in the inability to function sexually. Loss of sexual function is not an inevitable result of aging, although physical changes related to aging do affect the female sexual response. These physical changes, along with chronic conditions common in aging women, may alter a woman's sexual function. In addition, some medications used to treat the chronic conditions associated with aging can also alter the sexual response. It is the role of the nurse to educate women about the myths and misinformation about changes in sexual functioning and to provide information about ways to achieve optimal sexual health.

PHYSIOLOGIC CHANGES

Changes in aging women's sexual function often begin in the perimenopausal period as estrogen levels decrease. Estrogen-sensitive cells are found throughout the central nervous system and the cardiovascular system. These cells are involved in the female sexual response. With menopause comes a decrease in the levels of estradiol, which affects nerve transmission and the response in the peripheral vascular system. As a result, the timing and degree of vasocongestion during the sexual response are affected. The capacity for vasocongestion decreases during the plateau phase, as does muscle tension. In the orgasmic phase, the contractions are fewer and less intense. During the resolution phase, vasocongestion subsides more quickly.

NURSING CARE

The nurse's role in assisting aging women to reach optimal sexual functioning centers on teaching them about the physiologic and psychologic changes associated with menopause. In addition, the nurse should instruct the woman in how the effects of chronic illness and the medications used to treat these illnesses affect sexual functioning. The woman should be taught the importance of maintaining a healthy lifestyle, which includes a balanced diet, weight-bearing and aerobic exercises, stress management, and routine health examinations.

For problems related to vaginal dryness and dyspareunia, the nurse can recommend water-soluble vaginal lubricants or vaginal gels before intercourse. Intercourse on a regular basis and estrogen replacement therapy can also be suggested for these problems. Women who experience joint pain or other musculoskeletal pain due to conditions such as arthritis can benefit from instruction in how to adapt positions for intercourse.

Pathophysiology

Although the pathophysiology of PMS is not clearly understood, it is believed that hormonal changes such as altered estrogen–progesterone ratios, increased prolactin levels, and rising aldosterone levels during the luteal phase of the menstrual cycle contribute to the problem. Increased production of aldosterone results in sodium retention and edema. Decreased levels of monoamine oxidase in the brain are associated with depression, and reduced levels of serotonin can lead to mood swings.

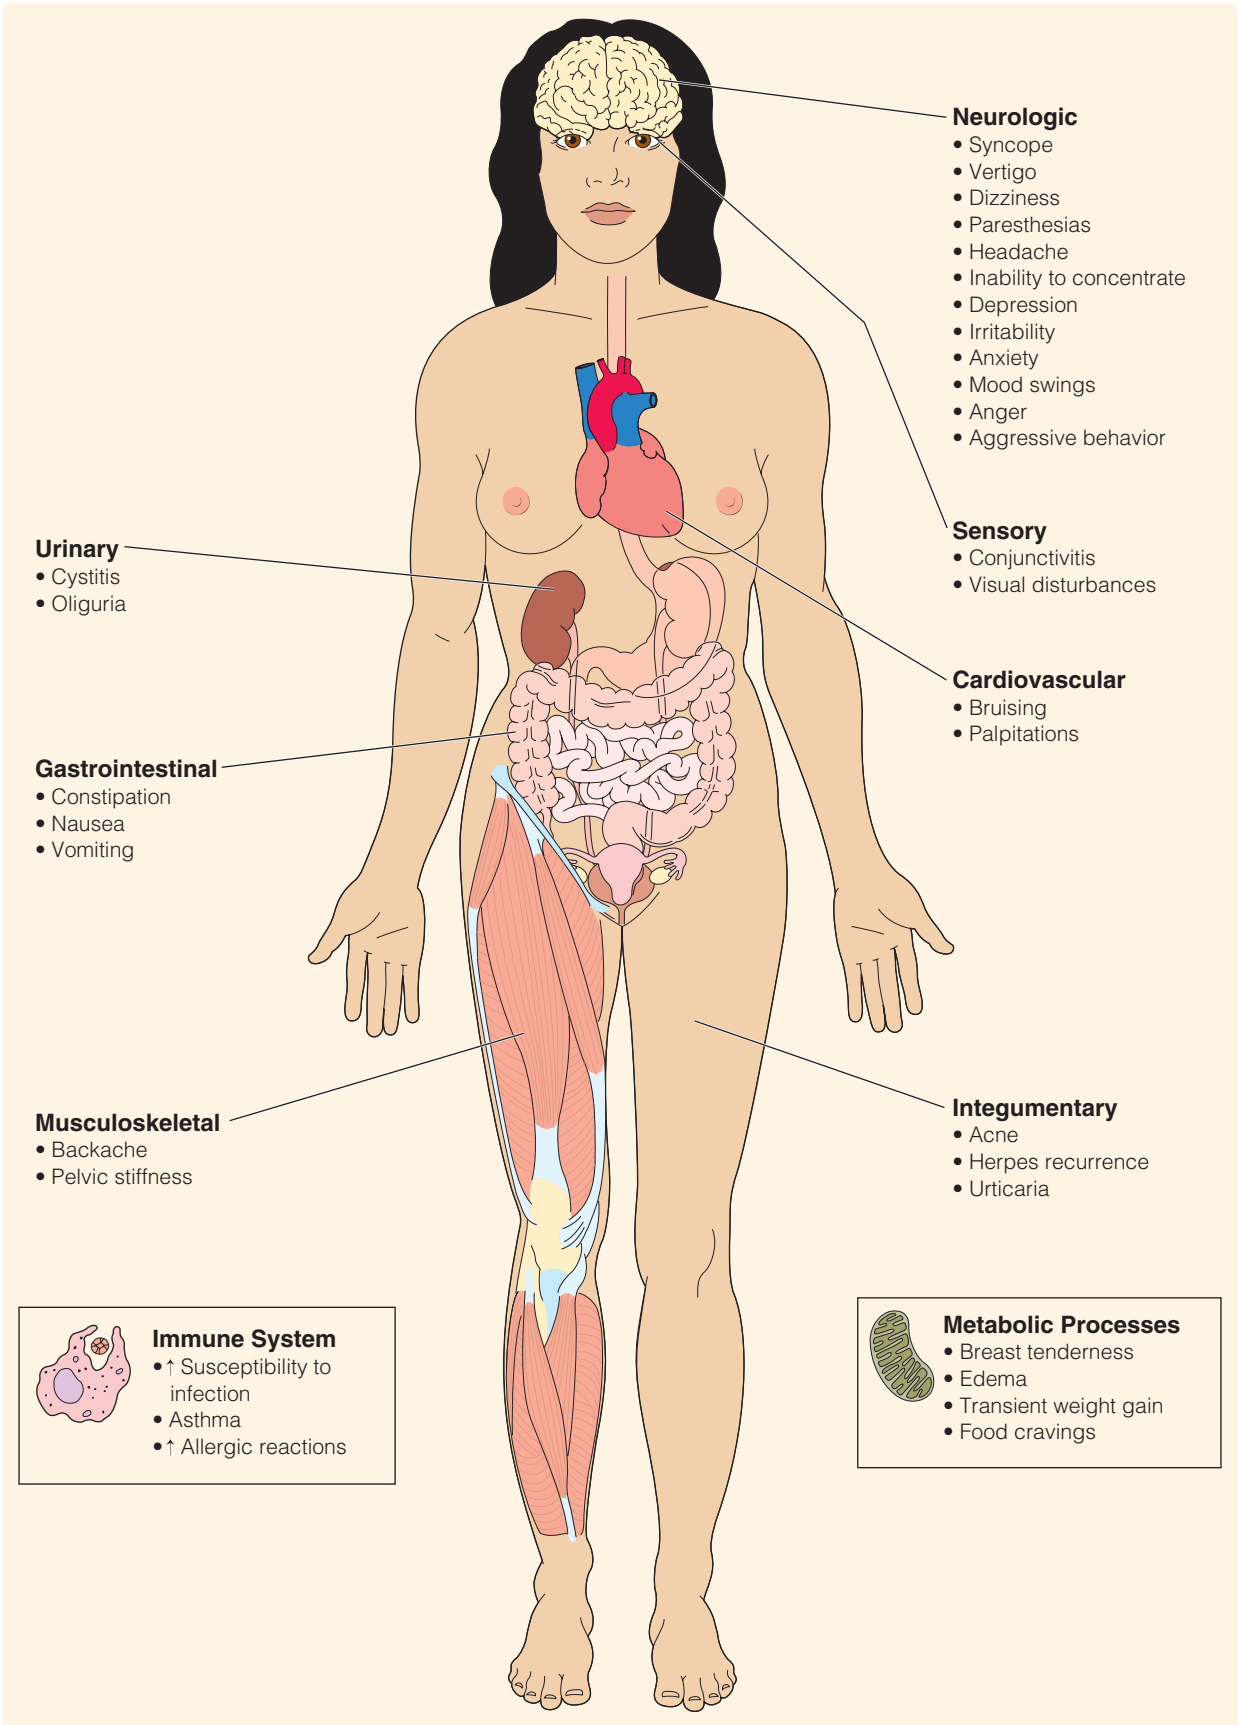
Manifestations

Manifestations of PMS occur during the luteal phase of the menstrual cycle (7 to 10 days prior to the onset of the menstrual flow), abating when the menstrual flow begins. See the accompanying Multisystem Effects of PMS feature. Although PMS may produce a variety of physiologic and psychologic manifestations, the exact nature of these manifestations and their intensity are individualized for each woman with this disorder. The manifestations may even differ from month to month in the same woman.

●○● INTERPROFESSIONAL CARE

If no organic cause can be identified, the goals of care are to relieve manifestations and to help develop self-care patterns that will help the woman anticipate and cope more effectively with future episodes of PMS. There are no definitive diagnostic tests for PMS; instead, the regular recurrence of manifestations preceding the onset of menses for at least 3 months leads to a diagnosis. The treatment of PMS integrates this self-monitored record of manifestations, regular exercise, avoiding caffeine, and a diet low in simple sugars and high in lean proteins (Huether & McCance, 2012).

MEDICATIONS



Although many different medications, vitamins, and herbal supplements have been used to treat the manifestations of PMS, the most promising appears to be the use of SSRIs. If the manifestations of PMS are severe or incapacitating, ovulation may be suppressed by the use of gonadotropin-releasing hormone (GnRH) agonists, oral contraceptives, or danazol (Cyclomen, an anabolic steroid). Progesterone and antiprostaglandin agents such as nonsteroidal anti-inflammatory drugs (NSAIDs) may help relieve cramping. Diuretics may be prescribed to relieve bloating. SSRIs such as fluoxetine (Prozac), sertraline (Zoloft), and paroxetine (Paxil) may be used to manage mood and some physical manifestations of PMS.

ALTERNATIVE AND COMPLEMENTARY THERAPIES

The woman with PMS may find diet, exercise, relaxation, and stress management helpful.

- A diet high in complex carbohydrates with limited salt, simple sugars, and alcohol is recommended to minimize reactive hypoglycemia, which can contribute to the manifestations of PMS. Caffeine is restricted to reduce irritability.
- Reduced sodium intake helps minimize fluid retention. Increased intake of calcium (1200 mg per day), magnesium (400 mg per day), vitamin B_6 (50 to 100 mg per day), and vitamin E (400 International Units per day) may be helpful (Mayo Clinic, 2012b).
- Herbal remedies include black cohosh, ginger, bilberry, chaste berry, red clover, thunder god vine, and evening primrose oil. Natural progesterone creams, derived from wild yams and soybeans, relieve manifestations in some women (Mayo Clinic, 2012b). Discussion about these alternative therapies with the healthcare provider is recommended.
- Exercise is beneficial, but adequate rest also is necessary.
- Techniques for relaxation and stress management include deep abdominal breathing, meditation, muscle relaxation, and guided imagery.

MULTISYSTEM EFFECTS OF PMS

●○● NURSING CARE

Diagnoses, Outcomes, and Interventions

Nursing care for the woman with PMS focuses on relieving manifestations. Most women experiencing PMS require interventions to manage pain and enhance coping.

Acute Pain

The woman with PMS may have pain from headache (including migraine), menstrual cramps, excessive fluid retention, breast swelling, joint and muscle pain, and backache.

Expected Outcome: Patient will demonstrate adequate pain management through use of prescribed pharmacologic and nonpharmacologic interventions for pain and symptom relief.

- Teach effective pharmacologic and nonpharmacologic self-care measures to relieve pain: application of heat, relaxation techniques (such as breathing exercises, imagery techniques, or meditation), and exercise. *Heat relieves muscle spasms and dilates blood vessels, increasing blood supply to the pelvis and uterine muscles. Relaxation and exercise aid the release of naturally produced pain relievers called endorphins.*
- Review daily activities and suggest ways to balance rest periods and activity. *During rest periods, energy and oxygen requirements decrease, increasing the amount of energy and oxygen available to muscles.*
- Review manifestations and, if possible, correlate these with dietary patterns and activity levels. Encourage the woman to keep a diary of PMS manifestations. *Maintaining a diary of PMS manifestations, activity, and foods eaten can provide data to identify modifiable causes of discomfort.*
- If appropriate, suggest sexual activity as a way to lessen menstrual cramps. *Orgasm may help relieve dysmenorrhea.*

Ineffective Coping

Many women experience wide mood swings during episodes of PMS, sometimes exhibiting self-destructive or aggressive behaviors toward others. These mood swings can interfere with a woman's ability to manage her responsibilities at home or at work.

Expected Outcome: Patient will demonstrate effective coping by use of strategies that reduce PMS symptoms.

- Encourage the woman to keep a journal of her menstrual cycle and to document her mood changes in the 7 to 10 days prior to menstruation. *Recognizing the signs and timing of PMS is the first step in developing methods to cope with the problem.*
- Explore possible ways to rearrange or reschedule activities when experiencing PMS. *Planning ahead enables the woman to assume more control and promotes coping methods.*
- Explore what, if any, self-care measures have helped cope with mood alterations in the past. *Encourage healthful coping mechanisms, such as relaxation techniques and exercise. Some women may rely on alcohol or other drugs during PMS, which only exacerbate the manifestations.*

THE WOMAN WITH DYSMENORRHEA

Dysmenorrhea (pain or discomfort associated with menstruation) is estimated to occur in 44% to 90% of menstruating women (Calis et al., 2011). Primary dysmenorrhea is most often seen in girls who have just begun menstruating, becoming less severe after the mid-20s or giving birth. Secondary dysmenorrhea most commonly is seen when a woman is in her 20s and 30s, beginning after years of relatively painless menstrual periods.

Pathophysiology

In primary dysmenorrhea, prostaglandins are released from sloughing endometrial cells, causing myometrial contraction and vasoconstriction. As the muscles contract, uterine circulation is compromised, resulting in uterine ischemia and pain. These contractions can range from mild cramping to severe muscle spasms. Psychologic factors, such as anxiety and tension, may contribute to dysmenorrhea. Secondary dysmenorrhea is related to underlying pathologic conditions that involve scarring or injury to the reproductive tract. Endometriosis, fibroid tumors, chronic pelvic inflammatory disease, endometrial polyps, and use of an intrauterine device (IUD) use may result in painful menses.

Manifestations

Manifestations of primary dysmenorrhea (see the accompanying Manifestations box) may be severe enough to disrupt activities of daily living, work activities, school attendance, and sexual function.

●○● INTERPROFESSIONAL CARE

Care of the woman with menstrual pain focuses on identifying the underlying cause, reestablishing functional capacity, and managing pain. A careful history and physical assessment are performed to rule out any underlying organic cause of dysmenorrhea. If no organic cause is found, the diagnosis is primary dysmenorrhea.

DIAGNOSIS

Various diagnostic tests are performed to identify structural abnormalities, hormonal imbalances, and pathologic conditions that could cause menstrual pain.

Diagnosis is made based on findings from a pelvic examination and diagnostic procedures, including a Papanicolaou (Pap) smear and cervical and vaginal cultures, ultrasound of the pelvis and vagina, and CT scan or MRI to detect structural abnormalities, malignancy, or infections. Laboratory tests used to assess possible causes of dysmenorrhea include FSH and LH levels to assess pituitary function, progesterone and estradiol levels to assess ovarian function, and thyroid function tests.

Laparoscopy is used to diagnose structural defects and blockages caused by scarring, endometriosis, tumors, and cysts (Figure 49–1 ■). See the accompanying box for nursing care of the woman having a laparoscopy. A dilation and curettage (D&C) of the uterus may be performed to obtain tissue for evaluation or to relieve dysmenorrhea and heavy menstrual bleeding. (This procedure is discussed later in this chapter.)

MEDICATIONS

Dysmenorrhea may be treated with analgesics, prostaglandin inhibitors such as NSAIDs, or oral contraceptives (see the accompanying Medication Administration box on page 1590).

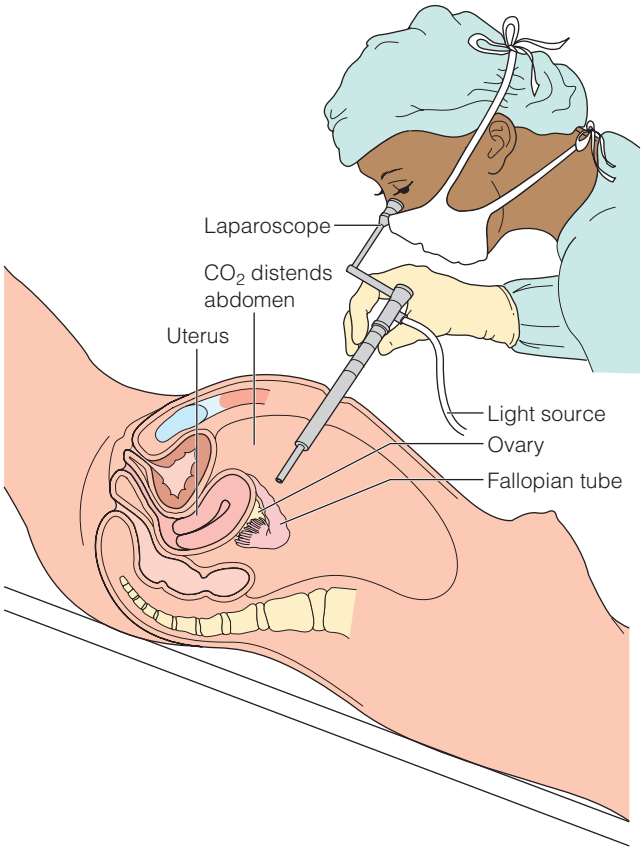


Figure 49–1 ■ Laparoscopy. In this surgical procedure, a flexible, lighted instrument (laparoscope) is inserted through a periumbilical incision. Laparoscopy allows visualization of the pelvic cavity.

MANIFESTATIONS OF PRIMARY DYSMENORRHEA

- Abdominal pain beginning with onset of menses and lasting 12 to 48 hours
- Pain radiating to lower back and thighs
- Headache
- Nausea
- Vomiting
- Diarrhea
- Fatigue
- Breast tenderness

●○● NURSING CARE

Nursing care for the woman with primary dysmenorrhea focuses on controlling manifestations and providing education about the normal physiology of the menstrual cycle and self-care measures. Care of the woman with secondary dysmenorrhea varies according to the underlying cause and is discussed in this chapter within sections on specific disorders. Nursing interventions previously described for the woman with PMS are also appropriate for the woman with dysmenorrhea.

THE WOMAN WITH DYSFUNCTIONAL UTERINE BLEEDING

Dysfunctional uterine bleeding (DUB) refers to vaginal bleeding that is usually painless but abnormal in amount, duration, or time of occurrence. A number of factors may predispose a woman to DUB. These factors include stress, extreme weight changes, use of oral contraceptive agents or IUDs, and perimenopausal status. Dysfunctional uterine bleeding is usually related to hormonal imbalances or pelvic neoplasms, either benign or malignant. DUB, depending on cause, may occur in women from early to late adulthood.

PATHOPHYSIOLOGY

The types of DUB include amenorrhea, oligomenorrhea, menorrhagia, metrorrhagia, and postmenopausal bleeding.

- **Amenorrhea** is the absence of menstruation. Primary amenorrhea, absence of menarche by age 16, or by age 14 if secondary sex characteristics fail to develop, may be caused by structural abnormalities, hormonal imbalances, polycystic ovary disease, or an imperforate hymen. Because a certain percentage of body fat is required for menstruation to occur, anorexia nervosa, bulimia, or excessive athletic training can also cause primary amenorrhea. Secondary amenorrhea, absence of menses for at least 6 months in a previously menstruating female, may also be caused by anorexia nervosa, excessive athletic activity or training, or a large weight loss. Other causes include hormonal imbalances and ovarian tumors. Normal (physiologic) secondary amenorrhea occurs during pregnancy, breast-feeding, and menopause.
- Oligomenorrhea (scant menses) usually is related to hormonal imbalances.

NURSING CARE OF THE PATIENT

Having a Laparoscopy

PREOPERATIVE CARE

- Instruct the woman to empty the bladder prior to the surgical procedure.
- Explain to the woman that referred shoulder pain or expulsion of gas through the vagina may occur postoperatively. *During the procedure, the woman's abdomen is insufflated with carbon dioxide gas to distend it and facilitate visualization of the pelvic organs. The surgical table is then tilted so that the intestines will fall away from the pelvic organs. Some carbon dioxide gas may remain in the abdomen after the procedure.*
- Explain that pain should be minimal. Instruct the woman to report excessive pain to the nurse or physician at once. *Excessive pain signals infection or other postoperative complication.*

POSTOPERATIVE CARE

- Apply a perineal pad. Teach the woman proper perineal hygiene, emphasizing the need to change pads at least every 4 hours. *Proper perineal hygiene reduces the risk of postoperative infection.*
- Ask the woman to keep a pad count. Minor bleeding is normal; excessive bleeding may indicate hemorrhage. *A pad count of more than one per hour is an indication of excessive blood loss and should be reported to the healthcare provider.*

MEDICATION ADMINISTRATION

The Woman with Dysmenorrhea

EXAMPLES OF ORAL CONTRACEPTIVES

norethindrone and ethinyl estradiol (Brevicon, Norinyl)

norgestrel and ethinyl estradiol (Ovral)

Oral contraceptives inhibit ovulation and help reduce cramping and bleeding. Side effects of oral contraceptives include breast tenderness, weight gain, nausea, midcycle bleeding, mood swings, depression, chloasma (skin discoloration) on the face and chest, hypertension, vascular complications, vaginal candidiasis, migraines, and glucose intolerance. Oral contraceptives are contraindicated in women with personal or family history of breast cancer in first-degree relatives, hypertension, history of stroke or transient ischemic attack (TIA), smoking, history of estrogen-dependent cancer, pregnancy, liver disease, or thrombophlebitis.

Nursing Responsibilities

- Assess the patient for potential contraindications to drug therapy.

Health Education for the Patient and Family

- Take the drug as prescribed until the physician indicates otherwise or until side effects prevent you from continuing to take them.
- If you are taking oral contraceptives, be sure to take them at the same time every day.
- Report to the physician suspected pregnancy and any side effects such as nausea, rash, drowsiness, stomach pain, ringing in the ears, tenderness in the calf of the leg, and shortness of breath.
- Do not smoke while taking oral contraceptives because of the risk of developing a thrombus (blood clot).

- **Menorrhagia** (excessive or prolonged menstruation) may result from thyroid disorders, endometriosis, pelvic inflammatory disease, functional ovarian cysts, or uterine fibroids or polyps. Clotting disorders and anticoagulant medications also can cause menorrhagia. A single heavy or long menses is not in itself a cause for concern; however, repetitive long or heavy menses can lead to hemorrhage, excessive blood loss, fatigue, and anemia.
- **Metrorrhagia** (bleeding between menstrual periods) may be caused by hormonal imbalances, pelvic inflammatory disease, cervical or uterine polyps, uterine fibroids, or cervical or uterine cancer. Because cancer is a possible cause of metrorrhagia, early evaluation and treatment are extremely important. Mittelschmerz (midcycle spotting and mild abdominal pain associated with ovulation) occurs in many women and is not considered metrorrhagia.
- Postmenopausal bleeding may be caused by cervical polyps, endometrial polyps, endometrial hyperplasia, or uterine cancer. The possibility of cancer makes early evaluation and treatment essential.

Hormonal imbalances, especially progesterone deficiency with relative estrogen excess, result in endometrial hyperplasia. Estrogen stimulates endometrial proliferation. However, without the support provided by progesterone, sloughing occurs, resulting in vaginal bleeding that may be irregular, prolonged, or profuse. Defects in the follicular phase shorten the proliferative phase of the menstrual cycle, resulting in spotting and breakthrough bleeding. Defects during the luteal phase result in excessive amount or duration of flow due to persistence of the corpus luteum. This leads to a deficiency of progesterone, resulting in vaginal bleeding. Anovulation (absence of ovulation) is associated with both estrogen and progesterone deficiencies. Emotional upsets or stress can cause hormonal imbalances and thus affect menstruation. Pelvic cancers, discussed later, also cause abnormal bleeding.

●○● INTERPROFESSIONAL CARE

The care of the woman with DUB focuses on identifying and treating the underlying disease. A careful history and physical examination are performed. Abdominal and pelvic examinations are performed to rule out abdominal masses. The woman may need to keep a menstrual history and basal body temperature chart for several months to determine whether ovulation is occurring.

DIAGNOSIS

A variety of diagnostic tests are used to diagnose the cause of DUB. Diagnostic tests include a Pap test to rule out or identify cervical carcinoma, a pelvic ultrasound to identify luteal cysts or ovarian tumors, and an endometrial biopsy to obtain endometrial tissue for histologic examination.

Laboratory studies may include a complete blood count (CBC) to rule out a systemic disease, coagulant factors, PT and PTT to rule out clotting disorders, thyroid function studies, serum progesterone levels, and endocrine studies to evaluate pituitary and adrenal function (thyroid and pituitary dysfunction may be manifested by menstrual irregularities).

MEDICATIONS

For many women, hormonal agents can correct menstrual irregularities. For anovulatory DUB, oral contraceptives may be prescribed for 3 to 6 months or a levonorgestrel-releasing IUD may be used. Progesterone or medroxyprogesterone (Depo-Provera, Provera) also may be prescribed to regulate uterine bleeding. Ovulatory DUB may be treated with progestins during the luteal phase. Oral iron supplements may be prescribed to replace iron lost through menstrual bleeding.

SURGERY

Surgical intervention emphasizes the least invasive method that provides effective relief, beginning with a therapeutic D&C, then endometrial ablation, and, lastly, hysterectomy.

THERAPEUTIC D&C In a therapeutic D&C, the cervical canal is dilated and the uterine wall is scraped. D&C is used to diagnose and treat DUB and other disorders of the female reproductive system. It may be performed to correct excessive or prolonged bleeding. D&C is contraindicated in any woman who has been taking anticoagulant drugs or whose condition precludes the use of regional or general anesthesia. Postoperative nursing care of the woman having a D&C is described in the accompanying Nursing Care box.

NURSING CARE OF THE PATIENT

Having a Dilation and Curettage (D&C)

- Monitor circulation and sensation in the legs, and avoid compression of the popliteal area. *The lithotomy position requires the woman's legs to be elevated in stirrups, which can impair circulation.*
- Instruct the woman to use perineal pads and avoid tampons for 2 weeks. *This reduces the risk of infection and allows tissues to heal.*
- Explain that the onset of the next menstrual period may be delayed. *The surgical procedure removes the endometrial lining.*
- Explain that intercourse should be avoided until after the postoperative checkup and after vaginal discharge has stopped. *This precaution reduces the risk of infection.*
- Instruct the woman to rest for several days after surgery, avoid heavy lifting, and report any bleeding that is bright red or exceeds that of a normal menstrual period. *Vigorous activity, lifting, or straining interferes with healing and may cause hemorrhage.*

ENDOMETRIAL ABLATION In an endometrial ablation, the endometrial layer of the uterus is destroyed by using a laser, thermal balloon, or electrocautery. It is performed in women for whom childbearing has been completed and who do not respond to pharmacologic management or D&C. This procedure usually produces amenorrhea but there are cases where menstrual flow returns. A woman going through endometrial ablation should understand that she should use contraception, because pregnancy may occur if not all endometrial tissue has been totally destroyed (American Society for Reproductive Medicine, 2011).

HYSTERECTOMY Hysterectomy (surgical removal of the uterus) may be performed when medical management of bleeding disorders is unsuccessful or cancer is present, particularly if the woman no longer wishes to have children. Approximately 600,000 hysterectomies are performed each year in the United States, and an estimated 20 million women have had a hysterectomy (Centers for Disease Control and Prevention [CDC], 2010). In premenopausal women the ovaries are usually left in place. In postmenopausal women a total hysterectomy, or panhysterectomy, may be performed; this procedure involves removal of the uterus, fallopian tubes, and ovaries.

Hysterectomy may involve either an abdominal or a vaginal approach. The choice depends on the underlying disorder, the need to explore the abdominal cavity, and the preference of the surgeon and woman. When a hysterectomy is performed, the woman is hospitalized for 1 to 3 days and requires a recovery period of from 4 to 6 weeks for an abdominal hysterectomy and from 1 to 2 weeks for a vaginal and laparoscopic hysterectomy.

Postoperative nursing care of the woman undergoing a hysterectomy is described in the accompanying Nursing Care box.

Abdominal hysterectomy is performed when a preexisting abdominal scar is present, when adhesions are thought to be present, or when a large operating field is necessary. For example, the woman with endometriosis is more likely to have an abdominal hysterectomy because endometrial tissue implants that may be present on other abdominal organs need to be removed. The surgical incision may be

NURSING CARE OF THE PATIENT

Having a Hysterectomy

- Monitor vital signs every 4 hours, auscultate lungs every shift, and measure intake and output. *These data are important indicators of hemodynamic status and complications.*
- Assess pain on a regular schedule, using a 1 (none) to 10 (severe) scale. Administer analgesics as prescribed. Splint incision, if present, to facilitate moving, coughing, and deep breathing. Assist with ambulation as prescribed. *Postoperative pain results from the surgery itself, as well as from gas pains prior to the return of peristalsis. Splinting the incision decreases pain from moving, turning, and deep breathing. Ambulation assists in the return of peristalsis.*
- Monitor for hemorrhage by keeping a perineal pad count and assessing abdominal dressing. Instruct the woman on how to conduct these assessments and to report abnormal findings to the surgeon. *As most women are discharged to home in 1 or 2 days, the woman's knowledge of possible hemorrhage is important.*
- Monitor voiding after surgery or after removal of a Foley catheter. *Voiding difficulty may occur after surgery or after the removal of a Foley catheter inserted prior to or during surgery. If the woman has not voided within 8 hours, notify the surgeon.*
- Instruct the woman about the manifestations of infection: increased or a change in color or odor of drainage from the incision or perineal pads, general malaise, fever. If any of these occur, the woman should notify the surgeon. Discuss action of prescribed antibiotics and need to continue them until they are gone. *Early discharge mandates providing information about the risk for infection*.
- Explain the rationale for antiembolic or compression stockings and encourage leg exercises. Discuss manifestations of deep venous thrombosis (leg pain, redness, localized heat and swelling) and pulmonary embolism (cough, difficulty breathing, rapid heart beat, chest pain) with importance of notifying the physician immediately if these occur. Instruct to avoid prolonged sitting in a chair that puts pressure behind the knees or sitting with legs crossed. *Positioning during surgery as well as postoperative edema and inactivity increase the risk for deep venous thrombosis, which in turn may break loose and travel to the lungs.*
- After an abdominal hysterectomy, instruct to restrict physical activity for 4 to 6 weeks. Heavy lifting, stair climbing, douching, tampons, and sexual intercourse should be avoided. The woman should shower, avoiding tub baths, until bleeding has ceased. *Infection and hemorrhage are the greatest postoperative risks; restricting activities and preventing the introduction of any foreign material into the vagina help reduce these risks.*
- Explain that appetite may be depressed and bowel elimination may be sluggish. *These are aftereffects of general anesthesia, handling of the bowel during surgery, and loss of muscle tone in the bowel while empty.*
- Encourage the woman to express feelings that may signal a negative self-concept. Correct any misconceptions. *Some women believe that hysterectomy means weight gain and the end of sexual activity.*
- Provide information about continuing to have regular gynecologic screenings. *If the cervix has not been removed, regular Pap tests should continue. Pelvic examination should continue regardless of removal of the cervix.*

either longitudinal, made in the midline from umbilicus to pubis, or a Pfannenstiel incision, also known as the bikini cut. Vaginal hysterectomy, removal of the uterus through the vagina, is desirable when the uterus has descended into the vagina or if the urinary bladder or rectum has prolapsed into the vagina. Vaginal hysterectomy leaves no visible abdominal scar. A laparoscopy-assisted vaginal hysterectomy (LAVH) and a laparoscopic supracervical hysterectomy (LSH) are minimally invasive options to an open procedure. The recovery time following these procedures is often only 1 to 2 weeks.

●○● NURSING CARE

DUB usually causes the woman anxiety. Her self image, sexuality, or reproductive capacity may be threatened, and she may fear the possibility of cancer. She may be embarrassed to discuss her menstrual history, sexual history, and hygiene practices.

Diagnoses, Outcomes, and Interventions

Interventions for the woman with DUB commonly address problems with anxiety and sexual function.

Anxiety

The anxiety associated with abnormal uterine bleeding can be intense. Until the cause of the bleeding is identified and has been addressed, the woman may fear cancer or other life-threatening conditions.

Expected Outcome: Patient will demonstrate anxiety relief related to abnormal uterine bleeding by focusing on knowledge about condition, treatment and surgical options, and interpersonal support systems.

- Discuss the results of tests and examinations with the woman. *This allows for open exchange of information.*
- Provide information about the causes, treatments, risks, long-term effects of treatments, and prognosis. *This allows the woman to assume responsibility for her own health and become involved in her own treatment plan.*
- Evaluate coping strategies and psychosocial support systems. Teach coping strategies if indicated. *The possibility of surgery or cancer represents a crisis for the woman and her support system. Support groups can provide assistance for the woman through crisis intervention.*

Sexual Dysfunction

The woman with DUB may be unwilling to express herself sexually, particularly if bleeding is frequent or heavy. Additionally, fatigue may prevent her from participating in sexual activity.

Expected Outcome: Patient will demonstrate willingness to discuss changes to sexual function and will adapt modes of sexual expression to accommodate illness-related changes.

- Offer information about engaging in sexual activity during menstruation. Explain that conception is possible during this time and that orgasm may help relieve symptoms. *Some women mistakenly believe that birth control measures are unnecessary during menstruation. Orgasm causes a release of tension and vascular congestion and frequently provides at least temporary relief of symptoms.*
- Provide an opportunity for the expression of concerns related to alterations in lifestyle and sexual functioning. *Some women have had a prolonged period of sexual abstinence related to DUB. Allowing women to verbalize concerns can assist them in working collaboratively with the healthcare provider to minimize the impact of illness and optimize function.*
- Encourage frequent rest periods. *This conserves energy and may allow sexual activities to resume.*
- Provide information about alternative methods of sexual expression. *Methods of sexual expression other than vaginal intercourse may satisfy the needs of both partners.*

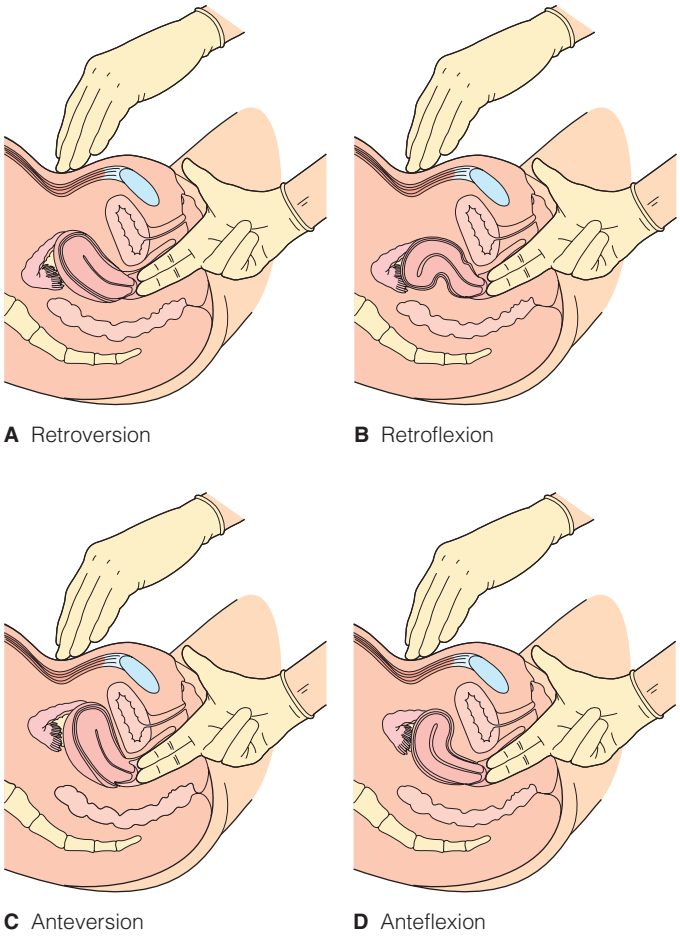
PRACTICE ALERT!

If the nurse is not comfortable with frank discussions about sexual activities, referral is indicated.

Continuity of Care

Provide support, appropriate reassurance, and information to help the woman and her family better understand her disorder and the therapeutic interventions indicated. Teaching also includes self-care measures that help minimize the effects of DUB on the daily functioning of the woman. The following topics should be included:

- Administration and side effects of prescribed medications, including iron.
- The need to maintain a balanced diet, increasing iron-rich foods such as eggs, beans, liver, beef, and shrimp. Inform the woman that while orange juice may improve the absorption of iron, foods high in calcium and oxalic acid, such as spinach, may reduce its absorption.
- Importance of maintaining a fluid intake of 2000 to 3000 mL a day.
- The need to immediately report recurring episodes of DUB, particularly in postmenopausal women, to the healthcare provider.



Structural Disorders

Structural disorders of the female reproductive system include displacement disorders and fistulas. Structural disorders may occur in women of any age.

THE WOMAN WITH A UTERINE DISPLACEMENT

The uterus may be displaced within the pelvic cavity or may descend into the vaginal canal. Displacement of the uterus within the pelvic cavity is classified according to the direction of the displacement, as illustrated in Figure 49–2 ■.

Prolapse of the uterus into the vaginal canal can vary from mild to complete prolapse outside of the body. First-degree prolapse involves a descent of less than half the uterine corpus into the vagina. Second-degree prolapse involves the descent of the entire uterus into the vaginal canal so that the cervix is at the introitus to the vagina. Third-degree prolapse, or procidentia, is complete prolapse of the uterus outside the body, with inversion of the vaginal canal (Figure 49–3 ■). Prolapse of the uterus is often accompanied by cystocele (herniation of the bladder into the vagina) or rectocele (herniation of the rectum into the vagina).

A Retroversion **B** Retroflexion

C Anteversion **D** Anteflexion

Figure 49–2 ■ Displacements of the uterus within the pelvic cavity. A, Retroversion is a backward tilting. B, Retroflexion is a backward bending. C, Anteversion is a forward tilting. D, Anteflexion is a forward bending.

Figure 49–3 ■ Prolapse of the uterus can vary from mild to complete. In third-degree uterine prolapse, or procidentia, the uterus prolapses completely outside the body, with inversion of the vagina.
Source: M. English/Custom Medical Stock Photo.

Pathophysiology

Displacement or prolapse of the uterus, bladder, or rectum can be a congenital or an acquired condition. Congenital tilting or flexion of the uterus is rare. More commonly, tilting or flexion disorders in which the uterus remains within the pelvic cavity are related to the scarring and inflammation of pelvic inflammatory disease, endometriosis, pregnancy, and tumors.

Downward displacement of the pelvic organs into the vagina results from weakened pelvic musculature, usually attributable to stretching of the supporting ligaments and muscles during pregnancy and childbirth. Unrepaired lacerations from childbirth, rapid deliveries, multiple pregnancies, congenital weakness, or loss of elasticity and muscle tone with aging may contribute to these disorders.

Manifestations

The manifestations of displacement disorders are listed in the accompanying box.

●○● INTERPROFESSIONAL CARE

Interprofessional care focuses on identifying the cause of the structural disorder, correcting or minimizing the condition, relieving pain, preventing or treating infection, and supporting and educating the woman.

A careful history and physical examination are performed. Diagnosis of uterine displacement is made after physical examination. If herniation of the rectum or bladder is suspected, the woman is asked to bear down or cough during the examination so the prolapse can be palpated and any leakage of urine or feces visualized. A history of infections, multiple pregnancies in rapid succession, and rapid labors support this diagnosis.

Treatment may include Kegel exercises to strengthen weakened pelvic muscles. Kegel exercises can be useful in the early stages of downward displacement. These exercises are discussed in Chapter 27.

SURGERY

Several surgical procedures are used to repair structural disorders. For women presenting with a cystocele, anterior colporrhaphy (repair of the cystocele) is the most common procedure. The anterior repair shortens the pelvic muscles, providing tighter support for the bladder. The Marshall-Marchetti-Krantz procedure involves

MANIFESTATIONS OF DISPLACEMENT DISORDERS

Uterine Displacement within the Pelvic Cavity

- Dysmenorrhea
- Dyspareunia
- Backache
- Infertility

Uterine Prolapse

- Backache
- Bearing-down sensation
- Constipation
- Urinary incontinence
- Hemorrhoids
- Dyspareunia

Cystocele/Rectocele

- Bearing-down sensation
- Constipation
- Fecal incontinence
- Hemorrhoids
- Urinary incontinence

resuspension of the urinary bladder in correct anatomic position. A rectocele is repaired with a posterior colporrhaphy, which shortens the pelvic muscles, providing a tighter support for the rectum. A prolapsed uterus may be surgically repositioned and the supporting muscles shortened to provide greater support. In postmenopausal women or women with procidentia, hysterectomy is the preferred treatment.

PESSARY

When surgery is contraindicated, a pessary (a removable device) may be inserted into the vagina to provide temporary support for the uterus or bladder. At regular intervals, the pessary is removed, cleaned, and reinserted.

●○● NURSING CARE

Nursing care focuses on education about the disorder, proposed treatments, and self-care measures for relief of symptoms.

Diagnoses, Outcomes, and Interventions

Nursing interventions for the woman with a displacement disorder address problems with urinary incontinence and anxiety.

Stress Incontinence

Relaxation of the pelvic floor can lead to stress incontinence. This can prove both troublesome and embarrassing and can increase the incidence of urinary tract infection.

Expected Outcome: Patient will demonstrate urinary continence, recognizing urge to void, performing perianal strengthening exercises, managing independent toileting, and maintaining a predictable pattern of voiding.

- Teach Kegel exercises. *These exercises strengthen perineal muscle tone, minimize urinary leakage, and minimize descent of the bladder and rectum into the vagina. In postmenopausal women, estrogen supplements also can improve muscle tone in the perineal area.*
- Suggest the use of perineal pads (ranging from thin panty liners to full-thickness incontinence pads) or special underwear (such as Depends) to absorb urine leakage. *Using pads or undergarments often allows the woman to once again take part in her usual social activities.*
- Explain perineal care and proper use of perineal pads. *Cleansing the perineum from front to back and applying and removing perineal pads the same way minimizes cross infection from the anus to the vaginal and urethral openings. Incontinence pads need to be changed frequently to minimize surface bacterial counts.*
- Suggest reducing or eliminating caffeine intake. *Reducing caffeine intake can reduce urinary frequency and urgency.*
- Stress the importance of cleaning the perineal area. *Urine is very irritating to the skin.*

Anxiety

Anxiety is common among women with a displacement disorder. Many women have only a cursory understanding of their reproductive anatomy. This lack of knowledge often compounds the anxiety. The nurse can use drawings and models to explain structural disorders and treatment options available.

Expected Outcome: Patient will demonstrate management of anxiety by use of effective coping strategies to deal with changes in body image related to the particular displacement disorder.

- Encourage questions from the woman and her partner. *This helps assess the level of understanding so that teaching can be more effective.*
- Explain that the relief from discomfort and fatigue may positively influence sexual expression, and reassure the woman that the capacity for orgasm will not be affected. *Many women and their partners have major concerns about the effects of the disorder and its treatment on their sex life and capacity for sexual pleasure.*
- Explore coping mechanisms that have been previously successful. *This can help relieve anxiety and boost self-esteem.*

Continuity of Care

If surgery is the treatment of choice, teaching centers on what to expect in the preoperative and postoperative periods. If medical treatment is used initially, teaching focuses on measures to relieve the manifestations, such as Kegel exercises, use of incontinence pads, or the use, care, and insertion of a pessary. Because obesity is a risk factor associated with relaxation of the pelvic and abdominal muscles, dietary counseling may be indicated. Preoperatively, a diet high in fiber may alleviate constipation, a particular concern during the postoperative period.

THE WOMAN WITH A VAGINAL FISTULA

A fistula is an abnormal opening or passage between two organs or spaces that are normally separated or an abnormal passage to the outside of the body. Vaginal fistulas may be vesicovaginal or rectovaginal. A vesicovaginal fistula is an abnormal opening between the urinary bladder and the vagina, leading to incontinent leakage of urine through the vagina. A rectovaginal fistula (less common) is an abnormal opening between the rectum and vagina, causing incontinent leakage of stool or flatus through the vagina.

Fistulas may develop as a complication of childbirth, gynecologic or urologic surgery, or radiation therapy for gynecologic cancer. Cancer of the bladder is sometimes involved. The woman with a vaginal fistula often presents with a complaint of involuntary leakage of urine or flatus and symptoms of infection.

●○● INTERPROFESSIONAL CARE

Fistulas are usually diagnosed by pelvic examination. A vesicovaginal fistula can be diagnosed by instilling dye into the urinary bladder through a catheter and observing the vagina for leakage. If no leakage is detected, a tampon or vaginal pack is inserted into the vagina, and the woman is asked to ambulate. If an abnormal opening is present, the tampon will absorb the dye. Dye may also be injected intravenously because it is excreted by the kidneys. Urine and vaginal cultures may be performed to rule out infections. Antibiotics are administered if infection is present.

A small vaginal fistula may resolve spontaneously. Otherwise, surgery is performed after inflammation has subsided, often a period of several months. Rarely, in the presence of a large, highly inflamed rectovaginal fistula, a temporary colostomy is performed, allowing inflammation and irritation to subside (refer to Chapter 24).

●○● NURSING CARE

Nursing care for the woman with repair of a vaginal fistula is similar to that for the woman with a displacement disorder. Teaching is an important component of nursing care. Stress the importance of careful perineal cleansing to reduce irritation and prevent further tissue breakdown. Suggest perineal irrigation or sitz baths for cleansing. Perineal pads or special underwear may be used to absorb urine or fecal drainage. For the woman with a rectovaginal fistula, provide information about avoiding gas-forming foods to minimize embarrassment from odor.

Disorders of Female Reproductive Tissue

Both benign and malignant tissue disorders affect the female reproductive system. Benign tumors and cysts include Bartholin's gland cysts, cervical polyps, endometrial cysts and polyps, ovarian cysts, and uterine leiomyomas (fibroids). Endometriosis is a condition in which endometrial tissue implants outside the uterus in various locations in the pelvic cavity. Malignant tumors of reproductive tissue include cervical cancer, endometrial cancer, ovarian cancer, and vulvar cancer.

THE WOMAN WITH CYSTS OR POLYPS

A cyst is a fluid-filled sac. A polyp is a highly vascular solid tumor attached by a pedicle or stem. Cysts or polyps of the female reproductive system can occur in the vulva, cervix, endometrium, or ovaries; depending on the type, they may occur at any age.

Pathophysiology

Following are different types of female reproductive tissue cysts and polyps:

- *Bartholin's gland cysts* are the most common cystic disorder of the vulva. These cysts are caused by the infection or obstruction of Bartholin's gland.
- *Cervical polyps* tend to occur in women over age 40 who have borne several children and have a history of using oral contraceptives. It is possible that cervical polyps develop from endocervical hyperplasia. The polyp develops at the vaginal end of the cervix, has a stem, and is highly vascular.
- *Endometrial polyps* are intrauterine overgrowths, similar to cervical polyps, and usually have a stalk. Although endometrial polyps are usually benign, some may be precancerous or malignant. Endometrial polyps usually affect women in perimenopause or menopause.
- *Endometrial cysts* (ovarian endometrioma) can develop on the ovary. They are caused by endometrial overgrowth and are often filled with old blood (the dark color leads to the label "chocolate cysts"). Endometrial cysts are the result of endometrial implants on the ovary and are associated with endometriosis.
- *Ovarian cysts* are classified as follicular cysts and corpus luteum cysts. Follicular cysts develop as a result of failure of the mature follicle to rupture or failure of an immature follicle to reabsorb fluid after ovulation. Corpus luteum cysts develop as a result of increased hormone secretion by the corpus luteum after ovulation. Most functional cysts regress spontaneously within two or three menstrual cycles.
- *Polycystic ovarian syndrome* (POS; also known as *Stein-Leventhal syndrome*) is an endocrine disorder characterized by an excess of androgens and a long-term lack of ovulation. The exact cause is unknown. As a part of the disease, as many as 8 to 10 cysts form in the ovaries from a failure to release ova. Manifestations include amenorrhea or irregular menses, hirsutism, obesity, acne, hypertension, sleep apnea, and infertility. Women with POS often have insulin resistance and are at increased risk for type 2 diabetes, as well as heart disease, breast cancer, and endometrial cancer.

Manifestations and Complications

The causes and manifestations of benign cysts and polyps of the female reproductive system are presented in Table 49–1. Complications associated with these disorders include infection, rupture, infertility, hemorrhage, and recurrence.

TABLE 49–1 Benign Cysts and Polyps of the Female Reproductive System

Site	Type	Etiologic Origin	Manifestations
Ovary	Functional cysts	Ovulation—includes follicular cysts and corpus luteum cysts	May resolve spontaneously; can cause pain, menstrual irregularity, or amenorrhea
	Polycystic ovarian syndrome	Unknown; possible hypothalamic-pituitary dysfunction	Hirsutism, obesity; amenorrhea or irregular menses; hyperinsulinemia; infertility
	Chocolate cysts	Endometrial overgrowth; filled with old blood	Usually asymptomatic Abdominal or pelvic pain, peritonitis with rupture
Vulva	Bartholin's cysts	Obstruction or infection of Bartholin's gland	Pain, redness, perineal mass, dyspareunia
Endometrium	Endometrial polyps	Unknown	Bleeding between periods
Cervix	Cervical polyps	Unknown	Bleeding after intercourse or after activities involving heavy lifting

●○● INTERPROFESSIONAL CARE

Care focuses on identifying and correcting the disorder and preventing its recurrence. A health history and physical examination are performed. Examination of the reproductive tract reveals the presence of most cysts and polyps. The menstrual history may include menstrual irregularities.

DIAGNOSIS

Diagnostic tests that may be used to diagnose cysts and polyps of the female reproductive system (and to eliminate the diagnosis of cancer) include a Pap smear, an endometrial biopsy, a laparoscopy to visualize ovarian cysts, an ultrasound or x-ray to differentiate cysts from solid tumors, and/or a pregnancy test when luteal cysts are suspected. Laboratory analysis will demonstrate elevated LH and testosterone levels, as well as a reverse in FSH/LH in the woman with polycystic ovary syndrome (POS).

MEDICATIONS

Antibiotics are used to treat infection or abscess, and oral contraceptives are used to promote regression of functional ovarian cysts. Clomiphene (Clomid, Serophene) may be prescribed to stimulate ovulation in the woman with POS who wishes to become pregnant. Dexamethasone (Decadron) suppresses ACTH and adrenal androgens, and may be added to increase the likelihood of ovulation.

SURGERY

Cervical polyps are visible through a vaginal speculum and usually are removed with a clamp. A transcervical approach is used to remove endometrial cysts or polyps. The specimen is sent to the laboratory for evaluation, and chemical or electrical cauterization may be applied after cyst removal. For Bartholin's gland cysts and any abscesses, the lesion is incised and drained, and a drainage device is left in place. Follicular cysts may be punctured through laser surgery, or a wedge resection of the ovary may be performed to restore ovulation. Rarely, oophorectomy (removal of the ovary) is performed if ovarian cysts are very large.

●○● NURSING CARE

Nursing care focuses on relieving pain and preventing recurrence and complications. Address the following topics for self-care at home:

- The condition, its treatment, and measures to relieve pain.
- The importance of keeping follow-up appointments.
- Manifestations of infection (for postsurgical care) and the need to notify the physician should they occur.
- If cervical polypectomy is performed, advise use of external pads for 1 week. The woman should be able to recognize that saturating more than one pad in an hour indicates the need for immediate follow-up.
- The importance of long-term follow-up care for the woman with POS.

THE WOMAN WITH LEIOMYOMA

Leiomyomas (fibroids) are benign tumors that originate from smooth muscle of the uterus. They are the most common form of pelvic tumor, believed to occur in one of every four or five women older than 35 years of age. Fibroids are seen more often in Black and Asian women than they are in White women (Huether & McCance, 2012).

Pathophysiology

The actual cause of fibroid tumors is not clearly understood, but there is a strong association with estrogen stimulation. Fibroid tumors usually develop in the uterine corpus, and may be intramural, subserous, or submucous (Figure 49–4 ■).

Intramural fibroid tumors (the most common type) are embedded in the myometrium. They usually present as an enlargement of the uterus. Subserous fibroid tumors lie beneath the serous lining of the uterus and project into the peritoneal cavity. They may become pedunculated (on a stem) and displace or compress other tissues, such as the ureter or bladder. Submucous fibroid tumors lie beneath the endometrial lining of the uterus. They displace endometrial tissue and are more likely to cause bleeding, infection, and necrosis than the other types.

Manifestations

Small tumors may be asymptomatic. The rate of growth varies, but they may increase in size during pregnancy or with use of oral contraceptives or HRT. Large fibroid tumors can crowd other organs, leading to pelvic pressure, pain, dysmenorrhea, menorrhagia, and fatigue. Depending on the location of the tumor, constipation and urinary urgency and frequency may occur.

●○● INTERPROFESSIONAL CARE

Treatment of the woman with uterine fibroids depends on the size and location of the tumors, the severity of the manifestations, and her age and childbearing status. Most fibroids grow as a woman ages, then shrink after menopause. Tests used to diagnose uterine fibroids may include an ultrasound to differentiate leiomyoma from endometriosis and a laparoscopy to visualize subserosal leiomyomas. In asymptomatic women who wish to bear children, the fibroid tumors are monitored for growth.

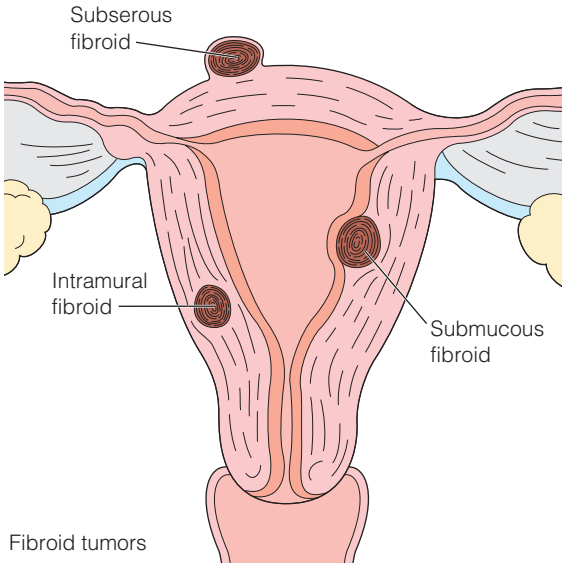


Figure 49–4 ■ Types of uterine fibroid tumors (leiomyomas). Intramural fibroid tumors lie within the uterine wall. Subserous fibroid tumors lie beneath the serous lining of the uterus and project into the peritoneum. Submucous fibroid tumors lie beneath the endometrial lining of the uterus.

MEDICATIONS

There are no medications to permanently shrink fibroids. Using birth control pills may decrease heavy vaginal bleeding. Medications that stop ovarian production of estrogen and progesterone (hormones necessary for fibroid growth) may provide a temporary decrease in manifestations. Injectable leuprolide acetate (Lupron) and nasal spray fluocinolone (Synalar) decrease bleeding and shrink the fibroids, but the tumors grow again when the medications are stopped. Long-term use of these medications is limited because of their side effects (hot flashes, vaginal dryness, and headaches) and significant risk of bone loss if treatment continues 6 months or more.

SURGERY

Myomectomy, removal of the tumor without removing the entire uterus, is the surgical procedure of choice for young women who wish to retain reproductive capability. Laparoscopic laser technique is used for many women. A hysterectomy is performed if tumors are large, and if bleeding or other problems continue in perimenopausal women. A nonsurgical method of treatment is a uterine fibroid embolization. In this procedure, a catheter is guided through the femoral artery to the uterus, where tiny particles are injected into the artery supplying the fibroid to cut off the fibroid's blood supply. This procedure requires only an overnight hospital stay with a return to normal activities in 1 week.

●○● NURSING CARE

If surgery is deferred, teaching emphasizes the importance of regular follow-up assessments to monitor tumor growth. If a hysterectomy is performed, teaching emphasizes appropriate preoperative and postoperative care (refer to the box on page 1591). Dietary modifications to increase iron intake, prevent constipation, and promote healing are important.

THE WOMAN WITH ENDOMETRIOSIS

Endometriosis is a chronic inflammatory disease in which functional endometrial tissue is found outside the uterus (Grossman & Porth, 2014). These implantations of endometrial tissue develop most commonly in the pelvic cavity, but also possibly in other areas of the body, such as the lungs. Endometriosis affects from 10% to 15% of women of childbearing age and is more common in women who postpone childbearing. Risk factors for endometriosis include early menarche, regular periods with a cycle of less than 27 days, menses lasting more than 7 days, heavier flow, increased menstrual pain, and a history of the condition in first-degree female relatives (Schuiling & Likis, 2013).

Pathophysiology

The cause of endometriosis is unclear, but several theories have been proposed. The metaplasia theory asserts that endometrial tissue develops from embryonic epithelial cells as a result of hormonal or inflammatory changes. The theory of retrograde menstruation suggests that menstrual tissue backs up through the fallopian tubes during menses, implants on various pelvic structures, and survives. The transplantation theory asserts that endometrial implants spread via lymphatic or vascular routes.

The abnormally located endometrial tissue responds to cyclic ovarian hormone stimulation, and bleeding at the time of menstruation occurs at the sites of implantation. Scarring, inflammation, and adhesions may develop. Endometrial implants on the ovary cause endometrial (chocolate) cysts, which are often filled with old blood and may rupture, causing peritonitis. Endometriosis is a slowly progressive disease, responsive to ovarian hormone stimulation. Thus, the implants regress during pregnancy and atrophy at menopause unless the woman is receiving HRT. Because progressive scarring may interfere with the ability to conceive, women with significant endometriosis are encouraged to have children early if they wish to do so.

Manifestations

Manifestations of endometriosis are summarized in the accompanying box.

●○● INTERPROFESSIONAL CARE

Endometriosis may be difficult to diagnose, but a history of dysmenorrhea, dyspareunia, and infertility strongly suggests this diagnosis. Interventions depend on the severity of symptoms, the extent of the disease, and the woman's age and desire for childbearing. Treatment goals focus on pain management and restoring fertility.

DIAGNOSIS

Diagnostic tests are ordered to rule out other medical conditions and identify the endometrial implants. The tests include a pelvic ultrasound and laparoscopy as well as a CBC with differential to rule out pelvic abscesses and infectious processes. A low hemoglobin and hematocrit may be noted if menorrhagia accompanies endometriosis or tissue implants bleed significantly during menses.

MEDICATIONS

A variety of medications may be used to decrease bleeding in and enlargement of the endometrial implants. Hormone therapy may include oral contraceptives. GnRH agonist therapy (e.g., goserelin [Zoladex], leuprolide [Eligard, Lupron], nafarelin [Synarel]) is used to lower estrogen, initiating a menopause-like state to shrink implants and reduce pain in most women. Oral or injectable progestin (such as Depo-Provera) increases progesterone levels similar to pregnancy, stopping ovulation and lowering estrogen to reduce the size of implants and relieve pain. Danazol, an anabolic steroid, suppresses release of FSH and LH by the pituitary to interrupt the cause of atrophy and involution of both normal and ectopic endometrial tissue. However, danazol may increase the risk of ovarian cancer and has masculinizing side effects. Aromatase inhibitors (aromatase, a protein responsible for producing estrogen, is found in the ovary, skin, adipose tissue, and ectopic endometrial tissue) used in combination with hormone therapy such as birth control pills or progestin have been shown to reduce pain and recurrence of endometrial

MANIFESTATIONS OF ENDOMETRIOSIS

- Heavy, throbbing pain of the lower abdomen and pelvis, radiating down the thighs and around the back. (The degree of pain, however, is not indicative of the severity of the disease.) Pain can begin 2 to 3 days prior to menses and last for several days.
- Feeling of rectal pressure and discomfort when having a bowel movement.
- Dyspareunia.
- Dysfunctional uterine bleeding.
- Infertility.

growths. Long-term use of aromatase inhibitors (e.g., anastrozole, exemestane, letrozole) may cause bone loss. Further information about these drugs is provided in the later discussion of hormone therapy used to treat endometrial cancer.

SURGERY

Surgical interventions include laparoscopy with laser ablation (excision or removal) of endometrial implants or a total hysterectomy.

●○● NURSING CARE

Nursing care includes providing pain relief, providing education about the condition and the treatment options, and helping the woman cope with treatment outcomes. The severity of the disease and its manifestations are not necessarily related. Advanced disease may exhibit few manifestations, whereas early disease may be quite painful. See the accompanying Case Study & Nursing Care Plan for a woman with endometriosis.

Priorities of Care

Anxiety related to the risk for loss of reproductive function is a priority diagnosis for the young woman with endometriosis.

Diagnoses, Outcomes, and Interventions

Interventions for pain, discussed previously, are also appropriate for the woman with endometriosis.

Anxiety

Anxiety about the unsure prognosis related to infertility is a particular problem for young women who plan to have a family in the future.

Expected Outcome: Patient will demonstrate management of anxiety by use of effective coping strategies to deal with uncertain prognosis and potential treatment options related to the particular cause of infertility.

- Encourage expression of fears and anxiety about infertility, and answer questions honestly. *Knowledge helps relieve anxiety and fear.*
- Provide information on fertility awareness methods, including measurement of basal body temperature and other techniques for recognizing ovulation. *Understanding these techniques helps the woman and her partner optimize the conditions for conception.*

Continuity of Care

Explain the cause of the disorder and the various treatment options, including their side effects. Discuss fertility awareness methods and the risks and benefits of long-term use of oral contraceptives. Stress the importance of exercise, smoking cessation, and weight control. If surgical treatment is chosen, provide preoperative and postoperative teaching.

THE WOMAN WITH CERVICAL CANCER

Cancer of the cervix is the second most common cancer in women worldwide, and the 14th most common in women in the United States. The incidence is higher in Black women than in White women. The death rate during the past 30 years has been reduced through effective screening for cervical cancer with the Pap smear test and the treatment of existing malignancies. Failure to have the recommended screenings and compliance with follow-up care after colposcopic procedures has been identified as a leading reason for development of the disease.

FAST FACTS

Cervical Cancer

- The American Cancer Society estimates that there will be more than 11,000 newly diagnosed cases and slightly more than 4000 deaths from cervical cancer each year.
- Cervical cancer is most often diagnosed in women between the ages of 20 and 50; however, about 20% of women diagnosed with cervical cancer are over 65 (making regular Pap tests essential at any age).
- Cervical cancer occurs most often in Hispanic women; the rate is almost twice that of non-Hispanic White women.

Source: ACS, 2012b, 2012d.

Risk Factors

Risk factors for cervical cancer include infection of the external genitalia and anus with HPV, first intercourse before 16 years of age, multiple sex partners or male partners with multiple sex partners, a history of STIs, and infection with HIV. Infection with HPV is the most important risk factor for cancer of the cervix. Other risk factors include smoking and poor nutritional status, obesity, multiple pregnancies, long-term use of birth control pills, family history of cervical cancer, and exposure to diethylstilbestrol (DES) in utero.

Pathophysiology

Most cervical cancers are squamous cell carcinomas that begin as neoplasia in the cervical epithelium. Precancerous dysplasia (cervical intraepithelial neoplasia, cervical carcinoma in situ) is estimated to occur in one of eight women before the age of 20 and is often associated with HPV infection. Studies have also found a strong association with reproductive infections with *Chlamydia trachomatis*. (These infections are discussed in Chapter 50.) The precursor lesions may spontaneously regress, persist, or progress and undergo malignant change. A very small percent become invasive (Lentz et al., 2012). Systems of grading of dysplastic changes in the cervix use the term cervical intraepithelial neoplasia (CIN) or the Bethesda system (Table 49–2). Carcinoma in situ is localized; invasive cancer spreads to deeper layers.

Cervical cancer spreads by direct invasion of accessory structures, including the vaginal wall, pelvic wall, bladder, and rectum. Although metastasis is most frequently confined to the pelvic area, distant metastasis may occur through the lymphatic system.

Manifestations

Preinvasive cancer is limited to the cervix and rarely causes manifestations. Invasive cancer causes vaginal bleeding after intercourse or between menstrual periods and a bloody or brown vaginal discharge that increases as the cancer progresses. These changes are subtle, and may be more readily noticed by the postmenopausal woman. Manifestations of advanced disease include referred pain in the back or thighs, hematuria, bloody stools, anemia, and weight loss.

TABLE 49–2 Classification Systems for Pap Smears

Dysplasia/ Neoplasia	CIN (Cervical Intraepithelial Neoplasia)	Bethesda System	Numerical
Benign	Benign	• Normal	1
Benign with inflammation	Benign with inflammation	• Normal	2
		• Atypical squamous cells of undetermined significance (ASCUS)	
Moderate dysplasia	CIN I	• Low-grade squamous intraepithelial lesion (SIL)	3
Severe dysplasia	CIN II	• High-grade SIL	3
Carcinoma in situ	CIN III	• High-grade SIL	4
Invasive cancer	Invasive cancer	• Invasive cancer	5

●○● INTERPROFESSIONAL CARE

The goals of treatment are to eradicate the cancer and minimize complications and metastasis. The type of treatment depends on the degree of malignant change, the size and location of the lesion, and the extent of metastasis.

DIAGNOSIS

Tests used to diagnose cervical cancer include a Pap smear, colposcopy, and cervical biopsy. A loop diathermy technique (loop electrosurgical excision procedure [LEEP]) allows simultaneous diagnosis and treatment of dysplastic lesions found on colposcopy. This procedure is performed in the healthcare provider's office, using a wire for both cutting and coagulation during excision of the dysplastic region of the cervix. An MRI or CT of the pelvis, abdomen, or bones may be performed to evaluate the spread of the tumor.

MEDICATIONS

Chemotherapy is used for tumors not responsive to other therapy, tumors that cannot be removed, or as adjunct therapy if metastasis has occurred (refer to Chapter 14).

CASE STUDY & NURSING CARE PLAN A Woman with Endometriosis

Angela Hall is a 31-year-old married accountant. She relates a history of severe dysmenorrhea and menorrhagia, a feeling of pelvic heaviness, and pain that radiates down her thighs. Because of her discomfort, her husband has complained about the quality of their sex life and has expressed concerns about their plans for having children. Mrs. Hall reports being so tired she doesn't care whether she has sex or not, and, in fact, would really prefer not to: "Sex hurts so much, I just can't stand it." Endometriosis is suspected, and a diagnostic laparoscopy has been scheduled.

ASSESSMENT

Christine Brigham, RN, NP, interviews Mrs. Hall and makes the following assessments: BP 110/70 mmHg, P 68 bpm, R 18/min, T 36.7°C (98.2°F). Mrs. Hall's weight is 59 kg (130 lb) and within normal limits for her height. Review of laboratory findings indicate a hemoglobin level of 9.8 g/dL (normal range: 12 to 16 g/dL) and a hematocrit of 33.1% (normal range: 35% to 45%). Physical examination reveals pelvic tenderness on manipulation of the cervix, and small masses that are palpable on abdominal/pelvic examination.

DIAGNOSES

- *Chronic Pain* related to endometrial pelvic implants
- *Anxiety* related to effect of endometriosis on fertility
- *Readiness for Enhanced Knowledge* related to diagnosis and treatment options
- *Sexual Dysfunction* related to the manifestations of endometriosis

EXPECTED OUTCOMES

- Patient will develop effective self-care measures to deal with the pain and discomfort.
- Patient will verbalize decreased anxiety.
- Patient will demonstrate understanding of the disease and treatment options.
- Patient will verbalize an improvement in sexual functioning and a decrease in interpersonal stress between herself and her husband.

PLANNING AND IMPLEMENTATION

- Identify the location, type, duration, and history of the pain.
- Recommend analgesics and heat therapy.
- Provide information on biofeedback, relaxation, and imagery to lessen pain.
- Discuss with Mr. and Mrs. Hall the causes of endometriosis and its manifestations.
- Encourage the Halls to discuss their feelings about the effect of the disease on their sex life, lifestyle, and fertility.
- Refer the couple to the local mental health center if appropriate.

EVALUATION

Two years after the initiation of treatment, Mr. and Mrs. Hall have become parents of a baby girl. Mrs. Hall states that the discomfort and other manifestations of endometriosis have eased. Relaxation and imagery have effectively minimized her pain and brought about improvement in her function as wife, mother, and sexual partner. Counseling has improved the interpersonal and sexual relations between the Halls. Dietary management has improved her anemia, although the menorrhagia persists. The Halls are trying to have a second child, understanding the advantages of rapid succession of pregnancies. They will be followed in the nursing clinic and referred to an infertility clinic if conception does not occur within 1 year.

Clinical Reasoning in Patient Care

1. Explain the pathophysiologic basis for Mrs. Hall's anemia.
2. How would you handle the situation if Mr. and Mrs. Hall were extremely uncomfortable and embarrassed about discussing their sexual problems?
3. Develop a plan of care for Mrs. Hall for the nursing diagnosis *Situational Low Self-Esteem* related to the manifestations of endometriosis.

See Evaluating Your Response in Appendix B.

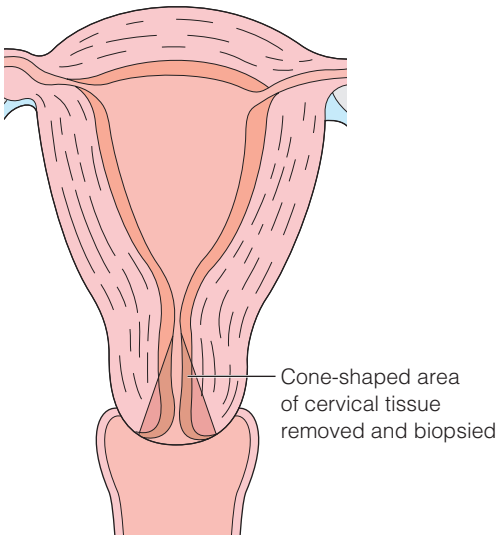

Figure 49–5 ■ Conization, the surgical removal of a cone-shaped section of the cervix, is used to treat microinvasive carcinoma of the cervix.

SURGERY

When combined with colposcopy, laser surgery is a viable treatment method if the cancer is limited to the cervical epithelium. Cryosurgery, which involves the use of a probe to freeze tissue, causing necrosis and sloughing, is also used for noninvasive lesions. Conization (Figure 49–5 ■) is performed to treat microinvasive carcinoma when colposcopy cannot define the limits of the invasion. For invasive lesions, hysterectomy or radical hysterectomy (removal of the uterus, fallopian tubes, lymph nodes, and ovaries) is performed.

A pelvic exenteration, the removal of all pelvic contents, including the bowel, vagina, and bladder, may be performed if the cancer recurs without involvement of the lymphatic system. An anterior exenteration is the removal of the uterus, ovaries, fallopian tubes, vagina, bladder, urethra, and lymphatic vessels and nodes. An ileal conduit is created for excretion of urine (refer to Chapter 27). A posterior exenteration is the removal of the uterus, ovaries, fallopian tubes, bowel, and rectum. A colostomy is created for excretion of feces (refer to Chapter 24). This is an extensive procedure with many possible complications, and it requires a lengthy recovering period.

RADIATION THERAPY

Radiation therapy is used to treat invasive cervical cancer. External radiation beam therapy and intracavitary cesium irradiation can be used. See Chapter 14 for more information about the types of radiation therapy and nursing care of the patient undergoing radiation therapy.

●○● NURSING CARE

Nursing care involves helping the woman cope with the physical and psychologic effects of a potentially life-threatening illness, providing information needed to make informed decisions, and minimizing the adverse effects of therapy. Pain relief measures are important, as is grief work on the part of the woman and family. The woman should be encouraged to perform self-care activities and resume normal everyday activities and sexual functioning to the extent possible. See the accompanying Case Study & Nursing Care Plan for a woman with cervical cancer on page 1602.

Health Promotion

Recommendations for cervical cancer screening vary somewhat. The most recent guidelines from the American College of Obstetricians and Gynecologists (2011) say that most women in their 20s can limit Pap tests to every 2 years. The American Cancer Society (2012d; Smith et al., 2014) recommends that a woman should begin screening for cervical cancer at 21 years of age with the Pap test every 3 years. Cervical cancer screening with HPV DNA tests and Pap tests may be performed every 5 years for the woman over age 30 with previous normal results. Women 65 to 70 years of age and older who have had three or more normal Pap smears in the past 10 years may choose to stop cervical cancer screening. Screening for women who have had a total hysterectomy (including the cervix) is not recommended unless the surgery was done as a treatment for cancer. Women who have a hysterectomy without removal of the cervix should continue to follow ACS guidelines. All women should discuss the schedule for examinations with their healthcare provider.

It is vital that nurses educate women of all ages about controlling risk factors for cervical cancer and about the importance of screening for this cancer throughout the life span. Teach young women about the relationship between early sexual activity, multiple partners, having a partner who has had multiple sex partners, and having sex with men who are not circumcised. Discuss safer sex alternatives and using condoms for protection. Emphasize the importance of continued screening exams for the older woman who may not see a gynecologic specialist on a regular basis.

Encourage women to have their daughters vaccinated with Gardasil (or Cervarix as an alternative) to prevent cervical cancer, precancerous genital lesions, and genital warts due to HPV types 6, 11, 16, and 18. Gardasil is given as three injections over a 6-month period and does not protect against HPV in a woman already infected. For this reason, a federal advisory panel is recommending that the vaccine be routinely given to girls ages 11 and 12 and catch-up vaccines to girls ages 13 to 18. Evidence is inconclusive regarding vaccination for all women ages 19 to 26. Women and parents of preteen and teenage girls should discuss risks and benefits with their physicians (ACS, 2012d). There has been controversy around the issue of vaccination for a sexually transmitted infection even though it prevents cancer. Many parents fear if they permit vaccination they are promoting premarital sex. Educating parents about the risks and the progression of HPV is important to ensure girls are permitted to receive the vaccination. Legislation to mandate vaccination for HPV is pending in many states. Nurses should become familiar with and advocate for health-related legislation.

Assessment

Collect the following data through a health history and physical examination (refer to Chapter 47):

- *Health history:* history of STIs, sexual history, partner's sexual history, family history of cervical cancer, vaginal bleeding or discharge, smoking history, maternal treatment with DES
- *Physical assessment:* pelvic examination, abdomen, lymph glands.

Evidence for Nursing Care

The Patient with Cervical Cancer

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Ackerson, K. (2011). Interactive model of client health behavior and cervical cancer screening of African-American women. *Public Health Nursing, 28*(3), 271–280.
- Berger, J., & Ramirez, P. (2012). Surgical management of cervical carcinoma. *Hematology/Oncology Clinics of North America, 26*(1), 63–78.
- McCormish, E. (2011). Cervical cancer. Who's at risk? *Nursing for Women's Health, 15*(6), 476–483.

Priorities of Care

The priorities of nursing care for the woman with cervical cancer include helping the woman and her family cope with the physical and psychologic effects of this disease, providing information needed to make informed decisions, and minimizing the adverse effects of therapy.

Diagnoses, Outcomes, and Interventions

This section discusses nursing interventions for the woman who has been diagnosed with cervical cancer and requires surgical and/or radiation treatment. Other nursing diagnoses and interventions that may be appropriate for the woman with cervical cancer are discussed in the sections discussing other female reproductive system cancers.

Fear

Many people believe that cancer equals death; however, this is no longer true in many cases, especially with early diagnosis. For cervical cancer that is diagnosed at an early stage, the 5-year survival rate is between 63% and 93% (ACS, 2012d).

Expected Outcome: Patient will discuss fears related to cervical cancer diagnosis and treatment by use of open communication and effective coping strategies.

- Explain that many women with cervical cancer survive for 5 years or more and that the earlier the cancer is detected, the better the prognosis. *This gives the woman hope, an essential ingredient in recovery.*
- Allow adequate time for the woman and her partner to express their concerns and to ask questions. *Unexpressed feelings and fears and lack of understanding may cause the woman to view the situation as worse than it is.*
- Refer to a cancer counselor or support group for additional information. *Cancer survivors who visit patients in the hospital provide proof that people can survive the diagnosis and treatment of cancer and lead normal, productive lives.*

Impaired Tissue Integrity

Surgery interrupts the integrity of the skin surface, providing a potential portal of invasion for bacteria. Radiation therapy causes an inflammatory response in the skin and mucous membranes within the field of radiation, creating further risk of tissue reaction and breakdown.

Expected Outcome: Patient will demonstrate skin integrity by supportive skin care to promote healing and reduce skin breakdown.

- Teach wound and skin care, particularly if pelvic exenteration is performed. Irrigations with saline or solutions of saline and hydrogen peroxide are performed at intervals, with dry heat applied thereafter to dry the area. *Open and damaged tissue increases the risk for infection. Meticulous skin and wound care is necessary to prevent infection and further tissue destruction.*
- If appropriate, teach stoma care, and care for the skin surrounding the stoma. (These procedures are discussed in Chapters 24 and 27.) *Urine and stool are irritating to the skin. Without proper care, the skin surrounding the stoma can become excoriated.*
- Apply non–oil-based lotions to skin surface. This may minimize itching and help maintain integrity. *Oil-based lotions are not recommended for tissue undergoing radiation.*
- Instruct the woman not to remove the markings used to localize the radiation beam to the target area. *Markings are used in future radiation treatments.*
- Monitor for evidence of fistula formation, and teach the woman to do the same. *Fistula formation is a potential complication of radiation to the pelvic or abdominal cavities. Vaginal fistulas may form between the vagina and the bladder or rectum. Fistulas may also develop between the bladder and rectum, resulting in the expulsion of stool in the urine or loss of urine through the anus.*

Continuity of Care

Teaching varies according to the stage of the cancer and the treatment selected. Provide information concerning radiation, chemotherapy, or surgery, as indicated. Preoperative teaching focuses on postoperative expectations, including management of urinary or fecal diversion, if indicated. Help the woman and family recognize signs of infection and understand the importance of follow-up care. In addition, suggest the following resources: the American Cancer Society, the National Cancer Institute, and the Women's Cancer Network.

THE WOMAN WITH ENDOMETRIAL CANCER

Endometrial cancer is the most frequently diagnosed cancer of the female reproductive organs in the United States. The ACS (2012b) estimates that each year more than 52,000 women are diagnosed with endometrial cancer, and more than 8500 women die annually from this disease. Most endometrial cancer is diagnosed in older women, with more than half of the cases diagnosed in women between the ages of 55 and 74. The incidence of endometrial cancer is higher in White women, but Black women are more likely to die from it. The overall 5-year survival rate is about 69%, but if found and treated early in the disease, that rate increases to over 91% (ACS, 2012e).

Risk Factors

Significant risk factors for endometrial cancer are prolonged estrogen stimulation and obesity. Recent studies report that obesity was a factor in endometrial cancer diagnoses (Schmandt et al., 2011). Other factors that increase risk are anovulatory menstrual cycles, increased number of menstrual cycles during one's lifetime, a high-fat diet, having cancer of the breast or ovary, prior radiation therapy of the pelvic region, atypical endometrial hyperplasia, decreasing ovarian

CASE STUDY & NURSING CARE PLAN A Woman with Cervical Cancer

Anna Eliza Gillam is a 45-year-old divorced mother of four children ranging in age from 16 to 23. She was married at age 18 and had several sexual partners prior to her marriage. She has had three sexual partners since her marriage ended. A Pap smear taken 2 weeks ago showed atypical cells, and she has come in for a repeat test.

ASSESSMENT

Judy Davis, RN, FNP, the admitting nurse, interviews Ms. Gillam and records the following assessment findings: BP 130/80 mmHg, P 72 bpm, R 18/min, T 37.3°C (99.2°F). Ms. Gillam weighs 142 lb (64.5 kg). Examination of the cervix reveals a large necrotic lesion at the 7 o'clock position. She has reduced her smoking to fewer than 10 cigarettes per day, and she does not drink alcohol.

Ms. Gillam is extremely fearful and anxious and has told no one about her abnormal Pap smear. She reveals that she has had back pain radiating down her thighs for several months and a foul vaginal discharge that increases after intercourse. Until 2 weeks ago, she had not had a Pap smear for 5 years. Ms. Davis performs the repeat Pap smear, which is positive for squamous cell carcinoma of the cervix. A CT scan and lymphangiography are scheduled. Laparoscopy shows the disease to be widespread in the pelvic cavity.

DIAGNOSES

- *Decisional Conflict* related to treatment options
- *Acute Pain* related to metastasis and surgery
- *Risk for Impaired Skin Integrity* related to radiation
- *Fear* related to diagnosis of cervical cancer
- *Grieving* related to potential loss of life

EXPECTED OUTCOMES

- Patient will gain knowledge to make informed decisions about treatment options.
- Patient will develop strategies for pain control.
- Patient will maintain skin and tissue integrity during radiation treatment.
- Patient will express her feelings about the fear of cancer and death.
- Patient will develop effective coping strategies for dealing with life-threatening illness and pain.

PLANNING AND IMPLEMENTATION

- Discuss treatment alternatives, including the prognosis with each option.
- Administer pain medications as prescribed.
- Inspect skin surfaces daily before and after radiation therapy.
- Provide information on biofeedback training and relaxation techniques for control of moderate pain.
- Assess for and assist with referrals for spiritual counseling because this has been shown to improve coping with life-altering cancer.
- Refer to a local cancer support group so that she can interact with cancer survivors.
- Refer Ms. Gillam to a social worker in preparation for her altered level of functioning.

EVALUATION

Ms. Gillam has begun radiation therapy following pelvic exenteration. She controls her pain with relaxation and imagery techniques, requiring only occasional analgesics. She uses a water-based lotion to soothe the skin surface and is careful not to remove the skin markings. She seems optimistic and has quit smoking. She and her family have continued to attend the cancer support group meetings. Ms. Gillam is planning for the future and has talked with her family about what it means to live with cancer.

Clinical Reasoning in Patient Care

1. Compare and contrast your teaching plan for health promotion interventions to decrease the risks of cervical cancer for a young woman of 17 and an older woman of 70. Would they differ and, if so, how?
2. Develop a teaching plan to help Ms. Gillam cope with the effects of radiation.
3. During a home visit, Ms. Gillam tells the nurse that she has been so tired since beginning radiation treatments that all she can do is sit in her chair. Design a plan of care for the nursing diagnosis *Fatigue*.

See Evaluating Your Response in Appendix B.

function (as from menopause), estrogen-secreting tumors, and unopposed estrogen (e.g., estrogen therapy without progesterone) (ACS, 2012e). Medical conditions that may alter estrogen metabolism and increase the risk of endometrial cancer are diabetes mellitus, hypertension, and polycystic ovary disease (Huether & McCance, 2012). Tamoxifen, a drug that blocks estrogen receptor sites and is used to treat breast cancer, has a weak estrogenic effect on the endometrium, and is also a risk factor. Endometrial cancer is the most commonly inherited gynecologic cancer. A family history of hereditary nonpolyposis colon cancer (HNPCC) may mean that a woman has an inherited mutation that is a mismatch of repair genes, and has a higher risk of developing endometrial cancer (ACS, 2012e). The risk for endometrial cancer is decreased by using birth control pills, use of an IUD without hormones to prevent pregnancy, and having multiple pregnancies.

Pathophysiology

Most endometrial malignancies are adenocarcinomas that are slow to grow and metastasize. These cancers develop in the glandular cells or endometrial lining of the uterus (the same tissue that is shed each month during a normal menstrual period). Endometrial hyperplasia (excessive growth) is a precursor of endometrial cancer. A second and much less common type of tumor is not estrogen driven, and occurs primarily in older menopausal women. These tumors are associated with endometrial atrophy and have a poorer prognosis (Schuiling & Likis, 2013).

Tumor growth usually begins in the fundus, invades the vascular myometrium, and spreads throughout the female reproductive tract. Metastasis occurs by means of the lymphatic system, through the fallopian tubes to the peritoneal cavity, and to the rest of the body via the bloodstream. Target areas for metastasis include the lungs, liver, and bone. The International Federation of Gynecology and Obstetrics (FIGO) classification of endometrial cancer is outlined in Table 49–3.

Manifestations

The major manifestation of endometrial hyperplasia or overt endometrial cancer is abnormal, painless vaginal bleeding. In menstruating women, this bleeding is manifested as menorrhagia or metrorrhagia. In postmenopausal women, any bleeding is abnormal. Later manifestations include pelvic cramping, bleeding after intercourse, and lower abdominal pressure. In advanced disease, lymph node enlargement, pleural effusion, abdominal masses, and ascites may be present.

TABLE 49–3 FIGO Staging Classification for Endometrial Cancer

Stage	Description
I	Tumor limited to endometrium or myometrium
II	Endocervical glandular involvement or invasion of cervical stroma
III	Metastasis or invasion of serosa, adnexa, vagina, and pelvic or para-aortic lymph nodes
IV	Tumor invasion of bladder or bowel mucosa; distant metastases

●○● INTERPROFESSIONAL CARE

The goals of care for the woman with endometrial cancer are to eradicate the cancer and minimize complications and metastasis. Following diagnosis, there are four basic types of treatment for endometrial cancer: surgery, radiation therapy, hormone therapy, and chemotherapy.

DIAGNOSIS

Tests used to diagnose cancer of the endometrium include a transvaginal ultrasound to determine endometrial thickening (which may indicate hypertrophy or malignant changes) and an endometrial biopsy or a D&C to provide tissue for a definitive diagnosis (refer to Chapter 47 for further information). Other tests to determine the extent of the disease include chest x-ray; cystoscopy and intravenous pyelogram (IVP) to examine the urinary system; proctoscopy (to assess the rectum); CT scan, PET, or MRI to look for cancer cells and tissue changes; bone scans to identify metastasis; CBC (to identify anemia from bleeding); and a CA-125 blood test to identify the presence of markers for endometrial and ovarian cancers.

SURGERY

After the diagnosis is confirmed, a total abdominal hysterectomy and bilateral salpingo-oophorectomy is performed for stage I cancer. A radical hysterectomy with node dissection is performed if the disease is stage II or beyond. Refer to the box on page 1591 for nursing care of the patient undergoing a hysterectomy.

RADIATION THERAPY

Treatment with external and internal radiation may be performed as a preoperative measure or as adjuvant treatment in advanced cases.

HORMONE THERAPY

Hormone therapy uses hormones or hormone-blocking drugs. They include the following:

- Progestins are progesterone-like drugs. Those used most commonly are medroxyprogesterone acetate (Provera, given by injection or orally) and megestrol acetate (Megace, given orally). These slow the growth of cancer cells. Side effects include hot flashes, night sweats, and weight gain. The drugs increase blood glucose levels in women with diabetes, and may rarely cause serious blood clots.
- Tamoxifen is an antiestrogen drug also often used to treat breast cancer. It is useful against endometrial cancer because it prevents estrogens from stimulating growth of cancer cells. It does not cause bone loss, but can cause hot flashes and vaginal dryness; there is additionally an increased risk for serious blood clots in the legs.
- Gonadotropin-releasing hormone agonists (GnRH-a) lower estrogen levels. Examples are goserelin (Zoladex) and leuprolide (Lupron). These drugs are injected every 1 to 3 months. Side effects are menopausal manifestations and, with long-term use, osteoporosis.
- Aromatase inhibitors stop estrogen from being formed to lower estrogen levels. Examples include letrozole (Femara), anastrozole (Arimidex), and exemestane (Aromasin). Often used to treat breast cancer, these drugs are also believed to be helpful in treating endometrial cancer. They may be taken for years, may cause osteoporosis, and are still being studied.

CHEMOTHERAPY

A combination of drugs may be used to treat endometrial cancer, including doxorubicin (Adriamycin), cisplatin, carboplatin, and paclitaxel (Taxol) (ACS, 2012e). Two or more drugs are often combined for treatment. Chemotherapy is discussed in detail in Chapter 14.

●○● NURSING CARE

Health Promotion

All perimenopausal and postmenopausal women need annual pelvic examinations. The ACS recommends that at the time of menopause all women be informed of the risks and manifestations of endometrial cancer and strongly encouraged to report any unexpected bleeding or spotting to their healthcare provider. Those in high-risk groups are advised to have endometrial biopsies every 2 years, beginning at age 35. In addition, control of diseases such as diabetes mellitus and hypertension decreases the risk of endometrial hyperplasia.

Assessment

Collect the following data through a health history and physical examination (refer to Chapter 47):

- *Health history:* abnormal vaginal bleeding, menstrual history, use of estrogen (without progesterone) to treat menopausal symptoms, breast cancer treated with tamoxifen, childbearing status, presence of chronic illnesses, family history of hereditary nonpolyposis colon cancer.
- *Physical assessment:* height and weight, pelvic examination, abdomen, lymph glands.

Priorities of Care

For the woman who has undergone hysterectomy to treat endometrial cancer, acute pain and preventing surgical complications (infection, venous thrombosis, atelectasis) are the nursing care priorities.

Diagnoses, Outcomes, and Interventions

Nursing care involves helping the woman cope with the physical and psychologic effects of a potentially life-threatening illness, make informed decisions, and minimize the adverse effects of therapy. Pain relief is a key component of care, as is grief work on the part of the woman and family. Encourage the woman to perform self-care and resume normal activities of daily living.

Acute Pain

A total abdominal hysterectomy can result in severe and prolonged pain, not only from the surgical incision but also from the manipulation of internal organs during surgery. Abdominal viscera are highly vascular and easily bruised by handling.

Expected Outcome: Patient will demonstrate adequate pain management through use of prescribed pharmacologic and nonpharmacologic interventions for pain relief.

- Administer analgesics as ordered. *Analgesics provide pain relief and promote early ambulation.*
- Encourage ambulation. *Ambulation facilitates the expulsion of flatus, which can cause distention as well as discomfort.*
- Apply heat to the abdomen, and recommend that the woman use a heating pad at home. *Heat dilates blood vessels, increasing blood supply to the pelvis, decreasing pain.*

Disturbed Body Image

For many women, the side effects of cancer treatment can be almost as difficult and painful as the disease itself. Although side effects of the different therapies vary among individuals, the woman's body image and quality of life are always affected. Such side effects as alopecia (hair loss), nausea, vomiting, fatigue, diarrhea, stomatitis, and surgical scarring disturb body image.

Expected Outcome: Patient will demonstrate appropriate self-esteem by use of effective coping strategies to deal with the temporary changes in body image and interventions to promote body image.

- Review the side effects of the treatment regimen proposed, and assist the woman to develop a plan to deal with these effects. *This promotes a sense of control.*
- Remind the woman and family that side effects are usually manageable and may be temporary. *Over-the-counter agents can be used to alleviate stomatitis. Frequent rest periods can relieve fatigue. Medications can be prescribed for nausea, vomiting, and diarrhea.*

Risk for Sexual Dysfunction

Altered sexuality may result from a feeling of unattractiveness, fatigue, or pain and discomfort. The woman's partner may fear that sexual activity will be harmful.

Expected Outcome: Patient will demonstrate willingness to discuss changes to sexual function and adapts modes of sexual expression to accommodate endometrial cancer treatment-related changes.

- Encourage expression of feelings about the effect of cancer on their lives and sexual relationship. *Verbalizing feelings helps relieve stress and maximizes relaxation.*
- Suggest that the couple explore alternative sexual positions and coordinate sexual activity with rest periods and times that are relatively free from pain. *This creates a more favorable environment for satisfying sexual activity.*

Continuity of Care

The American Cancer Society recommends that, at the time of menopause, all women should be told about the risks and manifestations of endometrial cancer. They should be strongly encouraged to report any unexpected bleeding to their healthcare provider. Women with or at risk for hereditary nonpolyposis colon cancer should be offered annual screening for endometrial cancer with endometrial biopsy beginning at age 35.

Provide information about the specific treatment and prognosis. Explain the expected side effects of treatment used (refer to Chapter 14). Pain control measures are also an essential part of the teaching plan (refer to Chapter 9). The resources listed for the woman with cervical cancer are also appropriate for the woman with endometrial cancer.

THE WOMAN WITH OVARIAN CANCER

Although ovarian cancer is the fourth most common gynecologic cancer in women in the United States, it is the fifth leading cause of cancer deaths among women (ACS, 2014). Approximately 22,000 women are diagnosed with ovarian cancer and an estimated 14,600 deaths result each year (ACS, 2012b). The cancer primarily develops in older women, with about two-thirds of the cases diagnosed in women ages 55 or older. Ovarian cancer is more common in White women than in other races (ACS, 2012f).

Risk Factors

Ten percent of cases of ovarian cancer have two or more first or second-degree relatives who have had the disease. Other types of inherited risks are genetic mutations such as those in *BRCA1* and *BRCA2* (breast and ovarian cancer) and Lynch syndrome (colorectal cancer). Women with a Lynch syndrome mutation have a 10% higher risk of developing ovarian cancer (Ketabi et al., 2011; National Cancer Institute [NCI], 2012).

Risk factors also include increasing age, having no children or giving birth after age 35, early menarche and late menopause, infertility drugs, obesity, eating a high-fat diet, and a personal history of breast cancer. There is also a possibility that polycystic ovarian disease and hormone replacement therapy after menopause may place a woman at risk. Protective factors include long-term contraceptive use, a low-fat diet, having a child before the age of 25, tubal ligation, breast-feeding, and hysterectomy (ACS, 2012f).

Pathophysiology

There are several types of ovarian cancers: epithelial tumors, germ cell tumors, and gonadal stromal tumors. Most ovarian cancers are epithelial tumors, originating from the surface epithelium of the ovary. Ovarian cancer usually spreads by local shedding of cancer cells into the peritoneal cavity and by direct invasion of the bowel and bladder. Cancer cells in peritoneal fluid can implant in the intestines, bladder, and mesentery. Tumor cells also spread through the lymph and blood to such organs as the liver, and across the diaphragm to involve the lungs. Both pelvic and para-aortic lymph nodes may be involved and tumor cells can block lymphatic drainage from the abdomen, resulting in ascites. FIGO staging for ovarian cancer is based on surgical and histologic evaluation (Table 49–4).

Manifestations

In early stages, ovarian cancer generally causes no warning signs or manifestations. When manifestations do develop, they are often vague and mild, such as feeling full quickly, abdominal bloating, urinary urgency and/or frequency, and pelvic or abdominal pain. Other manifestations include fatigue, back pain, pain during intercourse, constipation, and menstrual changes in women prior to menopause.

TABLE 49–4 FIGO Staging Classification for Ovarian Cancer

Stage	Description
I	Growth limited to the ovaries
II	Growth involving one or both ovaries with pelvic extension
III	Tumor involving one or both ovaries, with peritoneal implants outside the pelvis or positive retroperitoneal or inguinal nodes
IV	Growth involving one or both ovaries with distant metastasis

Abnormal vaginal bleeding may occur if the endometrium is stimulated by a hormone-secreting tumor or if the tumor erodes the vaginal wall. An enlarged abdomen with ascites signals later stage disease.

Complications

The complications of advanced ovarian cancer, with related assessments and treatment, are outlined in Table 49–5.

●○● INTERPROFESSIONAL CARE

As with other malignancies, care of the woman with ovarian cancer involves surgery to determine the stage of the tumor and to remove as much of the tumor as possible. Unfortunately, because there are no specific early manifestations, the disease may be well advanced prior to diagnosis. In younger women, an ovarian mass may be monitored for several menstrual cycles, but any ovarian mass must immediately be investigated in a postmenopausal woman. The treatment involves three modalities: surgery, chemotherapy, and radiation therapy.

DIAGNOSIS

Tests used in the diagnosis of ovarian cancer may include transvaginal or abdominal ultrasound, a CT scan of the abdomen and pelvis, an MRI of the abdomen, a PET scan, a laparoscopy, a colonoscopy, and/or an ovarian biopsy. The blood test most useful is a CA-125 antigen level. CA-125 is a tumor marker that is highly specific and elevated in epithelial ovarian cancer. Research is ongoing to develop a blood test to specifically identify ovarian cancer.

SURGERY

In young women with stage I disease who wish to have children, treatment may be limited to removal of one ovary. Usually, however, total hysterectomy with bilateral salpingo-oophorectomy (removal of the ovaries and fallopian tubes) is performed. Depending on the stage of the cancer and the woman's general state of health, surgery is combined with chemotherapy and radiation therapy.

CHEMOTHERAPY

Combination chemotherapy, discussed in Chapter 14, is primarily used following surgery.

RADIATION THERAPY

Radiation therapy using external-beam or intracavitary implants is performed for palliative purposes only and is directed at shrinking the tumor at selected sites.

Evidence for Nursing Care

The Patient with Ovarian Cancer

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Lebensohn, A., Kingham, K., Chun, N., & Kurian, A.(2011). Hereditary cancer. Counseling women at risk. *Contemporary OB/GYN*, *56*(4), 30–40.
- MacDonald, D. (2011). Germline mutations in cancer susceptibility genes: An overview for nurses. *Seminars in Oncology Nursing*, *27*(1), 21–33.
- Morgan, D., Sylvester, H., Lucas, F., & Miesfeldt, S. (2010). Perceptions of high-risk care and barriers to care among women at risk for hereditary breast and ovarian cancer following genetic counseling in the community setting. *Journal of Genetic Counseling*,*19*(1), 44–54.

TABLE 49–5 Complications of Advanced Ovarian Cancer

Complication	Assessments	Treatment
Ascites (accumulation of fluid in the abdominal cavity; a form of third spacing)	• Abdominal distention • Shiny abdominal skin • Dullness on percussion of dependent areas • Dyspnea, constipation • Abdominal pain	Paracentesis (removing fluid from the abdomen)
Intestinal obstruction	• Abdominal distention • Abdominal pain • Projectile vomiting • Constipation • Hyperactive bowel sounds	Nasogastric tube insertion, NPO
Deep venous thrombosis	• Leg edema • Leg pain • Redness, warmth	Anticoagulants
Lymphedema (leg)	• Edema of leg • Decreased range of motion • Tight, shiny skin on leg	Skin care, range-of-motion exercises, massage or physical therapy, compression bandaging

●○● NURSING CARE

Although individualized to each woman, nursing care is essentially the same as that provided for women with other gynecologic cancers. However, research findings support the need for education, because awareness of ovarian cancer manifestations and risk factors in the general population is low (CDC, 2013). The side effects of treatment of cancer and generally poor prognosis diminish the woman's quality of life and involve major psychosocial implications (refer to Chapter 14).

Continuity of Care

Address the following topics in preparing the woman and her family for self-care:

- If a positive family history of breast, ovarian, or colon cancer exists, stress the importance of obtaining regular pelvic examinations. Inform women in this risk group that annual screening with transvaginal ultrasound and CA-125 measurements may be recommended.
- It is crucial not to ignore manifestations such as indigestion, nausea, or urinary frequency, because these seemingly unrelated manifestations may be early signs of ovarian tumors. Emphasize that ovarian cancer may be asymptomatic in early stages.
- Discuss treatment options and their side effects and provide information on ways to minimize or manage side effects.
- Refer to hospice services when appropriate. The resources suggested for the woman with cervical cancer are also appropriate for the woman with ovarian cancer.

THE WOMAN WITH CANCER OF THE VULVA

Cancer of the vulva is a relatively rare malignancy, accounting for about 0.6% of all female cancers. It occurs most often in women over 50 years of age, with half of all cases being in women over age 70 (ACS, 2012g). The prognosis of vulvar carcinoma depends on the degree of invasion, general health status of the woman, presence of chronic diseases, and ability to withstand treatment.

The cause of vulvar cancer is unknown, but there is evidence to associate it with STIs, particularly HPV. Nearly 85% of malignant and premalignant cervical and vulvar lesions have been found to contain HPV DNA, HPV structural antigens, or both. Herpes simplex type 2 (HSV-2) infection and a history of leukoplakia (a precancerous lesion on the vulvar mucous membranes characterized by raised white patches) have also been associated with vulvar cancer. Other risk factors include smoking, HIV, precancerous lesions (vulvar intraepithelial neoplasia [VIN]), other genital cancers, and presence of melanoma or atypical moles.

Most vulvar cancers are epidermoid or squamous cell carcinomas. The primary site is usually the labia majora, but vulvar cancer is also found on the labia minora, clitoris, vestibule, and occasionally in multiple locations. Metastasis occurs by direct extension into the vagina, perineal skin, anus, and urethra. The cancer also spreads through the lymphatic system via the superficial and deep inguinal and femoral nodes, and to the pelvic lymph nodes.

The manifestations of vulvar cancer include pruritus, wart-like growths, patchy changes in color or density of the vulva, vaginal bleeding, dysuria, or changes in a mole on the vulva. Inguinal lymph nodes may be enlarged. If lesions are present, they are biopsied. Imiquimod, which is an immune response modifier used in the treatment of HPV warts, has recently shown positive results in reducing neoplasia; however, surgical resection is the usual treatment (ACS, 2012g). If lymph nodes are involved, radiation therapy is used postoperatively. Chemotherapy is reserved for distant metastases.

Nursing care is similar to that for the woman with endometrial cancer. The woman fears death as the ultimate outcome as well as the possible pain and suffering that surgery and other treatments may cause. Radical surgery represents a great loss to women of all ages.

Disorders of the Breast

Breast disorders are common conditions that primarily affect women (disorders of the male breast are discussed in Chapter 48). When a woman discovers a breast lump, her first response is often fear: of breast cancer, of losing her breast, and perhaps of losing her life. Because American society views the breast as a significant component of feminine beauty, any problem that threatens the breast often strikes at the core of a woman's self-image.

Nurses play a critical role in the care of women experiencing breast disorders by providing education, support, and advocacy. Part of the nurse's role is educating women about normal breast tissue, common benign breast disorders, screening recommendations, and risk factors for breast cancer.

THE WOMAN WITH A BENIGN BREAST DISORDER

Benign changes in a woman's breast tissue often correspond to hormonal changes of the menstrual cycle. Breast tissue also changes in response to nutritional, physical, and environmental stimuli. Benign breast disorders include fibrocystic breast changes, fibroadenomas, intraductal papillomas, duct ectasia, fat necrosis, and mastitis (Table 49–6).

Pathophysiology and Manifestations

FIBROCYSTIC CHANGES

Fibrocystic changes (FCC) (fibrocystic breast disease) is the physiologic nodularity and breast tenderness that increases and decreases with the menstrual cycle. An estimated 50% to 80% of all women experience some of these changes, which include fibrosis, epithelial proliferation, and cyst formation. FCC is most common in women 30 to 50 years of age, and is rare in postmenopausal women who are not taking hormone replacement (Schuiling & Likis, 2013).

FCC includes many different lesions and breast changes. The more common nonproliferative form does not increase the risk for breast cancer. The proliferative form, accompanied by giant cysts and proliferative epithelial lesions, does increase the risk for breast cancer.

TABLE 49–6 Summary of Common Breast Disorders

Condition	Age	Pain	Nipple Discharge	Location	Consistency and Mobility	Diagnosis and Treatment
Duct ectasia	35–55 years; median age 40	Burning around nipple	Sticky, multi-colored; usually bilateral	No specific location	Retroareolar mass with advanced disease	Open biopsy; local excision of diseased portion of breast
Fibroadenoma	15–39 years; median age 20	No	No	No specific location	Mobile, firm, smooth, well-delineated mass	Mammography, surgical or needle biopsy; excision of the tumor
Fibrocystic changes (FCC)	20–49 years; median age 30 (may subside with menopause)	Yes	May occur	Upper outer quadrant	Bilateral multiple lumps influenced by the menstrual cycle	Needle aspiration; observation; biopsy if there is an unresolved mass or mammographic changes
Intraductal papilloma	35–55 years; median age 40	Yes	Serous or sanguineous; usually unilateral from one duct	No specific location	Usually soft, poorly delineated mass	Pap smear of nipple discharge; biopsy; wedge resection
Mastitis, acute	Childbearing years	Tenderness, pain	No	No specific location	Generalized redness of overlying skin	Antibiotic therapy; incision and drainage if mastitis progresses to an abscess
Mastitis, chronic	Any age	Tenderness, pain; headache; high fever	No	No specific location	Generalized redness and swelling	Antibiotics, usually penicillin
Fat necrosis	Any age	Tenderness	No	No specific location	Firm, irregular, palpable	Surgical biopsy to rule out cancer

Nonproliferative changes may be cystic or fibrous. Cystic change refers to the dilation of ducts in the subareolar, lobular, or lobe areas. Cysts often go unnoticed unless pain and tenderness is associated with menses. Fibrous changes are infrequent but can occur during the menstrual years. A firm, palpable mass, 2 to 3 cm in size, is typically located in the upper outer breast quadrant following an inflammatory response to ductal irritation.

Women with fibrocystic changes experience bilateral or unilateral pain or tenderness in the upper, outer quadrants of their breasts, and report that their breasts feel particularly thick and lumpy the week prior to menses. Nipple discharge may be present. Pain is due to edema of the connective tissue of the breast, dilation of the ducts, and some inflammatory response; some women report an increase in breast size. Multiple, mobile cysts may form, usually in both breasts (Figure 49–6 ■). Fluid aspirated from these cysts ranges in color from milky white to yellow, brown, or green. If the fluid is tinged with blood, there is reason to suspect malignancy.

INTRADUCTAL DISORDERS

An intraductal papilloma is a tiny, wartlike growth on the inside of the peripheral mammary duct that causes discharge from the nipple. The discharge may be clear and sticky or bloody. When more than one of these growths is present, the condition is called intraductal papillomatosis. This condition is most common in women in their 30s and 40s. The lesion must be investigated to rule out malignancy.

Mammary duct ectasia (plasma cell mastitis) is a palpable lumpiness found beneath the areola. Duct ectasia involves periductal inflammation, dilation of the ductal system, and accumulation of fluid and dead cells that block the involved ducts. The condition usually occurs in perimenopausal women and is difficult to differentiate from cancer.

Manifestations of mammary duct ectasia include sticky, thick nipple discharge with burning and itching around the nipple, and inflammation. The discharge may be green, greenish brown, or bloody. Nipple retraction often is associated with duct ectasia in postmenopausal women.

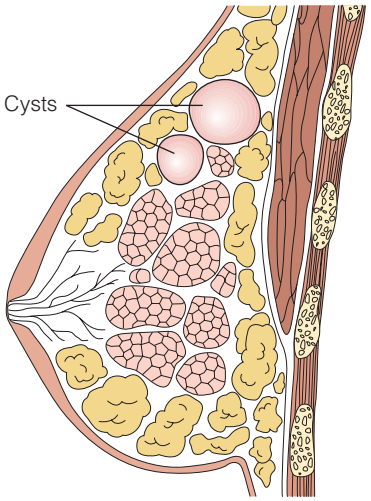

Figure 49–6 ■ Fibrocystic breast changes.

●○● INTERPROFESSIONAL CARE

Diagnosis of FCC is based on complete history, physical examination, and imaging studies. A biopsy may be required for diagnosis. Analysis of nipple discharge, mammography, and possibly ductography may be used to diagnose ductal disorders. The affected duct is excised in an open biopsy procedure.

The treatment of FCC is usually symptomatic. Cyst aspiration may relieve pain, and also allows examination of fluid to confirm the cystic nature of the disease. A well-fitting brassiere that provides good support worn day and night helps relieve discomfort. Some women report that eliminating xanthines (found in coffee, tea, cola, and chocolate) from the diet decreases symptoms. Aspirin, mild analgesics, local heat or cold, and vitamin E may help relieve breast pain. Hormone therapy is controversial because of the benign nature of the disease and potential adverse effects of therapy. Danazol, a synthetic androgen, may be prescribed for women with severe pain.

●○● NURSING CARE

When a woman presents with a breast mass, nursing responsibilities include taking a careful health history and facilitating follow-up care. If a palpable mass is present, it is important to ask how long the lesion has been present and whether the woman has noticed any pain associated with the mass, any change in its size, and any changes in association with the menstrual cycle.

In many cases, definitive diagnosis of the breast disorder requires surgical biopsy to rule out cancer. During the diagnostic process, the nurse can provide emotional support and education about diagnostic and therapeutic procedures, self-care and comfort measures, and resources to help the woman cope with the experience. Nursing care for the woman is similar to that for any patient with an open biopsy. It also is important to reassure the woman that these disorders are not breast cancer.

THE WOMAN WITH BREAST CANCER

Breast cancer is the unregulated growth of abnormal cells in breast tissue. Breast cancer is the most commonly occurring cancer in women and the second leading cause of cancer death in women in the United States. The ACS (2012b) estimates that more than 229,000 women will be diagnosed with breast cancer each year, and approximately 40,000 women will die from it annually. In addition, more than 63,000 women will be diagnosed with cancer in situ. However, the incidence of breast cancer has decreased, primarily as a result of findings from the Women's Health Initiative study, published in 2002, that indicated that use of HRT increased the risk of breast cancer and heart disease. These findings led to a subsequent drop in use of hormone therapy to treat menopausal symptoms. There are racial differences in the incidence and mortality of breast cancer (see the Focus on Cultural Diversity box).

FOCUS ON CULTURAL DIVERSITY

Breast Cancer in Women

- Breast cancer is slightly more prevalent in White women than in Black women.
- Asian, Hispanic, and American Indian women have a lower risk of developing breast cancer.
- Black women are more likely to die from the cancer because they tend to have more aggressive tumors.

Source: (ACS, 2012c).

Risk Factors

Of the various kinds of risk factors for breast cancer, some can be changed and some cannot. Those that cannot be changed are the following (ACS, 2012c):

- *Age and gender.* Women are 100 times more likely to have breast cancer than are men, with the risk increasing with age. Two out of three invasive breast cancers are found in women ages 55 and older. See the accompanying Nursing Care of the Older Adult box on page 1609.
- *Genetic risk factors.* Approximately 5% to 10% of breast cancers are believed to result directly from genetic mutations inherited from a parent (see the discussion in the Pathophysiology section).
- *Family history of breast cancer.* Having a first-degree relative (mother, sister, or daughter) with breast cancer approximately doubles the risk, and having two first-degree relatives increases it fivefold. Having a male family member with breast cancer also poses an increased risk.
- *Dense breast tissue.* Dense breast tissue (seen on a mammogram) has more glandular tissue and less fatty tissue, increasing the risk for the development of breast cancer.
- *Personal history of breast cancer.* A woman with cancer in one breast has a three- to fourfold increase in risk for developing a new cancer in the other breast or in a different part of the same breast.
- *Previous chest irradiation.* Radiation of the chest as a child or young woman for other cancer (such as Hodgkin's lymphoma) significantly increases the risk. The risk is greatest in women who had irradiation during adolescent breast development.
- *Menstrual history.* Women who begin menstruating before the age of 12 or who have menopause after the age of 55 are at a slightly higher risk, probably the result of a higher lifetime exposure to estrogen and progesterone.

Lifestyle-related factors that increase breast cancer risk include recent use of oral contraceptives, not having children or having them after the age of 30, long-term use of HRT, not breast-feeding, drinking alcohol (especially two to five drinks daily), being overweight and obese (especially after menopause), and physical inactivity. In contrast, breast-feeding, moderate or vigorous physical activity, and maintaining a healthy body weight lower the risk for breast cancer.

Pathophysiology

Possible causes of breast cancer include environmental, hormonal, reproductive, and hereditary factors. Two breast cancer susceptibility genes have been identified: *BRCA1* on chromosome 17 and *BRCA2* on chromosome 13. These genes may be responsible for the approximately 10% of women with hereditary breast cancer, with genetic mutations causing up to 80% of breast cancer in women younger than 50 years of age. A woman with identified mutations in *BRCA1* (known to be involved in tumor suppression) has a lifetime risk of 56% to 85% for breast cancer and also has an increased risk for ovarian cancer (NCI, 2012). Current research has found that a

family history of breast cancer is the greatest risk, even when the abnormal genes are not present. Changes in other genes that also might lead to inherited breast cancer are the *ATM* gene (normally helps repair damaged DNA), *CHEK2* gene (risk is greatly increased if mutated and there is a strong family history of breast cancer), *p53* gene (a tumor suppressor gene), and *PTEN* gene (normally helps regulate cell growth).

Cancer of the breast begins as a single transformed cell and is hormone dependent. Cancers of the breast are classified as noninvasive (in situ) or invasive, depending on the penetration of the tumor into surrounding tissue. Breast cancer may remain a noninvasive disease, or an invasive disease without metastasis, for long periods of time.

Breast cancer may be categorized as carcinoma of the mammary ducts, carcinoma of mammary lobules, or sarcoma of the breast. Most breast cancers are adenocarcinomas and appear to arise in the terminal section of the breast ductal tissue. There are many histologic types of breast cancer, and only examples are described here. The most common type is infiltrating ductal carcinoma. Two atypical types of breast cancer are inflammatory carcinoma and Paget's disease. Inflammatory carcinoma of the breast, a systemic disease, is the most malignant form of breast cancer. Edema with dimpling of the skin that results in the skin looking like the peel of an orange (peau d'orange) is usually present. Paget's disease is a rare type of breast cancer involving infiltration of the nipple epithelium.

Breast cancer can metastasize to other sites through the bloodstream or lymphatic system. The common sites of metastasis of breast cancer are bone, brain, lung, liver, skin, and lymph nodes. The staging of the breast cancer (Table 49–7) provides important information for making decisions about treatment options and is also used as a basis for prognosis.

NURSING CARE OF THE OLDER ADULT

Older Women with Breast Cancer

- Although the incidence of breast cancer is increasing among premenopausal women, it is still primarily a disease of older women. However, the needs of older women with breast cancer have been inadequately addressed in the professional literature and in the popular media.
- Women between the ages of 50 and 65 are the group most likely to benefit from annual screening mammography, yet many women in this age group have never had a mammogram. Reasons for lack of compliance with recommendations vary but reports cite costs of copays, indirect costs of obtaining a mammogram even if the mammogram is free, a lack of emphasis on obtaining mammograms by health practitioners and campaigns, and a women's anxiety of the possible breast cancer diagnosis (Lentz et al., 2012). Promotional campaigns for mammography send a confusing message by showing images of women in their 20s and 30s for whom mammography is largely ineffective, rather than women in older age groups who are more likely to benefit from mammography.
- For too long, mastectomy was perceived as the only treatment option open to most older women with breast cancer, even those with early-stage disease. Slowly that perception is changing as breast-conservation treatment gains greater acceptance. The choice of surgical treatment, particularly for older women, is highly individual. Many older women wish to preserve their breasts.
- Although older women with breast cancer may experience coexisting chronic illnesses and impaired physical function, research suggests that they show lower levels of emotional distress than younger women. However, the need for services such as personal care, shopping, housekeeping, and transportation may increase as the ages of the woman and the caregiver increase.

TABLE 49–7 Staging of Breast Cancer

Stage	Tumor	Node	Metastasis
0	T_{is}—Carcinoma in situ or Paget's disease of the nipple	N_0—No regional lymph node metastasis	M_0—No evidence of distant metastasis
I	T_1—Tumor no larger than 2 cm	N_0	M_0
IIA	T_0—No evidence of primary tumor	N_1—Metastasis to movable ipsilateral	M_0
	T_1	axillary nodes	
	T_2—Tumor no larger than 5 cm	N_0	M_0
IIB	T_2	N_1	M_0
	T_3—Tumor larger than 5 cm	N_0	M_0
IIIA	T_0	N_2—Metastasis to ipsilateral fixed	M_0
	T_1	axillary nodes	
	T_2		
	T_3	N_1	M_0
		N_2	M_0
IIIB	T_4—Tumor of any size with direct extension to chest wall or skin	Any N	M_0
	Any T	N_3—Metastasis to ipsilateral internal mammary lymph nodes	M_0
IV	Any T	N_0 and N_1	M_1—Distant metastasis

Manifestations

The manifestations of breast cancer may include a nontender lump in the breast (most often in the upper outer quadrant, the area with the most glandular tissue), abnormal nipple discharge, a rash around the nipple area, nipple retraction, dimpling of the skin, or a change in the position of the nipple (see the accompanying Manifestations box). There may also be nipple pain, scaliness, ulceration, skin irritation, or discharge. Breast cancer is usually painless, but some women report a burning or stinging sensation. Many women with breast cancer have no manifestations, and their tumors are detected by mammography. However, many breast cancers are found by the women themselves or by their partners.

MANIFESTATIONS OF BREAST CANCER

- Breast mass or thickening
- Unusual lump in the underarm or above the collarbone
- Persistent skin rash near the nipple area
- Flaking or eruption near the nipple
- Dimpling, pulling, or retraction in an area of the breast
- Nipple discharge
- Change in nipple position
- Burning, stinging, or pricking sensation

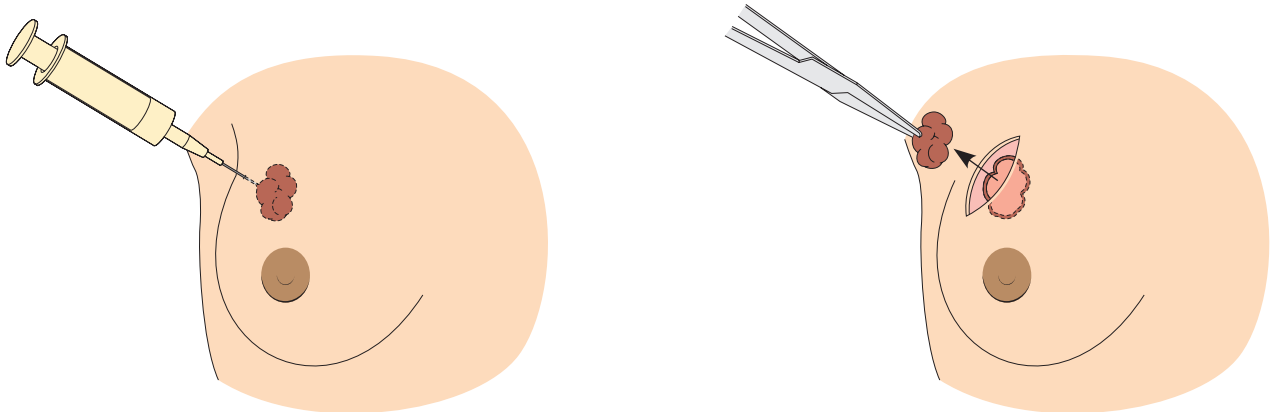
●○● INTERPROFESSIONAL CARE

Diagnosis of breast cancer begins with detection, either detection of asymptomatic lesions discovered through screening or by a partner or symptomatic lesions discovered by the woman. Any palpable mass requires evaluation. Once the diagnosis is made, a number of treatment options are available. The choice of treatment depends on several factors, such as the stage of the cancer, the age of the woman, and the woman's preferences.

DIAGNOSIS

Early detection of breast cancer is possible with clinical breast examination (CBE) and a mammogram (refer to Chapter 47 for further information). Mammography can detect breast tumors 2 years before they reach palpable size; most of these tumors have been present for 8 to 10 years. In addition, an ultrasound, MRI, or PET scan of the breast may be used to further identify breast tumors.

Other diagnostic tests include a percutaneous needle biopsy to define a cystic mass or fibrocystic changes and provide specimens for cytologic examination, and a breast biopsy (Figures 49–7 ■). In aspiration biopsy or fine-needle aspiration biopsy, a needle is used to remove cells or fluid from the breast lesion. In many facilities, fine-needle aspiration biopsies are performed using a stereotactic biopsy device; mammography and a computer are used to guide the needle.



MEDICATIONS

In addition to the hormone therapy described later, bisphosphonates may be used to help strengthen and reduce the risk of fractures in bones weakened by metastatic breast cancer and may help prevent thinning of bone resulting from treatment with aromatase inhibitors or from early menopause as a side effect of chemotherapy. Examples include pamidronate (Aredia) and zoledronic acid (Zometa). Bisphosphonates have many side effects, including flu-like manifestations and bone pain. A rare side effect is damage to the mandible, leading to loss of teeth or bone infection. All patients taking bisphosphonates should practice good oral hygiene and have regular dental checkups to help prevent this effect.

SURGERY

The different types of surgeries used to treat breast cancer are outlined in Table 49–8 and illustrated in Figure 49–8 ■. The type of surgery used depends on the size of the tumor, the woman's age, the type of tumor, and the choice made by the woman after discussing benefits and risks with the surgeon.

Axillary node dissection is generally performed during surgery for all invasive breast carcinoma to stage the tumor. This surgery can cause **lymphedema** (accumulation of fluid in the soft tissues caused by removal of lymph channels) in the arm on the operated side, nerve damage, and adhesions. Nonsurgical methods of detecting lymph node involvement are used to prevent these complications and preserve the role of the lymph nodes in immune system function. Sentinel node biopsy prior to a node dissection is conducted by injecting a radioactive substance or dye into the region of the tumor. The dye is carried to the first (sentinel) lymph node to receive lymph from the tumor that would be the node most likely to contain cancer cells if metastasis has occurred. If the sentinel node is positive, more nodes are removed. If it is negative, further node evaluation is usually not indicated.

A Aspiration biopsy

B Excisional biopsy

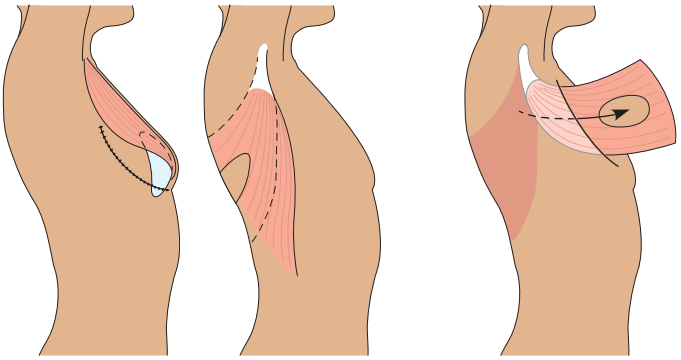
Figure 49–7 ■ Types of breast biopsy. A, In an aspiration biopsy, a needle is used to aspirate fluid or tissue from the breast. B, In an excisional biopsy, tissue from the breast lesion is removed surgically.

TABLE 49–8 Surgical Methods of Treating Breast Cancer

Method	Type	Considerations
Surgery	Breast conserving surgery: • Lumpectomy • Partial (segmental) mastectomy or quadrantectomy	• Lumpectomy removes only the breast lump and a surrounding margin of tissue (refer to Figure 49–8A). Radiation is usually given after a lumpectomy. • A partial mastectomy or quadrantectomy removes more tissue than a lumpectomy; a quadrantectomy removes one-fourth of the breast. Radiation usually follows these surgeries. • Both breast-conserving surgeries are as effective as a mastectomy for stage I or stage II breast cancer. • Radiation may be omitted for women over age 70 with a small tumor that is hormone receptor-positive, who are getting hormone therapy, and who have no lymph node involvement. • Side effects of the surgeries can include pain, temporary swelling, risk for bleeding and wound infection, and hard scar formation.
	Mastectomy (See the Nursing Care box for the woman having a mastectomy on page 1612.)	• A simple or total mastectomy removes the entire breast, but not axillary lymph nodes or muscles under the breast. • A modified radical mastectomy removes the entire breast and some of the axillary lymph nodes (refer to Figure 49–8B). • A skin-saving mastectomy, used for smaller tumors, leaves most of the skin over the breast (except the nipple and areola). • A radical mastectomy (infrequently performed) removes the entire breast, axillary lymph nodes, and pectoral muscles under the breast. • Side effects of these surgeries include postoperative pain, change in the shape of the breast, wound infection, hematoma formation, and seroma (buildup of clear fluid in the wound). If axillary lymph nodes are removed, the main long-term side effect in about one in four women is lymphedema of the arm.

After a mastectomy, some women may choose to have their breast reconstructed. They report that surgical reconstruction of the breast simplifies their lives and restores a sense of body integrity. Other women choose to use a removable breast prosthesis, and some women are comfortable without reconstruction or a prosthesis. Breast reconstruction may be performed at the time of the mastectomy or at any time thereafter, depending on the woman's preference. A number of procedures may be used for the breast reconstruction (Figure 49–9 ■). These include placement of a submuscular implant, the use of a tissue expander followed by an implant, the transposition of muscle and blood supply from the abdomen or back, or using (most often) the transverse rectus abdominis myocutaneous (TRAM) free tissue flap. Information about breast reconstruction surgery is summarized in Box 49–1 on page 1612.

RADIATION THERAPY



Radiation therapy is typically used following breast cancer surgery to destroy any remaining cancer cells that could cause recurrence or metastasis. If a tumor is unusually large, radiation may be used to shrink the tumor prior to surgery. Radiation therapy is most commonly used in combination with lumpectomy for early stage (I or II) breast cancer. Palliative radiation therapy is also used to treat chest wall recurrences and some bone metastases to help control pain and prevent fractures. Radiation therapy is administered by external-beam or tissue implants.

External beam radiation is most commonly used to treat breast cancer. It is performed on an outpatient basis, typically 5 days per week for 5 to 7 weeks. Treatment involves the entire breast; axillary lymph nodes also may be treated with radiation therapy. Intraoperative

A Lumpectomy **B** Modified radical mastectomy

Figure 49–8 ■ Types of mastectomies. A, In a lumpectomy, only the tumor and a small margin of surrounding tissue are removed. B, In a modified radical mastectomy, all breast tissue and the underarm lymph nodes are removed, but the underlying muscles remain.

A Implant **B** Latissimus dorsi musculocutaneous flap

Figure 49–9 ■ Types of breast reconstruction surgeries. A, A breast implant is inserted under the pectoris muscle. B, Autogenous procedures transfer a flap of skin, muscle, and fat from the donor site on the woman's body to the mastectomy site. The most frequently used donor muscle sites are the latissimus dorsi and the rectus abdominis (the TRAM flap).

radiotherapy, available only at selected treatment centers, is provided by a single, concentrated dose of radiation. During surgery, a probe is inserted into the cavity created by the lumpectomy and radiation equivalent to 6 weeks of doses is emitted for about 25 minutes. Another method being researched is using higher doses of radiation over a shorter period of time following lumpectomy (called *accelerated breast irradiation*). This method has shown favorable results in cancer treatment while at the same time limiting the cost and time constraints placed on women compared with traditional radiation treatments.

In brachytherapy (internal radiation), radioactive seeds or pellets are placed directly into the breast tissue following lumpectomy. It may be used to provide a supplemental dose of radiation after external beam radiation. Intracavity brachytherapy consists of inserting

BOX 49–1 Breast Reconstruction Information

- Controversy exists about the health effects of silicone. While there is no conclusive evidence that silicone implants induce cancer or autoimmune disease, they are associated with hardening and pain due to contracture of the capsule around the implant. The implant may rupture, releasing silicone gel, or infection may occur. Saline-filled breast implants may be an alternative.
- Reconstruction can be done immediately after a mastectomy, or at any time later on. Some surgeons believe that delayed reconstruction offers better cosmetic results.
- Reconstructive surgery can create a natural-looking breast that makes clothes fit better. Since it has no nerve endings, the reconstructed breast has no feeling or sensations.
- If a simple mastectomy is done, an implant approximately the same size as the other breast is placed under the pectoral muscle on the operative side. This creates a breast mound that closely resembles the natural breast in shape and softness. If the implant is placed over the pectoral muscle, a high degree of firmness may occur.
- With a simple mastectomy or modified radical mastectomy, a tissue expander may be used to replace the breast. The tissue expander is placed under the pectoral muscle and gradually expanded with saline injections every 2 to 3 weeks to stretch the overlying skin and create a pocket. After a period of time, usually 1 to 2 months, the tissue expander is exchanged for a saline implant.
- With more extensive surgery such as radical mastectomy, a flap of skin, fat, or muscle is transferred from a donor site to the operative area. A new nipple may be created by using tissue from the opposite nipple or from the inner thigh.
- Reconstructive surgery may require multiple surgeries, including all the risks associated with anesthesia. As the complexity of the procedures increases, so does the risk of complications such as infection.
- To decrease the risk of a fibrous capsule forming around the implant, it is important to perform breast massage as instructed.

NURSING CARE OF THE PATIENT

Having a Mastectomy

- Encourage deep-breathing exercises and use of incentive spirometry every 4 hours. *Deep-breathing exercises are important to assure effective ventilation of the lungs after general anesthesia, particularly with the restrictive surgical dressing that decreases chest expansion.*
- Monitor drainage from wound. *A suction apparatus may be placed in the wound to allow drainage of excess body fluids that accumulate when the lymph nodes are removed. This device is usually removed 3 to 5 days after surgery.*
- Administer, as ordered, intravenous fluids and antibiotics. *An IV line may be in place for fluid replacement and antibiotics to reduce the risk of postoperative infection.*
- Instruct the woman how to control pain by using a patient-controlled analgesia device or requesting analgesics before pain becomes severe. *Taking analgesics as needed facilitates deep breathing and movements during physical therapy interventions.*
- Monitor the dressing for bleeding. *Careful assessment for bleeding and of vital signs is important in preventing hemorrhage.*
- Instruct the woman about the following to decrease anxiety, promote healing, and decrease postoperative risks:
  - Numbness or feelings of "pins and needles" in the axillary area are common.
  - Lying on one's back or on the side not operated on helps fluid drain from the site.
  - Moving the arm on the operated side helps regain mobility; specific exercises will be prescribed for increasing mobility after the incisions have healed.
  - Use caution when lifting heavy objects with the arm on the operated side.
  - Be careful about injury and infection on the affected side; wear rubber gloves when washing dishes, garden gloves when working outside. Request that caregivers do not perform blood pressures or venipunctures on the operative side to reduce the risk of injury and infection.
  - Feelings of anxiety, sadness, and fear of looking at the incision are normal; mastectomy means abrupt change in body image. It is normal to mourn the loss of a breast and to fear the loss of one's life after a cancer diagnosis.
  - Sexual intimacy can be affected by mastectomy; it often helps to be able to discuss potential sexual problems with one's partner, with a counselor, or with a breast cancer support group.

MEDICATION ADMINISTRATION

Tamoxifen

TAMOXIFEN (NOLVADEX)

Tamoxifen is the most widely prescribed breast cancer drug, commonly given to prevent recurrence of estrogen-positive breast cancer in postmenopausal women. It inhibits tumor growth by blocking the estrogen receptor sites of cancer cells. Tamoxifen increases a woman's risk of developing endometrial cancer, deep venous thrombosis (DVT), and pulmonary embolism.

Nursing Responsibilities

- Assess for potential contraindications to therapy.
- Assess liver function tests; tamoxifen may interfere with liver function.

Health Education for the Patient and Family

- If in childbearing years, use a nonhormonal, barrier form of contraception; tamoxifen has adverse effects on the developing fetus.
- Take the drug as prescribed until the physician indicates otherwise.
- Side effects commonly experienced by women taking tamoxifen are hot flashes, vaginal dryness, irregular periods, and weight gain.
- Do not smoke while taking tamoxifen; smoking further increases the risk of DVT.
- Promptly report any abnormal vaginal bleeding (nonmenstrual bleeding, bleeding after menopause) to your primary care provider.

a small balloon attached to a small tube (that protrudes through the surgical site) into the cavity left by a lumpectomy. The balloon is filled with saline and a source of radioactivity is placed into the balloon and then removed. After 5 days of treatment, the balloon is removed. Interstitial brachytherapy is performed by inserting several small catheters into the breast around the lumpectomy. Radioactive pellets are inserted through the catheters for a short period of time each day and then removed. Clinical trials are being conducted to determine if these therapies might be used as the only source of radiation for women having a lumpectomy.

CHEMOTHERAPY

Chemotherapy has become the standard of care for the majority of breast cancer cases with axillary node involvement. In late metastatic disease, chemotherapy becomes the primary treatment to prolong the woman's life. Neoadjuvant chemotherapy is chemotherapy given before surgery; it can shrink large tumors so they are small enough to be removed by a lumpectomy instead of a mastectomy. Adjuvant (additional) systemic therapy following primary treatment for early-stage breast cancer refers to the administration of chemotherapy and other pharmacologic agents after surgery. This type of therapy has been widely studied; its use reduces the rates of recurrence and death from breast cancer. For example, letrozole (Femara, an aromatase inhibitor) has reduced the risk of recurrence after surgery (in some cases more effectively than tamoxifen).

HORMONE THERAPY

Tamoxifen citrate (Nolvadex) and toremifene (Fareston) are oral medications that block estrogen activity. They are used to treat advanced breast cancer, as an adjuvant for early-stage breast cancer, and as a preventive treatment for women at high risk of developing breast cancer. Nursing implications for tamoxifen are presented in the accompanying Medication Administration box. Tamoxifen can be used to treat metastatic breast cancer, and if taken for 5 years following surgery, can reduce the risk of cancer reoccurrence by about half (ACS, 2012c). Toremifene (Fareston) is mainly used to treat postmenopausal women with advanced cancers. Fulvestrant (Faslodex) is a drug that eliminates estrogen receptors. Given by injection once a month, it is currently only approved for postmenopausal women with advanced cancer that no longer responds to tamoxifen or toremifene.

Immunotherapy, using trastuzumab (Herceptin), is used to stop the growth of breast tumors that express the HER2/neu receptor (which binds an epidermal growth factor that contributes to cancer cell growth) on their cell surface. This drug is a recombinant DNA-derived monoclonal antibody that binds to the receptor, inhibiting tumor cell proliferation. It is given intravenously either once a week or as a larger dose every 3 weeks. Side effects include fever and chills, weakness, nausea, vomiting, cough, diarrhea, and headache. A more serious possible side effect is cardiac damage, leading to congestive heart failure. Other drugs that are used include lapatinib (Tykerb) and bevacizumab (Avastin), an oral drug that also targets the HER2 protein.

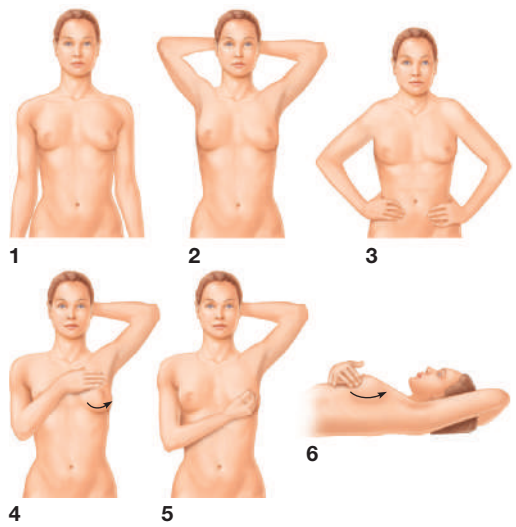
The aromatase inhibitors stop the production of estrogen in postmenopausal women by blocking the enzyme aromatase (which turns androgen into small amounts of estrogen in the body). The drugs, in oral form, are anastrozole (Arimidex), exemestane (Aromasin), and letrozole (Femara). In a comparison of aromatase inhibitors with tamoxifen in treating early-stage, hormone-receptor-positive breast cancer in postmenopausal women, most physicians recommend an aromatase inhibitor as the best hormone therapy to start with because it has more benefits and fewer serious side effects (Breastcancer.org, 2012).

●○● NURSING CARE

Breast cancer is not one disease entity, but many, depending on the affected breast tissue, the tissue's estrogen dependency, and the age of the person at onset. The psychosocial effect of breast cancer extends beyond the fear and threat of death. The diagnosis may transform the woman's sense of self and lead to reintegration or negotiation of family relationships. See the accompanying Case Study & Nursing Care Plan for a woman with breast cancer on page 1617.

Health Promotion

Although controversy exists about the ability of screening mammography to improve mortality rates for women under age 50, the ACS recommends an annual mammogram and clinical breast exam (CBE) by a healthcare professional beginning at age 40. Women in their 20s and 30s should have CBE at least every 3 years. A screening MRI is recommended for women with an approximately 20% to



25% or greater lifetime risk of breast cancer, including women with a strong family history of breast or ovarian cancer and women who have been treated for Hodgkin's lymphoma with radiation. As with any screening examination, decisions about timing should be made by the woman after discussion with her healthcare provider.

The ACS recommends breast self-examination (BSE) as an optional measure, but its use is supported by other cancer-related organizations as well as by many physicians. Information on how to perform BSE is included in Box 49–2 to enable nurses to provide teaching as prescribed or requested. Premenopausal women should perform BSE 7 to 10 days from the first day of their menstrual period, because hormonal changes increase breast tenderness and lumpiness prior to menses. Postmenopausal women should choose one date of the month (for example, the first day of the month) for BSE.

Educational messages about breast cancer screening need to be culturally sensitive to the intended audience. Media campaigns promoting mammography often show young White women, an approach that has proved ineffective among women of color (see the accompanying Moving Evidence into Action box), although cancer screening is increasing in this population. By working with women of different races and cultures, nurses can help make breast cancer education more meaningful to women in these groups.

BOX 49–2 Breast Self-Examination (BSE)

- Lie down on your back and place your right arm behind your head. (BSE should be done while lying down because this position spreads breast tissue evenly over the chest wall, making it easier to feel all the breast tissue.)
- Use the finger pads of the middle fingers on your left hand to feel for lumps in the right breast. Use overlapping dime-sized circular motions of the finger pads to feel the breast tissue.
- Use three different levels of pressure to feel all the breast tissue. Light pressure is needed to feel the tissue closest to the skin, medium pressure to feel a little deeper, and firm pressure to feel the tissue closest to the chest and ribs. A firm ridge in the lower curve of each breast is normal. Use each pressure level to feel the breast tissue before moving on to the next spot.
- Move around the breast in an up-and-down pattern starting at an imaginary line drawn straight down your side from the underarm and moving across the breast to the middle of the chest bone (sternum, breastbone). Be sure to check the entire breast area, going down until you feel only ribs, and up to the neck or collar bone.
- Repeat the exam on your left breast, using the finger pads of your right hand.
- Stand in front of the mirror with your hands pressing firmly down on your hips. Look at your breasts for any changes in size, shape, contour, or dimpling.
- Examine your underarm while sitting or standing and with your arm only slightly raised.
- If you find any changes, see your healthcare provider as soon as possible.

Assessment

Collect the following data through the health history and physical examination. Further focused assessments are described with nursing interventions.

- *Health history:* family history of breast cancer, breast changes, nipple discharge, use of HRT, previous diagnostic tests and treatment for cancer, menstrual history, pregnancies, alcohol intake, physical activity, dietary history
- *Physical assessment:* height and weight, breasts, axillary lymph glands.

Priorities of Care

Because lumpectomy and mastectomy are routinely performed in an ambulatory surgery basis and most continuing care (e.g., radiation therapy, chemotherapy) occurs in outpatient settings, education of the patient and her family is the nursing care priority.

Diagnoses, Outcomes, and Interventions

Although each woman has individual needs, nursing diagnoses prior to surgery are concerned with anxiety, decisional conflict, grief, risk for infection, risk for injury, and disturbed body image over the loss of a breast. Because the typical hospital stay is short, usually from 1 to 3 days, preoperative teaching is done on an outpatient basis.

Anxiety

A woman of any age with breast cancer is often anxious about the diagnosis, the surgery, the outcome of surgery if nodal involvement is found, and the possible changes in sexual and family relationships. Studies show that young women with breast cancer, a growing population, are particularly vulnerable for anxiety and other psychosocial effects, as are their spouses and their children. Young women with breast cancer often have a more aggressive disease and a lower survival rate when compared with older women with breast cancer (Schuiling & Likis, 2013).

Expected Outcome: Patient will demonstrate anxiety relief related to breast cancer by focusing on knowledge about condition, treatment and surgical options, and utilization of interpersonal support systems.

- Provide opportunities to express thoughts and feelings. In this process, the woman can name her fears. *Once the fears are named, the nurse may simply listen, educate, or dispel fears that stem from lack of understanding.*
- Discuss with the woman her knowledge of breast cancer. *Assessing the woman's knowledge of breast cancer helps the nurse plan more effective teaching.*

Evidence for Nursing Care

The Patient with Breast Cancer

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Easley, J., & Miedema, B. (2012). Rehabilitation after breast cancer: Recommendations from young survivors. *Rehabilitation Nursing*, *37*(4), 163–170.
- Heisey, R., Clemons, M., Granek, L., Fergus, K., Hum, S., Lord, B., . . . Fitzgerald, B. (2011). Health care strategies to promote earlier presentation of symptomatic breast cancer: Perspectives of women and family physicians. *Current Oncology*, *18*(5), 227–348.
- Quirion, E. (2010). Recognizing and treating upper extremity lymphedema in postmastectomy/lumpectomy patients: A guide for primary care providers. *Journal of the American Academy of Nurse Practitioners*, *22*, 450–459.

- Encourage discussion relating to immediate concerns about resuming her life at home and the changes she must make. *Anticipatory guidance can help her plan for and cope with changes in her life and relationships.*
- Explain the surgical procedure, including information about preoperative medications, anesthesia, and recovery. *Knowing what to expect helps to decrease anxiety.*
- Explain that it is normal to have decreased sensation in the surgical area. *Severed or damaged nerves reduce sensation.*

Decisional Conflict

The woman with breast cancer must make life-changing decisions about treatment within a relatively brief and highly stressful time. Her age, menopausal status, and stage of cancer are only some of the factors that affect her decisions. Culture, values, lifestyle, socioeconomic status, and self-esteem also are considered.

Expected Outcome: Patient will demonstrate reduced decisional conflict by participating in healthcare decisions.

- Provide an opportunity for the woman to ask questions; answer questions as simply and directly as possible. Make eye contact and pay attention to body language. *During this time, the woman can process information and make informed decisions.*
- Focus on immediate concerns, and provide up-to-date written material for the woman to review. *Written material provides easy reference to information not processed immediately because of anxiety and stress.*
- Listen to the woman in a nonjudgmental manner during her decision-making process. *Nonjudgmental, empathic listening helps the woman process information and make informed decisions. Only she knows the context of her life.*
- If the woman wishes, provide opportunities for her to meet with other women who have had breast cancer surgery. *Not all women are ready to meet others in their situation, but opening the door to this resource is appropriate. The woman may choose to talk with these women after the surgery.*
- Facilitate a team approach with the surgeon, anesthesiologist, oncologist, plastic surgeon, and other health professionals. *Being the woman's advocate during this time of anxiety and decision making reduces the stress of coordinating multiple healthcare provider schedules.*

Moving Evidence into Action

Improving the Diagnosis and Treatment of Black Women with Breast Cancer

Despite efforts to improve both the diagnosis and treatment of women with breast cancer, Black women die more often from breast cancer than other groups of women. To a certain extent, this is because of Black women's advanced stage of disease at diagnosis, primarily due to a delay in seeking treatment. Psychological, social, and cultural factors contribute to this delay, including a lack of culturally sensitive health information. Northington and colleagues (2011) studied actual and perceived barriers to breast cancer screening in an effort to develop and implement an effective integrated community education model for medically underserved women. Cost and inadequate financial resources were the primary reasons cited by participants for not obtaining a mammogram; access, lack of knowledge, and lack of trust in the healthcare system and healthcare providers also contributed.

Implications for Nursing

Nurses must consider multiple factors when considering what may or may not influence Black women to delay seeking diagnosis and treatment for breast cancer, including healthcare disparities, knowledge about breast cancer and its detection and treatment, as well as perceptions and health beliefs. It is important that nurses do not assume that a delay in seeking care exists, but rather make assessments and design interventions based on consideration of both individual and group cultural differences.

Moving Knowledge into Action

1. What barriers to breast cancer screening in women of all races can you identify? Do you think these barriers differ based on culture, race, or socioeconomic level? Why or why not?
2. Are there barriers to breast cancer screening that might be unique to Black women? To Hispanic women? To Asian American women?
3. What type of questions would you include in a health assessment to identify women who may be worried about breast cancer, but have not sought diagnosis?

Grieving

Breast surgery, even a lumpectomy, alters the appearance of the breast. This loss of appearance, as well as the diagnosis of cancer, is expressed through grief.

Expected Outcome: Patient will demonstrate successful resolution of grief by adapting to changes in body image, and role.

- Listen attentively to expressions of grief and watch for nonverbal cues (failure to make eye contact, crying, silence). *Not all women will express grief clearly; sometimes unspoken grief is the most painful. Grief is relieved only when expressed in a nonthreatening environment.*
- Allow time to interact and do not rush interactions. *Taking time to be with the woman communicates caring.*
- Explain that it is normal to have periods of depression, anger, and denial after breast surgery. *All these feelings are appropriate expressions of grief.*
- If the woman wishes to do so, involve the partner in helping the woman cope with her grief. *Remember that the partner may also be grieving. Not all women want to share their grief, and not all partners are interested and supportive.*

Risk for Infection

Like any surgical patient, the woman who has breast surgery is at risk for infection. Removal of lymph nodes and the presence of a draining wound increase the risk.

Expected Outcome: Patient will describe symptoms of postoperative incisional infection and importance of early reporting of symptoms.

- Assess the surgical dressings for bleeding, drainage, color, and odor every 4 hours for 24 hours and document your findings. Circle any visible bleeding and drainage on the dressing as a baseline for subsequent assessment. *Excessive bleeding or drainage signals postoperative complications that may require emergency attention.*
- Observe the incision and IV sites for pain, redness, swelling, and drainage. Assess the drainage system for patency and adequate suction; note the color and amount of drainage. *Careful observation for any signs of infection is essential because the woman's immune system is compromised. IV catheters should be placed on the uninvolved side only.*
- Change dressings and IV tubing using aseptic technique. *Moist dressings and intravenous tubing provide sites for bacterial growth. Routine dressing and IV tubing changes using aseptic technique reduce the risk for infection.*
- Encourage a protein-rich diet. Discuss the woman's nutritional status with the dietitian and request a consultation for the woman. *Adequate nutrition promotes healing and boosts the immune system.*
- Teach the woman how to care for the drainage system, if present (clean the site, empty the device, and record the amount, color, and type of drainage). *The woman is often discharged prior to removal of the drainage system and dressings and needs teaching to provide self-care.*
- At discharge, teach the woman to watch for and report to her healthcare provider the manifestations of infection: fever, redness or hardness at the surgical site, or purulent drainage. *Any of these manifestations should be reported to the physician/surgeon. Knowing the signs and symptoms of infection prepares the woman to seek prompt treatment if infection occurs.*
- Explain that she may experience scaling, flaking, dryness, itching, rash, or dry desquamation of the skin, particularly after radiation therapy. *Impaired skin integrity increases the risk of infection.*
- Tell the woman to avoid deodorants and talcum powder on the affected side until the incision is completely healed. *These substances may irritate the skin and impede healing.*

Impaired Tissue Integrity

Removal of the axillary lymph nodes puts the woman at risk for lymphedema (LE), a complication that involves an abnormal accumulation of lymph in the arm, shoulder, breast, or thoracic area. It is estimated that this complication affects as many as half of all breast cancer survivors. This complication may develop at any time following a mastectomy, but usually develops within the first 3 years after the surgery. (Quirion, 2010).

Expected Outcome: Patient will demonstrate skin integrity by supportive skin care to promote healing and reduce skin breakdown.

- Assess/monitor for manifestations of LE: swelling in the affected area (usually the hand and arm), pain, fatigue, and changes in sensations (such as heaviness, numbness, or burning) in the affected area. Assess skin color, temperature, texture, scars, or lesions. Ask about tighter rings. Measure the affected extremity 10 cm (4 in) above and 5 cm (2 in) below the olecranon process on a regular basis and record findings. *When an obstruction to the flow of lymphatic fluid develops, large proteins filter through the lymph vessels and accumulate in an area distal to the obstruction; fluid accumulates, causing tissue and skin changes. Accurate assessments are necessary to identify new-onset LE and to monitor already present LE for progression or improvement.*
- When obtaining blood pressure, blood draws, and starting IVs, use the nonsurgical side. *Compression of the arm on the surgical side may increase the risk of developing LE; if skin integrity is compromised, the risk for infection increases.*
- Following surgery and while sleeping, elevate the affected arm higher than the shoulder on a pillow, but do not abduct it; the hand should be higher than the elbow. *Elevating the arm permits drainage, prevents swelling, and promotes circulation.*
- Instruct the woman to report any manifestations of infection, including increased swelling, pain, heat, and redness in the affected area, as well as fever and generalized malaise. *Infection may involve cellulitis or lymphangitis, requiring medical treatment with antibiotics. Infection may also precipitate or worsen existing LE.*
- Explain about measures to control and/or reduce swelling and refer to a certified LE therapist: compression bandaging, manual lymph drainage, exercises, wearing a LE sleeve. *These lifelong measures can often control and even reduce the swelling of LE.*
- Teach the woman the following guidelines for care of the affected area *to prevent progression or onset of LE and to prevent infection in the affected area*:
  - Avoid injury from very hot water, popping grease when cooking, and playing sports such as golf.
  - Avoid tight clothing, jewelry, and elastic bands on the affected extremity.
  - Avoid carrying a purse or briefcase on the affected side.
  - Keep skin and nails clean and well cared for.
  - Use cream or lotion to keep the skin moist.
  - Treat small cuts with an antibiotic cream.
  - Use a thimble when sewing or doing handwork.
  - Wear gloves when gardening.

Disturbed Body Image

Breast surgery can change the woman's body image. The surgical changes may be compounded by weight gain and other side effects of chemotherapy or hormone therapy. Self-esteem also affects adjustment to a changed body image.

Expected Outcome: Patient will demonstrate appropriate body image by use of effective coping strategies to develop acceptance of changes in body.

- Assess how the woman views her body. Discuss with the woman what image of herself she had prior to surgery. *Self-image is related to self-esteem. Discuss whether her self-image has changed.*
- Explain that redness and swelling in the scar will fade with time. *The knowledge that the scar will fade may give the woman a more realistic view of the changes.*
- Include the partner and family if possible when discussing the plan of care and activities of daily living (ADLs). Request consultation with a psychologist or other professional if the woman is interested. *Discussion with the partner and family can facilitate the woman's emotional healing process.*
- Offer pamphlets and suggest books and videos that might increase knowledge about what lies ahead. *Knowing what to expect can help the woman cope.*
- Encourage the woman to look at her incision when she feels ready; often the reality is not as frightening as the woman had imagined.

Explain that it is normal to be afraid to look. *Reassurance that her behavior is normal decreases anxiety.*

- If the woman is interested in breast reconstruction, provide written material and encourage her to talk with a plastic surgeon and with women who have had reconstruction. *It is important for the woman to be fully informed about available options to make an informed decision.*

Continuity of Care

The woman with breast cancer and her family have much to learn to provide self-care at home. Address the following topics in preparation for home care:

- Manifestations of infection and the need to report any that occur to her healthcare provider.
- The importance of ADLs, such as eating, combing her hair, and washing her face.
- Postmastectomy exercises (see examples in Figure 49–10 ■) and lymphedema care as approved by the healthcare provider and physical/occupational/LE therapist.
- The need for adequate rest and emotional support.
- Participation in a breast cancer support group and online information services and bulletin boards for sources of education and support.
- Prosthesis management, if this option is chosen. (A temporary lightweight prosthesis may be worn immediately after the drains and sutures have been removed from the surgical site. Because prostheses are expensive, a permanent one should not be purchased until the wound has completely healed. Prostheses are available at medical stores and many larger department stores. Most private and government insurance policies pay for the first prosthesis.)
- Helpful resources include Reach to Recovery, the American Cancer Society, the National Breast Cancer Coalition, and the National Lymphedema Network.

CASE STUDY & NURSING CARE PLAN A Woman with Breast Cancer

Rachel Clemments is a 42-year-old mother of two: Sarah, age 12, and Jennifer, age 18. Because of a family history of breast cancer, she has been closely monitored (annual mammograms and CBE, monthly BSE, a needle aspiration biopsy with negative findings) for 4 years prior to her diagnosis. Mrs. Clemments discovers a lump in her left breast while taking a shower. An incisional biopsy reveals invasive lobular carcinoma in the left breast. Mrs. Clemments is debating whether to have reconstructive breast surgery. One of her greatest concerns is how her illness will affect her ability to support and care for her daughters. The breast cancer diagnosis seems part of the family legacy. She wonders, "When will it happen to Jennifer? To Sarah?"

ASSESSMENT

During the history, Laura Nelson, RN, the nurse admitting Mrs. Clemments, learns that her mother, two of her aunts, and one sister had been diagnosed with breast cancer. Her mother and one of the aunts died before age 45. Physical assessment findings include T 37.0°C (98.5°F), BP 110/62 mmHg, P 65 bpm, R 14/min. Her weight is 54 kg (120 lb); she is 168 cm (66 in.) tall. Modified radical mastectomy is performed; histologic examination shows a 3-cm tumor; axillary node dissection shows that 4 of 16 lymph nodes are positive.

DIAGNOSES

- *Risk for Infection* related to surgical incision
- *Acute Pain* related to surgery
- *Disturbed Body Image* related to loss of breast
- *Decisional Conflict* about treatment, related to concerns about risks and benefits
- *Fear* related to disease process/prognosis

EXPECTED OUTCOMES

- Patient will remain free of infection.
- Patient will experience minimal pain or discomfort during her recovery.
- Patient will maintain a positive body image, regardless of her decision about reconstruction.
- Patient will evaluate the treatment options in relation to personal values and decide on a course of action.
- Patient will identify the sources of her fear and demonstrate behaviors that may reduce fears.

PLANNING AND IMPLEMENTATION

- Teach her about hand hygiene and wound care.
- Assess her pain tolerance and administer analgesics as prescribed.
- Teach her to use caution when moving the arm on the operated side, to avoid lifting heavy objects, and to wear gloves when gardening.
- Encourage her to discuss her thoughts and feelings about her body changes.
- Suggest that she talk with a Reach to Recovery volunteer about her thoughts and feelings.
- Assess her interest in spiritual/religious support and refer if appropriate.
- Discuss the use of a temporary prosthesis and later the fitting of a permanent prosthesis (6 to 8 weeks after surgery), the need to be fitted by an experienced person, and insurance reimbursement for the prosthesis.
- Discuss the possibility of attending a breast cancer support group where she can draw on the experiences of other women who have undergone mastectomy, chemotherapy, or radiation.
- Encourage her to verbalize her fears about her own prognosis and about her daughters' future risk of breast cancer; assess the need/interest for referral to psychologic counseling.

EVALUATION

At discharge, Mrs. Clemments has no signs of physical complications and is looking forward to being at home with her daughters as temporary caregivers. Mrs. Clemments met with a Reach to Recovery volunteer, who brought her a temporary prosthesis and booklets about postmastectomy exercises, chemotherapy, and breast reconstruction. The volunteer also referred her to a local cancer support group. Mrs. Clemments has talked about her concerns related to breast reconstruction. "I want to avoid anything that would increase the risk of complications. The possibility of recurrence and my fear for my daughters' future health are more than enough to worry about."

Clinical Reasoning in Patient Care

1. What role could genetic counseling play in helping Mrs. Clemments and her daughters better understand the daughters' risk of breast cancer?
2. Describe the types of mastectomies and their implications for nursing care.
3. What medications might help minimize the side effects of chemotherapy?
4. Develop a plan of care for Mrs. Clemments for the nursing diagnosis *Disturbed Sleep Pattern*.

See Evaluating Your Response in Appendix B.

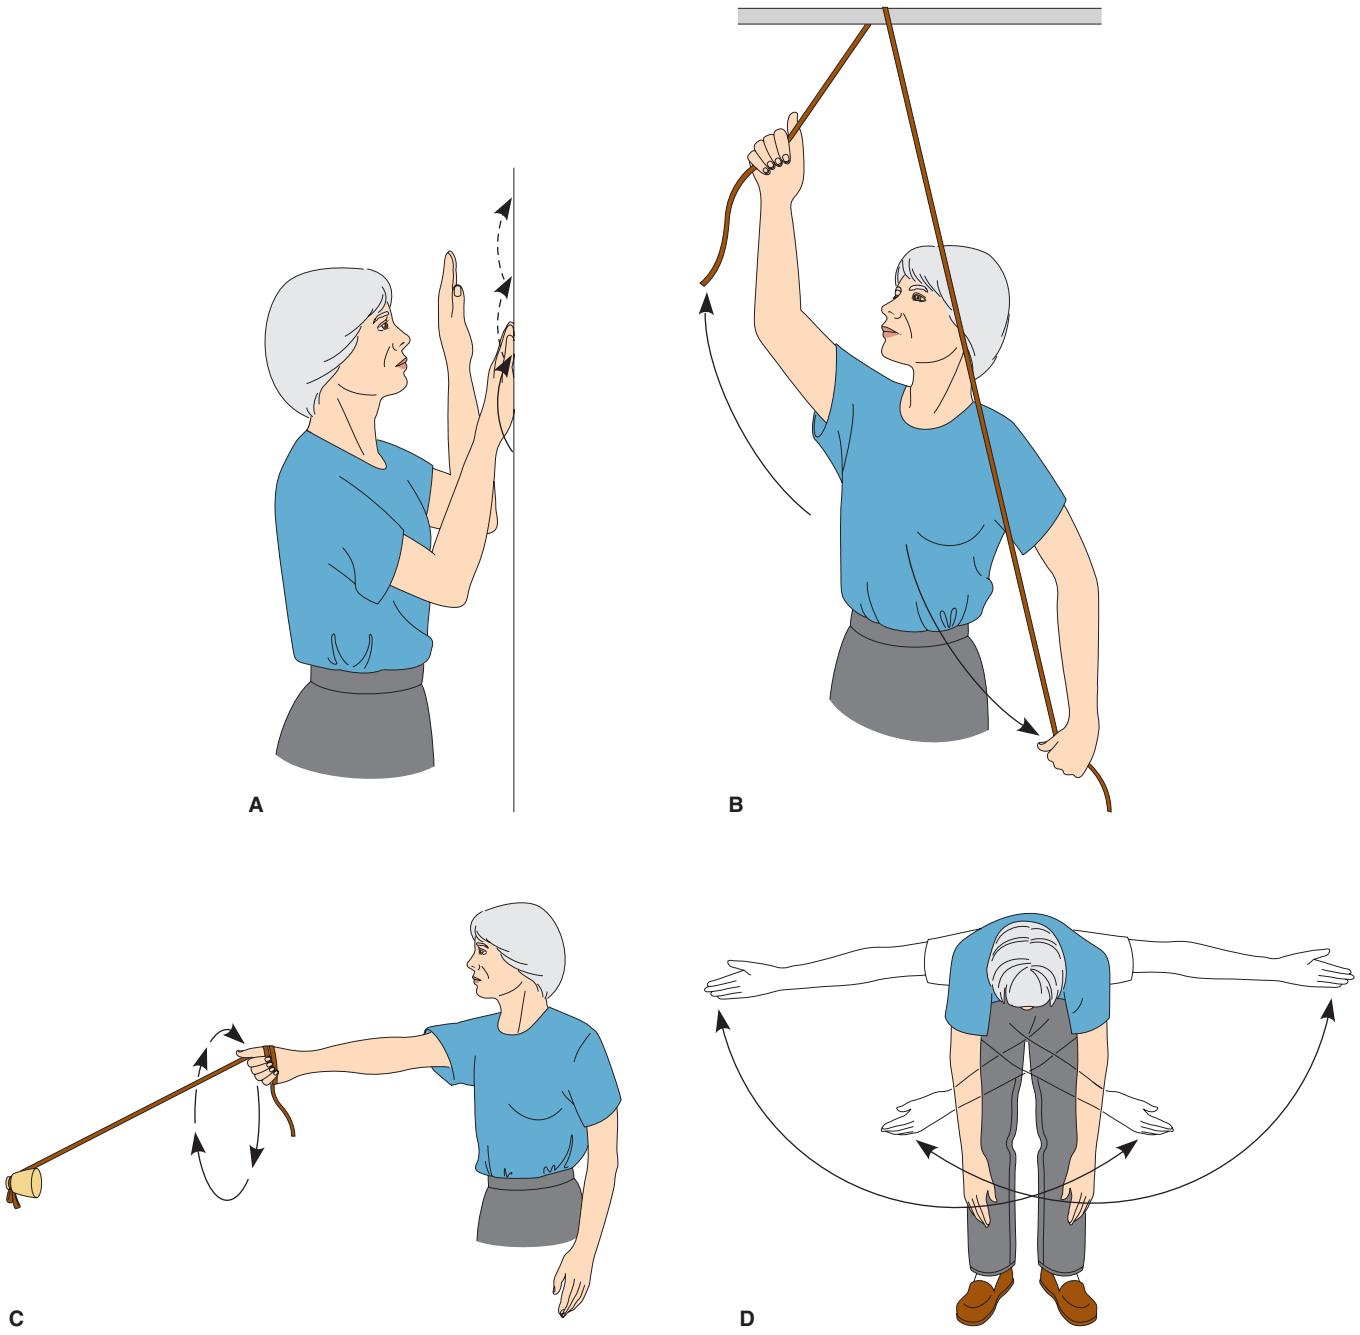


Figure 49–10 ■ Examples of postmastectomy exercises. A, Wall climbing: Stand facing wall with toes 6 to 12 inches from wall. Bend elbows and place palms against wall at shoulder level. Gradually move both hands up the wall parallel to each other until incisional pulling or pain occurs. (Mark that spot on wall to measure progress.) Work hands down to shoulder level. Move closer to wall as height of reach improves. B, Overhead pulley: Toss 6-foot rope over shower curtain rod (or over top of a door that has a nail in the top to hold the rope in place for the exercise). Grasp one end of rope in each hand. Slowly raise operated arm as far as comfortable by pulling down on the rope on opposite side. Keep raised arm close to your head. Reverse to raise unoperated arm by lowering the operated arm. Repeat. C, Rope turning: Tie rope to door handle. Hold rope in hand of operated side. Back away from door until arm is extended away from body, parallel to floor. Swing rope in as wide a circle as possible. Increase size of circle as mobility returns. D, Arm swings: Stand with feet 8 inches apart. Bend forward from waist, allowing arms to hang toward floor. Swing both arms up to sides to reach shoulder level. Swing back to center, then cross arms at center. Do not bend elbows. If possible, do this and other exercises in front of mirror to ensure even posture and correct motion.

CHAPTER HIGHLIGHTS

- **Many different illnesses, medications, and surgical procedures may affect female sexual function. It is important for nurses to initiate a conversation regarding sexual concerns with female patients and respond in a caring, nonjudgmental manner.**
- **Disorders of the female reproductive system can include benign as well as malignant diagnoses. It is important to understand the emotional concerns of anxiety and fear of the diagnoses as well as the treatments.**
- **Menopause is a normal physiologic life event but may result in many changes in the woman's body including osteoporosis, fractures, and cardiovascular disease.**
- **Cervical and breast cancer are common forms of cancer in women. Cervical cancer is linked to HPV infection and can be prevented or diagnosed early with cervical exams and pap smears. Mammograms can detect breast cancer at an early stage. Education is necessary to encourage early diagnosis and prevention.**

TEST YOURSELF NCLEX-RN® REVIEW

1. During a health assessment at a local clinic, a 50-year-old female patient tells the nurse about having some pain with intercourse. Because the nurse is uncomfortable discussing this topic, what should the nurse respond to the patient?
   1. "Do you normally enjoy sexual activity?"
   2. "What do you think is causing your problem?"
   3. "I don't know anything about that; please ask someone else."
   4. "I know this can be a problem; please discuss it with your physician."

2. The nurse is reviewing the effects of long-term estrogen deprivation with a premenopausal patient. About which physical disorders should the nurse discuss that the patient might be at risk for developing in the future? (Select all that apply.)
   1. fractures
   2. osteoporosis
   3. colon cancer
   4. cervical cancer
   5. cardiovascular disease

3. The nurse is conducting an educational seminar for postmenopausal women. When discussing calcium intake, what amount in milligrams per day should the nurse instruct as being recommended? _____ mg/day

4. The nurse is teaching a female patient with a uterine displacement disorder about Kegel exercises. Which health problem should the nurse explain that these exercises help to reduce?
   1. retroversion
   2. menorrhagia
   3. vaginal discharge
   4. stress incontinence

5. The nurse is preparing a health promotion seminar for high school students. Which topic should the nurse include to reduce the risk of cervical cancer?
   1. weight loss
   2. safer sex methods
   3. a diet high in iron
   4. yearly mammograms

6. When discussing dietary guidelines with a patient experiencing PMS, the nurse recommends reducing sodium intake. What is the rationale for this recommendation?
   1. Sodium restriction helps minimize fluid retention.
   2. In and of itself, sodium is not harmful but it may increase cancer risk.
   3. Sodium increases thirst, thereby facilitating increased oral fluid intake.
   4. Sodium increases reactive hypoglycemia, increasing physical manifestations.

7. A female patient with endometriosis is entering menopause. What should the nurse explain that occurs to endometrial implantations after menopause?
   1. Each implant enlarges.
   2. They tend to become malignant.
   3. The number of implants increases.
   4. They tend to atrophy and disappear.

8. The nurse is designing a home care teaching plan for a patient recovering from an abdominal hysterectomy. What interventions should be included in this plan? (Select all that apply.)
   1. Take regular rest periods.
   2. Restrict heavy lifting for 4 to 6 weeks.
   3. Take tub baths until bleeding has stopped.
   4. Avoid coughing and deep breathing at home.
   5. Report an increase in temperature or severe pain.

9. The nurse is preparing an educational session on women's health issues. Of the following female participants, which one would be most at risk for breast cancer?
   1. age 45, very thin
   2. age 23, two children
   3. age 33, never pregnant
   4. age 64, positive family history

10. The nurse observes a female patient scheduled for a mastectomy as treatment for breast cancer quietly crying in the room. Which nursing diagnosis should the nurse identify as being appropriate for the patient at this time?
   1. *Fatigue*
   2. *Grieving*
   3. *Risk for Injury*
   4. *Disturbed Body Image*

50 Nursing Care of Patients with Sexually Transmitted Infections

LEARNING OUTCOMES

1. Explain the incidence, prevalence, characteristics, and prevention/control of sexually transmitted infections (STIs).
2. Compare and contrast the pathophysiology, manifestations, interprofessional care, and nursing care of genital herpes, genital warts, vaginitis, chlamydia, gonorrhea, syphilis, and pelvic inflammatory disease.
3. Explain the risk factors for and complications of STIs.
4. Discuss the effects and nursing implications of medications and treatments used to treat STIs.

CLINICAL COMPETENCIES

1. With sensitivity and respect for diversity, assess the health status of patients with STIs and recognize, monitor, document, and report abnormal or unexpected manifestations.
2. Determine priority nursing diagnoses and select and implement evidence-based and patient-centered nursing interventions for patients with STIs.
3. Administer topical, oral, and injectable medications knowledgeably and safely.
4. Integrate interprofessional care into care of patients with STIs.
5. Provide teaching appropriate for prevention, control, and self-care of STIs.
6. Revise plan of care as needed to provide effective interventions to promote, maintain, or restore functional health status of patients with STIs.

MAJOR CHAPTER CONCEPTS

- Sexually transmitted infections (STIs) are infections transmitted by sexual contact, including vaginal, oral, and anal intercourse. STIs affect women more than men, and are more common in people who have multiple sexual partners, abuse drugs, and are of lower socioeconomic status.
- Genital herpes, caused by an infection with an HSV virus, is a commonly occurring STI in teens and young adults.
- Human papilloma virus (HPV) is the most commonly occurring STI in the United States. Some strains cause genital warts, a chronic, incurable STI manifested by warts of various forms. Other strains cause no initial symptoms but are associated with cancers of the cervix, vulva, and penis, as well as oropharyngeal cancer.
- Urogenital infections include vaginal infections (bacterial vaginosis, candidiasis, and trichomoniasis), chlamydia, gonorrhea, syphilis, and pelvic inflammatory disease (PID).
- Gonorrhea (caused by a bacteria) and syphilis (caused by a spirochete) affect both men and women, and may infect the newborn as it moves through the birth canal in an untreated woman.
- PID is an infection of the female pelvic organs, and may be caused by one or more infectious agents.

KEY TERMS

chancre, *1633*
chlamydia, *1630*
dyspareunia, *1630*
gonorrhea, *1631*
pelvic inflammatory disease (PID), *1636*
sexually transmitted infections (STIs), *1621*
syphilis, *1632*

Infections transmitted by vaginal, oral, and anal intimate contact and intercourse are referred to as **sexually transmitted infections (STIs)**. Infections transmitted by sexual intercourse are also labeled as *sexually transmitted diseases (STDs)* or *venereal diseases*. STIs also include systemic diseases (such as tuberculosis, hepatitis, and HIV/AIDS) that can be transmitted from an infected person to a partner. This chapter discusses STIs that involve the urogenital system. Vaginal infections are included in this chapter because they are also included in the Centers for Disease Control and Prevention (CDC) treatment guidelines.

Overview of Sexually Transmitted Infections

Sexually transmitted infections include those caused by bacteria, *Chlamydiae*, viruses, fungi, protozoa, and parasites. Portals of entry for these agents of transmission include the mouth, genitalia, urinary meatus, anus, rectum, and skin. STIs have many consequences, and nurses have the responsibility of teaching sexually active patients how to prevent STIs, regardless of their gender, age, or sexual orientation. Nurses have a critical role in the prevention of STIs by teaching patients about these diseases, their prevention, treatment, and potential complications.

Incidence and Prevalence

STIs have reached epidemic proportions in the United States and are on the increase worldwide. They are the most frequent infections encountered by professionals in the field of reproductive health, and occur in more than half of all people at some point in their life.

FAST FACTS

STIs

- About 110 million people in the United States are estimated to have an STI.
- More than 19.7 million new cases of STIs develop each year, the majority of which are caused by HPV.
- Individuals ages 15 to 24 years account for half (50%) of all new STIs.
- Nearly $16 billion is spent each year to diagnose and treat STIs and their complications.

Source: CDC, 2013a.

Women and infants are disproportionately affected by STIs. Many STIs are more easily transmitted from a man to a woman than from a woman to a man. Women often experience few early manifestations of the infection, delaying diagnosis and treatment. Furthermore, women are at greater risk for complications of STIs such as pelvic inflammatory disease (PID) and genital cancers.

Several factors help explain the escalating incidence of STIs. Earlier onset of intercourse, delay in finding marriage or monogamous co-habitating partners, and subsequent higher frequency in new partners or intercourse in general are related to higher incidences of STIs. In addition, since oral contraceptives were introduced to American women in 1961, they have replaced the condom as a birth control method for many couples. However, oral contraceptives do not protect against STIs, a fact of increasing importance.

STIs affect men and women of all ages, backgrounds, and socioeconomic levels. The incidence of STIs is highest in young adults ages 15 to 24 and in certain minorities (CDC, 2013b). Multiple physiologic (i.e., route of transmission, depression), behavioral (i.e., lack of condom use, alcohol and drug use), and social (i.e., social networks, socioeconomic status) factors are associated with STIs. See the accompanying Moving Evidence into Action box for the nursing implications of a study that looked at the relationship among STIs and violence in young adult women. Healthcare disparities—access to quality healthcare and STI prevention services, healthcare-seeking behavior, poverty, lack of insurance or ability to pay—are additional factors contributing to the increased incidence of STIs in adolescents, young adults, and ethnic minorities (CDC, 2013b).

STIs have an epidemiologic synergy with each other. STIs, such as syphilis, herpes simplex virus (HSV), and chancroid, facilitate the transmission of HIV/AIDS, and the immune suppression caused by HIV potentiates the infectious process of other STIs. In fact, individuals who are infected with STIs are at greater risk of acquiring HIV if they are exposed to the virus. This is the result of several factors: Genital ulcers create a portal of entry for HIV, nonulcerative STIs increase the concentration of cells in genital secretions that can be targets for HIV, and infection with both an STI and HIV results in an increased likelihood of having HIV in genital secretions and semen.

Characteristics

Although various organisms cause STIs, they have several characteristics in common:

- Most can be prevented by consistent and correct use of latex condoms.
- They can be transmitted during oral, vaginal, and anal intercourse and, in the case of HSV and HPV, skin-to-skin contact through microfissures in skin and mucous membranes.

Moving Evidence into Action

Risk Factors for STI

An often unassessed risk factor for STIs is intimate partner violence (IPV). In a large, nationally representative sample, women who were victims of IPV reported a lower prevalence of condom use with vaginal intercourse, greater beliefs that their partner had other sexual partners, and higher rates of STIs (Hess et al., 2012). This study supports findings from previous studies that women's experiences of violent victimization increase their risk for STIs.

Implications for Nursing

Research such as this study supports recommending assessment for intimate partner violence be included in all women's health exams. Furthermore, it supports referral for STI screening of women presenting for treatment of abusive injuries, depression, or substance abuse. Women who experience intimate partner violence may have difficulty negotiating protective sexual practice such as condom use; in fact, requesting condom use can precipitate violence. It is important to help abused women identify a range of safer sex practices, including options for safely negotiating condom use.

Moving Knowledge into Action

1. In this study women were the focus as victims of IPV. Do you think findings would differ if the focus of the study were on men? If so, how do you think the results would differ? Provide your rationale.
2. Correct and consistent condom use (male or female) during every sexual encounter is commonly recommended as part of safer sex practice. Discuss potential options you could provide for a woman who is fearful that a request for use of a condom would precipitate abuse by an intimate partner.
3. Develop a teaching plan for the nursing diagnosis *Risk for Infection (STI)* related to continuing history of intimate partner violence.

- For treatment to be effective, sexual partners of the infected person must also be treated.
- Two or more STIs frequently coexist in the same patient.

The complications of STIs in women include PID, ectopic pregnancy, infertility, chronic pelvic pain, neonatal illness and death, and genital cancer. Vaccination of preteens and teens before the onset of sexual activity can prevent HPV infection in men and women. Some bacterial STIs can be cured through appropriate early treatment with antibiotics. Others, such as genital herpes, are chronic conditions that can be managed but not cured, because they are caused by viruses. The most serious STI is AIDS, which at this time is incurable. HIV and AIDS are discussed in Chapter 13. Treatment guidelines for STIs are updated regularly and are available from the CDC.

Prevention and Control

The prevention and control of STIs is based on the principles of education, prevention, detection, effective diagnosis, and treatment of infected persons; and evaluation, treatment, and counseling of sexual partners of people who are infected.

Pre-exposure vaccination is an effective method of preventing the viral STIs HPV and hepatitis B. HPV-4 (Gardasil) is a quadrivalent HPV vaccine that prevents cervical cancer in women and genital warts in women and men. The CDC recommends that it be given to girls and boys ages 11–12 years and individuals age 13–26 years who have not previously been vaccinated; children young as 9 years may be vaccinated, (CDC, 2014d). Hepatitis B vaccine is recommended for unvaccinated, uninfected individuals being evaluated for an STI, and for men who have sex with men and for individuals who are injection-drug users (CDC, 2010).

The ability of the healthcare provider to obtain an accurate sexual history is essential to prevention and control efforts. Important information includes the number and gender of sexual partners, type of birth control used (if any), use of protection from STIs and HIV, sexual practices (e.g., vaginal, anal, oral), and any previous history of an STI or exposure to a partner known to have an STI. In the United States approximately 30% of people with HIV/AIDS are ages 50 and older, not only because the incidence of HIV in older people is increasing, but because treatments are helping people with the disease live longer.

MEMORY ALERT

One approach to collecting accurate information about key areas of interest has been summarized by the CDC (2010) as the "Five Ps":

Partners
Prevention of Pregnancy
Protection from STIs
Practice
Past history of STIs

Suggested questions to use are found on the CDC website.

The most effective way to prevent sexual transmission of HIV and most other STIs is to avoid sexual intercourse with an infected partner. It is recommended that both partners be tested for STIs, including HIV, before beginning to have sexual intercourse. If an individual chooses to have intercourse with an infected partner or one whose infection status is unknown, a new condom should be used for each act of intercourse. See the Meeting Individualized Needs box for recommended STI barrier guidelines (CDC, 2010).

Prevention teaching for the person who is an injecting-drug user includes the following:

- Enroll or continue in a drug treatment program.
- Do not use injection equipment that has been used by another person. If equipment is shared, first clean the syringe and needle with bleach and water (to reduce the risk of HIV transmission).
- If needles can legally be obtained in the community, obtain and use clean needles.

Eliminating further transmission and reinfection of STIs is critical to control. For treatable STIs, this means that referral of sexual

Meeting Individualized Needs

STI Barrier Guidelines

Barrier Protection	Teaching Topics
• Male condoms	✔ Use a new condom with each act of sexual intercourse. ✔ Handle carefully to avoid damaging the condom. ✔ Be sure no air is trapped in the end of the condom. ✔ Put the condom on when the penis is erect and before genital contact with partner. ✔ Ensure adequate lubrication exists during intercourse, using only water-based lubricants (e.g., K-Y Jelly, Astroglide, AquaLube, and glycerine) with latex condoms. Oil-based lubricants, such as petroleum jelly, massage oil, mineral oil, or body lotions can weaken latex. ✔ Nonlatex condoms made of polyurethane or other synthetic material protect against pregnancy and STIs; natural membrane condoms do not adequately protect against STIs and should not be used. ✔ Ensure adequate lubrication during vaginal and anal sex. ✔ Withdraw while the penis is erect and hold the condom firmly against the base of the penis during withdrawal.
• Female condoms	✔ The female condom (Reality) is a lubricated polyurethane sheath with a ring on each end that is inserted into the vagina. It is an effective mechanical barrier to viruses.
• Vaginal spermicides, sponges, diaphragms	✔ Spermicides used alone without condoms do not reduce the risk for cervical gonorrhea, chlamydia, or HIV infection. ✔ The diaphragm protects against cervical gonorrhea, chlamydia, and trichomoniasis, but not HIV.

BOX 50–1 Resources for Patients with STIs

- CDC National STD Hotline
- CDC National Prevention Information Network
- National Center for HIV, STD, and TB Prevention
- National HPV and Cervical Cancer Resource Center and Hotline
- National Herpes Hotline
- American Social Health Association

partners for diagnosis, treatment, and counseling is essential. Chlamydia, gonorrhea, syphilis, and chancroid are reportable diseases in every state; the CDC also collects HIV testing data from all states. When a healthcare professional refers infected patients to a local or state department of health, every effort is made to identify and contact sexual partners. Reports of STI and HIV infections are maintained in strictest confidence, and are protected by law from subpoena. Suggested resources for people with STIs are listed in Box 50–1.

Expedited partner therapy (EPT) is defined by the CDC (2010) as treatment of partners without an intervening personal assessment by a healthcare provider. EPT is one potential means of limiting the spread of STIs, and it may be implemented by any of several methods. The usual method for implementing EPT is *patient-delivered partner therapy* (PDPT), wherein clinicians provide their patients with drugs intended for the partners or write prescriptions in the partners' names. Providing clear instructions for follow-up care is an important component of EPT. Although many public health agencies and personnel endorse it, EPT may fall outside legal guidelines for prescribing in many states, and should not be used without clear direction.

THE PATIENT WITH GENITAL HERPES

The herpes simplex viruses HSV-1 and HSV-2 both cause genital herpes, although most are caused by HSV-2. Like most STIs, genital herpes are most commonly found in young, sexually active adults and are associated with early onset of sexual activity and multiple sexual partners. Approximately 50 million people ages 14 and older, or one out of every six teens and adults, have had genital HSV infections (CDC, 2012a). Exact incidence is unknown because HSV is not a reportable infection. While the overall percentage of young adults with genital herpes is decreasing, infection rates among non-Hispanic Blacks are significantly higher than among non-Hispanic Whites and Mexican Americans (CDC, 2012a). There is no cure, and the treatments are primarily symptomatic.

Pathophysiology

One hundred types of HSV viruses have been identified, with more than 30 affecting the urogenital area. HSV-2, the virus that causes genital herpes, is transmitted by sexual activity or during childbirth from an infected woman. HSV-1 is associated with cold sores, but may be transmitted to the genital area by oral intercourse or by self-inoculation through poor hand hygiene practices. HSV infections begin with an exposure to the virus by contact with infectious lesions or secretions. The virus then moves into the stratified squamous epithelium, stimulating the replication of the epithelium and infecting the neurons that innervate the area. HSV viruses are neurotropic viruses, meaning that they grow in neurons and can maintain their disease potential even when there are no manifestations. The virus ascends through the peripheral nerves to the dorsal root ganglia, where it can remain dormant. For unknown reasons, the virus may reactivate and return to the nerve root of the skin, causing lesions. During dormancy, the virus is impervious to treatment. Genital HSV-2 infection is more common in women (approximately one in four women) than it is in men (almost one of eight) (CDC, 2012a).

Manifestations

Within 2 to 10 days after exposure to the herpes virus, painful red papules appear in the genital area. In men, the lesions generally occur on the glans or shaft of the penis. In women, the lesions commonly occur on the labia, vagina, and cervix. Anal intercourse or oral–anal sexual contact may result in lesions in and around the anus.

Soon after the papules appear, they form small painful blisters filled with clear fluid containing virus particles (Figure 50–1 ■). The blisters break, shedding the highly infectious virus and creating patches of painful ulcers that last 6 weeks (or longer if they become infected). Touching these blisters and then rubbing or scratching in another place can spread the infection to other areas of the body (*autoinoculation*).

The first outbreak of herpes lesions is called *first episode infection*, with an average duration of 12 days. Subsequent occurrences, usually less severe, are termed *recurrent infections* (average duration of 4 to 5 days). The period between episodes is called *latency*, during which time the person remains infectious even though no symptoms are present. During latency, the virus withdraws into the nerve fibers that lead from the infected site to the lower spine, remaining dormant until recurrence, at which time it retraces its path to the genital area. There can be several recurrences within a year.

The manifestations of genital herpes are presented in the accompanying box. Prodromal symptoms of recurrent outbreaks of genital herpes can include burning, itching, tingling, or throbbing at the sites where lesions commonly appear. These sensations may be accompanied by pain in the legs, groin, or buttocks. Some authorities believe that prodromal symptoms signal increased levels of infectiousness, during which sexual contact should be avoided.

Figure 50–1 ■ Genital herpes blisters as they appear on the labia.
Source: Biophoto Associates/Photo Researchers, Inc.

MANIFESTATIONS OF GENITAL HERPES

- Herpetic lesions
- Regional lymphadenopathy
- Headache
- Fever
- General malaise
- Dysuria
- Urinary retention
- Vaginal discharge
- Urethral discharge (men)

A word of caution about clinical manifestations: Most people infected with HSV-2 are not aware they are infected. In fact, most people do not realize they have the infection until years after the infection is acquired.

●○● INTERPROFESSIONAL CARE

Presumptive diagnosis of genital herpes is based on history and physical examination of the patient, including lesions and patterns of recurrence. Because there is no cure for genital herpes, treatment focuses on relieving symptoms and preventing spread of the infection. Patient education is essential to prevent further transmission of the disease and to help patients integrate management of a chronic disease into their lifestyles.

DIAGNOSIS

Definitive diagnosis requires isolation of the virus in tissue culture. Ideally, tissue specimens should be obtained within 48 hours of the appearance of the blisters.

MEDICATIONS

Acyclovir (Zovirax) helps reduce the length and severity of the first episode and is the treatment of choice for genital herpes. The oral form is considered most effective for a first episode as well as recurrences. It is given for 7 to 10 days or until lesions heal. Evidence shows that some strains of HSV are becoming resistant to acyclovir, particularly in people who are HIV positive. In those cases, foscarnet (Foscavir) is used. Other antivirals used for treatment and prevention are valacyclovir (Valtrex) and famciclovir (Famvir). Suppressive therapy using an antiviral (acyclovir, valacyclovir, or famciclovir) for recurrent genital herpes has been shown to reduce the frequency of outbreaks as well as the risk of transmission of the infection to an uninfected heterosexual partner (CDC, 2012a).

●○● NURSING CARE

In planning and implementing nursing care for the patient with genital herpes, the nurse needs to consider both short-term and long-term implications. Although the immediate priority is symptom relief and prevention of further transmission, the patient needs assistance to deal with the life-changing diagnosis of a chronic disease.

Assessment

See the Manifestations and Interprofessional Care sections for the assessment of the patient with genital herpes.

- *Health history:* symptoms such as pain, burning, itching, tingling, or throbbing; presence of genital lesion(s); previous episodes; recent sexual activity with a new partner; use of safer sex practices and/or protection (e.g., condom)
- *Physical assessment:* inspection for red, papular lesions on penis (men), labia or vagina (women), or around the anus (either)

Priorities of Care

Collaborating with the interprofessional team to ensure appropriate treatment of genital herpes while providing care that supports symptom relief, prevention of future transmission, and physical and psychologic responses to this diagnosis is a priority of nursing care.

Diagnoses, Outcomes, and Interventions

Nursing diagnoses discussed in this section focus on pain and sexual dysfunction.

Acute Pain

Herpetic lesions are very painful and can become infected. Because the virus resides in the nerve ganglia, pain may also occur in the legs, thighs, groin, or buttocks. Although acyclovir diminishes the pain of herpes and accelerates the healing process, additional measures can relieve the discomfort further.

Expected Outcome: Patient will demonstrate pain control as evidenced by use of prescribed and preventive measures.

- Teach how to keep herpes blisters clean and dry. A gentle cleansing with soap and water is recommended, thoroughly drying the blisters afterward. It is important to wear loose cotton clothing that will not trap moisture; and to avoid wearing panty hose and tight jeans. *Keeping the lesions clean and dry reduces the possibility of secondary infection and speeds the healing process.*
- For dysuria, suggest pouring water over the genitals while urinating. Drinking additional fluids also helps dilute the acidity of the urine; however, fluids that increase acidity, such as cranberry juice, should be avoided. *These measures dilute the acid content of urine and thereby reduce the burning sensation.*
- Warm baths may be used to relieve pain. *The warm water is soothing and decreases pain from ulcers and an irritated urethral meatus. It also facilitates wound healing.*

Situational Low Self-Esteem

Patients who learn that they are infected with an incurable STI may believe they can no longer have a normal sex life. Fortunately, many people have learned to live with and manage genital herpes without infecting their partners or their children.

Expected Outcome: Patient will demonstrate self-esteem related to sexual patterns as evidenced by verbalization of self-acceptance.

- Provide a supportive, nonjudgmental environment for the patient to discuss feelings and ask questions about what this diagnosis means to future sexual relationships. *Feelings of guilt, shame, and anger are natural responses to such a diagnosis and can lead to a total avoidance of sexual intimacy.*
- Provide information about suppressive therapy for the patient who is in a mutually monogamous heterosexual relationship. *Although suppressive therapy does not eliminate the need to avoid sexual contact during an outbreak, it has been shown to be safe and effective in reducing outbreak frequency and the risk of transmission to the sexual partner (CDC, 2012a).*

- Offer information about support groups and other resources for people with herpes such as the National Herpes Information Hotline. *Information about how others cope with this disease can offset feelings of shame and hopelessness.*

Delegating Nursing Care Activities

As appropriate and allowed by the designated duties and responsibilities of unlicensed assistive personnel, the nurse may delegate nursing care activities such as collecting vital signs and nonpharmacologic skin care.

Continuity of Care

Health teaching for patients with genital herpes involves helping them manage this chronic disease with the least possible disruption in lifestyle and relationships. Understanding the disease process and factors that affect it helps the patient regain a sense of control and see the potential for future sexual intimacy without transmission of infection. The following topics should be addressed:

- How to recognize prodromal symptoms of recurrence and factors that seem to trigger recurrences (such as emotional stress, acidic food, sun exposure)
- The need for abstinence from sexual contact from the time prodromal symptoms appear until 10 days after all lesions have healed
- If lesions become infected, use of topical acyclovir (Painful lesions can be protected with sterile petroleum jelly or aloe vera gel.)
- Use of latex condoms due to viral shedding at any time and careful hygiene practices (such as not sharing towels or other personal items) even during latency periods.

THE PATIENT WITH HUMAN PAPILLOMAVIRUS

There are more than 100 human papillomaviruses (HPV), 40 of which affect the genital area. The most concerning are types 16 and 18, which are oncogenic and are associated with cervical, penile, vulvar, vaginal, and certain oropharyngeal cancers. Types 6 and 11 are not oncogenic, but cause genital warts. In most people, HPV infections are asymptomatic and resolve without treatment (CDC, 2012b). Currently, HPV is incurable.

Most HPV infections are asymptomatic or unrecognized. An estimated 20 million Americans are infected with the virus, and up to 6.2 million new cases are diagnosed annually (CDC, 2012b). Women are at greater risk for HPV genital infections because they have a larger mucosal surface area exposed in the genital area.

FAST FACTS

Genital HPV Infection

- At least 50% of sexually active adults acquire genital HPV infection at some point in their lives.
- The types that cause genital warts are different than those that can cause cancer.
- Most people with a genital HPV infection do not know they are infected.

Source: CDC, 2012b.

Pathophysiology

Human papillomaviruses are most often transmitted through vaginal and anal sex. They can also be passed on during oral sex and genital-to-genital contact (CDC, 2012b). The incubation period is 6 weeks to 8 months. HPV infects squamous epithelium, stimulating it to replicate and proliferate. Most HPV infections will have no clinical manifestations and resolve within 1 to 2 years. Some, however, do linger and may cause oncogenic complications or genital warts. The reasons why some resolve and others do not are unknown. Factors that are attributed to cervical cancer risk are long-term contraceptive use, high parity (five or more pregnancies), cigarette smoking, and co-infections with HIV or other STIs (Chelimo et al., 2012).

Manifestations

Most people with HPV do not have manifestations. When present, manifestations include single or multiple painless, soft, moist, pink, or flesh-colored swellings in the vulvovaginal area, perineum, penis, urethra, anus, groin, or thigh (Figure 50–2 ■). In women, the growths may be in the vagina or on the cervix and be apparent only during a pelvic examination.

The four types of genital warts are as follows:

- *Condyloma acuminata:* cauliflower-shaped lesions that appear on moist skin surfaces such as the vagina or anus
- *Keratotic warts:* thick, hard lesions that develop on keratinized skin such as the labia major, penis, or scrotum
- *Papular warts:* smooth lesions that also develop on keratinized skin
- *Flat warts:* slightly raised lesions, often invisible to the naked eye, that also develop on keratinized skin.

●○● INTERPROFESSIONAL CARE

Treatment is directed at removal of the warts, relief of symptoms, and health teaching to reduce the risk of recurrence and future transmission. Infection with HPV is considered chronic; however, research has shown that HPV becomes undetectable within 2 years in 90% of those infected (CDC, 2012b).

Genital and anal warts are diagnosed primarily by clinical appearance. Cervical cell changes are identified by routine Papanicolaou (Pap) tests. An HPV DNA test can be used along with Pap testing to identify high-risk HPV subtypes.

MEDICATIONS

Currently two vaccines can be used to prevent various types of HPV if given before the individual becomes sexually active. Cervarix will protect against types 16 and 18, which cause up to 70% of cervical cancers. A quadrivalent vaccine, Gardasil, is available to protect against the four types of HPV that cause most cervical cancers and genital warts. Both vaccines are administered by three intramuscular injections given over a 6-month period. Current recommendations are for immunization of all previously unvaccinated women through age 26 (CDC, 2014b). The CDC recommends that men up to the age of 26 years receive Gardasil to prevent genital warts. The vaccine does not protect against an existing HPV infection.

Topical agents used to treat genital warts include podophyllin and imiquimod, which can be applied by the patient. Podophyllin (Condylox, Podofin) is contraindicated during pregnancy and can

Figure 50–2 ■ Genital warts (*condyloma acuminata*) on the *A*, vulva and *B*, penis.
Source: Centers for Disease Control and Prevention (CDC).

have side effects in any patient, ranging from nausea, diarrhea, and lethargy to paralysis and coma (see the accompanying Medication Administration box).

OTHER TREATMENTS

Genital warts may also be removed by cryotherapy, electrocautery, laser vaporization, or surgical excision. Carbon dioxide laser surgery is becoming increasingly common for removal of extensive warts.

MEDICATION ADMINISTRATION

The Patient with Genital Warts

TOPICAL APPLICATIONS

podophyllin

trichloroacetic acid

Although cryotherapy using liquid nitrogen or a cryoprobe is more commonly used to treat genital warts, podophyllum preparations are sometimes used. Podophyllin is applied topically to the warts by the physician once weekly for 3 to 5 weeks.

Podophyllin is contraindicated during pregnancy; the alternative is cryotherapy. Podophyllin is also contraindicated in cervical, urethral, oral, or anorectal warts. It is important to avoid contact of podophyllin resin with the eyes.

Adverse effects of podophyllin include local irritation, severe ulceration of surrounding tissue, nausea, diarrhea, lethargy, paralysis, and coma.

Nursing Responsibilities

- Establish baseline data, including mental status, vital signs, and weight.
- Document and report any existing lesions (genital, anal, or oral).
- Cover the tissue surrounding the warts with petrolatum or a paste of baking soda and water to protect the tissue from the caustic treatment solution.

Health Education for the Patient and Family

- Wash off the treated area thoroughly within 1 to 4 hours after the first application; gradually increase this period to 6 to 8 hours after the second and subsequent applications.
- Return for regular treatment until warts are gone.
- Refer partners for examination and any necessary treatment.
- Report any adverse effects (nausea, diarrhea, local irritation, lethargy, numbness).
- Avoid sexual activity until you and your partners have been free of disease for 1 month.
- Use condoms to prevent future infections.
- Return for an annual Pap smear.

●○● NURSING CARE

Health promotion activities for adults of all ages should include information about the causes, treatments, and prevention of HPV infections.

Assessment

See the Manifestations and Interprofessional Care sections for the assessment of the patient with HPV infection.

Priorities of Care

Collaborating with the interprofessional team to ensure appropriate treatment of HPV while providing care that supports treatment, prevention of future transmission, and physical and psychologic responses to this diagnosis is a priority of nursing care.

Diagnoses, Outcomes, and Interventions

Nursing interventions are primarily directed toward problems of deficient knowledge and fear.

Deficient Knowledge

HPV is spread by contact with infectious lesions or secretions, with up to 70% of genital warts spread by people who do not know they

have the infection. Although there is no known cure, it is essential to prevent secondary infections.

Expected Outcome: Patient will demonstrate knowledge about HPV by articulating vaccine efficacy, increased risk for cervical cancer, and transmission prevention activities.

- Provide information to all women, particularly those who fall within the recommended age range and mothers of preteens and teens, about HPV vaccine and immunization recommendations. *A fully immunized population can have a significant impact on the incidence of and mortality related to cervical cancer.*
- Discuss the need for prompt treatment and the necessity for sexual abstinence until lesions have healed, or consistent condom use while lesions are present. *This reduces the risk of reinfection and further transmission of the disease. Some studies have found that using condoms promotes the regression of HPV lesions in both men and women.*
- Discuss the increased risk of cervical cancer associated with HPV and the importance of an annual Pap smear for all sexually active females. *Understanding the risk, the patient will be more motivated to seek annual screening.*
- Stress the importance of thorough hand hygiene. *Hand hygiene is essential to prevent the spread of HPV.*

Fear

Surgery engenders some degree of fear in most patients: fear of the procedure itself and of pain and possible complications. Surgery or cryotherapy in the genital area involves all of these fears plus fear of possible impaired sexual function.

Expected Outcome: Patient will demonstrate reduced fear by seeking information about the procedures and impact on sexual function.

- Allow the patient to express specific fears and feelings about the procedure. Explain the procedure, approximate recovery time, possible complications and ways to avoid them, and ways to cope with complications that do occur. *Knowing what to expect reduces the patient's fear and helps him or her feel a greater sense of control.*
- Explain that the procedure is performed with a local anesthesia. *Being awake during surgery gives the patient a greater sense of participation in the treatment process.*

Delegating Nursing Care Activities

As appropriate and allowed by the designated duties and responsibilities of unlicensed assistive personnel, the nurse may delegate nursing care activities such as collecting vital signs and nonpharmacologic skin care.

Continuity of Care

Health teaching emphasizes the need for the patient and infected partners to return for regular treatment until lesions have resolved, and to use condoms to prevent reinfection. Because of the increased risk of cervical cancer, annual Pap smears are essential for female patients.

THE PATIENT WITH A VAGINAL INFECTION

Yeasts, protozoa, or bacteria may infect the vagina. These infections can be sexually transmitted, but the male partner does not always have manifestations of the infection. Risk factors include the use of hormonal contraceptives or broad-spectrum antibiotics, obesity, diabetes, pregnancy, unprotected sexual activity, and multiple sexual partners. Manifestations of vaginal infections are outlined in Table 50–1.

Preventive measures include educating women about personal hygiene practices and safer sex. Women need to avoid frequent douching and wearing nylon underwear and/or tight pants. Unprotected sexual activity, particularly with multiple partners, increases the risk of vaginal infections.

Pathophysiology and Manifestations

Alterations in pH, changes in the normal flora, and low estrogen levels are conducive to the development of vaginal infections. When conditions are favorable, microorganisms invade the vulva and vagina.

BACTERIAL VAGINOSIS

Bacterial vaginosis (nonspecific vaginitis) is the most common cause of vaginal infection in women of reproductive age. *Gardnerella vaginalis* is one of the causative organisms, but others are also implicated. The relationship of sexual activity to this infection is not clear. The primary manifestation is a vaginal discharge that is thin and grayish-white, and has a foul, fishy odor. Complications include PID, preterm labor, premature rupture of the membranes, and postpartum endometritis. The infection is treated with oral or intravaginal antibacterial agents.

TABLE 50–1 Vaginal Infections

Infection	Type of Discharge	Typical Manifestations	Nursing Care
Candidiasis (*Monilia*, yeast)	Thick white patches adhering to cervix and vaginal wall, resembling cottage cheese; little odor	Itching of vulva and vaginal area, redness, painful intercourse	Teach perineal hygiene and proper use of vaginal applicators. Instruct the patient to complete the entire treatment.
Simple vaginalis (bacterial vaginosis, *Gardnerella* vaginosis)	Thin, white, "milk-like," or gray with fishy odor, especially when mixed with potassium hydroxide	None to mild itching or burning in vulvar area; clue cells on microscopic examination	Teach proper perineal hygiene. Instruct patient to complete treatment. Teach patient relationship of infection to PID.
Trichomoniasis	Frothy, yellow or white, foul odor	Burning and itching of vulva	Teach perineal hygiene. Instruct about need for both patient and her partner to complete treatment.
Atrophic vaginitis (senile vaginitis)	Thin, opaque discharge, occasionally blood tinged, odorless; pale, smooth, thin, dry vaginal walls	Painful intercourse, itching, vaginal dryness	Counsel patient on symptoms of menopause and sexual techniques to minimize trauma.

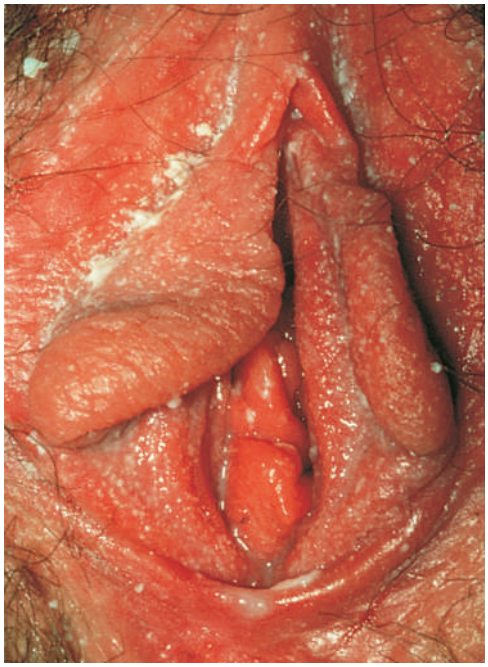

Figure 50–3 ■ Yeast infection on female genitalia.

CANDIDIASIS

Candidiasis (moniliasis or yeast infection) is caused by the organism *Candida albicans*, which has several strains of different virulence. Candida organisms are part of the normal vaginal environment in up to 50% of women, causing problems only when they multiply rapidly. When increased estrogen levels, antibiotics, diabetes mellitus, fecal contamination, or other factors alter the normal vaginal flora, the organism proliferates, resulting in a yeast infection. The manifestations include an odorless, thick, cheesy vaginal discharge. This is often accompanied by itching and irritation of the vulva and vagina, with dysuria and dyspareunia (Figure 50–3 ■). Uncircumcised men may develop a yeast infection over the glans penis, manifested by itching and dysuria. The infection is treated with oral or intravaginal antifungal agents.

TRICHOMONIASIS

Trichomoniasis is caused by *Trichomonas vaginalis*, a protozoan parasite. It is the most common curable STI in young, sexually active women. An estimated .3.7 million men and women in the United States are infected (CDC, 2012e). Symptoms usually appear 5 to 28 days after exposure. It most commonly infects the vagina in women and the urethra in men. Most men are asymptomatic, but when symptomatic may complain of dysuria and urethral discomfort. Women have a frothy, green-yellow vaginal discharge with a strong fishy odor, often accompanied by itching and irritation of the genitalia. Trichomoniasis increases a woman's risk of developing HIV if she is exposed, and it may increase the risk of transmitting HIV to her sexual partner. Trichomoniasis is treated with a single oral dose of metronidazole or tinidazole.

●○● INTERPROFESSIONAL CARE

Interprofessional care focuses on identifying and eliminating the infection and preventing recurrence.

DIAGNOSIS

Diagnostic tests vary with the suspected organism. Cervical cultures are examined to diagnose the causative organism. Trichomonas is identified by microscopically examining a specimen of vaginal discharge in saline. Ten percent potassium hydroxide is used to identify spores and filaments of candida.

MEDICATIONS

The pharmacologic treatment varies with the organism. The sexual partner of a woman with a trichomonas infection must also be treated to prevent reinfection. Some antifungal agents are available without prescription, which can lead to self-medication with the incorrect agent or allow repeated infections to go unreported.

●○● NURSING CARE

Nursing care focuses on teaching the patient, and if necessary, her sexual partner, to comply with the treatment regimen, use safer sex practices, and prevent future transmission of the infection.

Assessment

Careful history taking may also reveal high-risk sexual practices that require intervention, particularly if the patient has had repeated infections. The initial presenting symptom for many HIV-positive women is vaginal candidiasis, which may not respond to over-the-counter treatments. Treatment with some antibiotics destroys normal vaginal flora, resulting in superinfection with yeast.

See Table 50–1 for the assessment of the patient with vaginitis.

Priorities of Care

Collaborating with the interprofessional team to ensure appropriate treatment of vaginal infections while providing care that supports symptom relief, prevention of future transmission and recurrences, and physical and psychologic responses to the diagnosis is a nursing priority of care.

Diagnoses, Outcomes, and Interventions

Although each nursing care plan must be individualized, nursing diagnoses that often apply to patients with vaginal infections are Deficient Knowledge and Acute Pain.

Deficient Knowledge

Many women are unaware of the causes of vaginal infections and the self-care measures to prevent and treat these infections. If possible, both the woman and her sexual partner should be taught the information.

Expected Outcome: Patient will demonstrate knowledge about vaginal infections by describing self-care measures and plans to adhere to plan of treatment.

- Explain the transmission of the infection. Abstaining from sex or consistent condom use are the best ways to avoid transmission and reinfection. *A frank discussion of disease transmission and prevention with the woman and her partner can reduce the risk of reinfection.*

BOX 50–2 Self-Care Comfort Measures

- Do not wear panty hose; wear loose-fitting pants or skirts.
- Double-rinse underwear; do not use fabric softener on underwear.
- Do not use bubble bath, perfumed soaps, or feminine hygiene products.
- Use menstrual pads; not tampons.
- Use white, unscented toilet paper.
- Use a water-soluble lubricant for intercourse.
- Apply ice or a frozen blue gel pack wrapped in a towel to the vulva after intercourse to relieve burning.
- Rinse vulva with cool water after voiding and intercourse.

- The need to complete the course of treatment. *Many infections are asymptomatic in one partner. Incomplete treatment allows for recurrence of the infection and reinfection of the partner.*
- Advise women not to douche or use feminine hygiene sprays. *These interfere with the normal bacterial environment of the vagina, decreasing resistance to vaginal infection.*

Acute Pain

The symptoms of vaginitis can include dysuria, painful excoriation or ulceration of tissue, and painful intercourse (**dyspareunia**). Often these symptoms can be relieved by relatively simple self-care measures. See Box 50–2 for additional comfort measures.

Expected Outcome: Patient will demonstrate pain control as evidenced by use of prescribed and preventive self-care measures.

- Suggest the use of cool compresses. *Cool compresses relieve itching.*
- Recommend sitz baths to alleviate discomfort. *Sitz baths cleanse the perineal area and the warmth is soothing to inflamed, irritated skin and mucous membranes.*
- Wear cotton underwear. *Cotton absorbs moisture and allows better air circulation than other types of material.*
- If infected with trichomonas, avoid sexual contact until treatment is completed. *Treatment of the infected woman and her partner as well as sexual abstinence are necessary to facilitate healing and to prevent reinfection.*

Delegating Nursing Care Activities

As appropriate and allowed by the designated duties and responsibilities of unlicensed assistive personnel, the nurse may delegate nursing care activities such as collecting vital signs and nonpharmacologic skin care.

Continuity of Care

Teaching focuses on eradicating the infection, preventing further disease transmission, and relieving discomfort associated with the condition. Educating the patient and her partner(s) about safer sex and improved genital hygiene practices can reduce the incidence of recurrence.

THE PATIENT WITH CHLAMYDIA

Chlamydia are a group of STIs caused by *Chlamydia trachomatis*, a bacterium that behaves like a virus, reproducing only within the host cell. The bacterium is spread by oral, vaginal, or anal intercourse and to the neonate by passage through the birth canal of an infected mother. The infections caused by chlamydia include acute urethral syndrome, nongonococcal urethritis, mucopurulent cervicitis, and PID. Lymphogranuloma venereum (LGV) is an STI caused by several strains of *C. trachomatis*. LGV is less common in the United States and Europe than in the tropics, and primarily affects men who have sex with men (CDC, 2014a).

BOX 50–3 Risk Factors for Chlamydial Infection

- Intercourse during adolescence
- Unprotected sexual activity
- Multiple sexual partners

Chlamydia is the most commonly reported STI in the United States, affecting more than 2.8 million people each year (CDC, 2014a). Of that number, more than half of reported cases occurred in women ages 15 to 25 years. Risk factors for chlamydia are listed in Box 50–3.

Pathophysiology and Manifestations

Chlamydia trachomatis is an intracellular bacterial pathogen that resembles both a virus and bacteria. The organism enters the body as an elementary body, a form in which it is capable of entering uninfected cells. The infection begins when the organism enters a cell and changes into a reticulate body. The reticulate body divides within the cell, bursting the cell and infecting adjoining cells.

While the incubation period is from 1 to 3 weeks, chlamydia may be present for months or years without producing noticeable symptoms in women. Chlamydia typically invades cells of the cervix (in women) and urethra (in men and women). When present, manifestations include dysuria, urinary frequency, and vaginal discharge in women or urethral discharge in men. Patients may be asymptomatic; however, they are still potentially infectious.

Because chlamydia is asymptomatic in most women until the uterus and fallopian tubes have been invaded, treatment may be delayed, resulting in devastating long-term complications. Nearly a third of men with urethral chlamydia are also asymptomatic. In underdeveloped countries, chlamydia is a leading cause of preventable blindness in the newborn (Grossman & Porth, 2014).

Complications

If a chlamydial infection in women is not treated, it ascends into the upper reproductive tract, causing such complications as PID, which includes endometritis and salpingitis. Chronic pelvic pain may result. These infections are a major cause of infertility and ectopic pregnancy, a potentially life-threatening disorder in women. Complications of chlamydial infections in men include epididymitis, prostatitis, sterility, and Reiter's syndrome. Routine screening for sexually active adolescents and young adults has been suggested by the CDC to minimize these serious complications in asymptomatic people (CDC, 2014a).

●○● INTERPROFESSIONAL CARE

C. trachomatis is treated with medications to eradicate the infection. Its prevalence, particularly in younger populations, makes widespread screening necessary if the disease is to be controlled. Because chlamydia is often asymptomatic, treatment is often begun on a presumptive basis.

DIAGNOSIS

A urine specimen or swab of the vagina or endocervix, urethra, or rectum (as indicated) may be used to diagnose *C. trachomatis*. The specimen is cultured or subjected to tests for antibodies to chlamydia such as an enzyme-linked immunosorbent assay (ELISA), polymerase chain reaction (PCR), or nucleic acid amplification test (NAAT). NAATs performed on cervical and urethral swab specimens are highly sensitive and have become the diagnostic method of choice (CDC, 2014a).

MEDICATIONS

The antibiotic recommended by the CDC for chlamydial infections in men and nonpregnant women is azithromycin (Zithromax) orally in a single dose, or doxycycline (Adoxa, Apo-Doxy) orally for 7 days. Both sexual partners must be treated at the same time or prior to resuming sexual intercourse.

●○● NURSING CARE

Nursing care of the patient with chlamydia focuses on eradication of the infection, prevention of future infections, and management of any chronic complications. Nursing diagnoses for the patient with chlamydia are the same as for patients with any STI. Interventions are similar to those discussed later in the chapter for gonorrhea and previously for genital herpes.

Continuity of Care

Health teaching for the patient with chlamydia centers on the need to comply with the treatment regimen, refer partners for examination and necessary treatment, and the use of condoms to avoid reinfection. If the infection has progressed to PID (discussed later), the patient needs additional information on self-care and health promotion. The CDC recommends annual screening for chlamydia for young, sexually active women, and young sexually active men in selected settings (adolescent and STD clinics, correctional facilities) (CDC, 2014a).

THE PATIENT WITH GONORRHEA

Gonorrhea, also known as *GC* or *the clap*, is caused by *Neisseria gonorrhoeae*, a gram-negative diplococcus. Gonorrhea is the second most common reportable communicable disease in the United States. The CDC (2014b) estimates that more than 800,000 new cases occur annually, of which only about half are reported to the CDC.

Gonorrhea rates for African Americans are eight times that of non-Hispanic Whites. Young adults (15 to 24 years old), and young women in particular, have the highest rate of gonorrhea infection. In men, the highest rate of infection is among those 20 to 29 years of age. Geographically, gonorrhea infection rates in the South are higher than in other parts of the United States (CDC, 2013b).

Pathophysiology

The causative organism of gonorrhea is a pyogenic (pus-forming) bacteria that causes inflammation characterized by purulent exudate. Humans are the only host for the organism. Gonorrhea is transmitted by direct hetero- and homosexual intercourse and during delivery as the neonate passes through the birth canal. The portal of entry can be the genitourinary tract, eyes, oropharynx, anorectum, or skin. The incubation period is 2 to 7 days after exposure. The organism initially targets the female cervix and the male urethra. Without treatment, the disease ultimately disseminates (spreads widely) to other organs. In men, gonorrhea can cause acute, painful inflammation of the prostate, epididymis, and periurethral glands and can lead to sterility. In women, it can cause PID, endometritis, salpingitis, and pelvic peritonitis.

Manifestations

Manifestations of gonorrhea in men include dysuria and serous, milky, or purulent discharge from the penis. Some men also experience regional lymphadenopathy. About 20% of men and 80% of women remain asymptomatic until the disease is advanced. Women with symptoms experience dysuria, urinary frequency, abnormal menses (increased flow or dysmenorrhea), increased vaginal discharge, and dyspareunia.

Anorectal gonorrhea is seen most often in homosexual men. The manifestations include pruritus, mucopurulent rectal discharge, rectal bleeding and pain, and constipation. Gonococcal pharyngitis occurs primarily in homosexual or bisexual men or heterosexual women after oral sexual contact with an infected partner. The manifestations include fever, sore throat, and enlarged lymph glands.

Complications

The complications of untreated gonorrhea in both men and women may be permanent and serious. They include the following:

- PID in women, leading to internal abscesses, chronic pain, ectopic pregnancy, and infertility
- Blindness, infection of joints, and potentially lethal infections of the blood in the newborn, contracted during delivery
- Epididymitis and prostatitis in men, resulting in infertility and dysuria
- Spread of the infection to the blood and joints
- Increased susceptibility to, and transmission of, HIV.

●○● INTERPROFESSIONAL CARE

The goals of treatment for the patient with gonorrhea include eradication of the organism and any coexisting disease, and prevention of reinfection or transmission. It is important to emphasize the importance of taking all medications as prescribed and abstaining from sexual contact until the infection is cured in both patient and partners. Condom use to prevent future infections is essential, particularly for pregnant women whose partners may be infected.

DIAGNOSIS

Diagnosis of gonorrhea is based on NAAT of specimens obtained from infected mucous membranes (cervix, urethra, rectum, or throat) or a urine specimen. Culture and sensitivity testing is performed for gonorrhea infection that is resistant to treatment. Testing for other STIs (especially chlamydia and syphilis) at the same time is recommended. Pregnant women are routinely screened during their first prenatal visit.

MEDICATIONS

Most patients with uncomplicated gonorrheal infections are treated with a single intramuscular dose of ceftriaxone and an oral course of azithromycin or doxycycline. Because patients with gonorrhea frequently also are infected with *C. trachomatis*, concurrent treatment with azithromycin or doxycycline is recommended. Strains of *N. gonorrhoeae* resistant to the quinolone antibiotics

(e.g., ciprofloxacin, ofloxacin, and levofloxacin) are increasingly prevalent. In a change from previous years, the CDC now (2012e) recommends avoiding use of quinolones to treat anyone with gonorrhea.

●○● NURSING CARE

In planning and implementing care for the patient with gonorrhea, the nurse considers the possible coexistence of other STIs such as syphilis and HIV, the impact of the disease and its treatment on the patient's lifestyle, and the likelihood of noncompliance. See the Case Study & Nursing Care Plan for the patient with gonorrhea on page 1633.

Assessment

- *Health history:* difficult or painful urination, frequency; discharge from penis or vagina; change in menses or painful intercourse (women); other symptoms such as sore throat, fever, swollen or tender lymph nodes; sexual activity including number of partners, use of safer sex practices including condom use; previous STIs and their treatment
- *Physical assessment:* presence of penile, vaginal, or anal discharge, regional lymphadenopathy.

Signs and symptoms may be nonexistent as well, especially in women.

Priorities of Care

Collaborating with the interprofessional team to ensure adequate treatment of gonorrhea while providing care that supports the physical and psychologic responses to the infection is a priority of nursing care.

Diagnoses, Outcomes, and Interventions

Nursing diagnoses discussed in this section focus on noncompliance and impaired social interaction.

Noncompliance with Therapeutic Regimen

Although one-time treatment with the recommended antibiotic is highly effective in curing gonorrhea, noncompliance with the doxycycline regimen may leave any coexisting chlamydial infection unresolved. Noncompliance with recommendations for abstinence, follow-up, or condom use fosters a high rate of reinfection. Failure to refer partners for examination and treatment also leads to reinfection.

Expected Outcome: Patient will demonstrate compliance with therapeutic regimen by reporting abstinence, utilization of safer sex interventions, and taking medications as prescribed related to the infection.

Evidence for Nursing Care

Preventing/Treating STI

A selected resource that nurses may find helpful when planning evidence-based nursing care follows.

- Centers for Disease Control and Prevention. (2012). Update to STD treatment guidelines: Oral cephalosporins no longer a recommended treatment for gonococcal infections. *MMWR, 61*(31), 590–594.

- Reinforce the need to take all medications as directed and keep follow-up appointments to be sure no reinfection has occurred. Discuss the prevalence of gonorrhea and the potential complications if it is not cured. *The patient who understands the complications of incomplete or failed treatment is more likely to comply with the medication regimen.*
- Discuss the importance of sexual abstinence until the infection is cured, referral of partners, and consistent and correct condom use to prevent reinfection. *Understanding that cure is possible and reinfection is avoidable helps the patient cope with the disease and its treatment and is likely to increase compliance.*

Impaired Social Interaction

Diagnosis of any STI can make patients feel ashamed, guilty about their sexual behaviors, and unworthy to be with others.

Expected Outcome: Patient will demonstrate social interaction skills by interaction with friends and family members.

- Provide privacy, confidentiality, and a safe, nonjudgmental environment for expression of concerns. Help the patient understand that gonorrhea is a consequence of sexual behavior, not a punishment, and that it can be avoided in the future. *Being treated with respect and privacy helps the patient realize that the disease does not change an individual's worth as a person. This knowledge enhances the patient's ability to relate to others.*

Continuity of Care

Health teaching focuses on helping patients understand the importance of (1) taking any and all prescribed medication, (2) referring sexual partners for evaluation and treatment, (3) abstaining from all sexual contact until the patient and partners are cured, and (4) using a condom to avoid transmitting or contracting infections in the future. Patients also need to understand the need for a follow-up visit 4 to 7 days after treatment is completed.

THE PATIENT WITH SYPHILIS

Syphilis is a complex systemic STI caused by the spirochete *Treponema pallidum*, and it can infect almost any body tissue or organ. It is transmitted from open lesions during any sexual contact (genital, oral–genital, or anal–genital). The organism is highly susceptible to heat and drying, but can survive for days in fluids; thus, it may also be transmitted by infected blood or other body fluid such as saliva. The incubation period ranges from 10 to 90 days, averaging 21 days. If not treated appropriately, syphilis can lead to blindness, paralysis, mental illness, cardiovascular damage, and death. Syphilis often occurs with one or more other STIs, such as HIV/AIDS or chlamydial infection.

In 2000, the rate of syphilis infection reached its lowest level since reporting began in 1941. Unfortunately, since 2001, the rate of syphilis infection increased annually until leveling off in 2010 and 2011 (CDC, 2013b). Among ethnic groups, the rate of syphilis infection is highest in African Americans; the gap between Blacks and Whites is narrowing, however, as rates increase among all populations. Rates also remain high in many urban centers, with higher infection rates found in drug users, transients, and the homeless. The incidence of primary and secondary syphilis is highest in

CASE STUDY & NURSING CARE PLAN A Patient with Gonorrhea

Janet Cirit, a 33-year-old legal secretary, lives in a suburban Midwestern community. She is unmarried but dating a man named Jim Adkins, who lives in an adjacent suburb. Ms. Cirit visits her gynecologist because her periods have become irregular and she is experiencing pelvic pain and an abnormal amount of vaginal discharge. Recently she has developed a sore throat. The pelvic pain has begun to disrupt her sleeping pattern, and she is concerned that she might have cancer because her mother recently died of ovarian cancer.

ASSESSMENT

When Ms. Cirit arrives for her appointment at the gynecologist's office, Marsha Davidson, the nurse practitioner, interviews her. Ms. Davidson completes a thorough medical and sexual history, including questions about her menstrual periods, pain associated with urination or sexual intercourse, urinary frequency, most recent Pap smear, birth control method, history of STI and drug use, and types of sexual activity. Ms. Cirit reports her symptoms and her concern about ovarian cancer. She also indicates that she is taking oral contraceptives and therefore sees no need for her boyfriend to use a condom because she believes their relationship is monogamous.

Physical examination reveals both pharyngeal and cervical inflammation, and lower abdominal tenderness. Her temperature is 37.0°C (98.5°F). There are no signs or symptoms of pregnancy.

The gynecologist orders a Pap smear and cultures of the cervix, urethra, and pharynx to evaluate for gonorrhea and chlamydial infection. Blood is drawn for WBC. Test results are positive for gonorrhea and negative for chlamydia. The WBC is slightly elevated, indicating possible salpingitis. Because Mr. Adkins has been Ms. Cirit's only sexual partner, it is clear that he is the source of infection and needs to be treated as well.

DIAGNOSES

- *Acute Pain* related to the infectious process
- *Anxiety* related to fear about possible cancer
- *Situational Low Self-Esteem* related to shame and guilt because of having an STI
- *Sexual Dysfunction* related to the impaired relationship and fear of reinfection

EXPECTED OUTCOMES

- Patient will experience relief of pain, indicating that the infection has been eradicated.
- Patient will verbalize that she has nothing to be ashamed of and that she has been wise to seek treatment as soon as symptoms occurred.
- Patient will verbalize that she will insist her partner use condoms during future sexual activity.

PLANNING AND IMPLEMENTATION

- Administer ceftriaxone IM and azithromycin PO as ordered.
- Emphasize the need for regular Pap smears and pelvic examinations because of the family history of ovarian cancer.
- Discuss feelings and concerns about the diagnosis of gonorrhea. Stress that such a diagnosis does not reflect on one's self-worth as a person.
- Teach how to talk with a future sexual partner about condom use.

EVALUATION

A week later during her follow-up visit, Ms. Cirit states that she is feeling much better and sleeping well at night since the pain has ended. She has terminated her relationship with Mr. Adkins and is considering joining a health club in the hope of increasing her level of fitness and perhaps meeting someone new.

Clinical Reasoning in Patient Care

1. How are Ms. Cirit's manifestations related to the infectious process of gonorrhea?
2. Should the nurse have suggested that Ms. Cirit also be tested for HIV? Why or why not?
3. Develop a care plan for Ms. Cirit for the nursing diagnosis *Impaired Social Interaction.*

See Evaluating Your Response in Appendix B.

people 20 to 39 years of age. Men who have sex with men constitute 75% of all primary and secondary cases of syphilis (CDC, 2013b).

Pathophysiology and Manifestations

Any break in the skin or mucous membrane is vulnerable to invasion by the spirochete. Once it has entered the system, the spirochete is spread through the blood and lymphatic system. Congenital syphilis is transferred to the fetus through the placental circulation.

Syphilis is generally characterized by three clinical stages: primary, secondary, and tertiary. Each stage has characteristic manifestations (see Table 50–2 on page 1634). The patient with syphilis also may experience a latency period when no signs of the disease are evident.

PRIMARY SYPHILIS

The primary stage of syphilis is characterized by the appearance of a **chancre** (Figure 50–4 ■) and by regional enlargement of lymph nodes; little or no pain accompanies these early signs. The chancre appears at the site of inoculation (such as the genitals, anus, mouth, breast, fingers) 3 to 4 weeks after the infectious contact. In women, a genital chancre may go unnoticed, disappearing within 4 to 6 weeks. In both primary and secondary stages, syphilis remains highly infectious, even if no symptoms are evident.

SECONDARY SYPHILIS

Manifestations of secondary syphilis may appear any time from 2 weeks to 6 months after the initial chancre disappears. These symptoms can include a skin rash, especially on the palms of the hands

Figure 50–4 ■ Chancre of primary syphilis on the penis.
Source: Biophoto Associates/Photo Researchers, Inc.

TABLE 50–2 Manifestations of Syphilis

System	Primary Syphilis	Secondary Syphilis	Tertiary Syphilis
Reproductive	Genital chancre (may be internal in female)	Condyloma lata	
Integumentary		Rash on palms of hands and soles of feet	Granulomatous lesions involving mucous membranes and skin
Gastrointestinal		Anorexia Oral mucous patches	
Neurologic		Asymptomatic Meningitis Headache Cranial neuropathies	Asymptomatic Tabes dorsalis Neurosyphilis Seizures, hemiparesis, hemiplegia Personality changes, hyperactive reflexes, Argyll Robertson pupil, decreased memory, slurred speech, optic atrophy
Musculoskeletal		Arthralgias Myalgia Bone and joint arthritis Periostitis	Gummas
Cardiovascular			Aortic insufficiency Aortic aneurysm Stenosis of openings to coronary arteries
Renal		Glomerulonephritis Nephrotic syndrome	
Other	Regional lymphadenopathy	Generalized lymphadenopathy Fever Malaise Hepatitis Alopecia	

or soles of the feet, mucous patches in the oral cavity; sore throat; generalized lymphadenopathy; condyloma lata (flat, broad-based papules, unlike the pedunculated structure of genital warts) on the labia, anus, or corner of the mouth; flu-like symptoms; and alopecia. These manifestations generally disappear within 2 to 6 weeks, and an asymptomatic latency period begins.

LATENT AND TERTIARY SYPHILIS

The latent stage of syphilis begins 2 or more years after the initial infection and can last up to 50 years. During this stage, no symptoms of syphilis are apparent, and the disease is not transmissible by sexual contact. It can be transmitted by infected blood, however. Thus, all prospective blood donors must be screened for syphilis. In two-thirds of all cases, the latent stage persists without further complications. Unless treated, the remaining one-third of infected people progress to late-stage or tertiary syphilis. In the presence of HIV infection, disease progression seems to be more rapid.

Two types of late-stage syphilis occur. Benign late syphilis, of rapid onset, is characterized by localized development of infiltrating tumors (*gummas*) in skin, bones, and liver, generally responding promptly to treatment. Of more insidious onset is a diffuse inflammatory response that involves the central nervous system and the cardiovascular system. Though the disease can still be treated at this stage, much of the cardiovascular and central nervous system damage is irreversible.

●○● INTERPROFESSIONAL CARE

The goals of treatment are to inactivate the spirochete and educate the patient about how to prevent reinfection or further transmission. Treatment includes antibiotic therapy and identification and referral of partners for testing and treatment if necessary, follow-up testing, and education about condom use to prevent reinfection of self and transmission of disease to partners. In addition, patients should be screened for chlamydial infection and advised to have an HIV test.

DIAGNOSIS

Diagnosis of syphilis is complex because it mimics many other diseases. A careful history and physical examination are obtained, as well as laboratory evaluations of lesions and blood.

The VDRL (Venereal Disease Research Laboratory) and RPR (rapid plasma reagin) blood tests measure antibody production. People with syphilis become positive about 4 to 6 weeks after infection. However, these tests are not specific for syphilis, and other diseases may also cause positive results. Additional tests are required for definitive diagnosis.

The FTA-ABS (fluorescent treponemal antibody absorption) test is specific for *T. pallidum* and can be used to confirm VDRL and RPR findings. It may be used for patients whose clinical picture indicates syphilis but who have negative VDRL results. In immunofluorescent staining a specimen is obtained from early

lesions or aspiration of lymph nodes and is specially treated and examined microscopically for the presence of *T. pallidum*. Dark-field microscopy involves examining a specimen from the chancre for the presence of *T. pallidum* using a dark-field microscope.

MEDICATIONS

The treatment of choice for all stages of syphilis in adults is penicillin G, given intramuscularly (IM) in a single dose. Patients allergic to penicillin are given oral doxycycline or tetracycline for 28 days. For those who have had syphilis more than a year, additional doses may be needed.

Treatment of syphilis may result in a severe reaction called the *Jarisch-Herxheimer reaction*, involving fever, musculoskeletal pain, tachycardia, and sometimes hypotension. This is not a reaction to the penicillin itself, but to the sudden and massive destruction of spirochetes by the penicillin and the resulting release of toxins into the bloodstream. The Jarisch-Herxheimer reaction generally begins within 24 hours of treatment and subsides in another 24 hours. Treatment should not be discontinued unless symptoms become life threatening.

●○● NURSING CARE

In planning and implementing nursing care for the patient with syphilis, the nurse needs to consider the patient's age, lifestyle, access to healthcare, and educational level. Although each patient has individualized needs, nursing diagnoses for the patient with syphilis would be the same as for any patient with an STI. See the Case Study & Nursing Care Plan for a patient with syphilis on page 1636.

Assessment

- *Health history:* current or history of a painless genital lesion, rash on hands or feet, sore throat or flu-like symptoms; recent and past sexual activity including number of partners, use of safer sex practices including condom use; previous STIs and their treatment
- *Physical assessment:* inspection of genitalia for chancre or flat, broad-based papules; inspect palms and soles of feet for rash, mouth for mucous patches; palpate for lymphadenopathy.

Priorities of Care

Collaborating with the interprofessional team to ensure appropriate treatment of syphilis while providing care that supports symptom relief, prevention of future transmission, and physical and psychologic responses to this diagnosis is a priority of nursing care.

Diagnoses, Outcomes, and Interventions

Nursing diagnoses discussed in this section focus on risk for injury, anxiety, and self-esteem.

Risk for Injury

If syphilis is not diagnosed and treated promptly and effectively, it can have devastating effects on all body systems, particularly the neurologic and cardiovascular systems, eventually leading to a painful death.

Expected Outcome: Patient will demonstrate therapeutic regimen compliance to reduce risk of infection progression.

- Teach the importance of taking all prescribed medication. *Taking the prescribed antibiotic is important to ensure eradication of the infecting organism.*
- Encourage referral of sexual partners for evaluation and any necessary treatment. *Without treatment of both partners, reinfection can occur or the disease may be transmitted to other people through sexual activity.*
- Teach abstinence from sexual contact until patient and partners are cured and to use condoms to prevent future infections. *Abstinence until the organism is eradicated prevents reinfection. Condoms provide barrier protection, reducing the risk of infection during sexual activity.*
- Emphasize the importance of returning for follow-up testing at 3- and 6-month intervals for early syphilis, and 6- and 12-month intervals for late latent syphilis. *Follow-up testing is performed to ensure eradication of the disease.*
- Provide information about manifestations of reinfection. *Successful treatment of the disease does not prevent possible subsequent infections.*

Anxiety

The diagnosis of syphilis understandably causes the patient anxiety, not only about personal well-being but also about the well-being of partners and, in the expectant woman, her fetus.

Expected Outcome: Patient will demonstrate management of anxiety through information seeking and use of coping skills and relaxation techniques.

- Emphasize that syphilis can be effectively treated, preventing the serious complications of late-stage disease. *This information provides a sense of control and helps decrease anxiety.*
- Teach the pregnant patient that taking medications as directed and returning each month for follow-up testing will help ensure the well-being of her baby. *Knowing that treatment can reduce the risk to her baby relieves anxiety and possibly increases compliance.*

Situational Low Self-Esteem

Living with any chronic disease can be damaging to an individual's self-esteem. However, the patient with syphilis needs additional support to cope with the stigma of this kind of infection. Unfortunately, the populations most affected by STIs often lack family and other social support networks.

Expected Outcome: Patient will demonstrate self-esteem related to sexual patterns as evidenced by verbalization of self-acceptance related to stigma of syphilis diagnosis.

- Create an environment in which the patient feels respected and safe to discuss questions and concerns about the disease and its effect on his or her life. *Being treated with respect helps enhance self-esteem.*

Evidence for Nursing Care

The Patient with Syphilis

Selected resources that nurses may find helpful when planning evidence-based nursing care follow.

- Centers for Disease Control and Prevention. (2013). *Syphilis treatment and care*. Retrieved from http://www.cdc.gov/std/syphilis/treatment.htm
- Planned Parenthood. (2014). *Safer sex: Syphilis*. Retrieved from http://www.plannedparenthood.org/health-topics/stds-hiv-safer-sex/syphilis-4281.htm

CASE STUDY & NURSING CARE PLAN A Patient with Syphilis

Eddie Kratz, age 22, works as bellman at a large hotel. For the past year, he has shared a small apartment with Maria Jones, who is 6 months pregnant with his child. Although he intends to marry Ms. Jones before the baby is born, he has continued a previous relationship with a woman named Justine Simpson. His sexual activities with Ms. Simpson have increased in frequency as Ms. Jones's pregnancy has advanced. Recently Mr. Kratz has noticed a swelling in his groin and a sore on his penis.

ASSESSMENT

When Mr. Kratz comes to the community clinic, he is interviewed by the NP, Sally Morovitz. She takes a thorough medical and sexual history, including questions about drug use, allergies, difficulty with urination, urinary frequency, itching or discharge from the penis, recent sexual activities, precautions taken against infection, history of STIs, and sexual function. She determines that Mr. Kratz has been having unprotected sex with both Ms. Jones and Ms. Simpson. He believes that Ms. Jones is not having sex with anyone except him, but he is not sure.

Physical assessment reveals a classic syphilitic chancre on the shaft of the penis and regional lymphadenopathy. A specimen of exudates from the chancre is sent for dark-field examination. Ms. Morovitz discusses with Mr. Kratz the likelihood that he has syphilis and the need to tell both Ms. Jones and Ms. Simpson so that they can be tested and, if necessary, treated. Ms. Morovitz also suggests that Mr. Kratz be tested for HIV since he has been having unprotected sex with two women, at least one of whom may be sexually active with other partners. He agrees, and blood is drawn for an ELISA test. Dark-field analysis of the chancre exudate confirms the diagnosis of syphilis; the ELISA results are negative for HIV.

DIAGNOSES

- *Risk for Injury* to the patient, his partners, and the infant, related to the disease process
- *Ineffective Health Maintenance* related to a lack of knowledge about the disease process, its transmission, and the need for treatment
- *Interrupted Family Processes* related to the effects of the diagnosis of syphilis on the couple's relationship
- *Anxiety* related to the effects of the infection on the unborn child

EXPECTED OUTCOMES

- Patient will acknowledge the importance of prompt treatment to cure syphilis.
- Patient will verbalize understanding for the need to abstain from sexual contact during treatment, complete all medications, return for follow-up visits, and use condoms to prevent reinfection.
- Patient will verbalize ability to cope with the effect of diagnosis and treatment on the relationship.
- Patient will verbalize decreased anxiety following education and treatment.

PLANNING AND IMPLEMENTATION

- Administer IM injection of penicillin G as ordered.
- Discuss the importance of abstaining from sexual activity until he and his partners are cured, and of using condoms to prevent reinfection.
- Explain the need to return for follow-up testing in 3 months and again at 6 months. Provide a copy of the STI prevention checklist, and document that reminders need to be sent at 3- and 6-month intervals.
- Notify sexual partners that they need to come to the clinic for testing.
- Refer to a social worker for counseling about the effect of the disease on the couple's relationship.
- Teach the couple about the importance of treatment to the health of their infant.

EVALUATION

At the 3-month follow-up visit, the chancre on Mr. Kratz's penis has healed, and he reports that he is using a condom any time he has sex. Ms. Jones has also tested positive for syphilis and negative for HIV, so she, too, has been given penicillin G, and verbal and written follow-up instructions, including follow-up until the infant is born. The couple is meeting every other week with the social worker and say that their relationship is improving. Ms. Simpson has received similar test results and has been given a prescription for doxycycline because she is allergic to penicillin.

Clinical Reasoning in Patient Care

1. What manifestations might a patient with early syphilis experience?
2. List some appropriate questions for taking a sexual history when you suspect the presence of one or more STIs.
3. How might you counsel Mr. Kratz to help him break the news of the diagnosis to Ms. Jones?

See Evaluating Your Response in Appendix B.

- Provide privacy and confidentiality. *Patients are often embarrassed to discuss the intimate details of their sex lives.*
- Let patients know that the nurse and other healthcare providers care about them and the successful treatment of their disease. *Feeling valued enhances self-esteem.*

Continuity of Care

Education is an essential part of nursing care for the patient with any STI, and syphilis is no exception. The nurse emphasizes that untreated syphilis is a chronic disease that can be spread to others even though no symptoms are evident. Address the following topics:

- Taking all prescribed medication
- Referring sexual partners for evaluation and treatment
- Abstaining from all sexual contact as recommended by CDC guidelines
- Using condoms correctly and consistently to avoid transmitting or contracting infections in the future
- The need for follow-up testing (at 3 and 6 months for patients with primary or secondary syphilis, and at 6 and 12 months for those with late-stage disease). If patients are HIV positive, follow-up visits are recommended 1, 2, 3, 6, 9, and 12 months after treatment.

THE PATIENT WITH PELVIC INFLAMMATORY DISEASE

Pelvic inflammatory disease (PID) is a term used to describe infection of the pelvic organs, including the fallopian tubes (*salpingitis*), ovaries (*oophoritis*), cervix (*cervicitis*), endometrium (*endometritis*), pelvic peritoneum, and the pelvic vascular system. PID can be caused by one or more infectious agents, including *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, *Haemophilus influenzae*,

and enteric Gram-negative rods. *N. gonorrhoeae* and *C. trachomatis* are responsible for most PID; dual infection with both agents is common.

PID is not a reportable disease in the United States; however, it is estimated that more than 4% of women in the United States have been treated for PID at some point during their lifetimes. As a result of the infection, some women become infertile and the risk for ectopic pregnancies is increased by 6 times (CDC, 2014c). The disease may also cause pelvic abscesses and chronic abdominal pain.

Sexually active women ages 16 to 24 years are most at risk. Risk factors include a history of sexually transmitted infection (especially gonorrhea and chlamydia), bacterial vaginosis, multiple sexual partners, douching, and previous PID. Barrier contraceptive devices such as condoms reduce the risk of PID.

The prognosis depends on the number of episodes, promptness of treatment, and modification of risk-taking behaviors. Prevention includes educating women, especially young women, regarding the causes and transmission of infection and methods of self-protection, such as avoiding unprotected sexual activity.

Pathophysiology

Pelvic inflammatory disease is usually polymicrobial (caused by more than one microbe) in origin, with gonorrhea and chlamydia being common causative organisms. Pathogenic organisms ascend from the vagina via the endocervical canal to the fallopian tubes and ovaries. The endocervical canal is slightly dilated during menstruation, allowing bacteria to enter the uterus. Once in the reproductive tract, the organisms rapidly multiply and ascend to the fallopian tubes and ovaries. The infection can extend beyond the reproductive tract to involve the peritoneum (peritonitis or peritoneal abscess) or other abdominal organs.

Manifestations

Manifestations of PID include fever, purulent vaginal discharge, abnormal bleeding, lower abdominal or back pain, dyspareunia, and painful cervical movement. However, the manifestations may be so mild that the infection is not recognized.

Complications

Complications include pelvic abscess, infertility, ectopic pregnancy, chronic pelvic pain, and pelvic adhesions. Abscess formation is common.

●○● INTERPROFESSIONAL CARE

The goals of treatment are to eliminate the infection and prevent complications and recurrence. The physical examination may reveal abdominal, adnexal, and cervical pain.

DIAGNOSIS

Tests used in the diagnosis of PID may include a CBC with differential, which will show a markedly elevated WBC, and an increased sedimentation rate. If a laparoscopy or laparotomy is done, it may reveal inflammation, edema, or hyperemia of the fallopian tubes, or tubal discharge and, possibly, generalized pelvic involvement, abscesses, and scarring.

MEDICATIONS

Combination antibiotic therapy with at least two broad-spectrum antibiotics administered IV or orally is the typical treatment for PID. If PID is not acute, outpatient antibiotic therapy is prescribed. In acute cases, however, the patient may be hospitalized. Analgesics are given, and antibiotics and fluids are administered intravenously. Commonly prescribed antibiotics include parental cefoxitin (Mefoxin), or clindamycin (Cleocin), plus gentamicin (Garamycin) or doxycycline (Vibramycin). Nursing implications for antibiotic use are discussed in Chapter 12.

SURGERY

Surgery may be performed to drain an abscess or treat a life-threatening complication such as rupture of a fallopian tube or abscess.

●○● NURSING CARE

The goals of nursing care are to treat the infection and to prevent complications, such as scarring and infertility. The patient who is hospitalized maintains bed rest in the semi-Fowler's position to promote drainage and to localize the infectious process in the pelvic cavity.

Assessment

See the Manifestations and Interprofessional Care sections for the assessment of the patient with pelvic inflammatory disease.

Priorities of Care

Collaborating with the interprofessional team to ensure adequate treatment of the pelvic inflammatory disease while providing care that supports optimal function and physical and psychologic responses to the disorder is a priority of nursing care.

Diagnoses, Outcomes, and Interventions

PID is associated with the nursing diagnoses of *Risk for Injury* related to scarring of fallopian tubes and *Knowledge Deficit* related to lack of understanding about complications related to PID.

Risk for Complications

PID can have severe, even life-threatening, complications. Scarring of fallopian tubes can lead to ectopic pregnancy or pelvic abscess. Infertility is a common complication, as are recurrent or chronic PID, chronic abdominal pain, pelvic adhesions, hysterectomy, and depression. The woman who has severe infection and manifestations may be hospitalized for treatment.

Expected Outcome: Patient will recover from PID without long-term sequelae.

- Administer antibiotic therapy as ordered, and monitor closely for adverse effects. *Antibiotics used in acute PID are potent agents; some can have serious side effects.*
- Practice thorough hand hygiene and strict adherence to standard precautions when handling perineal pads and linens. Appropriate disinfection of bedpans, toilet seats, linens, and utensils is also important. *These practices help avoid disseminating the infection to others.*

Knowledge Deficit

PID is most common in young women, who often do not understand their own anatomy and physiology or STIs. Diagnosis and treatment

of PID offer an opportunity to increase that understanding, thereby preventing complications and recurrent infection.

Expected Outcome: Patient will demonstrate knowledge about PID by verbalizing understanding of PID pathophysiology and consequences of untreated infection.

- Explain how infection is spread and what measures to take to prevent future infection. *Understanding can improve compliance with treatment regimens and perhaps change high-risk behavior.*
- Explain the need to complete the treatment regimen and the importance of follow-up visits. If the patient or partner fails to take all of the medication as prescribed, the infection may not be completely cured. *Noncompliance and recurrence are common, particularly if follow-up appointments are not kept.*
- Teach proper perineal care, especially wiping from front to back. *This reduces transmission of fecal organisms to reproductive tissues and reduces the incidence of urinary tract infections.*
- Caution the patient about using tampons. Instruct the patient to change tampons or pads at least every 4 hours. *Menstrual flow and other discharges provide a favorable environment for microorganisms to multiply.*
- Provide information about safer sex practices and family planning. Instruct the patient to remove diaphragm within 6 hours after use. IUDs are contraindicated. Latex condoms offer the most effective protection against infection. *These measures help prevent recurrence of infection.*
- Teach the patient to report any unusual vaginal discharge or odor to the healthcare provider. *Treatment is most effective early in the disease process.*

Delegating Nursing Care Activities

As appropriate and allowed by the designated duties and responsibilities of unlicensed assistive personnel, the nurse may delegate nursing care activities such as collecting vital signs, measuring I & O, and assisting with hygiene and activities as allowed.

Continuity of Care

Provide general information related to STIs. Teach measures to eradicate the infection and prevent recurrence, and help the patient deal with the physical and psychosocial implications of treatment, including possible infertility. Inform the patient that the patency of the fallopian tubes can be evaluated after several menstrual cycles; this delay allows for complete resolution of the inflammatory process.

CHAPTER HIGHLIGHTS

- **Sexually transmitted infections (STIs) are infections transmitted by sexual contact, including vaginal, oral, and anal intercourse. STIs affect women more than men, and are more common in people who have multiple sexual partners, abuse drugs, and are of lower socioeconomic status.**
- STIs can coexist in the same person and can be transmitted by either heterosexual or homosexual sexual contact. Effective treatment mandates that both sexual partners be treated. Most STIs can be prevented by using latex condoms.
- **Genital herpes, caused by an infection with an HSV virus, is a commonly occurring STI in teens and young adults.**
- There is no cure for genital herpes and treatment is primarily symptomatic. Nursing care is directed toward relieving the pain of the lesions, mitigating sexual dysfunction, and relieving anxiety.
- **Human papilloma virus (HPV) is the most commonly occurring STI in the United States. Some strains cause genital warts, a chronic, incurable STI manifested by warts of various forms. Other strains cause no initial symptoms but are associated with cancers of the cervix, vulva, and penis, as well as oropharyngeal cancer.**
- Infection with HPV poses a major risk for cervical cancer. A vaccine against the virus is recommended for adolescent boys and girls and young women.
- **Urogenital infections include vaginal infections (bacterial vaginosis, candidiasis, and trichomoniasis), chlamydia, gonorrhea, syphilis, and pelvic inflammatory disease (PID).**
- Chlamydia, occurring most in young adults under age 25, is a bacterial infection that can spread to the uterus and fallopian tubes in women, causing PID, infertility, and ectopic pregnancy. Untreated chlamydia in men may result in epididymitis, prostatitis, sterility, and Reiter's syndrome.
- **Gonorrhea (caused by a bacteria) and syphilis (caused by a spirochete) affect both men and women, and may infect the newborn as it moves through the birth canal in an untreated woman.**
- Syphilis, if untreated, exists in the body in three stages, with the third stage lasting up to 50 years.
- Nursing care of gonorrhea and syphilis focus on education, preventing injury from complications, relieving anxiety, and supporting self-esteem.
- **PID is an infection of the female pelvic organs, and may be caused by one or more infectious agents.**
- Sexually active young women between the ages of 16 and 24 are most at risk for PID. The prognosis depends on the number of episodes, promptness of treatment, and modification of risk-taking behaviors. The goals of nursing care are to treat the infection and prevent complications.

TEST YOURSELF NCLEX-RN® REVIEW

1. The nurse is preparing a community health session on sexually transmitted infections. Which population should the nurse emphasize as being most often affected by these infections?
   1. men
   2. women
   3. older adults
   4. adolescent males
2. The nurse is evaluating teaching provided to a patient with a sexually transmitted infection. Which patient statement indicates an understanding of the treatment for the infection?
   1. "I know I can never have sex again."
   2. "My sex partner and I must both take medications."
   3. "I will douche after every sexual encounter with my partner."
   4. "My sex partner does not have an infection, so won't need medications."
3. The nurse is teaching a male patient about using condoms to prevent sexually transmitted infections. What topics should the nurse include with this teaching? (Select all that apply.)
   1. Withdraw when the penis is erect.
   2. Use a new condom with each sex act.
   3. Handle carefully to ensure no damage.
   4. Ensure a small amount of air in the tip.
   5. Use oil-based lubricants, such as petroleum jelly.
4. While assessing a young male patient, the nurse notes blisters and ulcerations on the shaft of the penis. What health problem is this patient most likely experiencing?
   1. gonorrhea
   2. chlamydia
   3. genital warts
   4. genital herpes
5. The nurse is preparing an educational session on genital warts for high school students. Which information about this sexually transmitted infection should the nurse include? (Select all that apply.)
   1. The infection cannot be cured.
   2. The infection can cause cancer.
   3. The infection is caused by a yeast organism.
   4. The infection may be transmitted to the fetus.
   5. The infection can be spread by any type of intercourse.
6. The nurse is counseling a young female patient diagnosed with a human papillomavirus genital infection. What screening test should the nurse recommend the patient have annually?
   1. stool for occult blood
   2. pelvic exam and Pap smear
   3. breast exam and mammogram
   4. CBC to detect anemia and infection
7. The nurse suspects that a female patient has a vaginal infection. What manifestation did the nurse assess during the health history to come to this conclusion?
   1. pain
   2. itching
   3. nausea
   4. diarrhea
8. The nurse is teaching a female patient with a sexually transmitted infection. What should the nurse recommend to relieve genital discomfort caused by the infection?
   1. Cut fingernails short.
   2. Wear nylon panty hose.
   3. Wear cotton underwear.
   4. Have sex more frequently.
9. The nurse is reviewing the mechanism of infection with the gonorrhea organism during health class with high school students. On which body parts should the nurse explain that the organism initially targets?
   1. male prostate
   2. female vulva and vagina
   3. male urethra and female cervix
   4. male and female external genitalia
10. A patient newly diagnosed with syphilis asks the nurse to explain the disease. What should the nurse include when teaching the patient about this sexually transmitted infection?
    1. Syphilis is caused by a virus.
    2. Syphilis is a systemic infection.
    3. Syphilis is a local genital infection.
    4. Syphilis has no effect on the developing fetus.

See Test Yourself answers in Appendix B.

UNIT

13 Building Clinical Competencies

Responses to Altered Reproductive Function

CLINICAL SCENARIO

Directions: *Read the following clinical scenarios and answer the questions that follow. To complete this exercise successfully, you will not only use knowledge of the content in this unit, but also principles related to priority setting and maintaining patient safety.*

You have been assigned to work with the following four patients for the 0700 shift on a medical-surgical unit. Significant data obtained during report is as follows:

- Wendy Torrell, 53 years old, had an abdominal hysterectomy yesterday afternoon. She has a history of CVA and stopped taking the prescribed clopidogrel (Plavix) 24 hours before surgery. Postoperatively she developed intra-abdominal bleeding, which was controlled by abdominal pressure and ice. She is to receive 2 units of packed red blood cells this morning. Vital signs are temperature 36.8°C (98.2°F), pulse 110 bpm, respirations 20/min, blood pressure 88/54 mmHg.
- Barney Green, 76 years old, is 3 days postoperative following a transurethral resection of the prostate (TURP). Vital signs are temperature 37°C (98.7°F), pulse 82 bpm, respirations 16/min, blood pressure 158/82 mmHg. His urinary catheter was removed at 0600. He is complaining of dribbling of urine after attempting to void.
- Tara Morris, 21 years old, is newly admitted from the emergency department with complaints of severe lower abdominal pain, purulent vaginal discharge, and cervical pain on pelvic exam. Her vital signs are temperature 39.2°C (102.6°F), pulse 88 bpm, respirations 20/min, and blood pressure 110/70 mmHg. She is to be started on ceftriaxone (Rocephin) and gentamicin (Garamycin) IV as soon as possible.
- Regina Perkins, 36 years old, has a history of uterine fibroids. She had a uterine fibroid embolization yesterday. Her vital signs have remained stable throughout the night. Her discharge is written and she is in a hurry to be discharged so her husband can get to work.

CLINICAL REASONING

1. Which clinical findings suggest that Ms. Torrell is hypovolemic?

Priority Setting

2. In what order would you visit these patients after report?

A. _____
B. _____
C. _____
D. _____

Health Promotion

3. What teaching regarding safer sex practices will you provide for Ms. Morris?

Nursing Process

4. Ms. Torrell asks the purpose of the abdominal binder. Which of the following would be the most appropriate explanation provided by the nurse?

A. "The abdominal binder will hold the abdominal muscles together until healing occurs."
B. "The abdominal binder puts pressure on the leaking blood vessels, stopping the internal bleeding."
C. "The abdominal binder is routinely used on all patients after abdominal surgery."
D. "The abdominal binder is used on all patients who are obese."

5. Prior to surgery, Ms. Perkins's hematocrit was 34% and hemoglobin was 10 g/dL. She was instructed to increase iron foods in her diet. Which of the following food selections made by Ms. Perkins indicates that she understands the instructions?

A. beef, eggs, brown rice
B. green leafy vegetables, chicken
C. fish, broccoli, kidney beans
D. liver, cheese, asparagus

Communication

6. Ms. Morris asks if she will be able to have children when the infection is gone. How will you respond?

7. Mr. Green asks if he will be able to urinate normally, or if he will always dribble and have to wear adult diapers. How will you respond?

Delegation

8. For each patient, what interventions can be delegated to an unlicensed assistive personnel (UAP)?

A. _____
B. _____
C. _____
D. _____

Interprofessional Care

9. Mr. Green suddenly develops nausea and vomiting, blood pressure is 170/100 mmHg, pulse is 58 bpm, and he becomes confused. Based on these findings why should the nurse contact the health care provider?

A. The patient may be experiencing an allergic reaction to the bladder-irrigating fluid solution.
B. The patient is experiencing an anxiety reaction to having prostate surgery.
C. The findings may be due to absorption of isotonic bladder-irrigating fluids.
D. The patient is demonstrating signs of hypovolemic shock, a complication of the surgery.

Continuity of Care

10. Which is most important to teach Ms. Morris about pelvic inflammatory disease prior to discharge? (Select all that apply.)

A. Take all antibiotics as prescribed.
B. Use latex condoms when having sex.
C. Wipe from front to back after urinating.
D. Change tampons or pads every 4 hours.
E. Remove diaphragm within 12 hours after intercourse

Safety

11. Ms. Morris's gentamicin (Garamycin) is to be infused intravenously over 1 hour. Which of the following activities performed by the nurse will ensure the safest infusion time?

A. Use a macrodrop tubing for the medication infusion, calculating the number of drops/minute at which it should be set.
B. Obtain an electronic infusion device.
C. Use a microdrop tubing for the gentamicin infusion, calculating the drops/minute at which it should be set.
D. Piggyback the gentamicin with the main intravenous solution.

Quality Improvement

12. The nurse manager has identified that newly admitted patients to the gynecological unit with infection are not receiving intravenous antibiotics in a timely fashion. What factors should be examined to determine the cause of the delay?

Informatics

13. If Mrs. Perkins is ordered home health care following discharge, what type of documentation would you expect the home health nurse to use during a home visit?

A. paper medical record
B. handheld device for in-home notes
C. electronic medical record via desktop computer
D. electronic medical record via laptop computer

Appendix A Standard Precautions

Standard precautions are designed to reduce the risk of transmission of microorganisms from both recognized and unrecognized sources of infection. They are the primary strategies for preventing nosocomial infections within institutions, and are important to protect healthcare workers as well. Standard precautions apply to (1) blood; (2) all body fluids, secretions, and excretions except sweat, regardless of whether or not they contain visible blood; (3) nonintact skin; and (4) mucous membranes. Standard precautions are applied to all patients receiving care in any healthcare setting, regardless of their diagnosis or presumed infection status. Although these precautions are specifically designed for healthcare settings, they also may be implemented in providing home care or in other community-based care settings.

HAND HYGIENE

- Avoid unnecessary touching of surfaces in the patient-care area.
- Perform hand hygiene (1) after touching blood, body fluids, secretions, excretions, and contaminated items, whether or not gloves are worn; (2) immediately after removing gloves, even if gloves appear to be intact; (3) between contacts with patients; and (4) when otherwise indicated to prevent transfer of organisms to other patients. You may need to wash your hands between tasks and procedures on the same patient to prevent cross-contaminating different body sites.
- Use soap and warm water for hand hygiene when hands are visibly dirty or contaminated with blood, other body fluids, or material containing body proteins.
- If hands are not visibly soiled, use an alcohol-based hand rub for routinely decontaminating hands in all other situations.

PERSONAL PROTECTIVE EQUIPMENT

Gloves

- Wear clean, nonsterile gloves when touching blood, body fluids, secretions, excretions, and contaminated items.
- Put on clean gloves just before touching mucous membranes and nonintact skin.
- Change your gloves between tasks and procedures on the same patient after contacting material that may contain a high concentration of microorganisms.
- Wear gloves for all invasive procedures such as performing venipuncture or other vascular or surgical procedures.
- Wear gloves if you have cuts, scratches, or other breaks in the skin.
- Remove gloves promptly after use, before touching noncontaminated items and surfaces, and before going to another patient; perform hand hygiene immediately after removing gloves.

Mask, Eye Protection, Face Shield

Wear a mask and eye protection or a face shield to protect mucous membranes of your eyes, nose, and mouth during procedures and patient-care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, or excretions (including suctioning of the respiratory tract or endotracheal intubation). Wear a surgical mask when assisting with lumbar puncture or when material is injected into the spinal canal or subdural space.

Gown

Wear a gown (clean, disposable) to protect your skin and prevent soiling of clothing during procedures and patient-care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, or excretions. Remove soiled gowns promptly, washing your hands immediately after gown removal.

RESPIRATORY HYGIENE/COUGH ETIQUETTE

Implement measures to control respiratory secretions of patients (and people accompanying them) with manifestations of a respiratory infection on entry into the healthcare setting:

- Post signs alerting patients to cover their mouths/noses when coughing or sneezing, to use and dispose of tissues, and to perform hand hygiene after contacting respiratory secretions.
- Provide tissues and no-touch receptacles (e.g., a waste container with a foot pedal) for tissue disposal.
- Provide instructions and resources (e.g., alcohol-based hand rub dispensers) for hand hygiene in or near patient waiting areas.
- As appropriate, offer masks to coughing patients, and encourage them to sit at least 3 feet away from other patients in the waiting area.

ENVIRONMENTAL CONTROL

Follow hospital procedures for routine care, cleaning, and disinfecting of environmental surfaces, beds, bed rails, bedside equipment, and other frequently touched surfaces.

Equipment

Handle used patient-care equipment that is soiled with blood, body fluids, secretions, and excretions in a way that prevents exposing your skin and mucous membranes, contaminating your clothing, and transferring microorganisms to other patients or environments. Ensure that reusable equipment is cleaned and appropriately reprocessed before using for the care of another patient.

Linen

Handle and transport linens soiled with blood, body fluids, secretions, and excretions in a manner that prevents exposing your skin and mucous membranes, contaminating your clothing, and transferring microorganisms to other patients and environments. Place soiled linen in leakage-resistant bags at the location where it is used.

OCCUPATIONAL HEALTH AND BLOODBORNE PATHOGENS

- Take care to prevent injuries when using needles, scalpels, and other sharps; when handling sharp instruments after procedures; when cleaning used instruments; and when disposing of used needles.
- Never recap used needles, manipulate them using both hands, or handle them in a manner that directs the point of a needle toward any part of your body. If it is necessary to protect the needle prior to disposal, use a one-handed "scoop" technique or mechanical device to hold the needle sheath.
- Do not remove used needles from disposable syringes by hand; do not bend, break, or otherwise manipulate used needles by hand.
- Place used disposable syringes and needles, scalpel blades, and other sharp items in appropriate puncture-resistant containers located as close as practical to the area in which the items were used.
- Place reusable syringes and needles in a puncture-resistant container for transport to the reprocessing area.
- Use mouthpieces, resuscitation bags, or other ventilation devices as an alternative to mouth-to-mouth resuscitation methods whenever possible.

Safe Injection Practices

When using needles, cannulas that replace needles, and intravenous delivery systems, do the following:

- Use aseptic technique to avoid contaminating sterile equipment.
- Needles, cannulas, and syringes are single-use items; never use the same syringe, needle, or cannula for more than one patient (even if used to enter or connect to a patient's IV fluid or administration set).
- Use intravenous fluid infusion and administration sets for one patient only and appropriately discard after using.
- Use single-dose vials of parenteral medications whenever possible; do not use the same single-dose vial for more than one patient or combine leftover contents with that from another vial.
- Use a sterile syringe and needle or cannula to access multiple-dose vials if necessary to use; do not store the vial in the patient-care area and discard if sterility is compromised or questionable.

PATIENT PLACEMENT

Place patients who contaminate the environment or who do not (or are not expected to) assist in maintaining appropriate hygiene or environmental control (e.g., an ambulatory, confused patient with fecal incontinence) in a private room.

Appendix B Test Yourself, End of Unit, and Evaluate Your Response Answers

Chapter 1: Medical-Surgical Nursing in the 21st Century

1. **Answer: 4 Rationale:** Teamwork and collaboration foster open communication, mutual respect, and shared decision making to achieve quality patient care. Patient-centered care recognizes the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs. Quality improvement uses data to monitor the outcomes of care processes and improvement methods to design and test changes to continuously improve the quality and safety of healthcare systems. Evidence-based practice integrates best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal healthcare. Cognitive Level: Understanding; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
2. **Answer: 1 Rationale:** Critical thinking occurs when the nurse challenges assumptions, considers the influence of context, and generates possible explanations. Divergent thinking is weighing the importance of information by sorting relevant from irrelevant data. Inductive reasoning is reasoning that moves from specific to the general. Deductive reasoning is reasoning that moves from general statements and analyzing the options to reach a specific conclusion. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
3. **Answer: 3 Rationale:** During the planning step, the nurse identifies the desired patient outcomes of care that are mutually established by the patient and nurse. The nurse will not focus on outcomes identified by the physician or family members since these may or may not be agreeable to the patient. The nurse will not plan patient care outcomes based on organizational policies and standards. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
4. **Answer: 4, 2, 1, 5, 3 Rationale:** The first step of the nursing process is assessment, during which patient needs are identified. From this step individualized goals and outcomes are established. The next step is planning, during which actions designed to meet the expected outcomes are identified. Implementation is placing the plan into action. The last step is evaluation, in which the plan is evaluated to determine the degree of goal and outcome achievement. It is during the evaluation step where the plan, goals, and outcomes may be changed to meet the patient's needs. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
5. **Answer: 2 Rationale:** The knowledge base is considered the science of nursing. Holistic care is based on a philosophical view that interacting wholes are greater than the sum of their parts and emphasizes the uniqueness of the individual. Practice and clinical competency develop after the knowledge base is mastered. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
6. **Answer: 1 Rationale:** A major component of the educator role is discharge planning, which is a systematic method of preparing the patient and family for exit from the healthcare agency and for maintaining continuity of care after the patient leaves the setting. As an advocate the nurse promotes the patient's rights to autonomy and free choice, speaks for the patient, mediates between the patient and other individuals, and/or protects the patient's right to self-determination. The caregiver role for the nurse today is both independent and collaborative. As a caregiver, nurses make assessments and plan and implement patient care based on nursing knowledge and skills. As a researcher, the nurse studies a broad variety of questions and issues in order to continually develop the knowledge of nursing. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
7. **Answer: 3 Rationale:** As a patient advocate the nurse assists and supports patient decision making. These actions promote the patient's rights to autonomy and free choice. As a caregiver the nurse would perform range-of-motion exercises. As a researcher the nurse would analyze the effectiveness of exercise. As a manager, the nurse would delegate responsibilities for patient care to others. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 4 Rationale:** As a leader/manager, the nurse assigns appropriate and effective work activities to other members of the healthcare team. As a caregiver, nurses make assessments and plan and implement patient care based on nursing knowledge and skills. As an advocate the nurse promotes the patient's rights to autonomy and free choice, speaks for the patient, mediates between the patient and other persons, and/or protects the patient's right to self-determination. As a researcher, the nurse studies a broad variety of questions and issues in order to continually develop the knowledge of nursing. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
9. **Answer: 3 Rationale:** A care bundle is a small set of evidence-based interventions designed to provide interprofessional care that is outcome driven and contains a timeline to achieve identified goals. A policy is a standardized approach to complete an action or perform an activity. A regulation is an expectation identified by a regulatory body. A quality indicator is an outcome that is used to promote the achievement of patient outcomes. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 2 Rationale:** When the nurse delegates nursing care activities to another person, that person is authorized to act in the place of the nurse, although the nurse retains the accountability for the activities performed. The nurse is ultimately responsible for the vital signs performed by UAP. The UAP cannot be responsible for delegated activities. The patient cannot be responsible for delegated responsibilities. The physician did not delegate the assessment of vital signs to UAP and cannot be responsible for this activity. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Chapter 2: Informatics and Evidence-Based Practice in Medical-Surgical Nursing

1. **Answer: 3 Rationale:** Four distinct levels of nursing informatics expertise have been identified. To be viewed as competent, the nurse will need to work consistently through the different levels of informatics competencies. Achieving competence in nursing informatics may or may not be accomplished by earning a nursing informatics

degree. Continuing to function as a nurse within the healthcare team might not provide the opportunities to become competent in nursing informatics. The nurse needs to seek out and plan opportunities to become competent in nursing informatics and not depend on nursing administration's interventions. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

2. **Answer: 1 Rationale:** The nurse must reduce the patient's fears of personal health information being breached. The best way to do this is to explain the computer, how it is used, and how the patient's confidential information is being protected such as through the use of passwords and access levels. Discussing the training used to learn about the computer will not reduce the client's anxieties about personal health information being breached. Summarizing the use of computers to streamline patient care and reduce errors does not support the patient's concern. The patient is also not asking about the amount of money invested to provide computers for all workers. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
3. **Answer: 3 Rationale:** Evidence-based practice is a problem-solving approach for clinical practice that is built on the foundation of external evidence, internal evidence, and patient preferences and values. Evidence-based practice is used to guide hospital policies. Evidence-based practice utilizes researchable evidence. And evidence-based practice is used to identify appropriate quality improvement outcomes. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
4. **Answer: 1 Rationale:** Reasons for implementing evidence-based practice in nursing include promoting the best patient outcomes and reducing costs. Evidence-based practice is not used to increase staff nurse participation in research projects or to expose nursing staff to research findings. The IOM's goal for evidence-based practice is to be achieved by 2020. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
5. **Answer: 1 Rationale:** Identifying methods for conducting a research study within the research process is comparable to the planning phase of the nursing process when goals are set and interventions are planned. Problem identification or research study purpose within the research process is comparable to the assessment phase of the nursing process. Information collection in the research process is similar to the implementation phase of the nursing process. Conducting a literature review and choosing a nursing theory within the research process is comparable to the nursing diagnosis phase of the nursing process. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
6. **Answer: 2 Rationale:** When appraising external evidence, a review is conducted that focuses on the validity of the study, the reliability of the study, and the applicability of the study. Research studies are not reviewed for quality, consistency, quantity, or cost effectiveness. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
7. **Answer: 4 Rationale:** In a quasi-experimental research design, the groups are not randomly assigned; experimental and control groups are used. Descriptive is a term used to describe how the findings will be shared. In an experimental research design, all three components must be present: an independent variable, a control group, and random group assignment. The experimental design is the most powerful to evaluate for cause-and-effect relationships. In a quasi-experimental research design, variables are manipulated, but there may or may not be random group assignment or a control group. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
8. **Answer: 2 Rationale:** The qualitative research approach of phenomenology focuses on the lived experience. The qualitative research approach of ethnography studies the meanings, patterns, and experiences of a defined cultural group in its natural setting. The qualitative research approach of grounded theory focuses on the development and evolution of a social experience. Existential theory is not a qualitative research approach. Cognitive Level: Analysis; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
9. **Answer: 1 Rationale:** Inferential statistics are based on the laws of probability and help the researcher draw conclusions on whether the results observed in the sample are likely to also occur in the population. Descriptive statistics only describe the findings. The goal of the research design is to control factors that could interfere with the validity of the findings or confounding variables. Cognitive Level: Analysis; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 3 Rationale:** Interval data are collected from a calibrated scale such as body temperature. Ratio data are collected from a calibrated scale with an absolute zero. This is the highest level of data that can be collected and includes the data of height, weight, age, and length. Ordinal data have a clear order or hierarchy. These data are not collected using a calibrated scale. Nominal data only name mutually exclusive data categories. There is no hierarchy in nominal data. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Chapter 3: Health and Illness Care of Adults

1. **Answer: 3 Rationale:** Cognitive development affects whether people view themselves as healthy or ill and cognitive levels also may affect health practices. Although certain diseases have a higher rate of incidence in some cultural and ethnic groups than in others, the cultural background of an individual influences health values, behaviors, lifestyle, and illness behaviors. Genetic makeup affects personality, temperament, body structure, intellectual potential, and susceptibility to alterations in health. The components of an individual's lifestyle that affect health status include patterns of eating, use of chemical substances, exercise and rest patterns, and coping methods. Exposure to environmental hazards can lead to disease; however, the patient does not rate health according to lifestyle and environmental factors. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
2. **Answer: 1 Rationale:** Psychosocial stressors for the older adult include the illness of a spouse. Physical stressors for the older adult are those that could lead to a physical illness such as falling and having a 30-year smoking history. Pharmacologic effects on the older adult could develop from the use of over-the-counter pain medication. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
3. **Answer: 2 Rationale:** The nurse promotes health by teaching the activities that maintain wellness, by providing information about the characteristics and consequences of diseases when risk factors have been identified, and by supplying specific information about decreasing risk factors. The purpose of health teaching is not to diagnose diseases, explain the success of medication treatments for illnesses, or adhere to prescribed medication regimens. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
4. **Answer: 2 Rationale:** Secondary prevention involves activities that emphasize early diagnosis and treatment of disease to effect an early cure or prevent disease progression such as obtaining regular physical examinations. Primary prevention focuses on activities and specific actions to prevent disease by eliminating risk factors for disease to the extent possible such as receiving recommended immunizations and

eliminating the use of alcohol and cigarettes. Tertiary prevention focuses on preventing further health decline and reducing complications associated with disease. Tertiary prevention activities primarily revolve around rehabilitation. Cognitive Level: Application; Nursing Process: Planning; Client Need: Health Promotion and Maintenance

5. **Answer: 4 Rationale:** The stage of assuming a dependent role begins when an individual accepts the diagnosis and planned treatment for an illness. A physician or other healthcare provider usually provides validation of illness. People who believe that they are ill and are encouraged by others to contact a healthcare provider make an appointment for diagnosis, prognosis, and treatment of the illness. In the second stage of illness behavior, the person assumes the sick role, accepting the symptoms as indicative of an illness. In the first stage of an acute illness, an individual experiences symptoms such as pain, fever, bleeding, or swelling that signal a change in normal health. Cognitive Level: Application; Nursing Process: Planning; Client Need: Psychosocial Integrity
6. **Answer: 3 Rationale:** The goal of transitional care is to improve the care and outcomes of chronically ill patients by improving the ability of patients and caregivers to manage care needs. Navigating through the healthcare system is a characteristic of care and disease management. Home healthcare is the delivery of services to restore or maintain the health of individuals and families in the home. Community care is an approach to manage acute or chronic health problems and to promote self-care. Cognitive Level: Analysis; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
7. **Answer: 2 Rationale:** The patient-centered medical home is a primary care model that focuses on all levels of illness prevention. For people with chronic diseases, the goal of this approach is to provide comprehensive care with a focus on preventing acute disease crises. Reducing health disparities, increasing preventive services, and improving the patient–primary care relationship are additional goals of this delivery approach; however, they may or may not be appropriate for patients with chronic diseases. Cognitive Level: Application; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
8. **Answer: 2 Rationale:** Medicare will reimburse home care visits if specific criteria or needs are being met. One need is teaching about the care of a new health problem such as teaching a patient how to self-administer insulin for a new diagnosis of diabetes. Medicare does not reimburse visits made to support general health maintenance, health promotion, or patients' emotional or socioeconomic needs. Medicare will not reimburse for the emotional needs of a new widow, assistance with basic care such as bathing and dressing, or for socialization during mealtimes. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
9. **Answer: 2 Rationale:** The disposal of toxic medications is a safety issue in the home. The nurse must address this issue with the patient, demonstrate safe disposal, and provide the necessary equipment for safe disposal. The nurse needs to do more than suggesting the medications be thrown out, reminding the patient to take the medications that are not expired, or moving the expired medications to the back of the patient's medication area. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 1 Rationale:** Infection control in the home centers on protecting patients, caregivers, and the community from the spread of disease. Health teaching is the single most important nursing intervention to control infection. Patients and caregivers need to know the importance of effective hand hygiene. The patient is recovering from bacterial pneumonia and may not need to be isolated from family members. The patient's disease process does not support the need to isolate bed linen and clothing from the rest of the family. The caregiver should be instructed to wash all of the family's eating utensils in hot soapy water and not just those of the patient who is recovering from an illness. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Unit 1 Dimensions of Medical-Surgical Nursing

1. The nurse should consider that the new rash may be a consequence of vancomycin. The nurse should hold the next dose and contact the healthcare provider for further instruction.
2.
   - **A.** The distance and travel time between patients.
   - **B.** The estimated time for each visit.
   - **C.** Tom Smith needs IV antibiotics at 0930.
     Rationale: An absolute plan cannot be addressed without knowing more about the setting. Because all patients are relatively stable, who is seen first is not critical. The nurse should plan a route that would allow adequate time for each visit. Mr. Smith's visit will take at least 90 minutes because IV vancomycin takes a minimum of 60 minutes to infuse. Thirty minutes will be allowed for setup and cleanup of the infusion. The dressing can be changed while the antibiotic is infusing. The route should be planned to avoid back-tracking (if possible) to be most efficient and cost effective.
3. **C.** Enrolling in a work training program for individuals with extremity weakness
   Rationale: Tertiary level of prevention includes providing training to a patient to become productive to society within the limitation of the patient's abilities. Primary level of prevention is developing a healthy lifestyle to prevent illness, such as maintaining a balanced diet and stopping smoking. Secondary level of prevention is screening for and treating illnesses.
4.
   - **A. Cora Swank:** Assess abdominal incision for healing. Assess skin around the ostomy, and the intactness of the ostomy appliance. Assess the amount, color, and consistency of stool. Assess pain control.
     Rationale: Ms. Swank is a postoperative patient and it is important to assess the amount of healing.
   - **B. Tom Smith:** Assess the leg wound for healing, amount and type of drainage, and intactness of wound dressing. Assess pain management. Assess condition of the IV site and the patency of the IV needle.
     Rationale: It is important for the nurse to evaluate the effectiveness of treatment by assessing the condition of the wound. The patency and condition of an IV must be determined before administration of any medication. Infection and slow healing of injuries can result in chronic pain, which must be evaluated.
   - **C. Marguerite Garcia:** Besides obtaining a blood pressure and blood glucose, assess heart and lung sounds. Assess the feet and lower legs for the condition of the skin, normal sensation, pulses, and the presence of swelling. *Rationale: Hypertension and congestive heart failure can cause irregular pulse, moist lung sounds, and swelling and decreased circulation in the feet. Diabetes can cause peripheral nerve damage.*
   - **D. Sebastian Huian:** Assess vital signs, neurologic status including the degree of left-sided weakness, and Mr. Huian's functional abilities for self-care.
     Rationale: Because Mr. Huian was just discharged from rehabilitation and this is the first time the home health nurse is responsible for his care, it is important to obtain a baseline of his neurologic and functional status.
5. A, C, E.
   - **A.** Establish trust and support.
   - **C.** Assess the home environment for safety.

E. Set goals for home healthcare and rehabilitation.
Rationale: The patient is more likely to follow the plan of care when the nurse has established an atmosphere of trust and has rapport with the patient. To develop a plan of care, the nurse needs to assess the environment to determine the patient's safety needs and to obtain the patient's input into the goals to be accomplished. A healthcare translator should be used if the patient is unable to understand English; family members may not understand medical terms and may edit patient responses. The scenario does not support that Mr. Huian is unable to feed himself.

6. Ask Mrs. Garcia to plan a menu for a week and then determine if she has selected low-sodium foods.
Rationale: The best way to determine a patient's understanding of teaching is to have him or her repeat the information or demonstrate his or her knowledge.
7. Report your assessment findings and the plan for home care that was established with the patient and family.
Rationale: It is important to communicate assessment findings and plan of care to provide a baseline for evaluating patient progress.
8. A home health aide can take Mrs. Garcia's blood pressure, blood glucose, and observe Mrs. Garcia taking her medication. If Mrs. Garcia takes her medication when the home health aide is not present, the aide can report that the medication is or is not in the medication container.
Rationale: Home health aides can be taught to take all vital signs and obtain capillary blood glucose values. In most cases, home health aides can remind patients to take their medication and can assist them in opening containers. Home health aides cannot evaluate the effectiveness of medication.
9. **C.** Bibasilar coarse crackles are auscultated in previously clear lungs.
Rationale: This may be indicative of inadequate diuretic therapy used in treatment of heart failure so the healthcare provider should be notified. A weight gain of 1 pound from 2 days ago is not significant; however, weights should continue to be trended. The blood glucose is an expected result prior to the next meal. Slight variations in blood pressure can be expected when comparing both upper extremity results.
10. **B.** The condition and size of Mr. Smith's wound
Rationale: The description of the wound in the electronic health record serves as a basis for comparison for the second nurse's assessment of wound healing. Although the other options contain important information, they do not provide information that helps to evaluate patient progress.
11. **C.** There is one smoke detector in the home.
E. Throw rugs are scattered throughout the living room.
Rationale: A single smoke detector in a home is not sufficient warning in case of fire. In addition, the client is a smoker. Because the patient has left-sided weakness, ambulation may be difficult and throw rugs can become a safety hazard.
12. Heightened medication teaching and emphasis on compliance. Adherence to fluid and sodium restrictions.
13. The nurse should explain that dating the patient is not allowed.
Rationale: Dating a patient or giving the patient the impression that a personal relationship will occur in the future violates professional boundaries and nursing ethics. Once the nurse-patient relationship is no longer established, and the nurse does not have a professional responsibility to provide nursing care, a personal relationship could be established.
14. _____C_____ Flow sheet
_____D_____ Progress note
_____B_____ Nursing care plan
_____A_____ Interprofessional communication notes

Chapter 4: Nursing Care of Patients Having Surgery

1. **Answer: 2 Rationale:** The nurse's primary responsibility to informed consent is serving as a witness to the patient signature on the consent form. Defining the risks and benefits of the surgery, explaining the right to refuse treatment or withdraw consent, and advising the patient and family about what is needed for the diagnosis are actions completed by the healthcare provider. Cognitive Level: Understanding; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
2. **Answer: 3 Rationale:** The nurse has an extensive role in ensuring that education is provided at all phases of the perioperative process, and that learning has occurred to reduce complications as patients have shorter lengths of stay and more patients have their surgical procedures performed on an outpatient basis. Although teaching about nutritional needs, pain control, and fluid and hydration status are important, these areas are not directly impacted by the shorter hospital stay after surgery. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 3 Rationale:** Nonsteroidal anti-inflammatory drugs (NSAIDs) are used to treat mild to moderate postoperative pain. This category of drugs should be given soon after surgery unless contraindicated. Although NSAIDs may not be sufficient to control pain completely, they allow lower doses of opioid analgesics to be used. NSAIDs are not given during the postoperative period to increase amnesia, stimulate appetite, or improve renal function. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 3 Rationale:** Renal function is evaluated on the basis of glomerular filtration rate, which is estimated by using serum creatinine. When creatinine is increased renal impairment needs to be considered. Increased chloride, decreased hemoglobin, and decreased glucose may or may not influence the decision to continue with the surgical procedure and could be related to the patient's current treatment regimen or other health problems. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 4 Rationale:** The patient could have developed a deep venous thrombosis distal to the operative site. Common assessment findings include cramping in the involved calf and redness and edema of the area with a slightly elevated temperature. Bounding pedal pulse, poor muscle tone in the foot, and skin that is cool to the touch are not manifestations associated with a deep venous thrombosis. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 3 Rationale:** In most organizations, orders written prior to surgery must be reordered following surgery because the patient's condition is presumed to have changed. The nurse should not resume the medications now because the healthcare provider has to determine the appropriate doses. Decreasing the doses by half for 36 hours is beyond the nurse's scope of practice. Withholding the medications until fully recovered from anesthesia is not an option because the healthcare provider needs to write new orders for the patient. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 4 Rationale:** Under anesthesia the manifestations of hypoglycemia are absent, so withholding insulin the morning of surgery when the patient is NPO is advisable. The patient is at risk for hyperglycemia during the surgery and will have blood glucose levels monitored throughout the procedure. The patient will not benefit from developing hypoglycemia during anesthesia since this can affect responses to anesthesia and recovery times. The patient most likely did not receive an extra dose of insulin the evening before the surgery although the dosage may have been adjusted the previous evening. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity

8. **Answer: 3 Rationale:** Persistent, severe pain is more difficult to treat; therefore, postoperative analgesics should be administered at regular intervals around the clock to maintain a therapeutic blood level. Administering analgesics as needed lowers the therapeutic level; therefore, prn administration of analgesics is not recommended in the first 36 to 48 hours postoperatively. Pain medications in the immediate postoperative period will begin with opioids. The route of administration will begin with parenteral and eventually change to oral. Pain medications in the immediate postoperative period are not provided to induce a strong sedative effect. Pain medications may or may not impact the patient's development of nausea. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 4 Rationale:** Positioning may cause complications in the older adult because intraoperative positioning of arthritic joints can cause postoperative joint pain unrelated to the operative site. Also, the longer the surgery, the greater the risk for decubitus ulcer formation. The older patient is at increased risk for developing decubitus ulcers because of decreased subcutaneous fat tissue and reduced peripheral circulation. There is no evidence to support that the older patient having a long surgical procedure is at increased risk for memory, hearing, or weight loss. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 4 Rationale:** Hypothermia in the postoperative patient can increase the patient's risk for infection, lead to myocardial ischemia and possible cardiac morbidity, and potentiate surgical bleeding. Being cold postoperatively does not reduce pain and promote comfort. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 5: Nursing Care of Patients Experiencing Loss, Grief, and Death

1. **Answer: 4 Rationale:** Only the person experiencing loss can evaluate his or her experiences. This is highly individualized and cannot be judged by others. Loss is not the same as grief and mourning. Loss may or may not be influenced by cultural values. The impact of loss may or may not be influenced by support from family and friends. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Psychosocial Integrity
2. **Answer: 1 Rationale:** In the anger stage, the person resists the loss, which in this case is directed toward the loss of health. The anger is often directed toward family and healthcare providers. A statement of denial would be "this cannot be happening to me." Bargaining is an attempt to postpone the reality of the loss by expressing a willingness to do anything to postpone the loss or change the prognosis. Depression is when the full impact of the actual or perceived loss is realized. The person prepares for the impending loss by working through the struggle of separation. Cognitive Level: Understanding; Nursing Process: Assessment; Client Need: Psychosocial Integrity
3. **Answer: 2 Rationale:** Grieving is painful and lonely. One's social support system is significant because of its potentially positive influence on the successful resolution of grief. The nurse should not place a value on the patient's loss when assessing the need for support. Social isolation, grief triggers, and acknowledging the loss may help the patient cope with loss but will not help the patient successfully resolve grief. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Psychosocial Integrity
4. **Answer: 2 Rationale:** Culture is the primary factor that dictates the rituals of mourning. The rituals of mourning may or may not be impacted by age, gender, or religion. Cognitive Level: Remembering; Nursing Process: Planning; Client Need: Psychosocial Integrity
5. **Answer: 1 Rationale:** A living will is a legal document that formally expresses an individual's wishes regarding life-sustaining treatment in the event of terminal illness or permanent unconsciousness. It is not a type of durable power of attorney and usually does not designate a surrogate healthcare decision maker. It is the responsibility of the nurse as patient advocate to request and record the patient's preference for care and include it in the plan of care. The healthcare provider can write for a no-code order. The patient does not perform this task. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
6. **Answer: 3 Rationale:** Hospice is a philosophy of care rather than a program of care. It is comprehensive and coordinated care for patients with limited life expectancy, provided at home, hospitals, and long-term care facilities, that reaffirms the right of every patient and family to fully participate in the final stages of life. It is based on a philosophy of death with comfort and dignity, encompassing biomedical, psychosocial, and spiritual aspects of the dying experience. Although most hospice care is provided in the home, it may also be provided in hospitals, long-term care facilities, or other community-based settings. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
7. **Answer: 4 Rationale:** The nurse is ethically and morally responsible to uphold the wishes of the patient so the patient medication should not be provided. Giving the patient medication is not upholding the client's wishes. Changing the dose of pain medication is beyond the nurse's scope of practice. The nurse cannot discuss the patient's care decisions without the patient's permission. This would be a violation of the Health Insurance Portability and Accountability Act (HIPAA). Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 4 Rationale:** A patient near death often has altered cerebral function, so the nurse must stand near the bedside and speak clearly. Hearing is thought to be the last sense a dying patient loses, so conversation should continue as if the patient could actively participate. There is no research evidence to support that the senses of smell, touch, or vision are the last senses to leave the patient who is approaching death. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
9. **Answer: 2 Rationale:** There is no maximum allowable dose for full agonist opioids such as morphine sulfate when caring for a patient who is dying. The dose should be increased to whatever is necessary to relieve pain. Only the patient can determine if pain is present. Pain medication should be provided as needed and necessary to control the dying patient's pain. Respiratory changes are not necessarily associated with the provision of pain medication and may occur as a part of the dying process. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
10. **Answer: 2 Rationale:** An effective nurse–patient relationship begins with acceptance of the patient's feelings, attitudes, and values related to the loss. If the patient is ready to talk, listening and being present are the most appropriate interventions. The open-ended statement of acknowledging to the patient "This must be a difficult time for you" provides an opportunity for her to express her feelings as she recognizes the nurse's willingness to listen. The other responses do not support the nurse–patient relationship and will not help the patient resolve grief. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity

Chapter 6: Nursing Care of Patients with Problems of Substance Abuse

1. **Answer: 2 Rationale:** The legal level of intoxication in many states is 0.08%. Toxic levels in excess of 0.5% can cause coma, respiratory

depression, peripheral collapse, and death. Cognitive Level: Comprehension; Nursing Process: Assessment; Client Need: Psychosocial Integrity

2. **Answer: 3 Rationale:** Questions should be asked in a nonthreatening, matter-of-fact manner, phrased as to not imply wrongdoing. For instance, a nonthreatening question such as "How much alcohol do you drink?" is preferable to the judgmental question "You don't drink too much alcohol, do you?" Open-ended questions that elicit more than a simple yes or no answer help to determine the direction of future counseling. Asking if the drinking has caused problems with the spouse is a judgmental question and should be avoided. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Psychosocial Integrity
3. **Answer: 4 Rationale:** Thiamine depletion is thought to cause the Wernicke-Korsakoff syndrome observed in people with chronic alcoholism. This syndrome is characterized by nystagmus, ptosis, ataxia, confusion, coma, and possible death. This is why the nurse should plan to provide the patient with thiamine supplements. Thiamine is not provided to patients with chronic alcoholism to prevent acute pancreatitis, cirrhosis of the liver, or hepatic encephalopathy. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** All CNS depressants, including alcohol, benzodiazepines, and barbiturates, have a potentially dangerous progression of withdrawal. Alcohol and the entire class of CNS depressants share the same withdrawal syndrome. Severe withdrawal or delirium tremens is a medical emergency that usually occurs 2 to 5 days following alcohol withdrawal and persists 2 to 3 days. Seizures may also occur, requiring the use of emergency equipment. Withdrawal from opiates, marijuana, amphetamines, hallucinogens, CNS stimulants, and amphetamines is not as severe as withdrawal from CNS depressants and alcohol. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 4 Rationale:** Medications used to treat alcoholism include disulfiram (Antabuse). This medication is a form of aversion therapy that prevents the breakdown of alcohol, causing physical illness such as intense vomiting if taken while drinking alcohol. All forms of alcohol, including OTC cough and cold preparations, must be avoided. Disulfiram (Antabuse) does not decrease the discomfort of withdrawal symptoms, decrease the pleasant effects of alcohol, nor does it block the manifestations of alcohol withdrawal. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 2 Rationale:** Behaviors consistent with an impaired nurse include unkempt appearance and disorganized and erratic behavior. Working overtime to complete documentation, learning that patients have effective pain control, and completing assignments early to attend continuing education are not behaviors typically seen in the nurse with a substance abuse problem. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Psychosocial Integrity
7. **Answer: 1 Rationale:** Smoking rates for women have steadily increased, and not declined; currently an estimated 21.5% of women in the United States are smokers. Women who smoke do have an increased risk for stroke and heart disease. Women who smoke during pregnancy do have a higher risk for spontaneous abortion. Smoking is the leading known cause of preventable death and disease among women. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
8. **Answer: 2 Rationale:** It is recommended that patients wear a medical alert bracelet stating they are on naltrexone, in case of emergency medical treatment. Naltrexone can help reduce the craving for alcohol by blocking the pathways to the brain that trigger a feeling of pleasure when alcohol and other narcotics are used. Because naltrexone blocks opiate receptors, patients should avoid taking any narcotics, such as codeine, morphine, or heroin, while on naltrexone. There are other analgesics that the patient can still take with this medication. Products with alcohol do not necessarily have to be avoided while taking this medication. While on naltrexone, psychosocial treatments such as Alcoholics Anonymous meetings, individual counseling, or group therapy are important, as the desire to "take a break" from treatment can overcome the patient's motivation to continue taking the medication. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** A realistic goal for patients who abuse substances is being able to identify healthy coping mechanisms, relaxation, and stress reduction techniques to decrease the risks of substance abuse. Many individuals with substance abuse problems are unable to use alcohol or drugs in moderation. Focusing on negative aspects of past behaviors and relationships could cause the person to seek substances to reduce the impact of the negative feelings. Many patients will not ever lose the craving for the substance so the goal of refraining from using substances until the cravings subside is not realistic. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Psychosocial Integrity
10. **Answer: 3 Rationale:** *Ineffective Coping* is the best choice. Interventions that focus on this diagnosis include establishing a trusting relationship, participation in therapeutic group activities, setting limits on manipulative behavior, encouraging the verbalization of feelings, fears, and anxieties, and focusing on strengths and accomplishments. There is no evidence to support that the patient has an infectious process or pain. There is also no evidence to support that the patient is experiencing excess fluid volume or imbalanced nutrition. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Psychosocial Integrity

Chapter 7: Nursing Care of Patients Experiencing Disasters

1. **Answer: 3 Rationale:** Although emergencies can typically be handled by available emergency services, disasters involve multiple services and agencies working together. Neither emergencies nor disasters can be controlled. Disasters can be natural or human generated. Disasters require the assistance of all available agencies in addition to local agencies. Cognitive Level: Understanding; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
2. **Answer: 2 Rationale:** Nurses usually do not serve in a leadership role at the command center during a disaster. There are specific competencies for providing care during disasters. Competencies for disaster nursing include communication, developing policies, planning for disasters, and providing community education to reduce the incidence of human-generated disasters. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
3. **Answer: 4 Rationale:** Reverse triage is based on the principle of doing the greatest good for the greatest number of people. Reverse triage is not saving scarce resources for future use. It is also not saving victims who are in the most critical condition. Reverse triage is not done to test first responders on triage classification categories. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
4. **Answer: 3 Rationale:** The literacy of non–English-speaking patients should be assessed in both their own language and in English. One cannot assume that individuals are literate in their own language. Assessing a foreign-born patient in both English and the patient's primary language is not done because the patient is more comfortable reading or speaking the primary language. It is also not done because the patient is self-conscious about communicating in English. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Psychosocial Integrity

5. **Answer: 3 Rationale:** Personal protective equipment is used to reduce the likelihood of occupational injury and/or illness. This equipment is not used to create a barrier against hazards. This equipment is to be used as needed but is not an expectation for all healthcare personnel to use. The use of personal protective equipment is in addition to adherence to universal precautions. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
6. **Answer: 2 Rationale:** Decontamination cannot begin in the hot zone because this is the area of greatest contamination. It is important to decontaminate the area outside of the hot zone to prevent its spread. Decontamination should be completed before the patient enters the hospital. It should be done by using sweeping strokes away from the nurse and the patient. And decontamination corridors should be established downwind from the hospital entrance. Cognitive Level: Analysis; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
7. **Answer: 4 Rationale:** A radiologic dispersion bomb or dirty bomb is a bomb that carries a radiologic signature and can cause contamination and radiation poisoning. A dirty bomb is not known to cause thermal injuries so burns will most likely not occur. Abdominal organ damage would be assessed for blunt trauma and not necessarily for a dirty bomb. Eye injuries are not associated with a dirty bomb but rather with a bright light flash associated with nuclear detonation. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** Reconstitution is an assessment of how well the community has achieved a new level of normal. Mitigation is reducing the harmful effects of the disaster. Evaluation is studying what did and did not work when responding to the disaster. Surge capacity is the local healthcare organizations' abilities to respond beyond normal services during a disaster. Cognitive Level: Application; Nursing Process: Evaluation; Client Need: Safe and Effective Care Environment
9. **Answer: 3 Rationale:** Older adults have individual needs. Some may be more independent than others regarding the degree of support needed in emergencies, whereas others may require multiple resources and support in an evacuation. Patients are not expected to take the lead in evacuation efforts in nursing homes. It is an expectation that all patients are removed from a facility in the event of evacuation. Cognitive Level: Application; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
10. **Answer: 4 Rationale:** Nurses often are so involved in caring for others they tend to neglect themselves. In disaster situations, nurses may also suffer from loss while caring for others. As a result the nurse may feel overwhelmed and be as traumatized as the victims of the disaster. Mental health professionals are not being used to determine which nurses need time off after the disaster. The mental health professionals are not meeting with the nurses to problem solve mental health issues of the victims. All nurses do not always need the help of a mental health professional while working as a nurse. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Psychosocial Integrity

Unit 2 Alterations in Patterns of Health

1. Because the patient was thrown 50 feet as a result of the tornado, new onset of numbness in the lower extremities may signify spinal cord trauma and should be immediately investigated.
2. **D.** Use a respectful, nonjudgmental approach to gain the patient's trust.
   Rationale: Use a nonjudgmental approach to develop a trusting nurse–patient relationship to be able to spend time with the patient to discuss his feelings, fears, and anxieties.
3.
   A. Louis Black: A complete neurologic assessment is needed with emphasis on the lower extremities. All abrasions and lacerations should be assessed for bleeding and signs of infection.
   B. Mary Black: Assess the left ankle for pain and bruising. All abrasions and ecchymotic areas should be assessed for bleeding.
   C. John Linzer: Assess for signs of impending death, including level of consciousness, mottling, and respiratory pattern.
   D. Paul Goetz: Assess for continued signs of alcohol withdrawal including combativeness, orientation, hallucinations, diaphoresis, and nausea.
4. **B.** "I will need to cough frequently to remove fluids from my lungs."
   Rationale: Frequent coughing helps to remove anesthetic agents and secretions from the lungs to prevent pneumonia.
5. **C.** baked chicken, broccoli and cheese, and lemonade
   Rationale: This meal plan contains the necessary nutrients with the fewest empty calories.
6. Give a brief report to the pediatric nurse regarding Mr. and Mrs. Black's condition, the change in Mr. Black's neurologic status, and Mrs. Black's upcoming surgery. *Rationale: The pediatric nurse needs information about both Mr. and Mrs. Black's condition in order to be supportive of the Black children. Other family members may be needed to make decisions regarding the children's healthcare if the parents are unable to make informed decisions because of their own health status.*
7.
   A. Louis Black: Obtaining vital signs and performing basic ADLs can be delegated to the nursing assistant. Mr. Black should not get out of bed; therefore, a urinal should be provided. Until specifically ordered by the physician, he should be kept NPO, so frequent oral care may be necessary.
   B. Mary Black: Besides obtaining vital signs, the nursing assistant can assist with elimination. Mrs. Black's ankle needs to remain immobile, so she will need assistance with transferring to the commode or a wheelchair if she is allowed to visit her children on the pediatric unit.
   C. John Linzer: Vital signs and physical care including hygiene, turning, and positioning can be delegated.
   D. Paul Goetz: Safety is an important factor for Mr. Goetz. A nursing assistant can be delegated to be a sitter in the room at all times. The nursing assistant can also obtain vital signs and assist with ADLs.
8. **D.** Administration of lorazepam (Ativan) 1 mg I. V. P. every 6 hours
   Rationale: Benzodiazepines are indicated because patient is exhibiting signs of alcohol withdrawal.
9. Patient has terminal cancer and a signed do-not-resuscitate order. Hospice will focus on the comfort of the patient by managing symptoms as they arise (e.g., pain, dyspnea, anxiety) and will provide support for the family.
10.
    A. Conduct a preprocedure verification process.
    B. Mark the procedure site.
    C. Perform a time-out.
11. **C.** Apply a pneumatic compression device to the nonoperative leg.
    Rationale: DVT prophylaxis is indicated for surgical patients. Antibiotics are administered within 1 hour of incision time. Hair in the operative area is clipped not shaved. Warmed IV fluids can increase risk for hyperthermia. Perioperative hypo/hyperthermia increase risk for postoperative infection. Normothermia should be maintained in this phase.
12. "No, Mr. Goetz, I cannot bring you a beer. I know you feel you need alcohol. Even though I cannot provide it for you, I can give you the prescribed medication that will help you get through the detoxification. I can also be sure the counselor sees you as soon as possible."
    Rationale: It is not ethical to provide alcohol to a patient with a chemical dependency. However, in order to maintain a therapeutic relationship, the nurse should offer prescribed medication and psychologic support.

13. **C.** National Guidelines Clearinghouse
    Unit-based quality improvement data are not publicly available. Quality improvement data are not considered generalizable. Basic nursing orientation would not provide detail of evidence-based care standards; instead, it provides instruction to the policies and procedures of the nursing department. National Guidelines Clearinghouse is an Internet-based, freely available website that houses evidence-based clinical guidelines, providing up-to-date care standards. A general Internet search is not appropriate due to lack of oversight of the results that would be generated by a broad search.

Chapter 8: Genetic Implications of Adult Health Nursing

1. **Answer: 3 Rationale:** An individual with an autosomal recessive health problem inherited one altered gene from the mother and one from the father. Autosomal dominant disorders occur when only one altered gene is inherited from either the mother or the father. They tend to be more severe and are often lethal. In autosomal recessive health problems, the gene alteration occurred on a nonsex chromosome so both males and females have an equal chance of inheriting the altered gene from the parent. For an autosomal recessive health problem, the parents are carriers of the condition and will not usually exhibit manifestations of the health disorder. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** With an X-linked recessive health problem, the altered gene appears on the X chromosome and the health problem will be expressed in all males. Since the female receives an X chromosome from both parents, the female will be a carrier. Because the female has two X chromosomes, the health problem will not be expressed because the unaltered gene will compensate for the altered gene. The health problem is not transmitted through direct blood contact. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** It is a nurse's responsibility to explain what is involved in genetic testing. The nurse will use information on three generations to create a pedigree. It is not the nurse's responsibility to discuss potential outcomes; this is the responsibility of the genetic counselor. The couple is seeking information on genetic testing prior to having children so the nurse should not suggest that testing be completed after the birth of a child. It is unknown if the couple will proceed with chromosome studies. It is unknown what genetic anomaly the couple is investigating and the impact of the anomaly on future children. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 1 Rationale:** Mitochondrial mutations are only passed from the mother. This is because mitochondria are primarily found in ova and not sperm. This is considered a matrilineal pattern of inheritance. An affected female will pass the condition on to her children; however, an affected male will not. The consequences of the altered gene on an X chromosome will be expressed in all males who inherit the altered chromosome. In autosomal dominant and recessive disorders, both males and females are affected equally. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
5. **Answer: 1 Rationale:** Family history has been a part of nursing assessment, but the importance of obtaining a family history has increased knowledge of the interaction of genes and the environment. It is an inexpensive first "genetic screen," often underused by healthcare professionals. Obtaining a family history is not done to help the nurse focus the body system assessment. It also is not used to predict the health problems the patient will face in the future. This information is not used to validate Health and Human Services data on family health. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
6. **Answer: 3 Rationale:** When discussing the findings and recommendations with the patient newly diagnosed with a genetic disorder, much information will be provided. It is typical for the retention of information by a patient facing a new genetic diagnosis to be very low. The extra time is needed to ensure the patient understands as much as possible about the disorder at this time. The extra time is not needed because the information is complex or high level. Extra time is not needed because the patient is resistant to learning or has difficulty learning. Cognitive Level: Analysis; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
7. **Answer: 1, 3, 5 Rationale:** Most genetic specialists will complete chromosomal studies, and provide information for important decision making and about the natural history of the condition. Examining photographs of family members is not a part of a genetic referral. The genetics professional also will not prescribe medication to treat the disorder. Cognitive Level: Application; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
8. **Answer: 3 Rationale:** After learning of having the gene that causes breast cancer the patient could be facing a mastectomy. This would affect the patient's body image. Learning of having a gene that causes breast cancer might or might not affect the patient's ability to cope or impact family processes. There is not enough information to determine if the patient has a knowledge deficit. Cognitive Level: Application; Nursing Process: Nursing Diagnosis; Client Need: Psychosocial Integrity
9. **Answer: 3 Rationale:** Coronary heart disease has a multifactorial inheritance pattern. Managing environmental and life-style factors is important to reduce the risk. A family history for mutation of the *MLH/MSH2* gene is not associated with CHD. Hematocrit levels are not indicated to evaluate risk. There is no information provided to support the need for statin or other drugs. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
10. **Answer: 4 Rationale:** GINA is a federal law designed to protect consumers from discrimination by employers and health insurance companies based on genetic information. This law has nothing to do with gender bias or sexual harassment. It also does not mandate genetic testing for all government employees and their children. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Chapter 9: Nursing Care of Patients in Pain

1. **Answer: 1 Rationale:** Chronic pain is defined as pain that has persisted long after the reason for the pain has healed or subsided. Low back pain is the most common cause of chronic pain. Somatic pain arises from nerve receptors originating in the skin, subcutaneous tissues, or deep body structures such as periosteum, muscles, tendons, joints, and blood vessels. Somatic pain may be either sharp and well localized, or dull and diffuse. Visceral pain arises from body organs and is dull and poorly localized because of the low number of nociceptors. Visceral pain may be described as deep cramping, splitting or stabbing pain, intermittent pain, or colicky pain. Neuropathic pain is the result of hyperactive nociceptive stimulation. Neuropathic pain may be acute, is usually chronic, and is associated with conditions such as diabetic neuropathy or postherpetic neuralgia. This pain is described as gnawing, electric shock–like, burning, shooting, or tingling. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** Initial or "fast" pain is sharp and well defined because the stimulus is transmitted along myelinated A delta fibers to the thalamus and cerebral cortex. The smaller unmyelinated C fibers transmit the stimulus more slowly, producing a second or "slow" pain that is less well localized, dull, and throbbing. The gate-control theory of pain is a base for further research about pain-modulating systems.

The change from acute sharp pain to dull throbbing pain does not indicate that the injury is less severe than initially perceived. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity

3. **Answer: 1, 2, 4 Rationale:** NSAIDs are more effective when taken on a scheduled basis for predictable pain rather than prn for occasional pain. These drugs can cause gastrointestinal bleeding and hypertension, necessitating regular follow-up. NSAIDs are not known to affect the respiratory tract and are not addictive. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 3 Rationale:** Transdermal patches are slowly absorbed, reaching a therapeutic level 12 to 72 hours after application. The drug can accumulate in the body tissues, leading to a toxic level accompanied by manifestations such as sleepiness or respiratory difficulty. A transdermal patch is applied to a clean, dry area on the upper torso. The patch is effective for about 72 hours. When transdermal therapy is initiated, the therapeutic level is not reached until approximately 12 to 24 hours have passed. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** The quality of the pain is assessed through descriptive statements such as *sharp*, stabbing, aching, burning, stinging, deep, crushing, viselike, or gnawing. Asking where it hurts identifies the location or region of the pain. Rating the pain on a scale determines pain intensity. Asking if the pain affects sleep helps to determine how the pain impacts the patient's quality of life. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 1 Rationale:** Pain is a subjective response and the patient provides the most accurate information about its intensity. The nurse should provide the medication as prescribed. Behavioral responses to pain may or may not coincide with the patient's report of pain and are not always reliable cues to the pain experience. Pain assessment is considered the fifth vital sign and not taking action after learning of pain is a violation of regulatory agency expectations for accreditation. Additional information is needed before determining if the patient is developing a tolerance to the pain medication. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** Constipation is a common side effect of opioid narcotics, especially when used on a regular basis. The nurse should instruct the patient to increase intake of fluids and fiber in the diet to prevent constipation. If this does not relieve constipation, the nurse should suggest the patient contact the provider if additional measures such as laxatives are needed to manage constipation. It is outside of the nurse's scope of practice to prescribe medications so suggesting the use of diphenhydramine (Benadryl) should not be done. The nurse also cannot instruct a patient to stop taking a medication without discussing it with the physician. Opioid analgesics are not known to interfere with urination. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 1 Rationale:** Research has shown that patients with moderate cognitive impairment can use a pain scale to indicate the intensity of pain. The faces pain scale may be more accurate and effective for use with adults who have cognitive impairments. The family will not be able to accurately evaluate the patient's pain. Providing around-the-clock pain medication might result in overmedicating the patient. Physical responses and behavioral cues to pain are not always consistent. The nurse needs to use a pain rating scale that is appropriate to the patient's cognitive status. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** The combination of glucosamine and chondroitin has been shown to reduce pain in patients with moderate to severe knee pain. Other natural products have been studied for the relief of pain associated with migraine and other musculoskeletal conditions with mixed results. The nurse cannot say that there is no evidence that natural products are effective when treating pain. Because the treatment of chronic pain presents additional challenges, a broader range of drug classes may be used such as antidepressant medications, anticonvulsants, and opioids. Acupuncture has been shown to be effective in reducing pain of the neck, lower back, and shoulder but not the knee. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 1 Rationale:** Rigorous physical activity such as running prompts the release of endorphins, which are natural opioid-like substances. Endorphins bind with opioid receptors in the CNS, which inhibits the transmission of pain signals. Physical activity does not create a gate in the spinal cord to block pain signals. Physical activity also does not change perception of pain in the brain. Exercise does not reduce the sensitivity of nociceptors in deep tissue. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance

Chapter 10: Nursing Care of Patients with Altered Fluid, Electrolyte, and Acid–Base Balance

1. **Answer: 4 Rationale:** Ringer's solution is an isotonic, balanced electrolyte solution that can expand plasma volume and help restore electrolyte balance. Three percent saline solution is hypertonic and not used to expand body fluid volume. Solutions containing 0.45% sodium chloride are used as maintenance solutions. Solutions containing 10% dextrose are hypertonic and not used to expand body fluid volume. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 4 Rationale:** In fluid volume deficit, there is less volume in the vascular system, which decreases venous return and cardiac output, leading to manifestations of dizziness, orthostatic hypotension, and flat neck veins. The heart rate increases and the blood pressure falls. Headache and muscle cramps are associated with hyponatremia. Dyspnea, respiratory crackles, and increased pulse rate and blood pressure are associated with fluid volume excess. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 1, 4, 5 Rationale:** Frequent neurologic checks are necessary as hypernatremia draws water out of brain cells, causing them to shrink. As the brain shrinks, tension is placed on cerebral vessels, which may cause them to tear and bleed. Hypernatremia affects mental status and brain function including orientation to time, place, and person. Fluid replacement is the primary treatment for hypernatremia. Maintaining intravenous access is necessary for administration of fluids and possible emergency medications. There is no reason to limit the length of visits for the patient with hypernatremia. Cognitive Level: Application; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** Hypokalemia affects nerve impulse transmission, including the transmission of cardiac impulses. The patient may develop ECG changes and atrial or ventricular dysrhythmias. Oxygen therapy is not indicated for hypokalemia. There is no risk of seizures in the patient with hypokalemia. The patient with hypokalemia should be kept on bed rest; however, this is not the priority action for this patient. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** Calcium should be taken with a full glass of water to allow maximum absorption. Calcium does not need to be taken with meals. These supplements are not used as needed to treat tremulousness. Calcium supplements should be taken 1 to 1.5 hours after meals and at bedtime. Cognitive Level: Analysis; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance

6. **Answer: 2 Rationale:** A positive Chvostek's sign indicates increased neuromuscular excitability, commonly associated with both hypomagnesemia and hypocalcemia. Additional manifestations of hypomagnesemia include confusion, hallucinations, and possible psychoses. Administration of magnesium sulfate helps restore magnesium balance and neuromuscular function. Calcium chloride would be administered for manifestations of hypocalcemia. Insulin and glucose are used to treat hyperkalemia. Sodium bicarbonate is used in the treatment of hyperkalemia and metabolic acidosis. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 1 Rationale:** The pH of less than 7.35 indicates acidosis. The bicarbonate level is less than 22 mEq/L, which indicates a deficit of bicarbonate because of the acidosis. The $PaCO_2$ of 32 is less than 35 mmHg. This indicates respiratory compensation for the excess acid. None of these blood gas values supports respiratory acidosis or metabolic or respiratory alkalosis. Cognitive Level: Analysis; Nursing Process: Evaluation; Client Need: Physiological Integrity
8. **Answer: 1, 2, 5 Rationale:** The slow respiratory rate leads to inadequate alveolar ventilation. As a result, carbon dioxide is not effectively eliminated from the blood, causing it to accumulate. This increases carbonic acid levels, leading to respiratory acidosis, as indicated by the low pH and high $PaCO^2$. The bicarbonate level is initially unchanged in acute respiratory acidosis because the compensatory response of the kidneys occurs over hours to days. Excess carbon dioxide causes vasodilation, leading to warm, flushed skin, particularly in acute respiratory acidosis. The increased carbon dioxide level will affect neurologic function and the patient will not be alert and oriented. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** Gastric suctioning removes highly acidic gastric secretions, increasing the risk of metabolic alkalosis. Gastric suctioning will not cause metabolic or respiratory acidosis. Respiratory alkalosis is caused by hyperventilation. Cognitive Level: Application; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 2 Rationale:** The patient is demonstrating classic manifestations of respiratory alkalosis, a potential complication of mechanical ventilation when the rate or volume of ventilations is too high. Arterial blood gases (ABGs) provide the data necessary to confirm and treat this problem. The nurse should obtain recent ABG values before contacting the physician. An analgesic is not going to reduce the patient's symptoms because the respiratory rate on the ventilator is set too high. The nurse should obtain an ABG to validate the patient's manifestations before contacting the respiratory therapist to change or evaluate the ventilator settings. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 11: Nursing Care of Patients Experiencing Trauma and Shock

1. **Answer: 3 Rationale:** The most common mechanical source of injury in all adult age groups is the motor vehicle. Guns are another common mechanical source of injury. Trauma from gunshot wounds has steadily increased during the past 20 years and remains a major reason for emergency department and trauma center admissions. An accidental fire is a thermal source of traumatic injuries. Swimming pools can lead to drowning, which is a physical source of traumatic injuries. Cognitive Level: Application; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Maintenance of the airway is of the highest priority for the trauma patient. Other injuries or concerns such as fractures, a hemorrhage, or shallow respirations may distract the nurse away from assessing the airway; however, if the airway is not patent and the patient is unable to deliver oxygen to vital organs, all other interventions are futile. After an airway is established the nurse can assess for breathing, circulation, and then injuries. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** The tests that a trauma patient is prescribed will depend on the type of injuries. A pregnancy test is included for any woman of childbearing age in order to rule out the potential for pregnancy and fetal injury. Serum electrolytes are not specifically prescribed for trauma patients. A complete blood count evaluates the components of blood and will most likely be prescribed for all trauma patients regardless of the patient's gender. Blood type and crossmatch will also most likely be prescribed for all trauma patients regardless of the patient's gender. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 1 Rationale:** A hemolytic reaction is the most dangerous type of transfusion reaction and usually results from an ABO incompatibility. Manifestations of a hemolytic reaction include dyspnea. If this manifestation appears the blood transfusion must be discontinued immediately. The patient is receiving blood for shock. An increase in blood pressure would be a desired outcome. Skin lesions are seen in a hypersensitivity reaction to the blood transfusion. An increase in body temperature of 0.3 degree is not significant when receiving a blood transfusion. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1 Rationale:** The endotoxins released from bacteria in septic shock stimulate the release of vasoactive proteins, causing peripheral vasodilation and decreased peripheral resistance. Obstructive shock is caused by an obstruction in the heart or great vessels that either impedes venous return or prevents effective cardiac pumping action. Cardiogenic shock occurs when the heart's pumping ability is compromised to the point that it cannot maintain cardiac output and adequate tissue perfusion. Hypovolemic shock is caused by at least a 15% decrease in intravascular volume. Cognitive Level: Analysis; Nursing Process: Planning; Client Need: Physiological Integrity
6. **Answer: 4 Rationale:** When the patient has suffered an injury that causes a hemorrhage, the bleeding must be controlled immediately. This may be done by applying direct pressure over the wound. Vessel clamps can only be used if a vessel is exposed. Limb elevation may slow the bleeding but will not stop it. A tourniquet might be indicated; however, it will need to be applied by the healthcare provider and not the nurse. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Trauma results from an abnormal exchange of energy between a host and a mechanism in a predisposing environment. The host is the person at risk of injury, and multiple factors influence the host's potential for injury including preexisting illnesses. Recreational activities, psychosocial status, and previous history of traumatic injuries are not factors to determine the patient's ultimate extent of the current chest injury. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** The gastrointestinal organs normally receive 25% of the cardiac output through the splanchnic circulation. Shock constricts the splanchnic arterioles and redirects arterial blood flow to the heart and brain. This causes gastrointestinal organs to become ischemic and ulcerate. Stress ulcers can develop within hours of severe trauma and may hemorrhage within 2 to 10 days following the original cause of shock. The patient would have other manifestations if liver lacerations, intracranial bleeding, or internal bleeding were occurring. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 1 Rationale:** When administering nitroprusside (Nipride), the nurse should monitor the patient for signs of thiocyanate poisoning if the infusion lasts longer than 72 hours. Urine output of less than

30 mL per hour should be assessed and reported for all patients. Nitroprusside (Nipride) can only be mixed with dextrose 5% and water or 0.9% normal saline. Infiltrated intravenous sites should be assessed. Ice is not always the treatment of choice for infiltrated intravenous medications. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity

10. **Answer: 3 Rationale:** Monitoring fluid status is essential in preventing shock and includes daily assessments of weight, fluid intake by all routes, measurable fluid loss, and fluid loss that must be estimated, such as profuse perspiration and wound drainage. The risk of neurogenic shock is increased in patients who have received spinal anesthesia. Preventive nursing care includes elevating the head of the bed 15 to 20 degrees following spinal anesthesia. Providing immediate pain relief helps prevent the onset of cardiogenic shock. Nursing care to prevent septic shock includes careful and consistent hand hygiene. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 12: Nursing Care of Patients with Infections

1. **Answer: 4 Rationale:** Acquired passive immunity is the result of a gamma globulin infusion following exposure to hepatitis A. This type of immunity is short lived and usually lasts only about 4 weeks. Natural passive immunity is acquired by the transfer of maternal antibodies to the fetus or neonate through the placenta or breast milk. Acquired active immunity occurs by immunization with an antigen, such as an attenuated live virus vaccine. Natural active immunity occurs after an infection with a pathogen, resulting in the production of antibodies. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Safe and Effective Care Environment
2. **Answer: 2 Rationale:** For the patient with an infection, the nurse should collect the specimen for culture and sensitivity (C&S) before the first dose of antibiotics is administered to ensure that the medication is effective against the microorganism. Assessing for a history of hypersensitivities and allergies would have been completed before the healthcare provider prescribed medication treatment. The medication should be provided after the C&S is obtained. The nurse would monitor for reactions to the prescribed anti-infective after providing the medication. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Prostaglandins are chemotactic substances that draw leukocytes to inflamed tissue. Aspirin inhibits prostaglandin synthesis and reduces fever, pain, and inflammation. Penicillin is an anti-infective that is used to kill bacteria. Morphine sulfate is an opioid analgesic that is used to control pain. Warfarin (Coumadin) is an anticoagulant and is not used to treat inflammation. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** Banded neutrophils are immature white blood cells. An increase in the number of circulating bands indicates an infection. A low number of lymphocytes are seen in renal failure. A low number of basophils are seen in hyperthyroidism. An increased number of eosinophils may indicate an autoimmune disorder. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** Contact precautions reduce the risk of transmission by direct or indirect contact. Since the patient has a draining wound with methicillin-resistant *Staphylococcus aureus*, contact precautions are needed. Droplet precautions reduce the risk of droplet transmission of infectious agents that are generated during coughing, sneezing, talking, or suctioning. Airborne precautions reduce the risk of airborne transmission of infectious agent droplet nuclei or particles containing the infectious agent. Reverse precautions are a type of precaution used to protect a patient from being exposed to infectious microorganisms. This type of isolation is often used for the patient with neutropenia. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
6. **Answer: 4 Rationale:** The inflammatory cytokines contribute to illness behaviors. Patients respond to increases in these chemicals with increased sleep, warmth-seeking behaviors, and reduced energy output. These are considered adaptive responses to illness. Interferons are a class of cytokine with broad antiviral and anticancer effects. Interferons also moderate the activity of NK cells and may be involved in preventing the spread of abnormal malignant cells. Neutrophils, monocytes, and macrophages, known as phagocytes, are the primary cells involved in phagocytosis. Once attracted to the inflammatory site, phagocytes select and engulf foreign material. The complement system consists of plasma proteins that are activated by a tissue injury or antigen–antibody reaction and are involved in both innate and adaptive immune responses. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
7. **Answer: 3 Rationale:** Neutrophilia is an increase in the numbers of circulating neutrophils and is a common response with infection or inflammation as the bone marrow responds to an increased need for phagocytes. Leukopenia is a decrease in total white blood cells. Neutropenia is a decrease in circulating neutrophils. Neutrophilia does not mean that there is an expected average number of white blood cells. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
8. **Answer: 2 Rationale:** The patient should be instructed to apply heat for no longer than 20 minutes at a time to reduce the risk of tissue damage from burns. The patient should be instructed to eat a well-balanced diet high in vitamins and minerals and with adequate protein and kilocalories for healing. Acutely inflamed tissue should be rested. This means that the patient should not engage in strenuous activity until the inflammation has subsided. All medication should be taken as prescribed. The course of antibiotics should be completed. Cognitive Level: Application; Nursing Process: Planning; Client Need: Safe and Effective Care Environment
9. **Answer: 2 Rationale:** Nursing interventions to reduce the risk of healthcare-associated infections include encouraging patients to take deep breaths, providing adequate fluids, and avoiding the use of invasive devices such as indwelling catheters unless medically necessary. Alcohol-based hand rub has been recommended by the CDC as the preferred method for hand hygiene followed by antiseptic soaps and detergents, with nonantiseptic soaps being the least effective. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 3 Rationale:** Wearing gloves, gowns, and goggles when coming in contact with contaminated body fluids is considered to be standard precautions. Hand hygiene is a part of standard precautions; masks are worn for droplet or airborne precautions. UAP should not be recapping any needles. UAP are not responsible for disinfecting working surfaces. The hands should be washed with antibacterial soap and water if visibly dirty or contaminated with blood. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Chapter 13: Nursing Care of Patients with Altered Immunity

1. **Answer: 1 Rationale:** Anaphylaxis is the most severe form of type 1 immediate reactions. When an allergen is introduced for which there is circulating IgE specific to the allergen, a cascade leading to anaphylaxis is initiated. Hemolytic anemia can be associated with a type II cytotoxic hypersensitivity reaction. Graft rejection is a type of cell-mediated hypersensitivity response. Systemic lupus erythematosus is an autoimmune disorder. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity

2. **Answer: 4 Rationale:** Acute tissue rejection is the most common and treatable type of rejection episode that occurs between 4 days and 3 months after the transplant. Hyperacute tissue rejection occurs immediately to 2 to 3 days after the transplant of new tissue. Rejection episodes do not occur within 8 to 24 hours after the transplant. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** *Pneumocystis* pneumonia (PcP) is the most common pneumonia affecting patients with AIDS and is caused by *Pneumocystis jiroveci*, a common environmental organism that is not pathogenic in patients with intact immune systems. Cytomegalovirus causes disseminated viral infections in the patient with AIDS. *Toxoplasma gondii* and *Cryptococcus neoformans* are parasitic infections that commonly affect the central nervous system in patients with AIDS. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 3 Rationale:** When a patient tests positive for HIV, this means that antibodies to the AIDS virus are present in the blood. Testing positive for HIV does not mean that the patient is diagnosed with AIDS. The move from asymptomatic disease or persistent lymphadenopathy to AIDS is defined by a CD4 T-cell count of less than 200/mcL. AIDS is the final, fatal stage of HIV infection. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 1 Rationale:** Zidovudine (Retrovir, AZT) is the first antiretroviral agent approved for use with HIV infection. It is now generally reserved for second- or third-line regimens because it causes neutropenia. This medication causes anemia and not polycythemia. Zidovudine is not documented as causing cardio- or nephrotoxicity. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 1 Rationale:** When testing for allergies, epicutaneous or prick testing is generally done first to avoid a systemic reaction. This test may be followed by intradermal testing of allergens if a negative response to prick testing occurs. Inhalation is not a method for allergy testing. Sensitization to allergens is accomplished through subcutaneous injections. Cognitive Level: Application; Nursing Process: Planning; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** When a hypersensitivity reaction is suspected, it is important to avoid any further exposure to the potential cause. The best way to do this is by replacing all tubing and attaching a new intravenous line primed with normal saline. The blood product is usually returned to the blood bank in the event of a hypersensitivity reaction. Flushing the line and running normal saline attached at the Y connection does not reduce exposure to the blood product. The intravenous catheter does not need to be removed; instead, the blood transfusion needs to be stopped. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 1 Rationale:** Protease inhibitors and nucleoside analogs are associated with serious metabolic problems such as diabetes mellitus. These medications do not cause lactose intolerance. Hashimoto's thyroiditis and systemic lupus erythematosus are autoimmune disorders and are not caused by specific medications. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 4 Rationale:** The priority when initiating or changing HIV drug therapy regimens is the patient's willingness to adhere to the drug regimen. Because the side effects can be difficult and challenging to overcome, many patients are not willing to continue with the therapy. Medication therapy for HIV and AIDS is expensive; however, adherence to prescribed drug regimen is the priority. Accessing dental care and potential toxicities are important, but they are not considered priorities when initiating or changing the drug regimen in a patient who is HIV positive. Cognitive Level: Application; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 4 Rationale:** Lymphocyte immune globulin is used to prevent immediate transplant rejection and to treat steroid-resistant rejection episodes. Azathioprine is used to inhibit immune responses in autoimmune disorders. Large doses of corticosteroids used after a transplant are associated with significant adverse effects. Muromonab-CD3 is a monoclonal antibody that binds with a surface antigen on T, B, and NK cells to prevent their activation and immune function. This medication is not used immediately after a transplant to prevent rejection. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 14: Nursing Care of Patients with Cancer

1. **Answer: 3 Rationale:** Metastasis occurs when cells from a primary tumor site travel through the lymphatic system or bloodstream to find a secondary target. Mutation is an action that occurs within genetic material that can cause the development of neoplasms. Dysplasia develops when DNA loses control over cell differentiation. It occurs in response to adverse conditions and causes abnormal variations in cell size, shape, appearance, and usual arrangement. Carcinogenesis is a process in which normal cells are transformed into cancer cells. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Early in the disease process, threats to or changes in health status, physical discomfort, impaired role functioning, or even socioeconomic status can cause psychologic and emotional disturbance, such as fear, anxiety, or hopelessness. The patient may report insomnia and feelings of tension and apprehension. A patient with moderate or severe anxiety can be managed by counseling and teaching new coping skills. Encouraging the patient to express feelings about the cancer diagnosis is the most valuable and powerful intervention that could be offered. Antianxiety and sleep medication might be indicated if talking about the disease process does not help reduce anxiety and insomnia. The nurse will most likely document the patient's difficulty with sleep and anxiety in the medical record; however, this would not be the most appropriate initial intervention. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Psychosocial Integrity
3. **Answer: 4 Rationale:** It is important not to rub or scratch the treated skin areas, because this can cause irritation to the surface of the skin and also breaks in the skin. Rubbing may also wipe off the ink markings, which are important landmarks to ensure that the radiation treatments are directed to the correct location. There is no reason for the patient to avoid contact with others. Antibiotic ointment should not be applied to the radiated skin. The skin should be cleansed only with plain water. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 4 Rationale:** The nurse can help the patient with nausea and vomiting from chemotherapy by administering antiemetic drugs prior to the treatment. Administering chemotherapy at bedtime will not prevent the development of nausea and vomiting resulting from the medication. It is not nutritionally sound to keep the patient on clear liquids or nothing by mouth status until daily chemotherapy treatments are completed. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 4 Rationale:** Although all of these choices can be a result of chemotherapy, the one that is directly related to bone marrow suppression is a low platelet count of 50,000. The excessive numbers of immature leukocytes in the bone marrow diminish erythrocyte and thrombocyte or platelet production, resulting in secondary anemia, neutropenia, and thrombocytopenia. Cytotoxic drugs can affect hair cells leading to alopecia. An elevated temperature is not an indication

of bone marrow depression. Nausea and vomiting are caused by the chemotherapeutic medication, but are not an indication of bone marrow depression. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity

6. **Answer: 1 Rationale:** Chemotherapy disrupts the cell cycle in various phases by interrupting cell metabolism and replication. It also works by interfering with the ability of the malignant cell to synthesize vital enzymes and chemicals. Different drugs work on some phases of the cell cycle and other drugs work through the entire cell cycle. Most chemotherapy involves combinations of drugs administered over varying periods of time according to different protocols. Chemotherapy does not promote the normal growth of cells. The side and toxic effects of chemotherapy vary with the drug used and the length of treatment. Tissues usually affected by cytotoxic drugs include mucous membranes, hair cells, bone marrow, and body organs such as the heart, lungs, bladder, kidney, and reproductive organs. Cognitive Level: Analysis; Nursing Process: Evaluation; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** External radiation therapy is when the radiation is initiated outside of the body, is directed toward the patient, and is set to deliver to a certain depth for a specified period of time. This exposure is meant to destroy the cancer cells with which the radiation comes into direct contact. Internal radiation is also called brachytherapy. With this approach radiation is given inside the body by implanting small amounts of radioactive material directly into a tumor or body cavity while avoiding scattering radiation to the surrounding tissues or organs. Biochemotherapy is the combining of biologic agents with chemotherapeutic drugs. Internal-beam radiation therapy is not a type of radiation therapy. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** Tumor lysis syndrome, a life-threatening emergency for patients with cancer, is characterized by a combination of two or more metabolic abnormalities, including hyperuricemia, hyperphosphatemia, hyperkalemia, and/or hypocalcemia. White blood cell count would be monitored for septic shock. There is not a specific laboratory test to monitor spinal cord compression. Superior vena cava syndrome is caused by the enlargement of a tumor adjacent to the superior vena cava, compressing the major blood vessel and leading to reduced blood flow to the heart. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 1 Rationale:** The S phase is when DNA replication occurs. This is when the cell is beginning mitosis and the chromosomes multiply from 23 to 46. They then migrate toward each axis in preparation for division of the cell. In the M phase, the parent cell divides into two exact copy cells called daughter cells, each having identical genetic material. G_1 is the beginning of the cell cycle. G_2 occurs when the cell is preparing for mitosis. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 3 Rationale:** Oncogenes are abnormal genes that promote cell proliferation, are capable of triggering cancerous characteristics, and can be classified according to their overall function. A decrease in the body's immune surveillance may allow the expression of oncogenes, which can occur during times of stress or in response to certain carcinogens. Oncogenes do not block cell growth. They are not strictly regulated, nor do they stimulate a complex signaling process. Cognitive Level: Application; Nursing Process: Planning; Client Need: Physiological Integrity

Unit 3 Pathophysiology and Patterns of Health

1. A change in level of consciousness, in this case increasing lethargy, may be an early indicator of hypovolemic shock. The nurse should assess the patient's oxygenation status and for evidence of tachycardia, weak peripheral pulses, and hypotension as a result of the fluid losses. The nurse should collaborate with the healthcare provider to obtain orders for intravenous access and isotonic intravenous fluids. The nurse should discuss with the healthcare provider the need for laboratory studies, such as hemoglobin and hematocrit, a metabolic panel, and type and screen. If the client's LOC continues to deteriorate a rapid response should be called.
2.
   A. **Tamra Sanders should be seen first.**
   Rationale: Severe chest pain and shortness of breath could indicate life-threatening change in conditions.
   B. **Allen Barber should be seen second.**
   Rationale: Post-op pain of 8/10 on day 4 is very unusual and could indicate beginning dehiscence.
   C. **Mia Windham should be seen third.**
   Rationale: Bloody diarrhea can lead to severe dehydration, hemorrhage, and shock, but there is no indication that Ms. Windham is in immediate danger.
   D. **Harry Anderson should be seen fourth.**
   Rationale: The patient's confusion can result in his calling for help. While he should be checked on to determine his safety, a CNA could be assigned to stay with him.
3. **B.** high protein, high kilocalorie
   Rationale: A high-protein and high-kilocalorie diet provides necessary nutrients to meet metabolic and tissue healing needs. High fiber can increase intestinal motility and cause diarrhea, further increasing weight loss. High vitamins can cause vitamin overdose.
4.
   A. **Allen Barber:** pain scale, direct visualization of surgical wound, and abdominal sounds
   Rationale: It appears the surgical wound is infected, which delays healing. This wound infection could result in abdominal complications and wound dehiscence.
   B. **Tamra Sanders:** heart and lung sounds, oxygen saturation
   Rationale: Sickle cells can obstruct circulation to any organ. Ms. Sanders's symptoms could indicate a blockage in circulation to the heart or lungs or both, which could be life threatening.
   C. **Mia Windham:** abdominal sounds, further incidence of bloody diarrhea, skin condition on hands and feet, location and description of rash
   Rationale: Ms. Windham must be assessed for worsening signs of tissue rejection.
   D. **Harry Anderson:** neuro assessment including pupils, clearness of speech, strength in arms and legs, and changes in levels of confusion. Observe for signs of seizure activity.
   Rationale: HIV/AIDS affects the nervous system. The nurse must observe for signs of worsening of the patient's condition.
5. **B.** high Fowler's
   Rationale: High-Fowler's position places the body angle at 90 degrees and helps to promote lung expansion. Sims' and Trendelenburg positions can impair lung expansion; dorsal recumbent does not promote lung expansion and ease of breathing.
6. **A.** metabolic acidosis
   Rationale: Diarrhea increases bicarbonate loss, resulting in metabolic acidosis ($pH < 7.35$ and $HCO_3^- < 22$ mEq/L).
7. **C.** "Both parents carry the gene for sickle cell disease and have a 25% chance of children born with the disease."
   Rationale: Each child born to carrier parents has a 25% chance of inheriting the gene for sickle cell disease from both parents.
8. Determine Ms. Sanders's level of cognitive development and communicate with her in developmentally appropriate terms.
   Rationale: People with Down syndrome have a wide variety of cognitive abilities. It is important to communicate in developmentally appropriate terms, not age-appropriate terms.

9.

A. Allen Barber: Delegate vital signs, obtaining blood glucose levels and assistance with ADLs including hygiene, elimination, and ambulation. *Rationale: Obtaining vital signs and BG values can be safely delegated to a trained nursing assistant. A 4-day postoperative patient should be able to provide much of his own care, but would need some assistance that could be provided by unlicensed personnel.*

B. Tamra Sanders: Delegate vital signs, ADLs, and a sitter. *Rationale: Ms. Sanders may need a sitter due to her Down syndrome and chest pain with shortness of breath. While the nursing assistant cannot assess changes in her condition, he or she can summon help and initiate CPR if necessary.*

C. Mia Windham: Delegate vital signs, ADLs, and I&O. *Rationale: The nursing assistant is able to record intake and output and notify the RN of further bloody diarrhea.*

D. Harry Anderson: Delegate vital signs, ADLs, and sitter. *Rationale: Due to Mr. Anderson's confusion and risk of seizure activity, a sitter may be necessary to maintain patient safety.*

10. A. white blood cell count/differential, erythrocyte sedimentation rate, C-reactive protein
Rationale: White blood cell count indicates extent of inflammatory process, erythrocyte sedimentation rate detects inflammation, and C-reactive protein indicates presence of inflammatory process.

11. A. "I can stop the antibiotic pills once I haven't had a fever for two consecutive days."
Rationale: A full course of the antibiotic therapy must be completed to ensure eradication of the infection.

12. B. analgesia level
C. sedation level
E. oxygen saturation
F. respiratory rate and effort
Rationale: Because an opioid is being administered via PCA, respiratory rate, effort, and oxygen saturation should be monitored due to the potential for depressant effects on the respiratory system. Analgesia level should be monitored to determine the effectiveness of the medication. The sedation level should be evaluated because if the patient is oversedated she will be unable to adequately oxygenate and ventilate. Opioids can result in urinary retention and constipation; however, these side effects are not life threatening and do not need evaluation every 2 hours.

13. Quality improvement strategies: Establish procedure for performing individual patient weights at the same time each day, using the same scale, assuring scale is properly balanced, and when possible assign the task to the same person.

14. C. shock
Rationale: Hypertension is elevated blood pressure. The patient described has a falling blood pressure. Cardiac output (CO) is the amount of blood pumped per minute into the aorta by the left ventricle. It does not completely describe the falling blood pressure of the patient described. Shock is triggered by a sustained drop in mean arterial pressure. This drop can occur after a decrease in cardiac output, a decrease in the circulating blood volume, or an increase in the size of the vascular bed due to peripheral vasodilation.
Blood loss can be a cause of shock, but there are other causes that lead to shock.

Chapter 15: Assessing the Integumentary System

1. Answer: 1 Rationale: The dermis is the second, deeper layer of skin. Most of the hair follicles and sweat glands are located in the dermis. The epidermis or the outermost part of the skin consists of epithelial cells. The stratum basale is the deepest layer of the epidermis and contains melanocytes, which produce the pigment melanin, and keratinocytes, which produce keratin. The next layer of the epidermis is the stratum spinosum, which contains abundant cells that arise from the bone marrow and migrate to the epidermis. Mitosis occurs at this layer. Cognitive Level: Application; Nursing Process: Implementation; Client Need: Physiological Integrity

2. Answer: 2 Rationale: Melanin is a pigment that forms a protective shield to protect the keratinocytes and the nerve endings in the dermis from the damaging effects of ultraviolet light. Melanocyte activity accounts for the difference in skin color in humans. Sebum is an oily substance that softens and lubricates the skin and hair and also decreases water loss from the skin. Carotene is a yellow-to-orange pigment found in areas of the body where the stratum corneum is thickest, such as the palms of the hands. This pigment is more abundant in the skins of persons of Asian ancestry and, together with melanin, accounts for the golden skin tone. Because the epidermis in White skin has very little melanin and is almost transparent, the color of the hemoglobin found in red blood cells circulating through the dermis shows through, causing the skin to appear pink. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

3. Answer: 2 Rationale: Inspection is the first assessment technique to check the skin surface. After inspection the next assessment step is palpation of any skin areas that appear abnormal in order to get a better understanding of depth and size of any lesions. The assessment techniques of percussion and auscultation are not used to assess the integumentary status. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

4. Answer: 4 Rationale: Erythema often occurs as a result of increased body temperature. This occurs when the capillaries in the skin dilate to release some of the heat caused from the increased body temperature. Pallor or paleness of the skin occurs with shock, anemia, or hypoxia from the reduction in number or oxygenation of red blood cells. Jaundice is a yellow-orange color caused by the breakdown of red blood cells or alteration in liver functioning. Cyanosis is a bluish color caused by poor oxygenation of hemoglobin. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

5. Answer: 2 Rationale: During the health history the nurse should ask questions that focus on the precipitating cause of the itching such as the use of any new medications, soap, skin care agents, cosmetics, pets, travel, stress, or dietary changes. It is redundant to ask a patient to explain how itching feels. Asking the patient why the itching is being scratched does not provide information about the possible cause. The patient's daily fluid intake will not provide sufficient information about the cause of the patient's itching. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

6. Answer: 1 Rationale: When assessing skin turgor the skinfold should return rapidly to a normal position. Tenting (in which the skin remains in a pinched position for a few moments before returning to the normal position) commonly occurs in older patients who are thin. Decreased skin turgor is also a sign of dehydration. Pallor is skin paleness caused by anemia or hypoxia. Cyanosis is a bluish discoloration of the skin caused by reduced oxygenation of hemoglobin. Increased skin moisture may be associated with shock, fever, increased activity, or anxiety. Lesions can be ulcerated, scaly, asymmetric, linear, or grouped. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Physiological Integrity

7. Answer: 3 Rationale: When documenting edema, 1+ is slight pitting without any obvious distortion; 2+ is a deeper pit without any obvious distortion; 3+ is an obvious pit and the extremity is swollen; and 4+ is a pit that remains with an obvious distortion. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity

8. **Answer: 4 Rationale:** Lichenification is rough, thickened, hardened areas of epidermis caused by chronic irritation from scratching or rubbing. Chronic dermatitis can cause lichenification. An ulcer is an area of skin erosion. A papule is an elevated, solid, palpable mass with a circumscribed border. Papules are smaller than 0.5 cm and include elevated moles, warts, and lichen planus. Atrophy is used to describe translucent, dry, paper-like or a wrinkled skin surface resulting from thinning or wasting of the skin due to loss of collagen and elastin. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 1 Rationale:** Angiomas are benign vascular tumors with dilated blood vessels that are found in the middle to upper dermis. They are a common finding in older patients and indicate aging skin. Angiomas do not develop because of poor hygiene. Ecchymotic areas might be present if caregiver strain is occurring within the patient's home. A high intake of vitamin A could cause a yellow-orange color to the skin caused by the intake of carotene. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** Head lice may be seen as oval nits or eggs that adhere to the base of the hair shaft. Head lice are usually accompanied by itching. Small white eggs on the hair shaft are not associated with head lichens or a viral or bacterial infection. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment

Chapter 16: Nursing Care of Patients with Integumentary Disorders

1. **Answer: 3 Rationale:** The best way to help moisturize the skin is to apply a moisturizing agent after bathing. Hot water can dry the skin, making the xerosis worse. A warm environment is not going to lubricate the patient's skin. Fabric softeners can cause skin irritations and should not be used. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 1 Rationale:** Dysplastic nevi are larger than other nevi and may be flat, slightly raised, or appear as lesions with a darker, raised center and irregular border. Because dysplastic nevi can transform into malignant lesions, it is important to monitor them for changes in size, thickness, color, bleeding, or itching. If any of these changes occur, the person should seek immediate professional assessment. A keloid is a thickening of the skin caused by fibroblasts and type III collagen. A skin tag is a benign skin lesion that can become irritated and bleed. An angioma is a benign vascular tumor. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** Psoriasis causes abnormal growth and division of epidermal cells, causing keratosis. The use of ultraviolet light therapy helps to slow down this cellular division, which decreases the lesions and keratosis associated with psoriasis. Ultraviolet light therapy does not need to be combined with hot baths to be effective. Ultraviolet-B light or narrowband UVB units may be purchased or constructed to be used in the patient's home. Ultraviolet light decreases the cellular division that causes keratosis and it does decrease itching. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 4 Rationale:** Actinic keratosis, also called senile or solar keratosis, is an epidermal skin lesion directly related to chronic sun exposure and photodamage. About 20% of actinic keratoses convert to squamous cell carcinoma. Folliculitis is a bacterial infection of the hair follicle, most commonly caused by *Staphylococcus aureus*. Pressure ulcers develop from external pressure that compresses blood vessels or from friction and shearing forces that tear and injure vessels. Pediculosis is an infestation with lice or parasites that live on the blood of an animal or human host. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
5. **Answer: 4 Rationale:** A linear pattern of painful vesicles indicates shingles, a varicella infection. The virus remains along a nerve from a previous infection with chickenpox. A rash of painful vesicles is not associated with acne, using tanning booths, or being sunburned as a child. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Safe and Effective Care Environment
6. **Answer: 4 Rationale:** Anyone can have lice. They affect people of all social classes but are associated with crowded or unsanitary living conditions. Major infestations often occur in areas where many people are in proximity, especially in the public school setting. Lice are a parasite and not a fungus. Pediculosis corporis is an infestation with body lice and pediculosis pubis is an infestation with pubic lice. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
7. **Answer: 2 Rationale:** Risk factors for the development of nonmelanoma skin cancer include fair skin, freckles, blue or green eyes, and blond or red hair. Alopecia, thin hair, and itching do not increase the risk of developing this skin disorder. Dark hair, dark or tanned skin, dry skin, and edema do not increase the risk of developing nonmelanoma skin cancer. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
8. **Answer: 1 Rationale:** A change in the color or size of a nevus is cause for concern when evaluating for the possibility of melanoma. Ichthyosis is an inherited dermatologic condition in which the skin is dry, fissured, and hyperkeratotic. The surface of the skin has the appearance of fish scales. Psoriasis is a chronic immune skin disorder characterized by raised, reddened, round circumscribed plaques covered by silvery white scales. A carbuncle is a group of infected hair follicles. The lesion begins as a firm mass located in the subcutaneous tissue and the lower dermis. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
9. **Answer: 2 Rationale:** Shearing forces result when one tissue layer slides over another. The stretching and bending of blood vessels cause injury and thrombosis. Patients in hospital beds are subject to shearing forces when the head of the bed is elevated and the torso slides down toward the foot of the bed. Pulling the patient up in bed also subjects the patient to shearing forces so, for this reason, always lift patients up in bed. In both cases, friction and moisture cause the skin and superficial fascia to remain fixed to the bed sheet, while the deep fascia and bony skeleton slide in the direction of body movement. Pulling a patient up in bed does not promote capillary blood flow, decrease tissue ischemia, or prevent tissue hypoxia. Lifting a patient up in bed is not done to provide a brief period of increased capillary circulation. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 3 Rationale:** Dermabrasion is a skin treatment that helps to reduce the appearance of acne scarring and other skin imperfections. A skin flap is a piece of tissue whose free end is moved from a donor site to a recipient site while maintaining a continuous blood supply through its connection at the base or pedicle. Liposuction is a method of changing the contours of the body by aspirating fat from the subcutaneous layer of tissue. A blepharoplasty is a cosmetic surgery in which loose skin and protruding periorbital fat is removed from the upper and lower eyelids. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity

Chapter 17: Nursing Care of Patients with Burns

1. **Answer: 3 Rationale:** During burn shock, which occurs in the emergent phase, potassium ions leave the intracellular compartment, predisposing the patient to developing cardiac dysrhythmias. The process of burn shock continues until capillary integrity is restored, usually

within 24 hours of the injury. During the emergent phase of burn management, the patient will receive high volumes of intravenous fluids. This will cause hematocrit to be diluted and the value will be decreased. Serum albumin is a measurement of nutritional status and is measured most often during the rehabilitative phase of burn management. During the early stages of the burn injury, renal blood flow and glomerular filtration rates are greatly reduced from the decreased intravascular blood volume and the release of antidiuretic hormone (ADH) by the posterior pituitary. The blood urea nitrogen level will increase. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity

2. **Answer: 2 Rationale:** A full-thickness burn involves all layers of the skin, including the epidermis, the dermis, and the epidermal appendages. The burn wound may appear pale, waxy, yellow, brown, mottled, charred, or nonblanching red. The wound surface is dry, leathery, and firm to the touch. There is no sensation of pain or light touch because pain and touch receptors have been destroyed. Superficial, superficial partial-thickness, and deep partial-thickness burns will still be very painful to the patient because the nerves remain intact or exposed. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 4 Rationale:** The larger the surface area of the burn and the deeper the burn, the more at risk the patient is for burn shock. Although the pathophysiologic mechanisms of postburn vascular changes and fluid volume shifts are not clearly understood, burn shock is seen in patients with >40% of total body surface area burned. A high-voltage electrical accident will cause a deeper burn and because >50% of this patient's body is affected, this patient is at the highest risk. The patient with 10% TBSA and the patient with superficial burns are at less risk for developing burn shock. The patient with radiation burns from cancer treatment is also at a low risk for developing burn shock. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 1 Rationale:** Silver sulfadiazine (Silvadene) cream can cause neutropenia. It is important for the nurse to monitor the patient's WBC count daily to assess for any changes, which could indicate neutropenia. Signs of dehydration should be monitored if sulfa crystals develop in the patient's urine. Daily monitoring of serum electrolytes is not indicated for this medication. Pain medication is not necessary before applying this medication, although providing pain medication before a burn dressing change would be a part of routine nursing care. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** The Parkland formula uses lactated Ringer's solution, administered at 4 mL × kg × % TBSA burn, with 50% of the total volume infused in the first 8 hours, and the remaining 50% over the next 16 hours. This would be 4 × 70 × 50% = 14,000 × 50% = 7000. The volume of 3500 mL is 25% of the total volume that should be infused. Both 10,500 mL and 14,000 mL indicate incorrect calculations of the amount of fluid that the patient is to receive during the first 8 hours of burn management care. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 4 Rationale:** Hourly urine output is often used as an indicator of effective fluid resuscitation, with about 0.5 mL/kg/h for an adult considered adequate. Another indicator is heart rate; however, if fluid resuscitation is adequate, the rate should be fewer than 120 beats per minute or in the upper limits of normal for the patient's age. But the fear, anxiety, and pain that accompany burn injuries often increase heart rate. Blood pressure changes are less reliable because significant hypotension does not develop until volume losses exceed 30% due to the body's compensatory mechanisms. A central venous pressure reading of 18 mmHg indicates overhydration. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** A decreased left radial pulse is cause for alarm in this type and location of burn. This can be the first symptom seen in compartment syndrome and is a surgical emergency. The patient is going to have pain, fluid-filled vesicles, and blanching of the extremity, findings that are all consistent with deep partial-thickness burns. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** The "rule of nines" is a method of quickly estimating the percentage of TBSA affected by a burn injury. It is most useful in emergency situations but is not accurate for estimating TBSA in adults who are short, obese, or very thin. In this method, the body is divided into five surface areas—head, trunk, arms, legs, and perineum—and percentages that equal or total a sum of nines are assigned to each body area. Only partial- and full-thickness burns are included in the estimation. For this patient the calculation is as follows: anterior trunk = 18%, perineum = 1%, left arm = 9%. These are added together to equal 28%. The other percentage choices reflect an inaccurate use of the rule of nines. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 3, 4, 5, 6 Rationale:** Teaching injury prevention is a very important job in nursing. Burns are a common injury in the home. It is important to help older adults understand ways to help prevent burns. The water temperature of the water heater should not be set above 120°F. This can help prevent burns from water scalding. Wearing close-fitting clothing when cooking can help prevent shirt sleeves or scarves from catching on fire. Installing antiscald devices can also help prevent water burns. Because older adults often have decreased olfactory senses, having a neighbor routinely check for the odor of gas can help prevent fires. A solar-powered nightlight will help prevent falls in the home. Smoke detector alarm batteries should be checked monthly. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** A 15% carbon monoxide level would cause only mild manifestations of dizziness at this stage. Carbon monoxide levels of 21% to 40% will cause the manifestations of drowsiness, hypotension, and dark-red skin color. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity

Unit 4 Responses to Altered Integumentary Structure and Function

1. **B.** respiratory rate below 8 breaths per minute
   Rationale: Morphine sulfate causes respiratory depression. Respiratory rate below 12 breaths per minute is depressed and may require intervention.
2.
   - **A. Mrs. Carter should be seen first.** ***Rationale:*** *She may need pain medications and should not have to wait for pain relief.*
   - **B. Mr. Johnson should be seen second.** ***Rationale:*** *It is important to have him ready for surgery on time at 0800. The nursing assistant can obtain vital signs and help him with urinary elimination while you are seeing Mrs. Carter.*
   - **C. Mr. Jenkins should be seen third.** ***Rationale:*** *If new lesions are appearing, they should be assessed and documented, but this is not urgent.*
   - **D. Mr. Ugandi should be seen last.** ***Rationale:*** *Discharge is anticipated and teaching should begin as soon as possible, but the other patients' needs are higher priority at this time.*
3. **A.** eggs and chicken
   Rationale: Foods high in protein, such as eggs, milk, and meat, are required for tissue growth and maintenance. Foods high in iron, such as meat, poultry, and eggs, are required for increased red blood cell production and preventing anemia.
4. 18%.
   Rationale: Arms are 4.5% each and the anterior trunk is 9%, for a total burn area of 18%.

5. **A.** redness, edema and pain in the right calf
   Rationale: Clinical manifestations of infection of the dermis and subcutaneous tissue are redness, swelling, and pain.
6. "Mr. Jenkins, I know this is very difficult for you and sometimes you might feel that dying would be better than the burning pain you are experiencing. I'm sorry, but because there is no cure for herpes zoster, the sores can come back. There are some medications you can take that decrease the chance of them recurring. I'll have your doctor talk with you about them. Is there anything else you want to talk about?"
   Rationale: Honest, direct answers to questions are preferred. At age 86, Mr. Jenkins may be telling you that he is feeling hopeless and may give up. It is important to keep communication lines open.
7.
   - **A. Mr. Johnson:** vital signs, assistance with elimination, transfer to stretcher/transport to surgery, preparing room for his return from surgery
   - **B. Mrs. Carter:** vital signs, hygiene, nutrition, turning/activity
   - **C. Mrs. Jenkins:** vital signs, hygiene, nutrition, turning/activity. Remind the nursing assistant of contact precautions to prevent spread of infection.
   - **D. Mr. Ugandi:** vital signs, hygiene, nutrition, turning/activity. Remind the nursing assistant of standard precautions to prevent spread of infection.
8. **C.** facial edema and pruritus
   Rationale: Hypersensitivity reactions to mafenide acetate include pruritus, edema, facial edema, and urticaria.
9. **D.** "Wear cotton clothing and keep room temperatures cool to decrease the pain and itching from the herpes zoster lesions."
   Rationale: A cool environment will decrease itching, and light cotton clothing will decrease pain from material rubbing on lesions.
10. **A.** Change gloves between cleansing of different burn wounds.
    Rationale: Gloves should be changed between cleaning and dressing of separate burn wounds to prevent cross-contamination.
11. The nurse manager can conduct a chart review on all patients with pressure ulcers to determine (1) frequency of turning and repositioning; (2) if the patient was admitted with a pressure ulcer or if the ulcer is healthcare associated; (3) nutritional status of patients with pressure ulcers; (4) presence of a nutrition consult; (5) patients' Braden scale scores on admission; and (6) activity level of each patient during hospitalization. Based on findings of chart reviews, staff education may be needed on prevention measures and well as better documentation.
12. _____B_____ Electronic order entry sheet
    _____D_____ Flow sheet
    _____C_____ Nursing care plan
    _____A_____ Interprofessional communication notes

Chapter 18: Assessing the Endocrine System

1. **Answer: 2 Rationale:** ADH (antidiuretic hormone) causes the distal tubules of the kidneys to reabsorb water, which would decrease the urine output. A decrease in the amount of ADH would cause an increase in urine output. ADH does not influence testosterone production or facial hair growth in women. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** A positive Trousseau's sign occurs with low serum calcium levels. A positive test causes the fingers and hand to contract on the arm where a blood pressure cuff is inflated. The contraction is a carpal spasm. Palpating skin turgor assesses for hydration status. Skin color is assessed for oxygenation. The urine test for 17-ketosteroids is done to assess adrenal cortex, pituitary, and gonadal hormone function. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
3. **Answer: 3 Rationale:** The glucocorticoids cortisol and cortisone affect carbohydrate metabolism by regulating glucose use in body tissues, mobilizing fatty acids from fatty tissue, and shifting the source of energy for muscle cells from glucose to fatty acids. Glucocorticoids are released in times of stress. Excessive amounts of glucocorticoids depress the inflammatory response and inhibit the effectiveness of the immune system. Excessive amounts of glucocorticoids do not affect maturation. The metabolic rate will be increased. The response to glucagon in the bloodstream is decreased. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Safe and Effective Health Environment
4. **Answer: 2 Rationale:** When assessing the endocrine system, it is important to look for manifestations of diabetes. One of the first manifestations is polydipsia, which is increased thirst. Questions about scar tissue, children's problems with urination, and abdominal pain do not focus on the patient's endocrine system assessment. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
5. **Answer: 2 Rationale:** The thyroid gland is palpated to assess for size and consistency. This helps determine if the patient has an enlarged gland which could indicate a goiter or the presence of nodules. The thyroid gland is not palpated to assess for pain, pulse rate, character, texture, edema, or movement. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
6. **Answer: 3 Rationale:** Chvostek's sign, a test for hypocalcemia, is assessed by tapping a finger in front of the patient's ear at the angle of the jaw. A positive Chvostek's sign causes facial grimacing due to repeated contractions of the facial muscle. A normal finding is no facial grimacing in response to tapping the patient's face in front of the ear. Depressing the skin over the shin would be assessing for edema. Pinching a fold of skin over the sternum is testing for skin turgor or hydration status. Inflating a blood pressure cuff above the antecubital space is assessing for Trousseau's sign which is another technique to assess for manifestations from a low calcium level. Cognitive Level: Application; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
7. **Answer: 2 Rationale:** Thyrotropic cells secrete thyroid-stimulating hormone (TSH) which in turn stimulates the synthesis and release of thyroid hormones from the thyroid gland. Growth hormone (GH) is released by the anterior pituitary gland. Fasting blood sugar (FBS) is a laboratory test to measure blood glucose level after a period of fasting. Aldosterone is a mineralocorticoid released by the adrenal cortex. This hormone promotes kidney tubule reabsorption of sodium and water and excretion of potassium in response to elevated levels of potassium and low levels of sodium to increase blood pressure and blood volume. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
8. **Answer: 3 Rationale:** Palpable thyroid nodules are considered an expected age-related change in the endocrine system. Normal heart tones would be expected and not associated with the endocrine system. The older female patient might have an increase in facial hair because of the loss of estrogen. The pituitary gland is located within the cranium. The nurse will not be able to directly palpate this gland to determine size and consistency. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
9. **Answer: 1 Rationale:** Rough, dry skin is often seen in patients with hypothyroidism. Smooth and flushed skin can be a sign of hyperthyroidism. Cold, clammy skin is not associated with any particular endocrine disorder. Hirsutism or excessive facial hair may indicate Cushing's syndrome. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
10. **Answer: 3 Rationale:** Increased deep tendon reflexes are seen in hyperthyroidism. Tetany is assessed by using the Trousseau's or

Chvostek's signs. Assessment for acromegaly will need to be done by measuring the patient's growth hormone level. Cushing's syndrome is assessed by measuring adrenal cortex hormone levels. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

Chapter 19: Nursing Care of Patients with Endocrine Disorders

1. **Answer: 4 Rationale:** Graves' disease is the most common cause of hyperthyroidism and is considered an autoimmune disorder. It is sometimes associated with the presence of other autoimmune disorders such as myasthenia gravis, diabetes mellitus, celiac disease, and pernicious anemia. The serum of patients with Graves' disease has an antibody that binds to TSH receptors in the thyroid follicles and causes the thyroid cells to hyperfunction. When this antibody binds to the TSH receptors, it stimulates hormone synthesis and secretion, enlarging the gland. The cause is unknown, but there is a hereditary link. Graves' disease is seen eight times more often in women than in men and occurs most frequently between the ages of 20 and 40. Even though there is a genetic link with this disease, it is categorized as being an autoimmune disorder. Graves' disease does not develop in response to an allergy or an infection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 1 Rationale:** Because the thyroid gland takes up iodine in any form, radioactive iodine (^{131}I) concentrates in the thyroid gland and damages or destroys thyroid cells so that they produce less thyroid hormone. Radioactive iodine is given orally and the patient will see results in 6 to 8 weeks. The patient is not hospitalized during treatment and does not require radiation precautions. This type of therapy is contraindicated in pregnant women because radioactive iodine crosses the placenta and can have negative effects on the developing fetal thyroid gland. Because the amount of gland destroyed is not readily controllable, the patient may develop hypothyroidism and require lifelong thyroid hormone replacement therapy. Adverse reactions include thyroiditis and cardiac instability due to liberation of stored thyroid hormone in the gland. Radioactive iodine does not impact the vascularity of the thyroid gland. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 2 Rationale:** When TH production decreases, the thyroid gland enlarges in a compensatory attempt to produce more hormone. The goiter that results is usually a simple or nontoxic form. People living in certain areas of the world where the soil is deficient in iodine, the substance necessary for TH synthesis and secretion, are more prone to become hypothyroid and develop simple goiter. In hypothyroidism the development of a goiter is associated with a lack of dietary iodine intake. A goiter does not develop because of excessive TH stimulating thyroid follicles. A goiter that develops in response to increased levels of TH is seen in hyperthyroidism. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 4 Rationale:** Cushing's syndrome is a chronic disorder in which hyperfunction of the adrenal cortex produces excessive amounts of circulating cortisol or ACTH. The disorder also may occur as the result of pharmacologic therapy (iatrogenic Cushing's). People who take steroids for long periods of time are at increased risk for developing the disorder. Acromegaly is caused by overproduction of growth hormone. Cortisone treatment for rheumatoid arthritis will not lead to the development of hypo- or hyperthyroidism. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** Addison's disease is a disorder resulting from destruction or dysfunction of the adrenal cortex. The result is chronic deficiency of cortisol, aldosterone, and adrenal androgens, accompanied by skin pigmentation. Addisonian crisis is a life-threatening response to acute adrenal insufficiency. Triggers include surgery, acute systemic illness, trauma, or abrupt withdrawal of long-term corticosteroid therapy. Patients with Addison's disease must learn to provide lifelong self-care that includes taking medications. The patient will need to learn how to self-administer steroids and the importance of carrying at all times an emergency kit containing parenteral cortisone and a syringe/needle. Medications for this disorder are to be taken continuously. Abruptly discontinuing the medication is dangerous. In the event of an illness or other stressor, the amount of medication the patient needs will be altered by the healthcare provider. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
6. **Answer: 1 Rationale:** Manifestations of SIADH occur as a result of water retention, hyponatremia, and serum hypo-osmolality. Blood volume expands, but the plasma is diluted. Aldosterone is suppressed and renal excretion of sodium increases. Water moves from the hypotonic plasma and the interstitial spaces into the cells. Urinary output decreases and the urine becomes very concentrated. Brain cells may swell, causing neurologic manifestations including irritability. Weight gain results from the retention of fluid. Constipation and hyperkalemia are not manifestations associated with SIADH. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Hyperparathyroidism results from an increase in the secretion of parathyroid hormone (PTH), which regulates normal serum levels of calcium. The increase in PTH affects the kidneys and bones, resulting in increased resorption of calcium and excretion of phosphate by the kidneys and increased release of calcium and phosphorus by bones. This leads to bone decalcification. Bone reabsorption results in pathologic fractures. Osteoporosis is disease process of bone demineralization. The combination of the two health problems increases this patient's risk for injury from fractures. There is not enough information to determine if these disease processes will lead to fear, social isolation, or a risk for chronic low self-esteem. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** Increased serum calcium decreases neuromuscular excitability, which decreases bowel motility. Manifestations of the effect of hypercalcemia on the gastrointestinal tract include constipation. Hypercalcemia does not affect urine output. A positive Chvostek's sign is a manifestation of hypocalcemia. Deep tendon reflexes are hyperactive in hypocalcemia, not hypercalcemia. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** Hypoparathyroidism results from abnormally low PTH levels. The most common cause is damage to or inadvertent removal of all of the parathyroid glands during thyroidectomy. The lack of circulating PTH causes hypocalcemia and an elevated blood phosphate level. The low calcium levels cause changes in neuromuscular activity, affecting peripheral motor and sensory nerves. The neuromuscular manifestations that result include numbness and tingling around the mouth and in the fingertips. Recovery from a thyroidectomy will not cause an Addisonian crisis, Cushing's syndrome, or hyperparathyroidism. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
10. **Answer: 3 Rationale:** In a patient with Cushing's syndrome the skin becomes thinner, leading to the development of abdominal striae or stretch marks. This is due to the inhibition of fibroblasts by excessive glucocorticoids, leading to a loss of collagen and connective tissue. Excessive mineralocorticoids that reduce the absorption of calcium cause osteoporosis and compression fractures. Excessive cortisol changes protein metabolism and protein catabolism, which leads to muscle weakness and wasting. Excessive glucocorticoids affect normal carbohydrate metabolism and cause fat deposits in the abdomen, under the clavicles, over the upper back, and a round "moon" face. Cognitive

Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 20: Nursing Care of Patients with Diabetes Mellitus

1. **Answer: 4 Rationale:** Immune-mediated type 1 diabetes mellitus leads to the destruction of beta cells and absolute insulin deficiency. The rate of beta-cell destruction is variable, usually more rapid in infants and children and slower in adults. Idiopathic type 1 diabetes mellitus has no known cause. It is believed to be an inherited disorder and the needs for insulin may be intermittent. Type 2 diabetes mellitus is a disorder that ranges from insulin resistance to insulin deficiency. There is no immune destruction of beta cells. Maturity-onset diabetes mellitus is caused by a genetic defect within the beta cell that causes hyperglycemia to occur before the age of 25. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Diabetic ketoacidosis (DKA) develops when there is a deficiency of insulin; this results in glucose deficiency at the cellular level. As the pathophysiology of untreated type 1 DM continues, the glucose deficit causes fat stores to break down to provide energy, resulting in mobilization of fatty acids with a subsequent ketosis. The lack of cellular glucose causes production of counterregulatory hormones. Glucose production by the liver increases, peripheral glucose use decreases, fat mobilization increases, and ketogenesis is stimulated. As a result of a loss of bicarbonate, which occurs when the ketone is formed, bicarbonate buffering does not occur, leading to metabolic acidosis. Diabetic ketoacidosis is not caused by decreased glucagon, low protein levels, excessive insulin, or a breakdown of glucose molecules. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 2 Rationale:** The risks for developing type 2 diabetes mellitus include increasing age, obesity, and a sedentary lifestyle. Of the newly admitted patients, the one who is at the highest risk for developing type 2 diabetes mellitus is the 70-year-old patient who is overweight and sedentary. Normal weight, active lifestyle, and stress level do not contribute to the risk of developing this endocrine disorder. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
4. **Answer: 3 Rationale:** The person with diabetes mellitus is at risk for injury from multiple factors. Neuropathies may alter sensation, gait, and muscle control. The impaired mobility, sensory deficits, and neurologic effects of complications of diabetes mellitus increase the risk of accidents, burns, falls, and trauma. The loss of normal reflexes may or may not increase the patient's risk for injuries. Having normal sensation would not increase the patient's risk for injuries. There are more appropriate diagnoses for the patient assessment of chest pain. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** Visual inspection of the feet each day is important in preventing more serious complications. Shoes should be purchased later in the day when feet are at their largest. Footwear should be worn at all times. The patient should be instructed to never walk barefoot. Foot wounds should be treated by a healthcare professional. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
6. **Answer: 1 Rationale:** Insulin glargine (Lantus) and insulin detemir (Levemir) are clear, unlike other intermediate or long-acting insulins, and can accidentally be mistaken for regular insulin. Regular insulin is short acting in 4 to 6 hours whereas Lantus and Levemir are long acting over 24 to 28 hours. These insulins are not activated by vigorous agitation. They are not combined with glucose to raise energy levels. These insulins are also not inactivated by light and must be kept cold. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
7. **Answer: 2 Rationale:** Regular insulin is clear in appearance and is used for subcutaneous injection as well as IV insulin therapy. Other insulins such as NPH, glargine, and Humalog are suspensions and could be harmful if given by the IV route. Regular insulin is used in insulin infusions, as an IV bolus, or subcutaneous by itself or in combination with intermediate-acting insulins to provide better glucose control. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 4 Rationale:** According to the American Diabetes Association diagnostic criteria, a hemoglobin A_1C greater than or equal to 6.5% indicates diabetes mellitus. The other laboratory values do not support the diagnosis of diabetes mellitus because they are below 6.5%. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** No intermediate- or long-acting insulin is given the day of surgery since dietary intake postoperatively is uncertain. Unless otherwise ordered, regular insulin is given at the usual dose to compensate for the anticipated stress-related increase in serum glucose until the patient is eating and drinking normally. If there is no food intake after surgery, intravenous dextrose is often prescribed with subcutaneous regular insulin. The insulin should not be chilled to slow absorption. The insulin does not need to be provided through the intravenous route. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 4 Rationale:** Although in theory any area of the body with subcutaneous tissue may be used for injections of insulin, certain sites are recommended. The rate of absorption and peak of action of insulin differ according to the site. The site that allows the most rapid absorption is the abdomen, followed by the subcutaneous tissue of the upper arm, thigh, and hip. Insulin sites are rotated within a given region with each injection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Unit 5 Responses to Altered Endocrine Function

1. A transient form of SIADH may follow a head injury. Manifestations of SIADH occur as a result of water retention, hyponatremia, and serum hypo-osmolality. Manifestations of SIADH are related to dilutional hyponatremia and water intoxication. Despite fluid retention, the patient may experience thirst. Brain cells may swell, causing neurologic manifestations including headache, changes in mental status or personality, lethargy, and irritability.
2.
   A. **Mrs. Rant should be seen first.** *Rationale: Relieving pain is a high priority, especially when the patient's blood pressure is elevated.*
   B. **Mr. Blew should be seen second.** *Rationale: The effectiveness of admission treatment of his extremely high blood glucose should be determined.*
   C. **Mr. Rite should be seen third.** *Rationale: While he has been stable, he is exhibiting signs of increased intracranial pressure and must be assessed.*
   D. **Mrs. Fox should be seen last.** *Rationale: Her vital signs are stable and she is waiting for labs to be drawn.*
3. Teach Mr. Blew to monitor his blood glucose, desired blood glucose readings, and when to contact the physician. He should be taught to provide foot care including inspecting his feet daily using a mirror, wearing well-fitting shoes/slippers at all times, caring for his nails, and reporting sores or red skin to his healthcare provider..
4. **A.** Increase fluids in the diet and avoid taking vitamin D supplements. *Rationale: Hyperparathyroidism causes high serum calcium levels. Increased fluids and decreased calcium and vitamin A and D supplements are the appropriate treatment.*
5. **B.** tachycardia, hypotension, and shakiness
   Rationale: Signs and symptoms of hypoglycemia are tachycardia, hypotension, and shakiness.

6. A, B, D, E
   - **A.** fasting blood glucose
   - **B.** glycosylated hemoglobin (Hb A1c)
   - **C.** serum electrolytes
   - **D.** serum cholesterol and triglyceride levels

   Rationale: Laboratory tests used to monitor diabetes management are fasting blood glucose levels, glycosylated hemoglobin, abnormal electrolyte levels indicating DKA or HHS, and cholesterol levels to monitor for increased risk of cardiovascular impairments.
7. **C.** "If my blood glucose drops below 60, I can drink 4 ounces of fruit juice to raise it."

   Rationale: Fast-acting carbohydrates, such as 4 ounces of fruit juice or 8 ounces of skim milk, may be administered to raise the blood glucose level.
8. "I don't know at this time if that will be necessary. We will be assessing Mrs. Fox's ability to care for herself. We will also get information from the doctor. I will have the discharge coordinator contact you to discuss these issues."

   Rationale: It is important for older adult patients to be given time to improve following a major health event. An evaluation of their ability to care for themselves is necessary as a part of discharge planning.
9.
   - **A. Mr. Blew:** vital signs, blood glucose
   - **B. Mrs. Rant:** vital signs, strain all urine for stones
   - **C. Mrs. Fox:** vital signs, assisting with ADLs with instruction for patient to be as independent as possible
   - **D. Mr. Rite:** vital signs

   Rationale: All tasks must be within the legal scope of practice for the nursing assistant and the facility policy.
10. **D.** instituting an intravenous infusion of 0.9% normal saline at a rate of 250 mL/h.

    Rationale: The hyperglycemia of DKA results in osmotic diuresis, which leads to dehydration and loss of electrolytes. If left untreated, fluid volume deficit leads to poor perfusion and lactic acidosis, further complicating the metabolic acidosis. The initial fluid replacement may be accomplished by administering 0.9% saline solution at high infusion rates to replace losses from polyuria and vomiting.
11. **B.** "I must take my pulse before taking the medication and report to the doctor a pulse greater than 100."

    Rationale: The patient must take a pulse prior to taking the medication; a pulse >100 must be reported to the physician because it may indicate an excessive dose or response to the medication.
12. **D.** Institute continuous cardiac rhythm monitoring.

    Rationale: Treatment of hyperparathyroidism focuses on decreasing the elevated serum calcium levels. Patients with hypercalcemia are urged to drink fluids and keep active. They should avoid immobilization, thiazide diuretics, large doses of vitamins A and D, antacids containing calcium, and calcium supplements. Severe hypercalcemia requires hospitalization and intensive treatment with intravenous saline. Hypercalcemia also affects the cardiovascular system, causing dysrhythmias so the patient should be on continuous cardiac monitoring.
13. A, D, E
    - **A.** presence of dehydration
    - **D.** use of excessive isopropyl alcohol to clean the skin
    - **E.** test strips that have been stored outside the original container

    Rationale: Factors that can affect accuracy of blood glucose meter readings include situations where the hematocrit is elevated, such as in the case of dehydration and sickle cell disease; when isopropyl alcohol, which is frequently used to clean the skin, mixes with the blood sample; and when test strips are incompatible with the glucose meter, outdated, or not stored according to directions.
14. **C.** Using a link in the electronic medical record, research diabetes mellitus guidelines at the National Guidelines Clearinghouse website.

    Rationale: Hearsay from fellow staff nurses would not be an appropriate action to research up-to-date clinical guidelines for care. Textbooks, while providing a good source for basic information, are not appropriate sources of the most recent information related to clinical guidelines. The National Guidelines Clearinghouse is an Internet-based, freely available website that houses evidence-based clinical guidelines, providing up-to-date care standards. Reviewing general nursing journals is an inefficient strategy to locate the detailed information for which you are searching.

Chapter 21: Assessing the Gastrointestinal System

1. **Answer: 1, 2 Rationale:** Proteins are classified as either complete or incomplete. Complete proteins are found in animal products such as milk and eggs. Incomplete proteins are found in legumes and vegetables. Fruits are considered carbohydrates. Butter is considered a fat. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 1, 4 Rationale:** Vitamin K is synthesized by coliform bacteria in the large intestines and is essential for the formation of clotting proteins in the liver. Evidence of a vitamin K deficiency would be bruising and surgical wound bleeding. A niacin deficiency could cause slow peristalsis. Poor wound healing could be a manifestation of a vitamin C deficiency. Keloid formation is not caused from a particular vitamin deficiency. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 4 Rationale:** The serum amylase level is used to measure the secretion of amylase by the pancreas. It is used to diagnose acute pancreatitis, when amylase level peaks in 24 hours and then drops to normal in 48 to 72 hours. An elevated amylase indicates that the pancreatic enzymes, released during acute pancreatic inflammation, are digesting their own tissues. Cheilosis or sores at the corners of the mouth are seen in vitamin B-complex deficiencies, especially riboflavin. The gallbladder stores bile, which is used to aid in the digestion of fats. An elevated serum amylase level is not associated with gastric reflux disease. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 3 Rationale:** The condition of the patient's teeth, difficulty swallowing, and dry mouth because of decreased production of saliva in the older adult may cause a nutritional deficit. The patient may tend to eat food that is easier to chew and swallow. The combined manifestations of dental caries, difficulty swallowing, and dry mouth will not necessarily cause the patient to experience acute pain, infection, or altered elimination. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
5. **Answer: 3 Rationale:** In a patient with ascites of the liver of more than 500 mL, a method of determining fluid presence is to palpate dullness in the abdomen in the supine position and then on the right side. The presence of dullness moving in these two positions indicates ascites with shifting dullness pattern. Flatness is not an identified percussion tone. Resonance is a term used when assessing the lungs and thorax. Alternating amplitude is a term used when analyzing an electrocardiogram rhythm strip. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 3 Rationale:** Internal hemorrhoids are clusters of dilated veins in swollen anal tissue and occur because of impaired venous return during evacuation of stool or increased abdominal pressure in pregnancy causing distention of veins in the anus. Internal hemorrhoids are not a part of the lymphatic system. Internal hemorrhoids are a part of the venous system. These structures are not bits of tissue that occur for no reason. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2, 3, 4 Rationale:** If the patient has an ostomy, the nurse should ask questions about the skin and associated care, consistency of stool, and foods that cause problems with flatus. Questions about

appetite and hemorrhoids do not focus on the patient's ostomy. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

8. **Answer: 3 Rationale:** A sample of stool is collected for gross and microscopic examination, as well as for form, consistency, and color. Gross examination includes volume and water content, and the presence of any blood, pus, mucus, or excess fat. Microscopic examination identifies the presence of WBCs, unabsorbed fat, and parasites. Colonoscopy, barium enema, or CT of the abdomen is not needed to confirm the diagnosis of intestinal parasites. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** A colonoscopy is the visual examination of the entire colon and is used to identify tumors, polyps, and inflammatory bowel disease and to dilate strictures. Because polyps have been documented as a risk factor for colon cancer, they are removed during the procedure to prevent future malignancies. Polyps are not removed to identify genetic disorders, facilitate further examination of the bowel, or to decrease future problems with constipation. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
10. **Answer: 2 Rationale:** Colon cancer is one of the most common inherited cancer syndromes. The nurse does not need to wait for further diagnostic testing before asking the patient about a family history of colon cancer. The nurse can ask the patient this question. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

Chapter 22: Nursing Care of Patients with Nutritional Disorders

1. **Answer: 2 Rationale:** Environmental influences and heredity contribute to the development of obesity; however, physical inactivity is the most important factor contributing to obesity. Inactive people may consume fewer calories than active people and continue to gain weight due to lack of energy expenditure. Environmental influences, such as fast-food restaurants, contribute to increased caloric intake. Heredity may contribute up to 40% of the risk for obesity. There is a strong correlation between the weight of adopted children and their biologic parents. Allergies to chocolate and strawberries are not risk factors for the development of obesity. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
2. **Answer: 4 Rationale:** The nurse should assist the patient to create attainable goals that incorporate achievement of improved health outcomes. A pound of body fat is equivalent to 3500 kcal. To lose 1 pound an individual must reduce daily caloric intake by 500 kcal for 7 days or increase activity enough to burn the equivalent kilocalories. A weight loss goal of 1 to 2 pounds per week and a 10% reduction in body weight in 6 months of therapy is recommended. Research indicates most patients set unrealistic goals related to their "dream weight." Treatment focuses on reducing the health risks associated with obesity by changing both eating and exercise habits. There is no evidence to suggest that the patient is not able to adhere to the prescribed diet plan. The patient should not be encouraged to take time off from the diet and exercise plan. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 1, 2, 4 Rationale:** Manifestations of protein-calorie malnutrition include thin hair, dry flaking skin, and a recent weight loss. The person with protein-calorie malnutrition will be weak and listless. There is no specific bowel sound associated with protein-calorie malnutrition. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 1, 2, 3 Rationale:** The interventions appropriate for the diagnosis of *Imbalanced Nutrition: More Than Body Requirements* include establish realistic weight loss goals, determine realistic activity objectives, and review behavior modification strategies. Determining strategies to prevent stress eating is an intervention appropriate for the diagnosis of *Ineffective Therapeutic Regimen Management*. Setting small goals and offering positive encouragement is an intervention appropriate for the diagnosis of *Chronic Low Self-Esteem*. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** Patients with eating disorders require extended treatment of the disorder. Involvement of the family and social support persons is vital to success. Encourage family members to participate in teaching and nutritional counseling sessions. Discuss the value of family therapy to address issues that have contributed to the disorder. Emphasize the need to provide consistent messages of support for healthy eating habits. Refeeding is gradually introduced to avoid complications so a weight gain of 2 lb per week would not be realistic. The patient should not be left alone after meals. Observing the patient during and after meals helps prevent disposal of food and purging behavior after eating. Consuming 2500 calories every day could lead to refeeding syndrome and would not be a realistic goal for this patient. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Psychosocial Integrity
6. **Answer: 4 Rationale:** A BMI greater than 25 and central obesity as indicated by a waist–hip ratio of 1 or greater tend to have more intra-abdominal fat and higher levels of circulating free fatty acids. This places the patient at a higher risk for hypertension, elevated lipid levels, heart disease, stroke, and elevated insulin levels. These conditions have the greatest effect on health over time. The patient with obesity can be at risk for ineffective coping; however, this is not the priority. The patient with obesity may have diet education needs and may be demonstrating health-seeking behavior; however, these diagnoses are not the priority for this patient. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
7. **Answer: 4 Rationale:** Patients recovering from bariatric surgery should be instructed to avoid foods high in simple carbohydrates since this could precipitate dumping syndrome. Meals should be small and liquids and solids should not be taken together. Caffeinated carbonated liquids will not aid with weight loss. The patient should be encouraged to follow a specific eating plan to support behavior modification strategies. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
8. **Answer: 1, 3, 4, 6 Rationale:** Many contributing factors influence nutrition in the home-bound older adult such as inability to shop for nutritional foods or the inability to afford and prepare nutritional food. There are also psychosocial issues of depression and loneliness since eating is a social affair; this could well influence the amount and proportion of caloric intake. Arranging for food to be brought to the patient and for the patient to be transported to a senior center for a meal may solve the weight loss issue and no further interventions may be necessary. Referral to the primary care provider is necessary. Diagnostic studies may be required after being examined by the primary care provider. The patient does not need to be placed in a residential care facility because of unplanned weight loss. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
9. **Answer: 4 Rationale:** The stress of surgery produces a state of hypermetabolism and catabolism, which increases energy expenditure and nutrient needs, resulting in protein-calorie malnutrition. Beginning oral intake of nutrients as soon as possible after surgery is the best way to prevent the development of this type of malnutrition. Measuring daily weights will provide information about fluid balance and not necessarily body weight. Aggressive pain management and intravenous fluids will not prevent the development of malnutrition. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 1 Rationale:** The risk for postoperative complications after bariatric surgery is high. One of the postoperative complications with gastric bypass surgery is an anastomotic leak causing peritonitis. These

manifestations could be related to this condition and the surgeon needs to be notified. The patient is experiencing increasing abdominal pain and absent bowel sounds. These findings would not be consistent with effectiveness of analgesia. The patient should be maintained on bed rest until evaluated by the surgeon. The nurse needs to do more than chart the findings and monitor the patient. Peritonitis can be a life-threatening health problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 23: Nursing Care of Patients with Upper Gastrointestinal Disorders

1. **Answer: 1 Rationale:** The primary risk factors for oral cancer are smoking, drinking alcohol, and chewing tobacco. The use of dental floss, consumption of spicy foods, and thumb sucking or pacifier use as a child are not risk factors for the development of oral cancer. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 2, 3 Rationale:** Placing the head of the bed on blocks and avoiding lying down for at least 3 hours after eating will help prevent backflow of gastric content into the esophagus by decreasing the pressure on the lower esophageal sphincter. Treatment for gastroesophageal reflux disease includes changing the diet and using proton-pump inhibitors, H_2-receptor blockers, and in some cases, surgery. Peppermint and chocolate can aggravate gastroesophageal reflux and should be avoided. The patient should be instructed to take prescribed medication as ordered for the full course of therapy, even if symptoms are relieved. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
3. **Answer: 4 Rationale:** The ingestion of aspirin or other NSAIDs, corticosteroids, alcohol, and caffeine is commonly associated with the development of acute gastritis. A period of gastric rest, followed by a slow progression to regular dietary intake, is advised. The patient does not need to eat only bland food. The patient will not need yearly upper endoscopy exams. Fully cooking all meat, poultry, and egg products is essential for all individuals and not just for those with acute gastritis. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
4. **Answer: 3 Rationale:** Erosion of a blood vessel with resultant hemorrhage is a significant risk for the patient with peptic ulcer disease. Acute bleeding can lead to hypovolemia and fluid volume deficit, which can lead to a decrease in cardiac output and impaired tissue perfusion. The diagnoses of *Nausea*, *Acute Pain*, and *Ineffective Health Maintenance* are important, but are not the priorities for the patient with a possible perforation from peptic ulcer disease. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 1, 2, 3, 5 Rationale:** Anemia may be a chronic problem after a major gastric resection. Iron is absorbed primarily in the duodenum and proximal jejunum; rapid gastric emptying or a gastrojejunostomy may interfere with adequate absorption. The cells of the stomach produce intrinsic factor, required for the absorption of vitamin B_{12}. Vitamin B_{12} deficiency leads to pernicious anemia. Vitamin B_{12} levels are routinely monitored following extensive gastric resections. Other nutritional problems seen following surgery include folic acid deficiency and decreased absorption of calcium and vitamin D and not vitamin C. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
6. **Answer: 2 Rationale:** Complications associated with radiation therapy to the esophagus include perforation and hemorrhage. Bright bleeding from the mouth could indicate perforation of the esophageal wall and vessel rupture. Weight loss and dysphagia are manifestations of esophageal cancer. Crackles in the base of the right lung could be due to atelectasis and not necessarily indicate a major respiratory problem. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** The medications used to treat PUD include agents to eradicate *H. pylori*, drugs to decrease gastric acid content, and agents that protect the mucosa. Eradication of *H. pylori* generally requires 14 days of therapy using a combination of two antibiotics with a proton-pump inhibitor or a bismuth compound. The patient needs to take the complete course of all medication as prescribed. The medications should be taken with sufficient water. Consuming yogurt or buttermilk might be appropriate if the patient is prone to developing a superinfection from antibiotic use. Omeprazole should be taken 30 minutes before breakfast on an empty stomach. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 4 Rationale:** The discomfort of stomatitis is aggravated by eating. Using a topical anesthetic, such as a mouthwash of 2% viscous lidocaine diluted with water, can promote comfort and the ability to consume oral food and fluids. Smoking cessation will help prevent the development of stomatitis; however, this is not the reason that the patient has developed this health problem. Selecting appealing foods will not promote nutrition if the patient is experiencing mouth pain. A solution of saline, sodium bicarbonate, or a combination of saline/bicarbonate promotes comfort and healing when used after and between meals. Mouthwash would be too irritating to the oral tissue. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** After surgery for esophageal cancer, do not move or manipulate the nasogastric tube. Low gastric suction should be maintained as prescribed. Manipulating or moving the nasogastric tube may disrupt suture lines, resulting in a leak into the mediastinum. Irrigating the tube with normal saline would be manipulating the tube and should not be done. The surgeon should be notified. The nurse needs to do more than chart the findings. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 1, 2, 3 Rationale:** When perforation occurs, gastric or duodenal contents enter the peritoneum, causing an inflammatory process and peritonitis. When an ulcer perforates, the patient has immediate, severe upper abdominal pain, radiating throughout the abdomen and possibly to the shoulder. The abdomen becomes rigid and board-like, with absent bowel sounds. Placing the patient in Fowler's or semi-Fowler's position allows peritoneal contaminants to pool in the pelvis. All food and fluids should be withheld and the physician notified. The patient needs more help than pain medication or prescribed proton-pump inhibitors. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 24: Nursing Care of Patients with Bowel Disorders

1. **Answer: 1 Rationale:** The nurse should first assess the duration and extent of diarrhea to include the number and character of the stools. Diarrhea is stool with a high water content, so refraining from all oral intake until the diarrhea subsides could exacerbate fluid and electrolyte imbalances caused by the diarrhea. The nurse should not prescribe or recommend the use of any medication. Once the nurse assesses the frequency and character of stools, the nurse can then assess if the patient has been exposed to spoiled food or contaminated water, which could be the source for the diarrhea. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 1 Rationale:** The acutely inflamed appendix can perforate within 24 hours, so rapid diagnosis and treatment are important. Because of this urgency and the low incidence of surgical complications, diagnostic testing and preoperative treatment may be limited. The patient is admitted to the hospital, and intravenous fluids and antibiotics are initiated. Oral food and fluids are withheld until a diagnosis

is confirmed. Once the diagnosis is established, an appendectomy is performed. Preoperative skin preparation would be done once the decision is made for surgery. There may not be enough time to teach the patient about deep breathing and coughing and leg exercises. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity

3. **Answer: 3 Rationale:** Sulfasalazine increases sensitivity to the sun, so the patient should be instructed to use a sunscreen to prevent burns. The patient should not take vitamin C without consulting with the prescribing healthcare provider. The medication should be taken after meals to decrease gastric distress. The patient should be instructed to drink at least 2 quarts of fluid each day to reduce the risk of kidney damage from taking this medication. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** Steatorrhea is impairment in fat absorption leading to excess fat in feces. Steatorrhea and diarrhea typically occur with celiac disease because fat, water, and other nutrients are poorly absorbed, remaining in the bowel to be eliminated in the stool. Foods with gluten can cause this manifestation to occur. Steatorrhea is not associated with colorectal cancer, alternating episodes of diarrhea and constipation, nor exposure to enterotoxins in food or water. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1, 2, 4, 5 Rationale:** Measures to prevent colon cancer that are considered to be effective and safe include consuming a diet high in fruits and vegetables and low in saturated fat and red meat, regular exercise, and maintaining a healthy weight. Alcohol consumption should be limited. The patient should also follow the recommended testing schedule for the early detection of colorectal cancer beginning at age 50. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
6. **Answer: 1, 3, 4 Rationale:** Since the nasogastric tube is being used to reduce gastric contents, the nurse should measure abdominal girth to determine the presence of distention. The nurse should also closely monitor the patient's intake and output every 2 to 4 hours and document the amount and color of nasogastric tube drainage every shift. Auscultation of bowel sounds should occur regardless of assessing the placement of the nasogastric tube. The patient should not be on nothing by mouth status when a nasogastric tube is being used for gastric decompression. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** It is most important to maintain the patency of the nasogastric tube to remove gastric secretions and air that may apply pressure to the anastomosis site and cause failure of the suture line. Keeping the stomach decompressed is important to prevent vomiting that could also cause damage to the anastomosis site. Although important, monitoring bowel sounds is not the most important action for the nurse to take. The patient will be acutely ill and most likely not able to get out of bed. The patient should be placed on nothing by mouth status and should not be provided with a clear liquid diet. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** Dietary modification is central to the management of diverticular disease. Dietary changes can reduce the risk of complications of diverticulosis. A high-fiber diet is recommended because it increases stool bulk, decreases intraluminal pressures, and may reduce spasm. The patient should be instructed to avoid foods with small seeds such as berries, which could obstruct diverticula. There is no reason for the patient to avoid eating soup, apples, or whole-wheat bread. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
9. **Answer: 1, 3, 4, 5 Rationale:** Actions to prevent constipation include ingesting fresh fruits and vegetables, whole-wheat bread, and bran cereal since these food items supply roughage and fiber in the diet that can assist in the evacuation of fecal material. Adequate liquid is needed to prevent hard, formed stools that are difficult to pass. Taking daily laxatives can decrease the normal bowel reflex and lead to laxative dependency. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** The priority for a patient with a small-bowel obstruction would be to maintain gastrointestinal decompression through the use of a nasogastric tube. This will remove gastric secretions, reduce the amount of accumulated fluid and gas proximal to the obstruction, and reduce the risk for bowel ischemia and necrosis. Analgesics can be provided after a pain assessment is completed. The head of the bed should be elevated to reduce the tension on the abdomen. The patient will be on nothing by mouth status; however, intravenous fluids and urine output measurements should be maintained. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance

Chapter 25: Nursing Care of Patients with Gallbladder, Liver, and Pancreatic Disorders

1. **Answer: 1 Rationale:** Right upper quadrant pain following ingestion of a fatty meal is the typical manifestation experienced by patients with cholelithiasis. Jaundice would occur if a gallstone blocks the common bile duct and is considered a complication of cholelithiasis. Chills, fever, nausea, and vomiting may indicate an infection and would contraindicate surgery at this time. Heartburn and acid reflux are associated with peptic ulcer disease. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 2, 3, 4 Rationale:** Acute cholecystitis usually develops from a stone obstructing the cystic duct, preventing release of bile from the gallbladder. High fatty foods like gravies and peanut butter stimulate contraction of the obstructed gallbladder, causing pain. The patient should be instructed to call the physician if severe abdominal pain and a fever are experienced. A low-carbohydrate diet has a protective effect to reduce the incidence of gallstones and cholecystitis. Laparoscopic cholecystectomy is the treatment of choice for symptomatic cholelithiasis or cholecystitis. Foods and fluid should be withheld during episodes of acute pain. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** Hepatitis A is transmitted by the oral–fecal route from an infected person handling food, water, or fish, or through direct contact without washing hands before handling food or after using the bathroom. Testing employees for the hepatitis A antigen will not prevent future outbreaks of the disease. Using gloves for handling food if cuts or scrapes are on the hands would be ineffective because this disease is not transmitted through the blood. If continued outbreaks occur it might be necessary to have all employees immunized or consider another source of the infection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 1 Rationale:** Hepatitis C is transmitted through contact with blood or body fluids. Alcohol and acetaminophen are irritating to the liver and should be avoided. The patient with hepatitis C is at risk for the development of liver cancer. A follow-up annual liver biopsy is not recommended for hepatitis C. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** The hepatitis A virus is transmitted through the fecal–oral route and can be transmitted before manifestations of the disease including jaundice develop. It is important to identify people who have had direct contact with the newly diagnosed patient because the incubation period is 2 to 6 weeks. The patient's immunization status will not help with exposure to the virus. Hepatitis A is not transmitted through body fluids. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity

6. **Answer: 4 Rationale:** Bleeding esophageal varices are life threatening and require intensive care management. Restoration of hemodynamic stability is the first priority. A central line is inserted and central venous and pulmonary artery pressures are monitored. The physician will determine if a nasogastric tube should be inserted. The head of the bed should be raised to prevent aspiration. Checking the stool for occult blood is not necessary to do at this time. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 1 Rationale:** The nurse should teach the patient to empty the bladder before the paracentesis to reduce the risk for bladder puncture. Excess flatus is not an adverse effect of a paracentesis. The nurse will cleanse the abdomen before the procedure. The patient does not need to do this at home. There are not restrictions on eating or drinking fluid before the procedure. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 4 Rationale:** Patients with cirrhosis and ascites may develop bacterial peritonitis. The inflammatory response to peritonitis worsens ascites by increasing the permeability of capillaries in the mesentery. The manifestations of spontaneous bacterial peritonitis may be subtle, with increased abdominal discomfort or pain, fever, and worsening encephalopathy. The nurse should assess bowel sounds and palpate for tenderness. A headache and nuchal rigidity are not applicable for the patient's manifestations. Measuring abdominal girth and percussing for shifting dullness are routine actions when assessing for ascites. Neck vein distention and auscultating lung sounds do not focus on the patient's problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Gallstones are the leading cause of acute pancreatitis, with alcohol being the second leading cause. Since the patient reports no alcohol intake, the nurse does not need to ask if the patient formerly drank alcohol. Smoking and intravenous drug use are not risk factors for the development of acute pancreatitis. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 1, 2, 4, 5 Rationale:** Nursing care for a patient recovering from a Whipple procedure includes using analgesics for pain control as prescribed, maintain in the semi-Fowler's position to facilitate lung expansion and reduce stress on the anastomosis and suture line, not repositioning the nasogastric tube to avoid disrupting the suture line, and frequently turning, deep breathing, and coughing to facilitate the drainage of pulmonary secretions. Early ambulation will not occur until the patient's condition stabilizes. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Unit 6 Responses to Altered Gastrointestinal Function

1. Anxiety and irritability may be indicators of delirium tremens from alcohol withdrawal.
2.
   - **A. Thomas Jones should be seen first.** *Rationale: Mr. Jones is becoming anxious and irritable, which are signs of DTs from alcohol withdrawal. He needs to be evaluated and treated.*
   - **B. Tonya Cooper should be seen second.** *Rationale: Ms. Cooper needs assistance to use the bedpan. Her orthostatic blood pressure is too low for it to be safe for her to get out of bed.*
   - **C. Paul Bruner should be assessed third.** *Rationale: Mr. Bruner is scheduled for a colonoscopy and needs a complete assessment noting specifically the effectiveness of the bowel prep.*
   - **D. Grace Freeman should be assessed fourth.** *Rationale: Although the colostomy bag needs to be changed, it is not harmful to leave it for a few minutes. Changing the bag is an optimal time for patient teaching, which will take some time.*
3. **A.** rectal bleeding
   Rationale: The most common initial clinical manifestation is rectal bleeding due to impaired integrity of the rectal tissue.
4. **C.** Administers a bowel preparation the evening before the procedure.
   Rationale: A bowel preparation, for example with citrate of magnesia, laxatives, or polyethylene glycol, is provided the evening before to cleanse the intestines prior to the procedure. A clear liquid diet is provided the day prior to the examination and the patient remains NPO for 8 hours before the procedure.
5. A, C, D, E.
   - **A.** AST
   - **C.** ALK
   - **D.** complete blood cell count
   - **E.** serum bilirubin

   Rationale: On admission a baseline for the extent of blood loss and life impairment must be determined.
6. The teaching plan should include types of appliances, how to remove and apply the appliance, how to remove flatus from the appliance, skin inspection, and skin care. Also include contact information for professional support and local ostomy support groups.
7. The nurse should respond with, "I understand your concerns. Have you discussed your feelings with your daughter and the doctor? I can have them come and talk with you before the colonoscopy if you would like. Remember that a definitive diagnosis has not been made yet and that is why the colonoscopy is being performed."
   Rationale: The nurse must respond to the patient's wishes. It is important to facilitate communication between Mr. Bruner, his daughter, and the surgeon and remind Mr. Bruner that a diagnosis has not yet been confirmed.
8. Instruct the unlicensed assistive personnel assisting Ms. Cooper with her meals to stay with her to prevent her from stimulating vomiting for at least 1 hour after she eats.
9. The nurse should collaborate with the healthcare provider regarding Ms. Cooper's orthostatic blood pressure changes because they may be indicative of dehydration and the need for further intravenous fluid replacement.
10. **B.** Use rewards for food and caloric intake rather than for weight gain.
    Rationale: Rewarding good behavior helps to develop a positive self-concept. Monitoring daily food intake provides data about balanced nutrients whereas weight gain does not.
11. **B.** Maintain suctioning of the oral cavity to remove excess secretions.
    Rationale: The esophageal balloon prevents the patient from swallowing oral secretions, increasing the risk for aspiration so frequent oral suctioning of salivary secretions is needed. The head of the bed is elevated to 45 degrees to reduce the risk of aspiration and promote gas exchange. Tension is applied to the tube to further compress the varices. When removing the tube the esophageal balloon is deflated before the gastric balloon to prevent movement of the tube and airway obstruction.
12. The nurse will need to complete an incident report form and be seen by the hospital infection control department or employee work health department. Blood should be drawn to establish a baseline in case the nurse becomes hepatitis B positive. Facility policy should be followed. History of the nurse's immunization status for hepatitis B must also be assessed. Postexposure prophylaxis is necessary for the unvaccinated individual within 24 hours of exposure as well as concurrent initiation of hepatitis B vaccine series.
13. The nurse manager should ensure that safety devices are available for providing injections. If in fact available, the manager should assess each individual's use of the safety device and provide further education to nursing staff as needed when incorrect use is observed.
14. A, C, D
    - **A.** pain assessment (0–10 scale)
    - **C.** administration of prescribed pain medication
    - **D.** reassessment of effectiveness of pain medication

    Rationale: Pain assessment includes quantitative assessment of pain severity, descriptive statements of pain quality by the patient,

administration of prescribed pain medication, and reassessment/evaluation of the effectiveness of pain-related interventions.

Chapter 26: Assessing the Renal System

1. **Answer: 1 Rationale:** Leakage of urine (urinary incontinence) is not a normal outcome of aging. Having to void during the night, urgency, and protein in the urine are all findings that are consistent with renal system changes in the older patient. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 1 Rationale:** The dilution or concentration of urine is largely determined by antidiuretic hormone (ADH), secreted by the posterior pituitary gland in response to blood volume and serum osmolality. When serum osmolality increases or blood volume falls, ADH is secreted. Pores of the collecting tubules enlarge in response, and more water is reabsorbed. This is the mechanism that occurs with vomiting. Renin is released in response to a drop in blood pressure. Thyroxin and aldosterone are not released in response to decreases in blood volume. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 4 Rationale:** The creatinine clearance test is a blood sample and 24-hour urine test to evaluate glomerular filtration rate and renal function. This test determines the filtering ability of the glomeruli and the blood circulation to them. If the clearance is decreased, the glomeruli are damaged or the circulation is slowed. A renal scan evaluates kidney blood flow, location, size, and shape to assess kidney perfusion and urine production. A renal biopsy is performed to determine the cause of renal disease, to rule out cancer metastasis to the kidney, or if rejection is occurring with a kidney transplant. A routine urinalysis is an examination of the constituents of a urine sample to establish a baseline, provide data for diagnosis, or monitor treatment results. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** The prostate gland encircles the urethra at the base of the bladder in males. The spleen is located in the left upper abdominal quadrant and is not an organ of the renal system. The adrenal glands are located on the top of the kidneys. The pancreas is located in the mid to left region of the upper abdomen and is not an organ of the renal system. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 2, 4 Rationale:** Pain or burning with urination should be documented as dysuria. Nocturia is defined as two or more episodes of voiding during the night. This should be documented in the medical record. Pyuria is pus in the urine. Polyuria is frequent episodes of high-volume urination. Hematuria is blood in the urine. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 1, 2, 5 Rationale:** For an intravenous pyelogram, the nurse should assess for allergies to seafood or iodine since these could indicate an allergy to the contrast dye. Instruct the patient to complete ordered pretest bowel preparation, including a prescribed laxative or cathartic the evening before the test, and an enema or suppository the morning of the test. Oral hypoglycemic agents are contraindicated for use with iodinated contrast. Food should not be eaten for 8 to 12 hours before the test although clear liquids are permitted. There is no reason to withhold taking prescribed diuretics before the test. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Before beginning the assessment, ask the patient to provide a clean-catch urine specimen if prescribed and give the patient a specimen cup. Assess the specimen for color, odor, and clarity before sending it to the laboratory. The patient will empty the bladder when providing a urine specimen. Deep breaths may or may not be appropriate prior to assessing the renal system. Drinking water before the examination could cause the bladder to fill with urine, making the examination uncomfortable for the patient. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
8. **Answer: 3 Rationale:** Anesthetic agents used during surgery may cause problems with initiating voiding. Palpation will determine if the bladder is distended. There is no need to percuss the abdomen for gastric tympany or auscultate for bowel sounds. There is not enough information to determine if the patient has edema of the urethra and this assessment is not considered routine for urine retention after surgery. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Bladder cancer is the fourth most common type of cancer in men. Genetic factors related to chromosome 9 are interrelated with risk factors such as smoking and exposure to industrial chemicals to cause bladder cancer. Hematuria may be a symptom of bladder cancer. Incontinence is not usually associated with bladder cancer. A kidney infection is caused by bacteria or viruses. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
10. **Answer: 1 Rationale:** Skin turgor is the best assessment technique to determine hydration of patients. Changes in skin turgor may indicate renal insufficiency with either excess fluid loss or retention. Kidney palpation is done to determine location and size of the organs. Auscultation of renal arteries is to determine changes in renal blood flow. Percussion for bladder dullness is performed to determine urinary retention. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

Chapter 27: Nursing Care of Patients with Urinary Tract Disorders

1. **Answer: 2 Rationale:** The use of a diaphragm and spermicidal compounds for birth control are risk factors for the development of urinary tract infections. Although important, the amount of fluid consumed each day is not going to cause a urinary tract infection. Asking about a partner having similar symptoms may or may not be appropriate. Symptoms of a urinary tract infection are largely relieved within 24 to 48 hours of starting antibiotic therapy. The reoccurrence time factor of the UTI is too long to be a failure to complete antibiotic treatment the first time. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 2, 4, 5 Rationale:** The nurse needs to inform the patient that a urine culture in 10 days is done to ensure antibiotic therapy was effective. In a perimenopausal woman vaginal cream may maintain tissue integrity to prevent bacterial colonization of perineal tissues; instructions on cleansing may prevent further infections. In general, further diagnostic testing is not indicated for women experiencing three or fewer UTIs per year. Instrumentation of the urinary tract such as with a cystoscopy is a major risk factor for UTI. Imaging studies such as intravenous pyelography are used to evaluate for structural or functional abnormalities of the kidneys, ureters, and bladder. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 4 Rationale:** Increasing fluid intake to 2.5 to 3.0 L/day is recommended, regardless of stone composition. A higher fluid intake helps to ensure the production of approximately 2.0 to 2.5 L of urine a day and prevents the stone-forming salts from becoming concentrated enough to precipitate. The urine pH is helpful in identifying the type of stone. Calcium should not be provided until the type of stone is identified because the majority of stones contain calcium. An indwelling urinary catheter is not routine treatment for urolithiasis. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity

4. **Answer: 2 Rationale:** A stone that completely obstructs the ureter can lead to hydronephrosis and acute kidney injury on the affected side. The nurse should report symptoms such as dull flank pain or aching. Straining the urine can be done after the physician is notified of the change in the patient's condition. An analgesic can be provided after the physician is notified. There is no evidence to suggest the patient is retaining urine and would need a bladder scan. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 2, 3 Rationale:** Cigarette smoking is the primary risk factor for bladder cancer. The risk in smokers is twice that of nonsmokers. The chemicals and dyes used in the plastics, rubber, and cable industries; substances in the work environment of textile workers, leather finishers, spray painters, and petroleum workers; and high levels of arsenic in drinking water also are associated with a higher risk of bladder cancer. Additional risk factors for bladder cancer include residence in an urban area, chronic UTIs, and bladder calculi. The risk for bladder cancer appears to be reduced by increasing the intake of fluids and vegetables. Emptying the bladder every 2 hours and limiting the intake of coffee and other caffeinated beverages does not reduce the risk of developing bladder cancer. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
6. **Answer: 1 Rationale:** Painless hematuria is the presenting sign in 75% of urinary tract tumors. Hematuria may be gross or microscopic and is often intermittent, causing delay in seeking treatment. The nurse should advise the participant to see a physician. Increasing fluids, tracking activities between urine color and activities, and waiting to notify the physician until pain or difficulty voiding occurs could delay potential diagnosis and treatment for bladder cancer. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** The patient with a newly created continent ileal diversion with a continent reservoir will have to demonstrate self-catheterization since this is the only way to empty the reservoir. This behavior indicates that teaching has been effective. There is no collection device for this diversion. This surgical procedure would have been performed for treatment of bladder cancer. Cloudy urine may occur as an effect of the urine on ileal mucosa. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
8. **Answer: 4 Rationale:** Stress incontinence should not be viewed as a normal result of aging, but as a treatable problem. Improved pelvic muscle strength helps retain urine and prevent stress incontinence by increasing urethral pressure. Exercises also decrease abnormal detrusor muscle contractions, decreasing pressure within the bladder. Being able to state the chronic and benign nature of the disorder and identifying products to protect clothing and furniture suggests this disorder is inevitable and untreatable. Beverages containing artificial sweeteners irritate bladder mucosa and the detrusor muscle, and can increase urgency and bladder spasms. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Inability to retain urine long enough to reach the toilet following perception of the need to urinate is characteristic of urge incontinence. Caffeine and artificial sweeteners are bladder irritants, causing instability of the detrusor muscle and aggravating manifestations. Restricting intake of fluids containing these substances in the evening reduces nocturia. Wearing clothing that is easily removed for toileting will not reduce the onset of urine leaks. A voiding schedule would be appropriate for the patient with urinary retention. Suspension of the bladder neck, a technique that brings the angle between the bladder and urethra closer to normal, is effective in treating stress incontinence associated with urethrocele in 80% to 95% of patients. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 3 Rationale:** Intermittent catheterization carries a lower risk of infection than does an indwelling catheter, and is preferred for patients who are unable to empty their bladder by voiding such as patients with spinal cord injury. Catheterizing the patient every 3 to 4 hours with a straight catheter prevents overdistension of the bladder. Increasing lower abdominal and bladder pressure with the Credé's method can stimulate autonomic dysreflexia in some patients with spinal cord injuries. The patient with a spinal cord injury will have bladder retention and not be able to void spontaneously. Inserting an indwelling urinary catheter could lead to a urinary tract infection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 28: Nursing Care of Patients with Kidney Disorders

1. **Answer: 3 Rationale:** The glomerular filtration rate (GFR) declines in an older patient due to age-related factors affecting the renovascular system. Decreased GFR in the older adult reduces the clearance of drugs excreted through the kidneys. This reduced clearance prolongs the half-life of drugs and may necessitate lower drug doses and longer dosing intervals. Common medications affected by decreased GFR include digoxin. Assessing the latest GFR may or may not provide enough information about the digoxin dose. Providing the medication with a large amount of water will not improve renal clearance of the medication. The patient does not need a larger dose of the medication. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** Polycystic kidney disease is a hereditary disease characterized by formation of fluid-filled cysts and massive kidney enlargement that affects both children and adults. This disease has two forms. The autosomal dominant form primarily affects adults and is common, affecting 1 in every 400 to 1000 people and accounting for approximately 4.5% of patients with end-stage renal disease in the United States. Genetic counseling and screening of family members for evidence of ADPD should be discussed. The autosomal recessive form is rare and usually is diagnosed prenatally or in infancy. Renal failure generally develops during childhood, necessitating kidney transplant or dialysis. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Acute postinfectious glomerulonephritis or acute poststreptococcal glomerulonephritis is the most common form of glomerulonephritis. The usual initiating event for this disorder is an infection of the pharynx or skin with group A beta-hemolytic streptococcus. Staphylococcal or viral infections, such as hepatitis B, mumps, or varicella, can lead to a similar postinfectious acute glomerulonephritis. Acute postinfectious glomerulonephritis is not associated with gastrointestinal disorders, urinary tract infections, or musculoskeletal trauma. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 3 Rationale:** When recovering from acute glomerulonephritis, the patient is at risk for infection. A nutritionally sound diet with complete proteins is important to maintain nutritional status and support immune function. Complete proteins are preferred when total protein intake is restricted, as it may be in acute glomerulonephritis. Fluids may be restricted to reduce fluid overload, edema, and hypertension; however, the amount of the fluid restriction is individualized for each patient. Hemodialysis is indicated for acute or chronic kidney failure or injury. There is no need for the patient to remain on bed rest until the urine returns to clear yellow. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
5. **Answer: 2, 4 Rationale:** While providing postoperative care to a patient recovering from a partial nephrectomy, the nurse should note

the placement, status, and drainage from ureteral catheters, stents, nephrostomy tubes, or drains and clearly label each drain. All catheters should not be connected to a single collection device. Catheters should only be irrigated as prescribed. Bright bleeding may indicate a surgical complication and should be reported to the surgeon. Cough suppressant medication is not a routine part of postoperative care of this patient. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

6. **Answer: 3 Rationale:** The most common causes of acute kidney injury are ischemia, sepsis, and exposure to nephrotoxins. The kidney is particularly vulnerable because of the amount of blood that passes through it. A fall in blood pressure or volume can cause ischemia of kidney tissues. Sepsis also produces hemodynamic effects with generalized vasodilation and a fall in GFR. Nephrotoxins in the blood damage renal tissue directly. Administering antihypertensive medications will not prevent the development of acute kidney injury. It is impossible to avoid all potentially nephrotoxic medications. When a nephrotoxic drug or substance must be used, the risk of AKI can be reduced by using the minimum effective dose, maintaining hydration, and eliminating other known nephrotoxins from the medication regimen. Although a history of diabetes or hypertension can increase a patient's risk of developing kidney disease, these health problems are not the most common cause of acute kidney injury in the intensive care unit. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Prior to discharge the patient should have been instructed to avoid nephrotoxic drugs and chemicals for up to 1 year following an episode of acute kidney injury. During recovery, nephrons are vulnerable to damage by nephrotoxins such as NSAIDs, some antibiotics, radiologic contrast media, and heavy metals. Because alcohol can increase the nephrotoxicity of some materials, alcohol ingestion should also be discouraged. A fluid restriction may or may not be applicable for the patient. The patient recovering from acute kidney injury is not retaining urine and will not need to self-catheterize for residual urine. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
8. **Answer: 2, 4 Rationale:** Nursing care for the patient undergoing hemodialysis includes measuring weight and orthostatic blood pressure changes. These data provide baseline information to help evaluate the effects of hemodialysis. The patient who is hypotensive may not tolerate rapid fluid volume changes during dialysis. Monitoring laboratory values helps determine the effectiveness of the treatment and the timing of future dialysis sessions. Restricting fluid and protein intake would affect renal function but not necessarily the hemodialysis treatments. The patient may not have a urine output to assess specific gravity and pH. The extremity with the fistula should not be used for blood pressure assessment. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** The patient's ability to state advantages and disadvantages of renal replacement therapies indicates understanding of treatment options and the ability to make informed decisions on treatment. Patients may be able to live independently or with the assistance of a part-time caregiver. Few patients perform hemodialysis in the home. Hospice care is not identified as a treatment goal for the patient with end-stage renal disease. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 2 Rationale:** Cloudy urine could be a manifestation of an infection. Prompt treatment is vital to preserve integrity of the transplanted organ in an immunosuppressed patient. The nurse needs to do more than record the finding. There is no evidence to support that the urinary catheter needs to be irrigated. Increasing the intravenous fluid rate would necessitate an order from a healthcare provider. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Unit 7 Responses to Altered Urinary Elimination

1. Mrs. Smith is demonstrating signs and symptoms of the early phase of septic shock (tachycardia, hypotension, and mental status changes) and requires fluid resuscitation to fill her dilated vascular beds. The nurse should insert an intravenous access for fluid resuscitation and antibiotic administration after cultures are obtained.
2. **A.** Monitor level of consciousness and urine output.
   Rationale: With kidney trauma, the nursing actions are to monitor for level of consciousness, vital signs, skin color and temperature, and urine output for possible signs of shock. Signs of shock, such as hypotension, tachycardia, tachypnea, cool and pale skin, and altered level of consciousness, may be present. The urine also is observed for presence of hematuria.
3. Mrs. Smith should be taught to drink plenty of fluids and to perform perineal care as needed to keep perineal tissues clean and dry once the confusion has resolved.
4. Mr. Rouse should be taught to drink adequate fluids and to limit foods high in calcium and oxalate.
5. Ms. Baldwin should be taught to limit fluids, and to follow the sodium and protein restrictions prescribed by the primary care provider.
6. **B.** Insert a urinary catheter and drain urine in 500-mL increments.
   Rationale: Draining urine in 500-mL increments may prevent a vasovagal response from draining the bladder too rapidly.
7. The nurse should respond, "The urinary complications you are having may be associated with the lupus. Let's ask the doctor to discuss this with you when she comes in this morning." *Rationale: By acknowledging that the urinary symptoms might be associated with the lupus, the nurse shows honesty. Because the nurse cannot diagnose medical problems, referring the patient to the primary care provider is appropriate.*
8. For each patient, the nursing assistant can obtain vital signs, record intake and output, and provide ADLs, to include assistance with meals particularly for Mrs. Smith due to her confusion.
9. **A.** 20 mL per hour
   Rationale: Urine output of less than 30 mL/hr is a sign of decreased cardiac output and renal perfusion. It needs to be reported to the physician promptly.
10. **D.** macaroni and cheese with stewed tomatoes
    Rationale: Foods high in purines are organ meats, such as liver; those moderate in purines are beef, chicken, and pork. The patient on a low-purine diet needs to decrease eating these types of foods.
11. **C.** Aspirate the urine specimen via the tubing port after thorough disinfection and using a sterile syringe.
    Rationale: Obtain urine specimens from a patient with an indwelling urinary catheter by briefly (15 minutes or less) clamping the proximal drainage tubing, then withdrawing urine directly from the port using sterile technique. Sterile technique is necessary to reduce the risk of catheter-associated UTIs.
12. Quality improvement projects could include (1) daily assessment of continued need for Foley catheter placement and obtaining healthcare provider order to discontinue if no longer necessary; (2) presence of Foley securement devices to prevent pistoning of the catheter on all patients with Foley catheters, and (3) use of condom catheters in lieu of Foley catheters for male patients with urinary incontinence.
13. **B.** microbiology results
    Rationale: Laboratory results would not be initially reported in the nurse's progress notes.
    Culture and sensitivity testing is completed in microbiology. General chemistry focuses on the chemical components (electrolytes, etc.) of the blood serum. Hematology focuses on the differential counts of the constituent blood cells (red blood cells, platelets, white blood cells, etc.)

Chapter 29: Assessing the Cardiovascular and Lymphatic Systems

1. **Answer: 2 Rationale:** Preload is the amount of cardiac muscle fiber tension, or stretch, that exists at the end of diastole, just before contraction of the ventricles. Preload is influenced by venous return and the compliance of the ventricles. It is related to the total volume of blood in the ventricles. Since hemorrhaging decreases the total volume of blood and venous return, the patient's cardiac output will decrease. Hemorrhaging will not increase afterload. Hemorrhaging will not affect cardiac muscle action potential. Hemorrhaging will decrease and not increase the ejection fraction. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 4 Rationale:** Pain intensity is assessed by using a pain rating scale that asks the patient to identify the amount of pain ranging from 0 to 10. Asking if the pain has moved into the left arm is assessing location. Asking if the pain is a pressure, burning, or tightness is assessing the quality and characteristics of the pain. Asking if the pain changes with activity assesses precipitating and aggravating factors. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** The apical impulse is a normal, visible pulsation in the area of the midclavicular line in the left fifth intercostal space. This location corresponds with the apex of the heart. The other anatomic locations would not be applicable when assessing the apical impulse. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
4. **Answer: 1 Rationale:** A heart rate of less than 60 beats/min is bradycardia. A heart rate that exceeds 100 beats per minute is tachycardia. The terms *hypotension* and *hypertension* are used to describe blood pressure. A blood pressure under 90/60 mmHg is considered to be hypotension. Consistent blood pressure readings over 140/90 mmHg in adults under the age of 40 is considered to be hypertension. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
5. **Answer: 1 Rationale:** Oxygen is carried by the hemoglobin molecule on the red blood cell. If this value is low, the patient will not be receiving sufficient oxygen to meet the body's demands. A manifestation of low oxygenation is fatigue. Low red blood cell counts do not cause nausea or a sore throat. Depending on the disease process, a low red blood cell count and subsequent low oxygenation levels could cause chest pain; however, fatigue is the most prominent subjective effect of a low red blood cell count. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
6. **Answer: 2 Rationale:** Platelets release mediators required for clotting. If platelet counts are low, the clotting mechanism will be adversely affected. In the event a tissue injury occurs, the lack of platelets will cause bruising. Low platelet counts are not associated with varicose veins or enlarged lymph nodes. A low platelet count will not affect pulse pressure. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 2, 4 Rationale:** Peripheral vascular resistance is affected by blood viscosity and the length and diameter of arteries and arterioles. Sunken eyeballs indicate dehydration, which could cause the patient's blood to be more viscous. An elevated blood pressure indicates that the diameter and length of the arteries and arterioles are affecting the patient's blood pressure. Joint pain, bowel sounds, and fatigue do not indicate a problem with peripheral vascular resistance. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 1, 2, 3 Rationale:** When assessing the carotid arteries, the nurse should inspect the arteries for pulsations, palpate the arteries for pulse rate, and auscultate the arteries for rhythm and other sounds. The techniques of percussion and deep palpation are not used when assessing the carotid arteries. Cognitive Level: Applying; Nursing Process: Assessment; Health Promotion and Maintenance
9. **Answer: 1 Rationale:** A bruit is a murmur or blowing sound heard over stenosed vessels. A dysrhythmia is an abnormal heart rate or rhythm. A bigeminal pulse is a decrease in pulse amplitude every second beat. A hypokinetic or weak pulse is associated with decreased stroke volume. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 3 Rationale:** This patient is showing signs of arterial disruption including cyanosis, feeling cool to the touch, and the absence of pulses. The blood flow to this limb is insufficient, and the physician needs to be notified immediately. The lack of oxygen to the leg tissues is causing ischemia and limb pain. The nurse needs to do more than document the findings. Relaxation techniques will not be helpful to reduce the pain at this time. Asking how long the limb has been hurting does not address the urgency of the patient's problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 30: Nursing Care of Patients with Coronary Heart Disease

1. **Answer: 1, 5 Rationale:** Modifiable risk factors for the development of coronary artery disease include obesity, smoking, and physical inactivity. Physical activity should not be restricted. The patient can take active steps to modify any identified risk factors. People who do not drink alcohol should not be encouraged to start consuming it as a heart-protective measure. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
2. **Answer: 3 Rationale:** Lovastatin (Mevacor) is a first-line drug for treating hyperlipidemia and can cause myopathy. All patients should be instructed to report muscle pain and weakness or brown urine, which is an indication of muscle breakdown. No particular instruction is required regarding alcohol intake and this medication. This medication can be taken on an empty stomach. No specific dietary fat intake level is indicated for this medication. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** Stable angina is the most common and predictable form of angina. It occurs with a predictable amount of activity or stress and usually occurs when the work of the heart is increased by physical exertion, exposure to cold, or by stress. Stable angina is relieved by rest and nitrates. Electrocardiogram changes are not seen with stable angina. Nocturnal pain is associated with Prinzmetal's angina. Impaired cardiac output is associated with unstable angina. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 4 Rationale:** Acute coronary syndrome is a dynamic state in which coronary blood flow is acutely reduced, but not fully occluded. Myocardial cells are injured by the acute ischemia that results. The most important goal of care is to reestablish tissue perfusion through the use of medication or surgery. The amount by which cardiac output is affected will depend on the number of vessels occluded and the subsequent amount of myocardial ischemia. The diagnoses of *Anxiety* and *Ineffective Health Maintenance* can be addressed after adequate tissue perfusion has been reestablished. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** The cardiac catheter used to insert the stent is usually inserted via the femoral artery, a large, high-pressure vessel. The leg is maintained in extension for a prescribed period after the procedure to reduce the risk of bleeding, hematoma formation, or clot formation at the insertion site. The patient will not have chest tubes after this procedure. Intravenous lines should be continued until the healthcare provider determines they can be discontinued. Chest pain should be reported to the healthcare provider since this could indicate

reocclusion of the coronary vessel. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

6. **Answer: 1, 2, 4, 5 Rationale:** Immediate treatment goals for the patient with an acute myocardial infarction are to reduce chest pain, reduce myocardial damage, decrease cardiac workload, and prevent complications. Blood viscosity is not implicated in the development of an acute myocardial infarction, but plays a role in peripheral vascular resistance. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Fibrinolytic therapy, administered to restore myocardial perfusion, disrupts the clotting cascade and can lead to potentially serious bleeding. Establishing bleeding precautions is vital to preserve physiologic integrity. The diagnosis of *Ineffective Protection* would be the priority for this patient. The diagnoses of *Anxiety*, *Risk for Powerlessness*, and *Ineffective Health Maintenance* can be addressed after myocardial perfusion is restored and the risk of postprocedure bleeding has been reduced. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** Creatine kinase is an important enzyme for cellular function found principally in cardiac and skeletal muscle and the brain. CK levels rise rapidly with damage to these tissues, appearing in the serum 4 to 6 hours after an acute myocardial infarction, peaking within 12 to 24 hours, and then declining over the next 48 to 72 hours. The CK level correlates with the size of the infarction; the greater the amount of infarcted tissue, the higher the serum CK level. AST is a liver enzyme. The hematocrit level and APTT are within normal limits. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Mobitz type II AV block often is associated with a large anterior myocardial infarction and has a high mortality rate. Pacemaker therapy may be necessary to maintain effective ventricular contractions and cardiac output. The nurse needs to do more than record the findings in the patient's chart. The Fowler's position is not going to improve this potentially life-threatening dysrhythmia. Class IB drugs are used primarily to treat ventricular dysrhythmias, including PVCs and ventricular tachycardia. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
10. **Answer: 1 Rationale:** Sinus bradycardia may be well tolerated in some patients and assessment is needed before treating. If decreased mental status and hypotension are present, intravenous atropine may be indicated. Assessment of peripheral pulses and determination of an apical-radial pulse deficit can be done at a later time if necessary. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 31: Nursing Care of Patients with Cardiac Disorders

1. **Answer: 1 Rationale:** Normal ejection fraction is 60%. An ejection fraction of 25% indicates severe impairment of ventricular function. With an ejection fraction of 25%, cardiac output is decreased. Ejection fraction does not measure the amount of blood remaining in the ventricles after systole. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** The main goals for care of heart failure are to slow its progression, reduce cardiac workload, improve cardiac function, and control fluid retention. A weight loss of 1 kg and crackles in the lung bases indicate control of fluid retention. A heart rate of 88 indicates reduced cardiac workload and improved cardiac function. The current treatment regimen is achieving the desired effect for this patient. There are no indications that more aggressive treatment is needed. The patient's condition has improved since admission. Because the patient continues to have crackles in the lungs, failure has not completely resolved. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
3. **Answer: 1, 4, 5 Rationale:** In left ventricular failure, the cardiac output falls and pressure in the pulmonary vascular system increases. Fatigue is a common early manifestation. Pulmonary congestion causes shortness of breath with minimal exertion. On auscultation of the lungs, inspiratory crackles may be heard in the lung bases. Jugular vein distention is a manifestation of right ventricular failure. Chest pain with exercise can be due to angina pectoris or valvular disease. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 2, 4 Rationale:** Calibrating and leveling the system during each shift ensures accuracy and consistency of measurements. To prevent infection, the tubing to the insertion site should be changed every 72 hours. There should be 300 mmHg of pressure on the flush solution at all times to prevent clot formation and catheter occlusion. The intravenous lines should not be secured to the bed linens. This could lead to accidental dislodging. Pressure trends and not individual readings should be monitored. Individual readings may not reflect the patient's true status. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 1 Rationale:** Morphine is administered intravenously to relieve anxiety and improve the efficacy of breathing. It also is a vasodilator that reduces venous return and lowers left atrial pressure. The nurse should provide the medication and monitor the patient's respiratory status. The medication should not be withheld to wait for the patient's respiratory status to improve. The medication order is correct as written and does not need to be questioned. The medication is not being used to treat chest pain. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 4 Rationale:** A pericardial friction rub, a grating sound, is a characteristic sign of pericarditis so it is expected, but should be documented in the patient's record. An electrocardiogram is not needed after auscultating this sound. The patient does not need to be resuscitated. The physician does not need to be notified with this auscultation sound. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 4 Rationale:** Antibiotic therapy effectively treats infective endocarditis in most cases. The goal of therapy is to eradicate the infecting organism from the blood and vegetative lesions in the heart. Since microorganisms may have a fibrin covering that protects them from antibiotic therapy, an extended course of multiple intravenous antibiotics is required. The patient will be fatigued and unlikely able to return to activities within 1 week of treatment. The condition is not benign and self-limiting. Cardiac transplantation is not a form of treatment for this health problem. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
8. **Answer: 4 Rationale:** The murmur of mitral valve stenosis would be heard during diastole when blood is flowing through the stenotic valve from the atrium to the ventricle at the apex of the heart. A cardiac heave and S_3 and S_4 heart sounds are associated with aortic regurgitation. Muffled heart sounds are associated with cardiac tamponade. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Lifetime anticoagulant therapy to prevent clot formation is necessary following insertion of a mechanical valve. Biologic valves are prone to deterioration. Drugs to prevent tissue rejection are not needed after biologic valve replacement surgery. Infections are easier to treat after biologic valve replacement surgery. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
10. **Answer: 4 Rationale:** In hypertrophic cardiomyopathy, manifestations may not develop until the demand for oxygen increases, such as with athletes during activity, causing sudden death due to a ventricular dysrhythmia. Hypertrophic cardiomyopathy is characterized by

decreased compliance of the left ventricle and hypertrophy of the ventricular muscle mass. This impairs ventricular filling, leading to small end-diastolic volumes and low cardiac output. Hypertrophic cardiomyopathy may be asymptomatic for many years. Symptoms typically occur when increased oxygen demand causes increased ventricular contractility. They may develop suddenly during or after physical activity; in children and young adults, sudden cardiac death may be the first sign of the disorder. This type of cardiomyopathy does not lead to ventricle rupture during exercise. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 32: Nursing Care of Patients with Vascular and Lymphatic Disorders

1. **Answer: 2 Rationale:** The early stages of primary hypertension typically are asymptomatic, marked only by elevated blood pressure. Hypertension is defined as systolic blood pressure of 140 mmHg or higher or diastolic pressure of 90 mmHg or higher, based on the average of three or more readings taken on separate occasions. All elevated blood pressure readings should be investigated. Blood pressure elevations are initially transient but eventually become permanent. When symptoms do appear, they are usually vague. Headache, usually in the back of the head and neck, may be present on awakening, subsiding during the day. The patient needs to have the blood pressure rechecked before 3 months. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
2. **Answer: 4 Rationale:** While lasagna made with whole-grain pasta, low-fat cheese, and vegetables or lean meats would be allowed, this answer demonstrates the need for additional teaching. The DASH (Dietary Approaches to Stop Hypertension) diet has proven beneficial effects in lowering blood pressure. This diet focuses on whole foods rather than individual nutrients. It is rich in fruits and vegetables—up to 10 servings per day—and low in total and saturated fats. Four to five servings of nuts are permitted each week. Five servings of low-fat sweets are permitted each week on this diet. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Health Promotion and Maintenance
3. **Answer: 1, 2 Rationale:** Primary adverse effects of angiotensin II receptor blockers are persistent cough and first-dose hypotension. The medication should be taken before meals. Potassium supplements or potassium-based salt substitutes should not be taken with this medication. This medication should be taken as prescribed and not stopped without direction from the healthcare provider. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 1 Rationale:** Manifestations of acute arterial occlusion include cool or cold skin, pain, and pulselessness distal to the blockage. This is an emergency and the healthcare provider should be contacted immediately. Immediate embolectomy is the treatment of choice for acute arterial occlusion by an embolus to prevent tissue necrosis and gangrene. Heparin therapy is initiated to prevent further clot formation. Keeping the extremity lower than the heart promotes collateral blood flow. Even though ischemic tissue is easily damaged by minimal trauma such as shearing by bed linens, this can be done after the healthcare provider is notified of the patient's manifestations. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 4 Rationale:** Percutaneously inserted endovascular splints provide an alternative to surgery for abdominal aortic aneurysms. This reduces the surgical risk and faster recovery for an older patient. Patients with aortic dissection are initially treated with intravenous medication. The risk of surgical repair is higher than the risk that the aneurysm will rupture for the older patient. Opening the abdomen for the surgical procedure increases the risk for postoperative infection. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
6. **Answer: 2 Rationale:** Manifestations of peripheral atherosclerosis include impaired sensation in the affected extremity. The legs are pale when elevated, but often are dark red when dependent. The skin often is thin, shiny, and hairless, with discolored areas. Pulses may be decreased or absent, which means blood pressure in the affected extremity will be lower. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 2, 5, 1, 4, 3 Rationale:** The nurse should first instruct in smoking cessation because nicotine causes vasoconstriction, further decreasing blood flow. Next daily skin inspections are needed to look for breaks in integrity to prevent infections. Third, the patient should be instructed to provide foot care through regular cleansing, wearing cotton socks, and protecting the feet by wearing shoes. Fourth, the patient needs to engage in regular daily exercise to develop collateral circulation. And the last area is weight loss if necessary to keep the patient mobile. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** Anticoagulation generally is continued for at least 3 months. Regular follow-up is necessary to be sure prothrombin times remain within the desirable range for anticoagulation. The patient should use a recliner chair or footstool when sitting to prevent pooling of blood in the extremities. Patients should ambulate as soon as possible and maintain a schedule of regular ambulation and foot and ankle exercises throughout the day. The development of deep venous thrombosis is not because of an elevated cholesterol level. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Elevating the legs and wearing elastic stockings may relieve the discomfort associated with varicose veins. Surgical treatment of varicose veins generally is reserved for patients who are very symptomatic, experience recurrent superficial venous thrombosis, and/or develop stasis ulcers. Surgery will relieve the discomfort associated with varicose veins but may not be indicated for the patient. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 4 Rationale:** Careful skin and foot care is a high priority to prevent skin breakdown and potential infection in the patient with lymphedema. The foot of the bed is raised by 15 to 20 degrees at night to promote lymph flow. Diuretic therapy may be used intermittently when the condition is exacerbated by the menstrual cycle or seasonal variability. Elastic graduated compression stockings may be ordered for use during the day. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 33: Nursing Care of Patients with Hematologic Disorders

1. **Answer: 4 Rationale:** When anemia develops gradually and the RBC reduction is moderate, successful compensatory mechanisms may result in few symptoms except when the oxygen needs of the body increase due to exercise. There is a lack of hemoglobin to carry oxygen to the tissues. Tissue hypoxia may cause dyspnea on exertion. Tachycardia and elevated white blood cell counts might be associated with a specific type of anemia. Hematocrit levels can remain within normal limits with moderate anemia. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 4 Rationale:** During gastric resection, intrinsic factor production may decrease, leading to vitamin B_{12} deficiency anemia with associated neurologic deficits such as numbness and tingling of extremities. Bone pain is associated with anemia caused by a reduction in red blood cell production. Steatorrhea is not a manifestation of anemia. Bronze skin color is a manifestation of thalassemia minor.

Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity

3. **Answer: 2, 3 Rationale:** Prior to bone marrow transplant, chemotherapy or total body irradiation is used to destroy leukemic cells in the bone marrow. Normal blood cells also are destroyed, causing significant risk for infection and bleeding. The diagnoses of *Anxiety*, *Disturbed Body Image*, and *Imbalanced Nutrition* are important, but would not be the highest priority when planning care for the patient receiving a bone marrow transplant. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 1, 2, 4 Rationale:** AML causes both neutropenia and thrombocytopenia, with resulting increased risk for infection and bleeding. A private room and oral hygiene help reduce infection risk, and a soft, bland diet reduces trauma to oral mucosal membranes. Invasive procedures such as rectal temperatures should not be assessed because of the risk for bleeding. The patient does not need to be in airborne infection control precautions; however, individuals with respiratory illnesses should be restricted. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** The nurse should assess the patient's perception of body image through subjective information such as what the patient likes most and least about his body, preillness perception of people who are sick or have a disability, current understanding of health and limitations imposed by illness or treatment, and feelings about the illness and its effect on perception of self and others. The patient's comment may not be related to hair loss. The nurse should not instill false hope by telling the patient not to worry. The nurse has no way of knowing if the patient's comment is related to the inability to have children. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
6. **Answer: 1 Rationale:** Multiple-drug chemotherapy regimens are effective at different phases of the cell cycle, allowing lower doses of individual drugs to decrease adverse effects and produce more effective tumor destruction. This regimen is not used to target malignant cells in different organs. These medications will not prevent the development of adverse effects. The CHOP regimen is not used to support growth and development of normal cells. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Pathologic fractures are a common and reoccurring problem with multiple myeloma. A new onset of severe pain may signal a pathologic fracture and needs to be reported. A back brace might be indicated; however, the new onset of pain needs to be reported and investigated first. Reassuring the patient that bone pain is an expectation of the disease process is not appropriate. The pain is new and should be reported. Knowing what medications the patient uses for pain control is important, but the onset of new pain should be reported. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 4 Rationale:** A platelet count of 60,000/mm^3 is significantly low (normal 150,000 to 450,000/mm^3), which increases the patient's risk of bleeding and bruising with minor trauma. More information is needed to determine if the INR of 4.0 is significant for this patient. A medication history and previous health history are required. A hematocrit of 28% would not cause bruising. A white blood cell count of 4,500/mm^3 is below normal, which increases the patient's risk for infection and not bleeding. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** Hemophilia A, the most common form, occurs in about 1 in 10,000 male births and is transmitted on the X chromosome: Each male offspring has a 50% risk of inheriting the defective gene. Each female offspring has a 50% risk of becoming a carrier. Von Willebrand's disease affects about 1 in 100 to 500 people, usually inherited as an autosomal dominant trait. Offspring of an affected person have a 50% risk of inheriting the trait and the disorder. It is unknown if the husband has this type of hemophilia. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** When bleeding is the major manifestation of DIC, platelet concentrates are given to restore clotting factors and platelets. An infusion of platelets does not replace specific clotting factors. The infusion of platelets is not used to restore tissue oxygenation. The patient is experiencing intravascular clotting and medications will be used to prevent further clot formation. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity

Unit 8 Responses to Altered Cardiovascular Function

1. Mr. Markus and Mrs. Williams need partial assistance with their ADLs to avoid excessive increases in heart rate. Mr. Jacoby needs total assistance with ADLs since he is febrile and hypermetabolic. Additional oxygen may be needed. He also has demonstrated signs of bruising, which suggests he has a coagulopathy so safety measures are a priority to prevent injury (e.g., careful repositioning). Mrs. Cartwright is receiving anticoagulation therapy so safety is also a consideration for her. Mrs. Cartwright should make sure she wears footwear when out of bed and avoids use of a regular razor. The nurse should make sure that both Mr. Jacoby and Mrs. Cartwright's intravenous catheters are taped securely to avoid disconnection.
2.
   - **A. Scott Jacoby should be seen first.** *Rationale: Mr. Jacoby needs to be ready for the bone marrow biopsy this morning. The degree of his mental abilities is unclear. The patient with Down syndrome often needs simple instruction and reassurance.*
   - **B. Arnold Markus should be seen second.** *Rationale: Mr. Markus has started having isolated PVCs and crackles in the lower lobes of the lungs. These signs can indicate a worsening of the CHF, which needs to be evaluated.*
   - **C. Theresa Cartwright can be seen third.** *Rationale: Mrs. Cartwright can summon help if needed. Treatment has been initiated, but the heparin IV must be monitored.*
   - **D. Betty Williams should be seen last.** *Rationale: Mrs. Williams's vital signs and heart rhythm are stable.*
3. Mrs. Williams should be taught to manage her type 2 diabetes, to stop smoking, and to control her hypertension. She should be given the resources (professional resources and support groups) she needs. She should be encouraged to eat a healthy diet and engage in exercise as recommended by her healthcare provider.
4. **C.** oxygen saturation
   Rationale: While fluid in the lungs will alter lung sounds, oxygen saturation levels indicate the ability of the lungs to function and the heart to circulate the blood.
5. **A.** Obtain a full symptom assessment.
   Rationale: Assessment should be completed before initiating interventions. A full symptom assessment should be completed before administering the prescribed nitroglycerine tablet.
6. **B.** fever and burning on urination
   Rationale: Fever and burning on urination would indicate a urinary tract infection. Mr. Jacoby is at risk for infection, so these symptoms are significant.
7. **A.** prothrombin time (PT)
   E. International Normalized Ratio (INR)
   Rationale: Prothrombin time (PT) and International Normalized Ratio (INR) are monitored to determine the dosage levels of warfarin therapy.
8. **C.** "I cannot continue to take birth control pills while I am taking these drugs."
   Rationale: Mrs. Cartwright needs to continue to take birth control pills to prevent pregnancy, because Coumadin is a teratogenic drug.

9. You should explain that her heart has been weakened by the heart attack, but with time it can heal and strengthen. It will be important for her to follow the doctor's instructions.
10.
    A. **Mrs. Williams:** The nursing assistant can obtain vital signs and assist with a bed bath unless the doctor has ordered a warm shower. Blood glucose values will also need to be obtained for Mrs. Williams.
    B. **Mr. Markus:** The nursing assistant can obtain vital signs and assist with a warm shower and ambulation.
    C. **Mrs. Cartwright:** The nursing assistant can obtain vital signs. Since Mrs. Cartwright will be on bed rest, she will need assistance with all ADLs.
    D. **Mr. Jacoby:** The nursing assistant can obtain vital signs, assist with ADLs, and assist with preparation for bone marrow biopsy. The nursing assistant may accompany the patient to the procedure if support is needed.
11. **B.** enalapril
    Rationale: ACE inhibitors such as enalapril interrupt the conversion of angiotensin I to angiotensin II. Angiotensin II causes intense vasoconstriction, increasing afterload and ventricular wall stress and increasing preload and ventricular dilation. It also stimulates aldosterone and ADH production, causing fluid retention. ACE inhibitors block this RAAS activity, decreasing cardiac work and increasing cardiac output. ACE inhibitors reduce the progression and manifestations of heart failure, resulting in fewer hospital admissions. The remaining medications are not part of standard treatment for heart failure itself, although the patient may receive aspirin, usually 81 mg daily, if associated with underlying coronary artery disease.
12. **B.** on admission to the healthcare facility
    Rationale: Cardiac rehabilitation begins with admission to the healthcare facility and continues through the inpatient stay and after discharge into the rehabilitative period.
13. **B.** Maintains the infusion on an intravenous "smart" pump.
    Rationale: A medication infusion pump is a safety-enhancing technology that helps to prevent human error through miscalculation of dosage. Gravity infusion could lead to an unsafe situation by too slow or too rapid infusion of the heparin. PTT, not PT, is an evaluation of a continuous heparin infusion's effectiveness. Amount of infused heparin should be calculated into the total intake but this is not the activity that is most focused on safety.
14. The nurse manager can complete a retrospective chart review to determine if patient education occurred during previous admissions. With the retrospective review regarding patient education, the nurse manager can determine if the patient received education on the following topics: fluid restriction, sodium restriction, medication compliance, and weight monitoring. The nurse manager can also interview the readmitted patients to identify if specific areas of noncompliance with any of the above could have contributed to readmission.
15. **C.** flow sheet
    Rationale: Progress notes are used to document patient responses to interventions, significant communication, etc. Laboratory results are limited to testing completed by medical technology laboratories. The flow sheet is the repository for real-time documentation of vital signs and other related signs such as pulse oximetry, etc. Diagnostic tests are reserved for testing conducted to assess specific clinical questions. For this population, the ECG report would be recorded in this section.

Chapter 34: Assessing the Respiratory System

1. **Answer: 2 Rationale:** The apex of each lung lies just below the clavicle. The base of each lung rests on the diaphragm. The hilus, on the mediastinal surface of each lung, is where blood vessels of the pulmonary and circulatory systems and the primary bronchus enter and exit the lungs. The parietal pleura line the thoracic wall and mediastinum. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
2. **Answer: 3 Rationale:** A familial history of lung cancer increases the risk of developing lung cancer, and small-cell lung cancer has a definite genetic component. Childhood obesity, family history of asthma, and frequent upper respiratory infections do not increase the risk of developing lung cancer. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
3. **Answer: 2 Rationale:** Bronchovesicular breath sounds are normal. The nurse should measure and record the vital signs as usual. The physician does not need to be notified of normal breath sounds. A respiratory treatment is not required. The nurse has not assessed breath sounds yet, so documenting the inability to hear the sounds would be incorrect data. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
4. **Answer: 4 Rationale:** The organic chemical 2,3-DPG is formed in red blood cells and increases the release of oxygen from hemoglobin by binding to it during times of increased metabolism such as when body temperature increases. This binding alters the structure of hemoglobin to facilitate oxygen unloading. The increase in body temperature does not decrease respiratory rate or increase lung compliance. Oxygen unloading is enhanced and not inhibited. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 1, 2, 3 Rationale:** A thoracentesis is done to obtain a specimen of pleural fluid for diagnosis, to remove excess pleural fluid, or instill medication. A large-bore needle is inserted through the chest wall and into the pleural space. Following the procedure, a chest x-ray is taken to check for a pneumothorax. General anesthesia is not required for the procedure. Strict bed rest is not required for 2 hours after the procedure. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 3 Rationale:** A health assessment interview to determine problems with respiratory structure and function may be conducted during a health screening, may focus on a chief complaint, or may be part of a total health assessment. If the patient has a problem with respiratory function, analyze its onset, characteristics, course, severity, precipitating and relieving factors, and any associated symptoms, noting the timing and circumstances. Amount of exercise each day does not focus on respiratory problems. Children's breathing or family member's health history does not provide information about the patient's health status or potential problems. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Wheezes are continuous musical sounds heard in the chest. Crackles are short, discrete, crackling or bubbling sounds. A friction rub is a loud, dry, creaking sound. Murmurs are not typically heard during the assessment of breath sounds. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 1 Rationale:** Breath sounds are absent over collapsed lung, surgical removal of lung, pleural effusion, and primary bronchus obstruction. The patient had a lung removed, which means breath sounds are absent because without air movement no sound would be generated. There are no other reasons in the patient's health history that would cause absent breath sounds. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2, 4 Rationale:** When assessing breath sounds the nurse should direct the patient to take slow deep breaths through an opened mouth. Holding the breath will not create any sounds. Breathing through the nose will not amplify the breath sounds. Repeating the number 99 assesses for lung consolidation, which may be done after

the breath sounds assessment is complete. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

10. **Answer: 1 Rationale:** Decreased diaphragmatic movement on the left side should be documented. This is an expected outcome with pneumothorax on the left since air movement and diaphragm movement would be decreased. The physician does not need to be notified with this finding. The assessment does not need to be repeated. Having the patient hold his or her breath is not going to change the finding. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

Chapter 35: Nursing Care of Patients with Upper Respiratory Disorders

1. **Answer: 3 Rationale:** Over-the-counter topical nasal sprays are effective to relieve URI manifestations, but because the patient has mild hypertension, the patient should discuss the use of this preparation with the healthcare provider before using. Antibiotics are not indicated for an acute URI. The use of vitamin C and zinc lozenges may not relieve the patient's symptoms. An over-the-counter decongestant may be contraindicated in the patient with hypertension and should not be recommended to this patient. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Older adults have a high incidence of complications such as pneumonia when exposed to influenza. Preventing influenza by immunizing at-risk populations is an important aspect of care. Annual immunization for influenza is recommended for all at-risk patients, including older patients and residents of nursing homes. Avoiding crowds and using effective hand hygiene will help reduce the spread of microorganisms; however, an annual influenza vaccination is the best defense against contracting the health problem. Scheduling exercise programs indoors during the winter months will not reduce the risk of influenza and pneumonia in the older adult. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
3. **Answer: 2 Rationale:** The nurse should focus on the importance of completing the entire course of prescribed antibiotics to achieve cure and prevent the development of antibiotic-resistant bacteria. A humidifier might be helpful to loosen secretions. The head of the bed should be adjusted for respiratory comfort. A liberal fluid intake will thin secretions; however, this approach is not the most important when instructing a patient on the care of a bacterial sinus infection. Cognitive Level: Applying; Nursing Process: Implementing; Client Need: Physiological Integrity
4. **Answer: 1 Rationale:** Posterior nasal packing is very uncomfortable, and can cause respiratory complications. Hypoxemia is common and supplementary oxygen is required. Although elevating the head of the bed facilitates ventilation, supplemental oxygen is the priority. Frequent oral hygiene would be required; however, supplemental oxygen is the priority. A cold compress decreases pain and promotes vasoconstriction, which will decrease bleeding and swelling but will not help with oxygenation. Supplemental oxygen is the priority for this patient. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** Fractures of other facial bones may accompany a broken nose, particularly when facial trauma is severe. Fractures in the nasoethmoidal or frontal region can disrupt the dura, causing CSF leakage or rhinorrhea. CSF rhinorrhea is suspected when watery nasal drainage tests positive for glucose. The nurse needs to do more than provide a box of tissues. Suctioning the nasopharynx would be contraindicated in the patient with facial trauma. Watery drainage is not expected after a nasal fracture. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 1, 2, 3, 4 Rationale:** The manifestations of sleep apnea include loud, cyclic snoring, hypertension, morning headache, and daytime fatigue and sleepiness. Decreased oxygen saturation while awake is not a manifestation of obstructive sleep apnea. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** Hoarseness and a breathy voice quality are manifestations of benign vocal cord tumors. The usual symptom of glottic cancer is hoarseness or a change in the voice because the tumor prevents complete closure of the vocal cords during speech. The most appropriate question would be for the nurse to ask how long the patient has been hoarse. Depending on the patient's response, asking about smoking or a sore throat might be appropriate. The nurse needs to assess the patient before suggesting treatment with throat lozenges. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** Radiation therapy is often the treatment of choice for early laryngeal cancer and is extremely effective for treating glottic cancer, with cure rates equal to those achieved by surgery. Radiation therapy preserves the voice, although the tone or timber of the voice may be affected. This cancer does metastasize to other areas. Stage 1 laryngeal cancer does need to be treated. The patient will not lose the ability to speak. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
9. **Answer: 2, 3, 1, 4, 5 Rationale:** Maintaining airway patency is of highest priority. The head may need additional support because of the removal of neck muscles. Frequent, small meals help meet metabolic needs; swallowing may be difficult and the effort may produce fatigue. Regaining speech will require practice and assistance from a speech therapist. Loss of the voice will result in grieving; encouraging expression of feelings can facilitate gradual acceptance of the loss. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 2 Rationale:** When providing tracheostomy care, the nurse should secure the clean ties before removing soiled ones to prevent accidental dislodgement of the tube. Precut gauze should be used for the dressing. The tracheostomy is cleaned following sterile technique. Normal saline and hydrogen peroxide are used to cleanse the incision. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 36: Nursing Care of Patients with Ventilation Disorders

1. **Answer: 3 Rationale:** Adequate oxygenation is a priority for all patients. The nurse should apply the prescribed amount of oxygen to the patient first. The sputum specimen should be obtained before beginning the prescribed antibiotic. The meal tray would be of the least priority. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 1, 3, 4, 2, 5 Rationale:** Overall gray skin color and bluish tinge to lips indicate hypoxemia; supplemental oxygen is highest priority. Second, raise the head of the bed to promote chest expansion and alveolar ventilation. Assessment of oxygen saturation and breath sounds can be completed next. The physician should be contacted after the patient is receiving oxygen and assessments are completed. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** A 9-mm area of induration is a positive tuberculosis test result in a patient with HIV disease. Being an intravenous drug user, born in Southeast Asia, and residing in a long-term care facility are not criteria for a positive tuberculosis test with a 9-mm area of induration. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity

4. **Answer: 3 Rationale:** When teaching a patient who is taking INH, the nurse needs to include information on adverse effects such as numbness and tingling of extremities and how these effects need to be reported to the physician. Rifampin may cause an orange-red coloration of saliva and urine. Ethambutol may affect red-green color discrimination and visual acuity. Periodic eye examinations are recommended. Aspirin may interfere with rifampin absorption and should not be taken concurrently. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
5. **Answer: 2 Rationale:** Smoking cessation is important with the diagnosis of lung cancer to prevent further damage from the chemicals in the cigarettes. Most people with lung cancer die within 1 year of the initial diagnosis. Successful treatment of lung cancer after the disease has spread is grim. The patient planning to do nothing but sit in an easy chair and wait to die indicates that teaching has not been effective. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
6. **Answer: 1, 3 Rationale:** Chest tube drainage that is red, free flowing, and exceeds 70 mL/h indicates hemorrhage and must be reported. Vital signs and level of consciousness are measured to evaluate cardiac output and hemodynamic stability. The drainage should not be emptied and pressure should not be applied to the chest tube insertion site. The nurse needs to notify the surgeon now and not wait for 30 minutes to reevaluate the patient's drainage. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** The patient having a thoracentesis needs to sit upright, leaning forward during the procedure to spread the rib cage for easier placement of the needle. The patient should not cough as fluid is withdrawn. The patient does not need to breathe deeply when the needle is inserted. The patient only needs to remain positioned on the unaffected side for 1 hour after the procedure to allow the pleural puncture to heal. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 1 Rationale:** A patient with a fractured rib should be urged to use a small pillow to splint the area when coughing to reduce the movement of rib cage and pain. Providing adequate analgesia to promote breathing, coughing, and movement is the primary intervention. Bed rest is not required with a rib fracture. Rib belts, binders, and taping to stabilize the rib cage are not recommended, because they may interfere with ventilation and lead to atelectasis. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 1 Rationale:** A respiratory rate of 36 indicates respiratory distress and is of greatest concern. Adventitious lung sounds like crackles can occur after an inhalation injury. Ash-like material in the sputum is expected after an inhalation injury. Pink mucous membranes and skin indicate adequate oxygenation. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
10. **Answer: 3 Rationale:** Maintaining or restoring adequate alveolar ventilation and gas exchange is of highest priority for the patient with a pneumothorax. Loss of negative pressure in the pleural cavity and the resulting collapse of lung tissue can cause poor chest expansion and loss of alveolar ventilation. *Acute Pain*, *Risk for Aspiration*, and *Ineffective Breathing Pattern* are not priority diagnoses for this patient. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity

Chapter 37: Nursing Care of Patients with Gas Exchange Disorders

1. **Answer: 3 Rationale:** *Ineffective Airway Clearance* is the highest priority. Bronchospasm and bronchoconstriction, increased mucous secretion, and airway edema narrow the airways and impair airflow during an acute attack of asthma. Both inspiratory and expiratory volumes are affected, decreasing the oxygen available at the alveolus for the process of respiration. Narrowed air passages increase the work of breathing, increasing the metabolic rate and tissue demand for oxygen. The diagnoses that address anxiety, ineffective breathing pattern, and ineffective health maintenance are important and can be focused on after the patient's ineffective airway clearance is addressed. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Respiratory status can change rapidly during an acute asthma attack and its treatment. Slowed, shallow respirations with significantly diminished breath sounds and decreased wheezing may indicate exhaustion and impending respiratory failure. Immediate intervention is necessary so the healthcare provider needs to be notified. The healthcare provider might prescribe a chest x-ray. Asking the family members to leave is not a priority. Allowing the patient to rest undisturbed could eventually lead to respiratory arrest. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** The anti-inflammatory effect of corticosteroids helps both prevent and treat acute episodes. Corticosteroids are used to reduce the frequency and severity of asthma attacks and allow reduced dosages of other drugs. These medications decrease the synthesis and release of inflammatory mediators, reduce inflammatory cell activation and infiltration, decrease airway edema, decrease mucous production in the airways, and increase the number and receptivity of $beta_2$ receptors. Press and hold the canister down while inhaling deeply and slowly for 3 to 5 seconds. Then hold the breath for 10 seconds, release pressure on the container, remove from the mouth, and exhale. Wait 20 to 30 seconds before repeating the procedure for a second puff. Administer anti-inflammatory inhaler doses after bronchodilators to facilitate transit of the medication to distal airways. Rinse the mouth after using the inhaler to reduce the risk of fungal infections. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 4 Rationale:** In the patient with chronic obstructive airway disease, air trapping and hyperinflation increase the anterior-posterior chest diameter, causing barrel chest. Mental confusion, oxygen saturation levels below 85%, and 3+ pitting edema of the ankles and lower legs are not expected assessment findings and should be reported to the healthcare provider. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1 Rationale:** During an acute exacerbation of COPD, keeping the SaO_2 above 90% is an appropriate goal. Lung function that has been lost from chronic obstructive pulmonary disease cannot be regained. Arterial blood gases will not be normal because the patient's oxygen and carbon dioxide levels are altered due to lung changes. The nurse should help the patient develop a smoking cessation plan to preserve remaining lung functioning. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
6. **Answer: 3 Rationale:** Administering oxygen to patients with chronic elevated carbon dioxide levels in the blood can actually increase the $PaCO_2$, leading to increased somnolence and even respiratory failure. Close monitoring of level of consciousness and arterial blood gases during oxygen therapy is vital. Long-term oxygen therapy is used for severe and progressive hypoxemia. It also reduces the rate of hospitalization and increases length of survival. Oxygen may be used intermittently, at night, or continuously. For severely hypoxemic patients, the greatest benefit is seen with continuous oxygen. The patient with chronic obstructive pulmonary disease should be working on a smoking cessation plan. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
7. **Answer: 1, 3, 4, 5 Rationale:** Thick, tenacious, milky white sputum and fever indicate possible infection. Difficulty coughing up mucus

and increased shortness of breath and fatigue indicate potential early manifestations of respiratory failure. Steatorrhea causing frequent, bulky, foul-smelling stools is a common manifestation as a result of associated pancreatic insufficiency. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

8. **Answer: 2, 3, 5 Rationale:** These manifestations may indicate pulmonary embolism. Oxygen should be administered to support gas exchange and tissue oxygenation. The high-Fowler's position facilitates oxygenation. Auscultating heart sounds can help detect cardiac compromise. Checking for Homans' sign would not be beneficial at this time. Pain medication should not be provided until a pain assessment is completed. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** The manifestations of respiratory failure are caused by hypoxemia and hypercapnia, as well as the underlying disease process. Dyspnea and headache are early signs. Hypoxemia causes dyspnea and neurologic symptoms such as restlessness, apprehension, impaired judgment, and motor impairment. Tachycardia and hypertension develop as the cardiac output increases in an effort to bring more oxygen to the tissues. As hypoxemia progresses, dysrhythmias, hypotension, and decreased cardiac output may develop. Increased carbon dioxide levels depress CNS function and cause vasodilation. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
10. **Answer: 4 Rationale:** A patent airway is necessary to maintain effective alveolar ventilation and gas exchange. Endotracheal suctioning as needed will ensure a patent airway for the patient. The supine position will not ensure effective alveolar ventilation. Providing oxygen as prescribed will not ensure effective alveolar ventilation. Increasing the tidal volume on the ventilator could cause lung tissue trauma. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Unit 9 Responses to Altered Respiratory Function

1. Thromboemboli, or blood clots, that develop in the venous system (deep venous thrombosis or DVT), as in the case of Ms. Sawyer, are the most frequent cause of pulmonary embolism. Ms. Sawyer is exhibiting some of the following common clinical manifestations of pulmonary embolism: dyspnea and shortness of breath, chest pain, anxiety and apprehension, cough, tachycardia and tachypnea, crackles, and low-grade fever.
2.
   A. **Mr. Mohr should be seen first.** *Rationale: Mr. Mohr has been coughing and may be unable to clear his airway. Immediate suctioning is needed to clear the airway.*
   B. **Ms. Sawyer should be seen second.** *Rationale: Ms. Sawyer could be having a pulmonary embolism, which can be life threatening.*
   C. **Mr. Holt should be seen third.** *Rationale: Mr. Holt's vital signs are elevated and he is experiencing pain with breathing. He may need medication for pain.*
   D. **Ms. Campbell should be seen last.** *Rationale: Although Ms. Campbell is wheezing, her vital signs and oxygen saturation level appear the most stable.*
3. Patients with COPD should be taught to consume more concentrated sources of high-energy foods to maintain caloric intake without promoting excess fatigue. A diet high in proteins and fats without excess carbohydrates is recommended to minimize carbon dioxide production during metabolism (carbohydrates are metabolized to form CO_2 and water).
4. Allow family members or significant others to remain with the patient while maintaining a quiet environment. Assist with guided imagery, relaxation techniques, and gentle massage, and administer medication as needed.
5. **C.** Wear a mask and gloves when suctioning the patient.
   Rationale: Wearing a mask is a standard precaution for a patient with a droplet infection.
6. **B.** right Sims' position with head in Trendelenburg
   Rationale: The patient is positioned with the area to be drained above the trachea or mainstem bronchus. Head down allows gravity to facilitate drainage of secretions.
7. "Chronic asthma is a lifelong disease, but with treatment it can be controlled. Most patients lead a very productive life."
8.
   A. **Jack Holt:** The nursing assistant can obtain vital signs and oxygen saturation, and assist with ADLs. Frequent oral care, disposing of contaminated tissues, and supplying clean ones are needed.
   B. **Maggie Sawyer:** The nursing assistant can obtain vital signs and oxygen saturation, assist with ADLs, assist with setup of oxygen, and stay with the patient in case further assistance is needed.
   C. **James Mohr:** The nursing assistant can obtain vital signs and oxygen saturation, and assist with ADLs. He or she should call the RN immediately if the patient coughs productively and indicates the airway is becoming blocked.
   D. **Amy Campbell:** The nursing assistant can obtain vital signs and oxygen saturation, and assist with ADLs. He or she should notify the RN immediately if the patient develops severe respiratory distress. Adjusting the oxygen is not a nursing assistant function.
9. **B.** Ms. Sawyer: pH 7.22; pO_2 50 mmHg; pCO_2 58 mmHg; HCO_3 29 mEq/L
   Rationale: The ABG results are reflective of partially compensated respiratory acidosis. Although respiratory acidosis is expected in COPD patients, the greatest concern is due to Ms. Sawyer's pCO_2 of 58 mmHg. Therefore, the healthcare provider should be promptly notified. The remaining patients have no acid–base or slight acid–base disturbance and no oxygenation issues.
10. **D.** Stop every 1 to 2 hours to stretch legs when traveling.
    Rationale: Stretching the legs and walking every 1 to 2 hours when traveling will reduce the risk of pulmonary embolism. Hose that bind around the knee and use of pillows can contribute to deep venous thrombus formation and subsequently pulmonary embolism.
11. **C.** Showering is allowed as long as the tracheostomy is covered with a washcloth.
    Rationale: Showering and bathing are allowed as long as the tracheostomy is protected from the flow of water.
12. **C.** Replace the defective device immediately.
    Rationale: Because the alarm is not functioning, it will not alert the nurse if the patient has deterioration in oxygenation status. As a result, the device requires immediate replacement. Although the biomedical department may need to be notified, the patient's safety is the priority.
13. Each new admission should be screened for the following: Did the patient receive the seasonal influenza vaccine? Has the patient previously been vaccinated with the pneumococcal vaccine? Does the patient meet the recommendations for the vaccine (people over age 65; those with chronic cardiac or respiratory conditions, diabetes mellitus, alcoholism, or other chronic diseases; and those who are immunocompromised)? Immunization should be provided to those meeting criteria for both vaccines, and admissions for pneumonias should then be reevaluated.
14. **A.** bar coding for use at medication administration
    C. electronic medication compatibility at order entry
    D. availability of printable patient teaching information regarding medications
    Rationale: The electronic medical record (EMR) will preclude use of paper-based medication administration records while using multiple technologies such as bar coding for correct medication, correct patient verification, compatibility verification, and printable patient education

materials that can be delivered to the patient during medication education.

Chapter 38: Assessing the Musculoskeletal System

1. **Answer: 2 Rationale:** Long bones have a midportion, or shaft, called a diaphysis, and two broad ends, called epiphyses. Flat bones are thin and flat, and most are curved. Short bones, also called cuboid bones, include the bones of the wrist and ankle. Irregular bones are of various shapes and sizes. Irregular bones include the vertebrae, the scapulae, and the bones of the pelvic girdle. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 3 Rationale:** Abduction is the term for moving an extremity away from the midline of the body. Flexion is bending a limb at the joint. Extension is straightening a limb at the joint. Adduction is moving a limb toward the midline of the body. Cognitive Level: Applying; Nursing Process: Assessing; Client Need: Health Promotion and Maintenance
3. **Answer: 4 Rationale:** Uric acid levels are used to diagnose and monitor the treatment of gout. Uric acid level has no relationship to bruising. A uric acid level is not used to diagnose rheumatoid arthritis. Asking about a family history of muscle or bone disease is not related to the uric acid level. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 1, 2, 4, 5 Rationale:** Age-related changes in the musculoskeletal system include decreased muscle mass and strength, reduced range of motion of joints because of a loss of elasticity of ligaments and tendons, and decreased height because of decreased bone mass, decreased calcium absorption, and thinning of intervertebral disks. Edema of the ankles, hips, and knees is not an age-related change of the musculoskeletal system. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
5. **Answer: 1, 2, 5 Rationale:** In preparation for an electromyogram, the nurse should instruct the patient to avoid drinking fluids containing caffeine for 3 hours before the test, avoid smoking for 3 hours before the test, and to avoid taking medications such as muscle relaxants. Avoiding oral hypoglycemic agents before the test and alerting the healthcare provider with an allergy to shellfish would be appropriate if the patient were having a diagnostic test using contrast dye. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 2 Rationale:** When assessing facial muscle strength, the nurse would ask the patient to stick out the tongue. Closing the eyes tightly assesses ocular muscles and lids. Clenching the teeth assesses jaw muscles. Bending the head forward assesses neck muscles. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
7. **Answer: 4 Rationale:** Crepitation is a grating sound as the joint moves. Crackles are sounds created by fluid or mucus in the lungs. Arthritis is a health problem that can cause crepitation. Synovitis is inflammation of the synovial membrane lining the articular capsule of a joint. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment
8. **Answer: 1 Rationale:** The ballottement test is used to assess for fluid in the knee joint. A positive ballottement test does not indicate an elbow deformity. This test is not used to assess for crepitus. Ballottement is not used to assess for a metatarsal infection. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** Scoliosis is the term used to describe a lateral curve in the spine. Lordosis is an increased lumbar curve. Kyphosis is an exaggerated thoracic curvature of the spine. Musculosis is a fictitious health problem. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** The primary manifestations of altered musculoskeletal function are pain and limited mobility. Pallor is associated with decreased blood flow. Decreased range of motion would be limited mobility. Cyanosis and decreased pulses indicate a problem with blood flow. Swelling and exaggerated reflexes could indicate a pathologic process. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

Chapter 39: Nursing Care of Patients with Musculoskeletal Trauma

1. **Answer: 4 Rationale:** Ice used on a sprained ankle immediately after injury will cause vasoconstriction of the blood vessels to decrease edema and pain. Ice is not used to increase white blood cells or lower the blood pressure or pulse. Heat increases the diameter of blood vessels. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** A compound fracture means bone has broken the skin, which is the first line of defense against bacterial invasion. An open fracture allows bacteria to enter the injured area and increases the risk of complications. The patient most likely will not be at risk for falls during the immediate postoperative period. *Impaired Transfer Ability* will be applicable as the patient resumes mobility. *Risk for Post-Trauma Syndrome* depends on the cause of the injury. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Pale, cold fingers in a patient with a cast could indicate decreased circulation to the hand. This finding needs to be investigated since the cast could be too tight or compartment syndrome could be developing. The fingers will be slightly edematous after an arm fracture occurs. Warm pink skin indicates adequate blood flow to the area. A pain rating of 2 on a scale from 0 to 10 indicates pain is being adequately controlled. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** After a fracture and during bone healing, osteoblasts continue to form collagen fibers and bone matrix, which are gradually mineralized with calcium and mineral salts. Sodium, potassium, and magnesium are not identified as minerals needed for bone healing. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 2, 3, 4, 5 Rationale:** Pain and normal or decreased pulses are early signs of compartment syndrome. This is what was documented as occurring on the previous shift. Now the patient is experiencing later manifestations of compartment syndrome, which include weakness, cyanosis, tingling, and severe pain with passive flexion. Fever is not a manifestation of compartment syndrome. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 3 Rationale:** The tail of the clot or the entire thrombus may dislodge and become an embolus, ultimately lodging in the pulmonary circulation (a pulmonary embolism). Patients with deep venous thrombosis of the lower extremity require careful monitoring of the respiratory system for manifestations of emboli. Deep venous thrombosis does not typically affect the renal, digestive, or hematologic systems. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 1 Rationale:** Patients who have suffered musculoskeletal injuries have soft tissue damage, muscle spasm, and swelling, causing acute pain. Chronic pain is pain that persists longer than 6 months. This pain is not usually associated with a traumatic musculoskeletal injury. The risk for infection is higher in patients who have sustained a fracture where the bone has broken through the skin surface. Not all musculoskeletal injuries cause body image changes. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
8. **Answer: 1, 2, 3, 5 Rationale:** The patient with a below-the-knee amputation should elevate the stump, keeping the knee extended. A knee immobilizer may be used to help maintain joint extension. All

joints should receive either active or passive ROM exercises every 2 to 4 hours. The patient with an above-the-knee amputation should not sit for prolonged periods of time because this can lead to hip contracture. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity

9. **Answer: 4 Rationale:** Phantom limb sensation is the sensation of tingling, numbness, cramping, or itching in the phantom foot or hand early in the postoperative period. It is often self-limited. A contracture is an abnormal flexion and fixation of a joint caused by muscle atrophy and shortening. Chronic stump pain is the result of neuroma formation, causing severe burning pain. The patient's pain is real and should not be viewed as attention seeking. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 3 Rationale:** After a traumatic amputation of a digit, the nurse should instruct those present to wrap the amputated part in a clean cloth, place in a plastic bag, and put the bag on ice. Do not let the amputated part come into direct contact with the ice or water. This will preserve the amputated finger so that it can be surgically reattached. The person does need to be transported to the hospital but the amputated digit needs to be addressed. Warm water should not be used to preserve an amputated digit. The digit should not be taped to the hand. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Safe and Effective Care Environment

Chapter 40: Nursing Care of Patients with Musculoskeletal Disorders

1. **Answer: 1, 2, 3, 4 Rationale:** The nurse should teach the patient taking alendronate (Fosamax) to take the medication with clear water only. The patient should avoid lying down for 30 to 60 minutes after taking the drug to prevent esophageal irritation. No food or fluids should be consumed for 30 minutes after taking the drug so as to not interfere with the drug's absorption. Calcium and vitamin D supplements are to be taken as prescribed. Tingling around the mouth or numbness and tingling of the fingers and toes could indicate an electrolyte imbalance and should be reported to the healthcare provider. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
2. **Answer: 2, 5 Rationale:** The pain of OA often can be managed through the use of mild analgesics such as acetaminophen or over-the-counter NSAIDs such as ibuprofen. Intra-articular hyaluronic acid (HA) is an option for patients with OA of the knee joint. HA is a component of synovial fluid; it also appears to have anti-inflammatory effects. It is given in a series of three or five weekly intra-articular injections, and may be effective for as long as 6 months following completion of the series. An opioid analgesic may be necessary for patients with advanced OA and moderate to severe pain. Hormones and antibiotics are not used to treat osteoarthritis. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Patients with gout have increased serum levels of uric acid. Creatinine level is used to evaluate kidney function. Hematocrit level is used to determine volume of red blood cells. Alkaline phosphatase is used to differentiate manifestations of osteoporosis, osteomalacia, and Paget's disease. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** In patients with osteoporosis and osteomalacia, fractures are a potential complication due to loss of bone mass or inadequate mineralization of bone matrix. Infection, blood clots, and contractures are not potential complications in osteoporosis or osteomalacia. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 4 Rationale:** Excessive weight contributes to the development of OA, especially in the hip and knee. Increasing body weight significantly increases the load placed on the knees during walking. A diet high in calcium has no effect on the development of osteoarthritis. Falls do not predispose an individual to developing osteoarthritis. Walking 30 minutes every day could help prevent the development of osteoarthritis. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
6. **Answer: 3 Rationale:** By monitoring vital signs, hemoglobin, and hematocrit, the nurse can determine early if the fluid volume is deficient due to excessive bleeding, or if the blood supply to the extremity is compromised. Monitoring of laboratory values and vital signs is not done to prevent the progression of infection. Teaching is necessary; however, not on the value of these assessments. Frequent vital sign and laboratory value monitoring is not done to promote rapport between the patient and healthcare providers. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Fever and weight loss are findings associated with rheumatoid arthritis. Stiffness relieved by activity is a manifestation of osteoarthritis. Abnormal joint findings are not limited to the hands in either RA or osteoarthritis. Heberden's nodes are characteristic of osteoarthritis. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** For *Ineffective Protection*, the most important intervention for the patient with SLE would be to practice careful hand hygiene because the patient is at risk for opportunistic and severe infections. Monitoring laboratory values, providing skin care, and administering prescribed medications are not interventions to address *Ineffective Protection.* Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Lyme disease is an inflammatory disorder caused by the spirochete *Borrelia burgdorferi* that is transmitted primarily by ticks. Most cases of Lyme disease occur when an infected tick remains embedded for at least 24 hours. Lyme disease is not contracted through the bite of an infected mosquito. Brief contact with an infected tick will not cause the disorder. This disease is not transmitted through droplets from infected people. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 2 Rationale:** Septic arthritis is a medical emergency requiring prompt treatment to preserve joint function. Osteoarthritis, gouty arthritis, and reactive arthritis are not considered medical emergencies. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity

Unit 10 Responses to Altered Musculoskeletal Function

1. Ms. Stevens is demonstrating manifestations of fat embolism syndrome (FES). It is a complication characterized by neurologic dysfunction, pulmonary insufficiency, and a petechial rash on the chest, axilla, and upper arms. Long bone fractures, such as femur fracture and other major trauma, are the principal risk factors for fat emboli.
2.
   A. **Joyce Stevens should be seen first.** *Rationale: Petechiae, difficulty breathing, and confusion can be signs of a life-threatening fat embolism that must be evaluated immediately.*
   B. **Jesse Drummond should be seen second.** *Rationale: Although phantom pain is common following an amputation, Mr. Drummond had a bilateral amputation, which increases his anxiety and pain. The nurse needs to assess the stumps to determine if complications are also adding to the pain level.*
   C. **José Rivera should be seen third.** *Rationale: Mr. Rivera may need pain medication. The upcoming surgery may be causing anxiety, which increases pain.*
   D. **Kim Wong should be seen last.** *Rationale: Her vital signs do not indicate immediate concern, and results from the blood tests are needed to determine the cause of the symptoms.*

3. Ms. Stevens should be taught to eat a diet high in protein to promote healing and high in calcium to strengthen bones. If she is prescribed anticoagulant medication, she may need to limit her intake of foods high in vitamin K.
4. **A.** pain
   C. pallor
   D. pulses
   E. paresis
   G. paresthesia
   Rationale: The 5 Ps of a neurovascular assessment are pain, pulses, pallor, paresis, and paresthesia.
5. **B.** Push the stump into soft and then harder surfaces.
   Rationale: Pushing the stump against soft and then harder surfaces will help toughen the skin.
6. "Mr. Drummond, I am sorry your legs hurt. What you are describing is called phantom pain and is very common immediately after amputation. Generally the pain eases as healing occurs. I will get you some medication. When your doctor gets here, I will have him talk with you more about your pain."
7. "Ms. Wong, I know it is hard for you to wait for the results of your tests, but until we have them, the doctor cannot determine if you have lupus or not. Once a diagnosis is made, the options for treatment can be discussed with you. I will have the doctor talk with you as soon as possible."
8. **A. Jesse Drummond:** The UAP can obtain vital signs and help with all ADLs.
   B. Joyce Stevens: The UAP can obtain vital signs and help with all ADLs.
   C. José Rivera: The UAP can obtain vital signs, help transfer the patient to surgery, and set up the post-op room for his return.
   D. Kim Wong: The UAP can obtain vital signs and help with all ADLs.
9. Interprofessional care is essential for the patient who has sustained an amputation. Physical therapy and occupational retraining both in acute care and rehabilitation facilities are necessary. The patient may also benefit from the presence of clergy. The care manager will assess the patient's discharge needs and prepare for the final transition to home as well as arrange for visits by a home care nurse.
10. The nurse should address the following topics when providing education for continuity of care: (1) the disease and its potential effects; (2) the importance of skin care; (3) the importance of avoiding exposure to infection; (4) the relationship between sun exposure and disease flares and how to reduce this risk; and (5) the need to follow the prescribed treatment plan, including rest and exercise, medications, and follow-up appointments. Discuss manifestations of an acute episode (often called a *flare*) and stress the importance of contacting the physician promptly if any of these manifestations occur. Promote an optimistic outlook, stressing that the majority of patients do not require long-term corticosteroid therapy and that the disease may improve over time.
11. **C.** Wearing sequential compression devices
    Rationale: These help prevent thromboembolism and pulmonary embolus by promoting venous return from the lower extremities for Ms. Stevens who has limited mobility following surgery.
12. Retrospective chart review should include asking these questions: (1) Was an assessment of need for anticoagulation completed? (2) Did the patient possess risks factors for deep venous thrombosis beyond the admitting diagnosis? (3) If sequential compression devices and/or antiembolism stockings were ordered, was there documented evidence that they were in use? (4) If patients had an order to get out of bed, was there documented evidence that the patients were out of bed?
13. **B.** nursing care plan (Kardex)
    Rationale: The admission note would contain information of admission assessment, diagnoses, and goals. The nursing care plan would provide instruction for the individualized plan of care including specifics regarding safe transfer techniques for Mr. Drummond. The flow sheet provides documentation space for individual data points such as vital signs. Electronic order entry provides a location for recording provider (MD or NP) prescribed treatments.

Chapter 41: Assessing the Nervous System

1. **Answer: 1 Rationale:** The blood–brain barrier controls the environment within by allowing oxygen, carbon dioxide, lipids, glucose, and water into the capillaries but preventing entry of urea, creatinine, toxins, proteins, and antibiotics. The structure of neurons and cerebrospinal fluid circulation do not protect the brain from harmful substances. The brain has a large oxygen demand to prevent cerebral cell damage. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 1, 5 Rationale:** Damage to lower motor neurons causes decreased muscle tone, muscle atrophy, fasciculations, and loss of reflexes. Damage to upper motor neurons results in increased muscle tone, decreased muscle strength, decreased coordination, and hyperactive reflexes. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
3. **Answer: 1, 2, 4, 5 Rationale:** Cerebrospinal fluid (CSF) cushions the brain tissue and spinal cord, protects them from trauma, provides nourishment to the brain, and removes waste products. Glucose is needed in brain cells for normal cell and brain functioning. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
4. **Answer: 2 Rationale:** The posterior spinal roots contain cells that discriminate fine touch sensations such as dull and sharp; therefore, damage to these roots would mean the patient would be unable to detect dull or sharp sensations. Flaccidity is seen with diseases or trauma of the lower motor neurons and early stroke. Anosmia or an inability to smell may be seen with lesions of the frontal lobe and may also occur with impaired blood flow to the middle cerebral artery. Loss of ability to taste may occur with brain tumors or with nerve impairment. Impaired vision may be seen with strokes and brain tumors. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** The sympathetic division of the ANS has the purpose of preparing the body to handle stressful events, such as almost being in an automobile crash, by increasing heart rate, force of contraction, vasodilation of coronary arteries, and increased mental alertness. The parasympathetic division of the ANS operates during nonstressful situations and causes pupil constriction, decreased heart rate, vasoconstriction of coronary arteries, constriction of the bronchioles, and increased peristalsis. *Adrenergic* is a term used to describe the effects of the neurotransmitter norepinephrine. Nerves that transmit impulses through the release of acetylcholine are called *cholinergic.* Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
6. **Answer: 4 Rationale:** The neurologic system is assessed through inspection, palpation, and percussion (by using a reflex hammer). Auscultation is not used in assessing the neurologic system. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
7. **Answer: 1 Rationale:** A cotton ball and a safety pin would be used to assess sensations of light, dull, and sharp on the face. If the safety pin is used to assess sharp touch, the pin is to be discarded as a sharp after use. A measuring tape and pencil might be used to assess cranial diameter. Various scents would be used to assess CN I olfactory nerve

function. A stethoscope is not used when assessing the neurologic system. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

8. **Answer: 1, 3, 4 Rationale:** The corneal reflex may be affected in patients who are unconscious or have a head injury. The reflex may be absent or decreased in patients who wear contact lenses. Being over the age of 50 does not cause loss of the corneal reflex. The level of the injury would determine if the corneal reflex would be affected in the patient with spinal cord trauma. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 4 Rationale:** The gag reflex is assessed by touching the back of the patient's throat with a tongue depressor. A safety pin is used to assess fine touch. A cotton ball is used to assess fine touch and the corneal reflex. A stethoscope is not used during the assessment of the neurologic system. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 3 Rationale:** In decorticate posturing the upper arms are close to the body; the elbows, wrists, and fingers are flexed; and the legs are extended with internal rotation. In decerebrate posturing the neck is extended, the arms are extended and pronated, and the feet are plantar flexed. The term *decorticate* is not used to describe posture changes that are associated with either the supine or prone positions. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity

Chapter 42: Nursing Care of Patients with Intracranial Disorders

1. **Answer: 4 Rationale:** When there is damage to the reticular activating system or cerebral hemispheres, neural control of these centers is lost, and lower brainstem centers regulate breathing patterns by responding only to changes in $PaCO_2$, resulting in irregular respiratory patterns. Blood in the ventricles or subarachnoid space irritates the meninges and brain tissue, causing an inflammatory reaction and impairing absorption and circulation of cerebrospinal fluid. Reflexive motor responses may occur as brain function declines. Loss of oculocephalic reflexes indicates a deterioration in brainstem functioning. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 1 Rationale:** The unconscious patient with a depressed or absent gag and swallowing reflex is at high risk for aspiration since saliva and any fluids taken by mouth could not be swallowed normally. There is no information to support that the patient has an ineffective breathing pattern. There is no information to support that the patient has increased intracranial pressure, which would impair intracranial adaptive capacity. There is also not enough information to support that the patient has imbalanced nutrition. In the absence of a gag reflex, nutrition can be provided through other, nonoral routes. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
3. **Answer: 4 Rationale:** Osmotic diuretics are hyperosmotic agents that draw fluid out of brain cells by increasing the osmolality of the blood. These medications excrete water and leave behind solutes. Osmotic diuretics are not used to treat hyperthermia, prevent seizures, or prevent gastrointestinal hemorrhages. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 1 Rationale:** The level of brain dysfunction and the side of the brain affected may be assessed by motor responses. These responses are the most accurate identifier of changes in mental status. In altered LOC, asking the patient to "squeeze my hand" would be used to determine mental status changes. Other questions such as "Tell me your name," "Are you having trouble breathing?" and "Look at the light while it is shined in your eyes" will not accurately determine mental status changes in the patient. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1, 3, 5 Rationale:** A patient with an altered LOC would probably have blood glucose level checked for hypoglycemia, electrolytes checked for metabolic disturbances, and blood and urine toxicology studies to test for drug or alcohol toxicity. Urine white blood cell levels would not be indicated for the patient's health problem. Spinal fluid osmolarity would be done after a lumbar puncture, which is a diagnostic test. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
6. **Answer: 4 Rationale:** Serum osmolality is an indicator of hydration status. The test measures the number of dissolved particles such as electrolytes, urea, and glucose in the serum. The complete blood count and urinalysis will not provide information about the patient's hydration status. Blood cultures are used to determine the presence of a bacterial infection in the blood. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 2, 5 Rationale:** Neurologic manifestations of a TIA vary according to the location and size of the cerebral vessel involved and have a sudden onset. Commonly occurring deficits include contralateral numbness or weakness of the leg, hand, forearm, and corner of the mouth; aphasia; and visual disturbances such as blurring. The patient may also experience a fleeting blindness of one eye. Eye pain is associated with a stroke of the vertebral artery. Loss of reflexes is associated with a contusion. Loss of sensation in the legs can be associated with a brain injury. Complete paralysis of the right arm and leg would indicate a stroke within the left cerebral hemisphere. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 1, 3, 4 Rationale:** The most important treatable conditions that increase the risk of stroke include hypertension, heart disease, and diabetes. Head trauma and high cholesterol levels are not identified as increasing the risk of stroke. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
9. **Answer: 4 Rationale:** The neurologic deficits that occur as a result of a stroke can often be used to identify its location. Because the motor pathways cross at the junction of the medulla and spinal cord, strokes lead to loss or impairment of sensorimotor functions on the side of the body opposite the side of the brain that is damaged. This effect, known as a contralateral deficit, means that a stroke in the right hemisphere of the brain is manifested by deficits in the left side of the body and vice versa. Contralateral does not mean that the effects of the stroke are evident on both sides of the body, below the level of the stroke, or on the same side of the embolic event. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
10. **Answer: 2 Rationale:** A tissue plasminogen activator is used to treat ischemic stroke. The drug converts plasminogen to plasmin, resulting in fibrinolysis of the clot. To be effective, it must be given IV within 3 hours of the onset of manifestations, after confirming with a CT scan that the patient has not had a hemorrhagic stroke. This medication is not used to increase platelet aggregation, reduce the risk of vasospasm, or decrease the risk of infection. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity

Chapter 43: Nursing Care of Patients with Spinal Cord Disorders and CNS Infections

1. **Answer: 2 Rationale:** SCI at the C_1–C_4 level produces respiratory paralysis and the patient will be unable to breathe on his or her own, so a ventilator will be necessary to maintain respiratory function. The nerves controlling lung function have been injured. The patient does not have a lung injury. The use of a ventilator is not because the patient is unconscious. The use of a ventilator will not be temporary.

Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

2. **Answer: 1, 3, 5 Rationale:** Analgesics such as nonsteroidal anti-inflammatory drugs (NSAIDs) and narcotics are administered to reduce pain. Vasopressors are used in the immediate acute care phase to treat bradycardia or hypotension due to spinal and neurogenic shock. Corticosteroids may be used to decrease or control inflammation and edema of the cord. Antibiotics and antihistamines are not indicated in the acute care of a patient with a SCI. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 3 Rationale:** Spinal shock is the response of the cord itself to injury. It involves temporary loss of reflex function below the level of injury at the cervical and upper thoracic spinal cord. Spinal shock is not damage to the lower motor neurons. Spinal shock interrupts sympathetic nerve functioning. Spinal shock leads to a loss of sympathetic input to the blood vessels of the peripheral system and the heart, leading to unopposed vagal tone. Control of cardiovascular mechanisms is not lost but altered. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
4. **Answer: 2 Rationale:** Autonomic dysreflexia is triggered by stimuli that would normally cause abdominal discomfort, by stimulation of pain receptors, and by visceral contractions. The most common cause is from a full bladder resulting from a blocked urinary catheter. Diarrhea and respiratory problems do not cause autonomic dysreflexia. An elevated blood pressure is a manifestation of this disorder. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1, 3, 4 Rationale:** In teaching prevention of back injuries, the nurse would incorporate principles of proper body mechanics, which include using large leg muscles to push when lifting, spreading the feet apart to widen the base of support, and working close to the object being moved. Bending from the waist to lift objects and lifting instead of pushing or rolling objects can contribute to back injuries. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
6. **Answer: 2 Rationale:** To monitor for signs of nerve root compression after a cervical laminectomy, the nurse should assess hand grips, arm strength, the ability to move the fingers, and the ability to detect touch. Wiggling the toes would be used to assess for nerve compression after a lumbar laminectomy. Auscultation of heart sounds will not detect cervical root compression after a cervical laminectomy. A reflex hammer is not used to assess for a Babinski reflex. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** Pain is often the first manifestation of a spinal cord tumor. It is caused by compression of the spinal cord, tension on the spinal nerves, or tumor attachment to the covering of the spinal cord. A physiological response to acute pain is an increase in heart rate. Fever, diarrhea, and urinary incontinence are not physiological responses to pain.
8. **Answer: 4 Rationale:** Pathogen entry into the CNS initiates the inflammatory response in the meninges, CSF, and ventricles. Meningeal vessels become engorged and permeability increases. Phagocytic white blood cells migrate into the subarachnoid space, forming a purulent exudate that thickens and clouds the CSF and impairs its flow. Intracranial pressure can increase and not decrease with meningitis. Meningitis does not cause bleeding into the central nervous system. An elevated systemic white blood cell count does not affect the cognitive status. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** To reduce the onset of CNS infections in a community, the nurse should focus on the control of mosquitoes with repellants, insecticides, and protective clothing. Community programs such as spraying to destroy the insect larvae and eliminate breeding places, such as pools of stagnant water, should also be provided. Garbage pickup, sanitation services, and the washing of fruits and vegetables will not reduce the infestation of mosquitoes. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 1 Rationale:** A proton-pump inhibitor, such as pantoprazole (Protonix), is often prescribed to prevent stress-related gastric ulcers. This medication is not prescribed to encourage healing of gastric nerves, promote digestion of enteral feedings, or support healthy bacteria in the gastrointestinal tract. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity

Chapter 44: Nursing Care of Patients with Neurologic Disorders

1. **Answer: 1, 4, 5 Rationale:** *Dementia* is a general term used to describe the outcome of the death of neurons, and the cognitive and behavioral manifestations of Alzheimer's disease. The hallmark of dementia is impairment of both short- and long-term memory. Dementia is not an acute disorder and is not the primary manifestation of Guillain-Barre syndrome. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** Memory loss is usually the first sign of Alzheimer's disease. Memory deficits are initially subtle and family members and friends may not suspect a problem until the disease progresses and manifestations become more noticeable. Inability to perform basic activities of daily living, loss of verbal communication, wandering, and changes in sleep patterns at night are later manifestations of the disease process. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Nursing diagnoses appropriate for the patient with multiple sclerosis relate to the inability to perform ADLs, such as *Fatigue*, *Self-Care Deficit*, and *Impaired Home Maintenance*. Other diagnoses reflect problems with musculoskeletal changes or altered nerve conduction such as *Impaired Physical Mobility*, *Ineffective Breathing Pattern*, *Constipation*, and *Functional Urinary Incontinence*. The patient with multiple sclerosis does not experience acute pain and is not necessarily at risk for aspiration or impaired gas exchange. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
4. **Answer: 3, 5 Rationale:** Immunomodulators are administered to patients with relapsing-remitting MS to prolong the time of onset to disability. Adrenocorticosteroids are used both to sustain a remission and to treat exacerbations of MS. Dopamine precursors are used in the treatment of Parkinson's disease. Antibiotics and antihistamines are not used to treat multiple sclerosis. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 3 Rationale:** The onset of MS is usually between 20 and 40 years of age. There is no cure for the disease. The patient should be advised to avoid temperature extremes, such as hot showers or exposure to cold. Maintaining a relatively constant body temperature may prevent exacerbation of the disorder. Heat can delay impulse transmission across demyelinated nerves, which contributes to fatigue. Many medications are available to aid in the treatment of this health problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 4 Rationale:** The usual balance of dopamine (an inhibitory neurotransmitter) and acetylcholine (an excitatory neurotransmitter) in the brain is disrupted, and dopamine no longer inhibits acetylcholine. The failure to inhibit acetylcholine is the underlying basis for the manifestations of Parkinson's disease. The cause of the disease is still unknown, but is believed to be the result of environmental and genetic factors, with genetic mutations especially implicated in early-onset Parkinson disease. This disease does not develop as an autoimmune

response to a viral infection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

7. **Answer: 1 Rationale:** Parkinson's disease is a common disorder in older adults, who are already at greater risk for falls resulting from orthostatic hypotension, osteoporosis, poor vision, and other problems causing disorientation and confusion. This safety issue needs to be addressed with the caregivers. The patient with Parkinson's disease does not have an issue with appetite but is at risk for poor nutrition because of tremors leading to the inability to self-feed. There is no reason for the patient with Parkinson's disease to avoid showers or baths. The skin is usually damp and oily, so bathing is needed. There is no reason to believe that the patient with Parkinson's disease is at risk for medication overdose. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 1 Rationale:** An antiglutamate was the first medication developed to treat ALS. It inhibits the presynaptic release of glutamic acid in the CNS and protects neurons against the excite-toxicity of glutamic acid. Anticholinergics and dopamine agonists are used to treat Parkinson's disease. Anti-inflammatory medications may be used to treat Bell's palsy. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 1 Rationale:** When teaching patients about Bell's palsy, the nurse needs to tell the patient that one side of the face will not move normally since the affected nerve supplies the muscles that produce expression on one side of the face. The disease does not affect lower extremity muscles. Pain from the ear along the jaw may precede the facial paralysis. There is no reason for the patient to boil home-canned foods since Bell's palsy is not caused by botulism. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
10. **Answer: 1 Rationale:** Riluzole is associated with the risk of elevated liver enzymes. The nurse should plan additional interventions that focus on the patient's liver while taking this medication. This medication does not adversely affect the heart, lungs, or kidneys. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity

Unit 11 Responses to Altered Neurologic Function

1. **B.** Call the physician about patient report of increasing headache.
   Rationale: Increased headache that is not controlled with medication indicates increased intracranial pressure and must be reported to the physician.
2.
   - **A. Cesar Phillips should be seen first.**
     Rationale: BP 170/110 before medication 1.5 hours ago. The effectiveness of this treatment must be evaluated.
   - **B. Louie Hernandez should be seen second.**
     Rationale: Mr. Hernandez may have swallowing difficulty and therefore may have difficulty keeping his airway clear. Aphasia may prevent him from summoning help if needed. Frequent observation is needed.
   - **C. Tonya Walton should be seen third.**
     Rationale: The increasing head pain can indicate complications after neurosurgery and must be evaluated.
   - **D. Jane Thomas should be seen last.**
     Rationale: Ms. Thomas is the most stable and has no urgent needs.
3. Ms. Thomas should be taught not to lift or move anything over 10 pounds until her surgeon approves. Once healing is complete, she must lift by using her legs, not her back.
   Rationale: Lifting can traumatize the incision and prevent adequate healing. Using the back to lift heavy objects can cause further injury to lumbar discs.
4. Both Mr. Hernandez and Mr. Phillips have been smokers for a long time. They should be informed that smoking increases blood pressure, which can lead to stroke. They should be provided with information on local stop-smoking programs. *Rationale: Research shows that smoking increases the risk of hypertension, strokes, and heart disease. Many stop-smoking programs are effective.*
5. **C.** Ms. Walton's pain level is now 1–2.
   Rationale: The previous nurse gave Ms. Walton Tylenol ES for a headache of 6 on a scale of 1 to 10. You should evaluate the effectiveness of this medication by determining the current pain level on the same 1-to-10 scale.
6. **D.** Mr. Phillips' blood pressure has decreased to 145/90 mmHg.
   Rationale: Mr. Phillips was given an antihypertensive medication 1.5 hours ago. Because his blood pressure was 170/110 mmHg when the medication was given, a blood pressure of 145/90 mmHg would indicate that the medication was effective.
7. Explain to Mrs. Phillips that the MRI indicated that a stroke has caused her husband's symptoms. Acknowledge that strokes are more common in older people, but that Mr. Phillips is at risk because of his uncontrolled hypertension and smoking. *Rationale: Mrs. Phillips is grieving the loss of her husband's function and needs accurate information and reassurance.*
8. Explain that it is too early to determine how much permanent neurologic deficit Mr. Hernandez will have. Explain that Mr. Hernandez's rehabilitation will be evaluated frequently and plans will be discussed with her at that time.
   Rationale: Over time, rehabilitation can be effective in restoring neurologic function. The amount of permanent neurologic deficit cannot be determined until this time.
9.
   - **A. Mr. Hernandez:** The UAP can obtain vital signs and assist with ADLs. Instruct him or her not to provide oral intake until swallowing evaluation is obtained.
   - **B. Ms. Thomas:** The UAP can obtain vital signs and assist with ADLs. Remind him or her to assist the patient to log roll to prevent twisting of the lumbar spine.
   - **C. Mr. Phillips:** The UAP can obtain vital signs and assist with ADLs. Mr. Phillips should remain in bed and will need assistance to turn every 2 hours.
   - **D. Ms. Walton:** The UAP can obtain vital signs and assist with ADLs. Ms. Walton should remain in bed, and will need assistance turning every 2 hours.
10. The disciplines the nurse should include in a discharge planning meeting would be medicine, physical therapy, occupational therapy, speech therapy, nutrition, and social work. The patient and/or a family member should also be included. These disciplines can provide valuable input for planning rehabilitation services.
11. **A.** Long-term care
    Rationale: Depending on the amount of permanent neurologic deficit and the specific patient, long term care may be required if the patient cannot be safely transitioned to the home setting.
    B. Rehabilitation setting
    Rationale: The rehabilitation setting is appropriate while the patient continues to regain neurologic function.
    C. Home setting
    Rationale: The home setting is the most common goal of patients and families following a stroke. Transition to home is based on safety and appropriate care support as well as the level of permanent neurologic deficit.
12. **A.** Perform a dysphagia screening
    Rationale: Patients admitted with stroke are at risk for dysphagia, which could result in aspiration. The professional nurse should perform a dysphagia screen in the emergency department and again upon transfer to the nursing unit. The professional nurse is responsible for notifying the healthcare provider of any swallowing issues and is also responsible for the documentation.

13. The nursing staff can provide educational offerings at community settings, such as senior centers, churches, and schools, on early recognition of stroke symptoms. It is important to increase public awareness of the signs of a TIA or stroke and of the need to call 911 or to seek care immediately if warning signs or symptoms occur so that the patient can be evaluated to determine if he or she is a candidate for fibrinolytic therapy. Tissue plasminogen activator is used to treat ischemic stroke and must be given IV within 3 hours of the onset of manifestations, after confirming (with a CT scan) that the patient has not had a hemorrhagic stroke. Emphasizing to the public that "time is brain" is essential in decreasing consequences of ischemic stroke.
14. **A.** fundamental computer skills and an understanding of information (i.e., nursing process, evidence-based practice, etc.) to deliver safe and effective care
    Rationale: Fundamental computer and information skills are indicative of the level 1 beginning nurse regarding nursing informatics. Level 2 (experienced nurse) is defined as the ability to identify relationships among disparate information sources. Level 3 (informatics specialist) is able to integrate and apply computer science to nursing. Level 4 (informatics innovators) conducts informatics research.

Chapter 45: Assessing the Eye and Ear

1. **Answer: 3 Rationale:** When the cornea is touched the patient will blink as a mechanism to protect it from foreign objects. Some tears are secreted when the cornea is touched; however, tearing is not excessive. The pupil should not dilate in response to the cornea being touched. Nystagmus is an involuntary rhythmic movement of the eyes and is associated with neurologic disorders and the use of some medications. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
2. **Answer: 2 Rationale:** Presbyopia develops in older adults as the lens of the eye loses its ability to adjust, requiring the patient to hold papers farther away in order to focus and read. Presbycusis is hearing loss associated with aging. Presbyopia is not associated with memory loss. Cognitive Level: Analysis; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
3. **Answer: 3 Rationale:** A tuning fork is used to determine hearing and differentiate if hearing loss is conductive or sensorineural. A penlight is used to assess pupil dilation. An otoscope is used to assess the ear canal. An ophthalmoscope is used to assess the internal structures of the eye. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
4. **Answer: 3, 4 Rationale:** When testing for accommodation the pupils are assessed for dilation or constriction depending on the focus of an object. For a distant object the pupils should dilate. For a near object, the pupils should constrict. Rhythmical blinking is not a finding when testing for accommodation. The eyes move in six different directions when assessing for extraocular movements. The eyes moving in the direction that the head is turned are an abnormal finding when assessing for doll's-eyes. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
5. **Answer: 3 Rationale:** Patients having a test of refraction will have the pupil dilated to examine the internal eye structures. The nurse should tell the patient that the pupils will be dilated with medication and may be enlarged for several hours. Dye is not used to complete refraction so an allergy to seafood is not an issue. The patient will not be blindfolded for a refraction test. This test does not cause discomfort. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
6. **Answer: 1, 2, 4 Rationale:** Age-related changes to the inner ear include loss of ability to hear high-frequency sounds and possibly lost or decreased middle and low-frequency sounds. Vestibular structures degenerate, leading to balance and equilibrium problems. Sounds made from one's own body and speech being louder is an age-related change to the middle ear. Impacted cerumen and an itchy external ear canal are age-related changes to the external ear. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
7. **Answer: 4 Rationale:** The Snellen eye chart measures the patient's ability to read letters at a standard distance of 20 feet. The patient reads the smallest line possible, and the numbers on the side indicate visual acuity, for example, 20/20, 20/30. The Rosenbaum chart is used to assess for near vision. The confrontation test is used to assess for visual fields. Convergence is assessed by asking the patient to follow an object as it is moved toward the patient's eyes. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
8. **Answer: 4 Rationale:** Hearing acuity is determined by using the whisper test. The examiner can whisper a word 1 or 2 feet behind the patient, asking the patient to repeat the word; this may provide a rough estimate of hearing acuity. The Rinne and Weber tests are performed with a tuning fork. Audiometry is used to evaluate and diagnose conductive and sensorineural hearing loss. This test is performed with the patient sitting in a soundproof room and responding when sounds are heard. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
9. **Answer: 1 Rationale:** An age-related change in the lens of the eyes is a loss of elasticity and reduced ability to change shape and focus light. The lens becomes thicker and loses clarity. The patient may experience glare. A slow reaction to light is an age-related change to the pupils. Dry itchy burning eyes are age-related changes in the accessory eye structures. The inability to discriminate blue and green tones is an age-related change of the retina and visual pathways. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
10. **Answer: 3 Rationale:** The visual fields of the examiner, which must be normal for this assessment, are used as the standard. If the examiner does not have a normal visual field, then the results of this part of the exam will be inaccurate. The examiner can wear glasses. The patient does not need to wear corrective lenses nor have greater than 20/30 vision to assess visual fields. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance

Chapter 46: Nursing Care of Patients with Eye and Ear Disorders

1. **Answer: 1 Rationale:** Maintaining safety is the priority of care for patients with vision and hearing disorders. Preventing sensory deprivation would be the next priority for these residents. Encouraging social interaction and promoting family relationships would be of the lowest priority for these residents. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
2. **Answer: 2 Rationale:** When teaching a patient with newly diagnosed glaucoma, the nurse should emphasize the importance of using eyedrops as prescribed on a continuing basis to control intraocular pressure and prevent vision loss. Reporting a decline in vision would be appropriate for the patient with macular degeneration. Avoiding coughing, sneezing, or straining with a bowel movement would be appropriate for the patient recovering from a corneal transplant or recovering from a detached retina. A loss of peripheral vision can occur in the patient with glaucoma; however, the patient is newly diagnosed and may not be experiencing this manifestation. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
3. **Answer: 1 Rationale:** Timolol is a beta-adrenergic blocker that can decrease myocardial contractility and impair cardiac function in the patient with heart failure. This medication should not be prescribed to treat glaucoma if the patient has a history of heart failure. Prostaglandin analogs such as latanoprost (Xalatan) are generally the drugs

of choice for treating chronic glaucoma because they can be administered daily and have a low adverse effect rate. Dorzolamide (Trusopt) is a carbonic anhydrase inhibitor that decreases the production of aqueous humor and reduces intraocular pressure. It is used with other drugs to control pressures and may be used in patients for whom beta-blockers are contraindicated because of heart failure. The adrenergic agonist brimonidine (Alphagan) may be prescribed if beta-blockers are contraindicated in a patient with heart failure. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Safe and Effective Care Environment

4. **Answer: 1, 2, 3 Rationale:** Between acute attacks, management of the patient with Ménière's disease is directed at preventing future attacks and preserving hearing. A low-sodium diet helps reduce labyrinthine pressure. Patients should avoid tobacco, which causes vasoconstriction and can precipitate an attack, along with alcohol and caffeine. Sitting down when an attack develops is a safety measure but will not prevent the onset of vertigo and tinnitus. Taking prescribed antiemetic medications will not prevent vertigo and tinnitus. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
5. **Answer: 3 Rationale:** Following eye surgery, the patient should be placed in the semi-Fowler's or Fowler's position on the unaffected side. Elevating the head of the bed and lying on the unaffected side reduce intraocular pressure in the affected eye. The patient should not be placed on the affected side. The patient does not need a private room nor does the patient need to be close to the nurses' station. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 1 Rationale:** Immediate referral to an ophthalmologist is necessary because the manifestations suggest a detached retina. Immediate treatment is necessary to preserve sight. Flashing lights are not associated with high blood pressure. Lying down might be indicated; however, the sensation is not going to pass. Flashing lights is not a usual occurrence and will not resolve without treatment. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 1, 2, 3, 4 Rationale:** The patient could be experiencing otitis externa or otitis media and should have vital signs and body temperature assessed. The nurse should then manipulate the pinna to help differentiate between the pain associated with otitis externa and otitis media, inspect the oral pharynx for inflammation, and palpate cervical lymph nodes, which would indicate an infection. The retina and cornea do not need to be assessed in the patient experiencing ear pain. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** Aging is a risk factor for impaction because less cerumen is produced and it is harder and drier. When the ear canal becomes occluded with cerumen, the patient experiences a conductive hearing loss in the affected ear. Manifestations include a sensation of fullness, along with tinnitus and coughing due to stimulation of the vagal nerve. The nurse should inspect the ear canal for patency. The primary care physician does not need to be notified as of yet. The patient does not need to be evaluated by an audiologist. The nurse cannot determine interventions to treat the patient until an assessment is completed. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
9. **Answer: 2 Rationale:** One-on-one social interactions in a quiet environment facilitate effective communication for the patient with a severe hearing deficit. Religious services may or may not help improve social interaction in the patient with a hearing deficit. Engaging in activities with a large number of people such as card tournaments, dancing, or community lunches will not help the patient be successful with hearing. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Psychosocial Integrity
10. **Answer: 3 Rationale:** Surgical removal of the cataract and lens is indicated when the cataract has developed to the point that vision and activities of daily living are affected. The nurse cannot diagnose when a cataract is ready to be removed. Cataracts may be removed prior to other health problems developing, which may or may not be convenient for the patient. Cataracts are not associated with eye pain or headaches. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance

Unit 12 Responses to Altered Sensory Function

1. **A.** caloric testing
   B. Rinne and Weber tests
   E. glycerol test
   Rationale: Diagnostic studies for Ménière's disease are caloric testing, Rinne and Weber tests, and glycerol test. These studies test for impaired vestibular function and hearing.
2.
   A. Kenneth Koch should be seen first.
   Rationale: Mr. Koch is having severe pain and needs to be assessed and medicated.
   B. Georgia Stanley should be seen second.
   Rationale: Ms. Stanley is scheduled for x-rays and an MRI. She must be assessed before she leaves her room.
   C. Andrew Hardy should be seen third.
   Rationale: Mr. Hardy's blood glucose level was 600 on admission and must be reevaluated to determine the effectiveness of treatment.
   D. Gladys Harvey should be seen last.
   Rationale: Ms. Harvey is experiencing routine post-op recovery and is stable.
3. Teach Mr. Hardy to control his diabetes and make appropriate referrals for diabetic education. Teach him to take his prescribed antihypertensive medication, to be seen by an ophthalmologist annually, and to report black spots, floaters, cobwebs, or eye pain immediately.
4. **D.** Wear ear protectors when exposed to loud noises.
   Rationale: Loud noises above 85 decibels may cause hearing loss.
5. **B.** semi-Fowler's position on the unaffected side
   Rationale: After eye surgery, place the patient in semi-Fowler's or Fowler's position on the unaffected side to reduce intraocular pressure.
6. **C.** grilled chicken sandwich with lettuce and tomato
   Rationale: Grilled chicken with lettuce and tomato are low in sodium. Ketchup, cheese, and potato chips are high in sodium.
7. **B.** Speak at a normal rate and avoid overarticulating.
   D. Face the patient to enhance lip-reading.
   E. Turn down the television or radio.
   F. Use short sentences and pause frequently.
   Rationale: To improve communication with a patient with hearing loss, speak in a normal tone while facing the patient, and use short sentences and pauses to increase comprehension. Speak at a normal rate and avoid overarticulating to make lip-reading easier. Reduce environmental noises to decrease distractions.
8.
   A. Andrew Hardy: The UAP can obtain vital signs and blood glucose by fingerstick, and assist with ambulating to maintain safety.
   B. Gladys Harvey: The UAP can obtain vital signs and assist with ADLs as needed, including ambulation to maintain safety.
   C. Georgia Stanley: The UAP can obtain vital signs, assist with ADLs, assist with ambulation to maintain safety, and prepare the room for the patient's return from radiology.
   D. Kenneth Koch: The UAP can obtain vital signs and assist with ADLs as needed, including ambulation to maintain safety.
9. **B.** nausea
   Rationale: The nurse should collaborate with the healthcare provider to obtain an order for an antiemetic to assist with alleviating the nausea.

10. **B.** Avoid coughing or sneezing.
    Rationale: Coughing or sneezing increases intraocular pressure and may lead to postoperative complications. Avoid lifting more than 5 pounds. Lie on the unaffected side. Maintain eye patch to prevent injury to the eye.
11. **A.** scanning the barcode on Ms. Harvey's eyedrops and her identification bracelet prior to instillation
    Rationale: Forced functions such as barcode scanning help to prevent medication administration errors.
12. A multidisciplinary team can be developed to examine barriers to annual screening for diabetic retinopathy. Factors to be considered are coverage by insurance or lack of insurance, patient knowledge of necessity of yearly examination, documentation of healthcare provider's yearly referrals, and patient follow-through to examination.
13. **C.** progress note
    Rationale: The medication administration record is for documenting administration of prescribed pharmacologic therapies. Vital sign flow sheet provides a graphical representation of vital sign values. The progress note allows for free text to fully describe the interaction between the nurse and the physician. Electronic order entry provides location for physician and/or NP prescribed orders.

Chapter 47: Assessing the Male and Female Reproductive Systems

1. **Answer: 3 Rationale:** Gynecomastia or abnormal enlargement of the breasts in men does occur with obesity. Phimosis is tightness of prepuce that prevents retraction of foreskin. Areolas are not typically absent in the male patient. Enlarged axillary lymph nodes are not a normal finding and would need to be further investigated. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
2. **Answer: 2 Rationale:** In the female, the clitoris is an erectile organ analogous to the penis in the male. Ovaries produce eggs, which would be analogous to the male testicles. There are no male organs analogous to the labia majora and minora. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 2 Rationale:** The explanation should begin by explaining that the prostate gland is about the size of a walnut. It encircles the urethra just below the urinary bladder and is surrounded by smooth muscle. The prostate gland does not press on bladder. This gland does not sit on top of the kidneys. This gland does not have any effect on renal function. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 1 Rationale:** The prostate-specific antigen (PSA) test is a blood test used to screen for prostate cancer and to monitor treatment of prostate cancer. Complete blood count or white blood cell count is not used to measure the success of prostate cancer treatment. The Venereal Disease Research Laboratory (VDRL) test is used to screen for syphilis. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Physiological Integrity
5. **Answer: 1, 5 Rationale:** Appropriate questions to determine the patient's health perception–health management would be to ask about smoking and if the patient performs testicular self-examination. Asking about urine dribbling and blood in the urine focuses on the functional health pattern of elimination. Asking about sexual relationships focuses on the health pattern of sexuality-reproduction. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
6. **Answer: 1, 2, 4, 5 Rationale:** With menopause, hormone production of estrogen decreases, which may cause pelvic floor muscles to weaken, loss of skin tone, and growth of facial hair. Estrogens are responsible for the normal structure of skin and blood vessels and reduce cholesterol levels. Estrogen does not influence the size of the cervix. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
7. **Answer: 3 Rationale:** When women of reproductive age become pregnant, menstruation normally stops until after delivery. Cessation of menstruation is not associated with the onset of puberty. The patient is young so menopause is not a consideration at this time. The patient is female so spermatogenesis is not a normal physiologic function of this patient. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
8. **Answer: 1 Rationale:** A Papanicolaou smear (or Pap test) is conducted to diagnose malignant and premalignant lesions of the cervix. A colposcopy may be done if a Pap test detects cell changes. A mammogram is a screening test for breast cancer. Blood cultures identify bacteria in the blood and not cancer cells. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
9. **Answer: 1, 3 Rationale:** The techniques of inspection and palpation are used to detect changes in breast tissue. The techniques of percussion and auscultation are not used when examining the breasts. Aspiration is not a physical examination technique. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Health Promotion and Maintenance
10. **Answer: 4 Rationale:** Postmenopausal bleeding is seen with endometrial hyperplasia, estrogen therapy, and endometrial cancer. This is not normal and should be reported to the healthcare provider. Sexual activity does not cause vaginal bleeding. The presence or absence of cramps is not an issue. The patient needs to see the healthcare provider for evaluation. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Chapter 48: Nursing Care of Men with Reproductive System and Breast Disorders

1. **Answer: 4 Rationale:** This is stated in an appropriate way to allow the patient to feel free to ask any questions about sexual concerns. Many men will not volunteer information about sexual function unless asked, but then are open about concerns and appreciate being asked. Questions about whether the patient misses sex or about sexual activity at a certain age are closed questions and do not address the patient's possible concerns. Asking if the patient is having problems with sexual intercourse after prostate surgery assumes the patient is sexually active. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
2. **Answer: 2, 3, 4 Rationale:** In a health teaching session with young men, the nurse should tell them about the relationship between HPV infection and penile cancer, instructing young men who have not been vaccinated against HPV to wear a condom during sexual intercourse to reduce the risk of contracting this infection. Retracting the foreskin while showering, and cleaning regularly to decrease the presence of secretions that can collect under the foreskin, has also been shown to decrease the risk of penile cancer. Wearing tight pants and hot showers may influence sperm production. Maintaining a regular schedule for testicular self-examination helps detect the development of testicular cancer. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 2 Rationale:** Sexually transmitted urethritis caused by *Neisseria gonorrhoeae* is the usual precipitating factor for epididymitis in younger men. Gonorrhea does not cause a hydrocele, gynecomastia, or erectile dysfunction. Cognitive Level: Applying; Nursing Process: Assessment; Client Need: Physiological Integrity
4. **Answer: 4 Rationale:** Testicular cancer accounts for only 1% of all cancers in men; however, it is the most common cancer in men between the ages of 13 and 35 and can occur from infancy through old age. Risk factors for testicular cancer include age and family history of the disorder. The first sign of testicular cancer may be a slight, painless

enlargement of one testicle. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance

5. **Answer: 3 Rationale:** Teaching plans for the man with prostatitis focus on symptom management. Men with chronic prostatitis should be taught to increase fluid intake to around 3 L daily and to void often. These measures help decrease irritation when voiding. Increasing fiber intake to promote regular bowel movements helps ease the pain associated with defecation; however, sexual activity does not need to be avoided. Local heat, such as sitz baths, may be helpful to relieve pain and irritation. Cold showers will not help the health problem. Oral fluids should not be restricted. A scrotal support and anti-inflammatory drugs are not part of the treatment for this health problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
6. **Answer: 1, 5 Rationale:** The tests used to diagnose prostate cancer include a digital rectal examination (DRE) and prostate-specific antigen (PSA) level. A DRE will find the prostate gland nodular and fixed in prostate cancer. PSA levels are used to diagnose and stage prostate cancer, and to monitor response to treatment. Transrectal ultrasonography (TRUS) and not a pelvic ultrasound may be used when the DRE is abnormal or if the PSA is elevated. Blood chemistries and sperm counts are not used to diagnose prostate cancer. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 3 Rationale:** The expanding prostatic tissue compresses the urethra and causes partial or complete obstruction of the outflow of urine from the urinary bladder. The detrusor muscles hypertrophy to compensate for increased resistance to urinary flow; however, eventually decreased bladder compliance and bladder instability occur. As a result, the man with BPH has manifestations from urinary obstruction and a decrease in bladder contractibility and compliance. Benign prostatic hyperplasia does not cause problems with skin integrity, bowel elimination, or peripheral vascular function. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 2 Rationale:** The man who has had prostate surgery is at risk for hemorrhage. Catheters may become occluded by blood clots or kinks, interfering with urinary drainage and increasing the risk of hemorrhage. Bladder spasms may be accompanied by strong urges to void and urine leakage around the catheter. Belladonna and opium (B&O) suppositories may be used to relieve bladder spasms; however, the nurse needs to report the assessment findings before medicating the patient. Assessing intake and output would not help the patient at this time. Doing nothing is not appropriate. The patient could be hemorrhaging. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** Cancer of the prostate is the most common type of cancer among men and the second leading cause of death in North America. Testicular cancer is common between the ages of 13 and 35. Lung and colon cancer frequency depends on genetic and environmental factors. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 4 Rationale:** A nutritional risk factor for the development of prostate cancer is a diet high in animal fat. Fiber is not identified as reducing the risk of prostate cancer. Lycopene and sodium are not identified as increasing the risk of prostate cancer. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance

Chapter 49: Nursing Care of Women with Reproductive System and Breast Disorders

1. **Answer: 4 Rationale:** If the nurse is not comfortable with frank discussions about sexual activities, referral is indicated. The nurse should acknowledge and refer the patient to discuss the issue with the physician. Asking questions about sexual activity would not address the patient's problem. The patient would not be asking the nurse about the problem if the patient knew what was causing it. The nurse should not deny knowing anything about the problem. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Psychosocial Integrity
2. **Answer: 1, 2, 5 Rationale:** Long-term estrogen deprivation results in an imbalance in bone remodeling and osteoporosis, leading to fractures and kyphosis. The risk for cardiovascular diseases increases in response to an increase in atherosclerosis. Colon and cervical cancer are not associated with long-term estrogen deprivation. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
3. **Answer: 1200 Rationale:** The recommended daily intake of calcium for women over age 50 is 1200 mg. This level can be achieved through diet and supplements if necessary. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 4 Rationale:** Kegel exercises strengthen perineal muscle tone and minimize stress incontinence. They also minimize descent of the bladder and rectum into the vagina. Kegel exercises do not prevent retroversion of the uterus, menorrhagia, or vaginal discharge. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
5. **Answer: 2 Rationale:** A health promotion seminar for reducing the risk of cervical cancer should contain information about safer sex methods that reduce the incidence of genital infections from HPV, which is the most important risk factor. Weight loss and a diet high in iron will not reduce the risk of cervical cancer. Yearly mammograms are not appropriate until the female reaches the age of 40. Mammograms help detect breast and not cervical cancer. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
6. **Answer: 1 Rationale:** For a woman with PMS, the nurse would recommend a decrease in sodium intake to help minimize the fluid retention due to the increased production of aldosterone, which results in sodium retention and edema. Sodium does not increase the risk of cancer. Sodium might cause the patient to have increased thirst; however, this is not the reason to limit the intake of sodium with PMS. Sodium does not impact glucose levels. Cognitive Level: Analyzing; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
7. **Answer: 4 Rationale:** Endometriosis is a slowly progressive disease, responsive to ovarian hormone stimulation. Endometrial implantations tend to atrophy and disappear after menopause since ovarian hormones no longer stimulate them. Endometrial implants do not enlarge, become malignant, or increase in number after menopause. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
8. **Answer: 1, 2, 5 Rationale:** A teaching plan for home care of a woman following an abdominal hysterectomy should include no lifting to decrease chances of hemorrhage, reporting temperature $>37.8°C$ ($>100°F$) since this may be a sign of infection, and taking regular rest periods since she may be tired for several days postoperatively. The patient should shower, avoiding tub baths, until bleeding has ceased. Deep breathing and coughing should be encouraged to mobilize respiratory secretions after the surgery. Cognitive Level: Applying; Nursing Process: Planning; Client Need: Physiological Integrity
9. **Answer: 4 Rationale:** Risk factors for breast cancer are doubled for the 64-year-old with a positive family history. The other participants have a lesser risk for developing breast cancer. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Health Promotion and Maintenance
10. **Answer: 2 Rationale:** Breast surgery, even a lumpectomy, alters the appearance of the breast. This loss of appearance, as well as the diagnosis of cancer, is expressed through grief. There is no evidence to support

that the patient is fatigued or is at risk for injury. The mastectomy did not yet occur so the diagnosis of *Disturbed Body Image* would be premature. Cognitive Level: Analyzing; Nursing Process: Planning; Client Need: Psychosocial Integrity

Chapter 50: Nursing Care of Patients with Sexually Transmitted Infections

1. **Answer: 2 Rationale:** Women and infants are disproportionately affected by STIs because women may not experience manifestations of the disease and pass the infection on to the infant through vaginal birth. Although the incidence of sexually transmitted infections is highest among young adults in general, women are affected more frequently than men. Men and older adults have lower incidence of sexually transmitted infections. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
2. **Answer: 2 Rationale:** Both partners are treated for sexually transmitted infections to prevent reinfection from one to the other, since manifestations are not always demonstrated when the infection is present. Sex is not contraindicated after being treated for a sexually transmitted infection. Women should be advised not to douche because it interferes with the normal bacterial environment of the vagina, decreasing resistance to vaginal infection. Both partners need to be treated if one partner has a sexually transmitted infection. Cognitive Level: Analyzing; Nursing Process: Evaluation; Client Need: Physiological Integrity
3. **Answer: 1, 2, 3 Rationale:** Topics of information when teaching a male to prevent an STI should include using a new condom with each sex act, careful handling to prevent damage to condom, and withdrawal from the vagina when the penis is erect, holding the condom against the base of the penis to prevent contamination of the penis. No air should be trapped in the end of the condom. Oil-based lubricants, such as petroleum jelly, massage oil, mineral oil, or body lotions, can weaken latex condoms and should not be used. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
4. **Answer: 4 Rationale:** Within 2 to 10 days after exposure to the herpes virus, painful red papules appear in the genital area. In men, the lesions generally occur on the glans or shaft of the penis. Soon after the papules appear, they form small painful blisters filled with clear fluid containing virus particles. Blisters and ulcers are not associated with gonorrhea, chlamydia, or genital warts. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
5. **Answer: 1, 4. 5 Rationale:** Genital warts are caused by the human papillomavirus, which has no cure. There are various strains of the virus and the ones that cause genital warts are not the same as the ones that cause cervical cancer. Genital warts are caused by a virus and not a yeast infection. The human papillomavirus can be transmitted to the fetus and the infection can be spread by any form of intercourse. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
6. **Answer: 2 Rationale:** Because of the increased risk of cervical cancer, annual Pap smears are essential for female patients with HPV. Checking the stool for occult blood is not done to determine the presence of cervical cancer caused by the human papillomavirus. A breast exam and mammogram are useful to detect the presence of breast cancer. The human papillomavirus does not cause anemia or an infection. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
7. **Answer: 2 Rationale:** Itching is the most common manifestation experienced by female patients with a vaginal infection. Pain is not a common manifestation of a vaginal infection. Nausea and diarrhea are not common manifestations of a vaginal infection. Cognitive Level: Analyzing; Nursing Process: Assessment; Client Need: Physiological Integrity
8. **Answer: 3 Rationale:** When teaching a woman with an STI experiencing severe genital discomfort, a simple recommendation is to wear cotton underwear because it absorbs moisture and provides for better airflow than other materials. The patient does not need to cut the fingernails short. Nylon panty hose will trap moisture and increase discomfort. Sex should be limited until the infection has been treated. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity
9. **Answer: 3 Rationale:** The organism that causes gonorrhea initially targets the female cervix and the male urethra. The organism does not target the prostate gland, the vulva, the vagina, or external genitalia. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Health Promotion and Maintenance
10. **Answer: 2 Rationale:** Syphilis is a systemic infection caused by a spirochete that enters the blood and lymphatic systems. Syphilis is not caused by a virus. Syphilis does affect the developing fetus. Cognitive Level: Applying; Nursing Process: Implementation; Client Need: Physiological Integrity

Unit 13 Responses to Altered Reproductive Function

1. Ms. Torrell's pulse of 110 bpm (tachycardia) and blood pressure of 88/54 mmHg (hypotension) are suggestive of hypovolemia.
2.
   - **A. Wendy Torrell should be seen first.**
     Rationale: Ms. Torrell has had major abdominal bleeding and is at risk for impaired tissue perfusion.
   - **B. Tara Morris should be seen second.**
     Rationale: She has an elevated temperature and a significant infection that must be assessed. Her IV antibiotics need to be administered on time.
   - **C. Barney Green should be seen third.**
     Rationale: Because Mr. Green is a postoperative patient, he is at risk for bleeding and infection. His output needs to be assessed because the Foley catheter was removed.
   - **D. Regina Perkins should be seen last.**
     Rationale: Ms. Perkins is stable and is ready for discharge. By assessing her last, the nurse can provide discharge teaching at the same time.
3. Ms. Morris should be instructed to abstain from sexual intercourse until the infection has cleared. She should be instructed to use condoms unless she is in a mutually monogamous relationship with an uninfected partner.
4. **B.** "The abdominal binder puts pressure on the leaking blood vessels, stopping the internal bleeding."
   Rationale: For Ms. Torrell the abdominal binder is used to control intra-abdominal bleeding. Abdominal binders can be used to support the abdominal muscles, especially in patients who are obese, but there is no indication that this was the purpose in Ms. Torrell's case.
5. **A.** beef, eggs, brown rice
   Rationale: Beef and eggs are high in heme iron. Brown rice is high in nonheme iron. Heme iron foods promote absorption of nonheme iron foods when eaten together. Broccoli, asparagus, kidney beans, and green, leafy vegetables are high in folic acid.
6. Some reproductive infections can cause scar tissue of the fallopian tubes. There would be a possibility of having difficulty becoming pregnant or developing a tubal pregnancy if that occurs. The physician or healthcare provider can provide more information in her specific case.
7. Dribbling urine after the Foley catheter is removed following a TURP is common. Usually the dribbling stops once complete healing occurs. It is too early to determine if dribbling will be permanent.
8. **A. Wendy Torrell:** The UAP can obtain vital signs, measure urine output every hour, and provide ADLs. He or she should be instructed not to get Ms. Torrell out of bed and to keep her NPO until it is determined further surgery will not be necessary.

B. Barney Green: The UAP can obtain vital signs and assist with ADLs. Mr. Green may need assistance with ambulation.

C. Tara Morris: The UAP can obtain vital signs and assist with ADLs. He or she should be instructed to obtain a temperature every 2 hours until it is within normal limits for 24 hours.

D. Regina Perkins: The UAP can obtain vital signs and offer breakfast prior to discharge. He or she can assist with packing belongings and can take Ms. Perkins to her car in a wheelchair once the discharge process is complete.

9. C. The findings may be due to absorption of isotonic bladder-irrigating fluids.
Rationale: Absorption of isotonic irrigating fluids during and after surgery may cause a hypervolemic and hyponatremic state, known as TURP syndrome. The patient's serum sodium and hematocrit should be evaluated.

10.

A. Take all antibiotics as prescribed.

B. Use latex condoms when having sex.

C. Wipe from front to back after urinating.

D. Change tampons or pads every 4 hours.
Rationale: The need to complete the antibiotic treatment regimen is essential for complete cure of the infection. Latex condoms offer the most effective protection against infection transmission and reoccurrence. Wiping from front to back reduces transmission of fecal organisms to reproductive tissues and reduces the incidence of urinary tract infections. Tampons or pads should be changed at least every 4 hours because menstrual flow and other discharges provide a favorable environment for microorganisms to multiply. Diaphragms should be removed within 6 hours after use to help prevent recurrence of infection.

11. B. Obtain an electronic infusion device.
Rationale: Electronic infusion devices ensure the medication is delivered intravenously over the prescribed time.

12. Factors to be examined include (1) time of order entry and time of delivery of medication from the pharmacy, (2) time of admission and time of insertion of intravenous access, and (3) individual nurse assignment.

13. D. electronic medical record via laptop computer
Rationale: A paper-and-pencil record is not the current standard of documentation practice. A handheld device that provides only free-text notes does not provide a complete EMR. A desktop computer is not portable. A laptop computer with EMR provides portability and complete documentation access in the home setting.

Evaluate Your Response Answers: Cues for Clinical Reasoning Questions

Chapter 4: Nursing Care of Patients Having Surgery

A Patient Having Surgery

1. Safety concerns include ambulating and not tripping over scatter rugs or clutter. See the information in Chapter 3 on safety in the home.
2. Medications used to prevent an occurrence such as infection are called prophylactic medications. Her risks for infection are from the surgical wound and microvascular circulation in bone. Teach her to take the complete course of antibiotics prescribed and about the possible side effects of the antibiotic. Encourage her to notify the physician if side effects or adverse events occur.
3. When blood stops flowing, it clots. Her immobility is a concern and puts her at risk for thrombosis and emboli. She has a risk for bleeding secondary to the anticoagulant and should inform healthcare providers such as dentists that she is taking the anticoagulant.
4. Consider Mrs. Overbeck's nutritional needs related to healing and age as well as her excess weight. She will need adequate protein, calcium, and vitamin D.

Chapter 5: Nursing Care of Patients Experiencing Loss, Grief, and Death

A Patient Experiencing Loss and Grief

1. Review the physical manifestations of grief described in the chapter and compare and contrast those with the ones verbalized by Mrs. Rogers.
2. Consider the benefits of including Mrs. Rogers's daughter in a meeting of the staff. What type of questions would be most useful in making the daughter feel a part of the plan of care? Why would a statement such as "Why don't you do more for your mother" be inappropriate?
3. Consider the losses Mrs. Rogers has experienced. Review the material in the chapter on responses to loss. Think about the reasons you would not say "Oh, you have a lot to live for." Think of two or three questions or statements that would help you assess the reason why Mrs. Rogers said this to you.

Chapter 6: Nursing Care of Patients with Problems of Substance Abuse

A Patient Having Withdrawal from Alcohol

1. Consider Mr. Russell's family history and the potential effect of his job loss on his self-esteem in developing your response to this question.
2. Think about Mr. Russell's BAL on admission to the ED and the circumstances of his accident. Also consider his safety while in the hospital, including the potential effects of anesthesia and alcohol withdrawal.
3. In developing a teaching plan, consider Mr. Russell's current nutritional status and elevated liver enzymes.
4. Consider the interactions of prescribed or over-the-counter medications with alcohol. What if the patient has not taken prescribed medications because of chronic alcoholism?
5. Review the effects of Antabuse. Make a list of possible interactions and side effects.
6. *Imbalanced Nutrition: Less Than Body Requirements* is an appropriate nursing diagnosis when a patient does not have sufficient nutritional intake to meet metabolic needs. What in Mr. Russell's history and physical assessment supports this diagnosis? What nutritional information should you provide?

Chapter 7: Nursing Care of Patients Experiencing Disasters

A Patient with Injuries from a Natural Disaster

1. Consider how Mr. Jones put himself at risk for infection (see Chapter 12). How could Mr. Jones have avoided exacerbating his skin lesions?
2. Because Mr. Jones has a history of elevated blood pressure that has not been consistently treated or monitored, cardiac status should be evaluated. Which tests are indicated? Also, could his decreased sensation and poor healing be related to cardiac impairment? Mr. Jones also has identifying data in his history and physical to suggest diabetes. Identify this data and tests that would be indicated.
3. Review risk factors for and causes and manifestations of infection in Chapter 12. Identify the factors that contributed to Mr. Jones's fever.
4. Consider Mr. Jones's environmental and personal situations. What information do you have about Mr. Jones that indicates a lack of interest in health maintenance? Are there signs of a change in outlook?

Chapter 9: Nursing Care of Patients in Pain

A Patient Experiencing Chronic Pain

1. Review the factors that affect an individual's response to pain. What have you observed in your own family and friends, as well as patients for whom you have cared?

2. Reflect on the benefits and disadvantages of each alternative. Make your decision based on knowledge about pain and about medications for pain.
3. What factors in Ms. Akers's illness and treatment increase her risk for constipation? What would you include in the plan specific to fluid intake and diet?

Chapter 10: Nursing Care of Patients with Altered Fluid, Electrolyte, and Acid–Base Balance

A Patient with Hyperkalemia

1. Review the causes and manifestations of hyperkalemia.
2. What are the potential effects of hyperkalemia on cardiac conduction? At what level of hyperkalemia are these likely to be seen?
3. Review collaborative treatment measures to rapidly reduce potassium levels. Why would these be used with a K^+ of 8.5?
4. Think about the effects of anxiety on learning as you develop a plan to provide teaching to avoid future episodes of hyperkalemia. As you develop your plan, remember the potential long-term effects of chronic renal failure.

A Patient with Acute Respiratory Acidosis

1. Review normal gas exchange across the alveolar-capillary membrane and the processes that drive this exchange. Then review the role that carbon dioxide plays as a potential acid.
2. Describe the effect of acidosis on cerebral neurons. What manifestations of mental impairment may result?
3. Think about the ABCs as you prioritize implementation of these orders.
4. Consider risk factors for choking such as alcohol consumption, taking large bites of food, or inadequate chewing.

Chapter 11: Nursing Care of Patients Experiencing Trauma and Shock

A Patient with Multiple Injuries

1. The definition of *Deficient Fluid Volume* is decreased intravascular, interstitial, and/or intracellular fluid. Which of Mrs. Souza's vital signs would support this definition? What other assessments could you make that would further support this diagnosis?
2. Consider the physiology of cellular metabolism. How long do brain cells live without oxygen? What happens if circulation is improved but the airway is blocked?
3. What can cause restlessness? Consider comfort, elimination, oxygenation, emotional status, and immobility.
4. List the multiple possibilities for entry of pathogens into the human body. Would age and physical condition increase the risk? What about transmission from healthcare personnel?

A Patient with Septic Shock

1. Review the pharmacologic effects of vasopressors. Consider the pathologic basis for septic shock and how these medications may be effective.
2. Review the content on respiratory acidosis in Chapter 10. What do these findings tell you? What is present in Ms. Huang's physical status that would cause these manifestations?
3. Review the content about colloidal intravenous solutions in this chapter. What would you expect these solutions to do when they are administered? How does this correlate to cardiac output? How do you assess increased circulatory volume?

Chapter 12: Nursing Care of Patients with Infections

A Patient with Acquired Immunity

1. Review the concept of acquired immunity and the discussion of immunization in this chapter. What effect could nonimmunized persons have on their family and community?
2. Consider current evidence regarding immunizations and immunization safety as you develop your response.
3. Identify possible systemic and local reactions associated with immunizations. List manifestations that the patient should report to the primary caregiver.

Chapter 13: Nursing Care of Patients with Altered Immunity

A Patient with HIV Infection

1. Think about the effects of HIV and ART on body systems as well as Mr. Lu's current manifestations.
2. Review current data regarding ART and HIV prognosis. Review the section about ART and the ART medication administration box.
3. Consider using credible online resources to identify potential responses to this question by Mr. Lu.
4. Think not only about safer sex practices but also recommended prophylactic measures to prevent HIV infection in partners of infected patients.

Chapter 14: Nursing Care of Patients with Cancer

A Patient with Cancer

1. Review content on altered nutrition in Chapter 22 and the content in this chapter on the nursing diagnosis *Imbalanced Nutrition: Less Than Body Requirements*. Make a list of diagnostic tests for malnutrition with normal values.
2. Consider the type of cancers Mr. Casey has been diagnosed as having. Where in the body do these malignancies commonly metastasize? What would cause the pain? Are there other causes of severe back pain that should be considered?
3. Review a pharmacology book for medications that increase appetite and make a list of those appropriate to Mr. Casey.
4. Review the content in Chapter 11 on septic shock and outline manifestations. Develop a plan of care for Mr. Casey that is structured by priority of nursing diagnoses.

Chapter 16: Nursing Care of Patients with Integumentary Disorders

A Patient with Herpes Zoster

1. Consider environmental, economic, and language barriers. What agencies in your own city or state exist to provide help? What can you do other than make referrals? If you do make a referral, to whom would it be?
2. Review skin assessment guidelines in Chapter 15. How would you determine that the lesions had not improved? What manifestations would indicate secondary infection of the lesions? What would you do next if the lesions are still very painful and have not improved?
3. *Ineffective Role Performance* is defined as patterns of behavior and self-expression that do not match environmental context, norms, and expectations. Related factors include inadequate or inappropriate linkage with the healthcare system and poverty. Based on this information, what interventions would you use? How would you evaluate the effectiveness of your interventions?

A Patient with Malignant Melanoma

1. List reasons why people do not seek healthcare. Do you believe nurses can effect change? If so, what community activities would be most effective?
2. Consider attitudes toward the possibility of future illnesses. How would this affect your plan? What do you believe would be most effective in teaching this age group?
3. Think about what you know about taking prescribed antibiotics as well as the side effects of antibiotic therapy. What would you suggest that Mr. Sanders do?

4. *Powerlessness* is the perception that one's own actions will not significantly affect an outcome. Is this a common response to the diagnosis of cancer? Consider types of communications and interventions that would allow greater decision making for Mr. Sanders.

Chapter 17: Nursing Care of Patients with Burns

A Patient with a Major Burn

1. Review the effects of the major burn wound on the renal and gastrointestinal systems. What assessments would indicate effective fluid resuscitation?
2. What type of burns did Mr. Howard have on his arms? Consider the effect of compression on the peripheral vascular system. What assessments would you make to identify this complication?
3. Consider the type of pain the patient has. What do you think might happen if the narcotics were given by other routes, such as oral or intramuscular?
4. Review the effects of a major burn. Consider the damage to cell wall integrity and capillary beds. What effect does the shift of proteins and sodium have on intravascular volume?

Chapter 19: Nursing Care of Patients with Endocrine Disorders

A Patient with Graves' Disease

1. What effect does increased TH have on metabolism and cardiac rate and stroke volume? How does this effect compare to that of sympathetic stimulation?
2. Consider the effect of elevating any body part, such as elevating your leg above heart level for a sprained ankle. How does this affect venous return?
3. You will need to consider Mrs. Manuel from both a medical and a surgical perspective. How would you teach her to care for her incision? With removal of most of the thyroid gland, what manifestations would you be sure she knew about? What should she do if these occur?

A Patient with Hypothyroidism

1. Make a list of changes in body systems that occur with aging and with decreased TH levels. How would you determine what assessment findings were abnormal?
2. Consider the effects of the following factors: weakness, fatigue, problems with memory. What would you recommend she do in her home to increase her safety?
3. Prepare a list of manifestations of hyperthyroidism. Be sure they are in terms a patient would understand.

A Patient with Addison's Disease

1. Review the functions of the hormones of the adrenal cortex in Chapter 18. Consider the effects of stress, and formulate your response with a rationale.
2. Review content on fluid imbalance in Chapter 10. Make a list of assessments you might make that would indicate severe dehydration. What is the pathophysiology of fluid loss in the patient with Addison's disease?
3. Review content on sodium and potassium in Chapter 10 and make a list of foods you would suggest Mr. Sardoff eat.

Chapter 20: Nursing Care of Patients with Diabetes Mellitus

A Patient with Type 1 DM

1. How do the increased urinary output and increased osmolarity of the blood plasma affect the fluid status of the body? What is the response of the body to decreased intravascular volume?
2. Consider the effects of nicotine on blood vessels. How would these effects, when combined with the pathologic effects of long-standing hyperglycemia, affect blood vessel walls?
3. Review the information about chronic illness in Chapter 3. Powerlessness is a perceived lack of control over a situation and/or one's ability to significantly affect an outcome. What types of statements by a patient would help you make this nursing diagnosis?
4. Compare and contrast the developmental needs and tasks of the young adult and the older adult (see Chapter 3). Consider the teaching materials that might have to be adapted to physical changes in the older adult. Also consider similarities and differences in the management and complications of type 1 and type 2 diabetes.

Chapter 22: Nursing Care of Patients with Nutritional Disorders

A Patient with Obesity

1. Review the physiology of cholesterol formation in the body and the factors that affect this process.
2. Consider developmental stages and teaching strategies for adult learners.
3. Think about individual factors, family and support group influences, and cultural factors that may affect recommended weight loss and exercise strategies.

A Patient with Malnutrition

1. Review the physiology of albumin and cholesterol formation in the body.
2. Review Mrs. Morris's diet and compare it to the food pyramid or recommendations for food intake to formulate your response.
3. Consider cultural influences and the patient's preferred foods as you plan a diet that is high in calories and protein.

Chapter 23: Nursing Care of Patients with Upper Gastrointestinal Disorders

A Patient with Oral Cancer

1. Review the major risk factors for oral cancer and identify the populations most likely to have these risk factors.
2. Work with your classmates to plan (and implement) an education program, considering the developmental/teaching needs of this group of young people.
3. Think about the possible causes for Mr. Chavez's refusal to talk (remember that assessment is the first step of the nursing process). How will you identify factors contributing to his behavior?

A Patient with Peptic Ulcer Disease

1. Review the physiology of the gastric mucosal barrier and the pathogenesis of peptic ulcer disease, and the effect of *H. pylori* infection on these processes.
2. Review physiologic responses to stress in your physiology or nursing fundamentals text; compare and apply this information with the physiology of the gastric mucosal barrier and the pathophysiology of ulcer development.
3. Consider Mr. O'Donnell's occupation and schedule, as well as the prescribed medications and when each should be taken.
4. Using journal and text resources as well as your classmates, identify as many stress reduction techniques as possible. Then sort your list into those that could be used while working, and identify ways to effectively teach each technique.

A Patient with Gastric Cancer

1. Review the healing process and the normal physiology of the stomach as you formulate your answer to this question.
2. Consider the surgery, immediate postoperative care, and what the patient and family should expect in developing your teaching plan.
3. Review Chapter 14 and nursing care related to chemotherapy.
4. Again, review Chapter 14 for nursing care measures for patients with cancer; also review Chapter 22 for strategies to prevent and manage malnutrition.

Chapter 24: Nursing Care of Patients with Bowel Disorders

A Patient with Acute Appendicitis

1. Review the acute inflammatory response to an infectious process and the role WBCs play in the immune response.
2. Review Chapter 4. Consider factors such as incision size, abdominal muscle disruption, and manipulation of the bowel in developing your response.
3. Consider points such as pain management, resumption of activities, incision care, and potential complications in developing your teaching plan. Consider the patient's education and developmental stage as well.
4. Review the effects of anxiety on recovery and learning. Identify nursing measures to reduce situational anxiety.

A Patient with Ulcerative Colitis

1. Review normal functions of the small and large intestine. Review the usual location of an ileostomy. Review fluid volume deficit in Chapter 10 for manifestations and assessment data.
2. Think about the effect of chronic blood loss and review the effect of malnutrition on the hemoglobin and hematocrit.
3. Review the home care section of inflammatory bowel disease for teaching points to include.
4. Review nursing care for the patient with diarrhea, as well as the procedure for ileostomy care.

A Patient with Colorectal Cancer

1. Review peripheral innervation and impulse transmission in your anatomy and physiology textbook; think about how nerves in the rectal region are disrupted in an abdominoperineal resection. Also review the phantom pain phenomenon in Chapter 9.
2. Compare elimination through a colostomy with "normal" bowel elimination through the anus. How do they differ in terms of the passage of flatus?
3. Review the procedure for administering an enema in your fundamentals or skills textbook.
4. Review this nursing diagnosis in your nursing diagnosis or nursing care planning handbook; be sure to individualize your plan to Mr. Cunningham's situation and needs.

Chapter 25: Nursing Care of Patients with Gallbladder, Liver, and Pancreatic Disorders

A Patient with Cholelithiasis

1. Review the composition of gallstones, as well as the physiology of gallbladder function and bile. Research and discuss dietary practices of the Chickasaw tribe (or of Native Americans).
2. Review Chapter 4 for care related to a laparotomy (incision into the abdomen).
3. As you develop your plan, consider Mrs. Red Wing's culture, job, and family obligations.

A Patient with Alcoholic Cirrhosis

1. Review the anatomy and physiology of the liver and its circulation, as well as the pathophysiology of cirrhosis and its complications.
2. Consult your nutrition textbook as needed for foods that are high in calories but low in protein and sodium. When planning for limited protein intake, be sure to include high-quality proteins and limit intake of lower-quality proteins such as legumes.
3. Review the pathophysiology of hepatic encephalopathy to develop your responses to this question.
4. Review therapeutic communication skills; consult your nursing diagnosis and care planning textbook as you develop this care plan.

A Patient with Acute Pancreatitis

1. Review Chapter 6 for assessment data indicative of alcohol withdrawal.
2. Review both the pathophysiology of acute pancreatitis and the acute inflammatory process.
3. Consult your nutrition textbook or the American Dietetic Association website.
4. Consult your nursing care planning textbook to develop this care plan.

Chapter 27: Nursing Care of Patients with Urinary Tract Disorders

A Patient with Cystitis

1. Consider the prescription provided for Mrs. Waisanen and its safe use.
2. See Chapter 12 for patient teaching about antibiotics and specific information about Mrs. Waisanen's prescription. Also refer to your pharmacology text and drug handbook or application.
3. Consider risk factors for UTI as well as factors affecting Mrs. Waisanen's immune function.
4. Consider the indications for short-course antibiotic therapy and the indications for conventional therapy. Think about factors such as cost, compliance, and the risk for adverse effects, as well as how antibiotics work to eradicate bacteria.
5. Identify why *Ineffective Self-Health Management* may be an appropriate nursing diagnosis for Mrs. Waisanen and the individual factors contributing to this diagnosis as you plan care.

A Patient with a Bladder Tumor

1. Consider Mr. Hussain's stated alcohol use and its potential effects on anesthesia and his post operative recovery.
2. Review the risk factors for urinary tract tumors, looking for commonalities and considering the physiology of the bladder and urine formation and elimination.
3. Review Chapters 4 and 9 as you develop your response to Mr. Hussain's statement.
4. Remembering that patients rarely present with one isolated health problem, review Mr. Hussain's health history for possible contributing factors to these manifestations. Then review Chapter 6 for nursing care of the patient with substance abuse. Why might Mr. Hussain experience alcohol withdrawal after 2 to 3 days of hospitalization?
5. Considering the surgery performed and its potential effects on physical function and body image, use your nursing care planning book or guide to identify possible interventions and outcomes for this nursing diagnosis.

Chapter 28: Nursing Care of Patients with Kidney Disorders

A Patient with Acute Glomerulonephritis

1. Review Chapter 12 and the use of antibiotics to treat infection.
2. Research the potential complications and immune responses to group A beta hemolytic streptococcal infections.
3. Consider information about when to contact a healthcare provider and the appropriate use of antibiotics as you develop your teaching plan.
4. Review Mr. Chang's history and the risk factors for acute glomerulonephritis.
5. Review Chapter 26 for patient teaching and nursing responsibilities related to diagnostic studies.
6. Review the diagnostic tests used to differentiate different forms of glomerulonephritis.

A Patient with End-Stage Renal Disease

1. Consider the systemic effects of altered hematology, electrolyte, and renal function tests on functional health as you plan your nursing interventions.
2. Review Chapter 20 for nursing care of the patient experiencing complications of diabetes.
3. Review the usual onset, pathophysiology, and long-term effects of type 1 and type 2 diabetes (Chapter 20).

4. Consider the effects of urea and ammonia (both neurologic toxins) on brain function.
5. Consider the physiology of dialysis, the composition of dialysis solutions (dialysate), as well as potential planned and unplanned effects of peritoneal dialysis.

Chapter 30: Nursing Care of Patients with Coronary Heart Disease

A Patient with Coronary Artery Bypass Surgery

1. Identify Mr. Clements's modifiable risk factors as you develop your plan. What barriers might need to be overcome to implement strategies to reduce his risk factors?
2. What strategies can you use to overcome denial without creating hostility or impairing the patient–nurse relationship?
3. Consider traditional family roles as well as those roles that are unique to these individuals. Identify measures you can use to enlist the spouse's support.
4. Think about therapeutic communications as you formulate your response. Will your age or gender potentially affect your ability to respond effectively to these concerns? Would referral to another healthcare provider be appropriate?

A Patient with Acute Myocardial Infarction

1. Review immediate treatment measures for MI. Are other means available for reestablishing coronary artery perfusion? If you are in a rural area without immediate access to a cardiac catheterization lab, how will this affect your response?
2. Review the section of this chapter on dysrhythmias and their treatment. Research protocols for treating frequent PVCs in the post-MI patient at your clinical facility.
3. Review the goals of cardiac rehabilitation and Mrs. Williams's individual risk factors as you develop your teaching plan.
4. Consider the value of using a therapeutic response to Mrs. Williams's statement concerning smoking. Also consider the risks associated with cigarette smoke. How can you respond without supporting Mrs. Williams's desire to smoke and without precipitating anger or resistance? Review Chapter 6.

A Patient with Supraventricular Tachycardia

1. Review the effects of sympathetic and parasympathetic nervous system stimulation on cardiac function.
2. Review the section on supraventricular tachycardias, as well as the antidysrhythmic medications for other treatment options.
3. Use your pharmacology textbook as you develop your teaching plan.

Chapter 31: Nursing Care of Patients with Cardiac Disorders

A Patient with Heart Failure

1. Review the prescribed medications and their interactions. Do not forget to consider Mr. Jackson's age in assessing his risk for toxicity and interactions.
2. Review therapeutic communication skills and the use of open-ended statements to evaluate the underlying message of Mr. Jackson's statement.
3. Review exercise recommendations for the patient with heart failure as well as cardiac rehabilitation principles (Chapter 30).
4. Review the rationale for aspirin therapy in the patient with CHD and its effects on platelets and clotting as you formulate your response.
5. Review Chapter 42 for causes of stroke and the section of Chapter 30 on atrial fibrillation.

A Patient with Mitral Valve Prolapse

1. Review the pathophysiology and manifestations of MVP, as well as the general treatment measures for valve disorders.
2. Think about the effects of progressive conditioning on cardiac function.
3. Consider the anxiety associated with heart conditions and with a potentially progressive disorder that could affect childbearing and other life activities, as well as ultimately necessitate surgery.
4. Review the manifestations of MVP and of mitral regurgitation.

Chapter 32: Nursing Care of Patients with Vascular and Lymphatic Disorders

A Patient with Hypertension

1. Review Mrs. Spezia's assessment data and the risk factors for primary hypertension.
2. Review the pathophysiology of primary hypertension and of obesity (Chapter 22), as well as the relationship between hypertension and coronary heart disease.
3. Think about resources that are available in your community for homeless people. Talk to community health and social service agencies to identify additional resources.
4. Correlate Mrs. Spezia's assessment data, the pathophysiology of hypertension, and the long-term effects of stress.
5. Use your nursing care planning and nursing diagnosis textbooks to help develop your care plan.

A Patient with Peripheral Vascular Disease

1. Review treatments for peripheral atherosclerosis, as well as lifestyle measures for preventing and treating atherosclerosis and coronary heart disease (Chapter 30).
2. Compare the pathophysiology of peripheral atherosclerosis, intermittent claudication, and coronary heart disease (Chapter 30) to identify similarities and differences.
3. Review the actions of beta-blockers and their role in angina prophylaxis.
4. Use your nursing care planning and nutrition textbooks to help develop your care plan.

A Patient with Deep Venous Thrombosis

1. Review the pathophysiologic processes of venous thrombosis and inflammation.
2. Think about questions you could ask for further information as well as potential resources for Mrs. Hipps.
3. Consider assessment data to evaluate Mrs. Hipps's limitations and resources, as well as community resources to help meet her needs.
4. Use your nursing diagnosis and care planning textbooks to develop your plan of care.

Chapter 33: Nursing Care of Patients with Hematologic Disorders

A Patient with Folic Acid Deficiency Anemia

1. Consider the effects of Mrs. Matthews's rapid weight loss on fluid balance, as well as the effects of tissue hypoxia on cardiac output.
2. Refer to this chapter and your nutrition text. Be sure to consider Mrs. Matthews's age in designing your menu.
3. Consider factors such as Mrs. Matthews's recent dietary history, the folic acid content of foods, and other pertinent factors in the history and physical assessment.
4. In addition to general factors to consider for the older adult (don't forget transportation among other factors), also consider the possible effect of Mrs. Matthews's recent loss and the grieving process.

A Patient with Acute Myelocytic Leukemia

1. Review the physiology of white blood cells, and the immune and inflammatory responses.
2. Think about the risks created by hospitalization in terms of exposure to infection and invasive procedures.
3. Think about the effect of inability to perform self-care on self-esteem, self-confidence, and perception of power and control.

4. Use information provided in the nursing care and home care sections of this chapter as well as in Chapter 12.
5. Use your nursing care planning and fundamentals texts to develop your care plan.

A Patient with Hodgkin's Disease

1. Review Chapter 14 and the effects of chemotherapy and radiation on cancerous cells. Think about the advantages of combining these two therapies in terms of short- and long-term desired and adverse effects.
2. Consider the primary and potential risks for infection in community settings as you design your teaching plan. What teaching strategies will you use for a young adult with Mr. Quito's education and experience?
3. Review theories of development and the developmental tasks for the young adult.
4. Use your nursing fundamentals and nursing care planning texts for reference in developing your care plan.

A Patient with Hemophilia

1. Review the pathophysiology of hemophilia and its effect on the clotting process.
2. Consider both the ABCs and Maslow's hierarchy of needs as you respond to this question.
3. Think about the genetic transmission of hemophilia. How might Mr. Cruise's hemophilia affect any children that he has? Grandchildren?
4. Review your nursing fundamentals book, nursing skills book, and intravenous therapy text to develop your teaching plan. Also consider previous learning and developmental levels.
5. What evidence supports this as an appropriate nursing diagnosis for Mr. Cruise?

Chapter 35: Nursing Care of Patients with Upper Respiratory Disorders

A Patient with Peritonsillar Abscess

1/2. Review the manifestations of upper respiratory infections and management of these disorders.
3. Think about the primary uses of the nose, mouth, and pharynx as you consider nursing diagnoses related to upper respiratory disorders.

A Patient with Nasal Trauma

1. Consider other measures to restore the patient's sense of control over the situation. Consider the potentially traumatic effects of suction on the mucous membranes as well as possible infection control risks.
2. Review the implications and potential dangers of CSF leakage to help you develop your care plan.
3. Think about the benefits and drawbacks of immediate and delayed rhinoplasty.

A Patient with Total Laryngectomy

1. Review the options for speech rehabilitation. If available, practice using a speech generator. Practice esophageal speech.
2. Use your nursing care planning and nursing diagnoses handbook to develop your care plan. Consider Mr. Tom's age, occupation, and marital status in your plan of care.
3. Review Chapter 4 for surgical nursing care interventions, as well as your nursing fundamentals textbook for wound care strategies.
4. Consider measures to promote airway clearance and ventilation of all lung fields.

Chapter 36: Nursing Care of Patients with Ventilation Disorders

A Patient with Pneumonia

1. Review Mrs. O'Neal's assessment data and compare her history with identified risk factors for pneumonia.
2. Review normal immune and inflammatory responses and the role of white blood cells in these processes.
3. Review Chapter 11 and altered immune responses for the physiology and effects of anaphylactic shock.
4. Use your nursing care planning and nursing diagnosis textbooks to help develop your care plan.

A Patient with Tuberculosis

1. Consider available resources for patients with mental illness, as well as community and public health resources. Consider measures to ensure compliance with the prescribed treatment.
2. Contact your local public health department, the discharge planner for your unit, or the social services department in your clinical facility to help identify available resources.
3. Use the nursing care section under Pneumonia, and your nursing diagnosis or care planning handbook as you develop your care plan.

A Patient with Lung Cancer

1. Review Chapter 14 and use your pharmacology text to research the effects of these drugs and the rationale for combination chemotherapy.
2. Use Chapter 14 and your pharmacology text to identify probable side effects of this treatment regimen. Then use your nursing care planning book to identify appropriate nursing diagnoses and interventions.
3. Review the pathophysiology and collaborative care sections for lung cancer to develop your response to this question.

Chapter 37: Nursing Care of Patients with Gas Exchange Disorders

A Patient with COPD

1. Review the processes by which cigarette smoke inflicts damage on lung tissue. Use your pediatric and pathophysiology texts for additional information.
2. Review the physiology of the respiratory drive, as well as the effects of chronic elevated carbon dioxide levels in the blood.
3. Review the manifestations of COPD and its complications as well as the section of this chapter on respiratory failure.
4. Use your nursing diagnosis handbook to help identify appropriate goals and interventions for this nursing diagnosis.

A Patient with ARDS

1. As you respond to this question, consider additional treatment measures for ARDS and respiratory failure. Also consider the potential long-term consequences and complications of intubation and mechanical ventilation. Discuss strategies for communicating with Ms. Adamson's family and supporting coping and decision making by Ms. Adamson and her family in an instance such as this.
2. Think about the precipitating factors for ARDS and the factors that may precipitate respiratory failure in a patient with COPD. Consider the probable overall respiratory and general health status of the individual affected by each of these conditions.
3. Review the precipitating factors for ARDS and discuss strategies to prevent them.
4. Use your nursing care planning book to identify appropriate goals and nursing interventions for this nursing diagnosis.

Chapter 39: Nursing Care of Patients with Musculoskeletal Trauma

A Patient with a Hip Fracture

1. Consider Mrs. Carbolito's age and the fact that she is postmenopausal. What effect does estrogen have on bone health? What might have increased her risk for falls?
2. Review the principles of traction application. What purpose does it serve prior to surgery? What words could you use that she would

understand? Think about the effects of trauma, pain, and suddenly finding oneself in a strange environment on listening and understanding verbal communications.
3. List how each of these manifestations would affect skin integrity, food intake, and bone healing.

A Patient with a Below-the-Knee Amputation
1. Consider your role as a nurse and therapeutic communications techniques you could use in responding to Mr. Rocke. You also may wish to review Chapter 5 in developing your response.
2. Review Mr. Rocke's subjective and objective assessment data, interprofessional care needs, and apparent stage of grieving to help prioritize nursing activities.
3. Review the roles of and resources available to various members of the interprofessional team.
4. Design a sequential plan for Mr. Rocke's self-care of the stump. Consider his readiness to learn and the complexity of the care. Is there a risk in letting him assume total responsibility from the beginning? Why or why not?
5. List the factors used to describe Mr. Rocke. How do these affect his ability or willingness to follow up with medical care? What community agencies are available where you live or go to school that would be good sources of assistance and support for Mr. Rocke?
6. Review the information about exercise. How would Mr. Rocke's choice not to do exercises affect his ability to use a prosthesis to walk?

Chapter 40: Nursing Care of Patients with Musculoskeletal Disorders

A Patient with Osteoporosis
1. Use an Internet search engine to find the World Health Organization FRAX Fracture Risk Assessment Tool.
2. Identify data needed but not provided in the scenario to complete this assessment.
3. What is the purpose of this tool and how will you explain the results obtained to Mrs. Bauer? Explain the information in terms Mrs. Bauer can understand and relate to.
4. Review the effects of nicotine and caffeine on blood circulation to bones. What effect does alcohol play in bone loss?
5. Review foods that increase blood cholesterol levels. What is considered a normal cholesterol level? You may need to read content in Chapter 31. Knowing the patient needs calcium, what type of dairy products would you recommend?
6. List activities for the patient who is not able to be ambulatory. How many of the activities on your list would help prevent osteoporosis?

A Patient with Osteoarthritis
1. Review information about Parkinson's disease, its treatment, and nursing care for the patient with Parkinson's disease in Chapter 44.
2. Consider the manifestations of Parkinson's disease and how those manifestations may affect Mr. Cerulli's ability to turn, cough, and deep breath as well as begin ambulating after surgery.
3. Using information in Chapter 44 and in your pharmacology text and drug handbook or application, identify potential interactions between medications used to manage Parkinson's disease, anesthetics, analgesics, and other medications likely to be prescribed for Mr. Cerulli. Also consider the effects of Parkinson's disease and risks for common postoperative complications.
4. Review information about serum creatinine and BUN in a laboratory studies textbook or on the web. What medications is Mr. Cerulli taking that may be affecting these findings? Consider what teaching is necessary related to these findings.
5. What assessments are significant for confusion? If necessary, review content related to confusion. Review Mr. Cerulli's history in the case study and determine factors that may have contributed to his risk for confusion before, during, and after surgery.
6. *Acute Confusion* is defined as an abrupt onset of reversible disturbances in attention, cognition, psychomotor activity, level of consciousness, and/or sleep–wake cycle. What assessments could you make to support this diagnosis for Mr. Cerulli? What interventions might you design for this diagnosis?

A Patient with Rheumatoid Arthritis
1. Review the diagnostic criteria and tests used to establish the diagnosis of RA.
2. Use Chapter 38 and your laboratory and diagnostic tests handbook to identify other potential causes of abnormal test results.
3. Review Chapter 38 for the nursing implications and patient teaching related to diagnostic testing for RA.
4. Think about the role differences in a 40-year-old woman and a 72-year-old woman. On the other hand, consider the effects of a chronic illness that may have been present for 30 years. Would your plan differ? Why or why not?
5. Review information about chronic illness in Chapter 3. List the possible disabilities that may be caused by rheumatoid arthritis. How do you believe these would affect Mrs. James? What agencies in your community are available for support of people with this type of illness? Where would you go for literature to give Mrs. James?
6. *Ineffective Role Performance* is defined as behaviors and expressions that do not match norms or expectations. Do you believe this is an appropriate nursing diagnosis for Mrs. James? Why or why not? What interventions could be implemented for this diagnosis?

Chapter 42: Nursing Care of Patients with Intracranial Disorders

A Patient with a Seizure Disorder
1. List the teaching topics you would include for Ms. Carlson. Consider how her needs (e.g., for safety) would differ if she lived alone.
2. Describe statements you could use to help Ms. Carlson understand not only the dangers but also the legal issues involved. What if Ms. Carlson does not recognize these concerns?
3. What type of questions could you ask Ms. Carlson to determine why she feels this way? Would you personally find it embarrassing? How can you facilitate Ms. Carlson's understanding of this recommendation?

A Patient with a Stroke
1. What subjective manifestations does the patient with hypertension have? (Review content in Chapter 32.)
2. Consider referral to community resources as a volunteer tutor for adult literacy, gardening, and/or woodworking. Tutoring college students is another option.
3. Use statements that will encourage Mr. Boren to talk about his arm and how he feels about being unable to use it.

A Patient with a Subdural Hematoma
1. Review the manifestations of the types of intracranial hematomas. What assessments are specific to a subdural hematoma? Why is it important to know this?
2. What are some other interventions that might be used? How could family help? What if no family members are available?
3. *Acute Confusion* is a sudden onset of changes in attention, cognition, psychomotor activity, level of consciousness, and/or sleep–wake cycle. What would you determine as priority nursing diagnoses and interventions for Mr. Lee?

A Patient with a Brain Tumor
1. Review content in the chapter on increased intracranial pressure and intracranial surgery. List collaborative and nursing interventions to decrease increased intracranial pressure.

2. What do these manifestations indicate? What would be your priority assessment? Who would you notify?
3. Practice the use of therapeutic communications and what response you would make.
4. Consider the reasons Ms. Lange feels powerless. What nursing interventions might decrease this feeling?

Chapter 43: Nursing Care of Patients with Spinal Cord Disorders and CNS Infections

A Patient with an SCI

1. What are the developmental tasks of a 19-year-old? How does the inability to meet these tasks affect emotional responses?
2. Think about questions that explore Mr. Valdez's fears in relation to sexuality. Practice questions and statements with friends until you are not embarrassed to ask them.
3. Consider how your own values and beliefs may differ from those of a patient.
4. What baseline assessments and information are necessary before developing a plan for urinary elimination needs? Why would self-catheterization be an option? What are the risks of long-term Foley catheterization?

A Patient with Bacterial Meningitis

1. List the environmental stimuli in the hospital setting. How could these be decreased? What effect do these stimuli have on cognition and behavior that is altered by an intracranial infection?
2. Think about how you would feel if Mr. Cook tried to hit you. How would you respond to him? To whom would you report this?
3. Why would Mr. Cook have pain? How would pain be manifested during the initial treatment period? Is it important to consider the respiratory effects of narcotics for him? Defend your answer.

Chapter 44: Nursing Care of Patients with Neurologic Disorders

A Patient with Alzheimer's Disease

1. Think about what information you would need and how you would collect it. Consider such factors as the age of family members, educational level of family members, and stage of the patient's AD. What else would you need to know?
2. Review the suggested activities in this section of the chapter. What others can you think of or have you seen used successfully? Osteoarthritis often results in joint stiffness and pain as well as problems with mobility. Would this affect your interventions? If so, how could they be adapted?
3. Consider the type of foods that might be prepared, the timing of meals, and interventions that might be used to decrease agitation before or during meals.

A Patient with Multiple Sclerosis

1. Outline a typical day's activities for Mr. McMurphy that would provide a balance between activity and rest. What assessments would you make to evaluate the effectiveness of this plan?
2. Consider how respiratory infections are spread. Why is Mr. McMurphy at increased risk?
3. The definition of *Risk for Injury* is that one is at risk as a result of environmental conditions interacting with the person's adaptive and defensive resources. What factors in this patient's history and physical status would support this diagnosis? What interventions would you include in the care plan and why?

A Patient with Parkinson's Disease

1. Consider the adaptations that might be made to clothing and shoes. What adaptive devices might be useful?
2. What information would you need to know before you develop your interventions? Include information obtained from Mr. Ralph and what might be available in the community and the long-term care facility.
3. *Chronic Sorrow* is a recurring pattern of sadness in response to continual loss. Consider the type of communications you would need to use with Mr. Ralph to identify his degree of sorrow. What other assessment might provide cues to support this diagnosis (think about eating and sleeping)? How might an activity such as reminiscence help?

Chapter 46: Nursing Care of Patients with Eye and Ear Disorders

A Patient with Glaucoma and Cataracts

1. Consider the class of each of these drugs and their potential adverse effects as you develop your response to this question.
2. Review the general risks associated with eye surgery as well as those specific to cataract surgery. Develop a teaching plan for Mrs. Rainey related to these risks, their manifestations, and how she should respond should they occur.
3. What is the pathophysiology of glaucoma? How does a cataract affect glaucoma?
4. Consider the effects of corticosteroids on glaucoma. If Mrs. Rainey is to administer several medications at home, identify specific teaching guidelines for her.
5. Would you request a referral for home health visits? Why or why not? Think about the effect of transferring her for a brief admission to an assisted-living facility.

Chapter 48: Nursing Care of Men with Reproductive System and Breast Disorders

A Man with Prostate Cancer

1. Why would Mr. Turner be at risk for altered skin integrity? Outline the interventions you would include on his teaching plan that would promote skin integrity as he cares for himself at home.
2. Noncompliance is defined as behaviors that do not coincide with the therapeutic plan agreed on by the person and the healthcare professional. Do you think Mr. Turner fully understood his treatment and agreed with his follow-up care? What could be done in the preoperative phase of Mr. Turner's care to better ensure his understanding and desire to have continued medical care?
3. What assessments indicate that Mr. Turner does or does not have bladder distention? Would you report this? If so, to whom?

Chapter 49: Nursing Care of Women with Reproductive System and Breast Disorders

A Woman with Endometriosis

1. What is the relationship between Mrs. Hall's manifestations and a decreased RBC count? Review the information in Chapter 32 and list assessments you would make to identify anemia.
2. List nonthreatening questions you would use to begin the discussion. How might it help to ask these questions at the beginning of the interview? Then list questions that you might use to collect data about the couple's sexual history. Would you be embarrassed to ask them? If so, how might this in turn affect their responses?
3. *Situational Low Self-Esteem* is the state in which a person develops a negative perception of self-worth in response to a current situation. What information in Mrs. Hall's history might provide data to support this nursing diagnosis?

A Woman with Cervical Cancer

1. Consider developmental needs and how they differ by age. Also consider current options for preventing HPV infection and reducing the risk for cervical cancer.
2. Review the effects of radiation, discussed in Chapter 14.
3. Does fatigue differ from "feeling tired"? Can the fatigue from radiation be decreased? If so, how?

A Woman with Breast Cancer

1. Review the information in Chapter 8 and in this chapter on the genetic factors that pose a risk for developing breast cancer. How could you explain this in terms understandable by Mrs. Clemments and her daughters?
2. List the different types of mastectomies. Consider the implications of the differences, and how this would affect your nursing care.
3. Review the information on chemotherapy in Chapter 14. List the types of chemotherapy and its common side effects. Consider the classifications of medications that are used to treat these side effects.
4. What factors in Mrs. Clemments's treatment might disrupt the amount and quality of her sleep? What interventions might be used to improve her sleep pattern?

Chapter 50: Nursing Care of Patients with Sexually Transmitted Infections

A Patient with Gonorrhea

1. What manifestations does Ms. Cirit have that are typical of the disease? Would you make other assessments? If so, what are they?
2. Review the discussion of HIV in Chapter 13. Do you believe it is true that infection with gonorrhea may increase the risk of HIV? If so, how would you explain this to Ms. Cirit?
3. *Impaired Social Interaction* is a state of aloneness or rejection experienced by an individual that is perceived as negative. What assessments of Ms. Cirit might support this diagnosis? What interventions and expected outcomes would you develop?

A Patient with Syphilis

1. Describe the assessments you would expect to find in a man or woman with early syphilis.
2. Consider topics such as number of sex partners, patterns of sexual activity, and use of safer sex practices. What other topics should be explored? How can you ask these questions without being embarrassed or embarrassing the patient?
3. List possible statements you might make. Do you believe this is a nursing responsibility? If you do not feel comfortable with this topic, what could you do?

Glossary

Abrasion Partial-thickness denudation of an area of integument, generally resulting from falls or scrapes.

Abscess A localized collection of pus.

Absence seizure (petit mal seizure) A type of generalized seizure characterized by a sudden brief cessation of all motor activity accompanied by a blank stare and unresponsiveness.

Accommodation The ability of the eye to adjust to variations in distance.

Accountable care organization (ACO) An organization aimed at providing accessible, comprehensive and coordinated primary care focused on illness prevention for patients and families.

Achalasia Absence of peristalsis of the esophagus and high gastro-esophageal sphincter pressure resulting in dilation and loss of tone in the esophagus.

Acidosis The condition in which the hydrogen ion concentration increases above normal (reflected in a pH below 7.35).

Acids A substance that releases hydrogen ions in solution.

Acne Disorder of the pilosebaceous (hair and sebaceous gland) structure, resulting in eruption of papules or pustules.

Acoustic neuroma or schwannoma Benign tumor of cranial nerve VIII.

Acquired immune deficiency syndrome (AIDS) A specific group of diseases or conditions that are indicative of severe immunosuppression related to infection with the human immunodeficiency virus.

Acquired immunity Immunity developed after exposure to a pathogen. See *Active immunity*.

Acquired immunodeficiency syndrome (AIDS) The final stage of HIV infection characterized by severe immune deficits and opportunistic infections.

Acromegaly Meaning literally "enlarged extremities," this is a condition resulting from excessive growth hormone secretion during adulthood.

Actinic keratosis Also called *senile* or *solar keratosis,* this is an epidermal skin lesion directly related to chronic sun exposure and photodamage.

Active immunity Production of antibodies or development of immune lymphocytes against specific antigens.

Active transport Movement of molecules across cell membranes and epithelial membranes against a concentration gradient; requires energy.

Acute coronary syndrome (ACS) A condition of unstable cardiac ischemia; includes unstable angina and acute myocardial ischemia with or without significant myocardial tissue injury.

Acute gastritis A benign, self-limiting disorder associated with ingestion of gastric irritants such as aspirin, alcohol, caffeine, or foods contaminated with certain bacteria.

Acute illness An illness that occurs rapidly, lasts for a relatively short time, and is self-limiting.

Acute kidney injury (AKI) A rapid decline in renal function with azotemia and fluid and electrolyte imbalances; also known as acute renal failure.

Acute lymphoblastic leukemia (ALL) Abnormal proliferation of lymphoblasts in the bone marrow, lymph nodes, and spleen; the most common type of leukemia in children and young adults.

Acute myeloblastic leukemia (AML) Uncontrolled proliferation of myeloblasts (granulocyte precursors) and hyperplasia of bone marrow and the spleen; the most common acute leukemia in adults.

Acute myocardial infarction (AMI) Necrosis (death) of myocardial cells.

Acute pain Pain of sudden onset that is usually self-limited and localized; it lasts for less than 6 months and has an identifiable cause, such as trauma, surgery, or inflammation.

Acute renal failure Abrupt onset of renal failure, also known as acute kidney injury.

Acute respiratory distress syndrome (ARDS) Noncardiac pulmonary edema and progressive refractory hypoxemia.

Acute tubular necrosis (ATN) A syndrome of abrupt and progressive decline in tubular and glomerular function.

Adaptive immune response A specific and systemic immune initiated by and directed against particular antigens.

Adaptive immunity Long-lasting and specific response of the lymphocytes to antigens.

Addiction A primary, chronic neurobiologic disease characterized by compulsive use of a substance despite negative consequences, such as health threats or legal problems.

Addison's disease Primary adrenal insufficiency characterized by chronic deficiency of cortisol, aldosterone, and adrenal androgens, and by skin pigmentation.

Addisonian crisis A life-threatening response to acute adrenal insufficiency. Triggers include surgery, acute systemic illness, trauma, or abrupt withdrawal of long-term corticosteroid therapy.

Advance directive Also called a *living will*, this is a document in which a patient formally states preferences for health care in the event that he or she later becomes mentally incapacitated, and names a person who has durable power of attorney to serve as a substitute decision maker to implement the patient's stated preferences.

Aesthetic surgery See *Cosmetic surgery*.

Afterload The force the ventricles must overcome to eject their blood volume; the pressure in the arterial system ahead of the ventricles.

Agnosia The inability to recognize one or more subjects that were previously familiar; agnosia may be visual, tactile, or auditory.

Agranulocytosis Severe neutropenia, with less than 200 cells/μm.

Aid in dying Is an end-of-life care option in which mentally competent, terminally ill adults can ask their physician to provide a prescription for medication that the patient can self-administer to end life peacefully.

Alcohol Alcohol and other CNS depressants act on other neurotransmitters in the brain such as gamma-aminobutyric acid (GABA). GABA is the most prevalent inhibitory neurotransmitter in the brain and has a major role in decreasing neuronal excitability. Alcohol creates an additive effect with GABA, further inhibiting arousal and depressing the autonomic nervous system.

Alcoholic cirrhosis (Laënnec's cirrhosis) The end result of alcoholic liver disease.

Alkalis Alkalis are bases that accept hydrogen ions in solution.

Alkalosis The condition where the hydrogen ion concentration decreases below normal (reflected in a pH above 7.45).

Alleles Different forms of a gene or DNA occupying the same place on a pair of chromosomes; an allele for each gene is inherited from each parent.

Allergy A hypersensitivity response to environmental or exogenous antigens.

Allografts Grafts between members of the same species but who have different genotypes and HLA antigens. See also *Homograft*.

Alopecia Loss of hair; baldness.

Alzheimer's disease (AD) A form of dementia characterized by progressive, irreversible deterioration of the general intellectual functioning.

Amenorrhea Absence of menstruation.

Amphetamine Central nervous system stimulant that causes arousal and an elevation of mood with a sense of increased strength, mental capacity, self-confidence, and a decreased need for food and sleep.

Amputation Partial or total removal of a body part.

Amyotrophic lateral sclerosis (ALS) Progressive, degenerative neurologic disease characterized by weakness and wasting of the involved muscles, without any accompanying sensory or cognitive changes; also called *Lou Gehrig's disease*.

Analgesic A medication that reduces or eliminates the perception of pain.

Anaphylactic shock Shock resulting from a widespread hypersensitivity reaction (called *anaphylaxis*). The pathophysiology in this type of shock includes vasodilation, pooling of blood in the periphery, and hypovolemia with altered cellular metabolism.

Anaphylaxis An acute systemic type I hypersensitivity reaction that occurs in response to an injected antigen.

Anaplasia The regression of a cell to an immature or undifferentiated cell type.

Anasarca Severe, generalized edema.

Androgens Hormones synthesized in the testes, ovaries, and adrenal cortex that promote expression of male sex characteristics.

Anemia An abnormally low number of circulating RBCs, hemoglobin concentration, or both.

Anergy Inability to react to specific antigens.

Anesthesia Use of drugs to produce sedation, analgesia, reflex loss, and muscle relaxation during a procedure.

Aneurysm Abnormal dilation of a blood vessel, commonly at a site of a weakness or tear in the vessel wall.

Angina pectoris (angina) Chest pain resulting from reduced coronary blood flow that causes a temporary imbalance between myocardial blood supply and demand.

Angioma (hemangioma) Benign vascular tumor.

Anion gap The difference between the sum of two measured anions, chloride and bicarbonate, and the principal measured cation, sodium.

Ankylosing spondylitis A chronic inflammatory arthritis that primarily affects the axial skeleton, leading to pain and progressive stiffening and fusion of the spine.

Anorexia nervosa An eating disorder characterized by a body weight less than 85% of expected for age and height, and an intense fear of gaining weight.

Anorexia Loss of appetite.

Anorgasmia Absence of orgasm.

Anosmia Inability to smell.

Anthropometric measurements Measurement of height, weight, triceps skin folds, and midarm circumference.

Antibodies Immunoglobulin molecules that bind with an antigen to inactivate it.

Antibody-mediated (humoral) immune response Activation of B cells to produce antibodies to respond to antigens such as bacteria, bacterial toxins, and free viruses.

Anticipatory grieving A combination of intellectual and emotional responses and behaviors by which people adjust their self-concept in the face of a potential loss.

Antigen A substance capable of evoking a specific immune response; usually a protein which the body recognizes as foreign, causing an immune response to be stimulated.

Antigenic substances Agents such as microorganisms, cells and tissues from other humans or animals, and some inorganic substances that stimulate an immune response.

Aortic valve The semilunar valve between the left ventricle of the heart and the aorta. It prevents blood from flowing backward into the ventricle.

Aortitis Inflammation of the aorta, usually the aortic arch.

Aphasia Defective or absent language function.

Apical impulse A normal, palpable pulsation (thrust) in the area of the midclavicular line in the left fifth intercostal space. It can be seen on inspection in about half of the adult population.

Aplastic anemia A condition manifested by failure of the bone marrow to produce all three types of blood cells.

Apnea Cessation of breathing lasting from a few seconds to a few minutes.

Appendectomy Surgical removal of the appendix.

Appendicitis Inflammation of the vermiform appendix.

Applicability How well research findings can be applied to specific patient care.

Appraisal Judgment of the value of external evidence.

Apraxia The inability to carry out a motor pattern (such as drawing a figure) even when strength and coordination are adequate.

Areflexia Lack of normal reflexes.

Arterial blood gas (ABG) A laboratory test used to evaluate acid–base balance and gas exchange.

Arteriovenous (AV) malformation A congenital intracranial lesion, formed by a tangled collection of dilated arteries and veins, that allows blood to flow directly from the arterial into the venous system, bypassing the normal capillary network.

Arthoscopy Insertion of an arthroscope into a joint for diagnosis or treatment.

Arthralgia Joint pain.

Arthritis Joint inflammation.

Arthroplasty The reconstruction or replacement of a joint.

Ascites Excess fluid in the peritoneal cavity.

Asphyxiation Oxygen deprivation.

Assisted suicide The means to end a patient's life is provide to the patient with knowledge of the patient's intention.

Association Indicates only a relationship, not cause and effect in research.

Asthma Chronic inflammatory disorder of the airways that is characterized by recurrent episodes of wheezing, breathlessness, chest tightness, and coughing.

Astigmatism A condition that develops with abnormal curvature of the cornea or eyeball, causing the image to focus at multiple points on the retina.

Ataxia Uncoordinated, irregular gait and muscle movement; weakness.

Atelectasis Collapse of lung tissue following obstruction of the bronchus or bronchioles.

Atherosclerosis A form of arteriosclerosis in which deposits of fat and fibrin obstruct and harden the arteries.

Atopic dermatitis (eczema) Common inflammatory skin disorder of unknown cause.

Atrial kick Delivery of an additional bolus of blood to the ventricles resulting from atrial systole; occurs just prior to ventricular systole.

Atrial natriuretic peptide (ANP) A hormone released by atrial muscle cells in response to distention from fluid overload.

Aura Sensation preceding generalized seizure activity; may be a vague sense of uneasiness or an abnormal sensation.

Auscultatory gap A temporary disappearance of sound between the systolic and diastolic BP.

Autograft A transplant of the patient's own tissue (e.g., skin, bone marrow).

Autografting Transplanting of the patient's own tissue; the most successful type of tissue transplant.

Autoimmune disorder Failure of immune system to recognize itself, resulting in normal host tissue being targeted by immune defenses.

Autonomic dysreflexia Exaggerated sympathetic response that occurs in patients with spinal cord injuries at or above the T_6 level.

Autosomal dominant Genetic conditions that result from an altered gene on any of the 22 autosomes in spite of the fact that one unaltered or normal gene exists.

Autosomal recessive Genetic conditions that require two copies of an altered gene on any of the 22 autosomes to express the condition.

Autosome A single chromosome from any one of the 22 pairs of chromosomes not involved in sex determination (X or Y); humans have 22 pairs of autosomes.

Azotemia Increased blood levels of nitrogenous waste products.

B lymphocytes (B cells) Bursa-equivalent lymphocytes responsible for synthesizing antibodies in response to specific antigens.

Bacterial vaginosis Nonspecific vaginitis.

Bactericidal Capable of killing organisms without immune system intervention.

Bacteriostatic Inhibits growth of microorganisms, leaving the destruction to the host's immune system.

Bacteriuria Bacteria in the urine.

Balanced suspension traction Traction in which several forces of pull work in unison to raise and support the patient's injured extremity off the bed and maintain its alignment.

Balloon tamponade The application of pressure to stop esophageal bleeding using an inflatable balloon.

Bariatrics The healthcare science that focuses on patients who are extremely obese.

Basal cell cancer An epithelial tumor believed to originate either from the basal layer of the epidermis or from cells in the surrounding dermal structures.

Basal cell carcinoma Epithelial tumor that is believed to originate either from the basal layer of the epidermis or from cells in the surrounding dermal structures. These tumors are characterized by an impaired ability of the basal cells of the epidermis to mature into keratinocytes, with mitotic division beyond the basal layer.

Basal ganglia Deeply placed mass of gray matter in the brain.

Basal metabolic rate (BMR) Test to measure the energy used when the body is at rest; rarely used due to the availability of more accurate thyroid tests.

Base excess (BE) A calculated value also known as buffer base capacity. Base excess reflects the degree of acid–base imbalance by indicating the status of the body's total buffering capacity.

Bases (or alkalis) Substances that accept hydrogen ions in solution.

Bell's palsy (facial paralysis) Disorder of the facial nerve (seventh cranial nerve), characterized by unilateral paralysis of the facial muscles.

Benign prostatic hyperplasia (BPH) Enlargement of the prostate gland.

Bereavement The time of mourning experienced after a loss.

Bile A greenish, watery solution containing bile salts, cholesterol, bilirubin, electrolytes, water, and phospholipids.

Biliary colic A severe, steady pain in the epigastric region or upper right quadrant of the abdomen caused by obstruction and increased pressure in the bile duct.

Binge-eating disorder A nutritional disorder characterized by recurrent episodes of binge eating—eating an excessive amount of food during a defined period of time and a sense of loss of control over eating during binge episodes.

Biofeedback An electronic method of measuring autonomic physiologic responses, such as brain waves, muscle contraction, and skin temperature, and then "feeding" this information back to the patient.

Biological markers Stable segments of DNA important for the construction of chromosome maps.

Bioterrorism Use of an etiologic agent (disease) to cause harm or kill a population, food, and/or livestock.

Biotherapy Treatment that modifies the biologic processes that result in malignant cells, primarily through enhancing the person's own immune responses.

Bivalving Process of splitting a cast down both sides to alleviate pressure on the injured extremity.

Blood clot See *Thrombosis*.

Blood flow The volume of blood transported in a vessel, in an organ, or throughout the entire circulation over a given period of time.

Blood pressure The tension or pressure exerted by blood against arterial walls.

Blunt trauma The type of trauma that occurs when there is no communication from the damaged tissues to the outside environment.

Body mass index (BMI) Used to identify excess adipose tissue, BMI is calculated by dividing the weight (in kilograms) by the height (in meters squared, m^2).

Bone marrow transplant (BMT) Infusion of bone marrow cells to restore bone marrow function after chemotherapy or radiation. Allogeneic BMT uses donor bone marrow cells from a donor; autologous BMT uses the patient's own bone marrow. See also *stem cell transplant*.

Borborygmi Loud rushing bowel sounds.

Borborygmus The presence of excessive loud and hyperactive bowel sounds.

Botulism A severe, life-threatening form of food poisoning caused by *Clostridium botulinum*.

Brachytherapy A type of radiation therapy in which the source of radiation is placed directly into or adjacent to the tumor, a technique that delivers a high dose to the tumor and a lower dose to normal tissue.

Bradycardia A heart rate of less than 60 beats per minute.

Bradykinesia Slowed movements due to muscle rigidity.

Bradypnea Abnormally low respiratory rate.

Brain abscess Infection with a collection of purulent material within the brain tissue.

Brain death criteria Clinical signs used to determine whether a comatose patient is brain dead.

Brain death The cessation of cerebral blood flow with global brain infarction and permanent loss of all brain function.

Breakthrough pain Pain that exceeds baseline chronic or persistent pain, with or without baseline analgesia.

Bronchiectasis Permanent abnormal dilation of one or more large bronchi and destruction of bronchial walls, usually accompanied by infection.

Bronchitis Inflammation of the bronchi (airways).

Bruit An adventitious sound heard during auscultation; of venous or arterial origin.

Buffer A substance that prevents major changes in pH by removing or releasing hydrogen ions.

Bulimia nervosa An eating disorder characterized by recurring episodes of binge eating followed by purge behaviors such as self-induced vomiting, use of laxatives or diuretics, fasting, or excessive exercise.

Burn shock Hypovolemic shock resulting from the shift of a massive amount of fluid from the intracellular and intravascular compartments into the interstitium following burn injury.

Burn An injury resulting from exposure to heat, chemicals, radiation, or electric current.

Bursitis Inflammation of the bursa.

Cachexia The wasted physical appearance characteristic of cancer and other chronic illnesses. It is characterized by rapid depletion of the body's protein, particularly in skeletal muscle, with less rapid loss of fat.

Caffeine A methylxanthine stimulant that increases the heart rate and acts as a diuretic.

Calculi Presence of abnormal concentration or stones in the body occur in the gallbladder, kidneys, ureters, bladder, or urethra.

Cancer A family of complex diseases with manifestations that vary according to body system and type of tumor cells involved; marked by uncontrolled growth and the spread of abnormal cells.

Candidiasis Infection of mucous membranes caused by *Candida albicans*, a yeast-like fungus.

Cannabis sativa Cannabis sativa is the source of marijuana.

Carbuncle A group of infected hair follicles.

Carcinogen Cancer-causing agent.

Carcinogenesis The production or origin of cancer.

Carcinoma A tumor arising from epithelial tissue.

Cardiac arrest Sudden failure of the heart to pump.

Cardiac cycle The contraction and relaxation of the heart during one heartbeat.

Cardiac index (CI) Cardiac output adjusted for body size.

Cardiac output (CO) The amount of blood pumped by the ventricles into the pulmonary and systemic circulations in 1 minute.

Cardiac rehabilitation A long-term program of medical evaluation, exercise, risk factor modification, education, and counseling designed to limit the physical and psychologic effects of cardiac illness and improve the patient's quality of life.

Cardiac reserve The ability of the heart to respond to the body's changing need for cardiac output.

Cardiac tamponade Compression of the heart due to pericardial effusion, trauma, cardiac rupture, or hemorrhage.

Cardiogenic shock Shock that occurs when the heart's pumping ability is compromised to the point that it cannot maintain cardiac output and adequate tissue perfusion.

Cardiomegaly Enlargement of the heart.

Cardiomyopathy Primary abnormality of the heart muscle that affects its structural or functional characteristics.

Cardiovascular disease (CVD) Generic term for disorders of the heart and blood vessels.

Care bundle A small set of evidence-based interventions for a defined patient population and care setting aimed at improving patient outcomes.

Carpal spasm Decreased calcium levels cause the patient's hand and fingers to contract in response to occlusion of the blood supply by a blood pressure cuff (Trousseau's sign).

Carpal tunnel syndrome Compression of the median nerve as a result of inflammation and swelling of the synovial lining of the tendon sheaths.

Carrier Any individual who carries a single copy of an altered gene or mutation for a recessive condition on one chromosome of a chromosome pair and an unaltered form of that gene on the other chromosome. A carrier generally is not affected by the gene alteration; on the average, each person in the general population is a carrier of five or six gene mutations for recessive disorders.

Carriers (related to infections) Harbor the pathogen without showing evidence ofclinical disease.

Catabolism Biochemical process involving the breakdown of complex structures into simpler forms.

Cataract Opacification (clouding) of the lens of the eye.

Causation Indicates factor(s) that lead to an outcome.

Celiac disease (celiac sprue, nontropical sprue) Chronic hereditary disorder characterized by sensitivity to the gliadin fraction of gluten, a cereal protein.

Cell cycle The four phases that occur during growth and development of a cell.

Cell-mediated (cellular) immune response Direct or indirect inactivation of antigen by lymphocytes.

Cellulitis A localized infection of the dermis and subcutaneous tissue.

Central nervous system depressants Central nervous system depressants, including barbiturates, benzodiazepines, paraldehyde, meprobamate, and chloral hydrate, are subject to abuse.

Central obesity See *Upper body obesity*.

Central pain Related to a lesion in the brain that may spontaneously produce high-frequency bursts of impulses that are perceived as pain.

Cerebral concussion Transient, temporary, neurogenic dysfunction caused by mechanical force to the brain.

Cerebral contusion Bruise on the surface of the brain.

Cerebral edema An increase in the volume of brain tissue due to abnormal accumulation of fluid in brain cells.

Cerumen Earwax.

Chalazion Granulomatous cyst or nodule of the lid.

Chancre Hard, syphilitic primary ulcer.

Cheilosis Cracks at corners of the mouth seen in vitamin B-complex deficiencies, especially riboflavin.

Chemotherapy Cancer treatment involving the use of cytotoxic medications to decrease tumor size, adjunctive to surgery or radiation therapy, or to prevent or treat suspected metastases.

Chlamydia A group of syndromes caused by *Chlamydia trachomatis*, a bacterium that behaves like a virus spreading within a host cell; spread by sexual contact and to the neonate by passage through the birth canal of an infected mother.

Cholecystectomy Removal of the gallbladder.

Cholecystitis Inflammation of the gallbladder, usually associated with stones in the cystic or common bile duct.

Cholelithiasis Formation of stones (calculi) within the gallbladder or biliary duct system.

Cholera Acute diarrheal illness caused by certain strains of *Vibrio cholerae*.

Chorea Jerky, rapid, involuntary movements.

Chromosome Genetic material carried by each cell; found in the cell nucleus.

Chronic bronchitis Excessive secretion of bronchial mucus characterized by a productive cough lasting 3 or more months in 2 consecutive years.

Chronic gastritis Disorders characterized by progressive and irreversible changes in the gastric mucosa.

Chronic hepatitis Chronic infection of the liver; the primary cause of liver damage leading to cirrhosis, liver cancer, and liver transplantation.

Chronic illness A condition that requires continuing management over a long period—years or even decades.

Chronic kidney disease (CKD) The presence of kidney damage for three or more months with loss of nephron units and decreased renal mass leading to progressive deterioration of glomerular filtration, tubular secretion, and reabsorption.

Chronic lymphocytic leukemia (CLL) Proliferation and accumulation of small, abnormal, mature lymphocytes in the bone marrow, peripheral blood, and body tissues; least common type of the major leukemias.

Chronic myelogenous leukemia (CML) Abnormal proliferation of all bone marrow elements, usually associated with a chromosome abnormality (the Philadelphia chromosome).

Chronic obstructive pulmonary disease (COPD) Chronic air flow obstruction due to chronic bronchitis and/or emphysema.

Chronic otitis media Condition involving permanent perforation of the tympanic membrane, with or without recurrent pus formation and often accompanied by changes in the mucosa and bony structures (ossicles) of the middle ear.

Chronic pain Prolonged pain, usually lasting longer than 6 months; pain that persists after the condition causing it has resolved; may be malignant or nonmalignant in origin

Chronic sorrow A cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced in response to continual loss, throughout the trajectory of an illness or disability.

Chronic stump pain The result of neuroma formation, causing severe burning pain.

Chronic venous insufficiency A chronic disorder of inadequate venous return.

Chvostek's sign Contraction of the lateral facial muscles in response to tapping the face in front of the ear; caused by decreased blood calcium levels.

Chyme Thick, fluid mixture of food and gastric juices formed in the stomach during the digestive process.

Circulating nurse A registered nurse who coordinates and manages a wide range of activities before, during, and after surgical procedures.

Cirrhosis A progressive, irreversible disorder, eventually leading to liver failure; the end stage of chronic liver disease.

Clinical reasoning A complex process using cognition, metacognition, and discipline specific knowledge to gather and analyze patient information, evaluated its significance, and weigh alternative actions.

Closed fracture (simple fracture) Break in continuity of bone with skin still intact.

Clubbing Enlargement and blunting of the terminal portion of the fingers; associated with chronic hypoxemia.

Cluster headache A severe, unilateral vascular headache that occurs in groups, or clusters and is characterized by exacerbations and remissions; predominantly experienced by men ages 20 to 40.

Coagulation The process of creating a fibrin meshwork that cements blood components together to form an insoluble clot.

Cocaine A highly addictive stimulant/euphoric drug extracted from the leaves of the coca plant.

Code of ethics An established and agreed-on group of principles of conduct that provide a frame of reference for nursing behaviors that are congruent with professional values.

Cold sore See *Herpes simplex*.

Cold zone Considered the safe zone during a disaster, it is adjacent to the warm zone and is the area where a more in-depth triage of victims would occur; survivors may find shelter in this area, and command and control vehicles would be found here as well as the emergency transport vehicles.

Colectomy Surgical removal of the colon.

Collateral channels Connections between small arteries.

Collateral vessels Accessory pathways connected to the smaller arteries in the coronary system.

Colorectal cancer Malignant tumor arising from the epithelial tissues of the colon or rectum.

Colostomy Ostomy made in the colon.

Comedones Noninflammatory acne lesions.

Community-based care Centers on individual and family healthcare needs. The nurse practicing community-based care provides direct services to individuals to manage acute or chronic health problems and to promote self-care. The care is provided in the local community, is culturally competent, and is family centered.

Compartment syndrome Condition in which excess pressure constricts the structures within a compartment and reduces circulation to muscles and nerves.

Compartment A space enclosed by a fibrous membrane or fascia.

Complex regional pain syndrome Extremity pain that is severe, diffuse, and burning, and accompanied by vasomotor changes that affect skin color and temperature.

Computer literacy Familiarity and skills to use a computer.

Conceptual variable Qualities of a variable of interest in research.

Concussion Brain injury resulting from a violent jar, shake, or impact with an object.

Conjunctivitis Inflammation of the conjunctiva.

Consanguinity Related by having a common ancestor; close blood relationship.

Conscious sedation Anesthesia that provides analgesia and amnesia, but in which the patient remains conscious. Patients are able to breathe independently and are cardiovascularly stable.

Consciousness A condition in which a person is aware of self and environment and is able to respond appropriately to stimuli; full consciousness requires both normal arousal and full cognition.

Constipation The infrequent (two or fewer bowel movements weekly) or difficult passage of stools.

Contact dermatitis Type of dermatitis caused by a hypersensitivity response or chemical irritation.

Continuous renal replacement therapy (CRRT) A form of hemodialysis in which blood is continuously circulated through a highly porous hemofilter from artery to vein or vein to vein.

Contractility The inherent capability of the cardiac muscle fibers to shorten.

Contracting The negotiation of a cooperative working agreement between the nurse and patient that is continuously renegotiated.

Contractures Permanent shortening of connective tissues.

Contralateral deficit Manifestations of a stroke on the side of the body opposite the side of the brain that is damaged.

Contusion Superficial tissue injury resulting from blunt trauma, such as a kick or blow from an object, that causes the breakage of small blood vessels and bleeding into the surrounding tissue.

Conventional weapons Weapons such as bombs and guns that are used more frequently than nonconventional terrorist weapons.

Convergence Moving the eyes inward toward the nose to see an object close to the face.

Co-occurring disorders Concurrent diagnosis of a substance-use disorder and a psychiatric disorder. One disorder can precede and cause the other, such as the relationship between alcoholism and depression.

Cor pulmonale Condition of right ventricular hypertrophy and failure that results from long-standing pulmonary hypertension.

Core competencies Standards that a profession agrees are essential for a person to be deemed competent in his or her field.

Corneal reflex Closure of eyelids (blinking) due to corneal irritation.

Corneal ulcer Local necrosis of the cornea, may be caused by infection, exposure trauma, or the misuse of contact lenses.

Coronary heart disease (CHD) Heart disease caused by impaired blood flow to the myocardium.

Coryza (rhinorrhea) Profuse nasal discharge.

Cosmetic surgery (aesthetic surgery) One of two fields within plastic surgery. Cosmetic surgery enhances the attractiveness of normal features.

Crackles Discontinuous lung sounds heard by auscultation; can be fine or coarse. Produced by air passing over airway secretions or the opening of collapsed airways.

Crepitation A grating sound heard on movement of a joint.

Creutzfeldt-Jakob disease (CJD, spongiform encephalopathy) Rare, progressive neurologic disease that causes brain degeneration without inflammation.

Critical pathway A healthcare plan designed to provide care with a multidisciplinary, managed action focus; developed for specific diagnoses, usually those that are high volume, high risk, and high cost.

Critical thinking Self-directed thinking that is focused on what to believe or do in a specific situation.

CRNA Certified registered nurse anesthetist; a nurse certified in anesthesia administration.

Crohn's disease (regional enteritis) Chronic, relapsing inflammatory disorder affecting the gastrointestinal tract.

Crossing over A process that occurs during meiosis in which homologous maternal and paternal chromosomes break and exchange corresponding sections of DNA and then rejoin; this process can cause an exchange of alleles between chromosomes and provides human diversity.

Cryosurgery The destruction of tissue by cold or freezing with agents such as fluorocarbon sprays, carbon dioxide snow, nitrous oxide, and liquid nitrogen.

Curettage The removal of lesions with a curette, a semisharp cutting instrument.

Curling's ulcers Acute ulcerations of the stomach or duodenum that form following a burn injury.

Cushing's syndrome A chronic disorder caused by excessive amounts of circulating cortisol.

Cushing's ulcers Stress ulcers occurring as sequelae of head injury or central nervous system surgery.

Cutaneous melanoma See *Malignant melanoma*.

Cyanosis A bluish discoloration of the skin and mucous membranes due to oxygen deficiency.

Cystectomy Complete surgical removal of the urinary bladder and adjacent muscles and tissues.

Cystic fibrosis (CF) Inherited disorder of the exocrine glands that results in the secretion of abnormal amounts of mucus.

Cystitis Inflammation of the urinary bladder.

Cysts Benign closed sacs in or under the skin surface that are lined with epithelium and contain fluid or a semisolid material.

Cytokines Hormone-like polypeptides produced primarily by monocytes, macrophages, and T cells. Cytokines act as messengers of the immune system, facilitating communication between the cells to adjust or vary the inflammatory reaction or to initiate immune cell proliferation and differentiation.

Dawn phenomenon A rise in blood glucose between 4 AM and 8 AM that is not a response to hypoglycemia.

Death anxiety Worry or fear related to death or dying.

Death Irreversible cessation of circulatory and respiratory functions or irreversible cessation of all functions of the entire brain, including the brainstem.

Debridement Process of removing dead tissue from a wound.

Decerebrate posturing Abnormal posture with the neck extended; the jaw clenched; arms pronated, extended, and close to the sides; legs extended; and feet plantar flexed. Results from lesions of the midbrain, pons, or diencephalons.

Decorticate posturing Abnormal posture with the upper arms close to the sides; the elbows, wrists, and fingers flexed; the legs extended and internally rotated; and the feet plantar flexed. Results from lesions of the corticospinal tracts.

Deep venous thrombosis (DVT) Blood clot (thrombus) formation and inflammation within a deep vein, usually in the pelvis or lower extremities; a common complication of hospitalization, surgery, and immobilization.

Deformation Alteration of the spinal cord and soft tissues caused by abnormal movements from acceleration and deceleration forces.

Dehiscence An unintended separation of wound margins due to incomplete healing.

Dehydration Loss of water.

Delayed healing Healing that occurs at a slower rate than expected.

Delegation To effectively assign appropriate work activities to other members of the healthcare team. When the nurse delegates nursing care activities to another person, that person is authorized to act in the place of the nurse, while the nurse retains the accountability for the activities performed.

Delirium tremens (DT) A medical emergency usually occurring 3 to 5 days following alcohol withdrawal and lasting 2 to 3 days; characterized by paranoia, disorientation, delusions, visual hallucinations, elevated vital signs, vomiting, diarrhea, and diaphoresis.

Delirium A state of consciousness when the patient may be restless, confused or agitated.

Dementia A global impairment of cognitive function that usually is progressive and may be permanent; interferes with normal social and occupational activities.

Demyelination Destruction or removal of the myelin sheaths of nerves.

Dependent variable Variable that is impacted by a manipulated variable; commonly an outcome variable.

Depolarization The rapid inflow of sodium ions, causing an electrical change in which the inside of a cell becomes positive in relation to the outside.

Dermatitis Acute or chronic inflammation of the skin characterized by erythema and pain or pruritus.

Dermatome Area of skin innervated by cutaneous branches of a single spinal nerve.

Dermatophytes Fungi that cause superficial skin infections.

Dermatophytoses Superficial fungal infection of the skin; also called *ringworm*.

Descriptive statistics Statistics used to depict variations within a data set.

Detoxification The process of helping an addicted individual safely through withdrawal.

Diabetes insipidus A deficit of ADH causes excretion of large amounts of dilute urine, in some instances as much as 12 L/day. The patient has extreme thirst and drinks large volumes of water. If unable to replace the water loss, the patient becomes dehydrated and hypernatremic. Even though hyperosmolality is present, the urine is dilute and has a low specific gravity.

Diabetes mellitus (DM) Group of chronic disorders of the endocrine pancreas, all categorized under a broad diagnostic label. The condition is characterized by inappropriate hyperglycemia caused by a relative or absolute deficiency of insulin or by a cellular resistance to the action of insulin.

Diabetic ketoacidosis (DKA) A form of metabolic acidosis induced by stress in a person with type 1 diabetes.

Diabetic nephropathy A disease of the kidneys characterized by the presence of albumin in the urine, hypertension, edema, and progressive renal insufficiency.

Diabetic neuropathies Disorders of the peripheral nerves and the autonomic nervous system manifesting one or more of the following: sensory and motor impairment, muscle weakness and pain, cranial nerve disorders, impaired vasomotor function, impaired gastrointestinal function, and impaired genitourinary function.

Diabetic retinopathy The collective name for the changes in the retina that occur in the person with diabetes. The retinal capillary structure undergoes alterations in blood flow, leading to retinal ischemia and a breakdown in the blood retinal barrier.

Dialysate Dialysis solution.

Dialysis The diffusion of solute molecules across a semipermeable membrane from an area of higher concentration to one of lower concentration.

Diaphoresis Copious production of sweat.

Diarrhea An increase in the frequency, volume, and fluid content of the stool.

Diastolic blood pressure The minimum pressure maintained by elastic arterial walls during diastole (cardiac relaxation) to maintain blood flow through capillary beds; averages 80 mmHg in a healthy adult.

Dietary reference intakes (DRIs) The recommended intakes of nutrients (vitamins & elements).

Differentiation A process occurring over many cell cycles that allows cells to specialize in certain tasks.

Diffuse brain injury (DBI) A brain injury from a high-speed acceleration–deceleration accident with widespread disruption of axons in the white matter.

Diffuse esophageal spasm Nonperistaltic contraction of esophageal smooth muscle.

Diffusion The process by which solute molecules move from an area of high solute concentration to an area of low solute concentration to become evenly distributed.

Dilemma A choice between two unpleasant, ethically troubling alternatives.

Diplopia Unilateral or bilateral double vision.

Disability The degree of observable and measurable impairment.

Disaster Event that requires extraordinary efforts beyond those needed to respond to everyday emergencies.

Disease Literally meaning "without ease," this term describes alterations in structure and function of the body or mind. Diseases may have mechanical, biologic, or normative causes.

Diskectomy The removal of the nucleus pulposus of an intervertebral disk. Diskectomy may be performed alone or in conjunction with a laminectomy.

Dislocation Separation of contact between two bones of a joint.

Dissection (aortic) A life-threatening emergency caused by a tear in the intima of the aorta with hemorrhage into the media.

Disseminated intravascular coagulation (DIC) A disruption of hemostasis characterized by widespread intravascular clotting and bleeding; a syndrome that develops as a complication of many other disorders.

Distributive shock Also called *vasogenic shock*, this includes several types of shock that result from widespread vasodilation and decreased peripheral resistance.

Diverticula Saclike projections of mucosa through the muscular layer of the colon.

Diverticulitis Inflammation in and around the diverticular sac; typically affects only one diverticulum, usually in the sigmoid colon.

Diverticulosis Indicates the presence of diverticula.

Dominant A characteristic or gene that is apparent even when the relevant gene is present in only one copy; a person with a dominant gene usually expresses that gene trait.

Do-not-resuscitate (DNR or "no-code") order Usually written by the physician for the patient who has a terminal illness or is near death, this order is usually based on the wishes of the patient and family that no cardiopulmonary resuscitation be performed for respiratory or cardiac arrest.

Dopaminergic Activity that involves dopamine and its pathways in the brain.

Dual diagnosis The coexistence of substance abuse/dependence and a psychiatric disorder in one individual (used interchangeably with *dual disorder* and *co-occurring disorders*).

Dual disorder See *Dual diagnosis*.

Dumping syndrome Complication of partial gastrectomy characterized by nausea, weakness, sweating, palpitation, syncope, sensation of warmth, and occasionally diarrhea.

Duodenal ulcers Peptic ulcer disease affecting the duodenum.

Durable power of attorney A document that can delegate the authority to make health, financial, and/or legal decisions on a person's behalf. It must be in writing and must state that the designated person is authorized to make healthcare decisions.

Dwarfism A condition characterized by short stature; insufficient pituitary growth hormone is one cause.

Dysarthria Difficulty speaking.

Dysfunctional uterine bleeding (DUB) Vaginal bleeding that is usually painless but abnormal in amount, duration, or time of occurrence.

Dysmenorrhea Pain associated with menstruation.

Dyspareunia Painful intercourse.

Dysphagia Difficulty swallowing.

Dysphonia Change in the tone of voice.

Dysplasia The loss of DNA control over differentiation occurring in response to adverse conditions.

Dyspnea Difficult or labored breathing.

Dysrhythmia Abnormal heart rate or rhythm.

Dysuria Painful urination.

Ecchymosis A flat, irregularly shaped lesion (bruise) of varying size with no pulsation; caused by blood collecting under skin.

Ectopic beats Impulses originating outside normal conduction pathways of the heart.

Edema Accumulation of fluid in the body's tissues; an excess accumulation of fluid in the interstitial space.

Ejection fraction (EF) The percentage of total blood remaining in the ventricle at the end of diastole (relaxation); normal is 50% to 70%.

Electrical bone stimulation Application of electrical current at the fracture site to treat fractures that are not healing appropriately. The electrical stress increases the migration of osteoblasts and osteoclasts to the fracture site. Mineral deposition increases, promoting bone healing.

Electrocardiography The graphic recording of the heart's electrical activity detected and recorded through electrodes placed on the surface of the body.

Electrolytes Substances that dissociate in solution to form charged particles called *ions*.

Electronic medical records (EMRs) Electronic repository of all patient-related information. Commonly computer-based.

Electrosurgery The destruction or removal of tissue with high-frequency alternating current.

Embolic CVA Cerebrovascular accident occurring when a blood clot or clump of matter traveling through the cerebral blood vessels becomes lodged in a vessel too narrow to permit further movement.

Embolism Sudden obstruction of a blood vessel by a clot or debris.

Emergency Encompasses an unforeseen combination of circumstances calling for immediate action for a range of victims from one to many.

Emphysema Destruction of the walls of the alveoli, with resulting enlargement of abnormal air spaces.

Empyema Accumulation of purulent exudate in the pleural cavity.

Encephalitis An acute inflammation of the parenchyma of the brain or spinal cord.

End of life The final days or weeks of life when death is imminent.

Endocarditis Inflammation of the endocardium.

Endometriosis A condition in which multiple, small implants of endometrial tissue develop throughout the pelvic cavity.

Endoscopy Inspection of organs or cavities of the body using an endoscope.

Endotoxins Found in the cell wall of gram-negative bacteria, endotoxins are released only when the cell is disrupted. They act as activators of many human regulatory systems, producing fever, inflammation, and potentially clotting, bleeding, or hypotension when released in large quantities.

End-stage renal disease The final stage of chronic renal failure in which the kidneys are unable to excrete metabolic wastes and regulate fluid and electrolyte balance adequately; characterized by a glomerular filtration rate of less than 5% of normal.

Enophthalmos Sunken appearance of the eyes.

Enteral nutrition Administration of liquid nutritional formulas to meet calorie and protein needs in patients unable to consume adequate food; also called *tube feeding*.

Enucleation Surgical removal of an eye.

Epicondylitis (tennis elbow, golfer's elbow) Inflammation of the tendon at its point of origin into the bone.

Epididymitis Infection or inflammation of the epididymis.

Epidural hematoma (extradural hematoma) A collection of blood between the dura and the skull.

Epilepsy A disorder characterized by chronic seizure activity.

Epistaxis Nosebleed.

Equianalgesia/Equianalgesic Approximate equivalent doses of opioid analgesics as compared to morphine sulfate.

Erectile dysfunction Inability to attain and maintain an erection sufficient to permit satisfactory sexual intercourse.

Erosive gastritis See *Stress-induced (erosive gastritis)*.

Erysipelas Infection of the skin most often caused by group A *streptococci*.

Erythema A reddening of the skin.

Erythropoiesis Red blood cell production.

Eschar Hard, leathery crust that covers a burn wound and harbors necrotic tissue.

Escharotomy Surgical removal of eschar from the torso or extremity to prevent circumferential constriction.

Esophageal varices Enlarged, thin-walled veins that form in the submucosa of the esophagus.

Esophagojejunostomy Removal of the entire stomach with anastomosis of the distal esophagus to the jejunum.

Estrogen Hormone produced by the ovaries.

Ethics Principles of conduct. Ethical behavior is concerned with moral duty, values, obligations, and the distinction between right and wrong.

Euthanasia From the Greek for painless, easy, gentle, or good death, now commonly used to signify a killing prompted by a humanitarian motive.

Euthyroid Term describing normal thyroid hormone function.

Evaluation phase The final phase of disaster planning which involves a detailed review of a disaster relief program to determine if goals were met, to assess the program's impact on the community and to identify lessons learned for the design of future plans.

Evidence-based practice (EBP) The practice of nursing in which the nurse makes clinical decisions on the basis of the best available current research evidence, his or her own clinical expertise including internal evidence of patient findings, and the needs and preferences of the patient.

Evisceration Protrusion of body contents through a surgical wound.

Exacerbation A period during chronic illness in which symptoms reappear.

Exfoliative dermatitis Inflammatory skin disorder characterized by excessive peeling or shedding of skin.

Exophthalmos Protrusion of the eyeballs.

Exotoxins Soluble proteins secreted into surrounding tissue by the microorganism. Exotoxins are highly poisonous, causing cell death or dysfunction.

External evidence Relevant research findings related to a specified clinical question.

External otitis Inflammation of the ear canal.

Extracapsular fractures Fractures of the trochanteric region.

Extracorporeal shock-wave lithotripsy (ESWL, transcutaneous shock-wave lithotripsy) Noninvasive technique for fragmenting kidney stones using shock waves generated outside the body.

Faith community nursing Also known as *parish nursing,* this is a nontraditional, community-based way of providing health promotion and health restoration nursing interventions to specific groups of people.

Family Two or more persons joined by emotional closeness and shared bonds and who identify themselves as being part of a family.

Fasciculations Involuntary twitching.

Fasciectomy (fascial excision) Process of excising the wound to the level of fascia.

Fat embolism syndrome (FES) Characterized by neurologic dysfunction, pulmonary insufficiency, and a petechial rash on the chest, axilla, and upper arms due to fat globules lodged in the pulmonary vascular bed or peripheral circulation.

Fecal impaction A rock-hard or putty-like mass of feces in the rectum.

Fecal incontinence Loss of voluntary control of defecation.

Fecalith A hard mass of feces.

Fibrocystic changes (FCC) Physiologic nodularity and breast tenderness that increases and decreases with the menstrual cycle.

Fibroid tumors (uterine leiomyoma) Solid benign tumors originating from smooth muscle of the uterus.

Fibromyalgia (fibrositis) A common rheumatic syndrome characterized by musculoskeletal pain, stiffness, and tenderness.

Filtration The process by which water and dissolved substances (solutes) move from an area of higher hydrostatic pressure to an area of lower hydrostatic pressure.

Fistula Abnormal opening or passage between two organs or spaces that are normally separated or an abnormal passage to the outside of the body.

Flaccidity Decreased muscle tone in disease or trauma of the lower motor neurons.

Flail chest Free-floating segment of the chest wall, resulting from two or more consecutive ribs fractured in multiple places.

Flap A piece of tissue whose free end is moved from a donor site to a recipient site while maintaining a continuous blood supply through its connection at the base or pedicle.

Flatus Gas in the digestive tract.

Fluid resuscitation Replacement of the extensive fluid and electrolyte losses associated with major burn injuries.

Fluid volume deficit (FVD) A decrease in intravascular, interstitial, and/or intracellular fluid in the body.

Fluid volume excess (FVE) Excess extracellular fluid resulting from retention of both water and sodium in the body.

Folic acid deficiency anemia An anemia resulting from folic acid deficiency, a necessary nutrient for DNA synthesis and RBC maturation.

Folliculitis Bacterial infection of the hair follicle, most commonly caused by *Staphylococcus aureus*.

Fracture A break in a bone usually due to trauma.

Freestanding outpatient surgical facilities Surgical units independent of a hospital with or without financial connections to a hospital or healthcare organization.

Friction rub The sound heard when two dry surfaces are rubbed together.

Frostbite An injury of the skin from freezing.

Full-thickness burn A burn that involves all layers of the skin, including the epidermis, dermis, and epidermal appendages.

Fulminant hepatitis Hepatitis with a rapid and severe onset and course.

Furuncle Often called a *boil,* but also an inflammation of the hair follicle.

Fusiform excision The removal of a full thickness of the epidermis and dermis, usually with a thin layer of subcutaneous tissue.

Fusion The insertion of a wedge-shaped piece of bone or bone chips (usually harvested from patient's ileac crest) between the vertebrae to stabilize them.

Galactorrhea Lactation not associated with pregnancy or nursing.

Gastric lavage Irrigation of the stomach with large quantities of normal saline.

Gastric mucosal barrier A protective barrier consisting of lipids, bicarbonate ions, and mucous gel that protects the stomach lining from the damaging effects of gastric juices.

Gastric outlet obstruction Obstruction of the pyloric region of the stomach and duodenum that impairs gastric outflow; a potential complication of peptic ulcer disease.

Gastric ulcers Ulcers of the stomach lining, usually in the lesser curvature and antrum; more common in older adults.

Gastritis Inflammation of the stomach lining.

Gastroduodenostomy (Billroth I) Excision of the pylorus of the stomach with the anastomosis of the upper stomach to the duodenum; commonly used partial gastrectomy procedure.

Gastroenteritis Inflammation of the gastrointestinal tract; not a specific disease, but a group of syndromes or a collection of related manifestations.

Gastroesophageal reflux Backward flow of gastric contents into the esophagus.

Gastroesophageal reflux disease (GERD) The reflux of acidic gastric contents into the lower esophagus.

Gastrojejunostomy (Billroth II) Subtotal excision of the stomach with closure of the duodenum and side-to-side anastomosis of the jejunum to the stomach; commonly used partial gastrectomy procedure.

Gastroparesis Slowed gastrointestinal motility, which causes early satiety.

Gene expression When the protein product of a gene is visible (for example, through the presence of a body structure or identifiable through biochemical tests such as insulin or phenylalanine levels).

Gene A sequence of DNA on a chromosome that represents a fundamental unit of heredity; occupies a specific spot on a chromosome (gene locus).

General anesthesia Deep sedation, which includes analgesia and muscle paralysis. This type of anesthesia requires respiratory maintenance without the aid of the patient's respiratory musculature.

Genital herpes (herpes simplex genitalis) An infection of the external genitalia caused by herpes simplex genitalis; transmitted by vaginal, anal, or oral–genital contact.

Genital warts (condyloma acuminatum, venereal warts) A sexually transmitted condition caused by the human papilloma virus.

Genotype The genes and the variations therein that a person inherits from his or her parents.

Germ cells Cells that give rise to a sperm or egg.

Gigantism Gigantism occurs when GH hypersecretion begins before puberty and the closure of the epiphyseal plates. The person becomes abnormally tall, often exceeding 7 ft (213 cm) in height, but body proportions are relatively normal.

Gingivitis Inflammation of the gums, characterized by redness and bleeding.

Gland Tissue that produces secretions or synthesizes hormones.

Glaucoma Condition characterized by increased intraocular pressure of the eye and a gradual loss of vision.

Glomerular filtration rate (GFR) The rate at which plasma is filtered through the glomeruli of the kidney.

Glomerulonephritis Inflammation of the capillary loops of the glomeruli.

Glossitis Inflammation of the tongue.

Glucocorticoid A group of hormones secreted by the adrenal cortex; they regulate carbohydrate levels in the body.

Gluconeogenesis Formation of glucose from fats and proteins.

Glucose-6-phosphate dehydrogenase (G6PD) anemia Anemia due to a hereditary defect in RBC metabolism.

Glucosuria Excessive glucose in urine.

Glycogenolysis Breakdown of liver glycogen to glucose.

Goiter An enlarged thyroid gland. Enlargement results from both inadequate and excessive synthesis of thyroid hormones.

Gonorrhea (GC, clap) An infection caused by *Neisseria gonorrhoeae* that is transmitted by direct sexual contact or during delivery of a neonate by an infected mother.

Gout A metabolic disorder characterized by hyperuricemia and acute inflammatoryarthritis triggered by urate crystallization within joints and deposits of insoluble urates in connective tissues of the body.

Grief The emotional response to loss and its accompanying changes.

Grieving The internal process the person uses to work through the response to loss.

Guillain-Barré syndrome (GBS) Acute demyelinating disorder of the peripheral nervous system characterized by progressive, usually rapid muscle weakness and paralysis.

Gynecomastia Breast enlargement in men.

Hallucinogens Drugs that produce hallucinations.

Hallux valgus (bunion) The enlargement and lateral displacement of the first metatarsal.

Hammertoe (claw toe) The dorsiflexion of the first phalanx with accompanying plantar flexion of the second and third phalanges.

Handicap The total adjustment to disability that limits functioning at a normal level.

Handoff When responsibility for care is transferred from one individual or care unit to another.

Hazardous materials Substances that pose a potential risk to life, health, or property if they are released because of their chemical, biologic, or physical nature.

Health information technology (HIT) The system supported by the U.S. government designed to promote free exchanges of health information while protecting patients' privacy and improving safety, efficacy, and quality of care.

Health literacy Peoples ability to obtain, process, communicate, and understand basic health information and services.

Health "A state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity" (WHO, 1974, p. 1).

Healthcare associates infections (HAIs) Infections acquired in a healthcare setting; also called *nosocomial infections*.

Healthcare surrogate An individual selected to make medical decisions when a person is no longer able to make them for his- or herself.

Health–illness continuum A visual representation of health as a dynamic process, with high-level wellness at one extreme of the continuum and death at the opposite extreme.

Heart block A block in the normal conduction pathways.

Heart failure Inability of the heart to pump adequate blood to meet the metabolic demands of the body.

Heave An excessive thrust.

Hemangioma See *Angioma*.

Hemarthrosis The collection of blood in a joint.

Hematemesis Blood in the vomit.

Hematochezia Blood in the stool.

Hematoma A contusion with a large amount of bleeding.

Hematopoiesis Blood cell formation.

Hematuria Blood in the urine.

Hemianopia Loss of half of the visual field of one or both eyes.

Hemiparesis Weakness of one side of the body.

Hemiplegia Paralysis in one-half of the body vertically.

Hemodialysis A procedure in which electrolytes, waste products, and excess water are removed from the body by diffusion and ultrafiltration as blood passes by an artificial semipermeable membrane outside the body.

Hemodynamics Study of the forces involved in blood circulation.

Hemoglobin The oxygen-carrying protein within RBCs; composed of the heme molecule and globin, a protein molecule.

Hemolysis The process of RBC destruction.

Hemolytic anemia Premature destruction (lysis) of RBCs.

Hemophilia A (classic hemophilia) The most common type of hemophilia, caused by clotting factor VIII deficiency.

Hemophilia B (Christmas disease) Hemophilia caused by factor IX deficiency.

Hemophilia A group of hereditary clotting factor disorders that lead to persistent and potentially severe bleeding.

Hemoptysis Bloody sputum.

Hemorrhage Rapid or excessive bleeding.

Hemorrhagic CVA (intracranial hemorrhage) Cerebrovascular accident occurring when a cerebral blood vessel ruptures.

Hemorrhoids (piles) Clusters of dilated veins in swollen anal tissue.

Hemostasis Control of bleeding.

Hemothorax Blood in the pleural space.

Hepatic encephalopathy Altered consciousness, mentation, and motor function affecting cirrhotic patients.

Hepatitis Inflammation of the liver, usually caused by a virus; may be acute or chronic.

Hepatorenal syndrome Renal failure accompanied by azotemia, sodium retention, oliguria, and hypotension in patients with cirrhosis and ascites.

Hernia A defect in the abdominal wall that allows abdominal contents to protrude out of the abdominal cavity.

Herniated intervertebral disk Rupture of the cartilage surrounding the intervertebral disk with protrusion of the nucleus pulposus.

Herniation The complication where the nucleus pulposus projects through the interrupted disk in a posterolateral direction, with compression of the associated nerve root. The resulting pressure on adjacent spinal nerves causes characteristic manifestations, which vary with the location

and the amount of protruding disk material. Occasionally the herniation is central rather than posterolateral, with pressure on the spinal cord.

Herpes simplex (fever blister, cold sore) Acute viral infections of the skin and mucous membranes caused by two types of herpesvirus: HSV I and HSV II.

Herpes zoster (shingles) Viral infection of a nerve supplying a dermatome section of the skin caused by varicella zoster, the same herpesvirus that causes chickenpox.

Heterograft (xenograft) Skin obtained from an animal, usually a pig.

Heterozygous Nonidentical copies of a particular gene (different alleles) on the paired chromosomes.

Hiatal hernia Protrusion of part of the stomach through the esophageal hiatus of the diaphragm into the mediastinal cavity.

Hirsutism Increased growth of coarse hair, usually on the face and trunk.

Histocompatibility The ability of cells and tissues to survive transplantation without immunologic interference by the recipient.

Holistic health care Care in which all aspects of a person (physical, psychosocial, cultural, spiritual, and intellectual) are considered as essential components of individualized care.

Home care Services for patients who are in need of treatment or support to function effectively in the home environment.

Home healthcare The delivery of services to restore or maintain the health of individuals and families in the home.

Homeostasis The body's tendency to maintain a state of physiologic balance in the presence of constantly changing conditions.

Homograft (allograft) Human tissue (skin, cornea, organs) used in skin graft or tissue transplant.

Homologous Chromosomes that are members of the same pair and normally have the same number and arrangement of genes; usually one copy is from the mother and the other copy is from the father.

Homonymous hemianopia Impaired vision or blindness in one side of both eyes.

Homozygous Identical copies of a particular gene (same alleles) on both paired chromosomes.

Hordeolum (sty) Staphylococcal abscess that may occur on either the external or internal margin of the lid.

Hormone Chemical messengers secreted via body fluids that have specific targets where they increase or inhibit organ functions.

Hospice (hospice care) A special component of home care, designed to provide medical, nursing, social, psychologic, and spiritual care for terminally ill patients and their families. Hospice care relies on a philosophy of relieving pain and suffering and allowing the patient to die with dignity in a comfortable environment.

Hot zone The site of a disaster where a weapon was released or where contamination occurred.

Human genome The total amount of the DNA (genes) in an individual's cells.

Human immunodeficiency virus (HIV) Virus responsible for AIDS.

Human-generated disasters Human generated disasters are those in which the principle direct causes are identifiable human actions, deliberate or otherwise.

Huntington's disease Progressive, degenerative, inherited neurologic disease characterized by increasing dementia and chorea; also called *chorea*.

Hydrocele Fluid-filled mass within the scrotum.

Hydrocephalus An abnormal accumulation of cerebrospinal fluid within the cerebral ventricles.

Hydronephrosis Distention of the kidney pelvis and calyces with urine behind an obstruction.

Hydroureter Distention of the ureter with urine.

Hypercapnia Increased blood levels of carbon dioxide.

Hyperglycemia Elevated blood glucose levels, which causes osmotic diuresis and, if chronic, damages blood vessel epithelium and renal glomeruli.

Hyperopia (farsightedness) A condition in which the eyeball is short, causing the image to focus behind the retina.

Hyperosmolar hyperglycemic state (HHS) A condition of very high blood glucose with adequate insulin to prevent ketosis, a complication of type 2 DM.

Hyperparathyroidism A disorder that results from an increase in the secretion of parathyroid hormone (PTH), which regulates normal serum levels of calcium.

Hyperplasia An increase in the number or density of normal cells.

Hypersensitivity Exaggerated response of the immune system to an antigen.

Hypertension Excess pressure in the arterial portion of systemic circulation.

Hyperthyroidism A disorder caused by excessive production and delivery of thyroid hormone to the tissues.

Hypertrophic scar Overgrowth of dermal tissue that remains within the boundaries of the wound.

Hypervolemia Excess intravascular fluid.

Hyphema Bleeding into the anterior chamber of the eye, possibly as the result of blunt eye trauma.

Hypoglycemia Low blood glucose levels.

Hypoparathyroidism A disorder that results from abnormally low PTH levels. The most common cause is damage to or inadvertent removal of all of the parathyroid glands during thyroidectomy. The lack of circulating PTH causes hypocalcemia and an elevated blood phosphate level.

Hypothyroidism A disorder that results when the thyroid gland produces an insufficient amount of TH.

Hypovolemia Decreased circulating blood volume.

Hypovolemic shock Shock caused by a decrease in intravascular volume of 15% or more. This form of shock is caused by the loss of whole blood, blood plasma, or extracellular fluid.

Hypoxemia Decreased oxygen concentration in the blood, measured by PaO_2.

Hypoxia Insufficient supply of oxygen to the tissues.

Ichthyosis An inherited dermatologic condition in which the skin is dry, fissured, and hyperkeratotic; the surface of the skin has the appearance of fish scales.

Ileostomy An ostomy made in the ileum of the small intestine.

Illness The response a person has to a disease; integrates the patient's perception, as well as the pathophysiologic alterations and the psychologic effects of those alterations.

Immunity The protection of the body from disease.

Immunocompetent Possessing an immune system that can identify antigens and effectively destroy or remove them.

Immunocompromised Possessing an immune response that has been weakened by a disease or an immunosuppressive agent.

Immunoglobulin (Ig) A protein that functions as an antibody.

Immunosuppression Inability of the immune system to respond to an antigen. Occurs in response to disease or medications; may be intentional to prevent rejection of transplants or a side effect of some medications.

Impairment A disturbance in structure or function resulting from physiologic or psychologic abnormalities.

Impetigo Infection of the skin caused by either *Staphylococcus aureus* or beta-hemolytic streptococci.

Impotence Inability to achieve or maintain an erection.

Incidental pain A type of breakthrough pain that is predictable because it is associated with movement such as turning or coughing.

Increased intracranial pressure (IICP, intracranial hypertension) Sustained elevated pressure (10 mmHg or higher) within the cranial cavity.

Independent nursing care Care provided by nurses within the scope of their practice without the direction or supervision of a physician.

Independent variable Variable that is manipulated (commonly an intervention).

Infection Colonization by and multiplication of an organism within a host. The host can be any organism capable of supporting the nutritional and physical growth requirements of the microorganism, for example, humans.

Inferential statistics Statistics that are based on the laws of probability. These statistics allow generalizable conclusions.

Inflammation A complex, nonspecific, adaptive response to injury that brings fluid, dissolved substances, and blood cells into the interstitial tissues where the invasion or damage has occurred.

Inflammatory bowel disease (IBD) Chronic inflammation of the bowel common to a group of conditions that includes Crohn's disease and ulcerative colitis.

Influenza Highly contagious viral respiratory disease characterized by coryza, fever, cough, and constitutional manifestations such as headache and malaise.

Information literacy The ability to ability to locate, evaluate, and use appropriate facts effectively.

Information technology (IT) The mechanical infrastructure that supports the collection, recording, and utilization of patient information.

Informed consent Disclosure of risks associated with the intended procedure or operation to the patient. The language of the document varies according to statutory and common law of each state.

Inhalants Inhaled solvents categorized into three types: anesthetics, volatile nitrites, and organic solvents.

Innate adaptive immunity Specific and nonspecific responses that prevent or limit the entry of invaders into the body, thereby limiting the extent of tissue damage and reducing the workload of the adaptive immune system.

Insulin reaction Hypoglycemia in patients with type 1 diabetes mellitus.

Insulin A hormone that facilitates entry of glucose into fat and muscle cells for energy.

Interdisciplinary care Care provided by members of the healthcare team in addition to medical professionals. Usually includes team members who address psychosocial and spiritual issues as well as physical care.

Intermittent claudication Cramping, aching ischemic pain in the calves, thighs, and buttocks that occurs with a predictable level of activity and is relieved by rest.

Internal evidence A type of evidence used in evidence-based practice that includes nursing expertise and results of quality improvement and outcome evaluation.

Interprofessional care Care delivered by intentionally created and usually relatively small work groups in health care as having a collective identity and shared responsibility for a patient or a group of patients.

Intracerebral hematomas A collection of blood in the brain tissue, most often located in the frontal or temporal lobes.

Intracranial aneurysm Saccular outpouching of a cerebral artery that occurs at the site of a weakness in the vessel wall.

Intracranial hypertension See *Increased intracranial pressure*.

Intracranial pressure (ICP) The pressure within the cranial cavity, usually measured as the pressure within the lateral ventricles.

Intraductal papilloma A tiny wartlike growth on the inside of the peripheral mammary duct that causes discharge from the nipple.

Intraoperative phase The time during surgery, from beginning to end.

Iron deficiency anemia The most common type of anemia; results from inadequate iron for optimal RBC formation.

Irritable bowel syndrome (IBS) A motility disorder of the gastrointestinal tract characterized by alternating periods of constipation and diarrhea.

Ischemia Deficient blood flow to tissue resulting in reduced oxygen delivery.

Ischemic Deprived of oxygen.

Islets of Langerhans Hormone-producing cells (alpha cells, beta cells, and delta cells) scattered through the pancreas.

Isograft Tissue transplant where the donor and recipient are identical twins.

Jaundice Yellow-to-orange color visible in the skin and mucous membranes; most often the result of a hepatic disorder.

Joint arthroplasty Reconstruction or replacement of a joint.

Kaposi's sarcoma (KS) A vascular malignancy (a tumor of the endothelial cells lining small blood vessels) that presents as vascular macules, papules, or violet lesions affecting the skin and viscera. It is often the presenting symptom of AIDS.

Keloid Elevated, irregularly shaped, progressively enlarging scar arising from excessive amounts of collagen in the stratum corneum during scar formation in connective tissue repair.

Keratin Keratin is a fibrous, water-repellent protein that gives the epidermis its tough, protective quality.

Keratitis Inflammation of the cornea.

Keratosis Any skin condition in which there is a benign overgrowth and thickening of the cornified epithelium.

Ketoacidosis A condition of very high blood glucose and insufficient insulin that results in accumulation of ketones and fatty acids in the blood; a form of metabolic acidosis.

Ketonuria The presence of ketones in the urine.

Ketosis An accumulation of ketone bodies produced during the oxidation of fatty acids.

Kidney failure Inability of the kidneys to effectively remove accumulated metabolites from the blood, leading to altered fluid, electrolyte, and acid–base balance.

Kindling Long-term changes in brain neurotransmission that occur after repeated detoxifications.

Kinesthesia The ability to perceive movement and sense of position.

Korotkoff's sounds Sounds heard during auscultation of blood pressure.

Korsakoff's psychosis Secondary dementia caused by thiamine (B_1) deficiency that may be associated with chronic alcoholism; characterized by progressive cognitive deterioration, confabulation, peripheral neuropathy, and myopathy.

Kussmaul's respirations Deep, rapid respirations associated with compensatory mechanisms.

Kwashiorkor (protein energy malnutrition, PEM) Chronic protein deficiency with adequate calories to meet body needs.

Kyphosis Exaggerated thoracic curvature of the spine, common in older adults.

Labyrinthectomy Surgical removal of the labyrinth.

Labyrinthitis Inflammation of the inner ear.

Laceration Open wound that results from sharp cutting or tearing. Injuries to the integument are at risk for contamination from dirt, debris, or foreign objects.

Lacunar strokes Thrombotic stroke of smaller cerebral blood vessels in deeper parts of the brain or brain stem.

Laminectomy Removal of the lamina of the vertebrae.

Laparoscopic cholecystectomy Removal of the gallbladder using an endoscope.

Laryngectomy Removal of the larynx.

Laryngitis Inflammation of the larynx.

Leiomyoma See *Fibroid tumor*.

Leukemia A group of chronic malignant disorders of white blood cells and WBC precursors; characterized by replacement of bone marrow by malignant immature WBCs, abnormal immature circulating WBCs, and infiltration of malignant cells into other tissues.

Leukocytes Also called white blood cells, these are the primary cells involved in both nonspecific and specific immune system responses.

These cells isolate the infecting organism or injury, destroy pathogens, and promote healing.

Leukocytosis An increase in the number of leukocytes in the blood (above 10,/mm^3), usually caused by infection.

Leukopenia Abnormal decrease of circulating leukocytes, usually below 5/mm^3; occurs when bone marrow activity is suppressed or when leukocyte destruction increases.

Leukoplakia Formation of white patches or spots on the mucous membranes or tongue; these lesions may become malignant.

Libido Sexual desire.

Lichen planus Benign inflammatory disorder of the mucous membranes and skin.

Lift A more sustained cardiac thrust than normal.

Lipoatrophy Atrophy of subcutaneous tissue.

Liposuction A method of changing the contours of the body by aspirating fat from the subcutaneous layer of tissue.

Lithiasis Stone formation.

Lithotripsy Crushing of renal calculi.

Living will A document that provides written directions about life-prolonging proceures to provide instructions when a person can no longer communicate in a life-threatening situation.

Lobectomy Surgical removal of a single lobe of lung.

Locked-in syndrome Patient is alert and fully aware of the environment, but is unable to communicate through speech or movement as a result of blocked efferent pathways to the brain.

Lordosis Increased lumbar curve.

Loss Loss may be defined as an actual or potential situation in which a valued object, person, body part, or emotion that was formerly present is lost or changed and can no longer be seen, felt, heard, known, or experienced. A loss may be temporary or permanent, complete or partial, objectively verifiable or perceived, physical or symbolic.

Lower body obesity (peripheral obesity) A waist-to-hip ratio of less than 0.8 in an obese individual.

Lung abscess Localized area of lung destruction or necrosis and pus formation.

Lung compliance Distensibility of the lungs.

Lyme disease An inflammatory disorder caused by a spirochete, *Borrelia burgdorferi*, which is transmitted primarily by ticks.

Lymphadenopathy The enlargement of lymph nodes (over 1 cm) with or without tenderness. It may be caused by inflammation, infection, or malignancy of the nodes or the regions drained by the nodes.

Lymphangitis Inflammation of a lymphatic vessel.

Lymphedema Edema of an extremity due to accumulated lymph; may be primary or secondary, resulting from inflammation, obstruction, or removal of lymphatic vessels.

Lymphocytes Lymphocytes account for 20% to 40% of circulating leukocytes. Lymphocytes are the principal effector and regulator cells of specific immune responses.

Lymphoid tissues Connective tissues containing lymphocytes; include tissues of the bone marrow, thymus, lymph nodes, and spleen.

Lymphoma Malignancy of lymphoid tissue.

Macrophages Monocytes mature into macrophages after settling into tissue. Macrophages are large phagocytes. They are important in the body's defense against chronic infections.

Macular degeneration Destructive changes in the macula due to injury or gradual failure of the outer pigmented layer of the retina (the retinal layer adjacent to the choroid), which removes cellular waste products and keeps the retina attached to the choroid.

Malabsorption A condition in which nutrients are ineffectively absorbed by the intestinal mucosa, resulting in their excretion in the stool.

Malignant hypertension A hypertensive emergency, marked by a diastolic pressure greater than 120 mmHg.

Malignant melanoma (cutaneous melanoma) Skin cancer that arises from melanocytes.

Malignant pain Pain associated with a life-threatening illness such as cancer but not limited to cancer pain.

Malnutrition Inadequate nutrient intake to meet body needs; may include deficiency of major nutrients (calories, carbohydrates, proteins, and fats) or micronutrients such as vitamins and minerals.

Manifestations Signs and symptoms of a disease or condition caused by alterations in structure or function.

Man-made disasters Either accidental or intentional, they are complex emergencies, technological disasters, material shortages, and other disasters not caused by natural hazards.

Marasmus (protein energy undernutrition) Insufficient protein and calorie intake to meet metabolic needs.

Mass casualty incidents Situations in which 100 or more casualties are involved, significantly overwhelming available emergency medical services, facilities, and resources.

Mastoidectomy Surgical removal of infected mastoid air cells.

Mastoiditis Bacterial infection of the mastoid process.

Maturity-onset diabetes of the young (MODY) Diabetes in young obese adults.

Mean arterial pressure (MAP) The average pressure in the arterial circulation throughout the cardiac cycle; the product of cardiac output and systemic vascular resistance (SVR).

Medical-surgical nursing The health promotion, health care, and illness care of adults, based on knowledge derived from the arts and sciences and shaped by knowledge (the science) of nursing.

Meiosis The reduction of division of the cell occurring only in the sex cells of the testes and ovaries when the amount of genetic material is reduced in half (23 chromosomes).

Melanin Skin pigment that forms a protective shield to protect keratinocytes and nerve endings in the dermis from the damaging effects of ultraviolet light.

Melena Black, tarry stool that contains old, digested blood.

Ménière's disease Chronic disorder of unknown cause characterized by recurrent attacks of vertigo with tinnitus and a progressive unilateral hearing loss.

Meningitis Inflammation of the meninges of the brain and spinal cord.

Menopause Permanent cessation of menses.

Menorrhagia Excessive or prolonged menstruation.

Menstrual cycle Cyclic buildup of the uterine lining, ovulation, and sloughing of the lining occurring approximately every 28 days in nonpregnant females of childbearing age.

Menstruation Periodic shedding of the uterine lining in a woman of childbearing age who is not pregnant.

Metabolic Syndrome A cluster of manifestations often associated with type 2 DM. Includes hypertension, visceral obesity, low HDL, high triglycerides, elevated C-reactive protein and fasting glucose > 110mg/dL.

Metabolism Consisting of the breakdown of complex structures into simpler forms to produce energy (catabolism) and the combination of simpler molecules to produce and maintain more complex structures necessary to living organisms (anabolism).

Metaplasia A change in the normal pattern of differentiation such that dividing cells differentiate into cell types not normally found in that location in the body.

Metastasis Secondary tumor; the process by which spreading of malignant neoplasms occurs; the transfer of disease from one organ or part to another not directly connected with it.

Methcillin-resistant *Staphylococcus aureus* (MRSA) A strain of antibiotic-resistant *S. aureus* that colonizes the skin and nares.

Metrorrhagia Bleeding between menstrual periods; may be caused by hormonal imbalances, pelvic inflammatory disease, cervical or uterine polyps, uterine fibroids, or cervical or uterine cancer.

Microalbuminuria Protein in the urine.

Micturition Releasing urine from the urinary bladder (voiding).

Mild concussion Brain trauma resulting in a brief loss of consciousness that lasts from seconds to hours.

Minor trauma Injury to a single part or system of the body, usually treated in the hospital or emergency department.

Mitigation The action taken to prevent or reduce the harmful effects of a disaster on human health or property, it involves future-oriented activities to prevent subsequent disasters or to minimize their effects.

Mitosis The process of making new cells by cell division. Cell division through mitosis results in two cells called *daughter cells* that are genetically identical to the original cell, or *mother cell*, and to each other.

Mitral valve (bicuspid valve) Valve between the left atrium and ventricle in the heart; prevents blood from flowing backwards into the atrium.

Monosomic (monosomy) When one member of the chromosome pair is missing, for example, Turner syndrome (45, XO).

Morbid obesity Weight greater than 100% over ideal body weight.

Morton's neuroma A tumor-like mass formed within the neurovascular bundle of the intermetatarsal spaces.

Mosaicism A chromosome variation or abnormality that occurs after fertilization during mitosis at an early cell stage so not all cells are affected with the variation; for example, a child who is mosaic for Down syndrome will have some cells with two copies of chromosome 21 and some that have an extra chromosome 21.

Mourning The actions or expressions of the bereaved, including the symbols, clothing, and ceremonies that make up the outward manifestations of grief.

Multifactorial Health conditions determined by multiple factors, including genetic and environmental factors, each having an additive effect.

Multiple casualty incidents Incidents in which more than 2 but fewer than 100 persons are injured.

Multiple myeloma A malignancy in which plasma cells multiply uncontrollably and infiltrate the bone marrow, lymph nodes, spleen, and other tissues.

Multiple sclerosis (MS) A chronic demyelating autoimmune disease of the central nervous system.

Multiple trauma Most often the result of a motor vehicle crash, this type of trauma requires immediate intervention specifically focused on ensuring survival.

Murmur Sound made by turbulent blood flow through the heart.

Muscular dystrophy (MD) A group of inherited muscle diseases that cause progressive muscle degeneration and wasting.

Myasthenia gravis Chronic, progressive neuromuscular disorder characterized by fatigue and severe weakness of skeletal muscles.

Myelin sheaths The insulation of the neuron which facilitates conduction of impulses.

Myelodysplastic syndrome A group of blood disorders characterized by abnormal-appearing bone marrow and cytopenia (low numbers of circulating blood cells). MDS is not a single disease; at least five variations of the disorder have been identified.

Myocarditis Inflammatory disorder of the heart muscle.

Myopia (nearsightedness) A condition in which the eyeball is elongated, causing the image to focus in front of the retina instead of on it.

Myringotomy Incision of the tympanic membrane.

Myxedema coma A life-threatening complication of long-standing, untreated hypothyroidism, characterized by severe metabolic disorders (hyponatremia, hypoglycemia, lactic acidosis), hypothermia, cardiovascular collapse, impaired cognition, and coma.

Myxedema Systemic condition that develops from inadequate levels of thyroid hormone (hypothyroidism).

Natural disasters Disasters caused by acts of nature or emerging diseases; some are unexpected and some are predictable through advanced meteorological technologies.

Natural killer cells (NK cells, null cells) Large, granular lymphocytes (found in the spleen, lymph nodes, bone marrow, and blood) that provide immune surveillance and resistance to infection, and play an important role in the destruction of early malignant cells.

Nausea An unpleasant sensation of sickness or queasiness; may or may not be followed by vomiting.

Necrosis Tissue cell death.

Neglect syndrome (unilateral neglect) A disorder of attention. In this syndrome, the person cannot integrate and use perceptions from the affected side of the body or from the environment on the affected side and, hence, ignores that part.

Neoplasm A mass of new tissue (a collection of cells) that grows independently of its surrounding structures and has no physiologic purpose.

Nephrectomy Removal of the kidney.

Nephrotic syndrome A condition marked by massive proteinuria, hypoalbuminemia, hyperlipidemia, and edema.

Neuralgia Nerve pain.

Neurogenic bladder Dysfunctional urinary bladder due to lesion of central or peripheral nervous system.

Neurogenic shock Shock resulting from an imbalance between parasympathetic and sympathetic stimulation of vascular smooth muscle. If parasympathetic overstimulation or sympathetic understimulation persists, sustained vasodilation occurs, and blood pools in the venous and capillary beds.

Neuropathic pain Pain resulting from abnormal impulse processing by the peripheral and central nervous systems following injury to the peripheral nerves.

Neuropathy Damage to peripheral nerves causing hyper- or hyposensation and leading to neuropathic pain and injury.

Neurotransmitters A substance (as norepinephrine or acetylcholine) that transmits nerve impulses across a synapse.

Neutropenia A decrease in circulating neutrophils.

Nevi (moles) Flat or raised macules or papules with rounded, well-defined borders.

Nicotine Nicotine, a stimulant, is found in tobacco and enters the system via the lungs (cigarettes and cigars) and oral mucous membranes (chewing tobacco as well as smoking).

Nociceptive pain Pain caused by stimulation of peripheral or visceral pain receptors.

Nociceptors Sensory nerve fibers that conduct pain impulses from the periphery to the central nervous system.

Nocturia Voiding two or more times at night.

Node Elements of the immune system connected by lymphatics. Upregulates immune function; does not synthesize hormones.

Non-Hodgkin's lymphoma (NHL) Lymphoid tissue malignancies that do not contain Reed–Sternberg cells.

Nonconventional terrorist weapons Chemical, biological, and nuclear weapons of terrorism; used less frequently than conventional terrorist weapons.

Nonunion A state that exists when the ends of a fracture fail to heal together.

Normal sinus rhythm (NSR) Normal heart rhythm, in which impulses originate in the sinus node and travel through normal conduction pathways without delay.

Nosocomial Pertaining to or occurring in a hospital.

Nosocomial infection Infection contracted during residence in a hospital or extended care facility.

Nuclear terrorism Use of a nuclear device to cause mass murder and devastation.

Nursing informatics Nursing specialty integrating nursing, computer science and information science.

Nursing process The series of critical thinking activities nurses use as they provide care to patients; this logical approach to care ensures that patients receive comprehensive and effective care.

Nursing-sensitive quality indicators (NSQIs) Patient outcomes that are influenced significantly by quality nursing interventions.

Nutrients Substances found in food that are used by the body to promote growth, maintenance, and repair.

Nutrition The process by which the body ingests, absorbs, transports, uses, and eliminates food.

Nystagmus Rapid involuntary eye movements.

Obesity An excess of body fat (adipose tissue).

Obstructive shock Shock caused by an obstruction in the heart or great vessels that either impedes venous return or prevents effective cardiac pumping action.

Occult blood/bleeding Blood or bleeding that is hidden or not readily apparent.

Office-based surgical suites A setting for many elective surgeries, although increasing malpractice insurance premiums have influenced their decline.

Oligomenorrhea Scant menses.

Oliguria Urine output of less than 400 mL in 24 hours.

Oncogene Gene capable of triggering cancerous characteristics.

Oncologic emergencies In caring for patients with cancer, nurses may encounter a number of emergency situations in which their role may be pivotal to the patient's survival. Most of these emergencies require astute observations, accurate judgments, and rapid action once the problem has been identified.

Oncology The study of cancer.

Onycholysis The separation of the distal nail plate from the nail bed.

Onychomycosis A fungal or dermatophyte infection of the nail plate.

Operational variable The description of how a research variable is measured (commonly a dependent variable).

Opiates Analgesics derived from the opium plant; produce analgesia by binding to opioid receptors within and outside the CNS; the most potent analgesics available, and the treatment of choice for acute moderate-to-severe pain. Examples include morphine, codeine, and fentanyl (Durgesic, Actiq). Also called *narcotic analgesics*.

Orchitis Infection or inflammation of the testicle.

Orthopnea Difficulty breathing when supine.

Orthostatic hypotension A decrease in systolic blood pressure of more than 10 to 15 mmHg and a drop in diastolic blood pressure on standing.

Osmosis The process by which water moves across a selectively permeable membrane from an area of lower solute concentration to an area of higher solute concentration.

Ossification The process of bone formation.

Osteitis deformans See *Paget's disease of bone*.

Osteoarthritis (OA) (degenerative joint disease) The most commonly occurring of all forms of arthritis. This disease is characterized by loss of articular cartilage in articulating joints and hypertrophy of the bones at the articular margins.

Osteoblast Cells that form bone.

Osteoclast Cells that resorb bone.

Osteomalacia (adult rickets) Metabolic bone disorder characterized by inadequate mineralization of bone matrix.

Osteomyelitis Infection within the bone that can lead to tissue death and necrosis.

Osteophytes Bony outgrowths often called *joint mice*.

Osteoporosis Literally defined as "porous bones," a metabolic bone disorder characterized by loss of bone mass, increased bone fragility, and an increased risk of fractures.

Osteotomy An incision into or transection of the bone.

Ostomy General term for an operation in which an artificial opening is created.

Otitis media Inflammation or infection of the middle ear.

Otorrhea Leakage of cerebrospinal fluid through the ear.

Otosclerosis Abnormal bone formation in the osseous labyrinth of the temporal bone causing the footplate of the stapes to become fixed or immobile in the oval window. The result is a conductive hearing loss.

Ovarian cycle The female cycle that occurs from puberty until menopause in which the production of ova occur.

Oxyhemoglobin The combined form of hemoglobin and oxygen; found in arterial blood, it carries oxygen to body tissues.

Pacemaker A pulse generator used to provide an electrical stimulus to the heart when the heart fails to generate or conduct its own at a rate that maintains the cardiac output.

$PaCO_2$ Partial pressure of carbon dioxide in arterial blood.

Paget's disease of bone (osteitis deformans) A skeletal disorder that results from excessive osteoclastic activity. Paget's disease is characterized by bone deformity, especially of the long bones of the lower limbs, the pelvis, the lumbar vertebrae, and the skull.

Pain threshold The point at which a stimulus elicits a pain response.

Pain tolerance The amount of pain a person can endure before responding to it.

Pain A subjective response to both physical and psychologic stressors.

Palliative care An area of care that has evolved out of the hospice experience, but exists outside of hospice programs and is not restricted to the end of life. Palliative care is focused on the relief of physical, mental, and spiritual distress for individuals who have an incurable illness and is used earlier in the disease experience than hospice care. The goal of palliative care is to prevent and relieve suffering by early assessment and treatment of pain and other physical, psychosocial, and spiritual needs to improve the patient's quality of life.

Pallor Lack of color; paleness of skin.

Pancreatitis Inflammation of the pancreas.

Pannus Granulation tissue that forms in joints affected by rheumatoid arthritis and leads to the formation of scar tissue that immobilizes the joint.

PaO_2 Partial pressure of oxygen in arterial blood.

Papilledema Swelling of the optic nerve.

Paracentesis Aspiration of fluid from the peritoneal cavity.

Paralytic ileus Impaired propulsion or forward movement of bowel contents.

Paraplegia Paralysis of the lower portion of the body, sometimes involving the lower trunk.

Parasites Organisms that live within, on, or at the expense of the patient.

Parenteral nutrition (PN or TPN) Intravenous administration of carbohydrates (high concentrations of dextrose), protein (amino acids), electrolytes, vitamins, minerals, and fat emulsions.

Paresthesia An abnormal sensation of the skin, such as numbness, burning, or pricking.

Parish nursing A nontraditional, community-based way of providing health promotion and health restoration nursing interventions to a spiritual community.

Parkinson's disease (PD) Progressive, degenerative neurologic disease characterized by nonintentional tremor, bradykinesia, and muscle rigidity.

Paroxysmal Abrupt onset and termination.

Paronychia An infection of the cuticle of the fingernails or toenails.

Paroxysmal nocturnal dyspnea (PND) Attacks of acute shortness of breath that occur at night, waking up the patient.

Partial gastrectomy Removal of a portion of the stomach, usually the distal half to two-thirds.

Partial seizures Seizures that involve a restricted part of one cerebral hemisphere; may be simple partial (without loss of consciousness) or complex partial (with loss of consciousness).

Partial-thickness burn Burn that involves the entire dermis and the papillae of the dermis (superficial partial-thickness burn) or extends into the hair follicles (deep partial-thickness burn).

Passive immunity Temporary protection—provided by antibodies produced by other people or animals—against disease-producing antigens. Protection is gradually lost when these acquired antibodies are used up either by natural degradation or by combining with the antigen.

Pathogens Virulent organisms rarely found in the absence of disease.

Patient The person, family, or community with who and for who nursing care is designed and implemented.

Patient preferences Individualized patient experiences and values that are considered when determining evidence-based nursing care.

Patient Protection and Affordable Care Act (ACA) Landmark federal legislation enacted in 2010 and designed to provide access to health care services for more Americans and create new models of health care.

Patient-centered medical home (PCMH) Accessible, comprehensive, and coordinated primary care focused on illness prevention for patients and families.

Patient-controlled analgesia (PCA) A pump with a control mechanism that allows the patient to self-manage pain.

Pediculosis capitis An infestation with head lice.

Pediculosis corporis An infestation with body lice.

Pediculosis pubis An infestation with pubic lice (often called *crabs*).

Pelvic inflammatory disease (PID) A term used to describe infection of the pelvic organs.

Pemphigus vulgaris Chronic disorder of the skin and oral mucous membranes characterized by vesicle (blister) formation.

Penetrance The percentage or likelihood that an individual who has inherited a gene mutation will actually express the disease signs and symptoms in his or her lifetime.

Penicillin-resistant *Streptococcus pneumoniae* (PRSP) Infection transmitted by droplets from the respiratory tract; requires transmission-based droplet precautions.

Peptic ulcer/peptic ulcer disease (PUD) A break in the mucous lining of the gastrointestinal tract where it comes in contact with gastric juice; may affect any area of the gastrointestinal tract exposed to acid-pepsin secretions, including the esophagus, stomach, or duodenum.

Pericarditis Inflammation of the pericardium.

Perioperative nursing A specialized area of nursing practice that incorporates the three phases of the surgical experience: preoperative, intraoperative, and postoperative.

Peripheral vascular disease (PVD) Impaired blood supply to peripheral tissues, particularly the lower extremities.

Peripheral vascular resistance (PVR) The opposing forces or impedance to blood flow as the arterial channels become more and more distant from the heart.

Peristalsis Alternating waves of contraction and relaxation of involuntary muscles.

Peritoneal dialysis Procedure in which electrolytes, waste products, and excess water are removed from the body by diffusion using the peritoneum surrounding the abdominal cavity as the dialyzing membrane.

Peritonitis Inflammation of the peritoneum.

Pernicious anemia Anemia resulting from failure to absorb dietary vitamin B_{12} due to lack of intrinsic factor.

Persistent vegetative state (PVS) Condition of complete unawareness of self and the environment.

Personal protective equipment (PPE) Equipment used for the protection of personnel including gloves, masks, goggles, gowns, and biologic disposal bags (red bags); may also include hoods, helmets, head gear, and impermeable suits.

Pertussis (whooping cough) A highly contagious acute upper respiratory infection caused by the bacterium *Bordetella pertussis.*

Phagocytosis A process by which a foreign agent or target cell is engulfed, destroyed, and digested. Neutrophils and macrophages, known as phagocytes, are the primary cells involved in phagocytosis.

Phantom limb pain A confusing pain syndrome that occurs following surgical or traumatic amputation of a limb. The patient experiences pain in the missing body part even though there is complete mental awareness that the limb is gone.

Pharyngitis Acute inflammation of the pharynx.

Phenotype The expression of a person's entire physical, biochemical, and physiologic makeup, as determined by the individual's genotype and environmental factors.

Phimosis Constriction of the foreskin so that it cannot be retracted over the glans penis.

Physician orders for life-sustaining treatment (POLST) A form used for patients with serious, progressive, chronic illness which translates their wished regarding life sustaining treatment into actionable medical orders.

PICOT Format for evidence-based practice question. PICOT is a mnemonic for patient, intervention, comparison group, outcome and time.

Plasmapheresis (plasma exchange) Removal of the plasma component from whole blood.

Plastic surgery The alteration, replacement, or restoration of visible portions of the body, performed to correct a structural or cosmetic defect.

Platelets (thrombocytes) Cell fragments that have no nucleus and cannot replicate.

Pleural effusion Collection of excess fluid in the pleural space.

Pleuritis Inflammation of the pleura.

Pneumonectomy Removal of an entire lung.

Pneumonia Inflammation of the lung parenchyma (the respiratory bronchioles and alveoli).

Pneumothorax Results when air enters the pleural space due to blunt and penetrating injuries to the chest.

Polycystic kidney disease A hereditary disease characterized by cyst formation and massive kidney enlargement.

Polycythemia (erythrocytosis) Excess RBCs characterized by a hematocrit higher than 55%.

Polydipsia Excessive thirst.

Polymorphisms The DNA sequences that are natural variations in a gene usually having no adverse effects on the individual.

Polymyositis A systemic connective-tissue disorder characterized by inflammation of connective tissue and muscle fibers leading to muscle weakness and atrophy.

Polyp Mass of tissue that arises from the bowel wall and protrudes into the lumen.

Polyphagia Excessive eating.

Polysubstance abuse The simultaneous use of many substances.

Polyuria Excessive output of urine.

Portal hypertension Elevated pressure in the portal venous system that causes rerouting of blood to adjoining lower pressure vessels.

Portal systemic (hepatic) encephalopathy Impaired consciousness and mental status due to the accumulation of toxic waste products in the blood (ammonia in particular) as blood bypasses the congested liver.

Positive urine glucose Presence of glucose found in urine, however, not reliable as an indicator of hyperglycemia as glucose doesn't appear in the urine below the renal threshold of 180mg/dL.

Postconcussion syndrome Persistent headache, dizziness, irritability, insomnia, impaired memory and concentration, and learning problems following a concussion; may last for several weeks or up to 1 year.

Postoperative phase Period when a procedure or surgery has been completed and the patient is recovering from the stress associated with the surgery.

Postpoliomyelitis syndrome A complication of a previous infection by the poliomyelitis virus.

Prediabetes Impaired glucose tolerance.

Preload The amount of cardiac muscle fiber tension or stretch that exists at end diastole, just before ventricular contraction.

Premature ejaculation A common ejaculatory disorder in which semen is ejaculated before completion of sexual intercourse.

Premenstrual syndrome (PMS) Complex of symptoms characterized by irritability, depression, edema, and breast tenderness preceding the monthly menses.

Preoperative phase Time when preparation of the patient for surgery is conducted and completed.

Preparedness Actions that address preparations for and actions in dealing with the consequences of a disaster.

Presbycusis Age-related loss of the ability to hear high-frequency sounds, may occur because of cochlear hair cell degeneration or loss of auditory neurons in the organ of Corti.

Presbyopia Impaired near vision resulting from a loss of elasticity of the lens of the eye.

Pressure ulcer Ischemic lesion of the skin and underlying tissue caused by external pressure that impairs the flow of blood and lymph.

Priapism Sustained, painful erection that lasts at least 4 hours and is not associated with sexual arousal.

Primary care Comprehensive first contact health and illness care across the life span.

Primary hypertension (idiopathic, essential) A persistently elevated systemic blood pressure.

Primary polycythemia (polycythemia vera) A neoplastic stem cell disorder characterized by overproduction of red blood cells and, to a lesser extent, white blood cells and platelets.

Professional boundaries The borders between the vulnerability of the patient and the power of the nurse.

Progesterone Hormone produced by the ovary; works with estrogen to control the menstrual cycle.

Proptosis Forward displacement of the eye.

Prostatitis Inflammation of the prostate gland.

Protein-calorie malnutrition (PCM) Deficient protein and calories to meet metabolic needs.

Proteinuria Abnormal proteins in the urine.

Proto-oncogenes Normal genes that promote cell growth and repair.

Pruritus Subjective itching sensation producing an urge to scratch.

Psoriasis Chronic, noninfectious skin disorder that is characterized by raised, reddened, round circumscribed plaques covered by silvery white scales.

Psychogenic pain Pain that is experienced in the absence of any diagnosed physiologic cause or event.

Psychostimulants Psychostimulants such as cocaine and amphetamines have a high potential for abuse. Euphoria is the main subjective effect associated with cocaine and amphetamines, leading to addiction.

Ptosis Drooping of the eyelid.

Pulmonary edema An abnormal accumulation of fluid in the interstitial tissue and alveoli of the lung.

Pulmonary embolism Sudden occlusion of blood flow in a portion of the pulmonary vascular system, causing a ventilation-perfusion imbalance and impaired gas exchange.

Pulmonary hypertension Condition in which the pulmonary arterial pressure is elevated to an abnormal level.

Pulmonic valve The semilunar valve between the right ventricle and the pulmonary artery.

Pulse deficit Condition in which the radial pulse is less than the apical pulse, indicating weak, inefficient left ventricular contractions.

Pulse pressure The difference between the systolic and diastolic blood pressure.

Pulse Rhythmic pressure wave that can be felt over an artery.

Puncture wound Wound that occurs when a sharp or blunt object penetrates the integument.

Pupillary light reflex Reflex in which the pupil contracts in response to a bright light.

Pyelonephritis Upper urinary tract inflammation affecting the kidney and renal pelvis.

Pyoderma Purulent bacterial infection of skin.

Pyuria Pus in the urine.

Quadriplegia See *Tetraplegia*.

Qualitative research A research approach that focuses on a participant's experience and the perceived meaning of the situation of interest.

Quality assurance The process of ensuring quality control activities that evaluate, monitor, or regulate the standard of services provided to the consumer.

Quality improvement Systematic evidence-based methods used to evaluate and improve patient care.

Quantitative research The use of numerical computations and statistical analysis to answer empirical questions.

Rabies Viral (rhabdovirus) infection of the central nervous system transmitted by infected saliva that enters the human body through a bite or an open wound.

Radiation sickness One of the results of DNA mutation inside cells exposed to ionizing radiation.

Radiation therapy Therapy that uses radiation to kill a tumor, to reduce its size, to decrease pain, or to relieve obstruction.

Radiculopathy A condition in which one or more nerves, especially nerve roots, do not function normally.

Radiological dispersion bomb Also called a *dirty bomb,* it consists of a conventional explosive such as trinitrotoluene (TNT) packed with radioactive waste by-products from nuclear reactors that discharges deadly radioactive particles into the environment.

Raynaud's disease/phenomenon Disorders characterized by episodes of intense vasospasm in the small arteries and arterioles of the fingers and possibly the toes.

Reactive arthritis (Reiter's syndrome) An acute, nonpurulent inflammatory arthritis that complicates a bacterial infection of the genitourinary or gastrointestinal tracts.

Rebound tenderness Pain that occurs with withdrawal or release of pressure applied during abdominal palpation.

Recessive A characteristic that is apparent only when two copies of the gene encoding it are present, one from the mother and one from the father.

Reconstruction The recovery aspect of disaster response; during this period restoration, reconstitution, and mitigation take place.

Recovery The fifth of 5 stages of disaster. Activities include rebuilding and returning to some semblance of "normalcy" but also includes mitigation activities or planning to prevent subsequent disasters or to minimize the effects of future disasters.

Red blood cell (RBCs, erythrocytes) Blood cells shaped like a biconcave disk that contain hemoglobin required for oxygen transport to body tissues; the most common type of blood cell.

Referral source A person recommending home care services and supplying the agency with details about the patient's needs. The source may be a physician, nurse, social worker, therapist, or discharge planner.

Referred pain Pain that is perceived in an area distant from the site of the stimuli.

Reflex sympathetic dystrophy A group of poorly understood post-traumatic conditions involving persistent pain, hyperesthesias, swelling, changes in skin color and texture, changes in temperature, and decreased motion.

Reflux, urinary Backflow of urine toward the kidneys.

Refraction The bending of light rays as they pass from one medium to another medium of different optical density.

Refractory period A period in which myocardial cells are resistant to stimulation.

Regional anesthesia Anesthesia that desensitizes the area to be operated but does not involve the full central nervous system or cause sedation.

Regurgitation (valvular) Backflow of blood through an incompletely closed valve into the area it just left.

Rehabilitation The process of learning to live to one's maximum potential with a chronic impairment and its resultant functional disability.

Reiter's syndrome See *Reactive arthritis (ReA)*.

Reliability Describes that findings of a research study. Instrument reliability refers to the consistency of the measurement of the variable.

Remission A period in which symptoms are not experienced even though the disease is still clinically present.

Renal artery stenosis Narrowing of the renal artery.

Renal colic Acute, severe, intermittent pain in the flank and upper outer abdominal quadrant generally associated with acute obstruction of a ureter and resulting ureteral spasm.

Renal failure A condition in which the kidneys are unable to remove accumulated metabolites from the blood, resulting in altered fluid, electrolyte, and acid–base balance.

Renal impairment (decreased renal reserve) A glomerular filtration rate of approximately 50% of normal with normal BUN and serum creatinine levels.

Renal insufficiency A glomerular filtration rate of 20% to 50% of normal with azotemia and some manifestations of renal failure.

Renal transplant The surgical insertion of a functioning kidney.

Renin–angiotensin mechanism An intrinsic system that responds to renal perfusion; a fall in renal blood flow (e.g. due to low BP or cardiac output) stimulates renin release, ultimately leading to vasoconstriction and sodium and water retention and increased BP and cardiac output.

Repolarization Restoration of the resting cell membrane potential following generation of an action potential.

Research design Provides the structure for conducting a research study. The goal is maximum control of factors to reduce the potential that findings would be influenced by variables that were not part of the study.

Respiratory failure Inability of lungs to oxygenate the blood and remove carbon dioxide adequately to meet the body's needs, even at rest.

Respite care Short-term or intermittent home care, often using volunteers. These services exist to give the primary caregiver some relief from the burden of full-time care.

Response Occurs in the emergency stage of disaster response, after the impact of the disaster event has occurred, the community has been rapidly assessed for damage, and the types and extent of injuries suffered as well as the immediate needs of the community have been determined.

Reticular activating system (RAS) A system of reticular neurons within the reticular formation that passes steady streams of impulses through thalamic relays in order to stimulate the cerebral cortex into wakefulness.

Retinal detachment Separation of the retina or sensory portion of the eye from the choroid.

Retinitis pigmentosa Hereditary degenerative disease characterized by retinal atrophy and loss of retinal function progressing from the periphery to the central region of the retina.

Retractions A pulling in of the tissue of the precordium; a slight retraction just medial to the midclavicular line at the area of the apical impulse is normal and is more likely to be visible in thin patients.

Retrograde ejaculation Seminal fluid discharged into the bladder.

Reverse triage Working from the principle of the greatest good for the greatest number, reverse triage is an "upside-down triage" used in mass casualty events in which the victims who are most severely injured, requiring extensive resources with little chance of surviving, are treated last.

Rheumatic disorders Inflammatory diseases of connective tissues that affect joints, the muscles, and bones.

Rheumatic fever A systemic inflammatory disease caused by an abnormal immune response to pharyngeal infection by group A beta-hemolytic streptococci.

Rheumatic heart disease (RHD) Slowly progressive valvular deformity following acute or repeated attacks of rheumatic fever; characterized by rigid and deformed valve leaflets, fused valve commissures, and fibrosis of chordae tendineae.

Rheumatoid arthritis A chronic systemic autoimmune disease that causes inflammation of connective tissue, primarily in the joints.

Rhinitis Inflammation of the nasal cavities.

Rhinoplasty Surgical reconstruction of the nose.

Rhinorrhea Leakage of cerebrospinal fluid through the nose.

Ruptured disk See *Herniated intervertebral disk*.

Salmonellosis A form of food poisoning caused by ingestion of foods contaminated with one or more varieties of *Salmonella* bacteria.

Sarcoidosis Systemic disease characterized by granulomas in the lungs, lymph nodes, liver, eyes, skin, and other organs.

Sarcoma A tumor arising from supportive tissues.

Sarcopenic obesity The process of muscle loss combined with increased body fat as people age leading to a loss of function and reduced quality of life.

Scabies Parasitic infestation caused by the mite *Sarcoptes scabiei.*

Sciatica Pain over the sciatic nerve.

Scleroderma (systemic sclerosis) Hardening of the skin, a chronic condition characterized by the formation of excess fibrous connective tissue and diffuse fibrosis of the skin and internal organs.

Sclerotherapy The removal of benign skin lesions with a sclerosing agent that causes inflammation with fibrosis of tissue.

Scoliosis A lateral curvature of the spine.

Scrub person Prepares the sterile field, surgical supplies, and equipment for surgical procedures; also assists surgeon and physician assistant by passing instruments, suctioning blood, and maintaining the sterile field.

Seborrheic dermatitis Common and chronic inflammatory disorder of the skin that involves the scalp, eyebrows, eyelids, ear canals, nasolabial folds, axillae, and trunk. The cause is unknown.

Sebum Sebaceous glands are found all over the body except on the palms and soles. These glands secrete an oily substance called *sebum,* which softens and lubricates the skin and hair and also decreases water loss from the skin in low humidity. Sebum also protects the body from infection by killing bacteria.

Secondary hypertension Elevated blood pressure resulting from an identifiable underlying process.

Seizure An episode of excessive and abnormal discharge of electrical activity within the central nervous system.

Semen Fluid containing sperm secreted by the male reproductive system glands.

Seminoma A tumor from seminal or germ tissue.

Septic arthritis The type of arthritis that develops when a joint space is invaded by a pathogen.

Septic shock One part of a progressive syndrome called *systemic inflammatory response syndrome (SIRS)*. Beginning with an infection, SIRS progresses to bacteremia, then sepsis, then septic shock, and finally multiple organ failure syndrome.

Septicemia Systemic disease associated with the presence of bacteria or their toxins in the blood.

Seroconversion Antibody response to a disease or vaccine.

Serum bicarbonate The serum bicarbonate (HCO_3^-) reflects the renal regulation of acid–base balance. It is often called the metabolic component of arterial blood gases. The normal HCO_3^- value is 22 to 26 mEq/L.

Severe acute respiratory syndrome (SARS) Lower respiratory illness of unknown etiology; spread by close person-to-person contact.

Sex chromosomes The chromosomes X or Y that indicate gender.

Sexually transmitted infection (STI, sexually transmitted disease, venereal disease) Any infection transmitted by sexual contact, including vaginal, oral, and anal intercourse.

Shigellosis (bacillary dysentery) An acute bowel infection caused by microorganisms of the *Shigella* genus.

Shingles See *Herpes zoster*.

Shock A clinical syndrome characterized by a systemic imbalance between oxygen supply and demand. This imbalance results in a state of inadequate blood flow to the peripheral tissues, causing life-threatening cellular dysfunction, hypotension, and oliguria.

Sickle cell anemia A hereditary, chronic hemolytic anemia characterized by episodes of sickling, during which RBCs become abnormally crescent shaped.

Sickle cell crisis Severe episodes of fever and intense pain that are the hallmark of sickle cell anemia.

Sickle cell disease A hereditary, chronic hemolytic anemia. It is characterized by episodes of *sickling*, during which RBCs become abnormally crescent shaped. The disorder is transmitted as an autosomal recessive genetic defect.

Sinusitis Inflammation of the mucous membranes of one or more of the sinuses.

Sjögren's syndrome An autoimmune disorder that causes inflammation and dysfunction of exocrine glands throughout the body.

Skeletal traction Application of a pulling force through placement of pins into the bone.

Skin graft Surgical method of detaching skin from a donor site and placing it in a recipient site, where it develops a new blood supply from the base of the wound.

Skin tags Soft papules on a pedicle.

Skin traction Traction in which the cradle-like sleeve placed around the extremity exerts its pulling force through the patient's skin.

Sleep apnea Absence of airflow through the upper airways for 10 or more seconds.

Somatic cell Any cell in the body that is not a sex cell (ova and sperm).

Somatic pain Pain arising from nerve receptors originating in the skin or close to the surface of the body.

Somogyi phenomenon A morning rise in blood glucose to hyperglycemic levels following an episode of nocturnal hypoglycemia and a counterregulatory hormone response.

Spasticity Increased muscle tone in diseases involving the corticospinal motor tract.

Spermatocele A mobile, usually painless mass containing dead spermatozoa that forms in the epididymis.

Spinal cord injury (SCI) Injury to spinal cord, usually due to trauma.

Spinal cord tumors Benign or malignant, primary or metastatic tumor of the spinal cord.

Spinal shock Temporary loss of reflex function below the level of injury to the spinal cord.

Splenomegaly Enlargement of the spleen.

Sprain Tearing or stretching of a ligament that results from a twisting motion.

Sprue A chronic primary disorder of the small intestine in which the absorption of nutrients, particularly fats, is impaired.

Squamous cell cancer A malignant tumor of the squamous epithelium of the skin or mucous membranes

Squamous cell carcinoma Malignant tumor of the squamous epithelium of the skin or mucous membranes.

Standard A statement or criterion that can be used by a profession and by the general public to measure quality of practice.

Starvation Inadequate dietary intake; the condition of being without food for long periods of time.

Statistical analysis The manipulation and testing of data in quantitative studies to determine if changes seen are due to the experiment or due to chance.

Status asthmaticus Severe, prolonged asthma that does not respond to routine treatment. Without aggressive therapy, status asthmaticus can lead to respiratory failure with hypoxemia, hypercapnia, and acidosis.

Status epilepticus Continuous seizure activity with only very short periods of calm occurring between intense and persistent seizures.

Steatorrhea Greasy, frothy, yellow stools resulting from excess fat in the feces.

Stem cell transplant (SCT) An alternative to bone marrow transplant. SCT results in complete and sustained replacement of the recipient's blood cell lines (WBCs, RBCs, and platelets) with cells derived from the donor stem cells. Donors must have tissue that is closely matched with that of the recipient.

Stem cells (hemocytoblasts) Bone marrow precursor cells for all blood cells.

Stenosis Condition where valve leaflets fuse together and are unable to open or close fully.

Stoma Surface opening.

Stomatitis Inflammation of the oral mucosa.

Straight traction A pulling force applied in a straight line to the injured body part resting on the bed.

Strain Stretching or tearing of muscle fibers that results in bleeding into the tissues.

Stress incontinence Loss of usually less than 50 mL of urine occurring with increased abdominal pressure.

Stress-induced (erosive) gastritis Inflammation and superficial erosions of the gastric mucosa that may occur as a complication of other life-threatening conditions such as shock, severe trauma, major surgery, sepsis, burns, or head injury.

Striae A line above or below tissue that differs in color and texture from surrounding tissue.

Stridor High-pitched, harsh inspiratory sound indicative of upper airway obstruction.

Stroke (brain attack, cerebrovascular accident, CVA) A condition in which neurologic deficits occur as a result of decreased blood flow to a focal (localized) area of brain tissue from a blood clot, an embolus, or a cerebral vessel rupture.

Stroke volume (SV) The amount of blood pumped into the aorta with each contraction of the left ventricle.

Subdural hematoma A localized mass of blood that collects between the dura mater and the arachnoid mater.

Subluxation Partial separation (or dislocation) of the bones of a joint.

Substance abuse The use of any chemical in a fashion inconsistent with medical or culturally defined social norms despite physical, psychologic, or social adverse effects.

Substance dependence A severe condition occurring when the use of a chemical substance is no longer under an individual's control for at least 3 months. Continued use of the substance usually persists despite adverse effects on the person's physical condition, psychologic health, and interpersonal relationships (used interchangeably with addiction).

Sudden cardiac death (SCD) Unexpected death occurring within 1 hour of the onset of cardiovascular symptoms.

Sundowning A behavioral change in Alzheimer's disease characterized by increased agitation, time disorientation, and wandering during afternoon and evening hours.

Superficial burn Burn involving only the epidermal layer of the skin; most often results from damage from sunburn, ultraviolet light, minor flash injury (from a sudden ignition or explosion), or mild radiation burn associated with cancer treatment.

Surfactant A lipoprotein produced by the alveolar cells; interferes with adhesion of water molecules, reducing surface tension and helping to expand lungs.

Surge capacity The healthcare system's ability to rapidly expand beyond normal services to meet the increased demand for qualified personnel, medical care, and public health in the event of a large-scale disaster.

Surgery An invasive medical procedure performed to diagnose or treat illness, injury, or deformity. Although surgery is a medical treatment, the nurse assumes an active role in caring for the patient before, during, and after surgery.

Surgical debridement The process of excising a wound to the level of fascia (fascial excision) or sequentially removing thin slices of a burn wound to the level of viable tissue (sequential excision).

Surveillance Collecting and analyzing data to establish a baseline and determine a point at which there is a change or trend in the health of the population.

Syndrome of inappropriate ADH secretion (SIADH) A disorder characterized by high levels of ADH in the absence of serum hypoosmolality. Manifestations of SIADH occur as a result of water retention, hyponatremia, and serum hypo-osmolality. Blood volume expands, but the plasma is diluted.

Synovitis Inflammation of the synovial membrane lining the articular capsule of a joint.

Syphilis A sexually transmitted infection caused by a spirochete that may invade almost any body tissue or organ. It enters the body through a break in the skin or mucous membranes, and can be transferred to the fetus through the placental circulation.

Systemic lupus erythematosus (SLE) A chronic, inflammatory immune complex connective tissue disease.

Systemic sclerosis (scleroderma) Hardening of the skin; a chronic disease characterized by the formation of excess fibrous connective tissue and diffuse fibrosis of the skin and internal organs.

Systole A phase during which the ventricles contract and eject blood into the pulmonary and systemic circuits.

Systolic blood pressure The arterial pressure wave produced by ventricular contraction (systole); averages 120 mmHg in healthy adults.

T lymphocytes (T cells) Type of lymphocyte that matures in the thymus gland.

Tachycardia A heart rate exceeding 100 beats per minute.

Tachypnea Abnormally rapid respiratory rate.

Tendonitis Inflammation of a tendon.

Tension headache Poorly localized headache characterized by ill-defined bilateral head aching, tightness, pressure, or a viselike feeling.

Tension pneumothorax A condition in which an injury to the chest allows air to enter but not escape the pleural cavity.

Terrorism Defined by the U.S. Department of Defense as the "calculated use of violence or the threat of violence to inculcate fear; intended to coerce or to intimidate governments or societies in the pursuit of goals that are generally political, religious or ideological."

Testicular torsion Twisting of the testes and spermatic cord.

Testosterone Male hormone produced in the testes.

Tetanus Disorder of the nervous system caused by a neurotoxin elaborated by *Clostridium tetani*.

Tetany Tonic muscular spasms.

Tetraplegia (formerly called *quadriplegia*) Injury to cervical segments of the cord thus impairing function of the arms, trunk, legs, and pelvic organs.

Thalassemia An inherited disorder of hemoglobin synthesis in which either the alpha or beta chains of the hemoglobin molecule are missing or defective.

Third spacing The accumulation and sequestration of trapped extracellular fluid in an actual or potential body space as a result of disease or injury.

Thoracentesis Invasive procedure in which fluid (or occasionally air) is removed from the pleural space with a needle.

Thoracotomy Incision of the chest wall to gain access to the lung for surgery.

Thrill Palpable vibration over the precordium or an artery.

Thromboangiitis obliterans (Buerger's disease) An occlusive vascular disease involving inflammation, spasm, and clot formation in small- and medium-sized peripheral arteries.

Thrombocytopenia A platelet count of less than 100, per milliliter of blood.

Thromboembolus A thrombus that breaks loose from the vessel wall.

Thrombophlebitis See *Venous thrombosis*.

Thrombotic cerebrovascular accident Cerebrovascular accident caused by occlusion of a vessel by a thrombus (a blood clot) on the interior wall of an artery.

Thrombus A blood clot that adheres to a vessel wall.

Thrust A visible pulsation.

Thyroid storm or crisis An extreme state of hyperthyroidism that is rare today because of improved diagnosis and treatment methods. Those affected are usually people with untreated hyperthyroidism (most often Graves' disease) and people with hyperthyroidism who have experienced a stressor, such as an infection, trauma, untreated diabetic ketoacidosis, or manipulation of the thyroid gland during surgery. Thyroid crisis is a life-threatening condition.

Thyroidectomy Surgical removal of the thyroid gland.

Thyroiditis Inflammation of the thyroid gland.

Thyrotoxicosis Another term for hyperthyroidism.

Tidal volume (TV) The amount of air (approximately 500 mL) moved in and out of the lungs with each normal, quiet breath.

Tinea capitis A fungal infection of the scalp.

Tinea corporis A fungal infection of the body.

Tinea pedis A fungal infection of the toenails and feet.

Tinnitus Perception of sound such as ringing, buzzing, or roaring in the ears.

Titrate To increase or decrease the dose in small increments.

Tolerable upper intake level (UL) The maximum level of daily nutrient intake that is likely to pose no risk of adverse effects.

Tolerance A cumulative state in which a particular dose of a chemical elicits a smaller response than before. With increased tolerance, the individual needs higher and higher doses to obtain the desired effect.

Tonic-clonic seizures Alternating contraction (tonic phase) and relaxation (clonic phase) of muscles during seizure activity.

Tonsillitis Acute inflammation of the palatine tonsils.

Tophi Small white nodules in subcutaneous tissue composed of urate deposits resulting from gout.

Total colectomy Surgical removal of the entire colon.

Total gastrectomy Removal of the entire stomach.

Total hip arthroplasty (THA) Replacement of both the femoral head and the acetabulum.

Total parenteral nutrition (TPN) Intravenous administration of carbohydrates (high concentrations of dextrose), protein (amino acids), electrolytes, vitamins, minerals, and fat emulsions.

Toxic epidermal necrolysis (TEN) Rare, life-threatening disease in which the epidermis peels off the dermis in sheets, leaving large areas of denuded skin.

Toxic megacolon A condition characterized by acute motor paralysis and dilation of the colon.

Traction The application of a straightening or pulling force to return or maintain the fractured bones in normal anatomic position.

Transcutaneous electrical nerve stimulation (TENS) A unit that consists of a low-voltage transmitter connected by wires to electrodes that are placed by the patient as directed by the physical therapist. The patient experiences a gentle tapping or vibrating sensation over the electrodes. The patient can adjust the voltage to achieve maximum pain relief.

Transdermal Medication absorbed through the skin without injection.

Transfusion An infusion of blood or blood components.

Transient ischemic attack (TIA) Brief period of localized cerebral ischemia that causes neurologic deficits lasting for less than 24 hours.

Transitional care Interventions designed to improve the ability of patients and caregivers to manage care needs in preparation for transitions from one healthcare setting to another or to home.

Transjugular intrahepatic portosystemic shunt (TIPS) Used to relieve portal hypertension and its complications of esophageal varices and ascites. A channel is created through the liver tissue using a needle inserted transcutaneously; an expandable metal stent is inserted into this channel to allow blood to flow directly from the portal vein into the hepatic vein, bypassing the cirrhotic liver. The shunt relieves pressure in esophageal varices and allows better control of fluid retention with diuretic therapy. Generally it is used as a short-term measure until liver transplant is performed.

Translocation The joining of a part of or a whole chromosome to another separate chromosome.

Trauma The injury to human tissues and organs resulting from the transfer of energy from the environment.

Traumatic brain injury (TBI) A traumatic insult to the brain capable of causing physical, intellectual, emotional, social, and vocational changes.

Tremors Rhythmic movement.

Triage Means "sorting." Triage is a continuous process in which patient priorities are reassigned as needed treatments, time, and the condition of the patients change.

Tricuspid valve The valve between the right atrium and right ventricle of the heart; prevents blood from flowing backwards into the atrium.

Trigeminal neuralgia (tic douloureux) A chronic disease of the trigeminal cranial nerve (cranial nerve V) that causes severe facial pain.

Triglycerides Molecules of glycerol with fatty acids used to transport and store fats in body tissues.

Triple Aim An initiative launched by the Institute of Health Improvement aimed at simultaneously improving the patient care experience, improving the health of population and reducing the per capita costs of health care.

Trisomy 21 Possessing three chromosomes instead of the usual two as in trisomy 21 or Down syndrome where an additional copy of chromosome 21 is present.

Trousseau's sign Contraction of the hand and fingers (carpal spasm) in response to occlusion of the blood supply by a blood pressure cuff; caused by decreased blood calcium levels.

Tuberculosis (TB) Chronic, recurrent infectious disease caused by *Mycobacterium tuberculosis*; usually affects the lungs, although any organ can be affected.

Tumor marker A protein molecule detectable in serum or other body fluids. This marker is used as a biochemical indicator of the presence of a malignancy.

Tympanoplasty Surgical reconstruction of the middle ear.

Type 1 diabetes One of two types of diabetes characterized by the destruction of beta cells, usually leading to absolute insulin deficiency.

Type 2 diabetes One of two types of diabetes, the characteristics of which may range from predominantly insulin resistance with relative insulin deficiency to a predominantly secretory defect with insulin resistance. There is no immune destruction of beta cells.

Ulcer A lesion of the skin or mucous membranes.

Ulcerative colitis Chronic inflammatory bowel disorder of the mucosa and submucosa of the colon and rectum.

Ultrafiltration Removal of excess body water using a hydrostatic pressure gradient.

Uniform Anatomical Gift Act Legislation that requires people to be informed about their options related to organ donation.

Unilateral neglect State in which a patient is unaware of and inattentive to one side of the body.

Upper body obesity (central obesity) Excess intra-abdominal fat characterized by a waist-to-hip ratio greater than 1 in men and 0.8 in women.

Urea An end product of protein metabolism, eliminated in the urine.

Uremia Literally "urine in the blood"; the syndrome or group of symptoms associated with end-stage renal failure.

Ureteral stent Thin catheter inserted into the ureter to provide for urine flow and ureteral support.

Ureteroplasty Surgical repair of a ureter.

Urgency A sudden, compelling need to urinate.

Urinary calculi Calculi or stones in the urinary tract.

Urinary diversion Procedure to provide for urine collection and drainage following cystectomy. The most common urinary diversion is the ileal conduit.

Urinary drainage system The ureters, urinary bladder, and urethra.

Urinary incontinence (UI) Involuntary urination.

Urinary retention Incomplete emptying of the bladder.

Urine ketone tests Used to detect the presence of ketones in the urine.

Urolithiasis Development of stones within the urinary tract.

Urticaria Hives.

Vaccine Suspensions of whole or fractionated bacteria or viruses that have been treated to make them nonpathogenic.

Validity The soundness of the scientific methods used in a study including control to reduce bias. Instrument validity describes how well an instrument measures the concept or variable it is supposed to measure.

Valsalva's maneuver Closing the glottis and contracting the diaphragm and abdominal muscles to increase intra-abdominal pressure.

Valvular heart disease Interference of blood flow to, within, and from the heart.

Vancomycin intermediate-resistant *Staphylococcus aureus* (VISA) A form of *S. aureus* with intermediate resistance to vancomycin.

Varicocele Dilation of the pampiniform venous complex of the spermatic cord.

Varicose veins Irregular, tortuous veins with incompetent valves.

Vasectomy Sterilization procedure in which a portion of the spermatic cord is removed.

Vasoconstriction Smooth muscle contraction that narrows the vessel lumen.

Vasodilation Smooth muscle relaxation that expands the vessel lumen.

Vasogenic shock See *Neurogenic shock*.

Venous thrombosis (thrombophlebitis) Blood clot (thrombus) formation on the wall of a vein, accompanied by inflammation of the vein wall and obstructed venous blood flow.

Ventilator-associated pneumonia A preventable secondary complication from intubation and mechanical support.

Vertigo Sensation of whirling or rotation.

Very low calorie diet (VLCD) A protein-sparing modified fast (400 to 800 kcal/day or less) under close medical supervision that may be used to treat significant obesity.

Vesicoureteral reflux Condition in which urine moves from the bladder back toward the kidney.

Visceral pain Pain arising from body organs. It is dull and poorly localized because of the low number of nociceptors.

Vital capacity The sum of TV (tidal volume) + IRV (inspiratory reserve volume) + ERV (expiratory reserve volume); approximately 4500 mL in healthy patients.

Vitamin B_{12} deficiency anemia Anemia due to inadequate vitamin B_{12} consumption or impaired absorption.

Vitiligo Abnormal patchy loss of melanin from the skin.

Volatile acids Acids eliminated from the body as a gas.

Volkmann's contracture A common complication of elbow fractures; can result from unresolved compartment syndrome. Arterial blood flow decreases, leading to ischemia, degeneration, and contracture of the muscle.

Vomiting The forceful expulsion of the contents of the upper GI tract resulting from contraction of muscles in the gut and abdominal wall.

Von Willebrand's disease The most common hereditary bleeding disorder, caused by a deficit of or defective von Willebrand factor.

Warm zone Adjacent to the hot zone of a disaster, the area where decontamination of victims or triage and emergency treatment takes place; also called the control zone.

Warts (verrucae) Lesions of the skin caused by the human papillomavirus.

Weaning Process of removing the patient from ventilator support and reestablishing spontaneous, independent respirations.

Weber test A test of hearing; a vibrating tuning fork is placed on the midline of the top of the head and the patient is asked to describe where the sound is heard. Normally, sound is heard equally in both ears.

Wellness An integrated method of functioning oriented toward maximizing an individual's potential within the environment.

Wernicke's encephalopathy Caused by thiamine (B_1) deficiency and characterized by nystagmus, ptosis, ataxia, confusion, coma, and possible death. Thiamine deficiency is common in chronic alcoholism.

Wheezes Continuous, musical sounds caused by narrowing of the lumen in a respiratory passage.

White blood cell (WBCs, leukocytes) The blood cells that contribute to the body's defense against microorganisms.

Wild-type gene The most common type of gene; designated as normal.

Withdrawal symptoms Constellation of signs and symptoms that occurs in physically dependent individuals when they discontinue drug use.

Withdrawal Cessation of use of a substance to which an individual has become addicted.

Xenograft A transplant from an animal species to a human.

Xeroderma A chronic skin condition characterized by dry, rough skin.

Xerosis Dry skin.

Xerostomia Excessive dryness of the mucous membranes due to chemotherapy or radiation.

X-linked dominant Rare conditions with differential gender outcomes from an altered gene on the X chromosome. For example, if a male is affected, the condition is severe and often lethal. A family history of multiple male miscarriages may be a sign of an X-linked dominant condition.

X-linked recessive The result of an altered gene on the X chromosome. All males with this alteration will express the consequences due to only having one X chromosome. Females may not express the consequence if they have a second normal X chromosome.

X-linked Any gene found on the X chromosome, or traits determined by such genes; also refers to the specific mode of inheritance of such genes. One altered gene on an X chromosome in a male can produce disease, such as hemophilia.

Zollinger–Ellison syndrome Peptic ulcer disease caused by a gastrinoma, or gastrin-secreting tumor of the pancreas, stomach, or intestines.

resources for, 1025*t*
aneurysms
assessment, 985–986
continuity of care, 987
diagnoses, outcomes, and interventions
anxiety, 986–987
risk for ineffective tissue perfusion, 986, 986*t*
risk for injury, 986
priorities of care, 986
resources for, 986*t*
angina pectoris
assessment, 875
continuity of care, 877–878
delegating nursing care activities, 877
diagnoses, outcomes, and interventions
ineffective tissue perfusion, 877
overview, 875
risk for ineffective therapeutic regimen management, 877
health promotion, 875
priorities of care, 875
ankylosing spondylitis, 1301
anorectal lesions, 688
anterior pituitary gland disorders, 497
appendicitis
assessment, 639
Case Study & Nursing Care Plan, 640*t*
continuity of care, 640
diagnoses, outcomes, and interventions
acute pain, 639, 639*t*
risk for infection, 639, 639*t*
health promotion, 639
priorities of care, 639
arteriovenous malformation, 1382
asthma
assessment, 1173
continuity of care, 1175
diagnoses, outcomes, and interventions
anxiety, 1174
ineffective airway clearance, 1173, 1173*t*
ineffective breathing pattern, 1173–1174
ineffective therapeutic regimen management, 1174, 1174*t*
health promotion, 1172–1173
priorities of care, 1173
resources for, 1173*t*
atelectasis, 1187
autoimmune disorders
continuity of care, 307–308
diagnoses, 307
bacterial skin infections
assessment, 398
continuity of care, 399
delegating nursing care activities, 399
diagnoses, outcomes, and interventions, risk for infection, 398–399, 399*t*
priorities of care, 398
resources for, 399*t*
Bell's palsy, 1466–1467
benign breast disorders, 1608
benign prostatic hyperplasia
continuity of care, 1570–1571, 1570*t*
diagnoses, outcomes, and interventions
readiness for enhanced knowledge: benign prostatic hypertrophy, 1569
risk for imbalanced fluid volume, 1570, 1570*t*
risk for infection, 1570
urinary retention, 1569–1570, 1570*t*
benign scrotal masses, 1561
bone tumors
continuity of care, 1317
diagnoses, outcomes, and interventions
acute and chronic pain, 1317
impaired physical mobility, 1317
risk for injury, 1317
brain tumors
assessment, 1392
Case Study & Nursing Care Plan, 1395*t*
continuity of care, 1394–1395
diagnoses, outcomes, and interventions
acute pain, 1394, 1394*t*

chlamydia, 1631
chronic kidney disease
assessment, 816
continuity of care, 819–820
delegating nursing care activities, 819
diagnoses, outcomes, and interventions
Case Study & Nursing Care Plan, 818*t*
disturbed body image, 819
imbalanced nutrition: less than body requirements, 817
impaired kidney function, 817, 817*t*
overview, 816–817
risk for infection, 817–819, 818*t*
chronic venous insufficiency, 1005, 1006*t*
cirrhosis
assessment, 714–715
Case Study & Nursing Care Plan, 717*t*
continuity of care, 718
diagnoses, outcomes, and interventions
excess fluid volume, 715
imbalanced nutrition: less than body requirements, 716–718
impaired skin integrity, 716
risk for acute confusion, 715
risk for bleeding, 715, 716*t*, 718*t*
health promotion, 714
priorities of care, 715
resources for, 715*t*
CNS infection
assessment, 1421
Case Study & Nursing Care Plan, 1422*t*
diagnoses, outcomes, and interventions
ineffective protection, 1421, 1421*t*
risk for imbalanced fluid volume, 1422, 1422*t*
health promotion, 1421
importance of, 1420–1421
priorities of care, 1421
colorectal cancer
assessment, 676
continuity of care, 679
diagnoses, outcomes, and interventions
acute pain, 676–678
Case Study & Nursing Care Plan, 678*t*
grieving, 679
imbalanced nutrition: less than body requirements, 678–679
rectal procedures with abdominoperineal resection, 676*t*
risk for sexual dysfunction, 679
health promotion, 676
priorities of care, 676
resources for, 678*t*
conjunctivitis
assessment, 1494
continuity of care, 1495
delegating nursing care activities, 1495
diagnoses, outcomes, and interventions
risk for impaired vision, 1495
risk for infection, 1494–1495
health promotion, 1494, 1494*t*
priorities of care, 1494
resource for, 1495*t*
constipation
assessment, 632, 632*t*
continuity of care, 633
diagnoses, outcomes, and interventions, constipation, 632–633
health promotion, 632
priorities of care, 632
contusions, sprains, and strains, 1236
COPD
assessment, 1180
continuity of care, 1184–1185, 1184*t*
diagnoses, outcomes, and interventions
Case Study & Nursing Care Plan, 1183*t*
compromised family coping, 1182–1184
decisional conflict: smoking, 1184
imbalanced nutrition: less than body requirements, 1182
ineffective airway clearance, 1181–1182, 1182*t*
health promotion, 1180, 1181*t*
priorities of care, 1180
resources for, 1182*t*

grieving, 794–795
ineffective breathing pattern, 794, 794*t*
overview, 792–793
risk for impaired urinary elimination, 794, 794*t*
repetitive use injury
continuity of care, 1239
diagnoses, outcomes, and interventions
acute pain, 1239
impaired physical mobility, 1239
respiratory acidosis
assessment, 224
Case Study & Nursing Care Plan, 225*t*
continuity of care, 225
delegating nursing care activities, 224–225
diagnoses, outcomes, and interventions
impaired gas exchange, 224
ineffective airway clearance, 224
health promotion, 224
priorities of care, 224
respiratory alkalosis
continuity of care, 226
diagnoses, outcomes, and interventions, ineffective breathing pattern, 226
health promotion, 226
retinal detachment
continuity of care, 1516
diagnoses, outcomes, and interventions
anxiety, 1515–1516
ineffective tissue perfusion: retinal, 1515, 1515*t*
priorities of care, 1515
rheumatic fever/rheumatic heart disease
assessment, 940
continuity of care, 941
delegating nursing care activities, 941
diagnoses, outcomes, and interventions
activity intolerance, 941
acute pain, 940–941
health promotion, 940
priorities of care, 940
rheumatoid arthritis
assessment, 1298
Case Study & Nursing Care Plan, 1300*t*
continuity of care, 1300–1301
delegating nursing care activities, 1300
diagnoses, outcomes, and interventions
chronic pain, 1299
fatigue, 1299
ineffective role performance, 1299

Nurses (*cont.*)
readiness for enhanced self-health management, 1298–1299
health promotion, 1298
priorities of care, 1298
resources for, 1299*t*
scoliosis and kyphosis, 1322
seizures
assessment, 1368, 1368*t*
Case Study & Nursing Care Plan, 1369*t*
continuity of care, 1370
diagnoses, outcomes, and interventions
anxiety, 1369–1370
readiness for enhanced knowledge, 1370
risk for ineffective airway clearance, 1369
health promotion, 1368
priorities of care, 1368–1369
resources for, 1369*t*
septic arthritis, 1315
severe acute respiratory syndrome
assessment, 1126
continuity of care, 1127
diagnoses, outcomes, and interventions
impaired gas exchange, 1126–1127, 1126*t*, 1127*t*
risk for infection, 1127
health promotion, 1126
priorities of care, 1126
shock
assessment, 254, 256*t*
Case Study & Nursing Care Plan, 256*t*
continuity of care, 257
diagnoses, outcomes, and interventions
altered tissue perfusion, 255–256
anxiety, 256–257
decreased cardiac output, 255, 255*f*
health promotion, 254
priorities of care, 254
resources for, 255*t*
short bowel syndrome, 670–671
sinusitis
assessment, 1089
continuity of care, 1089–1090
diagnoses, outcomes, and interventions
imbalanced nutrition: less than body requirements, 1089
pain, 1089
health promotion, 1089
priorities of care, 1089
Sjögren's syndrome, 1309
spinal cord injury
assessment, 1406–1407
Case Study & Nursing Care Plan, 1410*t*
continuity of care, 1411
delegating nursing care activities, 1411
diagnoses, outcomes, and interventions
autonomic dysreflexia, 1408, 1408*t*
impaired gas exchange, 1407, 1407*t*, 1408*t*
impaired physical mobility, 1407
impaired urinary elimination and constipation, 1408–1409, 1409*t*
ineffective breathing pattern, 1407–1408
sexual dysfunction, 1409–1410
situational and chronic low self-esteem, 1410–1411
health promotion, 1406
priorities of care, 1407
resource for, 1407*t*
spinal cord tumors, 1417–1418
stomach cancer
assessment, 621
continuity of care, 622
diagnoses, outcomes, and interventions
grieving, 622
imbalanced nutrition: less than body requirements, 622
health promotion, 621
priorities of care, 621, 621*t*
stomatitis
assessment, 594
continuity of care, 595–596
delegating nursing care activities, 596
diagnoses, outcomes, and interventions, 594–595
imbalanced nutrition: less than body requirements, 595
impaired oral mucous membrane, 595
health promotion, 594
priorities of care, 594
stroke
assessment, 1377, 1378*t*
Case Study & Nursing Care Plan, 1381*t*
complex nature of, 1376–1377
diagnoses, outcomes, and interventions
impaired physical mobility, 1378–1379, 1378*t*
impaired swallowing, 1380, 1380*t*
impaired urinary elimination and risk for constipation, 1379–1380
impaired verbal communication, 1379
risk for ineffective tissue perfusion: cerebral, 1377–1378
self-care deficit, 1379
health promotion, 1377, 1377*t*
priorities of care, 1377
resources for, 1378*t*
substance abuse
assessment, 108–110, 109*t*, 110*t*, 111*f*
continuity of care, 113, 113*t*
delegation of nursing care activities, 113
diagnoses, outcomes, and interventions, 110, 112–113, 112*t*
health promotion, 108, 109*t*
safety considerations, 108, 108*t*
sudden cardiac death, 915–916
surgery
continuity of care, 74, 76
intraoperative nursing care, 68–69, 68*t*
older adults, 74, 74*t*
postoperative, 69–70
postoperative complications, 70–74, 70*f*, 71*t*, 72*f*, 74*t*
preoperative, 66
preoperative patient preparation, 68, 69*t*
preoperative teaching, 66–68, 67–68*t*
syphilis
assessment, 1635
Case Study & Nursing Care Plan, 1636*t*
continuity of care, 1636
diagnoses, outcomes, and interventions
anxiety, 1635
risk for injury, 1635
situational low self-esteem, 1635–1636
priorities of care, 1635
resources for, 1635*t*
systemic lupus erythematosus
continuity of care, 1307, 1307*t*
diagnoses, outcomes, and interventions
impaired skin integrity, 1306
ineffective protection, 1306, 1306*t*
readiness for enhanced self-health management, 1306–1307
focus of, 1305–1306
systemic sclerosis (scleroderma), 1308–1309
testicular cancer
continuity of care, 1564
diagnoses, outcomes, and interventions
readiness for enhanced knowledge: testicular cancer surgery, 1563–1564
risk for sexual dysfunction, 1564
health promotion, 1563, 1563*t*
resources for, 1564*t*
tetanus, 1423
thoracic injury
assessment, 1150
continuity of care, 1151
diagnoses, outcomes, and interventions
acute pain, 1150–1151, 1150*t*
impaired gas exchange, 1151
ineffective airway clearance, 1151, 1151*t*
health promotion, 1150
priorities of care, 1150
thromboangiitis obliterans, 993
thrombocytopenia
assessment, 1052
continuity of care, 1053*t*
diagnoses, outcomes, and interventions
impaired oral mucous membranes, 1052
ineffective protection, 1052, 1052*t*
priorities of care, 1052
tissue and organ transplants
assessment, 311
continuity of care, 314
delegating nursing care activities, 314
diagnoses, outcomes, and interventions
anxiety, 314
ineffective protection, 311, 311*t*, 313
risk for transplant rejection, 313–314
health promotion, 311
priorities of care, 311
tonsillitis, 1091–1092
trauma
assessment, 241
continuity of care, 244
delegating nursing care activities, 244
diagnoses, outcomes, and interventions
Case Study & Nursing Care Plan, 243*t*
impaired physical mobility, 242, 242*f*
ineffective airway clearance, 241
post-traumatic stress disorder, 243–244
risk for infection, 241–242, 241*t*
spiritual distress, 242–243
health promotion, 240
overview, 239
priorities of care, 241
resources for, 241*t*
traumatic brain injury
assessment, 1387
Case Study & Nursing Care Plan, 1388*t*
continuity of care, 1389
diagnoses, outcomes, and interventions
decreased intracranial adaptive capacity, 1387–1388, 1388*t*
ineffective airway clearance, 1389
ineffective breathing pattern, 1389, 1389*t*
health promotion, 1387
priorities of care, 1387
resources for, 1388*t*
trigeminal neuralgia
continuity of care, 1466, 1466*t*
delegating nursing care activities, 1465
diagnoses, outcomes, and interventions
acute pain, 1465
risk for altered nutrition: less than body requirements, 1465
priorities of care, 1465
tuberculosis
assessment, 1136
continuity of care, 1140
diagnoses, outcomes, and interventions
Case Study & Nursing Care Plan, 1139*t*
deficient knowledge, 1136
ineffective therapeutic regimen management, 1136, 1138, 1138*t*
risk for infection, 1138–1140, 1139*t*
health promotion, 1135–1136
priorities of care, 1136
resources for, 1136*t*
urinary calculi
assessment, 759–760
continuity of care, 761
delegating nursing care activities, 761
diagnoses, planning, and interventions
acute pain, 760, 760*t*
impaired urinary elimination, 760, 760*t*
readiness for enhanced knowledge, 760–761
health promotion, 759
priorities of care, 760
resources for, 760*t*
urinary incontinence
assessment, 775
continuity of care, 776
delegating nursing care activities, 776
diagnoses, planning, and interventions
impaired social interaction, 776
readiness for enhanced urinary elimination, 775, 775*t*
toileting self-care deficit, 775–776
health promotion, 775, 775*t*
priorities of care, 775
resources for, 776*t*
urinary retention, 768, 768*t*
urinary tract infection
assessment, 751–752, 752*t*
continuity of care, 754
delegating nursing care activities, 754
diagnoses, outcomes, and interventions
acute pain, 752–753
Case Study & Nursing Care Plan, 755*t*
impaired urinary function, 753, 753*t*, 754*t*
readiness for enhanced self-health management, 753–754
health promotion, 751
priorities of care, 752
resources for, 753*t*
urinary tract tumor
assessment, 763
continuity of care, 766–767
delegating nursing care activities, 766
diagnoses, outcomes, and interventions
Case Study and Nursing Care Plan, 767*t*
disturbed body image, 765–766
impaired urinary elimination, 764–765, 764*t*, 765*t*
risk for impaired skin integrity, 765
risk for infection, 766, 766*t*

health promotion, 763
priorities of care, 764
uterine displacement
continuity of care, 1594
diagnoses, outcomes, and interventions
anxiety, 1594
stress incontinence, 1594
vaginal fistula, 1595
vaginal infections
assessment, 1628*t*, 1629
continuity of care, 1630
delegating nursing care activities, 1630
diagnoses, outcomes, and interventions
acute pain, 1630, 1630*t*
deficient knowledge, 1629–1630
priorities of care, 1629
valvular heart disease
assessment, 957–958
continuity of care, 959, 960*t*
delegating nursing care activities, 959
diagnoses, outcomes, and interventions
activity intolerance, 958
decreased cardiac output, 958, 958*t*
ineffective protection, 959, 959*t*
risk for infection, 958–959
health promotion, 957
priorities of care, 958
resources for, 958*t*
varicose veins
assessment, 1007
continuity of care, 1008
diagnoses, outcomes, and interventions
chronic pain, 1007
ineffective tissue perfusion, peripheral, 1007–1008
risk for impaired skin integrity, 1008
risk for peripheral neurovascular dysfunction, 1008
health promotion, 1007
priorities of care, 1007
venous thrombosis
assessment, 1001, 1002*t*
continuity of care, 1003–1004
diagnoses, outcomes, and interventions, 1002*t*, 1003*t*
impaired bed mobility, 1003
ineffective protection, 1003, 1003*t*
ineffective tissue perfusion: peripheral, 1001–1003
pain, 1001
risk for ineffective tissue perfusion: cardiopulmonary, 1003
health promotion, 999, 1001
priorities of care, 1001

Special Features

ASSESSMENT OF THE PATIENT

Cardiovascular Assessments 851
Ear and Hearing Assessments 1488
Endocrine Assessments 472
Eye and Vision Assessments 1479
Female Reproductive System Assessments 1549
Integumentary Assessments 384
Male Reproductive System Assessments 1541
Musculoskeletal Assessments 1228
Neurologic Assessments 1343
Reflex Assessments 1348
Respiratory Assessments 1075
Special Neurologic Assessments 1349
Urinary System Assessments 743

CASE STUDY & NURSING CARE PLAN

A Man with Prostate Cancer 1577
A Patient Experiencing Chronic Pain 169
A Patient Having Surgery 75
A Patient with a Below-the-Knee Amputation 1262
A Patient with a Bladder Tumor 767
A Patient with a Brain Tumor 1395
A Patient with a Hip Fracture 1256
A Patient with a Major Burn 455
A Patient with a Peritonsillar Abscess 1091
A Patient with a Seizure Disorder 1369
A Patient with a Stroke 1381
A Patient with a Subdural Hematoma 1388
A Patient with Acquired Immunity 276
A Patient with Acute Appendicitis 640
A Patient with Acute Glomerulonephritis 789
A Patient with Acute Myelocytic Leukemia 1040
A Patient with Acute Myocardial Infarction 896
A Patient with Acute Pancreatitis 724
A Patient with Acute Respiratory Acidosis 225
A Patient with Addison's Disease 496
A Patient with Alcoholic Cirrhosis 717
A Patient with Alzheimer's Disease 1437
A Patient with an SCI 1410
A Patient with ARDS 1212
A Patient with Bacterial Meningitis 1422
A Patient with Cancer 370
A Patient with Cholelithiasis 697
A Patient with Colorectal Cancer 678
A Patient with COPD 1183
A Patient with Coronary Artery Bypass Surgery 886
A Patient with Cystitis 755
A Patient with Deep Venous Thrombosis 1002
A Patient with End-Stage Renal Disease 818
A Patient with Folic Acid Deficiency Anemia 1027
A Patient with Gastric Cancer 621
A Patient with Glaucoma and Cataracts 1512
A Patient with Gonorrhea 1633
A Patient with Graves' Disease 482
A Patient with Heart Failure 936
A Patient with Hemophilia 1056
A Patient with Herpes Zoster 404
A Patient with HIV Infection 327
A Patient with Hodgkin's Disease 1046
A Patient with Hyperkalemia 204
A Patient with Hypertension 979
A Patient with Hypothyroidism 486
A Patient with Injuries from a Natural Disaster 129
A Patient with Lung Cancer 1162
A Patient with Malignant Melanoma 418
A Patient with Malnutrition 583
A Patient with Mitral Valve Prolapse 960
A Patient with Multiple Injuries 243
A Patient with Multiple Sclerosis 1445
A Patient with Nasal Trauma 1099
A Patient with Obesity 574
A Patient with Oral Cancer 598
A Patient with Osteoarthritis 1288
A Patient with Osteoporosis 1273
A Patient with Parkinson's Disease 1452
A Patient with Peptic Ulcer Disease 615
A Patient with Peripheral Vascular Disease 991
A Patient with Pneumonia 1125
A Patient with Rheumatoid Arthritis 1300
A Patient with Septic Shock 256
A Patient with Supraventricular Tachycardia 912
A Patient with Syphilis 1636
A Patient with Total Laryngectomy 1111
A Patient with Tuberculosis 1139
A Patient with Type 1 DM 530
A Patient with Ulcerative Colitis 662
A Patient Withdrawing from Alcohol 112
A Woman with Breast Cancer 1617
A Woman with Cervical Cancer 1602
A Woman with Endometriosis 1599
Loss and Grief 93

DIAGNOSTIC TESTS

for Ear Disorders 1485
of the Cardiovascular and Lymphatic System 841
of the Endocrine System 466
of the Eye 1477
of the Female Reproductive System 1545
of the Gastrointestinal System 548
of the Integumentary System 382
of the Male Reproductive System 1539
of the Musculoskeletal System 1225
of the Neurologic System 1340
of the Renal System 739
of the Respiratory System 1073

EVIDENCE FOR NURSING CARE

Fluid Volume Excess 191
Health Promotion for Adults 34
Planning Nursing Care 8
Preventing/Treating STI 1632
The Patient with a Stroke 1378
The Patient with Acute Coronary Syndrome 882
The Patient with Acute Kidney Injury 806
The Patient with Acute Myocardial Infarction 893
The Patient with Acute Pain 173
The Patient with Acute Respiratory Distress Syndrome 1204
The Patient with Alzheimer's Disease 1433
The Patient with Amputation 1261
The Patient with an Infection 293
The Patient with Aortic Aneurysm 986
The Patient with Asthma 1173
The Patient with Bacterial Infection of the Skin 399
The Patient with Bone Marrow Transplant 1037
The Patient with Brain Death 241
The Patient with Breast Cancer 1615
The Patient with Cardiogenic Shock 252
The Patient with Cervical Cancer 1601
The Patient with Chronic Kidney Disease 816
The Patient with Chronic Pain 174
The Patient with Cirrhosis 715
The Patient with Colorectal Cancer 678
The Patient with Compartment Syndrome 451
The Patient with Conjunctivitis 1495
The Patient with COPD 1182
The Patient with Curling's Ulcers 452

The Patient with Deep Venous Thrombosis 1001
The Patient with Fracture 1255
The Patient with Gastroesophageal Reflux Disease 603
The Patient with Glaucoma 1510
The Patient with Glomerulonephritis 788
The Patient with Heart Failure 933
The Patient with Hemophilia 1055
The Patient with Hepatitis 705
The Patient with HIV Infection 326
The Patient with Impaired Hearing 1530
The Patient with Inflammatory Bowel Disease 659
The Patient with Influenza 1087
The Patient with Iron-Deficiency Anemia 1025
The Patient with Irritable Bowel Syndrome 635
The Patient with Low Back Pain 1320
The Patient with Malignant Melanoma 416
The Patient with Malnutrition 581
The Patient with Multiple Sclerosis 1444
The Patient with Nausea and Vomiting 591
The Patient with Obesity 572
The Patient with Osteoarthritis 1286
The Patient with Osteoporosis 1272
The Patient with Ovarian Cancer 1605
The Patient with Parkinson's Disease 1450
The Patient with Peptic Ulcer Disease 614
The Patient with Pertussis 1094
The Patient with Pleural Effusion 1143
The Patient with Pneumonia 1124
The Patient with Pneumothorax 255
The Patient with Prostate Cancer 1576
The Patient with Pulmonary Hypertension 1196
The Patient with Rheumatoid Arthritis 1299
The Patient with Seizures 1369
The Patient with Spinal Cord Injury 1407
The Patient with Substance Use Disorders 110
The Patient with Syphilis 1635
The Patient with Testicular Cancer 1564
The Patient with Thyroid Disorders (Hypo, Hyper, or Both) 480
The Patient with Traumatic Brain Injury 1388
The Patient with Tuberculosis 1136
The Patient with Type 1 DM 528
The Patient with Urinary Calculi 760
The Patient with Urinary Incontinence 776
The Patient with Urinary Tract Infection 753
The Patient with Valvular Heart Disease 958

FOCUS ON CULTURAL DIVERSITY

BiDil for Treating Heart Failure in African Americans 932
Biologic Variations among Cultures 29
Breast Cancer in Women 1608
Cirrhosis 706
Colorectal Cancer Risk 672
Cultural Aspects of Terminal Illness Care 84
Estimates of Prevalence of Diabetes Mellitus 503
Gallstones 693
Heart Disease 863
Heart Disease 921
HIV/AIDS 316
Hypertension in African Americans 970
Incidence and Prevalence of IBD 652
Inherited Hemolytic Anemias 1019
Lactase Deficiency 669
Obesity 564
Risk and Incidence of Cancer 336
Risk and Incidence of Prostate Cancer 1571
Risk for Testicular Cancer 1562
Sickle Cell Disease 1019
Substance Use and Ethnicity 99
The Patient with Osteoporosis 1267
Tuberculosis 1132
Use of CAM Therapies 168

GENETIC CONSIDERATIONS

Adult Polycystic Kidney Disease 781
Chronic Obstructive Pulmonary Disease 1177
Cystic Fibrosis 1185
Examples of Cardiovascular Disorders 845
Examples of Ear Disorders 1485
Examples of Endocrine System Disorders 470
Examples of Eye Disorders 1478
Examples of Female Reproductive System Disorders 1547
Examples of Gastrointestinal Disorders 546
Examples of Integumentary Disorders 381
Examples of Male Reproductive System Disorders 1540
Examples of Musculoskeletal Disorders 1224
Examples of Neurologic Disorders 1342
Examples of Renal System Disorders 738
Examples of Respiratory Disorders 1072
Family Risk Factors for Alcoholism 98
Focus on Hemophilia 1053
Focus on Lymphoma 1042
Patients with Marfan Syndrome 953
Primary Lymphedema 1009
Thoracic Aortic Aneurysms 983

MANIFESTATIONS

A Herniated Intervertebral Disk 1412
A Stroke by Involved Cerebral Vessel 1372
Acute and Chronic Gastritis 617
Acute and Chronic Hydronephrosis 758
Acute and Chronic Pancreatitis 721
Acute Arterial Occlusion 995
Acute Asthma 1167
Acute Hepatitis 701
Acute Myocardial Infarction 887
Addison's Disease 494
Amyotrophic Lateral Sclerosis 1455
Anaphylactic Shock 251
Angina 873
Bacterial Meningitis 1419
Bone Tumors 1316
Brain Tumors by Location 1391
Breast Cancer 1610
Carbon Monoxide Poisoning 441
Cardiac Tamponade 947
Cardiogenic Shock 249
Chronic Venous Insufficiency 1005
Compartment Syndrome 1244
Complications of Eating Disorders 584
Complications of Spinal Cord Injury by Body System 1403
Complications of Stroke by Body System 1373
Concussion 1386
Cystitis 748
Death 88
Diabetic Ketoacidosis (DKA) 521
DIC 1057
Displacement Disorders 1593
Endometriosis 1597
Esophageal Cancer 605
Genital Herpes 1625

Varicose Veins 1006
Venous Thrombosis 997

MEDICATION ADMINISTRATION

Acne Medications 408
Addison's Disease 495
Antianginal Medications 876
Antibiotic Therapy 289
Anticoagulant Therapy 1000
Antidiarrheal Preparations 627
Antidysrhythmic Drugs 906
Antifungal Agents 400
Antihypertensive Drugs 974
Antiplatelet Drugs 881
Antiprotozoal Agents 650
Antiretroviral Drugs 324
Antituberculosis Drugs 1137
Antiviral Agents 292
Asthma 1171
Blood Transfusion 240
Calcium Salts 207
Cholesterol-Lowering Drugs 871
Colloid Solutions (Plasma Expanders) 254
Decongestants and Antihistamines 1082
Diuretics for Fluid Volume Excess 190
Drugs to Treat Anemia 1024
Drugs to Treat Chronic Hepatitis 703
Drugs to Treat Obesity 567
Drugs Used to Prevent and Treat Nausea and Vomiting 592
Drugs Used to Treat GERD, Gastritis, and Peptic Ulcer Disease 602
Drugs Used to Treat Stomatitis 595
Heart Failure 930
Hyperkalemia 203
Hyperthyroidism 479
Hypokalemia 198
Hypothyroidism 485
Immunosuppressive Agents 312
Immunosuppressive Agents for SLE 1305
Increased Intracranial Pressure 1362
Inflammatory Bowel Disease 658
Insulin 511
Intravenous Insulin 522
Laxatives and Cathartics 630
Magnesium Sulfate 211
Neuromuscular Blockers 1200
Noninsulin Hypoglycemic Agents 516
Nonsteroidal Anti-Inflammatory Drugs 162
Opioid Analgesics 164
Safely Administering Ketorolac 61
Safely Administering Midazolam and Propofol 60
Seizures 1367
Tamoxifen 1613
The Patient in Shock 253
The Patient with Acute Kidney Injury 800
The Patient with Alzheimer's Disease 1432
The Patient with Chronic Pancreatitis 723
The Patient with Cirrhosis 712
The Patient with Genital Warts 1627
The Patient with Glaucoma 1509
The Patient with Gout 1279
The Patient with Multiple Sclerosis 1443
The Patient with Myasthenia Gravis 1459
The Patient with Neurogenic Bladder 770
The Patient with Osteoporosis 1271
The Patient with Parkinson's Disease 1448
The Woman with Dysmenorrhea 1590
Therapeutic Baths 392
Topical Burn Medications 447
Urinary Anti-Infectives and Analgesics 751
Vitamin and Mineral Supplements 579

MEETING INDIVIDUALIZED NEEDS

Assessing Intimate Partner Violence (IPV) 231
Burns in the Older Adult 451
Constipation and the Older Adult 632
Discharge Instructions after Prostate Surgery 1570
Foot Care Teaching Session 529
Nutrition for the Older Adult 575
Patients with Obesity after Gastrointestinal Surgery 506
PD in the Older Adult 1447
Recognizing a Myocardial Infarction in Women and Older Adults 887
Risk Factors for Stroke in Women 1378
Safety Interventions for the Patient with Alzheimer's Disease 1435
STI Barrier Guidelines 1623
Teaching for Home Care of Trigeminal Neuralgia 1466
Teaching for Patients Experiencing a Loss 92
Teaching Older Adults to Prevent Falls 1254
Teaching the Patient with a Ruptured Intervertebral Disk 1416
The Patient with an Amputation 1263

MOVING EVIDENCE INTO ACTION

Applying Evidence to Practice 704
Assessing Postoperative Pain 62
Complementary Treatment for Nausea and Vomiting 590
Cultural Interventions on Adherence to TB Therapy 1138
Defining Informatics Competencies 18
Determining Fluid Needs in Long-Term Care 188
Diarrhea 646
Disaster Education 128
End-of-Life Care: Supporting Families 83
Enterally Fed, Seriously Ill Patient 644
Health Promotion for Young Adults 31
Hearing Loss 1530
Hypothyroid 487
Improving Prostatectomy Teaching 1574
Improving the Diagnosis and Treatment of Black Women with Breast Cancer 1615
Irritable Bowel Syndrome 635
Lower Urinary Tract Symptoms in Women 773
Meaning in Bone Marrow Transplant Nurse's Work 1044
Patients Undergoing an Awake Craniotomy 1393
Patients with Acute or Chronic Leukemia: Outpatient Management with Clofarabine 1037
Patients with Malnutrition 582
Physical Activity in Patients with ESRD 819
Preventing Falls in Hospitalized Older Adults 1252
Preventing Pressure Ulcers in Acute Care and Home Care Settings 422
Quality Improvement 8
Reducing Catheter-Associated Complications 754
Reducing Incidence of Ventilator-Associated Pneumonia 1408
Relationship of Anxiety to Morbidity and Mortality in Patients with CHD 867
Resilience and Diabetes Outcomes in African American Women 528
Risk Factors for STI 1622
Self-Care for Patients Undergoing Bariatric Surgery 572
Sexual Assertiveness as a Risk Factor for HIV Infection 316
Smoking Cessation in Hospitalized Patients 100
Sudden Cardiac Death 962

Teaching to Take Antibiotics Appropriately 288
The Care of ICU Patients Sustaining Multiple Trauma 241
The Patient Experiencing Pain 172
The Patient Having Joint Replacement Surgery 1286
The Patient Undergoing Laryngectomy 1109
The Patient Who Is Intubated 1207
The Patient with a Major Burn 454
The Patient with COPD 1179
The Patient with Primary Hypertension 976
The Patient with Venous Leg Ulcers 1005
Women Following Myocardial Infarction 888

NURSING CARE OF THE OLDER ADULT

Age-Related Cardiovascular Changes 850
Age-Related Changes in Pain Perception and Response 159
Age-Related Changes in the Ear 1486
Age-Related Changes in the Eye 1479
Age-Related Changes in the Female Reproductive System 1549
Age-Related Changes in the Male Reproductive System 1542
Age-Related Changes in the Musculoskeletal System 1227
Age-Related Changes in the Neurologic System 1342
Age-Related Changes in the Respiratory System 1075
Age-Related Endocrine Changes 471
Age-Related Gastrointestinal Changes 553
Age-Related Renal System Changes 742
Age-Related Skin Changes 383
Anemia 1018
Cardiac Dysrhythmias 897
Changes in Immune Function in the Older Adult 298
Chronic Kidney Disease 809
Chronic Venous Stasis 1006
Diabetes Mellitus 508
End-of-Life Checklist 90
Epilepsy in Older Adults 1365
Fluid Volume Deficit 184
Heart Failure 921
HIV Infection 322
Hypertension 970
Infections in Older Adults 287
Minimizing the Risk for UTI 752
Older Adults with Cancer 337
Older Women with Breast Cancer 1609
Pain Management for the Older Adult 173
Peripheral Vascular Disease 989
Pneumonia 1116
Pressure Ulcer Prevention 420
Reducing the Risk for UI 771
Seasonal Influenza 1083
Sexual Function in the Aging Woman 1586
Special Needs of Older Adults Living Alone 42
Substance Abuse in the Older Adult 109
Surgical Risk with Increased Age 64
Tuberculosis 1134
Variations in Assessment Findings—Shock 256

NURSING CARE OF THE PATIENT

Halo Fixation 1406
Having a Bladder Neck Suspension 774
Having a Carotid Endarterectomy 1376
Having a Coronary Artery Bypass Graft 884
Having a Cystectomy and Urinary Diversion 765
Having a Dilation and Curettage (D&C) 1591
Having a Hysterectomy 1591
Having a Kidney Transplant 815
Having a Laparoscopic Cholecystectomy 695
Having a Laparoscopy 1589
Having a Mastectomy 1612
Having a Nephrectomy 793
Having a Percutaneous Rhizotomy 1465
Having a Permanent Pacemaker Implant 911
Having a Posterior Laminectomy 1414
Having a Prostatectomy 1568
Having a Subtotal Thyroidectomy 481
Having a Thymectomy 1459
Having a Total Laryngectomy 1108
Having an Adrenalectomy 492
Having an Ileostomy 660
Having Bowel Surgery 675
Having Ear Surgery 1522
Having Eye Surgery 1498
Having Lithotripsy 759
Having PCR 883
Having Surgery of the Aorta 985
Having Total Joint Replacement 1287
Memory 1433
Receiving Fibrinolytic Therapy 891
Receiving Immunotherapy 359
Receiving Radiation Therapy 358
Receiving Radiation Therapy 1160
Treated with Plasmapheresis 1460
Undergoing a Thoracentesis 1142
Undergoing Bariatric Surgery 573
Undergoing Hemodialysis 804
Undergoing Hemodynamic Monitoring 928
Undergoing Liver Transplantation 716
Undergoing Lung Surgery 1159
Undergoing Paracentesis 713
Undergoing Peritoneal Dialysis 805
Undergoing Surgical Debridement for Osteomyelitis 1313
Undergoing Whipple's Procedure 726
Who Is Blind 1493
With a Cast 1249
With a Colostomy 677
With a Ureteral Stent 752
With Chest Tubes 1146
With Nasal Packing 1096

PATHOPHYSIOLOGY LINKAGE

Acute Glomerulonephritis 784
Acute Pain and Associated Manifestations 156
