1. *Keep messages short*. Text messages should be short and concise. The entire message should be <160 characters, including spaces and punctuation and any branding or links to additional information (p. 25).
2. *Make messages engaging*. Write relevant, timely, clear, and actionable messages. Try to begin each message with an interesting fact or question so that users will be more likely to open the text message and read the remainder of the message.
3. *Make content readable*. Content should be at or below an 8th grade reading level.
4. *Use abbreviations sparingly.* Because text messages have a character limit, it is acceptable to use abbreviations, but only use those that are easily understood and don't change the message's meaning.
5. *Limit foreign language characters.* Depending on the mobile carrier, for instance, accented letters do not work well in texts.
6. *Provide access to additional information*. Be sure to include your agency's name in the text so users know who is sending the message and include a way for users to follow up or respond to the message (e.g., URL, phone number, mobile Web site).
7. *Include opt-out options*. Text messages may also include information on how to opt-out of the text message program (p. 25).
8. *Promote your text messaging efforts.* To maximize your reach, create a promotion plan that includes advertising on mobile sites and social media.
9. *Evaluate your efforts.* Evaluation can be accomplished with surveys and metrics reviews (p. 25).

Applications

Mobile phone health applications are available to both health care providers and individuals.

A mobile software application (app) is a program created for use on such devices as smartphones and tablet computers. Most devices are purchased with several apps as preinstalled software. Additional apps (those that are not preinstalled) are obtained through digital distribution platforms or app stores. In 2008, apps began to be popularized and are operated by mobile operating system owners, including Apple's App Store or iTunes Store, Windows Phone Store, Google Play, and Blackberry World. Some apps are free, and others must be purchased. It is common for a simplified version of an app to be available at no cost, which may entice the user to ultimately purchase the full version. Usually, they are downloaded from the platform to a target device, but sometimes they can be downloaded to laptops or desktop computers (Wikipedia, 2016).

Apps may be defined as a software program developed to help the user perform specific tasks (Nelson & Staggers, 2014). Apps are self-contained programs, used to enhance existing functionality, in a simple and user-friendly way. Today's modern smartphones come with powerful web browsers, meaning nearly anything that can be done on a desktop computer can be done with a smartphone's browser. Mobile applications may be a limited version of a larger program and perform limited functions as compared to a more complete Internet-based program, such as is seen in banking. Mobile apps are easily installed and are

typically cheaper than those designed to run on laptop and desktop computers. The portability of the app that allows the user to remain connected is very appealing to both clinicians and patients. Mobile platforms have become more user friendly, computationally powerful, and readily available, leading to the development of mobile apps of increasing complexity to leverage the portability mobile platforms can offer. Many new mobile apps are targeted to assist individuals in their own health and wellness management. Some apps may assist family caregivers. Other mobile apps are targeted to health care providers as tools to improve and facilitate the delivery of patient care (Nelson & Staggers, 2014).

Application developers have noticed the potential of health care apps. Apple had more than 1,500,000 apps on iTunes as of September 2015, with nearly 43,700 identified as health or medical apps. Android features more than 3,300 medical apps. Sixty-nine percent of apps targeted consumers and patients, whereas 31% were developed for use by clinicians. It is unclear if the apps are evidence based, developed without conflicts of interest, and reliable. Health professionals are necessary in app development to peer-review the reliability, usability, and usefulness of the medical apps. Data are not available regarding the number of "real" health care apps, and this presents problem for users. The Institute for Healthcare Informatics (2015) report, *Patient Adoption of mHealth: Use, Evidence and Remaining Barriers to Mainstream Acceptance*, includes a prediction that patient adoption of mHealth apps will move from novelty to mainstream within 5 years (Institute for Healthcare Informatics, 2015). As the use of tablets and smartphones increase, the app market will also expand; one estimate is over 60% by the end of 2017, making it worth $26 billion (Deruy, 2013).

The Food and Drug Administration (FDA) is responsible for the protection of public health by assuring the safety, effectiveness, quality, and security of human and veterinary drugs, vaccines and other biological products, and medical devices (Smith, 2014). The FDA intends to apply regulatory oversight to medical mobile apps and identifies apps as medical devices whose functionality could pose a risk to an individual's safety if the mobile app did not function as intended (FDA, 2015). Some app developers express concern about the FDA's new role in app development. However, it is important to consider that if dangerous errors and disproven apps are allowed to proliferate, distrust could undermine acceptance of other useful products.

Cellular phones are all around, and the number of smart phone users is growing rapidly. Text messaging, the use of applications, and other mHealth interventions can reduce geographic and economic barriers to health information and services. These interventions have the potential to reduce health disparities and leverage a profound effect on health (USDHHS, 2014). mHealth apps are more likely to be used by Hispanics and African Americans than Whites, and this information is not lost on government agencies. For instance, apps that target Type II diabetes and obesity, as well as cancer, among minority populations are being developed to engage hard-to-reach communities (Deruy, 2013).

FastStats

FastStats is an official, free application from the Centers for Disease Control and Prevention's (CDC) National Center for Health Statistics (NCHS). Over 100 public health topics are alphabetically organized and readily available including diseases and conditions, family life, health care and insurance, health status and risk factors, injuries, life stages and populations, and reproductive health. Links provide sources of more data and related Web pages. When the device, phone, tablet, or computer is connected to the Internet, updates occur automatically. Along with getting the most up-to-date health statistics available, the app allows for highlighting, annotating, and bookmarking, as well as sharing of data through social media such as Facebook and Twitter; the mobile app is available through Apple's App Store or for Android phones from Google Play (CDC, 2015b). FastStats homepage and statistics by topics are available at: http://www.cdc.gov/nchs/fastats/

Twitter

Twitter is a micromessaging/microblogging technology and an online social networking service that enables users to send and read short 140-character messages called "tweets." Posts are delineated by a hashtag (#) symbol to organize topics (Nelson & Staggers, 2014). Microblogging began with the advent of Twitter in 2006 and is a method of mass communication. "Followers" or users sign up to follow the microblog. Most microblogs have a setting that requires acceptance of new followers (Nelson et al., 2013). Twitter is real time and designed for mobility (Kvedar et al., 2011). E-registered users can read and post tweets, but those who are unregistered can only read them. Users can post tweets on a smartphone. Twitter is very simple and easy to use and exists somewhere between the worlds of e-mail, blogging, and instant messaging, with the users getting almost immediate responses to tweets. Twitter is extremely popular between individuals looking for means of promotion such as bloggers, online marketers, and entertainers, as it acts as a communication stream that has a continuous flow unlike most other networks. Twitter is one of the top three social media applications, used by 19% of all adults and 23% of online adults in the United States (Duggan, Ellison, Lampe, Lenhart, & Madden, 2015). Access to Twitter is through the Web site interface, text messaging, or mobile device app. Twitter was initially a convenient way to stay in touch with friends and family, but is now emerging as a potentially valuable means of real-time, on-the-go communication of health care information and medical alerts (Liebert, 2009). When an individual tweets or sends a message via Twitter, all of the people who have chosen to follow them will receive it.

Duggan et al. (2015) found that Twitter was used by more men than women and by more young adults (18 to 49 years) than older adults (50 to ≥65 years). Twitter use rates are higher for non-Hispanic Blacks and Hispanics than for non-Hispanic Whites. Nurses/clinicians and health care systems can use Twitter to communicate timely information, both within the medical community and to patients, as well as the general

public. Short messages, or "tweets," are delivered to a group of recipients simultaneously, providing an easy and quick method to reach large groups in limited time. There are obvious advantages for sharing time-critical information such as disaster alerts and drug safety warnings, tracking disease outbreaks, or disseminating health care information. Twitter applications can deliver information about clinical trials, for example, or to link brief news alerts from the CDC to reliable Web sites that provide more detailed information (Liebert, 2009).

Professionals are now using Twitter to share informational and web resources. Organizations use Twitter to share news and member updates, and it can be used to share information among professional conference presenters in real time. Clinicians can "tweet" from the operating room or a disaster site allowing live updates (Hebda & Czar, 2013).

Twitter and texting services both have character limits, so acronyms and shortened forms of the words are used in messages. The character limit of Twitter is 140 characters, whereas the usual character limit of texting is 160 characters. The biggest difference is that Twitter is an Internet-based service and texting is provided through the user's mobile network or cellular phone service. The original intention was that access to Twitter would be via the computer, whereas texting is done using a mobile phone. Twitter has been considered and is described as a social networking program, whereas texting is more of a personalized way of sending messages. In general, texts only go to a single recipient or a small group, whereas tweets on Twitter can be visible to the general public. Individual messages can be sent via Twitter, but it is largely a social networking tool.

Twitter is a free service, whereas texting is a service that usually incurs charges from the mobile companies that provide the services. Both tweet and text contain various characters (e.g., #, &, @, etc.) that allow the messenger to use fewer words. Using characters like # and @ has another function at Twitter where the hash symbol is used to make the tweets more searchable, and @ is used to link another user to the message. The use of these specific functions attached to specific characters is not seen in texting. Unlike some other social media sites, an individual can follow anyone they want on Twitter, even if they don't know them personally (Hebda & Czar, 2013; McGonigle & Mastrian, 2015).

Twitter can be useful to public health agencies and in other health care situations. For instance, it could be used to collect data for epidemiological investigations (e.g., foodborne illness), as a means of tissue recruitment (e.g., organs, blood), for disaster alert and response, as a means of providing FDA drug safety alerts, for Amber alerts, for prescription management, for food and product safety alerts, for community health outreach and policy discussion, and for public safety announcements (Baumann, 2016). A list of 140 health care uses for Twitter can be found at: http://philbaumann.com/140-health-care-uses-for-twitter/

Blogging and Online Support Communities

Blogs or weblogs are web-based chronological journals (Nelson & Staggers, 2014). They are free or low cost and easy to use. Blogs typically include date-stamped, multiple entries in chronological order and are updated frequently. Blogs usually focus on a particular subject or topic. One type of blog, referred to as a simple blog, is a form of online personal diaries. Other blogs relate to group causes such as political or social concerns, and some may ask for contributions. Blogs may contain reflections, commentaries, comments, images, videos, and often hyperlinks to other information of interest to the blogger or that she/he feels will be of interest to their readers. Blogger is the term used for the person who creates and maintains the blog site. The ability for readers to leave comments on a blog post depends on the settings that the blog administrator uses (Nelson et al., 2013).

The popularity or success of a blog is judged by its ability to draw individuals together who are interested in a specialized topic. Many journals, health care systems, nursing and other professional organizations, health care provider networks, and educational institutions create blogs to provide the latest information and promote discussion (Nelson & Staggers, 2014). Many people create personal blogs when faced with an illness or are a family member/support for someone facing health challenges. Participating in the creation of health information through blogging and social networking contributions influences experiences and supports an individual's understanding of their role in health care management and information (DeGroot & Carmack, 2012). Individuals may turn to the Internet to grieve and manage the traumatic experience of loss or to cope with emotional pain after a loss. Personal blogs are often established following the death of a parent, spouse or partner, sibling, close family member, or child. Blogging may serve as an emotional release, therapy, and healing. It can serve as a public way to cope with grief (DeGroot & Carmack, 2012). Some report comfort in sharing information on the Internet, even among those that choose not to share with family or close friends. Individuals or relatives of a person suffering from cancer or other life-changing or threatening disease are affected both physically and psychologically. Canning, Rosenberg, and Yates (2013) found that blogging among family member of cancer patients facilitated everyday life, introduced the relatives to others with similar experiences, assisted in their grief process, and helped to preserve memories.

Advances in medical treatment allow many to survive for long periods of time with diagnoses that previously would have been rapidly fatal. Individuals and families face the physical as well as the social and emotional consequences of chronic pain and extended illness. This creates a new paradigm of medical care for chronic conditions and a need for effective interventions that could provide support throughout the journey of diagnosis, treatment, and management. Many have suggested that expressing emotional or traumatic experiences with the written word through the process of expressive writing may have therapeutic benefit for individuals. Internet-based blogs allow this expression (Ressler, Bradshaw, Gualtieri, & Chui, 2012).

Traditional forms of contact and support groups are limited to certain hours of the day, week, or month. Some face-to-face support groups meet weekly or monthly and may require considerable travel and effort. Telephone help lines may be available only during office hours. Contact and support are available at any hour of the day or night via the Internet. Those with a home computer can access an extraordinary range of resources for private and anonymous communications with others in real time. Individuals who have joined an online support group benefit from venting their feelings and from the support they receive, as well as feeling connected by helping and supporting others (Diefenbeck, Klemm, & Hayes, 2014). Online supportive relationships generally provide a safe environment (Varga & Paulus, 2014). Others' experiences can induce feelings of compassion, and one becomes less self-absorbed and may gain a better perspective (Varga & Paulus, 2014). In a study of online support groups, Mo and Coulson (2014) describe the process of being emotionally empowered when information is exchanged and emotional support is shared, as well as a recognition gained through sharing experiences. Chung (2014) suggests the online support groups simply help people feel better. Ziebland and Wyke (2012, p. 219) stated their study respondents saw this process as important, meaning that you knew you "were not alone" because hearing about other people's experiences gave you a sense of "being supported." Finding a safe place to share can be very empowering.

A study of parents of children with a genetic condition (Schaffer, Kuczynski, & Skinner, 2008) reported most trusted and valued source of information was not clinicians but the other parents in internet communities, whose shared information was combined with a personal stake. As cancer patient Dave de Bronkert (known as e-patient Dave in his popular TED Talk) stated, "Patients know what patients need to know" and are, therefore, the most underused resource in health care. For individuals who have unusual or stigmatizing conditions, who are undergoing atypical treatments, or who are geographically isolated, the online resources may be their best source of support (Mo & Coulson, 2014). The value of first-person accounts, the appeal and memorability of stories, and the need to make contact with peers all strongly suggest that reading and hearing others' accounts of their own experiences of health and illness will remain an important component of health management/care.

PatientsLikeMe, available at: (https://www.patientslikeme.com/), is a great example of a free Internet-based tool for sharing and learning. Individual and clinician accounts are available. Two brothers, Jamie and Ben Heywood, began this site when their brother Stephen was living with amyotrophic lateral sclerosis (ALS). A quote attributed to the brothers is on the home page "Our brother Stephen was living with ALS and we thought, 'there has to be a better way.' There is. By sharing our experiences, we can all contribute new data that can accelerate research and help create better treatments. Our experiences can actually change medicine… for good" (Heywood & Heywood, 2015, para. 4).

Video Games

Half of American adults have played video games, and 10% call themselves gamers. Public attitudes toward video games and the people who play them are complex and often mixed (Duggan, 2015). Video games are typically thought of as entertainment. However, there is a growing interest in video games as a means to facilitate healthy behaviors (Kim, Prestopnik, & Biocca, 2014). Exercise programs based on video game activities (VGA) provide an alternative to motivate and increase adherence to activity and pulmonary rehabilitation programs, especially in the younger population (del Corral, Percegona, Seborga, Rabinovich, & Vilaró, 2014).

A great deal of attention has been given to the negative effects of playing video games, but there can be positive effects of engaging in this activity. Health or training goals can be met using existing commercial games. Tailor-made games may engage patients and make it easier to meet treatment goals. Video games may be used for educational purposes for clinicians. Video games have been used with patients since the 1980s. Tailor-made games for different disease groups are a more recent endeavor and are evaluated in scientific trials (Kim et al., 2014).

Games can serve as a means to engage patients behaviorally in order to improve their health outcomes. Behaviors, often necessary to maintain and improve health, are reinforced. With game play, tension and fears are released in a safe setting, and aversive or shameful aspects of an illness may be managed. The focus of attention on an engaging distraction (the game) may explain how individuals manage aversive symptoms through video game play. An example of distractive use of a game is SnowWorld (see Table 10–4 for description) that is used to distract patients during burn care. The repetitive nature of video game play may promote learning (Kato, 2010; Pauschenwein, Goldgruber, & Sfiri, 2013).

Table 10–4 Selected Tailor-Made Video Games for Health

Name of Game if Specifically Named	Medical Condition Targeted	Game Description
Snow World	Burn pain	Users travel through an "icy landscape of a canyon, cold river, and waterfall through gently falling snow." Along the way, they can "shoot snowballs at snowmen, penguins, igloos, and robots." This game was "designed specifically to minimize body motion during gameplay to enable wound care (debridement) by nurses." Players control movements and activities by manipulating a fixed joystick (p. 116).
Packy and Marlon, originally made for the Super Nintendo game console system.	Diabetes for children	The game characters are two elephants attending a diabetes summer camp. The goal is to get rid of a "gang of marauding rats" that keep campers from their healthy food and diabetic supplies. To win, players have to "successfully manage their insulin levels and food intake while keeping their characters' glucose levels within an acceptable range" (p. 116).
Bronkie the Bronchiasaurus is a video game on the Super Nintendo Entertainment	Asthma for children	This game takes place in prehistoric times when the world was covered in dust. A fan needed to control the dust has broken. Players help the characters keep their asthma in control by "avoiding triggers such as dust and smoke" while on their quest. Question-and-answer inserts, needing correct responses, are interspersed and must be successfully answered in order to keep going (p. 116).
SpiroGame	Compromised lung function for preschool children	Measures and gives a readout of breathing function for spirometry and is helpful for patients with compromised lung functioning associated with asthma or cystic fibrosis. Spirometry depends highly on patient cooperation and effort during the procedure. Measurement conducted with *SpiroGame* promotes lung functioning in preschool children, inhalation and exhalation, and helps to control their breathing. Children control an animated caterpillar with their breathing. The caterpillar crawls to an apple over a period of 30 seconds as long as the child's breathing reaches predetermined targets. Another mini-game teaches children how to do a breathing test by "moving an animated bee flying from flower to flower" (p. 116).
Nonspecifically titled games that use biofeedback to control gameplay	Bladder and bowel dysfunction Pediatric voiding dysfunction in children	The child's compliance and motivation influence the success of biofeedback. Children are often not interested in dealing with embarrassing topics and may have difficulty staying focused on a biofeedback- training task. When combined with a game interface, interest and motivation in biofeedback are increased. Sensors are placed on the child's perineum to detect pelvic floor muscle activity. "Leads from the sensors connect to a port on the computer in which electrical activity from the sensors is transformed through algorithms to relate to actions in the game" (p. 117). The games included golf, spaceships, baseball, basketball, and a safari adventure. For example, in the golf game, the distance a golf ball traveled was determined by pelvic floor contractions. "In the basketball game, accuracy of shooting a basketball through a hoop was related to the patient's ability to relax the pelvic floor muscles" (p. 117). The games helped improve symptoms and treatment compliance, "even in children young as 4 years old, a group previously thought to be too young for biofeedback muscle training" (p. 117).
Nonspecifically titled games that employee biofeedback to control gameplay	Irritable bowel syndrome in adults	A computer biofeedback game designed for patients with IBS. The game teaches "stress management through deep relaxation exercises" (p. 117). Biofeedback sensors on the patients' fingers measure electrodermal activity (e.g., microchanges in sweat response). Patients control an "animated representation of bowel movement through changes in electrodermal conductivity" detected by biofeedback sensors when the patient engaged in both physical and mental relaxation (p. 117). The patients had more control of the animated gut movement when they were more relaxed.
Re-Mission	Cancer in adolescents and young adults	The goal of the game is to improve treatment, and players control a nanobot named Roxxi, who flies through tumors with chemotherapy and radiation. Roxxi "also combats side effects of treatment such as pain, nausea, infection, and constipation" (p. 117). Animations and direct interactions with environments provide information. Studies revealed greater knowledge, self-efficacy, and treatment compliance.

Kato, P. M. (2010). Video games in health care: Closing the gap. Review of General Psychology, 14(2), 113–121.

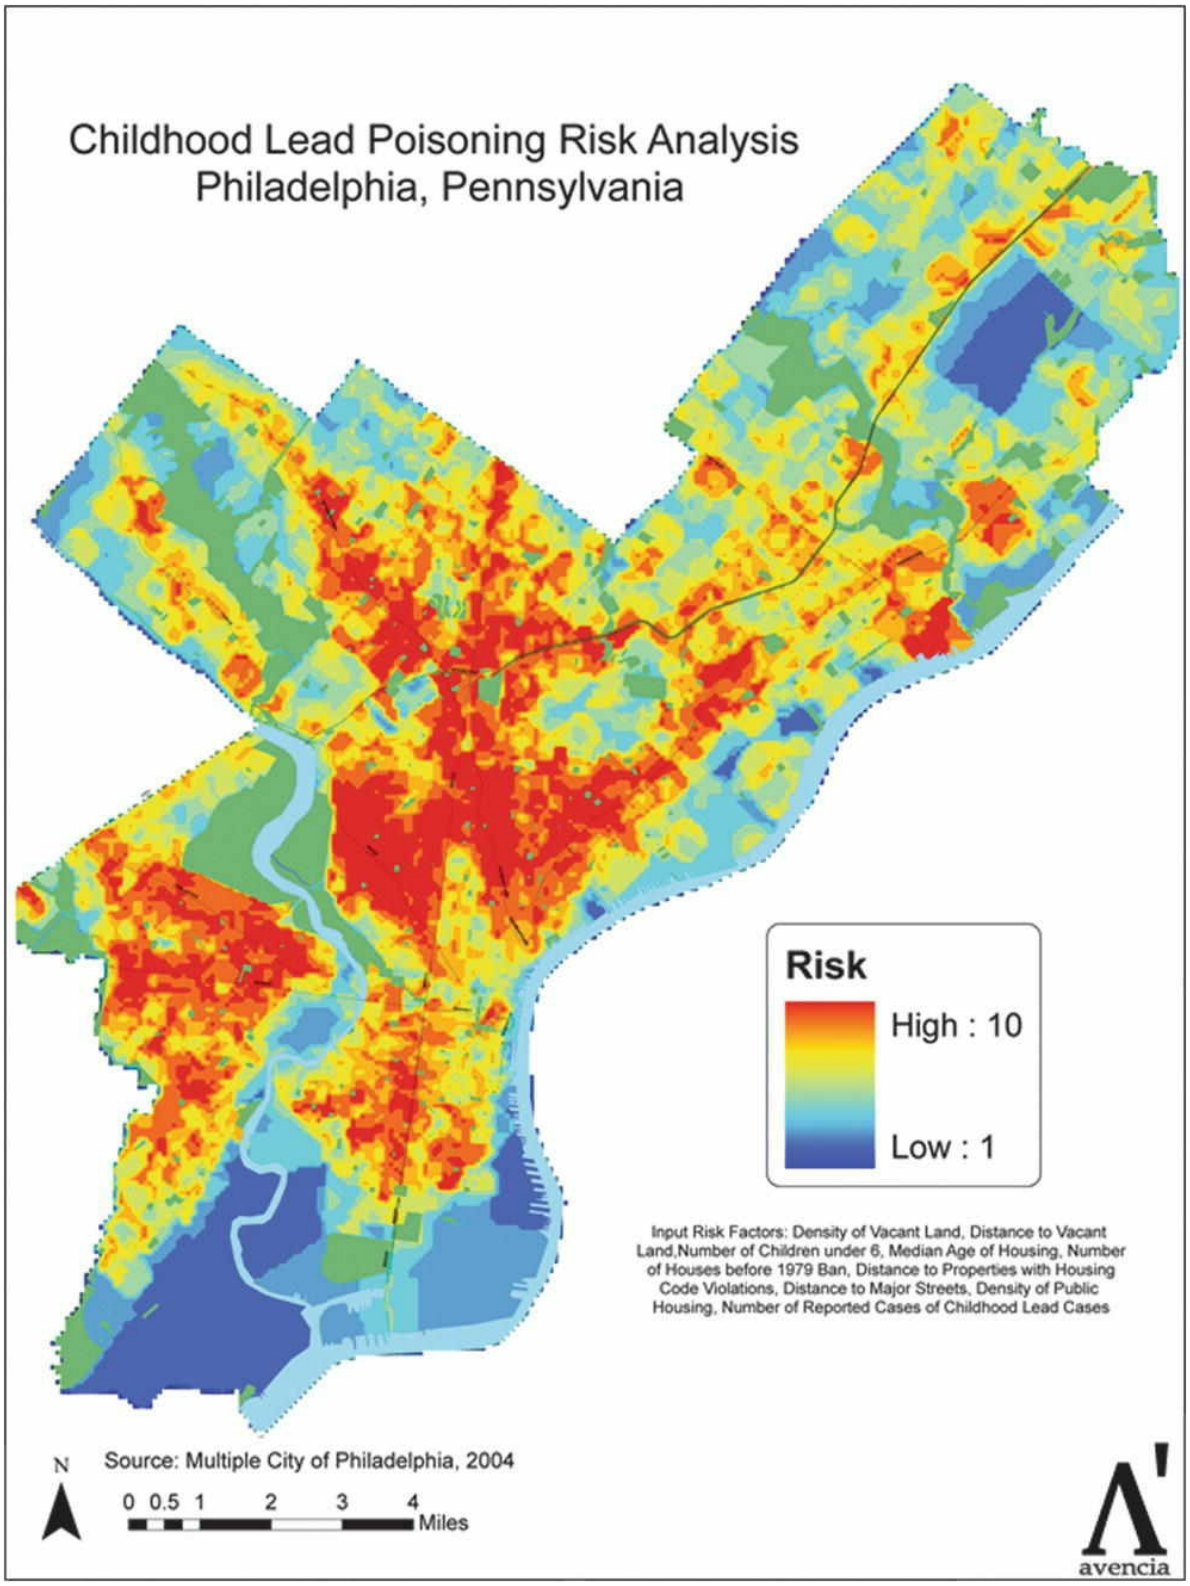
Telehealth

Telehealth gives the public health nurse an opportunity to see and speak with clients located at remote sites, as well as provide education and counseling.

Telehealth is the use of technology to deliver health care, health information, or health education at a distance (National Advisory Committee on Rural Health & Human Services, 2015). The American Academy of Ambulatory Care Nursing's definition of telehealth is:

> The delivery, management, and coordination of health services that integrate electronic information and telecommunication technologies to increase access, to improve outcome and contain or reduce costs of health care. Telehealth is an umbrella term used to describe the services delivered across distances by all health professions (Espensen, 2012, p. 42).

Telehealth provides access to care and the ability to export clinical expertise to individuals who require care, regardless or geographic location of the patient or the clinician (Nelson & Staggers, 2014). The boundaries of telehealth are limited only by the technology available, and new applications are being developed and tested every day. Telehealth can be divided into two general types of applications: real-time or synchronous communication and store-and-forward or asynchronous communication. Real-time



communication scenarios include a patient and clinician consulting with a specialist via a live audio/video link or a clinician and a patient in an exam room communicating through an interpreter connected by phone or webcam. Another example is a meeting with a clinician in one location and an individual in another who communicate through Skype. A clinician holding a teleconference with other clinicians about new best practices also could be classified as telehealth. With synchronous or real-time telehealth communication, all members are technologically present at the same time. Asynchronous or store-and-forward applications utilize the transmission of digital images, records or results for a diagnosis, consultation, and information sharing and/or treatment interventions and suggestions. With asynchronous telehealth, members are not technologically present at the same time, but share the same information at the time most convenient to each one (National Advisory Committee on Rural Health & Human Services, 2015). Many online education programs utilize asynchronous methods of instruction.

The American Telemedicine Association (2015) states telehealth has been growing rapidly because it offers four fundamental benefits:

- Improved Access—For over 40 years, telehealth has been used to bring health care services to patients in distant locations.
- Cost Efficiencies—Telehealth has been shown to reduce the cost of health care and increase efficiency through improved management of chronic diseases, shared health professional staffing, reduced travel times, and reduced hospital stays.
- Improved Quality—Studies have consistently shown that the quality of health care services delivered via telehealth is equal to those given in traditional in-person care.
- Patient Demand—Consumers want telehealth that reduces travel time and related stresses for patients/families. Services and/or providers may not be available otherwise (para. 7).

Telehealth applications require IT, but not every use of health-related technology is telehealth. Stand-alone systems like EHRs, discussed earlier, are not typically thought of as a telehealth application. One outstanding value of telehealth is that it can increase contact between an individual patient or a family with the health care system. Additional expertise can be brought to the patient's home or bedside, clinicians can reach out to patients when they are at home, and save travel time and expense for both practitioners and patients. Telehealth shows great potential for advancing preventative medicine and the treatment of chronic conditions (American Telemedicine Association, 2015). The first year of reimbursement for telehealth services delivered outside of care settings occurred in 2015 (Wicklund, 2015).

Geographic Information Systems (GIS)

Example of GIS use in a lead poisoning project. (Photo courtesy of USA.gov.)

A geographic information system (GIS) is a computer-based information system designed to capture, store, manipulate, analyze, manage, and present all types of spatial (relating to space) or geographical data. GIS allows the user to visualize, question, analyze,

and interpret data to understand relationships, patterns, and trends. Spatial or mappable data are integrated with conventional data. GIS can be thought of as a two-dimensional Google earth map. Google earth allows you to zoom in and out and pan around, and GIS additionally allows users to select a feature on the map and, in return, will be provided with any information in the database associated with that feature (University of Mary Washington, 2016). Much of community health is spatially related, so the use of GIS can provide information about demographic, epidemiological, and logistical issues and emerging trends. GIS output is location-based information. GIS can provide:

- Better understanding of a current situation
- Planning/targeting of appropriate interventions
- Monitoring and revision of interventions as needed
- An opportunity for cooperation with other organizations and government departments through a culture of data sharing and working together

Sharing, comparing, and integrating data will eliminate silos and result in better outcomes (Detres, Lucio, & Vitucci, 2014; Edward & Biddle, in press; Jones & Ku, 2015).

There is great potential for GIS to inform public health nursing. Nurses can play an important role in demonstrating how various data sources come together to enable informed decisions for populations and individuals (Kolifarhood, Khorasani-Zavareh, Salarilak, Shoghli, & Khosravi, 2015). It can be helpful in eliminating access barriers and providing policy-based interventions to decrease health inequities (Edward & Biddle, in press). Understanding of GIS may be considered an essential skill for the evolution of nursing practice (Semple et al., 2013). Smartphone and other devices are fitted with GIS technology, and many of us have GIS satellite navigation units in our vehicles or in our pockets. People rely on satellite imagery and digital mapping to get to their destination. These data are often freely available; each time a person asks for directions, the device connects to the satellite network (Mason, 2015).

The tremendous potential of GIS to benefit health care delivery is being realized. Both public and private organizations are developing innovative ways to use GIS, from public health departments and public health policy and research organizations to hospitals, medical centers, and health insurance organizations. Public health uses of GIS include tracking child immunizations, evaluating the spread and clustering of diseases, conducting health policy research, and establishing service areas and districts. Medical information is significantly more useful when combined with knowledge of the environmental factors associated with patients, locations, and conditions (Edward & Biddle, in press; Mason, 2015). A health system utilizing GIS technology will provide a more precise understanding of the links between an individual's health and where they reside, work, and play (Cromley & McLafferty, 2012).

Electronic Health Literacy and the Digital Divide

The rapid development of communication technology affects every aspect of society. Information is instantly available. The rapid proliferation of mobile devices makes information retrieval easier than ever before (Robb & Shellenbarger, 2014). The multitude of electronic health applications (e.g., online health information Web sites, interactive EHRs, health decision support programs, tailored health education programs, health care system portals, mHealth communication programs, advanced telelectronic health applications) hold great promise to increase access to health information, enhance the quality of care, reduce health care errors, increase collaboration, and encourage the adoption of healthy behaviors (Berkowitz & McCarthy, 2013).

Health communication and health information technology competencies are identified as vital skills of an informed consumer and essential for improving population health outcomes and health care quality. The term digital literacy appeared in the literature since the 1990s. A consensus definition may not exist but Nelson et al. (2013, p. 15) define digital literacy as including:

- Competency with digital devices of all types, including cameras, eReaders, smartphones, computers, tablets, video games
- The skills to operate the above devices as well as the knowledge to understand their functionality
- The ability to creatively and critically use these devices to access, manipulate, evaluate, and apply data, information, and wisdom
- The ability to apply basic emotional intelligence in collaborating and communicating with others
- The ethical values and sense of community responsibility to use digital devices for the enjoyment and benefit of society

Electronic health literacy is how people use electronic information and communication to improve health and access health care (Vajaean & Baban, 2015). People with low electronic health literacy represent a vulnerable population who are at risk (Levy, Janke, & Langa, 2015). As mentioned earlier, computer literacy and knowledge of the use of current technologies are part of health literacy. *Healthy People 2020* goals endeavor to increase health literacy skills and acknowledge that these skills may have a significant positive impact on improving health care quality and safety. Potential areas include supporting care, facilitating health care decision making, and building health skills and knowledge (Robb & Shellenbarger, 2014; USDHHS, 2016). Individuals must be able to use technology and navigate through a vast array of information, tools, and sources to acquire and critically analyze the information necessary to make appropriate and informed decisions (Vajaean & Baban, 2015).

Recent technological developments have elevated the importance of assessing how

electronic health tools have empowered patients and improved health, especially among the most vulnerable populations. With an awareness of disparities in chronic health outcomes across racial/ethnic and social groups, it is essential that clinicians work to strengthen electronic health skills, particularly in groups that bear a disproportionate burden of disease (Kontos, Blake, Chou, & Prestin, 2014).

> The idea of the "digital divide" refers to the growing gap between the underprivileged members of society, especially the poor, rural, elderly, and handicapped portion of the population who do not have access to computers or the internet; and the wealthy, middle-class, and young Americans living in urban and suburban areas who have access (Stanford University, n.d., para. 2).

Kontos et al. (2014) describe the digital divide through a generational lens; younger generations who have grown up with technology are described as "digital natives" and are more comfortable using technology for everyday needs. Older generations are described as "digital immigrants" and have had to acquire the skills needed to use the Internet; thus they are less comfortable using technology. Technology is continually advancing, and the "digital divide" must be considered when addressing individual and population needs in public health nursing. Those with computers and access to the Internet are gaining skill, knowledge, and power through access to information (Stanford University, n.d.).

Technological literacy cannot be promoted if basic literacy skills are lacking. One in four adults in the United States is illiterate or has limited literacy skill. Adults with low literacy scores may not possess the basic skills required to function successfully within the health care system. Tasks such as reading prescription labels or care instructions, interpreting directions, and managing the health of their family may be daunting (Toronto & Weatherford, 2015). With new and exciting health technology developments comes the daunting responsibility to design interoperable, easy-to-use, engaging, and accessible electronic health applications that communicate the right information needed to guide health care and health promotion for diverse audiences (Kreps & Neuhauser, 2010). There is potential for electronic health technologies to aid in reducing communication inequalities and disparities in health. The need exists to educate at-risk and needy groups (e.g., chronically ill) and design technology in a way that works for them. Addressing these areas may not diminish the digital divide, but it may ameliorate its consequences (Neter & Brainin, 2012).

SUMMARY

Communication and collaboration are important tools for community health nurses to promote aggregate health. Communication involves the transfer and understanding of meaning between individuals (see Display 10–13). The communication process comprises seen parts: a message, a sender, a receiver, encoding, a channel, decoding, and a feedback loop. Barriers to effective communication include selective perception, language barriers, clients filtering out parts of the message, and emotional influence. Core skills essential to effective communication in community health nursing include sending skills, which allow the nurse to transmit messages effectively; receiving skills, which allow the nurse to receive accurate and complete messages; and interpersonal skills, which allow the nurse to interact and respond to the messages from clients. These skills include special techniques of active listening, the ability to show respect regardless of the message (whether positive or negative), the ability to empathize with clients' thoughts and feelings, and the ability to develop trust. Many factors can influence the quality of communication, such as negative previous experience, cultural influence, and relationships among the people involved. The community health nurse must consider all of these factors when trying to foster good communication.

In community health, nurses frequently need to promote communication in groups and in-group decision making. Decisions made by groups have many advantages, including sharing of members' experience and expertise, diversity of opinions, potential for broadening members' perspectives, and a focus on arriving at consensus solutions. Several methods of enhancing group decision making are available, including brainstorming, nominal group technique, and multivoting technique. IT, encompassing all of the computer-generated and other tools created to enhance communication, is changing the form of communication in PHN, as it has in the acute care setting.

Collaboration and partnership building are purposeful interactions among the nurse, clients, community members, and other professionals based on mutual participation and joint effort. It is characterized by shared goals, mutual participation, maximized use of resources, clear responsibilities, and set boundaries. Clients play an important role in the collaborative relationship.

Contracting is a helpful tool in promoting clients' participation, independence, and motivation. It is used at all levels of public health nursing to promote partnership in the collaborative process, to encourage commitment to health goals, and to ensure a format and a means for negotiation among the collaborating parties. Contracts may be formal or informal, written or verbal, and simple or complex. The nurse must know the needs and abilities of clients and must tailor the type of contracting to best suit the client's particular situation. Health technology incorporates large information systems and the use of EHRs. These are common in acute care settings, but are beginning to be used in public health settings. HIEs provide a hub for public health agencies, hospitals, health care providers, and

others to share information to improve the health of individuals and populations.

Big data include very large and complex data sets that are analyzed to uncover trends, associations, and patterns. This is very helpful in public health agencies in the areas of disease surveillance, population health management, and immunization trends.

mHealth involves the use of mobile devices (e.g., smartphones, tablets, notebooks) for communication between clients and PHNs. Trends in mHealth include interactive (two-way communication), integrative (patient/provider and tracking systems), and multimedia uses (games/quizzes to promote health). A majority of Americans and people around the world have mobile phones. Text messaging can be useful in promoting health and encouraging immunizations, reminding clients of appointments or the need to pick up prescriptions, as well as encouraging exercise, or diabetes management behaviors, and blood pressure self-checks.

Applications are used for computers, tablets, and smartphones, and more health-related apps are available every year. Because of a lack of regulation, the quality or effectiveness of health apps is not researched. The FDA intends to provide oversight and identify apps that may be detrimental. FastStats is a free app from the CDC that provides information on more than 100 health topics. Twitter is a popular social networking site that has potential public health uses (e.g., disaster alert/response, epidemiological investigations).

Blogging and online support communities have proven to be helpful to those with chronic diseases or others needing emotional support. Those living in rural areas may especially find them useful, as they can connect to a larger group of people for information and support.

Video games are being used for health applications, in addition to their usual entertainment value. Exercise programs, and others that are specifically developed for patients with particular illnesses or conditions (e.g., pulmonary rehabilitation, burn patients), have been found to be beneficial.

Telehealth provides health information or health care to many individuals and groups who may otherwise not be able to access it. It may be done synchronously (in real time) or asynchronously (store-and-forward; accessed when convenient). GIS are mapping programs that can be used along with data to analyze and interpret relationships between a location and a disease or condition (e.g., area of a city and diabetes rates). Both telehealth and GIS have great potential for public health, as access barriers can be eliminated and disease patterns can be more closely studied and addressed. Childhood immunizations can be better tracked, as well as the spread of diseases, and vulnerable groups can be better served.

Electronic health literacy and the digital divide often prevent full use of technology among vulnerable and rural populations. It is important for PHNs to keep these in mind when working with elderly, disabled, poor, and rural clients, for instance, who may need additional assistance, education, and accommodations.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Practice active listening with a colleague and subsequently analyze the factors that interfered with your total concentration. Identify three actions to take to improve your active listening, and apply them during the next week, keeping a log of your progress.
2. Think of a patient you have worked with who may have low health literacy. What kinds of things can you do to help them better communicate with their physician and other health professionals? Why is good health literacy important not only for the patient as an individual, but for the community and society as a whole?
3. Use nominal group technique with a group of classmates to arrive at a rank ordering of barriers to cross-cultural communication. What did you learn about arriving at a quality decision in the process?
4. Attend an open meeting (e.g., student body council, school board, city council) and watch for task and maintenance roles among the members. Are any members displaying nonfunctional role behaviors? Can you recognize task, maintenance, and nonfunctional role behaviors in some of the student groups in which you participate?
5. Organize a group of classmates to represent a group of clients, professionals, and community members who are collaborating to address the needs of an inner-city homeless population. Analyze how well you integrated the five characteristics of collaboration into your activity.
6. Explain the concept of contracting as it applies to aggregates. Discuss its four distinctive characteristics and the advantages that contracting offers to the community health nurse.
7. Develop a hypothetical contract with a group of elderly widows who need support and outlets to alleviate their loneliness. What other community members and professionals might be helpful as part of a collaborative team to address the widows' needs? How could your collaborative team plan for online support group to meet their needs? Name three benefits to clients who participate in online groups. Discuss any downside or barriers to participation.
8. Search state and local public health agency Web sites (or speak to PHN administrators) about use of electronic health records (EHRs). How common is this practice compared with hospitals in the same locality? Compare and contrast the functionality and use of the EHRs in public health and acute care.
9. Search for state and national examples of the use of big data in assessing public health problems and designing interventions. How are these data more helpful than traditional data? How is this most useful in public health?
10. Consider the various types of technology available (e.g., mHealth, mobile health applications, video games, telehealth, GIS). Which would you find most helpful as

you design public health interventions for various age groups and populations (e.g., low-income, Spanish-speaking Latino women needing nutritional information; adolescents needing information on STDs and sexual health; addressing an outbreak of foodborne illness in a large metropolitan area; exercise needs of elderly living in rural areas; a group of young mothers wanting information on normal child development; parents of newly diagnosed children with muscular dystrophy; 10 to 14 year olds with asthma)?

11 CHAPTER

Health Promotion: Achieving Change Through Education

"As I see it, every day you do one of two things: build health or produce disease in yourself."
—*Adelle Davis (1904–1974)*, Nutritionist and Author

KEY TERMS

Adult learners
Affective domain
Anticipatory guidance
Change
Cognitive domain
Empiric–rational change strategy
Force field analysis
Health promotion
Learning theories
Normative–reeducative change strategy
Planned change
Power–coercive change strategy
Psychomotor domain
Social determinants of health
Social marketing
Stages of change
Transtheoretical Model

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Explain the three stages of change.
- Identify three planned-change strategies.
- Summarize six principles for effecting change in community health.
- Describe the community health nurse's role as educator in promoting health and preventing or postponing morbidity.
- Identify educational activities for the nurse to use that are appropriate for each of the three domains of learning.
- Identify health teaching models for use when planning health education activities.
- Discuss methods of education and social marketing that may be used to improve health promotion with communities and populations.
- Develop teaching plans focusing on primary, secondary, and tertiary levels of prevention for clients of all ages.

- Identify teaching strategies for the community health nurse to use when encountering clients with special learning needs.
- Describe social determinants of health and how each relates to health inequities.

Think of a time when you were so influenced by a teacher that you stopped an unhealthy habit, altered a long-held belief, or embarked on a new endeavor. What precisely was it that motivated the change? Was it simply the content of the teaching, or was it how the teacher presented the content or your involvement in the learning process? What is good teaching, and why is it so important to community health nursing?

Teaching has been a critical part of the community health nurse's role since the origins of the profession, and it frequently is the primary role or function. PHNs develop partnerships with clients to achieve behavior changes that promote, maintain, or restore health. This partnership focuses on self-care—the ability to effectively advocate and manage a person's own health. The rationale for health teaching is to equip people with the knowledge, attitudes, and practices that will allow them to live the fullest possible life for the greatest length of time. The vision of *Healthy People 2020* is for "a society in which all people live long, healthy lives" (U.S. Department of Health and Human Services [USDHHS], 2016a, para. 3). Figure 11–1 depicts a graphic model of *Healthy People 2020*, including overarching goals. This model demonstrates the influence of social determinants of health to the positive health outcomes envisioned in the Healthy People initiative. *Healthy People 2020* objectives for educational, community-based programs, which address the goal of increasing the "quality, availability and effectiveness of educational and community-based programs designed to prevent disease and injury, improve health and enhance the quality of life," are listed in Table 11–1 (USDHHS, 2016b, para.1). These objectives when viewed in the broader context depicted in the model can be used to identify client needs and align educational efforts that will advance this national initiative.

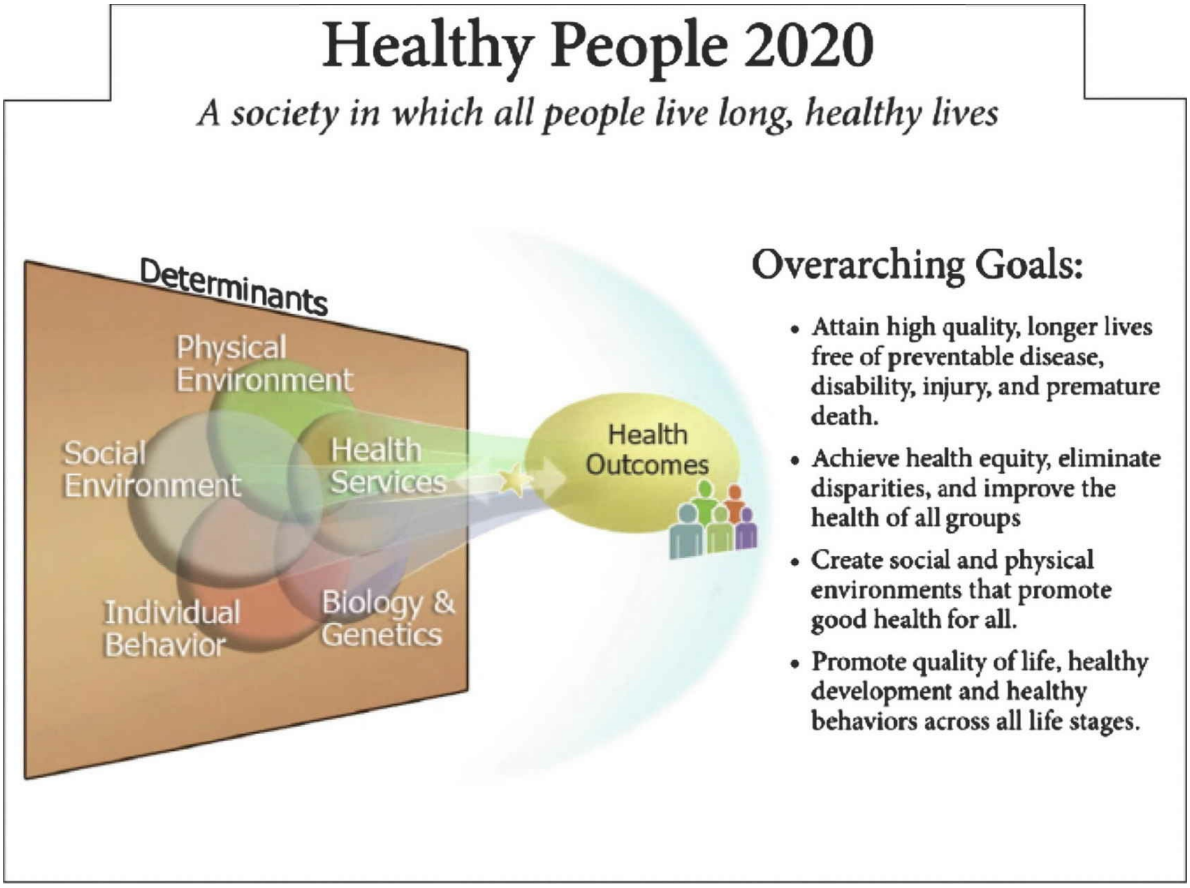

Figure 11–1 Health People 2020 framework. (From U.S. Department of Health and Human Services (USDHHS), Office of Disease Prevention and Health Promotion. (n.d.). *Healthy People 2020*. Healthy People 2020 Framework: The vision, mission, and goals of Healthy People 2020. Retrieved from http://www.healthypeople.gov/sites/default/files/HP2020Framework.pdf)

Table 11–1 *Healthy People 2020* Objectives for Educational and Community-Based Programs

	Objective	2020 Goal
ECBP-1	Preschool health education	Increase the proportion of preschool Early Head Start and Head Start programs that provide health education to prevent health problems in the following areas: unintentional injury; violence; tobacco use and addiction; alcohol or other drug use; unhealthy dietary patterns; and inadequate physical activity, dental health, and safety
ECBP-2	School health education	Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, HIV/AIDS, and STD infection; unhealthy dietary patterns; and inadequate physical activity
ECBP-3	School health education standards	Increase the proportion of elementary, middle, and senior high schools that have health education goals or objectives which address the knowledge and skills articulated in the National Health Education Standards (high school, middle, and elementary).
ECBP-4	School health education on personal growth and wellness	Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene, oral health, growth and development, sun safety and skin cancer prevention, benefits of rest and sleep, ways to prevent vision and hearing loss, and the importance of health screenings and checkups
ECBP-5	School nurse-to-student ratio	Increase the proportion of elementary, middle, and senior high schools that have a full-time registered school nurse-to-student ratio of at least 1:750
ECBP-6	High school completion activities	Increase the proportion of the population that completes high school education
ECBP-7v	Health risk behavior information in higher education	Increase the proportion of college and university students who receive information from their institution on each of the priority health risk behavior areas (all priority areas; unintentional injury; violence; suicide; tobacco use and addiction; alcohol and other drug use; unintended pregnancy, HIV/AIDS, and STD infection; unhealthy dietary patterns; and inadequate physical activity)
ECBP-8	Worksite health promotion programs	Increase the proportion of worksites that offer an employee health promotion program to their employees
ECBP-9	Participation in employer-sponsored health promotion	Increase the proportion of employees who participate in employer-sponsored health promotion activities
ECBP-10	Community-based primary prevention services	Increase the number of community-based organizations (including local health departments, tribal health services, nongovernmental organizations, and state agencies) providing population-based primary prevention services in the following areas: injury, violence, mental illness, tobacco use, substance abuse, unintended pregnancy, chronic disease programs, nutrition, physical activity
ECBP-11	Culturally appropriate community health programs	Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs.
ECBP-12	Clinical prevention and population health training—M.D.—granting medical schools	Increase the inclusion of core clinical prevention and population health content in M.D.—granting medical schools
ECBP-13	Clinical prevention and population health training—D.O.—granting medical schools	Increase the inclusion of core clinical prevention and population health content in D.O.—granting medical schools
ECBP-14	Clinical prevention and population health training—undergraduate nursing	Increase the inclusion of core clinical prevention and population health content in undergraduate nursing
ECBP-15	Clinical prevention and population health training—nurse practitioner	Increase the inclusion of core clinical prevention and population health content in nurse practitioner training
ECBP-16	Clinical prevention and population health training—physician assistant	Increase the inclusion of core clinical prevention and population health content in physician assistant training
ECBP-17	Clinical prevention and population health training—PharmD—granting colleges and schools of pharmacy	Increase the inclusion of core clinical prevention and population health content in Doctor of Pharmacy (PharmD) granting colleges and schools of pharmacy
ECBP-18	Clinical prevention and population health training—DDS/DDM—granting colleges and schools of Dentistry	Increase the inclusion of core clinical prevention and population health content in Doctor of Dental Surgery and/or Doctor of Dental Medicine granting colleges and schools of Dentistry.
ECBP-19	Clinical prevention and population health training	Increase the proportion of academic institutions with health professions education programs whose prevention curricula include interprofessional educational experiences

From U.S. Department of Health and Human Services (USDHHS). (2016). *Healthy People 2020: Educational and community-based programs*. Retrieved from http://www.healthypeople.gov/2020/topics-objectives/topic/educational-and-community-based-programs/objectives

When the community health nurse identifies a need that is best met through health education, the nurse is faced with a series of questions: What is the overall goal? How can I teach effectively? What content should I cover? What method of presentation will communicate most effectively? What resources can I use as teaching tools? How do I know when the client has grasped the information or mastered the skills? How do I involve the client in the learning process? How do I assist clients with special learning needs? The nurse must understand what makes teaching effective, how teaching skills are acquired, and how mastery is measured. The PHN might also need to consider why some individuals adopt new health practices and others do not, as well as how social determinants influence health outcomes. This chapter addresses these questions and discusses teaching as a basic intervention tool in community health nursing practice. For health education to be effective, awareness of the underlying principles of behavior change is vital. The community health nurse should consider what motivates individuals and groups to adopt new behaviors and what factors may inhibit or prevent that change. By understanding the principles of teaching and behavior change, the community health nurse can work toward the ultimate goal of health promotion for individuals, families, groups, and communities (USDHHS, 2016d).

HEALTH PROMOTION THROUGH CHANGE

Health promotion has been defined as health behaviors that improve well-being and lead to a desire to meet one's human potential (Pender, Murdaugh, & Parsons, 2015). Another term often confused with health promotion is *disease prevention* (or *health protection*), which is "behavior motivated by a desire to actively avoid illness, detect it early, or maintain functioning within the constraints of illness" (Pender et al., 2015, p. 17). These two terms, so often used interchangeably, are clearly both important aspects of health education efforts, yet they imply a decidedly different motivation. For the PHN, both terms relate to practice at the primary level of prevention. The Levels of Prevention Pyramid at the end of this chapter describes educational activities within both of these approaches in relation to primary prevention. For instance, a community health nurse may plan an educational program for community-dwelling older adults to learn about the need for a balanced diet, rich in fruits and vegetables. This would be an example of a health promotion focus, because there is no clear disease or condition at issue. As the nurse continues to work with these individuals, the nurse learns that several clients have had recent falls. Fortunately, none of the falls were serious, yet the nurse recognizes the need to discuss foods that will help reduce bone loss and promote healthy bone growth. To protect the clients' health, the nurse provides information on a variety of foods rich in calcium and explains the need for adequate vitamin D. This effort would be still primary prevention, but with the purpose of health protection.

For the community health nurse, teaching is the primary means to influence health at all levels, primary, secondary, and tertiary. But consider the educational program just described: The PHN has provided a well-developed educational program that was well received by the participants. They listened attentively, took the nurse's well-prepared handouts home, and even promised to add more fruits, vegetables, and calcium-rich foods to their diet. A few weeks later, in another educational program, the nurse learns from the participants that they have not altered their dietary patterns in the slightest. This is an example of how understanding the principles of behavior change may provide guidance to this PHN in planning a more effective program, with a greater chance for success.

The Nature of Change

To be a PHN is to be a health educator with the goal of effecting change in people's behaviors. When nurses suggest that families adopt healthier communication patterns, they are asking them to change. Teaching parenting skills to teenagers is introducing a change. Promoting a community's self-determination in choosing a safer environment requires that the individuals involved must change. Therefore, it becomes imperative for community health nurses to understand the nature of change, how people respond to it, and how to effect change for improved community health.

Definitions and Types of Change

Change is "any planned or unplanned alteration of the status quo in an organism, situation, or process," per Lippitt's (1973, p. 37) classic definition. This definition explains that change may occur either by design or by default. Over the years, various theorists have contributed to understanding the nature of change (Burke, 2013). From a systems perspective, change means that things are out of balance or the system's equilibrium is upset (Roussel, Harris, & Thomas, 2016). For instance, when a community is ravaged by floodwaters, its normal functioning is thrown off balance. Adjustments are required; new patterns of behavior become necessary.

Other classic theorists have explained change as the process of adopting an innovation (Spradley & McCurdy, 1994). Something different, such as an organization-wide smoke-free policy, is introduced; change occurs when the innovation is accepted, tried, and integrated into daily practice. Some have explained change in terms of its effect on behavior —change requires adjustment in thinking and behavior, and people's responses to change vary according to their perceptions of it. Change threatens the security that people feel when abiding by established and familiar patterns. It generally requires adopting new roles. Change is disruptive. The way people respond to change depends partly on the type of change required. Others have categorized groups or populations by their willingness to accept innovation and change. Rogers' diffusion of innovation theory helps explain how new ideas or healthy behaviors gain momentum and diffuse (or disperse) throughout a population and are then adopted (Boston University School of Public Health, 2013). People fall into five categories of adopters: (a) innovators who are usually the first to try something new, (b) early adopters who are often opinion leaders that have some awareness of a need for change, (c) early majority who are usually followers (not leaders) who want to examine the evidence before trying out a new behavior, (d) late majority who often are suspicious of change and only adopt a behavior after the majority of the population have done so, and (e) laggards who are very traditional, skeptical, and conservative and represent the most difficult group to convince. For instance, when jogging first gained widespread attention in the early 1970s, only a small number of people were involved (e.g., innovators). Over time, more people heard about the benefits and wanted to improve their fitness (e.g., early adopters, early majority). Now, regular exercise of some type is

considered to be necessary for good health. The change process can be described as sudden or drastic (revolutionary) or gradual over time (evolutionary).

Evolutionary change is change that is gradual and requires adjustment on an incremental basis. It modifies rather than replaces a current way of operating. Some examples of evolutionary change include becoming parents, gradually cutting back on the number of cigarettes smoked each day, and losing weight by eliminating desserts and snacks. Because it is gradual, this kind of change does not require radical shifts in goals or values. For the most part, people resist discarding their own ideas. Accepting another's idea may reduce their self-esteem and is therefore resisted. Gradual change may "ease the pain" that change brings to some individuals. Sometimes, this type of change may be viewed as *reform*.

Revolutionary change, in contrast, is a more rapid, drastic, and threatening type of change that may completely upset the balance of a system (Borwick, 2013). It involves different goals and perhaps radically new patterns of behavior. Sudden unemployment, stopping smoking overnight, losing the town's football team in a plane accident, removing children from abusive parents, or rapidly replacing human workers with computers are examples of revolutionary changes. In each instance, the people affected have little or no advance warning and little or no time to prepare. High levels of emotional, mental, and sometimes physical energy and rapid behavior change are required to adapt to revolutionary change. If the demands are too great, some may experience defense mechanisms such as incapacitation, resistance, or denial of the new situation.

The impact of a proposed change on a system clearly depends on the degree of the change's evolutionary or revolutionary qualities, a factor to be considered in planning for change. Some situations lend themselves better to one kind of change than to another. A community in need of improved facilities for the handicapped (e.g., ramps, wider doors) can introduce this change on an evolutionary, incremental basis, whereas a community that is involved in an unsafe, intolerable, or life-threatening situation, such as a hurricane or serious influenza epidemic, may require revolutionary change.

Two powerful examples of social and public health change occurred during the last decades of the 20th century—dramatic decreases in both motor vehicle crashes and tobacco consumption. These changes did not come about simply through education alone. Rather, "multilevel and multicomponent" approaches were used, and social norms were changed by the use of epidemiology and surveillance as a basis for social marketing in bringing the problems to the attention of the American public; with the social influence of individuals, along with supportive legislation and policies, changes in health behaviors occurred (Gielen & Green, 2015, p. 21s). Because of research, surveillance, monitoring of risk factors, and subsequent interventions related to these two problems, more people became aware of the significance of them. Although cigarettes had been proclaimed a health risk in 1964, many people still smoked. It was not until smoking cessation research began to show promise and new over-the-counter treatments and medications became available that more people attempted to stop smoking. In 1992, secondhand smoke was declared to be a carcinogen. Mass media was used to educate the public on the risks and the benefits of quitting; this

also began to change public opinion. At the same time, legislation to control the advertising of tobacco products and tighten sales to minors gained momentum. Smoke-free policies were enacted, and higher cigarette taxes made it more difficult for some to smoke. Counseling and education strategies were increasingly empowering individuals and communities to change health behaviors, and multiple attempts at quitting were accepted. Cigarette sales began to drop, and stroke and heart attack death rates quickly improved after smoke-free zones were established. Child asthma admissions to hospitals and premature births also significantly declined within a year after the United States enacted bans on smoking in public places. Researchers point to the synergistic effect of the interventions (Gielen & Green, 2015). Similarly, with environmental (e.g., safer cars, improved roads, better signage) and behavioral changes (e.g., use of seat belts and child safety seats, buying newer/safer vehicles, fewer drunk drivers), motor vehicles crashes drastically dropped. Public information campaigns led by individuals who had been impacted by drunk drivers (e.g., MADD, SADD), along with education and training programs for beverage servers, tougher laws and penalties for drinking and driving, periodic sobriety checkpoints, and campaigns to encourage designated drivers and discourage driving for those who have been drinking led to a change in social norms and reductions in motor vehicle crashes. Because federal highway money was used as an incentive for states to lower the legal limit for drinking and driving, and to move to graduated driver licensing programs for teen drivers, the changes became widespread and more lasting. With the change in public opinion and health behaviors, seat belt use increased from 11% in 1981 to 86% in 2012 and child safety seat use is often cited at 92% to 99%. In this nation that prizes individual rights, public opinion was reframed from "a matter of personal risk to one of imposing risks on others" (Gielen & Green, 2015, p. 24s).

Stages of Change

The phrase stages of change refers to the three sequential steps leading to change:

- Unfreezing (when desire for change develops)
- Changing (when new ideas are accepted and tried out)
- Refreezing (when the change is integrated and stabilized in practice)

Kurt Lewin first described these stages in the 1940s and early 1950s, and they have become a cornerstone for understanding the change process (Kaminski, 2011; Lewin, 1947, 1951; Lippitt, Watson, & Westley, 1958).

Unfreezing

The first stage, unfreezing, occurs when a developing need for change causes disequilibrium in the system. A system in disequilibrium is more vulnerable to change. People are motivated to change either intrinsically or by some external force. People have a sense of dissatisfaction; they feel a void that they would like to fill. The unfreezing stage involves

initiating the change. Unfreezing may occur spontaneously: A family requests help in solving a problem with alcoholism, a group seeks assistance in adjusting to retirement, and a community desires a solution to noise pollution. However, the nurse as change agent may need to initiate the unfreezing stage by attempting to motivate clients, through education or other strategies, to see the need for change. Rarely do individuals understand the immediate impact of unhealthy decisions and tend to develop poor health habits over time (Koeppl & Robertson, 2015). Being proactive and recognizing the importance that daily choices influence health instead of being reactive to negative health behaviors is essential. The reactive behavior has been termed as "just-in-time" involvement, when clients are motivated to change once illness seems imminent. This concept is discussed further in Chapter 17 in relation to emergency preparedness.

Changing/Moving

The second stage of the change process, changing or moving, occurs when people examine, accept, and try the innovation (Kaminski, 2011). For instance, this is the period when participants in a prenatal class are learning exercises or when elderly clients in a senior citizens' center are discussing and trying ways to make their apartments safe from accidents. During the changing stage, people experience a series of attitude transformations, ranging from early questioning of the innovation's worth to full acceptance and commitment and then to accomplishing the change. The change agent's role during this moving stage is to help clients see the value of the change, encourage them to try it out, and assist them in adopting it.

Refreezing

The third and final stage in the change process, refreezing, occurs when change is established as an accepted and permanent part of the system (Kaminski, 2011). The rest of the system has adapted to it. Because it is no longer viewed as disruptive, threatening, or new, people no longer feel resistant to it. As the change is integrated, the system becomes refrozen and stabilized. It is evident that refreezing has occurred when weight loss clients, for example, are routinely following their diets and losing weight, when senior citizens are using grab bars in their bathrooms and have removed scatter rugs from their homes, or when a community has erected stop signs and established crosswalks at dangerous intersections. Refreezing involves integrating or internalizing the change into the system and then maintaining it. Because a change has been accepted and tried does not guarantee that it will last. Often, there is a tendency for old patterns and habits to return. Consequently, the change agent must take special measures to ensure maintenance of the new behavior (Wills, 2014). A later section discusses ways to stabilize change.

Planned/Managed Change

Leaders in community health nursing have been change agents for decades. They have planned and managed change in a variety of systems. Planned change is a purposeful, designed effort to effect improvement in a system with the assistance of a change agent per Spradley's classic definition (1980). Planned change, also known as managed change, is crucial to the development of successful community health nursing programs (Roussel et al., 2016). In fact, the ability to manage and influence change is considered to be an important competency in the field of public health (Reyes, Bekemeier, & Issel, 2014). The following characteristics of planned change are key to its success:

- *The change is purposeful and intentional:* There are specific reasons or goals prompting the change. These goals give the change effort a unifying focus and a specific target. Unplanned change occurs haphazardly, and its outcomes are unpredictable.
- *The change is by design, not by default:* Thorough, systematic planning provides structure for the change process and a map to follow toward a planned destination.
- *Planned change in community health aims at improvement:* That is, it seeks to better the current situation, to promote a higher level of efficiency, safety, or health enhancement. Planned change aims to facilitate growth and positive improvements. Plans to provide shelter and health care for a homeless population, for example, are designed to improve this group's well-being.
- *Planned change is accomplished through an influencing agent:* The change agent is a catalyst in developing and carrying out the design; the change agent's role is a leadership role, often as an educator.

Planned-Change Process

The planned-change process involves a systematic sequence of activities that follows the nursing process. Following its eight basic steps leads to the successful management of change: (1) recognize symptoms, (2) diagnose need, (3) analyze alternative solutions, (4) select a change, (5) plan the change, (6) implement the change, (7) evaluate the change, and (8) stabilize the change (Spradley, 1980). Figure 11–2 shows how forces acting on a system create a need for change using the planned-change model.

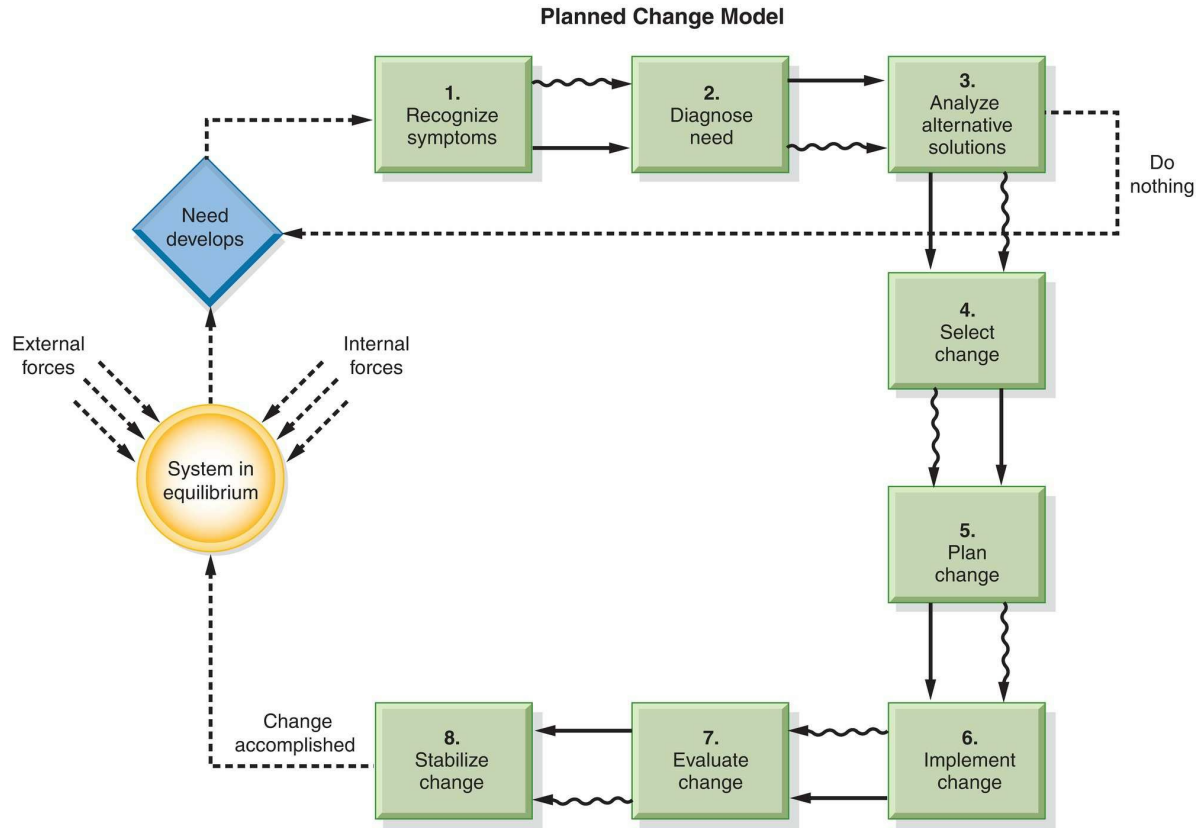

Figure 11–2 Planned-change model. The planned-change process begins when one recognizes a need. When the change agent fails to respond to a need for change, the need continues and may escalate. Client system (those involved and affected by the change) and change agent must work together throughout the entire planned-change process. Their respective roles vary depending on the situation and the players' abilities, but no planned change is truly effective without utilization of this collaborative relationship. The client system (*wavy arrow*), which may be an entire community, will fluctuate in its involvement with the change process. The change agent (*straight arrow*), as a good leader, analyzes the situation thoroughly, plans carefully, and sets a steady course for effecting the change.

Step 1: Recognize (Assess) Symptoms

The first step in managing change is to recognize and assess the symptoms that indicate a need for change (DiClemente, Salazar, & Crosby, 2013). This step requires gathering and examining the presenting evidence, not diagnosing or jumping ahead to treatment. For instance, assume that a group of clients shows interest in receiving help with parenting skills. The nurse cannot assume that these clients feel inadequate in the parent role, nor can the nurse assume that they lack information about parenting or are having difficulty with their children. The nurse must assess the specific needs to discover that some of the parents have trouble talking to their teenagers, others wonder whether their children's behavior is normal, a few question how strictly they should set limits, and still others are not certain about how to handle discipline. These symptoms are pieces of evidence that will assist

diagnosis in the next step. This first step is an assessment phase. Before moving on, however, change agents need to ask themselves what their motives are for pursuing this change. Inappropriate motives on the change agent's part, such as wanting to feel needed, can cloud judgment and interfere with effective management of change.

Step 2: Diagnose Need

Diagnosis involves analyzing the symptoms and reaching a conclusion about what needs changing. First, describe the situation as it is now (the real) and compare it with the way it should be (the ideal). For example, loud arguing and conflict may be normal and functional behavior for an adolescent support group. There is no discrepancy between the real and the ideal and, therefore, no need for change within the group. If, however, a discrepancy exists between the real and the ideal, then a need exists and a change effort is justified (Hersey, Blanchard, & Johnson, 2012). For example, the community health nurse, in talking with a group of parents, hears the following comment: "I'm not sure how much freedom to allow Ashley. She came in late twice last week and I'm not sure how to discipline her." Clearly, the nurse notices a discrepancy between this family's present and ideal situations; so, a need exists.

The next step is to determine the nature and cause of the need (Hersey et al., 2012). Gathering data by questioning clients, checking the literature, or seeking consultation is important for making a more accurate diagnosis. The parents should be questioned in more detail about the difficulties that they are having with their children. The nurse asks questions such as the following: What are your concerns? How do you feel about being parents? What are the most difficult aspects of parenting for you? Have you read any books or used any other resources to help with parenting activities? To whom do you talk about parenting problems? When you have a problem with your children, how do you usually solve it? Secondary data should be obtained by checking the literature to determine the most effective approaches to solving parenting problems or by consulting an expert on family life to get ideas about what this group of parents might need. The parents also should be asked directly what information they desire or need. Conclusions should be drawn about the specific changes needed for these parents. Unless the diagnosis is made accurately, the entire change effort may address the wrong problem. Also, the clients help the nurse to diagnose their problem; the first question the nurse should ask the parents is what it is that they want and need.

These findings should be formulated into a single, diagnostic statement that also includes the problem's cause. After data collection, the nurse discovers that the parents are insecure in their parenting roles, partially because of lack of knowledge about how to carry out parental responsibilities, but primarily because they lack a support system. Most of them live some distance from relatives or no longer maintain close ties with them. The diagnosis for these parents is insecurity in the parenting role resulting from a lack of support and knowledge.

Step 3: Analyze Alternative Solutions

Once the diagnosis and its cause are determined, it is time to identify solutions or alternative directions to follow. Brainstorming is helpful here, and the client system should be involved as much as possible in the process. Reviewing the literature is helpful at this point to suggest solutions tried by others. Make a list of all reasonable, broad alternatives and then analyze them thoroughly to determine the advantages, disadvantages, possible consequences, and risks involved in each (Hersey, Blanchard, & Johnson, 2012). For the parents, general alternatives might be considered, such as family counseling, a support group, or parenting education. Each of these alternatives includes some advantages and disadvantages toward meeting the parents' need for confidence in their roles.

Next, each alternative should be analyzed. For example, the counseling solution could provide insight and awareness into family behavior. It would give family members opportunities to express feelings and gain understanding of how other family members feel. However, it would not provide a frame of reference that the clients could use to compare their own parenting behaviors with other acceptable ones, nor would it provide adult peer support for the parents. The consequences of this alternative most likely would be to promote parents' self-understanding and better family communication. Risks would include the possibility that children, especially teenagers, might not be willing to participate and that parents might not gain self-confidence in their roles. Each alternative should be examined to determine its usefulness and feasibility; again, literature and other resources (e.g., consultants) can be used to determine the best ways to meet the parents' need for change.

Step 4: Select a Change

After all alternatives have been carefully analyzed, the best solution must be selected. The parents favor the idea that the best solution is a parenting support group. The risks involved in the choice of change should be reexamined, such as whether this action might be too costly in terms of time, money, or potential for failure. Ways to reduce these risks might be explored.

To know what the change is aiming to accomplish, a clearly stated goal should be formulated. For this parenting group, the mutually agreed-on goal is to provide a supportive, reinforcing climate while increasing members' parenting skills. "Useful goals should be (1) specific; (2) attainable (doable); and (3) forgiving [less than perfect]" (National Heart Lung and Blood Institute, 2012). For example, setting a goal of walking 30 minutes a day, 5 days a week is more likely to be successful than a goal of walking 5 miles every day because the first goal is specific, doable, and forgiving.

Step 5: Plan the Change

This step is at the heart of planned change, because at this stage, the change agent and client system together prepare the design, or blueprint, that guides the change action. In steps 1 through 4, data are gathered, a diagnosis is made, resources are assessed, and a goal is established— all preparatory actions for planning the change. The plan tells the change agent and the clients how to meet that goal. Preferably, they develop the plan together.

The nurse talks with the parents about ways to meet their goal, considering such possibilities as weekly discussion groups on selected topics, monthly meetings with an informed speaker, or reading books and articles on parenting and holding regular sessions to discuss their application. After analysis and discussion, the group decides to meet one evening a month, rotating the location among members' homes. Group sessions will include a variety of approaches: a speaker will be invited every 2 months, a book or article discussion will be held quarterly, and the remaining meetings will be spent on topics of the group's choice. All sessions will provide opportunities for parents to discuss their concerns or problems. The nurse and the group design this plan around a set of objectives.

The most important activity in planning is to have clear, specific objectives. These should be measurable and, preferably, stated as outcomes. For example, the following objective is measurable and describes an outcome: "By the end of the second session, each parent in the group will have participated in the discussion at least once." It is helpful to prepare a list of activities to help accomplish each objective and to develop a time plan. It also is important to assess the potential costs in terms of time, money, materials, and the number of people needed, as well as determine the resources available. Then the evaluation plan is designed, and a list of ways to maintain (refreeze) the change is made.

During planning, it is useful to perform a force field analysis (Hersey et al., 2012), a technique developed by Kurt Lewin for examining all positive (driving) and negative (restraining) forces that are influencing a change situation. *Force field theory* describes driving forces, which favor change, and restraining forces, which decrease or discourage change. Examples of driving forces include clients' desire to be healthier, to be more productive, or to have a safer environment. Examples of restraining forces include apathy, habits, anxiety or fear of something new, perceived loss of power, low self-esteem, insecurity, and hostility (Roussel et al., 2016). When the strength of the driving forces is equal to the strength of the restraining forces, equilibrium exists. To introduce a change and move the client system to a higher level of health, that balance must be altered. The change agent increases the driving forces, decreases the restraining forces, or both. The change agent uses force field analysis to study both sets of forces and to develop strategies to influence the forces in favor of the change (Fig. 11–3).

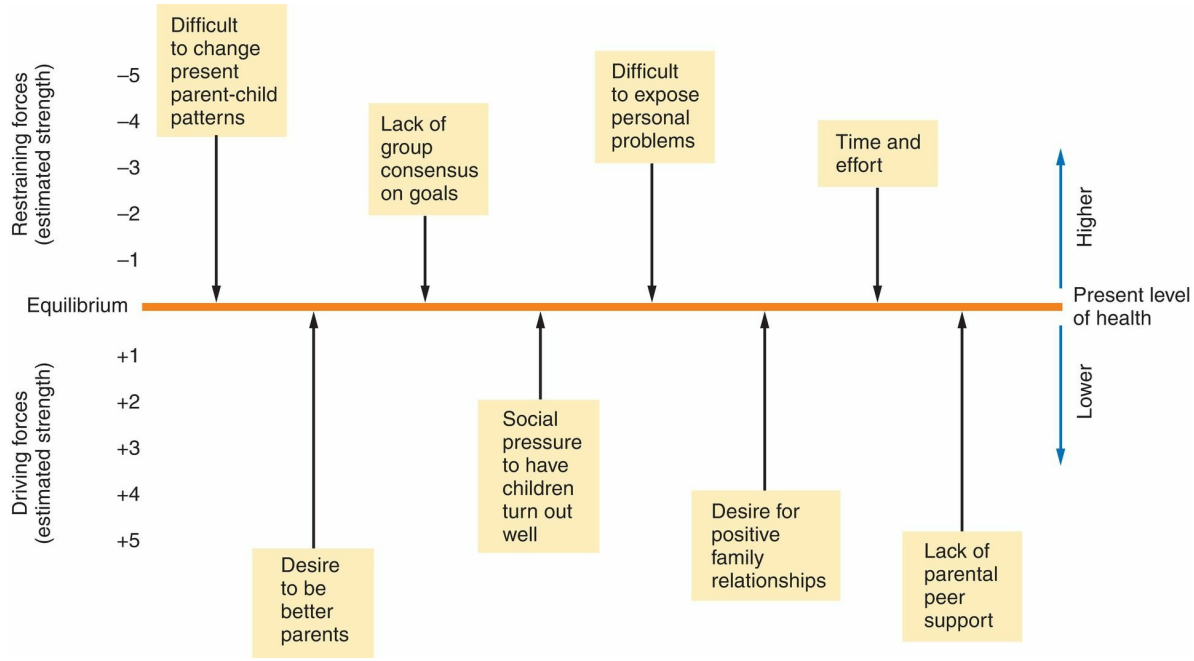

Figure 11–3 Analysis of restraining and driving forces.

The procedure for conducting a force field analysis follows a few simple steps. The change agent may perform the analysis alone but preferably consults with clients and a change-planning resource group such as public health colleagues. Steps for conducting force field analysis include the following (Minnesota Department of Health, n.d.):

- Brainstorm to produce a list of all driving and restraining forces. (For the parenting group, one driving force is the parents' desire to be more successful parents; a restraining force might be lack of group agreement on discussion topics.)
- Estimate the strength of each force.
- Plot the forces on a chart such as the one shown in Figure 11–3.
- Note the most important forces, then research and analyze them.
- List and document possible responses or actions that might strengthen each important driving force or weaken each important restraining force.

Finally, as a consideration in planning the change and in analyzing the driving and restraining forces, the change agent studies the social network and interactions within the system involved in the change. The change agent needs to be aware of formal and informal leaders, cliques within larger groups, influential persons, and all other social network influences on the change process. For instance, one nurse attempting to improve the infant-feeding practices among a group of young Southeast Asian mothers failed to consider the strong cultural influence of the infants' grandmothers living nearby. The older women had strong opinions based on long-held cultural traditions about what infants were to eat and how they were to be fed. To ignore their influence could cause the proposed change to fail; involving the grandmothers could be a way of turning their influence into a driving force for the change.

Step 6: Implement the Change

The implementation step involves enacting the change plan. Because the objectives and activities have been clearly defined in previous steps, the change agent and clients know what needs to be done and how to begin the process (Davies, 2011). For example, the parenting group and their nurse/change agent begin group discussions meeting every Tuesday evening at a local school.

At the start of implementation, be certain that all persons concerned clearly understand and are prepared for the change. When working with an aggregate, for example, the nurse may do most of the planning with a few key members. The nurse must be sure that each member who will be affected by the proposed change understands (a) what to expect, (b) the meaning of the change, and (c) what will be required of them in adapting to it. An unprepared client system, especially in a large group or organization, may lead to failure. No matter how well a change effort is planned, people who are unprepared for it may resist it strongly and render it useless.

When implementing change that will affect a large group of people, such as introduction of a mass screening or immunization program, it is helpful to do a *pilot study*. The pilot study is done to test the change on a small scale, iron out problems, and revise the change before implementing it in the larger system. One advantage of a pilot study is that it demonstrates the change to the client system on a small scale, which is less threatening, so that clients are more receptive. It gives people time to adjust their thinking and to discover that the change will not disrupt their lives too much or require drastic adaptations. It is also useful in working out the kinks and making necessary improvements before moving to the larger scale program.

Step 7: Evaluate the Change

The success of step 7 depends on how well the change is planned. Well-written objectives with specific criteria for their measurement make the evaluation step simpler. However, evaluation does not end with saying whether the objectives were met. Each objective requires analysis: Was it met? What evidence (documentation) shows that it was met? Was it accomplished using the best means possible, or would another method have been better? The objective for the parenting group stated that each member should enter into the discussion by the end of the second session. Although the nurse leader could easily evaluate this objective, the objective could have been improved by a more specific description of how this participation would occur. A better method to achieve this objective would have been to suggest that more active group members solicit ideas from those who did not have an opportunity to speak. This would facilitate more group participation, rather than having the nurse educator call on less verbal participants to speak. Finally, considering the evaluation, the change agent makes needed modifications in the change before stabilization.

Step 8: Stabilize the Change

The final step in the planned-change process requires taking measures to reinforce and maintain the change. A well-developed change plan includes a design for stabilization. The change agent actively encourages continued use of the innovation by establishing two-way communication. In this way, future resistance can be overcome, and the client's full commitment to the change can be maintained (Davies, 2011). Stabilization occurs by soliciting reactions from the client system. Do the clients perceive any potential problems? Do they have doubts? Reinforcing the desired behavior and following up on the change as long as necessary will help to ensure its continuation.

Alcoholics Anonymous, for example, stabilizes the change to nondrinking by providing a regular support group that reinforces the nondrinking pattern. The group rewards compliance with praise and replaces drinking with other satisfying experiences, such as social support and acceptance, to keep the alcoholic from returning to the old behavior. In the example of the parenting group, the nurse stabilizes changed behaviors by focusing on the group's increased confidence in their parenting roles and emphasizing the increased success in coping with their children, as group members share their experiences and stories. The group decides to reward successes by giving a "Parent of the Month" award to the member who demonstrates the most growth in parenting skills, and they agree to nominate one member as "Parent of the Year" in the community newspaper contest. After stabilization occurs and the system achieves a new equilibrium, the change agent–client system relationship may no longer be needed.

Applying Planned Change to Larger Aggregates

We have viewed the planned-change process primarily in the context of introducing change to smaller aggregates. Community health nurses also use these eight steps when managing change at organization, population group, community, and larger aggregate levels. For example, a nurse may suspect that there is a widespread lack of confidence among young parents. This hypothesis could be tested through a social media survey to determine parenting needs among the entire community's population of young parents. If symptoms are present (step 1), the nurse, in collaboration with health department personnel or other appropriate professionals, could analyze the symptoms and reach a diagnosis (step 2) that many young parents in the community are lacking in confidence and knowledge of parenting skills. Several approaches to meeting this need could be considered, such as instituting a parenting center in the community with satellite clinics, organizing churches or clubs to sponsor parenting support groups, or working through the community college system to hold workshops and classes on parenting skills (step 3). The most feasible and useful alternative could be selected (step 4), and a parenting program for the community could be planned (step 5) and implemented (step 6). The nurse, with parents and other professionals involved, would then evaluate the outcomes (step 7) and make necessary adjustments in the parenting program before finally stabilizing it (step 8), making certain

that this change, undertaken to meet a population group need, remains an established and effectively functioning service (Fig. 11–4).

Figure 11–4 An aggregate, mothers with infants, at a new mothers' class.

Change and Health Promotion Within Communities/Populations

Changes in behavior and health promotion can also be directed to even larger audiences—communities and larger populations. Similar approaches can be used, but may be varied depending upon age, most pertinent issues, and how to best reach targeted audiences. For instance, in an effort to address cardiovascular health by encouraging prevention and health promotion, researchers stratified their approaches based upon what they determined were the most beneficial age ranges. They began with 3- to 5-year-olds, and a family-centered educational strategy about hearts and how to keep them healthy by reducing obesity and other risk factors. Then, between 25 and 50 years of age, the focus changes to education about screening and early detection of potential problems. Over age 50, the approach is directed more toward education about discovering cardiovascular disease and early treatment. In 2015, Mount Sinai Hospital in New York began an educational program for preschoolers and their parents that had been piloted in Spain and Colombia (Science Daily, 2015). This shift to prevention of cardiovascular disease is expected to eventually lead to shorter hospital stays and increased ambulatory care options. A classic systematic review by Jepson, Harris, Platt, and Tannahill (2010) on the effectiveness of interventions used in

population health promotion found that workplace or school-based programs, along with mass media efforts, were effective in changing health behaviors.

One model for communicating with populations is CDCynergy Lite, developed by the Centers for Disease Control and Prevention (CDC, n.d.). It involves six phases in developing a social marketing campaign:

1. Problem definition and description (e.g., health problem of concern, who this affects, how you can address it)
2. Problem analysis/market research (e.g., analyze data on problem, target audience's values, behaviors, beliefs, attitudes, and barriers/facilitators to changing behavior)
3. Planning communication/market strategy (e.g., determine target audience, what behaviors that you wish to address, benefits offered [such as better health] with interventions to support change)
4. Program planning/interventions (e.g., methods you will use to influence change [for instance, a Web site to promote better nutrition/physical activity for adolescents], plan, objectives)
5. Program evaluation (e.g., is your program useful, feasible, accurate, ethical)
6. Implementation (e.g., plan for launching program, publicity, threats/opportunities)

This method has been used with many health problems and issues (e.g., arthritis, breast-feeding, drug abuse prevention, smoking cessation, HIV/AIDS, colorectal cancer screening, chronic fatigue syndrome, immunizations, influenza) and is a helpful means of reaching targeted populations (CDC, 2014). See Chapters 10, 12, and 15 for more on health promotion, communication, and use of technology in assessing communities and developing programs for health promotion.

Planned-Change Strategies

Here we focus on the three major change strategies: (1) empiric–rational, (2) normative–reeducative, and (3) power–coercive. In a given situation, the change agent may use one or a combination of these strategies to effect a change (Burke, 2013).

Empiric–Rational Change Strategies

Empiric–rational change strategies are used to effect change based on the assumption that people are rational and, when presented with empiric information, will adopt new practices that appear to be in their best interest (DiClemente et al., 2013). To use this approach, which is common in community health, new information is offered to people. For instance, most family planning programs use empiric–rational strategies. Clients are given basic information (communication-related strategy) on reproductive anatomy and physiology, and they are told about the benefits of contraception with an explanation of a variety of family planning methods. Health workers hope that once clients have this information,

they will adopt some method of family planning. Some clients respond well to this approach, and others do not. The difference lies in client ability and interest in self-help. The nurse/change agent uses empiric–rational strategies with clients who can assume a relatively high degree of responsibility for their own health.

Normative–Reeducative Change Strategies

Normative–reeducative change strategies are used to influence change that not only presents new information but also directly influences people's attitudes and behaviors through persuasion. It is a sociocultural reeducation. This approach assumes that people's attitudes and practices are determined by sociocultural norms and that they need more than presentation of information to change behavior (DiClemente et al., 2013). This approach strengthens client self-understanding, self-control, and commitment to new patterns through direct urging and influence. For example, a health education program that aims to increase safety practices in an industrial setting not only provides safety information, such as posters and warning signs, but also uses persuasive tactics, such as individual rewards for safe practices, division recognition for minimum number of accidents, or discipline for noncompliance. Nurses use normative–reeducative strategies with clients who have a measure of self-care skill but at the same time need external assistance to effect lasting behavioral change. This type of client is often found in teaching, counseling, and therapy situations.

Power–Coercive Change Strategies

Power–coercive change strategies use coercion based on fear to effect change (DiClemente et al., 2013). Change agents may derive power from the law (health regulations, administrative policies), from position (political, social, or managerial), from a group (social, work, or professional), or from personal power (personal charisma, competence, respect of followers). They use this power to coerce change; the result is forced compliance on the part of the client system. Some situations, particularly those that are life threatening, may require power–coercive strategies. In public health practice, power–coercive strategies may be used with people who cannot help themselves or in situations that threaten individuals' safety or the public's health. An example is the stringent enforcement of infection control policies regarding the treatment of contaminated objects such as used needles and the safe disposal of infectious wastes. In another example, if officials find a restaurant to be in violation of health codes, they will either force compliance with the code or close the restaurant. Occasionally, clients cannot exercise responsibility because of temporary or permanent physical or psychological incapacitation; examples may include mentally ill individuals, abusive parents, or developmentally disabled persons. In such cases, the nurse may need to use the power of the law to effect changes that are in clients' best interests. Although power–coercive strategies are appropriate in some situations, they should be used with caution because they can rob people of opportunities to grow in

autonomy and capacity for self-care.

Planned-change strategies may be combined; for instance, a normative–reeducative approach might have a power–coercive backup. This combination is evident in programs that educate and persuade groups of people to be immunized against an impending epidemic or to keep their garbage contained to avoid insect and rodent infestation. Behind this normative–reeducative strategy is an implied coercive threat of official disapproval, or worse, if the clients are noncompliant.

The effectiveness of a change strategy varies with each situation and particularly with the degree of client capacity for self-care. The community health nurse as a change agent must adapt strategies to fit each change situation. It is important to remember that not only strategy, culture, and systems change but also the person's perception of the proposed change and how it affects his or her feelings and behaviors toward the change are important.

Principles for Effecting Positive Change

Community health nurses introduce change every day that they practice. Every effort to solve a problem, prevent another problem from occurring, meet a potential community need, or promote people's optimal health requires changes. For these changes to be truly successful, so that desired outcomes are reached, they must be well thought out and managed. The following six principles provide guidelines for effecting positive change: (1) principle of participation, (2) principle of resistance to change, (3) principle of proper timing, (4) principle of interdependence, (5) principle of flexibility, and (6) principle of self-understanding.

Principle of Participation

Persons affected by a proposed change should participate as much as possible in every step of the planned-change process. This involvement is important for several reasons. Collaboration with those who have a vested interest in the change can produce a wealth of ideas and insights that can greatly improve the change plan. Furthermore, such participation can help remove obstacles and reduce resistance. One nurse, for instance, when planning with a school's parent–teacher association for a drug education program, involved students as well as teachers and parents. As a result, the nurse secured this group's support and cooperation, gained many helpful suggestions that had not been previously considered, and discovered that students were more responsive to the program because the change plan was specifically tailored to their needs. Participation ensures a greater likelihood that the change will be accepted and maintained. Participation is the mainstay of community-based participatory research (CBPR), a method of ensuring that community needs are being met and encouraging buy in (see Chapter 4). In cross-cultural or international arenas, community participation is paramount to effective change. For example, a project targeting improved hygiene practices in India involved various

community outreach initiatives and partnerships aimed to reduce overall childhood mortality (World Health Organization, 2014). A national examination of CBPR studies involving cancer noted that when interventions were adapted to the local area with integration of cultural wisdom and local investigators were used, mistrust was diminished and cancer disparities were reduced (Simonds, Wallerstein, Duran, & Villegas, 2013).

Principle of Resistance to Change

Because all systems instinctively preserve the status quo, the change agent can expect people to resist change. The homeostatic mechanism operating in any system seeks to maintain equilibrium; change poses a threat to that stability and security. Furthermore, all systems experience inertia, that is, they resist beginning movement. People do not undertake a change until they are convinced of its worth. Resistance may also come from a conflict over goals and methods or from misunderstanding about what the change will mean and require. Involving people in the planned-change process, as discussed in the previous section, is one way to overcome resistance. Another way is establishing and maintaining open lines of communication to make ideas clearly understood and to resolve disagreements quickly. The nurse must prepare clients thoroughly for the change, provide support and patience during the change process, and encourage response and expression of feelings. The world of business can offer great suggestions for PHNs facing resistance from clients and communities. Goulston (2013), a business psychiatrist, offers these words of wisdom, shut up and listen when faced with resistance, and realize that "you never win on the strength of your argument, you win on the strength of your relationship" (para. 20). Building rapport and listening to client/community concerns will engender consensus more quickly than repeated lectures on the why something is needed.

Principle of Proper Timing

Sometimes, a change, even a well-designed and much-needed one, should be postponed because it is not the right time to introduce it. For example, perhaps the client system is experiencing too many other changes to handle the stress of this one. Other projects or activities in which the client system is currently engaged may compete for energy and other resources, depleting the energy and resources needed to make the proposed change successful. For example, in November, some middle-aged women, eager to start a book club that focused on preparing for midlife changes (including menopause, "empty-nest" syndrome, and planning for retirement), had to postpone the project because the holidays were approaching. Shopping, entertaining, and vacations made it impossible to give the kind of time and energy needed to make the book club effective. In hospitals, for instance, major changes to nursing procedures or processes are not usually initiated during flu season when hospitals are overcrowded.

Proper timing is as important to a planned change as well-timed seed planting is to a

good harvest. The change idea must be appropriate, the change recipient prepared, the climate right, and the resources available before the change can be fostered to grow into full maturity and usefulness.

Principle of Interdependence

Every system has many subsystems that are intricately related to and interdependent on one another. A change in one part of a system affects its other parts, and a change in one system may affect other systems (Trickett et al., 2011). For example, a county public health nursing agency made a change in its use of home health aides. Because many homebound clients needed more care than the agency staff could provide, the agency contracted with a private home care service for extra home health aides. These paraprofessionals worked in the homes of agency clients, supplementing the care given by agency staff. The private company preferred to supervise its own aides, whereas the county agency had a policy of using community health nurses to supervise aides. The county agency was legally responsible and professionally accountable for the quality of care given to clients. The private company wanted to retain control of its workers. The matter was resolved by contracting with a different private service that would accept the county agency's supervision. The change, however, had affected the roles of nurses and aides within the system, as well as the relationships between the two systems.

This principle of interdependence reminds the nurse that change does not take place in a vacuum. When workers learn new health and safety practices associated with their jobs, their relationships with one another, and their bosses, their overall productivity in the organization may easily be affected. One must anticipate and prepare for the impact of the proposed change on the clients involved, other persons, departments, organizations, or even geographic areas. Also, community interventions should be "ecologically based, multilevel, collaborative approaches to health" and should reflect the complexities of each unique community (Trickett et al., 2011, p. 1410) (Fig. 11–5).

Figure 11–5 PHN leading a group.

Principle of Flexibility

Unexpected events can occur in every situation. This fifth principle—flexibility—emphasizes two points. First, the nurse needs to be able to adapt to unexpected events and make the most of them. Perseverance and flexibility are the marks of a creative change manager (Roussel et al., 2016). One community health nurse had tried unsuccessfully to contact a young mother who was reportedly abusing her 2-year-old son. After several phone calls and visits to an empty house, the nurse finally found the mother and son at home with a neighbor who insisted on staying for the entire visit. At first, the nurse was irritated by the neighbor's presence and viewed it as interfering with the goal of getting to know the mother and child. When the nurse realized that the neighbor's presence offered an opportunity to learn more about the situation through the neighbor's input, the nurse viewed it as an opportunity to influence another client as well. She asked whether the neighbor had children and began to include both women in the discussion, explaining what could be offered in terms of health teaching and support. This nurse was flexible in her approach to this situation.

The second point to remember about flexibility is that a good change planner anticipates possible blocks or problems by preparing strategies and alternative plans. During step 3 of the planned-change process, it is helpful to rank the alternative solutions considered. Then, if the first choice does not work out for some reason, an alternative is ready to be put into action. Flexibility involves a willingness to consider a variety of options

and suggestions from many sources, and it is the hallmark of public health professionals, along with curiosity and communication skills (Morris, 2014).

Principle of Self-Understanding

Self-understanding is essential for an effective change agent (Hersey et al., 2012). The community nurse (as change agent) should be able to clearly define his or her role and seek to understand how others define it. It is important to understand your own values and motives in relation to each change that you are asking people to make. Nurses should also understand their own personality traits, so that they can capitalize on or adjust them in order to be more effective change agents. Understanding yourself is crucial to learning to make use of your best qualities and skills in order to effect change (Jerome & Powell, 2016). Change is inevitable. Understanding the principles of planned change can assist the community health nurse in guiding individuals, families, and communities toward achieving the highest level of health.

SOCIAL DETERMINANTS OF HEALTH

Social justice has long been a tenant of our society, dating back to the industrial revolution (Hendrickson, 2015). Social justice, as it relates to health, is an increasing concern primarily because of the growing inequity in the distribution of disease, illness, and wellness across our society. Social determinants of health are "conditions in the environments in which people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks" (USDHHS, 2016c, para. 6). *Healthy People 2020* initiative addresses social determinants of health as a new topic, with the goal of "creating social and physical environments that promote good health for all" (USDHHS, 2016c, para. 1) (Fig. 11–6).

Figure 11–6 Social determinants of health, or the environments in which we live and work, affect our health and our quality of life.

Understanding social determinants of health requires examination of numerous factors, beyond individual behavior, that contribute to our state of health. Factors that influence an individual's ability to maintain good health include social, economic, and physical factors such as access to social and economic opportunities; safe housing; quality education; clean water, food, and air; safe workplaces; equitable social interactions (class, race, and gender); and adequate community resources (USDHHS, 2016c, n.d.). Addressing these factors in a manner that has a positive impact on social, economic, and physical conditions and

supports positive health behavior change can improve the health of our communities over time.

"Nursing has a clear mandate to ensure access to health and health-care by providing sensitive empowering care to those experiencing inequities and working to change underlying social conditions that result in and perpetuate health inequities" (Reutter & Kushner, 2012, p. 269). The public health nurse can play a significant role in addressing social determinants of health by first being aware and educated about factors that influence health beyond an individual's choices, looking at root causes of disease.

Secondly, the PHN can incorporate social determinant factors when assessing individuals, families, and communities. One resource for this is the Health Impact Project. This project seeks to advance policies for healthier communities by examining social, economic, and environmental influences, building consensus across community members and other stakeholders, and advocating for health considerations in all policies (Pew Charitable Trusts, 2015).

Finally, community health nurses can educate their client base on the social determinants of health, facilitate community action that supports positive change, and advocate for policies that address the root causes of disease and health inequities (USDHHS, 2016c, 2010e).

The Robert Wood Johnson Foundation conducted research to determine the most effective messages on social determinants of health that are meaningful and understandable to Americans (Robert Wood Johnson Foundation, 2015). The community health nurse educator can use these messages to communicate concepts about social determinants of health to clients and communities (see Display 11–1). See Chapters 15, 19, and 25 for additional information.

DISPLAY 11–1 SIX WAYS TO TALK ABOUT SOCIAL DETERMINANTS OF HEALTH

1. Health starts—long before illness—in our homes, schools, and jobs.
2. All Americans should have the opportunity to make the choices that allow them to live a long, healthy life, regardless of their income, education, or ethnic background.
3. Your neighborhood or job shouldn't be hazardous to your health.
4. Your opportunity for health starts long before you need medical care.

5. Health begins where we live, learn, work, and play.
6. The opportunity for health begins in our families, neighborhoods, schools, and jobs (p. 53).

Facilitating community action is most effective when using participatory action research approaches (Bergold & Thomas, 2012). One such approach is known as the Community Action Model (Fig. 11–7) that seeks to identify actions that are achievable, sustainable, and compels change for the well-being of all. This model builds on concepts presented in the planned-change process earlier in this chapter. The cyclical five-step process is outlined more fully in Display 11–2. The community health nurse educator can use this model to facilitate community participation and ownership of change that has a positive impact on the community's health. An example of a successful application of the Community Action Model is Pennsylvania's School Nutrition Policy Initiative, targeted to combat obesity in 4th to 6th graders. About 48 hours yearly of interactive nutrition lessons are presented in classrooms, and families and local community partners also participate. Incentives are provided to students who choose healthier snacks, and program evaluation found that there was a reduction in overweight incidence by 50%. Overall prevalence rate was decreased for those in the program (10.3%) versus those not participating (25.9%). Other examples incorporate farm-fresh foods into school lunches and snacks or aim to reduce consumption of soda (Healthy Sonoma, 2015).

Community action training. Retrieved from http://www.sfdph.org/dph/files/CAMdocs/intro_and_overview/CAMCreatingChangebyBu Brennan Ramirez, L. K., Baker, E. A., & Metzler, M. (2008). Promoting health equity: A resource to help communities address social determinants of health. Atlanta, GA: Centers for Disease Control and Prevention.)

DISPLAY 11–2 FIVE-STEP COMMUNITY ACTION MODEL

Step 1. Skills-based trainings where advocates choose an area of focus

Step 2. Action research where advocates define, design, and do a community diagnosis (action research)

Step 3. Analysis where advocates analyze the result of the diagnosis and prepare findings

Step 4. Organizing where advocates select, plan, and implement an action for change and education to support it

Step 5. Implementing where advocates ensure that the policy outcome is enforced and maintained (p. 360)

From Hofrichter, R., & Bhatia, R. (2010). Tackling health inequities through public health practice, theory to action (2nd ed.). New York, NY: Oxford University Press.

Policy advocacy is most successful when approached through intersystem collaboration involving key stakeholders as well as beneficiaries of the policies (Reutter & Kushner, 2012). This requires that the community health educator think beyond health and engage with sectors to tackle inequities through policy analysis and advocacy. Advocating for "Health in All Policies" (HiAP) is one approach to addressing multisector policy change as it relates to social determinants of health (World Health Organization, Government of South Australia, 2010). Because many factors outside of health impact health outcomes, it is vital that all policies, regardless of the sector, be viewed from a health lens. Examples of sectors that often have a direct impact on health include agriculture, education, energy, environment, global warming, housing, trade, and transportation, among others (Aspen Institute, 2012). See Chapter 13 for more on policy and advocacy in public health nursing.

CHANGE THROUGH HEALTH EDUCATION

Early in this chapter, you were introduced to one definition of health promotion, with a clear focus on individual and aggregate behavior (Pender et al., 2015). Consider another viewpoint: "the health of populations varies with the interaction of behavior, environment, human biology, social conditions, and community organization" (Green, Ottoson, & Roditis, 2014, p. 478). This definition points out the need for a system-wide approach to promoting healthy behaviors, one that includes education. For the community health nurse, health education is a foundation of practice. Whether the nurse is providing one-on-one education to a new mother about the benefits of breast-feeding, briefing county officials on the need to maintain breast-feeding support centers, or working with community partners and grant funders to develop a Web-based social marketing campaign to promote breast-feeding among adolescent mothers, educational techniques are being used to promote health in the community. Knowledge of educational theories and teaching methods can assist the nurse to frame these "health messages" for the greatest impact and chance of success.

Teaching is a specialized communication process in which desired behavior changes are achieved. The goal of all teaching is learning. Learning is gaining knowledge, comprehension, or mastery. These can seem like vague terms, and a more concrete definition suggests that *learning* is a process of assimilating new information that promotes a permanent change in behavior. All people have been presented with information that was not interesting, relevant to their needs, or even understandable. In such situations, learning is difficult, if not impossible. The PHN as teacher seeks to convey information in such a way that the client demonstrates a relatively permanent change in behavior. After learning, clients are capable of doing something that they could not do before learning took place. Effective teaching is a cause; learning becomes the effect. To teach effectively, especially in the community where teaching is the focus of care, nurses need to understand the various domains of learning and related learning theories.

DOMAINS OF LEARNING

Learning occurs in several realms or domains: cognitive, affective, and psychomotor. Understanding of the differences among the domains and of the related roles of the nurse provides the background necessary to teach effectively.

Cognitive Domain

The cognitive domain of learning involves the mind and thinking processes. When the meaning and relationship of a series of facts is grasped, cognitive learning has occurred. The cognitive domain deals with the recall or recognition of knowledge and the development of intellectual abilities and skills (Bloom, 1956). There are six major levels in the cognitive domain (Miller, Linn, & Gronlund, 2012): knowledge, comprehension, application, analysis, synthesis, and evaluation. To *operationalize* these levels (i.e., put these ideas or concepts into words that can be used), action verbs are used. As the goal of the learning or behavioral objective changes, so do the verbs, indicating the learning to be accomplished within that particular level of the cognitive domain. Notice that the objectives at the beginning of each chapter in this text follow this format, using a variety of verbs to indicate the expected level of learning. A representative sample of behavioral objectives focusing on nutrition and appropriate cognitive-level verbs is included in the discussion of each level.

Knowledge

Knowledge, the lowest level of learning, according to Bloom's taxonomy, involves recall (Miller et al., 2012). If students remember material previously learned, they have acquired knowledge. This level may be used with clients who are unable to understand underlying reasons or rationales, such as young children or people who have had strokes. Stroke clients may need to remember that medication should be taken daily, that regular exercise restores function, and that drinking alcohol should be avoided, although they may not grasp the reasons behind these measures. Five-year-olds may need to identify healthful foods, but may not understand why they are nutritious.

A knowledge-level behavioral objective might be "The client can *recall* the names of six fruits to eat as nutritious snacks." Other knowledge-level verbs include *repeat*, *define, list*, and *name*.

Comprehension

The second level of cognitive learning, comprehension, combines remembering with understanding (Miller et al., 2012). Teaching aims at instilling at least a minimal understanding. Nurses want clients to grasp the meaning and to recognize the importance of suggested health behaviors.

An example of a comprehension-level behavioral objective might be, "The pregnant client will *describe* a well-balanced diet during pregnancy." Other appropriate verbs at the comprehension level include *discuss*, *explain*, *identify*, *summarize*, and *report*.

Application

Application is the third level of cognitive learning, in which the learner cannot only understand material but also apply it to new situations (Miller et al., 2012). Application

approaches the possibility of self-care when clients use their knowledge to improve their own health. The test of application is a transfer of understanding into practice. Therefore, to encourage application, the nurse can design teaching plans that provide clients with knowledge that they can put into practice. In the home setting, a PHN may suggest that a diabetic client write down glucometer readings to show the nurse at the next visit. A school nurse could ask adolescents in a weight loss group to keep a food and exercise record for a week, draw up a diet plan, and share this plan with the group at the next meeting. In contrast, the construction worker who understands on-the-job hazards, but seldom wears a protective hat in the work area, has yet to transfer knowledge and comprehension into practice or application.

An example of an application-level behavioral objective might be "The client will *practice* eating well-balanced meals at least two times a day." Other verbs at this level include *apply*, *use*, *demonstrate, discover, prepare*, and *illustrate*.

Analysis

The fourth level of cognitive learning is analysis; at this level, the learner breaks down material into parts, distinguishes between elements, and understands the relationships among the parts. This level of learning becomes a preliminary step toward problem solving. The learner carefully examines all of the variables or elements and their relationships to each other in order to explain the situation (Miller et al., 2012). A family that studies its own communication patterns to identify sources of conflict is using analysis. A mother analyzes when she seeks to determine the cause of an infant's crying. After viewing the total situation, she breaks it down into variables such as hunger, pain, overstimulation, loneliness, type of crying, and intensity of crying. She examines these parts and draws conclusions about their relationships. In health teaching, community health nurses foster clients' analytic skills by (a) demonstrating how to isolate the parts in a situation and (b) encouraging the clients to consider the relationships among the parts and to draw conclusions from their thinking. It is also important to help clients distinguish between facts and what may be inferred.

Figure 11–8 A community health nurse demonstrates CPR to clients before having them return the demonstration to show that they can put this learning into practice.

An analysis-level behavioral objective for senior citizens trying to learn more about low-fat foods might be "The seniors should be able to *distinguish* the fat content in a variety of packaged foods." Other verbs at the analysis level include *differentiate, discriminate, select*, *contrast*, *debate*, *question*, and *examine*.

Synthesis

Synthesis, the fifth level of cognitive learning, is the ability not only to break down and understand the elements of a situation but also to form elements into a new whole. Synthesis combines all of the earlier levels of cognitive learning to culminate in the production of a unique plan or solution. Clients who achieve learning at this level not only analyze their problems but also find solutions for them (Miller et al., 2012). For example, a community health nurse may assist mental health clients in a therapy group to examine their frequent depression and then to generate their own plan for alleviating it. A young couple that wants to toilet train their 2-year-old child may learn the physiologic and psychological dimensions of toilet training, then begin to analyze their own situation, and develop strategies (their own plan) for working with the child. Nurses facilitate synthesis by assisting and encouraging clients to develop their own solutions with specific plans. After a problem is identified, the client should be asked, "What are some possible causes? Do you see anything that has been overlooked about the problem?" If the client asks for a quick

solution, the PHN could encourage synthesis by asking, "What are some possible solutions to this problem that you might carry out?"

An example of a synthesis-level behavioral objective for a client on a sodium-restricted diet might be, "The client will be able to *create* an enjoyable meal using low-sodium foods." Other verbs at this level include *compose, compile*, *design*, *formulate*, *create, plan*, and *organize*.

Evaluation

The highest level of cognitive learning is evaluation; at this level, the learner judges the usefulness of new material compared with a stated purpose or specific criteria (Miller et al., 2012). Clients can learn to judge their own health behavior by comparing it with standards established by others—such as complete abstinence from smoking, maintenance of normal weight, or exercising three times a week. Alternatively, clients may establish their own criteria. For example, a parent support group might design activities to enhance parent–child communication and then judge their performance by using their desired outcomes as evaluation criteria. When nurses aim for this level of client learning, they have made self-care a concrete objective. Evaluation, because it goes beyond attempts at problem solving, enables the client to judge the adequacy of solutions, to critique lifestyle and health-related behaviors, and to anticipate needed improvements.

An example of a behavioral objective at the evaluation level might be, "The clients in a nutrition class will be able to *appraise* the fat content in one serving of the low-fat dish they brought to share." Other verbs at this level include *judge, compare, contrast, rate*, *conclude*, and *summarize*.

How to Measure Cognitive Learning

Cognitive learning at any of the levels described can be measured easily in terms of learner behaviors. Nurses know, for instance, that clients have achieved teaching objectives for the application of knowledge if their behavior demonstrates actual use of the information taught. Client roles in cognitive learning range from relatively passive (at the knowledge level) to a more active role (at the evaluation level). Conversely, as clients become more active, the nurse's role becomes less overtly directive. Not all clients need to be brought through all levels of cognitive learning, and not every client needs to reach the evaluation level for each aspect of care. For some clients and situations, comprehension is an adequate and effective level; for others, the nurse should focus on the application level. Table 11–2 illustrates client and nurse behaviors for each cognitive level.

Table 11–2 Cognitive Learning: Case Study in Controlling Diabetes

Level	Illustrative Client Behavior	Illustrative Nurse Behavior
Knowledge (recalls, knows)	States that insulin, if taken, will control own diabetes	Provides information
Comprehension (understands)	Describes insulin action and purpose	Explains information
Application (uses learning)	Adjusts insulin dosage daily to maintain proper blood sugar level	Suggests how to use learning
Analysis (examines, explains)	Discusses relationships between insulin, diet, activity, and diabetic control	Demonstrates and encourages analysis
Synthesis (integrates with other learning, generates new ideas)	Develops a plan, incorporating above learning, for controlling own diabetes	Promotes client formulation of own plan
Evaluation (judges according to a standard)	Compares degree of diabetic control (outcomes) with desired control (objectives)	Facilitates evaluation

Affective Domain

The affective domain involves learning that occurs through emotion, feeling, or *affect*. This kind of learning deals with changes in interest, attitudes, and values (Bloom, 1956; Miller et al., 2012). Here, nurses face the task of trying to influence what their clients may value and feel. Nurses want clients to develop an ability to accept ideas that promote healthier behaviors, even if those ideas conflict with the clients' own values.

Attitudes and values are learned. They develop gradually, as family, peers, experiences, and culture influence the way an individual feels and responds (see Chapter 4). These feelings and responses are the result of imitation and conditioning. In this way, clients acquire their health-related beliefs and practices. Because attitudes and values become part of the person, they are difficult to change unless the nurse is aware of how they develop.

Affective learning occurs on several levels as learners respond with varying degrees of involvement and commitment. At the first level, learners are simply receptive; they are willing to listen, to show awareness, and to be attentive. The nurse aims at acquiring and focusing learners' attention (Miller et al., 2012). This limited goal may be all that clients can achieve during the early stages of the nurse–client relationship. An example of an affective objective at this level might be "The client closely *attends* to the lesson on child development." Other verbs might include *asks*, *gives*, *points to*, and *uses*.

At the second level, learners become active participants by responding to the information in some way. Examples are a willingness to read educational material, to participate in discussions, to complete assignments (e.g., keeping a diet record), or to voluntarily seek out more information (Miller et al., 2012). An example of an objective at this level is "The client actively *participants* in group discussions about living with diabetes." Some other verbs indicative of affective learning at this level include *answers*, *compiles*, *presents*, *tells*, and *reports*.

At the third level, learners attach value to the information. Valuing ranges from simple acceptance through appreciation to commitment (Miller et al., 2012). For example, a PHN taught members of a support group several principles concerning group effectiveness. An explanation of the importance of a democratic group process and ways to improve group skills was given. Members showed acceptance when they acknowledged the importance of these ideas. They showed appreciation of the ideas by starting to practice them. Commitment came when they assumed responsibility for having their group function smoothly. Some verbs for objectives related to valuing are *follows*, *initiates*, *justifies*, *proposes*, *shares*, and *works*.

The final level of affective learning occurs when learners internalize an idea or value. The value system now controls learner behavior. Consistent practice is a crucial test at this level (Miller et al., 2012). Verbs used at this level include *acts*, *performs*, and *verifies*. Clients who know and respect the value of exercise, but only occasionally play tennis or go for a walk, have not internalized this value. Even several weeks of enthusiastic walking are not

true evidence of an internalized value. If the walking continues for 6 months, 12 months, or longer, learning may have been internalized.

Affective learning often is difficult to measure and is often attempted through self-report surveys or tools (Miller et al., 2012). This elusiveness may influence PHNs to concentrate their efforts on cognitive learning goals instead. Yet, client attitudes and values have a major effect on the outcome of cognitive learning—which is desired behavioral changes. Therefore, both cognitive and affective domains must be linked when teaching clients about health-related topics; otherwise, results may quickly fade (Hales, 2014).

Attitudes and values can change in the same way that they were first learned, that is, through imitation and conditioning. Role models, particularly individuals from the client's peer group who practice the desired health behaviors, can be a strong influence. Effective health education considers group norms and seeks to influence them (Centers for Disease Control and Prevention [CDC], 2015). Support groups, such as mastectomy or chemical dependency support groups, can have a powerful role model effect. Frequently, clients view nurses as a positive role model; for this reason, nurses should try to demonstrate healthy behaviors. The American Nurses Association (ANA), working with Pfizer, conducted a health risk appraisal study and discovered that RNs found their workplaces stressful, citing instances of incivility, bullying, and physical assaults by patients/families (39% worked in acute care/hospital settings). The majority was overweight, and a cited safety risk was talking on the phone or texting while driving. However, few nurses smoked, and most had access to workplace health promotion or wellness programs (ANA, 2015). They continue to collect data and recognize the importance of a healthy nursing workforce, as well as the example (good or bad) that nurses can set for their clients/patients.

Encouragement is key. Attitudes often change when the PHN provides clients with a satisfying experience during the learning process. The community health nurse who recognizes clients' participation in a group, praises them for completing assignments, or commends them for sticking to diet plans will have more success than the nurse who only criticizes failures. Another point to remember is that clients can develop a close relationship with the PHN during the teaching–learning process. When this occurs, you may want to share a few of your own experiences in managing personal health issues. This can help develop trust and rapport with your clients. Table 11–3 delineates client and nurse behaviors for each level of affective learning.

Table 11–3 Affective Learning: Case Study in Family Planning

Level	Illustrative Client Behavior	Illustrative Nurse Behavior
Receptive (listens, pays attention)	Attentive to family planning instruction	Directs client's attention
Responsive (participates, reacts)	Discusses pros and cons of various methods	Encourages client involvement
Valuing (accepts, appreciates, commits)	Selects a method for use	Respects client's right to decide
Internal consistency (organizes values to fit together)	Understands and accepts responsibility for planning for desired number of children	Brings client into contact with role models
Adoption (incorporates new values into lifestyle)	Consistently practices birth control	Positively reinforces healthy behaviors

To influence affective learning requires patience. Values and attitudes seldom change overnight. Remember that other forces continue to reinforce former values. For example, a single young mother may want to pursue an exercise and weight loss plan, but she might not do so because she has several small children and feels that their needs come first. A young man who can verbalize to the nurse the importance of safe sex may be uncomfortable discussing the subject with his partner, thus affecting his compliance with the health teaching plan. Knowledge alone is not usually sufficient to change behaviors. Motivation and attitude are needed.

Psychomotor Domain

The psychomotor domain includes visible, demonstrable performance skills that require some kind of neuromuscular coordination (Miller et al., 2012). Clients in the community need to learn skills such as infant bathing, temperature taking, breast or testicular self-examination, prenatal breathing exercises, range-of-motion exercises, catheter irrigation, walking with crutches, and how to change dressings (Fig. 11–8).

For psychomotor learning to take place, three conditions must be met: (1) learners must be capable of the skill, (2) learners must have a sensory image of how to perform the skill, and (3) learners must practice the skill.

PHNs must be certain that the client is physically, intellectually, and emotionally capable of performing the skill. It may be difficult for an elderly diabetic man with tremulous hands and fading vision to give his own insulin injections; it could frustrate and harm him. He may need some assistance or accommodations. Clients' intellectual and emotional capabilities also influence their capacity to learn motor skills. It may be inappropriate to expect persons with significant developmental delays to learn complex skills. The degree of complexity should match the learners' level of functioning. However, educational level should not be equated with intelligence. Many clients have had limited formal schooling, but are able to learn complex skills for themselves or as caregivers after appropriate instruction. Developmental stage is another point to consider in determining whether it is appropriate to teach a particular skill. For example, most children can put on some article of clothing at 2 years of age, but are not ready to learn to fasten buttons until they are past their third birthday.

Learners also must have a sensory image of how to perform the skill through sight, hearing, touch, and sometimes taste or smell. This sensory image is gained by demonstration. To teach clients motor skills effectively, the PHN has to provide them with an adequate sensory image. It is best to demonstrate and explain slowly, one point at a time, and sometimes repeatedly, until clients understand the proper sequence or combination of actions necessary to carry out the skill.

The third necessary condition for psychomotor learning is practice. After acquiring a sensory image, clients can start to perform the skill. Mastery comes over time as clients repeat the task until it is smooth, coordinated, and unhesitating (Miller et al., 2012). During this process, the PHN should be available to provide guidance and encouragement. In the early stages of practice, you may need to use hands-on guidance to give clients a sense of how the performance should feel. When clients give return demonstrations, you can make suggestions, give encouragement, and thereby maximize the learning. For example, a community health nurse demonstrates passive range-of-motion exercises on a client's wife to show her how the exercises should feel (giving her a sensory image). The wife then learns to perform the exercises on her husband. During practice, feedback from the nurse enables the wife to know whether the skill is being performed correctly. At this

guided response stage, objectives may include action verbs such as *fastens*, *manipulates*, *measures*, *organizes*, and *calibrates*.

The psychomotor domain, like the cognitive and affective domains, ranges from simple to complex levels of functioning. It is necessary to exercise judgment in assessing a client's ability to perform a skill. Even clients with limited ability often can move to higher levels once they have mastered simple skills. Nurse behavior that influences psychomotor learning is shown in Table 11–4.

Table 11–4 Nurse Behaviors in Psychomotor Learning

The Nurse	Provides Sensory Image	Encourages Practice
Determines capability: assesses client's physical, intellectual, and emotional ability	Demonstrates and explains	Uses guidance and positive reinforcement

LEARNING THEORIES

A learning theory is a systematic and integrated look into the nature of the process whereby people relate to their surroundings in such ways as to enhance their ability to use both themselves and their surroundings more effectively. Each nurse has and uses a particular theory of learning, whether consciously or unconsciously, and that theory, in turn, dictates the way the PHN teaches clients. It is useful to discover what each nurse's learning theory is and how it affects the role of health educator.

Some of the learning theories developed by educational psychologists in the 20th century remain influential. They are grouped into four categories: behavioral, cognitive, social, and humanistic. Additionally, the adult learning theory of Malcolm (Knowles, 1980, 1984, 1989, 1990; Knowles, Holton, & Swanson, 2015) has influenced client teaching. A brief examination of these categories and the specific theories follows.

Behavioral Learning Theories

Behavioral theory (also known as stimulus–response or conditioning theory) approaches the study of learning by focusing on behaviors that can be observed, measured, and changed. Developed early in the 20th century, behavioral theory work is associated primarily with three famous names: Ivan Pavlov (1957), Edward Thorndike (1932, 1969), and B. F. Skinner (1974, 1987). To a behaviorist, learning is a behavioral change—a response to certain stimuli. Therefore, the behavioristic teacher seeks to significantly change learners' behaviors through a series of selected stimuli.

The stimulus–response "bond" theory proposes that, with conditioning, certain causes (stimuli) evoke certain effects (responses). The teacher promotes acquisition of the desired stimulus–response connections so that transfer of learning can occur in another situation having the same stimulus–response elements. You undoubtedly learned about Pavlov's work with stimulus–response and involuntary reflex actions in your psychology classes. Pavlov conditioned a dog to anticipate food by ringing a bell at feeding time. Initially, the dog would salivate as the food was brought to the cage. However, after time, the dog would salivate at hearing the bell, before seeing or smelling the food (Pavlov, 1957).

Two other behavioral theories are conditioning with no reinforcement (Thorndike) and conditioning through reinforcement (Skinner). With the no-reinforcement approach, the focus is on the learner's innate reflexive drives to accomplish the desired response after conditioning (e.g., when the PHN repeatedly emphasizes to a group of pregnant women that their prenatal classes promote a positive delivery experience and healthy newborns). In contrast, the reinforcement theorists use successive, systematic changes in the learner's environment to enhance the probability of desired responses. For example, a school nurse might give rewards (e.g., stickers, activity books) to children who attend each class on safety.

Cognitive Learning Theories

Jean Piaget is the most widely known cognitive theorist. His theory of cognitive development contributed to the theories of Kohlberg (moral development) and Fowler (development of faith). Piaget (1966, 1970) believed that cognitive development is an orderly, sequential, and interactive process in which a variety of new experiences must exist before intellectual abilities can develop. His work with children led him to develop five phases of cognitive development, from birth to 15 years of age (Table 11–5).

Table 11–5 Piaget's Five Phases of Cognitive Development

Age	Stage	Behavior
Birth to 2 years	Sensorimotor stage	The child moves focus from self to the environment (rituals are important).
2–4 years	Preconceptual stage	Language development is rapid and everything is related to "me."
4–7 years	Intuitive thought stage	Egocentric thinking diminishes, and words are used to express thoughts.
7–11 years	Concrete operations stage	Child can solve concrete problems and recognize others' viewpoints.
11–15 years	Formal operations stage	Child uses rational thinking and can develop ideas from general principles (deductive reasoning) and apply them to future situations.

Adapted from Young, G. (2011). Development and causality: Neo-Piagetian perspectives. New York, NY: Springer Publishing.

Each stage signifies a transformation from the previous one, and a child must move through each stage sequentially. The three abilities of *assimilation* (reacting to new situations by using skills already possessed), *accommodation* (being sufficiently mature so that previously unsolved problems can now be solved), and *adaptation* (the ability to cope with the demands of the environment) are used to make the transformation. Nurses must understand their audience's learning stage to ascertain how to approach teaching for that developmental stage. The nurse can see how the use of puppets with 3-year-olds may be a beneficial addition to a presentation on safety, whereas a group of young teens with diabetes may respond to group discussion on the benefits and consequences of taking or not taking their insulin.

The Gestalt-field family of cognitive theories assumes that people are neither good nor bad—they simply interact with their environment, and their learning is related to perception (Wertheimer, 1945/1959, 1980). A principal assumption of this approach is that every person hears, interprets, and reacts to a variety of situations in a way that is unique to them (Bates, 2016).

The first Gestalt-field theory, called *insight theory*, regards learning as a process in which the learner develops new insights or changes old ones. Learners intuitively and intelligently sense their way through problems. However, the "insight" is useful only if the learner understands its significance. For example, Amy dropped out of high school after the birth

of her daughter; after attending a career planning class offered by a community health nurse, she realizes that she has limited job skills and that if she learned more about computer skills, she could get a better job. This learner understood the significance of her insight.

The second theory, *goal–insight*, is similar to the insight theory but goes beyond intuitive hunches to tested insights. Teachers subscribing to this theory promote insightful learning but assist learners in developing higher-quality insights. For example, Amy takes a beginning and then an advanced computer class and is offered a higher-paying job. The community health nurse discusses Amy's successes with her and asks Amy whether she ever thought about going to college. The nurse mentions the added benefits of college-level course work. Amy then reflects on this for a while and begins to think about completing the requirements to go to community college, because if she had an associate degree she could be promoted to a supervisory position and make more money.

In the third theory, *cognitive-field theory*, the learner is seen as purposive and problem centered. Teachers seek to help learners gain new insights and restructure their lives accordingly. For example, Amy confers with the community health nurse about her choices and has changed her thinking about herself so much that she is planning to get an apartment in a neighborhood that is better for her child and she may continue taking classes "for the fun of it" after she completes her degree in a few months.

Social Learning Theories

The aim of social learning theory is to explain behavior and facilitate learning (Bates, 2016). Bandura (1977, 1986), an important theorist, pointed out that apparent but not real relationships often are dysfunctional and produce undesirable or inappropriate behavior. He described three ways that dysfunctional beliefs develop:

1. In *coincidental association*, outcomes typically are preceded by numerous events, and the client selects the wrong events as predictors of an outcome. For example, Juanita had a negative experience with a man who wore a hearing aid. Afterward, all of her experiences with men who wore hearing aids were negative. She reached the conclusion that all men who wear hearing aids were undesirable. This client's beliefs became a self-fulfilling prophecy.
2. In *inappropriate generalization*, one negative experience provokes negative feelings for future experiences. For example, Dorothy, a senior citizen, had a purse snatched by a teenager and generalized that all teenagers are bad. Three-year-old Ryan accidentally drank some spoiled milk. He generalized that milk tastes bad and now refuses to drink it.
3. In *perceived self-inefficacy*, "Persons who judge themselves as lacking coping capabilities, whether the self-appraisal is objectively warranted or not, will perceive all kinds of dangers in situations and exaggerate their potential harmfulness" (Bandura, 1986, p. 220). For example, an older client, William, tells the community health nurse about two missing Social Security checks, but he refuses to take a bus to the post office. He states that he does not know what to say to the postal clerk and has read about senior citizens getting mugged on buses. He refused to follow up on his lost income.

Social learning theory focuses on the learners, who are influenced by role models, building self-confidence, persuasion, and personal mastery. Self-efficacy can lead to the desired behaviors and outcomes. Juanita may begin to separate her negative experiences with men from their hearing disabilities after attending a class on building self-esteem suggested by the PHN. Through some positive experiences with teenagers organized by the community health nurse working with the senior center, Dorothy may come to learn that not all teenagers are bad. The nurse can suggest to Ryan's mother that she might have Ryan try chocolate milk. She then can slowly reintroduce plain milk. William might find the courage and self-confidence to solve future problems after the PHN introduces him to another gentleman in the apartment complex who feels confident in the neighborhood.

Humanistic Learning Theories

Humanistic theories assume that people possess a natural tendency to learn and that learning flourishes in an encouraging environment. Two of the best-known humanists are Abraham Maslow and Carl Rogers (Bates, 2016). Abraham Maslow developed the classic hierarchy of human needs in the 1940s. It suggests that a person's first needs are physiologic (air, food, water). Once these needs are met, people work to fulfill safety and security needs. Next is the need for love and a sense of belonging; then come self-esteem needs (positive feelings of self-worth). Only after these needs are met do people work toward self-actualization or becoming all that we are meant to be (Maslow, 1970). Maslow's work is often taught in psychology and early nursing courses.

In community health nursing, the clients' needs must be considered when planning health education programs. For example, it would be difficult for a group of young mothers to concentrate on learning about proper infant nutrition if they are worried about their babies crying in the next room or anxious about an abusive partner who doesn't want them to leave the house to participate in activities. Their need to care for their children (need for love and belonging) or for their personal well-being (security and safety) would be greater than the need to learn about future health considerations (self-esteem and self-actualization). Likewise, it is impossible for learning to take place if a room is so warm that the participants are falling asleep (i.e., physiologic needs are not being met).

Carl Rogers developed the client-centered counseling approach that has long been important in psychotherapy. He believed the role of the therapist should be nondirective and accepting, and proposed approaching clients in a warm, positive, and empathetic manner to get in touch with their feelings and thoughts (Bates, 2016). Rogers (1969, 1989) soon applied his beliefs to education, suggesting that the learning environment be learner centered. The outcome of a learner-centered educational environment is that students become more self-directed and guide their own learning. Rogers believed that the learner is the person most capable of deciding how to find the solutions to problems. The client identifies the problem and, given time and space, can find a way through the problem to a solution. The PHN acts as a facilitator in this learning process when, for example, a 55-year-old man wants to quit smoking after a prolonged upper respiratory tract infection that is aggravated by his habit, and comes to a stop-smoking class led by the PHN at the county health department.

Knowles' Adult Learning Theory

In the last 20 to 30 years, a variety of techniques have been developed to help adults learn. One of the main discoveries is that adults as learners are different from children. They do not learn differently, but rather are a different kind of learner (Bates, 2016). Knowles (1984) and Knowles et al. (2015) suggested that there are four characteristics of "adult learners", and these characteristics have implications for learning. Adults are self-directed in their learning; they have a lifetime of experience to draw on when learning; their readiness to learn is focused on requirements for their personal and occupational roles; and adults have a problem-centered time perspective, in that the learners have a need to learn so that it can be applied and tried out quickly. Display 11–3 describes the characteristics of adult learners and implications for nurses working with adults in more detail.

DISPLAY 11–3 CHARACTERISTICS AND IMPLICATIONS FOR KNOWLES' ADULT LEARNING THEORY

Characteristics	Learning Implications
Self-Concept	
Adult learners are self-directed.	Openness and respect between teacher and learner. The learner plans and carries out own learning activities. Learner evaluates own progress toward self-chosen goals.
Experience	
Adults have a lifetime of experience and define self in terms of this experience.	Teaching methods focus on experiential activities. Discovering how to learn from experience is key to self-actualization. Mistakes are opportunities for learning.
Readiness to Learn	
Learning is focused on social and occupational roles.	Experiential learning opportunities focus on requirements for occupational and social roles. Learning peaks when there is a need to know. Adults can best assess own readiness to learn and teachable moments.
Need to Learn	
Adults have a problem-centered time perspective.	Teaching needs to be problem centered rather than theoretically oriented. Teacher needs to teach what the learners need to learn. Learners need to apply and try out learning quickly.

CHARACTERISTICS OF EFFECTIVE INSTRUCTORS

There are certain characteristics of teachers that most students (yourself included) will recognize. These can apply to PHNs who do health promotion education. Common characteristics include the following:

- Organization and ability to make things clear—The teacher has clear knowledge of the material; objectives and material are organized, presented in context and in an orderly manner, and explained by using examples, case studies, and a variety of methods to hold the learner's interest.
- Positive, enthusiastic attitude—The instructor is excited about teaching; is welcoming, engaged, positive, and interested in individual students; and also works well with groups. Being respectful, approachable, and responsive are also characteristics often mentioned by students as helpful. Use of humor and a professional attitude are also cited.
- Good communicator—The teacher listens as well as provides information and gives thorough responses to student questions. Constructive feedback is appreciated, and empowerment approaches are utilized to encourage participation and learning (Goodenough, Galway, Badenhorst, & Kelly, 2013; Singh et al., 2013).

Public health nurses can incorporate these principles by exhibiting thorough preparation for instruction (e.g., well-planned and well-executed presentations), displaying positive and welcoming behaviors with clients (e.g., encouraging participation, showing respect), and listening carefully to clients' questions and comments, as well as encouraging positive social interactions and fostering ability and self-efficacy.

HEALTH TEACHING MODELS

Theories on learning provide a general understanding of how people learn. In addition, various health teaching models specifically focus on explaining individual health experiences, behaviors, and actions. These models fit with the learning theories to give nurses a more accurate picture of the client and the clients' learning needs. Four useful models are described here: the Health Belief Model (HBM), Pender's Health Promotion Model (revised) (HPM), the Transtheoretical or Stages of Change Model, and the PRECEDE and PROCEED models (Fig. 11–9).

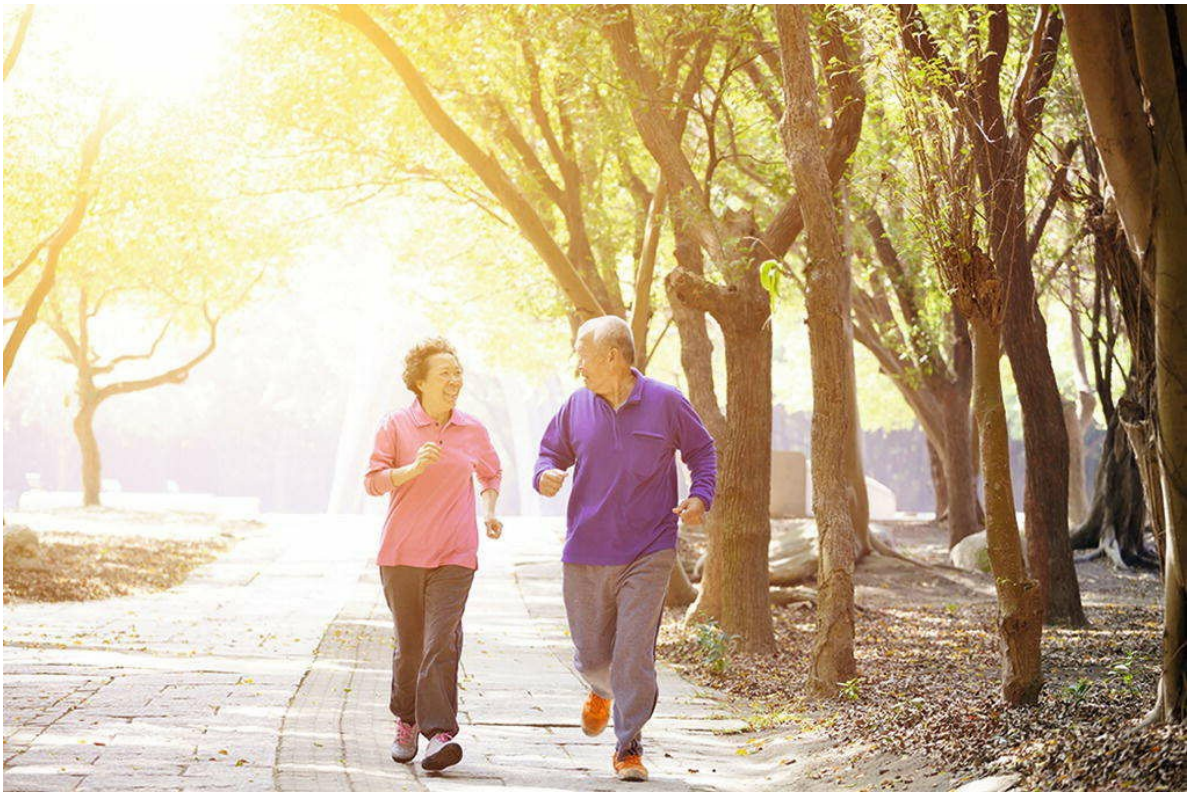

Figure 11–9 A goal of health promotion is to encourage clients to develop healthy behaviors.

Health Belief Model

This section and the next describe two closely associated health models. The Health Belief Model (HBM), which was developed by social psychologists and brought to the attention of health care professionals by Rosenstock (1966), has undergone much empiric testing. The HBM is useful for explaining the behaviors and actions taken by people to prevent illness and injury. It postulates that readiness to act on behalf of a person's own health is predicated on the following (Skinner, Tiro, & Champion, 2015):

- Perceived susceptibility to the condition in question
- Perceived seriousness of the condition in question
- Perceived benefits to taking action
- Barriers to taking action
- Cues to action, such as knowledge that someone else has the condition or attention from the media
- Self-efficacy—the ability to take action to achieve the desired outcome

For example, researchers in Iran used the HBM to evaluate an educational program intervention to improve self-management among diabetic patients. The findings revealed improved self-management among those diabetics that participated in the HBM-based education program (Jalilian, Motlagh, Solhi, & Gharibnavaz, 2014). Community health nurses may find the use of the HBM (and variations) to be helpful in assessing the health behaviors and beliefs of culturally diverse populations.

Pender's Health Promotion Model

First published in the 1980s by nurse Nola Pender, the Health Promotion Model (HPM) was envisioned as a framework for exploring health-related behaviors within a nursing and behavioral science context (Pender et al., 2015). Reflecting the growing body of literature relevant to the HPM, Pender revised the model to reflect a number of major theoretical changes. Consistent with the original, the revised model is derived from social cognitive theory and expectancy–value theory. The revised HPM includes three general areas of concern to health-promoting behavior: *Individual characteristics and experiences* are seen to interact with *behavior-specific cognitions and affect* to influence specific *behavioral outcomes* (Pender et al., 2015). The revised HPM focuses on predicting behaviors that influence health promotion. In addition, the HPM includes the variable of interpersonal influence of others, including family and health professionals.

Being able to predict health promotion behaviors enhances the community health nurse's ability to work with clients. Awareness of their characteristics, experiences, comprehension of their health-related issues, perceived barriers, self-efficacy, support (or lack of it) from significant others, and commitment provides the nurse with a picture that clarifies the client–nurse role and gives direction for action taking. The HPM (Fig. 11–10) is based on the theoretical propositions found in Display 11–4.

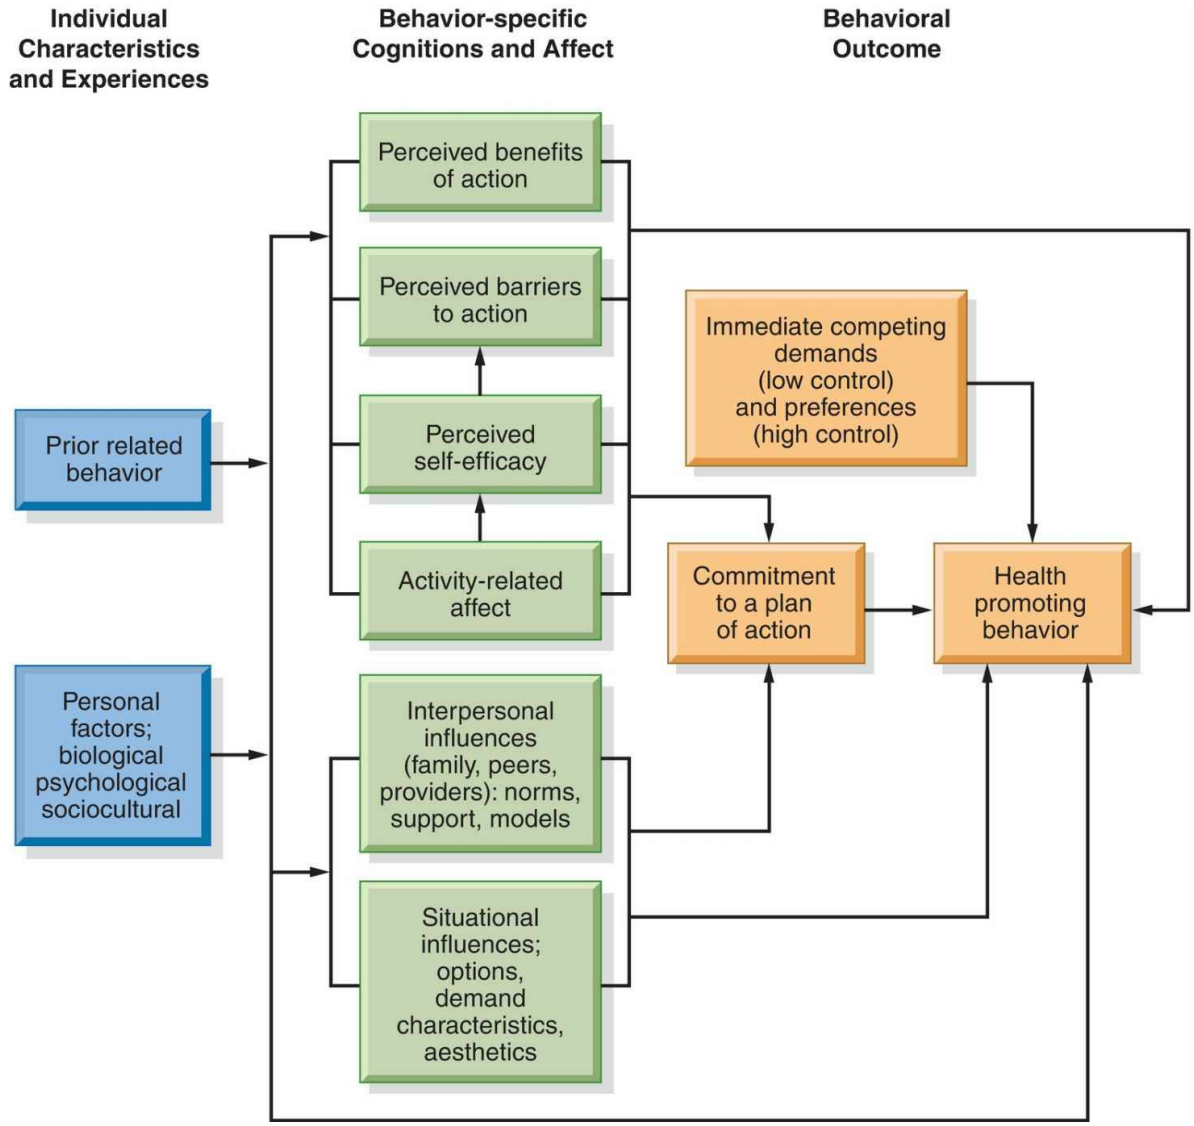

Figure 11–10 Health promotion model. (From Pender, N. J., Murdaugh, C. L., & Parsons, M. A. (2015). Health promotion in nursing practice (7th ed.). Upper Saddle River, NJ: Pearson Education, Inc., with permission.)

DISPLAY 11–4 THEORETICAL PROPOSITIONS OF THE HEALTH PROMOTION MODEL

1. Inherited and acquired characteristics along with prior behavior influence beliefs, affect, and health-promoting behavior.

2. People engage in behaviors from which they anticipate deriving personally valued benefits.
3. Perceived barriers can constrain action to change behavior and the behavior itself.
4. Perceived self-efficacy to embrace a given behavior increases the likelihood to commit to action and implementing the behavior.
5. Greater perceived self-efficacy results in fewer perceived barriers.
6. Positive affect toward a behavior results in greater perceived self-efficacy, which can result in increased positive affect.
7. When positive affect is associated with a behavior, commitment and action are increased.
8. People are more likely to commit to and participate in health-promoting behaviors when significant others model the behavior, expect it, and provide assistance and support for the behavior.
9. Others—family members, peers, and health care providers—are important sources of influence that can positively or negatively influence commitment to and implementation of health-promoting behavior.
10. Situational influences can positively or negatively influence commitment to and implementation of health-promoting behavior.
11. The greater the commitment to a behavior change, the more likely the change will be maintained over time.
12. Distracting demands over which the person has little control may affect commitment to a behavior change.
13. Commitment to a behavior change is less likely to be maintained when other actions are more attractive and preferred.
14. People can modify the interpersonal and physical environments to create incentives for behavior changes.

Adapted from Pender, N. J., Murdaugh, C. L., & Parsons, M. A. (2015). Health promotion in nursing practice (7th ed.). Upper Saddle River, NJ: Pearson Education, Inc.

Using these propositions, researchers explored clients' health behaviors in many studies conducted in the 1980s, 1990s, and into the 21st century. Examples of research using the model include surveying health-promoting behaviors and predictors of health among Iranian women (Mirghafourvand et al., 2014) and surveying health-promoting lifestyle behaviors among adult survivors of childhood cancer in Israel (Liebergall-Wischnitzer, Buyum, & Ganz, 2015). Research on incorporating anger management training with high-risk soldiers (Asadzandi, Sekarifard, Ebadi, Morovvati Sharif Abad, & Salari, 2015) and surveying health behaviors in pregnant minority women (Kominiarek, 2014) have been completed. And, research using this model has also been done with nurses and nursing students (Belguzar, 2015; Rector, Gilchrist, Camarena, & Cauthen, 2014).

Transtheoretical or Stages of Change Model

Researchers discovered, when working with smokers who wanted to quit smoking, that behavioral change doesn't suddenly happen after an "aha" moment during a health education class, but rather occurs in small increments or stages. This discovery led to a new approach in health promotion programs (Glanz et al., 2015). We have all tried to change a behavior (e.g., consistent dental hygiene, exercising regularly, eating a better diet, being careful to not text while driving), but have we all found immediate success after one attempt? Most people have to work up to making a significant change (e.g., gorge over the holidays and then diet at the start of the new year) and then are often not successful and relapse into old, familiar behaviors. The Transtheoretical Model (TTM) recognizes this human frailty and addresses it by anticipating relapses and recognizing them as an opportunity to better plan for how to sustain the needed change in future attempts (Bartholomew et al., 2015; Prochaska, Norcross, & DiClemente, 2007). The model, sometimes called Stages of Change, is not linear but is depicted as a spiral, with plateaus, relapses, and false starts. It can be used with individuals, groups, and populations. The stages include the following (Prochaska, et al., 2007, p. 39):

- Precontemplation—This is usually the normal state of denial or the problem may not be perceived (either don't know about it or don't want to think acknowledge it). Clients may say, "I don't really smoke that many cigarettes, so I don't have to worry about lung cancer or the other health problems."
- Contemplation—At this stage, the client is more realistic and may be more open to discussing the problem of smoking. However, the client may not be able to seriously consider behavior change or feel able to confront the issue. The client may say, "I know I should probably try to quit smoking, but I am really stressed right now and can't think about it."
- Preparation—During this stage, the client is moving away from contemplation toward action. The client may be trying to gather information and may be talking to others about how they quit smoking. They may be concerned that it may take more than one try to accomplish their goal. A client may talk to the physician about medications that are helpful, tell friends and family that he or she is planning to quit smoking, and may even begin to cut back on the number of cigarettes smoked each day.
- Action—This stage is the beginning of the behavioral change. The client sets a date to quit smoking, begins using a nicotine patch or medication, and finds replacement behaviors for smoking (e.g., using breath mints, exercising during usual smoking breaks). The client knows that this attempt may not be successful the first time and should be encouraged to acknowledge and plan for this.
- Maintenance—In this stage, the behavior has been changed. The smoker has stopped smoking, but now needs to be vigilant in avoiding a relapse. The client needs a support system and rewards to encourage maintenance. If the client relapses, the

PHN and others can help the client learn from this and begin their preparation and action stages again until longer periods of maintenance are achieved.

- Termination—This occurs when the former behavior is no longer appealing. The smoker no longer has an interest in cigarettes and does not have to exert the constant vigilance needed in the maintenance stage. Prochaska et al. (2007) note that not everyone can truly reach this stage, and therefore, it is not always included in health promotion programs or research.

Researchers have used this model with many topics related to health promotion and prevention (e.g., substance abuse, smoking cessation, weight loss, physical activity). One research study found that this model could help determine which patients had lower adherence scores for antiretroviral medications (ART). Those clients in the action and maintenance stages had significantly higher adherence scores than those in the earlier stages. This was consistent, despite demographic characteristics or HIV risk factors. The researchers determined the stages of change by asking questions on a survey tool, validated by previous research. For those stating yes to the question, "I do not take and right now am not considering taking my ART as directed," they were placed in the precontemplation stage, and those indicating that they were not currently taking ART but were "considering taking my ART as directed" were categorized as being in the contemplation stage. Indicating that they were "planning to start taking my ART as directed" verified that they were in the planning stage, and stating that they "consistently take my ART as directed" showed that they were in the action stage (Genberg, Lee, Rogers, Wiley, & Wilson, 2013, p. 568). Determining a client's stage and tailoring education and interventions at that level can be helpful.

This model has shown mixed results in other research. A Cochrane systematic review indicated that studies showed "inconclusive evidence" of the model's effectiveness in weight loss and physical activity studies, often because of the need for additional well-designed research and consistent application of the model (Mastellos, Gunn, Felix, Car, & Majeed, 2014, para. 6). Nigg, Geller, Horwath, Wertin, and Dishman (2011) found that the model's strength lies in being able to make individually based interventions relevant to the population level when it comes to physical activity research. Selecting those aggregates that are only beginning to consider starting an exercise program, and targeting specific interventions to them, is an efficient means of addressing this issue. It is also a model that is easy to understand and apply in public health settings, but cross-sectional studies may not be the best application and more longitudinal or trend studies may be needed.

The PRECEDE and PROCEED Models

First published by Green in 1974, the PRECEDE model was developed for educational diagnosis (Glanz et al., 2015). The acronym PRECEDE has been slightly revised from the original to stand for *p*redisposing, *r*einforcing, and *e*nabling *c*onstructs in *e*ducational/ecological *d*iagnosis and *e*valuation (Bartholomew, Markham, Mullen, & Fernandez, 2015; Green & Kreuter, 2005).

The PROCEED model (Green & Kreuter, 1991, 2005) works in tandem with the PRECEDE model as the community health nurse proceeds to plan, implement, and evaluate health education programs. This acronym stands for *p*olicy, *r*egulatory, and *o*rganizational *c*onstructs for *e*ducational and *e*nvironmental *d*evelopment (Bartholomew et al., 2015). The entire PRECEDE–PROCEED model includes eight phases in the formulation and evaluation of health educational programs. The first five of these phases are included in the PRECEDE portion of the model and include (1) social, (2) epidemiologic, and (3) education/ecological assessments, followed by (4) administrative and policy assessment and intervention alignment, and (5) implementation. The PROCEED model is emphasized in the last three phases: (1) process evaluation, (2) impact evaluation, and (3) outcome evaluation.

A hallmark of the PRECEDE–PROCEED model is the emphasis on the desired outcome. The model both begins and ends with *quality of life*, which includes "subjectively defined problems and priorities of individuals and communities" (Green & Kreuter, 2005, p. 11). The emphasis on what the individual or community perceives as the problem, not what the professional believes it to be, is crucial. Outcome evaluation is logically linked back to that same individual or community in assessing achievement of the desired change.

The steps in this model are similar to those of the nursing process. Because of this familiarity, the model has become a useful tool for nurses teaching in the community. The nurse builds on the assessment formulated from the PRECEDE model, determines the best interventions, and then proceeds to evaluate the outcome of those interventions. The emphasis on the perceived needs of the individual or community as the starting point for all community efforts is consistent with public health nursing practice. The model reminds us of the importance of an organized approach to health educational programs, one that begins and ends with the "experts"—the individuals, families, and communities we hope to help through our efforts. The PRECEDE–PROCEED model can be seen in Figure 11–11.

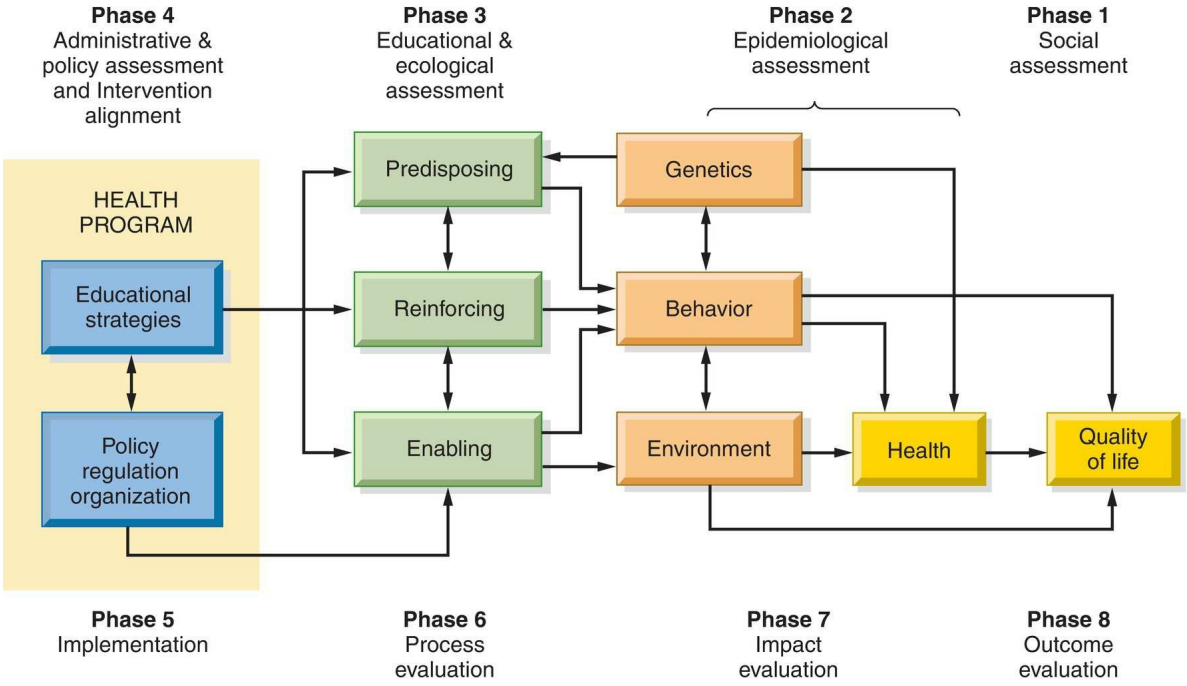

Figure 11–11 The PRECEDE–PROCEED model. (From Green, L. W., & Kreuter, M. W. (2005). Health program planning: An educational and ecological approach (4th ed., p. 10). New York, NY: McGraw-Hill, with permission.)

This model has been used to address many public health problems. Over 1,000 examples of published applications of PRECEDE–PROCEED may be found at www.lgreen.net, including studies on health care workers' hand hygiene behaviors, follow-up with multicultural women with abnormal mammograms, implementation of church-based heart health promotion programs for older adults, developing a healthy-eating curriculum for schools, evaluation of a physical activity and nutrition program for senior citizens, and determining health promotion motivators in Asian populations. Other models used in community assessment and intervention may be found in Chapter 15.

TEACHING AT THREE LEVELS OF PREVENTION

PHNs should develop teaching programs that coincide with the level of prevention needed by the client. The three levels of primary, secondary, and tertiary prevention are demonstrated in the Levels of Prevention Pyramid for nurses who teach clients, families, aggregates, or populations.

Ideally, the community health nurse focuses teaching at the primary level. If nurses were able to reach more people at this level, it would help to diminish years of morbidity and limit subsequent incapacity. Many people experience disabilities that could have been prevented if primary prevention behaviors had been incorporated into their daily activities.

Because the primary level of prevention is not possible in all cases, a significant share of the nurse's time is spent teaching at the secondary or tertiary level. An example is an 88-year-old woman with a fractured hip who has returned home after 3 weeks of physical therapy at a skilled nursing facility. The PHN assesses the client's environment, gait, functional limitations, safety, and adherence to medication and then initiates needed referrals. The teaching focuses on rehabilitation and prevention of a secondary problem that may affect the healing process and the client's health and safety in general.

LEVELS OF PREVENTION PYRAMID

SITUATION: Several examples of teaching at three levels of prevention.

GOAL: Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest possible potential is restored.

TERTIARY PREVENTION		
Rehabilitation	**Primary Prevention**	
	Health Promotion and Education	*Health Protection*
• Restore function: a nurse teaches a stroke survivor about home safety, alternative housing options, physical therapy, and retraining opportunities	• Health teaching: a nurse teaches about the importance of diet, rest, and exercise to prevent a secondary health problem	• Maintenance: a nurse observes clients with tuberculosis where they live while taking their oral medication on a daily basis (DOT—Directly Observed Therapy)

SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
• Screening and case finding: a nurse takes blood pressure measurements from all family members at each home visit and teaches them the importance of maintaining a healthy blood pressure reading	• Treatment: a nurse teaches clients how to navigate through the complexities of the health care delivery system to receive prompt treatment

PRIMARY PREVENTION	
Health Promotion and Education	**Health Protection**
• Health education: a nurse teaches a class on sensible weight control for teenagers	• Immunizations: a nurse teaches about the importance of pneumonia and flu vaccines for seniors, followed by an immunization clinic

EFFECTIVE TEACHING

Teaching is an art. It can be performed with such skill and grace that the client becomes part of a well-orchestrated event, with learning as the natural outcome. Instead of relying on prescribed teaching methods, the skillful PHN can make judgments based largely on client qualities, situations, and needs that guide the experience. The desired changes emerge in the course of the interaction rather than at a level conceived before the teaching. Before the community health nurse can reach this level of artistry, there is much to learn about being an effective teacher.

Teaching–Learning Principles

Teaching lies at one end of a continuum. At the other end is learning. Without learning, teaching becomes useless in the same way that communication does not occur unless a message is both sent and received. Both the teacher and the learner have responsibilities on that continuum. Learners must take responsibility for their own learning. Teachers obstruct that process if they assume complete responsibility for bringing about changed behavior. Clients can be directed toward health knowledge, but they will not acquire knowledge unless they have the desire to learn. Davies (2011) lists the factors that influence clients' lifestyle-related health behaviors:

- Attitudes (how someone feels about or values health)
- Beliefs (personal opinions or convictions about health)
- Motivation (incentive or drive for choosing healthy behaviors)
- Intention (a plan for engaging in healthy behaviors)
- Volition (one's own choice or decision to be healthy)
- Planning (developing specific goals and objectives)
- Social support
- Self-monitoring
- Social and material environment (changing one's environment to improve health)

Teaching, then, becomes a matter of facilitating both the desire and the best conditions for satisfying it (Gilbert, Sawyer, & McNeill, 2015). Teaching in community health nursing means to influence, motivate, and act as a catalyst in the learning process. Nurses bring information and learners together and stimulate a reaction that leads to a change (Muma & Lyons, 2012). Nurses facilitate learning when they make it as easy as possible for clients to change. To do this, the PHN needs to understand the basic principles underlying the art and science of the teaching–learning process and the use of appropriate materials to influence learning (Table 11–6).

Table 11–6 Seven Principles for Maximizing the Teaching–Learning Process

Teaching Principles	Learning Principles
1. Adapt teaching to clients' level of readiness.	1. The learning process makes use of clients' experience and is geared to their level of understanding.
2. Determine clients' perceptions about the subject matter before and during teaching.	2. Clients are given the opportunity to provide frequent feedback on their understanding of the material taught.
3. Create an environment that is conducive to learning.	3. The environment for learning is physically comfortable; offers an atmosphere of mutual helpfulness, trust, respect, and acceptance; and allows for free expression of ideas.
4. Involve clients throughout the learning process.	4. Clients actively participate. They assess needs, establish goals, and evaluate their learning progress.
5. Make subject matter relevant to clients' interest and use.	5. Clients feel motivated to interest and learn.
6. Ensure client satisfaction during the teaching–learning process.	6. Clients sense progress toward their goals.
7. Provide opportunities for clients to apply material taught.	7. Clients integrate the learning through application.

Adapted from Knowles, M. (1980). The modern practice of adult education: Andragogy versus pedagogy (2nd ed.). Chicago, IL: Follett; Knowles, M. S., Holton, E. F., & Swanson, R. A. (2015). The adult learner: The definitive classic in adult education and human resource development (8th ed.). New York, NY: Routledge.

Client Readiness

The client's readiness to learn influences the PHN's teaching effectiveness. Four facets of client readiness have been identified (Kitchie, 2011, p. 115):

1. Physical readiness, which deals with their ability, task complexity, environment, health status, and gender
2. Emotional readiness, which deals with the state of receptivity to learning (e.g., motivation, anxiety, developmental stage, risk-taking behavior)
3. Experiential readiness, which reflects the learner's past experiences with learning (cultural background, orientation, locus of control, coping mechanisms used)
4. Knowledge readiness, which encompasses the learner's knowledge and understanding (e.g., learning disabilities, learning style, current knowledge base)

For instance, one community health nurse found that a young primipara was not ready for prenatal teaching on fetal growth and development. She had strong fears that she would be unable to lose her baby weight and that this would make her sexually unattractive to her partner. Until these anxieties were addressed, the teaching would remain ineffective. Clients' needs, interests, motivation, stress, and concerns determine their readiness for learning.

Another factor that influences readiness is educational background. If a group of women who never completed grade school meet to learn how to care for a sick person in the home, material should be presented in a factual and easily accessible manner and in terms that they understand. To discuss complex concepts of health, illness, and scientific research would be above their level of readiness. However, you can begin to introduce more complex concepts as you work with the women and assess their readiness for additional

knowledge.

Maturational level also affects readiness. An adolescent mother who is still working on the normal developmental tasks of her age group, such as seeking independence or selecting a career path, may not be ready to learn parenting skills. Readiness of the client determines the amount of material presented in each teaching session. The pace or speed with which information is presented must be manageable. A small amount of anxiety often increases client receptivity to learning; however, high levels of anxiety can have the opposite effect.

Client Perceptions

Clients' perceptions also affect their learning, serving as a screening device or filter through which all new information must pass. Individual perceptions help people interpret and attach meaning to things. A wide range of variables affects human perception. These variables include values, past experiences, culture, religion, personality, developmental stage, educational and economic level, surrounding social forces, and the physical environment. One client may view the experience of parenting as a positive, growth-producing relationship; another may see it as a conflict-ridden, unhappy experience to avoid. Each kind of perception has a different consequence for teaching and learning (Wesely, 2012).

Frequently, clients use selective perception. They screen out some statements and pay attention to those that fit their values or personal desires. For example, a PHN is teaching a client about the various risk factors in coronary disease; the individual screens out the need to quit smoking and lose weight, paying attention only to factors that would not require a drastic change in lifestyle. Nurses must know their clients, understand their backgrounds and values, and learn about their perceptions before health teaching can influence their behavior (Kitchie, 2011).

Davies (2011, p. 22) describes motivational interviewing skills (e.g., empathy, overcoming resistance, promoting self-efficacy, active listening, empowerment) and effective strategies, such as:

- Communication (using open-ended questions; affirmations; reflective listening; summarizing to ensure understanding)
- Tools and strategies (setting the scene; agreeing on the agenda; exploring a client's typical day; assessing confidence level; exploring two possible futures; looking back and looking forward; exploring options; agreeing on goals; agreeing on a plan)

Educational Environment

The setting in which the educational experience takes place has a significant impact on learning (Kitchie, 2011). Students probably have had the experience of sitting in a cold room and trying to concentrate during a lecture or of being distracted by noise, heat, or uncomfortable seating. Physical conditions such as ventilation, lighting, room temperature,

view of the speaker, and noise level should be controlled to provide an environment that is conducive to learning.

Equally important for learning is an atmosphere of mutual respect and trust. The nurse needs to convey this attitude both verbally and nonverbally. The way the PHN addresses clients, shows concern, and gives recognition makes a considerable difference in establishing clients' rapport and trust. Both nurse and clients need to be mutually helpful and considerate of one another's needs and interests. All participants in the educational experience should feel free to express ideas, should know that their views will be heard, and should feel accepted despite differences of opinion and perspective. According to the adult learning theorist Knowles, this requires that the nurse refrain from seeming judgmental or inducing competitiveness among learners. Knowles (1980, p. 58) adds that teachers should share their own feelings and knowledge "as a colearner in the spirit of inquiry."

Client Participation

The degree of participation in the educational process directly influences the amount of learning (Moffett, Berezowski, Spencer, & Lanning, 2014). One nurse discovered this principle while working with a group of clients who were nearing retirement. After talking to them about the changes they would face and receiving little response, the nurse shifted to a different method of teaching. Handouts on Social Security benefits were distributed, and everyone was asked to read them during the week and come the next week with questions generated by the pamphlets. The PHN began the next session with a story about an older couple unprepared for retirement and the problems that they incurred. He then asked the group to share questions and concerns they had about retirement. This strategy prompted the group to slowly begin to participate in their own learning.

When the nurse works with clients in a learning context, one of the first questions to discuss is: What does the client want to learn? PHNs should begin from the client's place of interest. Learning is facilitated when the student is engaged and fully participates in the learning process. When the client chooses own directions, helps to discover own learning resources, formulates own problems, decides own course of action, and lives with consequences of each of these choices, then the client has significantly maximized his or her learning.

The amount of learning is directly proportional to the learner's involvement. In another example, a group of senior citizens attended a class on nutrition and aging yet made few changes in eating patterns. It was not until the members became actively involved in the class, encouraged by the nurse to present problems and solutions for food purchasing, understanding how to read nutrition labels, and preparation of meals on limited budgets, that any significant behavioral changes occurred.

Contracting, in which the client participates in the process as a partner to determine goals, content, and time for learning, can contribute to client learning (see Chapter 10). Contracting in the context of teaching assists clients to develop a sense of accountability for

their own learning (Richards & Digger, 2011) (Fig. 11–12).

Figure 11–12 Client participation is a key to successful health promotion programs.

Subject Relevance

Subject matter that is relevant to the client is learned more readily and retained longer than information that is not meaningful. Our interest in a subject can predict our attention, processing speed, and retention of the material (Paul, 2013). Learners gain the most from subject matter that is immediately useful to their own purposes. This is particularly true for adult learners, who have more life experiences that can be related to learning and who tend to see the immediate relevance of the material taught (Bastable et al., 2011; Knowles, 1980).

Consider two middle-management men taking a physical fitness course offered by their employer. One, the father of a Boy Scout, has agreed to colead his son's troop on a 2-week backpacking trip in the mountains. He wants to get in shape. The second man is taking the course because it is a requirement of his company. Its only relevance to his own purposes is that it demonstrates his willingness to go along with company policies. There is little question about which man will learn and retain the most. The course has considerable relevance and meaning to the first man and little to the second.

Relevance also influences the speed of learning. Many adolescents complain that they will never use high school algebra; it holds no relevance for them. However, diabetic clients, who must give themselves daily injections of insulin in order to live, often learn that skill

quickly. When clients see the relevance in learning, they accomplish it more promptly. When the subject matter is relevant to the learner, more knowledge is retained. On seeing the usefulness of the material, the learner develops a strong motivation to acquire and use it, and he is less likely to forget it (Bastable et al., 2011). Even in instances when a previously learned motor skill has not been used for years, it often is quickly recaptured when it is needed.

Client Satisfaction

To maintain motivation and increase self-direction, clients must derive satisfaction from learning. Learners need to feel a sense of steady progress in the learning process. Obstacles, frustrations, and failures along the way discourage and impede learning. Many clients who have had strokes and have potential for rehabilitation often give up trying to regain speech or move paralyzed limbs because they become frustrated and discouraged. On the other hand, clients who experience satisfaction and progress in their speech and muscle retraining maintain their motivation and may work on exercises without prompting. PHNs can promote client satisfaction through support and encouragement.

Realistic goals contribute to learner satisfaction. Objectives should be set within the learner's ability, thereby avoiding the frustration resulting from a task that is too difficult and the loss of interest resulting from one that is too easy. Setting objectives requires agreement on goals, periodic reviews, and revision of goals if they become too easy or too difficult (Bastable et al., 2011). PHNs further promote client's learning satisfaction by designing tasks with rewards. One school nurse led a class for obese adolescents, and together, they set the goal of a weekly 2-lb weight loss. The nurse helped the group design a plan that included counting calories, reducing fast food in their diets, increasing physical activity, and a buddy system to bring about behavior change. As members in the group achieved monthly goals, they were encouraged to reward themselves with a pair of earrings, new nail polish, time playing a favorite video game, or a special outing as a group. These students found this learning experience satisfying because goals were attainable, and their progress was rewarded. Instead of competing with one another, the group members set out to help each member achieve the goal. As a result, most kept the weight off after the class finished.

Client Application

Learning is reinforced through application (Bastable et al., 2011). Learners need as many opportunities as possible to apply the knowledge in daily life. If such opportunities arise during the teaching–learning process, clients can try out new knowledge and skills under supervision. Learners are given an opportunity to begin integrating the learning into their daily lives at a time when the teacher is there to help reinforce that pattern. Take a prenatal class as an example. The learning begins with explanations of proper nutrition and exercise during pregnancy, breathing techniques, hygiene, and avoidance of alcohol and tobacco. More learning occurs as the group members discuss these issues and apply them

intellectually, exploring ways to practice them at home. Additional reinforcement comes by demonstrating how to do these activities. Sample diets, demonstrations of exercises, posters, pamphlets, or models may be used. The group can begin application in the classroom by making weekly diet plans, exercising, group role-play of parenting behavior, or engaging in problem-solving activities. The members then can be encouraged to apply these activities on a daily basis at home and to share their results with the group at future sessions.

Frequent use of newly acquired information fosters transfer of learning to other situations. The major goal of illness prevention and health promotion depends on such a transfer. For instance, mothers who learn and practice a well-balanced diet that is free of nonnutritious snacks can be encouraged to offer more nourishing foods to other family members. A family that practices good hand washing and sterile technique when caring for a family member's postsurgical wound can learn to transfer this same principle to prevention of infection in daily living.

Teaching Process

The process of teaching in community health nursing follows steps similar to those of the nursing process:

- *Interaction:* Establish basic communication patterns between clients and nurse.
- *Assessment and diagnosis*: Determine client's present status and identify client's need for teaching (keeping in mind that clients should determine their own needs).
- *Setting goals and objectives*: Analyze needed changes and prepare objectives that describe the desired learning outcomes.
- *Planning:* Design a plan for the learning experience that meets the mutually developed objectives; include content to be covered, sequence of topics, best conditions for learning (place, type of environment), methods, and materials (e.g., visual aids, exercises). A written plan is best; it may be part of the written nursing care plan.
- *Teaching*: Implement the learning experience by carrying out the planned activities.
- *Evaluation:* Determine whether learning objectives were met, and if not, why not. Evaluation measures progress toward goals, effectiveness of chosen teaching methods, or future learning needs.

Interaction

Reciprocal communication must occur between nurse and client. It is essential in the nurse–client relationship and requisite to effective use of the nursing process. Community health nurses need to develop good questioning techniques and listening skills to determine clients' learning needs and levels of readiness (Davies, 2011).

Assessment and Diagnosis

Identifying client's learning needs presents a challenge to the nurse. Too often, teaching occurs based on the nurse's assumption of what the learner needs to know. In client education, nurses have a responsibility to tailor their teaching to client's real and perceived needs. Knowles (1980, 1984, 1989) and Knowles et al. (2015) described educational needs as gaps between what people know and what they need to know in order to function effectively. He related that the potential learners, the sponsoring organization, and the community all help to determine the needs to be addressed in the teaching–learning situation.

Assessing educational needs may be accomplished in several ways. The nurse can use surveys, interviews, open forums, or task forces that include representative clients as members. The principle to remember is that clients should be involved in identifying what they want to learn. When a "need" to learn something, such as the importance of immunizing children, is identified by the nurse rather than by clients, the nurse may need

to "sell" clients on the importance of the topic in order to gain interest. Nurses may need to use approaches that assist clients toward their own awareness needs; however, it is usually best to begin with the client's most pressing needs or interests.

Setting Goals and Objectives

Once a need has been clearly identified, the nurse and clients can establish mutually agreed-on goals and objectives. *Goals* are broad statements of intent, and *objectives* are more specific descriptions of intended outcome (Miller et al., 2012). Sometimes, in a teaching situation, an objective may be broken down into short- as well as long-term goals. For example, the nurse may have identified a group's desire to stop smoking. The need and teaching goals might be stated as follows:

Need: A group of smokers wish to end their addiction to nicotine.

Short-term goal: Within 1 month, all members of the group will reduce the number of cigarettes smoked.

Long-term goal: Ninety percent of group members will remain tobacco-free for 6 months.

Objectives should be stated in measurable behavioral terms, using a grammatical structure that contains a subject, verb, condition/criterion, and time frame. That is, each objective should include a single idea that describes an outcome that can be measured within a certain time frame. To accomplish the short- and long-term goals of smoking cessation, educational objectives are developed from the levels of cognitive learning covered earlier in this chapter. Each behavioral objective is stated in measurable terms and includes a verb that describes with one of the six levels within the cognitive domain, discussed earlier (11.3). Objectives might appear in the following format.

At the end of the program, all clients should be able to do the following:

- *List* three reasons why smoking is unhealthy.
- *Identify* at least two factors that influence their smoking habit.
- *Apply* a series of action steps leading to smoking cessation within 1 month.
- *Examine* the steps as they work to live tobacco-free in the first 3 months.
- *Design* a way to live a fulfilled, tobacco-free life.
- *Evaluate* successful strategies to remain tobacco-free for 6 months.

Each of these objectives (a) refers to a subject; (b) can be readily measured, because each describes a specific outcome, condition, criterion, or expected behavior; (c) uses a verb for stating cognitive outcomes; and (d) includes a specific time frame (see Display 11–5). Well-written objectives meet these four criteria and enhance evaluation of the success of the educational effort.

DISPLAY 11–5 SAMPLE VERBS FOR STATING COGNITIVE OUTCOMES

Knowledge	Comprehension	Application	Analysis	Synthesis	Evaluation
Define	Translate	Interpret	Analyze	Compose	Judge

Planning

Teaching preparation and planning for it are all-important to successful educational experiences (Bastable et al., 2011). Although nurses teach individuals and families informally, it is generally a good idea to have a written lesson plan. The formalization of creating a written plan provides a framework and permits organization of the topic in a well-thought-out manner that has been individualized for a specific client group. This plan should include the following eight items: (1) purpose, (2) statement of the overall goal, (3) list of objectives, (4) outline of the related content, (5) instructional methods, (6) time allotted for the teaching of each objective, (7) instructional resources, and (8) evaluation methods and criteria.

Teaching

The class, seminar, workshop, or small-group teaching should be conducted according to the plan described earlier. Even with one-on-one teaching, these eight steps should be planned in advance, because each client has a different cultural background, educational and intellectual level, as well as learning need. Use of a variety of teaching methods addresses the unique needs of learners and makes the teaching more engaging and

interesting. Include and combine such methods as lectures, discussions, role-playing, demonstrations, and videos (see "Teaching Methods and Materials").

If necessary, assignments can be made, such as readings, watching suggested videos on the Web, presentations, or journaling, and practice experiences (or return demonstrations) can be used to reinforce and synthesize the learning. The teaching methods used and activities selected are important parts of the teaching plan. A well-designed plan enhances the flow of knowledge in the teaching situation. Poorly thought-out or unorganized plans may lead to inferior outcomes.

Evaluation

The final step of evaluation is critical in the teaching–learning process. Evaluation is the process for verifying the degree to which behavioral changes are actually occurring. At this point, the nurse determines whether the goals and objectives for the educational experience have been met and, if not, why they have not been met. Clear, measurable objectives facilitate evaluation.

If objectives have not been met or have been met only partially, the nurse should explore this outcome with clients to determine what factors hindered their success and what actions might be helpful. Client evaluation is very important to the PHN organizing the session. It is helpful to know that clients found it helpful and interesting and were engaged or not. Partially met objectives can be addressed at the start of the next meeting.

Teaching Methods and Materials

Teaching occurs on many levels and incorporates various types of activities. It can be formal or informal, planned or unplanned. Formal presentations, such as group lectures, usually are planned and fairly structured. Some teaching is less formal but still planned and relatively structured, as in group discussions in which questions stimulate the exploration of ideas and guide thinking. Informal levels of teaching, such as counseling or anticipatory guidance (in which the client is assisted in preparing for a future role or developmental stage), require the teacher to be prepared, but there is no defined presentation plan. The PHN may use a handout or agency protocol steps as a guide. PHNs use one or a combination of methods, along with a variety of materials, to facilitate the teaching–learning process. However, nurses need to expand their diversity of teaching techniques and avoid relying on only one or two methods (Bastable et al., 2011). Generating variability of teaching methods stimulates creative thinking. Nurses use knowledge from physiology, pathology, sociology, and psychology in their practice, and, when teaching, nurses can benefit from using concepts, principles, and teaching methods derived from education, especially adult education. Four commonly used teaching methods (lecture, discussion, demonstration, and role-playing), along with teaching materials for enhanced learning, follow.

Lecture

The community health nurse sometimes presents information to a large group, such as a local parent–teacher association, a senior citizen's group, or a county board of commissioners. Under such circumstances, the lecture method, a formal kind of presentation, may be the most efficient way to communicate general health information. However, lecturers tend to create a passive learning environment for the audience unless strategies are devised to involve the learners. Many individuals are visual rather than auditory learners. To capture their attention, computer-generated slide programs or video presentations can supplement the lecture. Allowing time for questions and discussion after a lecture also actively involves learners. This method is best used with adults, but even they have a limited attention span, and breaks should be given every 30 to 60 minutes. Distributing printed material that highlights and summarizes, or supplements, the shared content also reinforces important points. Excellent suggestions for giving dynamic lectures and presentations may be found by searching the Web.

DISCUSSION

Two-way communication is an important feature of the learning process. Learners need an opportunity to raise questions, make comments, reason out loud, and receive feedback to develop deeper understanding. When discussion is used in conjunction with other teaching methods, such as demonstration, lecture, and role-playing, it improves their effectiveness. During group teaching sessions, discussion enables clients to learn from one another as well as from the nurse. The nurse must exercise leadership in controlling and guiding the discussion so that learning opportunities are maximized and objectives are met. Discussions that are organized around specific questions or topics are generally a good way to begin discussion.

Demonstration

The demonstration method often is used for teaching psychomotor skills and is best accompanied by explanation and discussion, with time set aside for return demonstration by the client or caregiver. It gives clients a clear sensory image of how to perform the skill. Because a demonstration should be within easy visual and auditory range of learners, it is best to demonstrate in front of small groups or a single client. Use the same kind of equipment that clients will use, show exactly how the skill should be performed, and provide learners with ample opportunities to practice until the skill is perfected.

This is an ideal method to use in a client's home, as well as in groups. The materials and supplies that the client will use when unaided by the PHN should be employed in the demonstration. But, you may need to use improvising skills. Helping families figure out ways to accomplish goals with materials found at home often becomes the hallmark of an experienced community health nurse. The new mother learns how to bathe her baby safely in the kitchen sink. The PHN assists several low-income parents in using household items to make inexpensive toys (e.g., mobiles from plastic coat hangers, string, and pictures from a magazine; bean bags using dry beans and scraps of fabric). The husband learns how to change dressings over the site of his wife's central venous line using sterile technique while conserving supplies purchased on their fixed income. Each activity takes a different type of psychomotor skill and ingenuity on the part of the PHN.

Role-Playing

At times, having clients assume and act out roles maximizes learning. A parenting group, for example, found it helpful to place themselves in the role of their children. In doing so, their feelings about various ways to respond became more apparent. Reversing roles can effectively teach conflicting spouses better ways to communicate. To prevent role- playing from becoming a game with little learning, it should be planned with clear objectives in mind. What behavioral outcomes should be achieved? Define the context (the "stage") clearly, so that everyone shares in the situation. Then define each role ahead of time, making sure that participants understand their performance roles. Emphasize that no wrong or right performance exists and that participants should behave the way people behave in everyday life. Avoid having people play themselves, because it can embarrass them and make it difficult for them to achieve objectivity. After the drama has concluded, begin discussion with carefully prepared questions. This technique can be used with staff, coworkers, young children, teenagers, and adults. However, it can be a risk-taking experience for some people, and they may be reluctant to participate. The nurse should use judgment, begin with volunteers, and avoid pushing this technique on unwilling or nonreceptive people. It is best to build up to full participation.

Teaching Materials

Many different kinds of teaching materials are available to the nurse. They often are employed in combination and are useful during the teaching process. Visual images—such as PowerPoint presentations (using graphics, photos), pictures, posters, chalkboards, flannel boards, DVDs, online videos, bulletin boards, flash cards, pamphlets, flyers, charts, and gestures—can enhance most learning. Americans readily learn from television and the Web, as there is visual and auditory appeal. Learning of both positive and negative health behaviors through television or the Web can be more effective and efficient than traditional teaching methods. Other tools, such as anatomic models and improvised or purchased equipment, provide clients with both visual and tactile learning experiences. Still others, such as interactive computer games or instruction, actively involve the learners (Fig. 11–13).

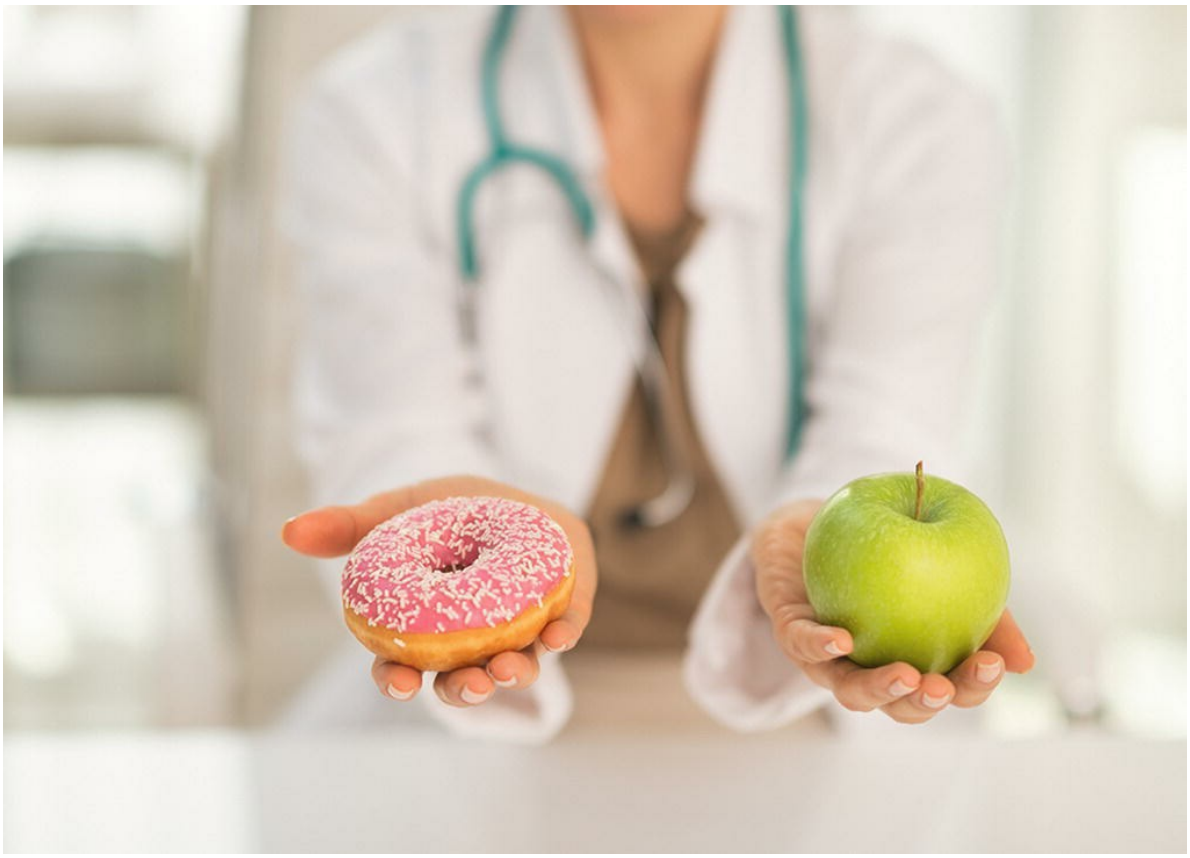

Figure 11–13 Teaching materials help to make your point.

The choice of teaching materials varies with the client's interests and abilities and the resources available. Teaching often occurs in casual conversations, spontaneously in situations when clients raise unexpected questions, or when a crisis arises. In these instances, PHNs draw on their background of knowledge and exercise professional judgment in their selection of content, methods, and materials.

Printed educational support materials are available, such as pamphlets, brochures, booklets, flyers, and informational sheets. Each should be evaluated for appropriateness and effectiveness with particular individuals, families, or groups. Many come from state and

local public health sources. Nurses can create their own handouts, customizing them to the needs of individual clients. The nurse can get educational information from state, federal, and international health agencies such as state health departments, the U.S. Food and Drug Administration (FDA), the Centers for Disease Control and Prevention (CDC), the National Institutes of Health (NIH), and the World Health Organization. Other materials come from nonprofit national agencies such as the American Diabetes Association (ADA), the March of Dimes, the American Association for Retired Persons (AARP), and the American Heart Association (AHA).

Factors to be considered with all educational literature include the material's content, complexity, and reading level. There are several ways to assess the readability of the printed word. One easy way is to use the Fry Readability Graph or the Gunning-Fog formula. These tools are rough way of determining the years of schooling needed to understand printed material. It works by analyzing words and sentence length; the higher the number, the more difficult the reading level. A Gunning-Fog Index of 6 is a sixth-grade reading level, and a score of 11 is at the junior year in high school. Fortunately, most word processing programs now include a feature to allow assessment of the reading level in text. Another very common tool is the Flesch Reading Ease program, available in Microsoft Word grammar checker, which evaluates reading material. Similar to the Fry Graph, the Flesch-Kincaid Grade Level readability score rates the material in terms of typical grade level; however, it may not be as accurate and you may need to adjust results downward (Medline Plus, 2015). The nurse should always consider the population when selecting a reading level, as many individuals cannot understand materials at even the 6th grade level. Also, clients, including those speaking a language other than English, may not be able to read and write in their dominant language.

Culturally appropriate health education materials must be acquired or developed for the predominant cultural and linguistic minority populations taught by the nurse. Developing printed materials is an important first step, but the development of video, audio, and public service announcements in community-appropriate languages is also necessary. When translating printed materials from English into another language, it is strongly suggested that a separate translator "back-translate" the materials. This added step helps assure that the meaning from the original has not been distorted or lost in the translation. Essentially one person or group translates the material, and another individual or group translates it back into English. This can add time and cost to the project, but it may prevent inaccuracies in the final material (Huff, Klein, & Peterson, 2015).

Finally, nurses teach by example. Actions speak louder than words. If a nurse teaches the importance of washing hands to reduce disease transmission and then begins a newborn assessment without hand washing, the message of observed actions carries more impact than the words. Nurses who exhibit healthy practices use themselves as teaching tools and serve as role models as well as health teachers.

Clients with Special Learning Needs

At times, the nurse experiences a challenging teaching situation with an individual, family, or group. These challenges may involve clients who have cultural or language differences, hearing impairments, developmental delays, memory losses, visual perception distortions, and problems with fine or gross motor skills, distracting personality characteristics, or demonstrations of stress or emotions. Regardless of the situation, the PHN will feel most comfortable and confident if he is prepared to deal with these situations before they are experienced.

Before beginning to teach a client, family, or aggregate, thorough preparation is important for successful learning to occur. This includes finding out whether it is possible to teach in English or whether other modifications are needed as the teaching plan is being developed. Community health nurses should never assume anything, including the primary language spoken by clients, their visual or hearing ability, or their capacity to understand. When teaching unfamiliar groups, the nurse can obtain information regarding the interests and abilities of the members from a center manager, caretaker, or program director. These human resources are invaluable in planning any teaching when English may be a second language or when other barriers exist that may impede success if they are not known by the nurse. Interpreters may be needed, and the PHN should work closely with the interpreter to assure that the intended message is sent and received by the clients (Huff et al., 2015). The phases of the nursing process continue to guide the nurse as a teacher.

Another difficulty that can arise is unexpected behavior from a client who disrupts the group process. The client may monopolize the discussion, answer questions asked of others, burst out with personal experiences that have no relevance to the topic, become irate at the comments of others, or sit silently and never speak. This can be unnerving to even the most experienced nurse. The PHN must tactfully diffuse any behavior that has the potential to distract the other learners. This is accomplished by considerately giving the recognition sought by the person while also setting limits.

SUMMARY

The purpose of health education is to effect change, which alters the equilibrium in a system. Change may occur gradually, with time for people involved to adjust, or it may occur in a drastic fashion, such as in a crisis or natural disaster. Change occurs in three stages: *unfreezing* when the system is ready for change, *changing* when the innovation is implemented, and *refreezing* when the change is stabilized.

Planned or managed change is a purposeful, designed effort to effect improvement in a system with the help of a change agent. It involves a process of eight steps, similar to the nursing process, which nurses can use to create change. These steps include assessing symptoms, diagnosing need, analyzing alternative solutions, selecting a change, planning the change, implementing the change, evaluating the change, and stabilizing the change. During planned change, the nurse can use one or a combination of several change strategies. However, the three major change strategies—a rational approach of providing information to influence people to change, an educative approach of combining new information with persuasion to effect change, and a coercive approach of enforcing compliance—are encompassing strategies. Several important principles serve as guidelines for community health nurses to effect change. They include involving all persons affected by the change, introducing change in a timely fashion, considering the impact of the change on other systems, being flexible, and understanding oneself and one's own qualities, which can be groomed to provide the most effective leadership.

Much of community health nursing practice involves teaching. More than simply giving health information to clients, the purpose of teaching is to change client behavior to healthier practices. If these practices are internalized and implemented regularly, years of morbidity and premature mortality can be avoided, thus contributing to the quality and length of the human lifespan. *Healthy People 2020* objectives foster recognition that social determinants of health must be factored into any educational or health promotion effort.

Understanding the nature of learning contributes to the effectiveness of teaching in community health. Learning occurs in three domains: cognitive, affective, and psychomotor. The cognitive domain refers to learning that takes place intellectually. It ranges in levels of learner functioning from simple recall to complex evaluation. As learners move up the scale of cognitive learning, they become more self-directed; the nurse then assumes a more facilitative role.

Affective learning involves the changing of attitudes and values. Learners may experience several levels of affective involvement, from simple listening to adopting the new value. Again, as the client increases involvement, the nurse uses a less directive approach.

Psychomotor learning involves the acquisition of motor skills. Clients who learn psychomotor skills must meet three conditions: they must be capable of the skill, they must develop a sensory image of the skill, and they must practice the skill.

Learning theories can be grouped into four broad categories: (1) behaviorist theories, which view learning as a behavioral change accomplished through stimulus–response or conditioning; (2) cognitive learning theories, which seek to influence learners' understanding of problems and situations through promoting their insights; (3) social learning theories, which explain dysfunctional behavior and facilitate learning; and (4) humanistic theories, which assume that people have a natural tendency to learn and that learning flourishes in an encouraging environment. Knowles' adult learning theory provides a framework for understanding adult characteristics and appropriate teaching interventions.

Health teaching models work together with the learning theories to give nurses a more accurate picture of the client and the client's learning needs. Four models were explored in this chapter. The HBM is useful in explaining the behaviors that are triggered by people with an interest in preventing diseases, and the revised HPM focuses on predicting behaviors that influence health promotion. The Health Promotion Model helps to predict behaviors that lead to health promotion and includes concepts about the interpersonal influence of others, such as health professionals, friends, and family. The Transtheoretical or Stages of Change Model is not a linear model, but recognizes that behavior change occurs more like a spiral, with plateaus, relapses, and false starts. Determining the current stage of the client (individual, group, or population) helps the PHN target education and health promotion efforts more accurately. The PRECEDE–PROCEED model is designed to guide health educational program development. The model has a strong focus on the perceived problems and priorities of a particular individual or group as they impact quality of life. Educational interventions are developed following a thorough assessment, which includes administrative and policy issues, and evaluation is conducted at three levels: process, impact, and outcome.

Teaching in community health nursing is the facilitation of learning that leads to behavioral change in the client. Ideally, this is done at the primary level of prevention. However, much of the nurse's work is done at the secondary and tertiary levels. The nurse uses several teaching–learning principles to facilitate the learning process, such as client's readiness for learning, client's perceptions, learner's physical and emotional comfort within an educational setting, degree of client participation, relevant subject matter, allowing clients to derive satisfaction from learning, and reinforcing learning through application. PHNs can incorporate behaviors associated with characteristics of effective instructors in an effort to better address learner needs.

The teaching process in community health nursing is similar to the nursing process, including steps of interaction, assessment and diagnosis, goal setting, planning, teaching, and evaluation. The teaching may be formal or informal, planned or unplanned, and methods may range from structured lecture presentations and discussions to demonstration and role-playing.

Selection of teaching materials depends on how well they suit learners and help to meet the desired objectives. Sources of teaching materials that are free or inexpensive can enhance the nurse's teaching efforts, but need to be evaluated for effectiveness and appropriateness.

The nurse needs to know how to help learners with special needs, those with physical or mental disabilities, and those who are from a different culture or who speak a different language, as well as those who monopolize the discussion, become emotional, or are hostile. The nurse must be prepared for each situation to effectively teach the individual, family, or group.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a staff public health nurse, you have been asked to chair an ad hoc committee in your health department made up of interdisciplinary colleagues and community members. The committee's task is to plan a health fair for the local community.
   a. Outline the specific planned-change steps that your committee needs to ensure a successful health fair with outcomes that promote improved levels of community health.
   b. Select one specific objective of your health fair (e.g., cholesterol screening of an at-risk aggregate with the goal of reduced cholesterol levels in a year). Does the proposed objective require an evolutionary or revolutionary change in citizen's health-related behaviors? Justify your choice of the type of change.
   c. Explain the strategies that you would use to effect the change.
   d. Six principles for effecting positive change are presented in this chapter. Briefly discuss how you would use each one as you and your committee develop the health fair.
2. What learning theories discussed in this chapter most closely resonates with you? How can they be applied in your practice?
3. Your city governmental officials often make decisions that appear to reflect a lack of knowledge regarding health and health care. How might you "educate" them using the concepts and principles described in this chapter?
4. Using behavioral objectives that match the learning level desired, develop a flyer or program for an educational presentation for clients.
5. Select one of the health teaching models. Use the model to plan an educational program for a group of teenagers. How did the use of the model enhance your teaching?
6. You are teaching an aggregate of middle-aged women about menopause. One woman monopolizes the class by telling stories and talking negatively about her husband. The other women are getting upset with her. How do you tactfully resolve the situation?
7. Interview an adolescent, a young adult, and a middle-aged as well as an older adult about their thoughts on health and what makes people healthy. What do they do to maintain their health? Do they have any dietary or other restrictions? What do they find the most difficult thing to do on a regular basis and why? Do you notice differences between the younger and older subjects? Is there a consistent theme among all of those that you interviewed? Compare your results with a peer's results.

12 CHAPTER

Planning and Developing Community Programs and Services

"True genius resides in the capacity for evaluation of uncertain, hazardous, and conflicting information."
—*Winston Churchill (1874–1965)*, British Prime Minister (1940–1945; 1951–1955)

KEY TERMS

Advisory group
Authoritative knowledge
Benchmarking
Enabling factors
Geographic information system (GIS)
Grant
Grant writing
Letter of inquiry
Logic models
Predisposing factors
Quality indicators
Reinforcing factors
Request for proposal (RFP)
Social marketing

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- List sources of information that can be used to identify group and community health problems.
- Identify change strategies that maximize cooperation of target populations.
- Identify methods to gain input from target populations to define the scope of a health problem.
- Identify and evaluate the effectiveness of intervention methods targeting health problems.
- Classify health problems based on their changeability.
- Identify barriers to solving health problems.
- Discuss the role of the nurse within quality measurement and improvement programs in community/public health nursing.
- Recognize the role of social marketing in health promotion programs.
- Locate appropriate grant funding sources for select health promotion programs.

A public health nurse collaborates with the county housing authority to implement a comprehensive fall prevention program for community-dwelling seniors; another nurse works into the night to complete a multimillion-dollar grant to fund

comprehensive human immunodeficiency virus (HIV) educational programs in Kenya; community health nursing students volunteer to assist the local public health department with a social marketing campaign on health promotion. The efforts described may seem very different, but each represents a health promotion program targeting populations, not just individuals. A fall prevention program could potentially reduce the number of hospitalizations in the community resulting from serious falls, the HIV program may ultimately save tens of thousands from contracting this disease, and the social marketing campaign may reach thousands in the community, prompting them to think about their own health habits and engage in health-promoting behaviors. Each of these examples represents the emerging role of the public health nurse and argues for the acquisition of a new set of skills. The skills of grant writing, social marketing, and collaborating with county officials all require new abilities that may require additional training or working with a mentor. These roles may seem foreign to you now, as you begin your career, but they may be the very skills needed to help bring vital health promotion programs to fruition.

In many communities across the country, local health departments struggle to recruit nurses to provide much-needed services. With shrinking budgets, many communities are forced to change long-held views on the scope and nature of services provided by public health nurses. The home visiting model, once a mainstay of public health nursing, has been eliminated in many communities. Increasingly, public health nurses find themselves providing health promotion and educational programs to larger and larger audiences. To meet this need, public health nurses must become skilled at planning and implementing health promotion programs. As with any activity, the need for the program must be justified, and with limited resources, the benefit to the community must be demonstrated. Additionally, communities are rarely in a position to fund the entire realm of needed health programs and must turn to outside agencies for funding, through either grants or contracts. The public health nurse often assumes responsibility for locating, securing, and maintaining grant funding.

Whether or not program funding comes from the county or an outside agency, program results must be assessed. Evaluation of programs is vital for their continuation and is a requirement of most funders, whether public or private. A nurse who receives $500 to start an emergency preparedness program with low-income families may not be expected to provide the level of evaluation data that a million-dollar effort to address methamphetamine use in the community would likely require. However, some level of evidence that demonstrates the impact of the program will be needed. Even the populations served want to know whether the programs were successful and why. For instance, a mother agrees to have her daughter enrolled in an after-school program to increase self-esteem. At the end of the first 6-week session, the mother is asked to give permission for her daughter to attend the second session. Her daughter says she enjoys the sessions but would also like to go to a dance class that is held at the same time. With competing demands on the daughter's time, the mother may ask for details on what was accomplished in the first

session and what expectations the providers have for this second session. With this information, she can discuss various options with her daughter. The funders, consumers, and the nurse all need to be aware of the demonstrated outcomes of programs.

In Chapter 11, you were introduced to the concept of change—how it influences the adoption of health behaviors and what factors impede change in individuals. Educational methods are often used to influence change in behaviors and play a vital role in those efforts. In this chapter, we build on the concepts of change and appropriate educational techniques and apply them to larger groups and populations. The discussion of the PRECEDE–PROCEED model (Green & Kreuter, 1999, 2005; Green, Ottoson, & Roditis, 2014; Ottoson & Green, 2008) will be expanded upon as you are introduced to the basics of health program planning, intervention, and evaluation to maximize successful results. Meeting the Institute of Medicine's (IOM, 2003, 2011) call for enhanced quality and safety in nursing education and the impact this has on performance and outcome assessment of community health programs and services will be addressed, as well as the Quality and Safety Education for Nurses (QSEN, 2014) project that evolved from this call for action. Within this overall context, the subsequent IOM reports, the *Future of Nursing* (IOM, 2011) and *For the Public's Health* (IOM, 2012), will build on the challenges specific to public health and public health nursing. *Social marketing*, a tool for reaching large audiences with health information will be presented. Several well-known models familiar to nurses will be explored in terms of facilitating the evaluation of programs and services. Finally, as the need for grant funding becomes increasingly important, information on the various types of available funding will be provided.

PROGRAM PLANNING: THE BASICS

In the classic text by Ottoson and Green (2008, p. 590), public health education programs are defined as interventions "designed to inform, elicit, facilitate, and maintain positive health practices in large numbers of people." Even the American Nurses Association (ANA), *Public Health Nursing: Scope and Standards of Practice* (2013), is centered on the role of the nurse in planning, implementing, and evaluating population-focused health promotion/health education programs. Specifically, Standard 5B calls on the public health nurse to "employ multiple strategies to promote health, and a safe environment" (p. 37), through programs and services that include appropriate teaching–learning methods, that are culturally and age appropriate, and that also include an evaluation component. Advanced PHNs plan "evidence-based health promotion programs and services" and engage with consumers and advocacy groups in promoting health and modifying programs (p. 38).

With so much emphasis on planning and developing health education/health promotion programs, the process can seem overwhelming to the new public health nurse or even to the acute care nurse who may be involved in some aspect of health initiative development within an agency. The first part of this chapter is designed to take some of the mystery out of the process. You will be guided through the complex problem of obesity in school-aged children. This particular issue is of great importance to the health of our children, and the principles applicable to this example can be utilized in other situations and other programs, even those that are very broad in scope and involve many practice partners. In your nursing program, you may even have been tasked with developing a health program, working on an existing community program, or simulating the process in a written assignment. Whatever your experience level, the essential elements are the same. As you begin this next section, think about past experiences you have had, such as taking blood pressures at a local health fair or developing a pamphlet on the need for prostate screening for non–English-speaking residents. Did these actions have the impact you hoped for? Successful health promotion programs do not occur by accident; they take skill, time, patience, and most of all listening to and understanding the needs and opinions of the individuals who are the focus of your program (the target population) (Fig. 12–1).

FIGURE 12–1 Every community has unique health problems that need to be identified.

IDENTIFYING GROUP OR COMMUNITY HEALTH PROBLEMS

Nursing education emphasizes practice with a focus on individuals, families, and communities, yet nurses often practice at the individual and family level. When is it appropriate for a nurse to expand his or her practice to the community level? Perhaps the most natural time is when a nurse identifies an ongoing issue that does not change with traditional interventions. Examples might include overuse of the emergency room for urgent care; recurrent hospitalization of the elderly from several nursing homes for dehydration, sepsis, and malnutrition; or hospitalization of 6- to 8-year-olds for injuries caused by insufficient car seat restraint. These types of recurrent problems might lead the nurse to investigate the feasibility of a community-based intervention.

Individually or in a group, identify a possible issue to explore—one that you believe is leading to poor health outcomes in your community. How do you know if this problem is widespread or if others also find it to be a problem? Several methods can be used to validate the importance of the issue. One method would be to consider *Healthy People 2020* objectives for the nation (U.S. Department of Health and Human Services [USDHHS], 2016). What are the major issues that are of concern to improving health outcomes for the United States? What are the priorities of the state in which you live? You might take some time to review Web sites for federal agencies to identify the programs they are promoting to meet the *Healthy People 2020* goals and objectives. Your state department of health may also have a Web site with information on achievement of *Healthy People 2020* objectives, including those objectives that remain challenging. Local communities also establish priorities that reflect the *Healthy People 2020* objectives for the nation. These overarching national goals are as follows:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, 2016, para. 5).

Community agencies and organizations frequently network to establish community-wide goals, and the local health department often spearheads this effort. It may also be organized by community-based health agencies and volunteer organizations. Improved outcomes for individuals who have diabetes or asthma are issues a local community might want to address. Another topic of concern is childhood obesity. Nurses can work collaboratively with these types of special interest groups to find solutions for individuals and families with identified problems.

As a specific problem is identified, it is crucial to analyze the extent to which individuals and families are affected by the problem. It is a poor use of resources to set up a program if there is a very small incidence of the condition or situation. For example, it would be a waste of resources to establish a program on diabetes and pregnancy for a local homeless shelter that only serves 35 women a year. Of those 35 women, none may be pregnant, and because 4.6% to 9.2% of the population of pregnant women develops gestational diabetes, it may be a number of years before an eligible client is found (DeSisto, Kim, & Sharma, 2014). A better use of resources would be to target a community with a higher proportion of individuals at risk for diabetes during pregnancy (Hedderson et al., 2012). An example might be a program targeting a community with a large population of young Asian/Pacific Islander or Hispanic mothers, as the incidence of gestational diabetes is higher in this population (16.3% and 12.1%, respectively) than for non-Hispanic Whites (6.8%). Yet another target group may be older women who are also at increased risk (DeSisto et al., 2014). There are many ways a nurse can decide if a problem has affected a sufficient percentage of the population to warrant intervention. The best way to start is by reviewing the local, state, and national data available through government repositories. This can be done by searching the Internet, by going to a university library for assistance, and by asking for sources of specific data from your local health and social service agencies, police and judicial departments, and local school districts. Hospital discharge data are also reported to state agencies, and this information is sometimes available at the local level.

As nurses and other community groups narrow their focus, they can often map data by zip codes and neighborhoods, which helps to identify the best places to target groups and communities. Currently, many organizations have this ability and are able to identify target groups by race, age, and family status. These types of data, known as geographic information system (GIS) information, are widely available. At the federal level, the National Center for Health Statistics (NCHS) Web site maintains GIS maps on the major causes of mortality in the country. Additional GIS data can be found through a variety of federal sources, including the CDC, the National Cancer Institute, the Center for Mental Health Services, the National Library of Medicine, and the Environmental Protection Agency (Public Health Partners, 2016) (see Chapter 10; Fig. 12–2).

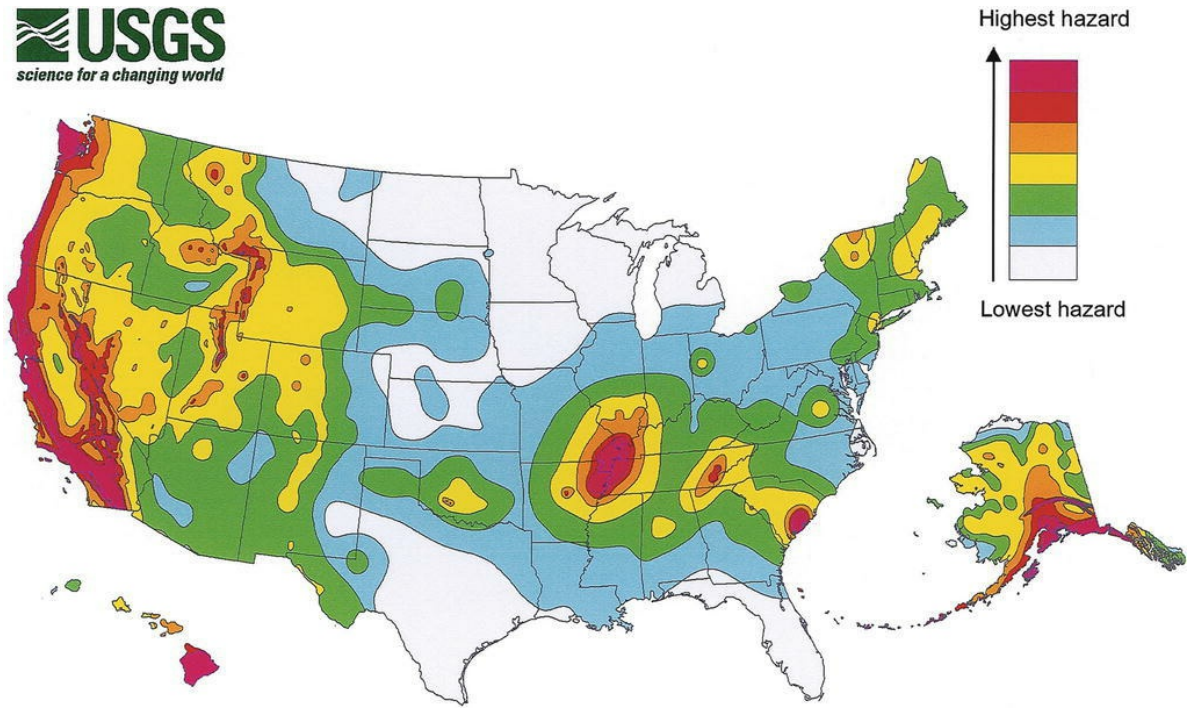

FIGURE 12–2 2014 USGS earthquake hazard map.

Another effective approach is to talk to other nurses and other health care professionals within and outside of your organization. Get their ideas about the problem and ideas about what should be done to alleviate the problem. In addition, find out what has been tried in the past and get their input on why past interventions failed. One very helpful source of information is the *Guide to Community Preventive Services: What Works to Promote Health?* (Community Preventive Services Task Force, 2014), a federally sponsored initiative that provides recommendations regarding population-based interventions, including which are recommended, which need more evidence to determine effectiveness, and which are not recommended. The interventions with limited evidence may actually be very effective but need to be demonstrated by more studies; perhaps your idea is among those listed. Publication of program results not only is professionally gratifying but adds to the body of evidence on which health promotion programs can be evaluated. For example, in Chapter 6 of the guide, recommendations to increase community demand for vaccinations include client reminder and recall systems, yet there is not enough evidence to support client or family incentives, or the use of patient-held medical records (see pp. 223–224) (see Chapter 15).

The next step of intervention is the most important of all, as it will determine whether your interventions succeed or fail. A nurse may think, "I know what the problem is—now I will think up an intervention to alleviate it!" This approach may be well intentioned but will lead the nurse down the path of failure. At this point, only part of the assessment is completed; the most important part of the assessment is to find out the views of the target population about the identified problem. What do they think may be causes for this? What ideas do they have about solving it? Which approaches do they think will work, and which

are doomed to failure? These are all important questions the nurse needs to ask. It is crucial that the views of the target population be heard and respected. Anthropologists talk about a concept called authoritative knowledge. This is based not on whose knowledge may be right but rather on what is "accepted as legitimate and accurate" because it may come from medical experts, for instance (McCoyd, 2010, p. 591). Nurses may think that they know more about a topic than their target population does (e.g., diabetes), and therefore feel that their solutions are better than the target population's solutions. Members of a target population hold just as strongly to their own belief systems. If nurses don't learn about the target population's beliefs and only consider their own, they will not be able to work out an acceptable and appropriate solution with the target population. Interventions that fail to engage the target population will likely be unsuccessful because of this. It is crucial that chosen interventions involve effective use of health resources and that positive working relationships be established with high-risk target communities.

Getting Started

When working with target groups, it's important to get as much information about the population as possible. Start by asking those you know, as colleagues and as patients/clients, about their local community. What do they see as issues regarding the problem about which you are concerned? What do they think about the quality of services currently available? What do they see as barriers to services? What about barriers to adherence to treatment and other health care recommendations?

Additional issues to explore include the following: Who else do they think you should speak with to gain insight about the issues relevant to this problem? Who are key people with whom you should build relationships? What are their customs in regard to health care? Who are the leaders within a family? If you want to establish linkages with this population, what is the best method? Who are their *formal* and *informal leaders*? What types of events bring them together? What are the roles of family, church, and health care providers within their community? Should you go through church groups, school groups, or other organizations? What radio stations do they listen to, and what television stations are they most likely to watch? What are the most common Web sites used by this population when accessing health topics? This information will not only help you gain insight into factors influencing the health problem, it will also give you information about how most effectively to reach out to the target population. Concepts from community-based participatory research and health promotion are useful (Kulbok, Thatcher, Park, & Meszaros, 2012) (see Chapter 4).

As you start to gain insight into the environmental and social factors that influence the problems about which you are concerned, you are also building interest in the issue. As you participate in discussions with others, be open to their input. It may be that the ideas you start out with need to change in response to feedback from members of the target and service communities. For example, an experienced public health nurse was involved in a project developed to serve Hispanic women with gestational diabetes. When interviewed, the monolingual Spanish-speaking women expressed concern that they were told to go on a diabetic "diet" and were then chastised for not eating enough. To these women, going on a "diet" meant they should eat less. They were also told that if they followed the diabetic diet, they wouldn't have such "big babies." They thought a "big" baby was a healthy baby and couldn't understand why they were being told to avoid having a larger baby. These were simple issues to fix but required knowledge of how the "diabetic teaching plan" was interpreted by the target audience. Another key factor was that the clinic was a family event; thus, all of the children were brought along. The clinic staff had been consistently irritated by the presence of large groups of children but learned that they needed to alter the clinic setup and resources to accommodate the expectations of their clients. Modifications were made based on dialogue with members of the target population that positively influenced the eventual success of the clinic's program.

This example demonstrates how use of *local knowledge* can increase the effectiveness of a community- based intervention. The participation of members of the target population also builds greater community capacity for resolution of health problems within target communities. Working with community partners, including members of the target populations, is a technique that has been used in providing services within developing countries. This type of approach ensures community *buy-in* for an intervention. It also builds networks that can continue to increase the capacity of communities to resolve other health care issues, both current and emerging (Bolton, Moore, Ferreira, Day, & Bolton, 2016; Buta et al., 2011; Kulbok et al., 2012; Zlotnick, Wright, Sanchez, Kusnir, & Te'o-Bennett, 2010).

It is essential to review literature regarding health problems, factors influencing the outcomes of interventions, and the role of families and communities in adherence to interventions. The search for evidence-based practice is important to program success. The literature review can offer the opportunity to develop additional insights that may shape interviews with members of the target and service communities. How does this target group compare to other target groups? What else should be addressed that wasn't found in the literature? For instance, a public health nurse wanted to know why parents were using emergency rooms for after-hours urgent care. A literature review found studies focused heavily on the "misuse" of emergency rooms by parents to treat urgent ambulatory care health problems, such as otitis media. Based on input from an emergency room nurse, the PHN decided to go directly to the source and asked families what their doctors had told them to do if their child became ill at night. The families indicated that they were told to take their children to the emergency room! None of the literature addressed what the families had been told to do for after-hours care. This is an example of how being open to information from a variety of sources (in this case the emergency room nurse) enhanced the PHN's understanding of the problem beyond what could be learned by solely relying on the literature.

As nurses work with community members to identify factors contributing to a health problem, individuals will begin to stand out because of their knowledge, their network capabilities, and their interest in the subject. A key factor for ensuring the success of any intervention is to appoint an advisory group that includes representatives from the target and service communities. Findings from interviews, literature reviews, and data analyses need to be reviewed with this advisory group. To ensure success of the advisory group, all meetings should be carefully planned, so that they are well organized, punctual, and efficient. Strategies to encourage input from the advisory group should be employed; meetings should focus on getting the advisory group to interpret findings and community feedback and to develop possible solutions. Contributions from each member should be sought and valued equally. Depending on the size of the group, it may be most effective to have some breakout sessions as well as larger group sessions. Every member should do an evaluation at the conclusion of each meeting, so that any problems can be addressed before the next meeting. Maintaining a record of these meetings—in the form of either minutes or

a brief written overview—is also very helpful. Be certain to also keep a record of attendees. Maintaining a *paper trail* is always important (Fig. 12–3).

FIGURE 12–3 Educational programs for schoolchildren can address problems such as childhood obesity.

Delineating the Problem to be Addressed

With the help of the advisory group, it's important to delineate the problem or problems to be addressed. The following is a case example. A group of nurses identified childhood obesity as a problem. Input from community members, as well as a review of data, demonstrated a greater rate of childhood obesity in a local elementary school where a high proportion of the children were African American. Although the original plan made by the nurses was to establish a special educational program for overweight children, ages 10 to 12, input from members of the service and target community indicated major problems with this approach:

1. It would be embarrassing for any child identified as needing the program.
2. Children this age usually don't pick the menu for their home or school.
3. Diet is culturally dependent, and the nurses knew very little about the dietary practices of African American families within the targeted community.

The use of an advisory group helped the nurses first identify what behavioral factors contributed to childhood obesity in the target population. These behavioral factors included the following:

- School breakfasts and lunches served were high in fat and salt, with limited fresh vegetable and fruit choices.
- Physical education classes were conducted for 45 minutes, once a week.
- No sports equipment was available for use during school recess and lunch periods.
- Participation in after-school sports cost $150 per student for uniforms and fees.
- The students aged 10 to 12 preferred to drink sodas and eat French fries for lunch.
- Most parents were working and often bought "fast food" for their children for dinner.
- Local parks were unsafe for children to play in, and there were no outdoor recreational activities that were free (at no cost).
- Children in the target group described feeling very stressed because of high homework demands and expectations to score well on national tests.
- Children in the target group indicated that they went home after school and watched TV or played video games because their parents wouldn't allow them to play outside while they were at work.
- When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played video games, and had snacks.
- The favorite after-school snacks eaten by children in the target group were macaroni and cheese from a box or packaged noodles—both of which are high in fat, carbohydrates, and salt.

Rating the Importance and Changeability of Identified Behavioral Factors

To achieve success, programs must narrow their focus to a limited number of health behaviors that can be addressed successfully within a specific time frame (Green & Kreuter, 2005; Green et al., 2014). To prioritize which behaviors to address, the authors suggest that they be rated in terms of importance and changeability. The final list should include problems that are both important and easy to change.

Importance is determined by rating how frequently the identified behavior occurs and how strongly it is linked to a health problem. The advisory group for childhood obesity ranked the importance of the identified behaviors; their ranking and rationale (basis) for the ranking can be seen in Table 12–1. For instance, the lack of available sports equipment was not rated very highly because the advisory group observed that children could be physically active without sports equipment. A highly rated item was the poor quality of the school-provided breakfasts and lunches; as a primary source of nutrition for many of the school's children, it could contribute to obesity in this population.

Table 12–1 Importance of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School

Important	Basis for Rating
• School breakfasts and lunches were served that were high in fat and carbohydrate, with limited fresh vegetable and fruit choices.	A number of children ate their main meals at school, and studies have shown that high-fat, high-carbohydrate diets contribute to childhood obesity.
• Physical education classes were conducted for 45 min once a week.	Increasing exercise frequency will increase muscle mass as well as metabolic rates.
• The students aged 10–12 preferred to drink sodas and eat French fries for lunch.	Peer pressure can adversely influence food choices.
• Most parents were working and often bought "fast food" for their children for dinner.	Fast foods are high in carbohydrates and fat.
• Children in the target group described feeling very stressed because of high homework demands and expectations to score well on national tests.	High stress levels in adults contribute to obesity by increasing cortisol levels.
• Children in the target group indicated they went home after school and watched TV or played video games because their parents wouldn't allow them to play outside while they were at work.	Sedentary activities contribute to childhood obesity.
• When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played video games, and had snacks.	Sedentary activities contribute to childhood obesity.
• The favorite after-school snacks eaten by children in the target group were macaroni and cheese from a box or packaged noodles—both of which are high fat, high carbohydrate, and high salt.	These foods are high in fat and carbohydrates.
Less Important	
• There was no sports equipment available for use during school recess and lunch periods.	Children can be physically active without sports equipment.
• Participation in after-school sports cost $150 per student for uniforms and fees.	High costs for participation in sports are a deterrent for low-income children.
• Local parks were unsafe for children to play in, and there were no outdoor recreational activities that were free.	Although important, there isn't a direct linkage between the lack of safe parks and free recreation and childhood obesity.

The advisory group was then asked to rate the changeability of the behaviors. In their classic book, Green and Kreuter (2005) indicate that those behaviors that are easiest to change:

- Are usually still developing
- Are more recently adopted
- Do not have deep roots in culture or lifestyle
- Have been attempted before with some success

The advisory group's changeability ratings for the behaviors can be seen in Table 12–2. In this round of assessments, the advisory group found that the lack of sports equipment, although not as important, could be potentially changed. This rating was based on the fact that the underfunding of the play equipment was a relatively new occurrence, and funding might be redirected if attention was brought to the problem. The poor nutritional quality of the breakfasts and lunches was seen as less changeable because of existing contracts with outside businesses to provide the meals.

Table 12–2 Changeability Ratings of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School

More Changeable	Basis for Rating Behavior
There was no sports equipment available for use during school recess and lunch periods.	Trends in underfunding school play equipment are relatively recent.
The students aged 10–12 preferred to drink sodas and eat French fries for lunch.	Peer pressure often changed student behavior and could be used to encourage healthy choices.
Children in the target group described feeling very stressed because of high homework demands and expectations to score well on national tests.	Pressure for children to perform well on standardized tests is a recent phenomenon of questionable value.
When asked what they did when stressed, children in the target group indicated they watched TV, listened to music, played video games, and had snacks.	This was rated as easier to change because of the newer interactive video games that include movement.
Less Changeable	
Physical education (PE) classes were conducted for 45 min once a week.	Trends to decrease PE time per week are relatively recent—limited funding creates barriers to PE.
School breakfasts and lunches were served that were high in fat and salt, with limited fresh vegetable and fruit choices.	For a number of years, schools have contracted out for lunch services from businesses based on bids.
Participation in after-school sports cost $150 per student for uniforms and fees.	Sports have been privately funded for a number of years.
Most parents were working and often bought "fast food" for their children for dinner.	Most parents are working, and fast food restaurants have become part of the American culture.
Local parks were unsafe for children to play in, and there were no outdoor recreational activities that were free.	Funding for parks and recreation has steadily declined for a number of years.
Children in the target group indicated they went home after school and watched TV or played video games because their parents wouldn't allow them to play outside while they were at work.	This has become commonplace in the modern culture.
The favorite after-school snacks eaten by children in the target group were macaroni and cheese from a box or packaged noodles—both of which are high fat, high carbohydrate, and high salt.	These are cheap and easy foods to fix.

After rating the identified problems based on changeability and importance, the nurses and advisory group sought to narrow their focus to specific goals. Ranking the behaviors in a simple table, as seen in Table 12–3, is suggested (Green & Kreuter, 2005; Green et al., 2014). This effort yielded a table with the problems categorized in four groups: more important/more changeable, less important/more changeable, more important/less changeable, and less important/less changeable. The issues seen as most important and changeable included fifth and sixth grade students choosing high-fat, high-sugar foods for lunch and breakfast; children feeling stressed by homework demands; and children engaging in sedentary activities.

Table 12–3 Rankings of Behaviors Contributing to Childhood Obesity at Stevens Place Elementary School by Importance and Changeability

	More Important	Less Important
More Changeable	Fifth and sixth grade students chose high-fat, high-sugar foods for lunch and breakfast. Children stressed by homework demands Children engaged in sedentary activities (watch TV, play video games) after school.	Limited sports equipment
Less Changeable	High-fat and high-carbohydrate school food Limited physical education classes Favorite after-school snacks high fat, high carbohydrate, and high salt	Participation in after-school sports cost $150 per student. Parents often bought "fast food" for dinner. Local parks unsafe; lack of free recreational activities

The use of this grid enabled the advisory group to focus on more changeable and important issues. They wrote behavioral objectives for each identified factor they hoped to change. These objectives identified *who* was targeted, *what* they hoped would change or what action would be taken, *how* the change would be measured, and what the *time frame* was for achieving the expected outcome. The following are their behavioral objectives:

1. By the end of the fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy, and starch (bread, potatoes) at each meal.
2. By the end of the school year, the teachers will schedule homework that can easily be done by a low-average student within a half hour.
3. By the end of the fall semester, all fifth and sixth grade students will be provided physically interactive games free of charge.

Factors That Influence Behavior Change: Predisposing, Reinforcing, and Enabling Factors

Three categories of factors affecting individual behavior can be addressed, as factors are delineated that contribute to successful behavioral change and create barriers to behavioral change (Green & Kreuter, 2005; Green et al., 2014). Per the PRECEDE–PROCEED model, these factors are as follows:

- Predisposing factors provide the rationale or *motivation* for subsequent behavior.
- Reinforcing factors provide a continued motivation to repeat or persist in the behavior.
- Enabling factors promote or facilitate the behavior based upon availability.

Predisposing factors include the knowledge, beliefs, values, attitudes, and confidence of the target population that influence their behavioral choices. Reinforcing factors include the knowledge, values, beliefs, and attitudes of the family and friends of the target population. It also includes authority figures such as teachers or managers, as well as agency and community decision-makers, as these individuals also influence the target population. Finally, enabling factors include the availability of resources; the accessibility of resources, laws, and government support for the health behaviors or for the health program; as well as skills (Green & Kreuter, 2005; Green et al., 2014).

The advisory group, following the PRECEDE–PROCEED model, identified the predisposing, enabling, and reinforcing factors that affected each behavioral objective. Table 12–4 shows the grid they developed for the first behavior objective—"By the end of the fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy and starch (bread, potatoes) at each meal." For example, one enabling factor that supported the change was the identification of a community group that agreed to provide incentives to students making positive food choices. On the other hand, the lack of school funding for educational intervention programs for obese children was seen as inhibiting change.

Table 12–4 Predisposing, Enabling, and Reinforcing Factors That Influence Meal Choices of Fifth and Sixth Grade Students Attending Stevens Place Elementary School

Factors That Support the Change	Factors That Inhibit the Change
Predisposing	
Fifth and sixth grade students tend to believe what they are taught by teachers; thus educating them on food choices could positively affect their choices. Fifth and sixth grade students like to be similar to other children their age.	Fifth and sixth grade students are beginning to feel some independence from adults and may like to eat what they want vs. what adults tell them they should do. Students like the taste of sodas and French fries more than balanced food choices.
Reinforcing	
Students emulate behavior of popular students. Teachers and parents are concerned about poor food choices being made by fifth and sixth grade students. Local community leaders expressed outrage about the obesity rates of African American children at Stevens Place Elementary School.	Media shows teens eating French fries and drinking sodas.
Enabling	
A local community-based organization has offered to provide incentives to students who model positive food choices. The principal has offered to allow time for the nurses to work with an identified group of student leaders to educate them about modeling better food choices. The local Parent–Teacher Association has offered to help monitor student behavioral changes.	The school has no funding for educational intervention programs for obese children.

The advisory group decided to establish a peer-mentoring program, in which student leaders would work with the advisory group and model food choices from all food groups. The advisory group had teachers nominate students for this intervention. The principal allowed the nominated students to attend special educational classes conducted by the nurses to increase their knowledge about the food groups. The nurses worked collaboratively with the students to ensure their teaching approaches were effective. Students suggested rewards that the students could work for that would encourage them to eat more balanced meals. One of the rewards that students felt should be offered is sports equipment for student use during recess and lunch periods. One local community-based organization offered to sponsor a fund-raising event that would allow them to purchase sports equipment for the school.

Grids similar to that shown in Table 12–4 were developed for the remaining two objectives. This process allowed the nurses and the advisory group to develop program intervention strategies that maximized their potential to achieve desired outcomes. Working with the advisory group, the nurses developed a program plan map outlining activities for each objective, as well as the individual responsible for the activity, the date by which the activities were to be accomplished, and how outcomes would be documented. Display 12–1 shows the program plan that was developed for the first objective. This type of mapping allows the group to stay focused, share responsibilities, and monitor outcomes. For instance, student leaders were tasked with modeling balanced food choices at breakfast and lunch and completing a checklist of their food choices each day. The nurses were tasked with meeting each week with the student leaders to provide peer-mentoring training sessions.

DISPLAY 12.1 SAMPLE PROJECT PLAN MAP

Goal: Fifth and sixth grade students attending Stevens Place Elementary School will engage in behaviors designed to decrease their obesity levels.

Objective	Activity	Who Is Responsible	Due Date	Evaluation
1. By the end of the fall semester, 75% of the fifth and sixth grade students will choose a breakfast and lunch diet that includes fruit, vegetables, protein, dairy, and starch (bread, potatoes) at each meal.	1a. Teachers will identify student leaders from the fifth and sixth grade classes who can participate in leadership training for peer mentoring.	1a. J. Jamison, school principal	September 20, 2012	1a. A list of student leaders will be available for review.
	1b. Students will be approached to participate in the program.	1b. J. Jamison, school principal	September 25, 2012	1b. Student response will be documented.
	1c. Permission slips for student leaders to participate will be sent home to parents.	1c. J. Jamison, school principal	September 27, 2012	1c. Copies of permission slips will be maintained by the principal.
	1d. Nurses will meet with the student leaders weekly during the designated time period to provide them training for their peer mentoring.	1d. Nurses	September 28–October 31, 2012	1d. Copies of the meeting notes and educational plans will be maintained by the nurses.
	1e. Student leaders will model balanced food choices during breakfast and lunch meals.	1e. Student leaders	November 1–December 22, 2012	1e. Student leaders will provide a checklist of their food choices to the principal at the end of each day.
	1f. A checklist of possible food choices for students' breakfast and lunch meals using the school menus will be developed.	1f. Nurses	December 1, 2012	
	1g. PTA volunteers will monitor student food choices during breakfast and lunch meals 1 day each week for 3 weeks.	1g. PTA volunteers	December 3, 12, and 17, 2012	1g. Results of checklists will be tabulated and available for review.

Working with the advisory group allowed the nurses to contextualize the problem about which they were concerned within the target community. The advisory group ensured that the nurses identified solutions that were culturally acceptable, appropriate, and ultimately effective. This process also helped them to develop outcome measures that were consistent with the concerns of the community. As data were gathered, findings could be interpreted with input from the advisory group. This approach grounded the findings and ensured that interpretations were culturally consistent with the target population. Evaluation was facilitated by clearly defined goals that could be measured against actual results.

This particular case study is an example of the program development needed in schools to address obesity and overweight. The *Guide to Community Preventive Services* (Community Preventive Services Task Force, 2014) systematic review of published school-based programs indicated that more evidence was needed to determine the effectiveness of these types of programs. Although they noted some positive effects in the studies reviewed, the results were too varied to make any conclusions. Their review supports continued efforts to demonstrate program effectiveness in school-based programs. Clear and verifiable outcome measures are needed.

EVALUATION OF OUTCOMES

The IOM (2002) report, *The Future of the Public's Health in the 21st Century*, called for examining the benefits that accreditation of governmental public health departments might bring. Responding to this challenge, the Exploring Accreditation Steering Committee published *Final Recommendations for a Voluntary National Accreditation Program for State and Local Public Health Departments* in 2006, outlining this first-ever accreditation program for health departments (Benjamin, Fallon, Jarris, & Libbey, 2006). Later, participating health departments characterized the benefits of accreditation as:

- Helping them to identify their strengths
- Documenting their capacity for delivery of core public health functions and 10 Essential Public Health Services
- Promoting transparency in government and accountability to the community, policy-makers, and stakeholders, as well as communication with governing body
- Improving the processes of management and competitive abilities in opportunities for funding
- Stimulating quality improvement and organizational performance (Centers for Disease Control and Prevention [CDC], 2016b).

In 2008, 17 states were selected to lead a national initiative that would advance accreditation and quality improvement among public health departments (Robert Wood Johnson Foundation, 2014). Areas explored by these states in the initiative included culturally appropriate services, use of health data, and integration of customer service into health programs. The Public Health Accreditation Board is a nonprofit entity that is the independent accrediting body. With support from the Centers for Disease Control and Prevention, Office for State, Tribal, Local, and Territorial Support (2016); and the Robert Wood Johnson Foundation, the Public Health Accreditation Board was launched in 2011 and accredited the first cohort of health departments in 2013 utilizing Standards and Measures version 1.0. Version 1.5 of the Standards and Measures came into effect during July 2014, adding ethics, data management, communication science, workforce development, and equity as important new areas for evaluation. The National Association of County and City Health Officials (2016) offers resources that assist health departments to assess the feasibility of becoming accredited and tools to further support a successful accreditation process if departments choose to seek accreditation. Of the 12 domains in Standards and Measures version 1.5 for accreditation, three are particularly applicable to program development and outcome measurement (Public Health Accreditation Board, 2014):

Domain 4: Engage with the community to identify and address health problems.

Domain 9: Evaluate and continually improve health department processes, programs, and interventions.

Domain 10: Contribute to and apply the evidence base of public health.

As more agencies seek accreditation, there will likely be increased pressure to achieve this status at all levels (local, county, or state) to demonstrate excellence. Public health nurses can work with state and local health departments to achieve accreditation. Accreditation not only serves to promote high-quality services to the public and demonstrate a commitment to meeting the specific needs in these communities but also supports the need for public health nursing services to meet those challenges.

The previous section of this chapter discussed the issues of program planning, implementation, and evaluation as they related to a small health program. This section focuses on the programs and services provided by agencies. Although the scope of the effort to address outcome evaluation is understandably broader, the concepts are essentially the same. The accreditation initiative has raised the issue of demonstrating in real and objective terms the outcomes resulting from health promotion programs provided through public health agencies. The principles discussed have relevance in many community settings and should be considered whenever health promotion programs and services are provided. Public health nurses at local, state, and global levels are instrumental to many of the health promotion programs and services offered through health departments; their expertise with and understanding of the communities served are invaluable to assuring ongoing quality assurance and outcome evaluation.

An important step in evaluating any program entails constructing a clear model of what the program is meant to achieve (Cornell University, 2016). Logic models, or pathway logic models, are often used to articulate the causal relationship between planned program activities and the expected outcome. Whereas community problems may be easy to recognize, it is harder to determine which strategies offer the highest likelihood for successful change and, more importantly, what evidence will indicate progress or success. In their seminal work for the Annie E. Casey Foundation, the Organizational Research Services (2004) report on community change theories and underscore that a helpful change theory can be used as a road map for planning and accomplishing individual and community change. Based on the change theory, logic models offer a clear picture of the desired impact, or outcome, the changes that need to be realized in order to achieve the outcome, the activities and resulting outputs that will affect the change, and the inputs necessary to carry out the planned activities. In other words, logic models provide a process for planning backward in order to implement forward (Allmark, Baxter, Goyder, Guillaume, & Crofton-Martin, 2013; Naimoli, Frymus, Wuliji, Franco, & Newsome, 2014).

Causal Pathway Framework hypothesizes that this set of inputs and activities will result in these products and services, which will facilitate these changes in the population, which will contribute to the desired impact (Kellogg Foundation, 2006). See Display 12–2 for a diagram of the causal pathway.

DISPLAY 12.2 CAUSAL PATHWAY FRAMEWORK

Plan backward; implement forward! Plan this way:

Inputs ← Activities ← Outputs ← Outcome ← Impact

Implement this way:

Inputs → Activities → Outputs → Outcome → Impact

An example of the use of logic model for program planning, monitoring, and evaluation of a blood safety project in Kenya is shown in Display 12–3.

DISPLAY 12.3 CASE STUDY ON LOGIC MODELS FOR PROGRAM PLANNING, MONITORING AND EVALUATION

Overview

A logic model is a framework that graphically depicts causal relationships between elements of a program and is used for program planning, monitoring, and evaluation. When using a logic model for program planning, focus is placed on the ultimate outcomes or results, and planners work backward to determine the following key aspects:

Example of using a logic model to design, monitor, and evaluate a blood safety project in Kenya

Inputs	Activities	Outputs	Outcomes	Impact
• Human resource • ICT resources • Financial support • Test kits and consumables • Blood bags • Technical assistance	• Blood donor mobilization, education, and recruitment • Blood collection • Blood testing and grouping • Preparation of blood components • Training of staff • Mentorship of staff • On-site support of staff • Blood donor notification • Stakeholder data review meetings • Surveillance	• Individuals reached with information on blood donation • Facilities for blood bank and transfusion • Blood donors mobilized • Blood units collection • Screening for transfusion transmissible infections (TTIs) • Blood donor notification and referral • Blood components prepared, stored, and transported • Appropriate use of blood and blood components • Data review meetings held • Individuals trained in blood transfusion services	• Improved equity and access to safe blood and blood products • 100% testing for TTIs • Increased proportion of repeat blood donors • Increased knowledge on the importance of blood donation • Increased proportion of donors notified of their TTIs test results	• Reduced mortality related to blood and blood component issues • Reduced morbidity related to blood and blood product issues • Reduced incidence and prevalence of TTIs

(Contributing Authors: Missie Oindo, BA, MCHD and Serah Malaba-Kambale, Bsc, MPH, PRINCE2® Practitioner, both of Kenya)

Use of these types of models can be very helpful in developing new programs and can help guide community health nurses who are not familiar with methods of program planning, monitoring, and evaluation. See Perspectives: From the Field.

PERSPECTIVES FROM THE FIELD

As a Country Director for a large CDC-funded HIV program in Kenya, one of my greatest joys was working closely with Kenyan staff to plan, implement, and evaluate effective programs. Teaching staff to develop logic models to guide programs was extremely effective in terms of ensuring that staff had common understanding of the program and their specific role in ensuring success from inceptions through to evaluation. Feedback from staff years later indicates that they continue to use logic models to guide their work and that having this skill has helped them advance their careers. Later, as a professor of nursing, I teach public health nursing students to use logic models in order to conceptualize and plan community-based projects. Students report that the experience is challenging, yet one of the most rewarding learning experiences of the semester.

Debra Millar, MSN, RN, APHN-BC

Setting Measurable Goals and Objectives

Using the logic model as a guide, planned programs should have specific goals to help identify who the program is supposed to serve, what services are provided, the length of time the services are to be provided, and the resources that are needed. Then, measurable objectives are developed that describe the expected outcomes. Use of selected verbs indicates the expected level of achievement, such as "clients will be able to demonstrate safe administration of insulin after three home visits" or "parents will have their infants' recommended immunizations up to date by 24 months of age." Goal setting is imperative when developing an educational program for an entire health program or service (see Chapter 11). These statements of measurable goals are then examined during the program evaluation. Without such statements, accurate evaluations cannot be conducted.

One helpful acronym, SMART has been attributed to a number of authors since the 1960s including a 1981 publication by G.T. Doran (Morrison, 2010). Regardless of the original source, the acronym is frequently used in developing outcome measures. The general consensus is that SMART stands for *S*pecific, *M*easureable, *A*ttainable, *R*elevant, and *T*imely, and often, *E*valuate and *R*eevaluate are added (SMARTER). Display 12–4 describes specific questions that must be asked and answered at each step of the SMART process.

DISPLAY 12-4 DEVELOPING SMART OBJECTIVES

Specific

- What: What do we want to accomplish?
- Why: Specific reasons, purpose, or benefits of accomplishing the goal.
- Who: Who is involved?
- Where: Identify a location.
- Which: Identify requirements and constraints.

Measurable

- How much?
- How many?
- How will we know when it is accomplished?

Attainable

- How can the goal be accomplished?

Relevant

- Does this seem worthwhile?
- Is this the right time?
- Does this match our other efforts/needs?
- Are we the right group or agency?

Time-Bound or Timely

- When?
- What can we do 6 months from now?
- What can we do 6 weeks from now?
- What can we do today?

From Doran, G. T. (1981). There's a S.M.A.R.T. way to write management's goals and objectives. Management Review (American Management Association Forum), 70(11) 35–36; Meyer, P. J. (2003). What would you do if you knew you couldn't fail? Creating S.M.A.R.T Goals. Attitude is everything: If you want to succeed above and beyond. Waco, TX: Meyer Resource Group, Inc.; Wikipedia. (2016). SMART criteria. Retrieved from https://en.wikipedia.org/wiki/SMART_criteria

In evaluating programs and care, outcomes must be measured against certain standards. *Standards* are generic guidelines of expected functioning. They can focus on the client, the caregiver, or the organization (finances). All care and services must also be measured against these guidelines. The core standards of care, practice, and finance must be integrated and compatible if they are to ensure quality care.

Evaluating Outcomes

The outcomes or results of care (having the right things happen) are the desired effect of the structure (having the right things) and the processes (doing the right things). The focus on client outcomes demands continued analysis of structure and process, because these two components produce the desirable or undesirable outcomes. With the focus on outcomes, there has been an impetus to include positive outcome terms such as improved health status, functional ability, perceived quality of life, and client satisfaction. Client satisfaction is measured by how closely a client's expectations of nursing care match the perception of the nursing care actually received (Gordon, 2016). Client satisfaction, as one outcome measurement, can be determined by a telephone survey or a mailed questionnaire as well as confidential online surveys.

Using the causal pathway logic model as a guide, it is easy to link between planned program implementation and evaluation of success at all levels. See Display 12–5 for an example using a causal pathway logic model.

DISPLAY 12.5 CAUSAL PATHWAY FRAMEWORK EXAMPLE

Inputs	→	Where inputs available and utilized?
Activities	→	Were activities performed as planned?
Outputs	→	Were outputs produced?
Outcome	→	Were expected outcomes or effects observed?
Impact	→	Did the project achieve the desired long-term impact?

If the responses indicate that a program is meeting its goals, maintaining set standards, and having positive client outcomes and satisfied clients, the program is providing quality care. However, the accuracy of using outcomes as a primary measure of quality care is limited, because some clients have unsatisfactory outcomes despite receiving good care. Factors other than specific health interventions influence outcomes. These factors include a client's adherence to medically prescribed treatments; the progress of chronic or terminal disease beyond the capabilities of medicine, nursing care, or client behaviors; and the client's ability to respond to care as a result of such situations as a compromised immune system. Public health nurses need to keep such factors in mind when evaluating care.

Quality indicators of client outcomes are the quantitative measures of a client's response to care (Gordon, 2016). Defining and quantifying client outcomes from these indicators are worthwhile processes that enable the nursing staff to evaluate the results of

the care they provide. The goal of care in the community is successful client outcomes. By starting with measurable indicators, successful outcomes can be demonstrated in quantifiable terms. When client care meets the standards set, client satisfaction—another quality outcome indicator—is greater.

Quality indicators are part of the broader quality management program and are used to determine goal achievement. A chart audit is a useful method by which to measure the frequency of quality indicator occurrence. For example, an agency may have a quality indicator such as "all infants younger than 6 months of age are weighed on each home visit." Every fifth chart of infants visited in March, June, September, and December during a designated year is audited for documentation of the number of home visits and the number of infant weights recorded. A sampling of charts is sufficient to measure goal achievement and specific quality indicators. It is generally accepted that a sample of 20 randomly selected cases will provide useful information. If the population to be sampled numbers more than 200, some sources recommend that the sample include more than 20 cases.

Quantifying the indicators also can be accomplished through a rate or ratio of events for a defined population and time frame. Such indicators can be tailored to express almost any patient outcome. For example, in Display 12–6, the nursing staff sets a standard for the number of urinary tract infections (UTIs) the agency will tolerate in clients with indwelling urinary catheters (perhaps 5% to 7%, depending on client age, diagnosis, family support, and home environment). In another situation, a community/public health nursing service has a standard to make home visits within 5 days of delivery to first-time mothers and babies born at one hospital 95% of the time. To evaluate this goal, the dates of initial home visits to first-time mothers and the birth dates of the infants are measured from a sample of client records during several measurement periods. These are both examples of assessing quality outcome indicators.

DISPLAY 12.6 QUANTIFYING OUTCOME INDICATORS

$$\text{Outcome indicators} = \frac{\text{Number of patient care events}}{\text{Total number of clients of total number of times at risk for event during a given period}}$$

Example:

$$\text{Occurrence of urinary tract infections in clients with indwelling urinary catheters} = \frac{\text{Number of clients experiencing urinary tract infections related to long-term use of indwelling urinary catheters from January 1 to March 1, 2012}}{\text{Number of clients with long-term indwelling urinary catheters from January 1 to March 1, 2012}}$$

It is necessary to have indicators when setting standards in order to measure the success and quality of programs at home or in the community. The same types of indicators are used in acute care settings, with the focus appropriate to that population. If the standards are being met, but client outcomes are unacceptable, the process indicators are explored for possible areas of weakness. Such areas may need further study to identify the cause of the poor client outcomes. For example, a process indicator such as the catheter-care protocol used by an agency or the communication system between hospital and health department nurses may be examined to determine, respectively, the cause of infections or the reason why initial home visits are delayed. In addition, Medicaid and Medicare regulations in some states mandate that a percentage of records be audited each year.

While striving for excellence and best practices, agencies use the benchmarking process (Ettorchi-Tardy, Levif, & Michel, 2012). Benchmarking uses continuous, collaborative, and systematic processes for measuring and examining internal programs' strengths and weaknesses; benchmarking includes studying another's processes in order to improve one's own (Diffenderfer, Dunham-Taylor, & Malcolm, 2015). Internal benchmarking occurs within the organization, between departments or programs. External benchmarking occurs between similar agencies providing like services. For example, a home care agency may have developed a clinical pathway that has proved useful with clients with congestive heart failure; another agency could benefit by using the same clinical pathway. In another example, an agency may use clinical practice guidelines obtained from a specialty organization along with information from a national database; another agency could benefit from this knowledge. In this way, an agency identifies what is achievable while comparing and contrasting how others provide quality services. One example of benchmarking is a descriptive, comparative study of benchmark attainment by maternal and child health clients using the Omaha System (discussed later in this chapter and in Chapter 14). This study supported the use of benchmarking both to compare individual progress toward benchmark standards and to assess overall attainment of standards between programs offering similar services (Monsen et al., 2011a).

FIGURE 12–4 PHNs are team members in quality improvement.

Role of the Nurse in Quality Measurement and Improvement

Although nurses who deliver care directly to clients are not managers, as such, improving quality is a "management" activity. This is not only true of administration personnel but of the practicing nurses, as members of the team (Fig. 12–4). Public health nurses may or may not be responsible for a staff or agency budget and functioning, but they may be responsible for managing a caseload of clients with needs of varying degrees of urgency. With judicious use of the resources available, they must provide priority services that promote the highest possible level of personal and group functioning and health. Any activities the public health nurse engages in to realize these goals contribute to the quality management program.

Some quality improvement activities for public health nurses include daily prioritizing of care needs for a caseload of clients, seeking supervision or skills development for a difficult case, systematizing charting so that needed documentation is efficiently completed (e.g., using flow sheets to chart maternal–child health visits), proposing better ways to organize care of chronically ill clients, and establishing new agency procedures. All of these actions demonstrate that nurses are evaluating their work and looking for ways to improve care. Staff meetings, peer review, and case conferences are common settings for nurses to bring the lessons of their practices to the larger group for examination and potential adoption.

It is the role of nursing administration to develop a formalized quality management program that includes a three-pronged focus, based on a classic approach to quality management: (1) review organizational structure, personnel, and environment; (2) focus on standards of nursing care and methods of delivering nursing care (process); and (3) focus on the outcomes of that care (Donabedian, 2003). These formal evaluations include peer review audits (documented care delivered by peers), client satisfaction assessments, review of agency policies and procedures, analysis of demographic information, and the like (American Nurses Association, 2013; Issel, 2014; Stubbs & Achat, 2011). The issue of quality and safety has more recently been addressed through the QSEN project (QSEN, 2014). Building on the IOM reports *To Err is Human: Building a Safer Health System* (1999), *Keeping Patients Safe: Transforming the Work Environment for Nurses* (2004), and *The Future of Nursing: Leading Change, Advancing Health* (2011), the QSEN project provides a framework for nursing education. It also forms a sound basis for community health program evaluation, especially as it relates to professional quality. The QSEN competencies are consistent with the Donabedian approach to quality improvement. The project is discussed in more detail later in this chapter.

Nurses who are new to formal quality improvement activities in the work setting need to recognize the value of these efforts and their part in ensuring that quality care is being delivered. Direct service providers are the best judges of care problems and their potential solutions. For this reason, it is critical that quality assurance reviews and other quality

improvement activities focus on issues relevant to staff and client concerns and be structured so that they can be accomplished quickly and with minimal effort. When these activities are clear, concise, and well integrated into daily routines, they become less time-consuming, and staff members can see the positive client outcomes as rewards for their contributions to the process. Moreover, when health care providers have the opportunity to systematically examine the care they provide, they can generate useful ideas for improving that care and can identify care issues sooner.

Whether small or large, health care agencies are complex organizations with interrelated components. The nursing staff has input into or some control over the quality of care delivered to clients who use the services of the agency. The following paragraphs review the nurse's role in each of the three areas of structure, process, and outcomes.

Structure

The organizational structure and financial stability of the agency should allow the mission statement or philosophy to be realized (Dunham-Taylor, 2015). The agency should be client focused, with sufficient resources to maintain present services and introduce additional services as needed. Public agencies need to operate within budget and also have a well-developed system of acquiring additional funding for new services through grants and contract expansion. Private agencies should operate efficiently enough to realize a profit that encourages the owners and boards of directors to continue to support the services. They should look for additional ways to solicit clients, in addition to employing highly motivated and qualified staff.

Process

The agency should maintain standards set by the professional staff that comply with or surpass those recommended by the relevant accrediting bodies (Sills, 2015). The staff is encouraged to contribute to the evaluation of the standards and to revise them as needed. Staff members need to keep themselves current by attending in-service training sessions and acquiring additional education appropriate to their job requirements. The staff members work collaboratively with others across disciplines to improve the quality of care given in the community by using a variety of participative management tools (e.g., audit instruments, peer review). The agency is supportive of its staff and the needs of individuals. Staff turnover is minimal because employee values are compatible with the goals of the agency. Administration and staff have a compatible working relationship. A system of quality review is in place, and each staff member contributes to this process as a member of a peer review committee or quality improvement or assurance committee. Staff members also listen to clients and provide an outlet to evaluate the care received (e.g., questionnaires, surveys, interviews), and the agency acts on client suggestions and comments.

Outcomes

All services an agency provides should be reviewed periodically to determine whether standards are meeting the present needs of their population and whether the nursing staff are implementing these standards (Dunham-Taylor, 2015). The nursing services used most frequently, such as well-child care, self-care education with chronically ill adults, and various screening programs, are excellent places to begin the review. Usually, these services involve the entire nursing staff and consume a significant amount of nursing care time.

The focus on commonly served high-risk groups presents an opportunity to optimize care delivery as well as to benefit high-risk clients. Children living in neighborhoods that are known to have high lead toxicity rates from leaded paint in older homes stand to benefit tremendously from a consistently implemented lead screening, treatment, and advocacy program. Without review, such a program may not achieve its goals of decreasing toxic levels of lead affecting the area's children.

Incidents of poor client outcomes are important areas for further study. Through clinic or home visit records, community nurses can routinely review documentation of deceased or hospitalized clients to assess whether any aspect of the clinic's care or home visit activities might have prevented these occurrences. For instance, the case of a child with repeated high serum lead levels that requires hospitalization for chelation might stimulate a clinic's examination of the adequacy of parent education regarding environmental sources of lead. The clinic could also explore the effectiveness of its advocacy with the area's lead-abatement staff to ensure needed repairs in leaded homes and the removal of families to safe housing while repairs are being made.

As another example, a review of the charts of hospitalized clients who take multiple medications can be conducted to ascertain whether teaching or compliance issues regarding medication contributed to each client's hospitalization. The results may prompt a change in home visit teaching techniques, an increase in the frequency of visits, or a change in vital sign parameters for notifying a physician. Persistence of problems and deficiencies could be a clue that the public health nurse needs additional education in this area or that the nurse's caseload is too heavy and therefore exceeds the ability of the nurse to provide minimally expected care. Once the cause is determined, implementation of appropriate changes can commence, after allowing adequate time for the staff to address critical issues. Should additional education be needed, it is the responsibility of the coordinating, in-service, or staff education nurse to provide or arrange for the needed education.

Given adequate resources, including sufficient time, information, and support, good care is the norm. Occasionally, quality-of-care problems result from an individual provider's performance. Recommendations are made for counseling or another type of intervention by that person's supervisor, and appropriate corrective action should be taken to resolve the problem and preserve the employee's potential contributions as a successful team member.

Identification of quality health care characteristics and "checkpoints" for quality helps the community/public health care practitioner recognize the quality indicators of best

practice. These also give public health nurses direction for their role in quality measurement and improvement. This role is grounded in the structure, process, and outcomes of caregiving and services provided.

MODELS USEFUL IN PROGRAM EVALUATION

Models of client caregiving are based on structure, process, and outcome; ideally, they provide *structure* to guide nurses through the *nursing process* to reach desired *client outcomes*. Each of the following models has all three components; some work more effectively than others, depending on the agency and its philosophy.

Donabedian Model

Donabedian (1966, 1969, 1981, 1985, 2003), the country's premier researcher on health care quality, proposed a model for the structure, process, and outcome of quality that has been widely used as the framework for more elaborate models. The care environment structure—from philosophy to facility resources to personnel—is the first component. Next are the processes responsible for improving or stabilizing the client's health status, such as standards, attitudes, and effectiveness of tools used in caregiving (e.g., nursing care plans). Finally, the resultant outcomes are causally linked indicators of quality, such as client health care goals and effectiveness of service. The Donabedian model is recognized as a simplistic and basic method of measuring quality. Evaluation of this model found that the concepts were relevant to common domains of nursing and that it is helpful in program evaluation (Cohen & Shang, 2015). Structure, process, and outcome can be depicted in a box-shaped model (see Fig. 12–5).

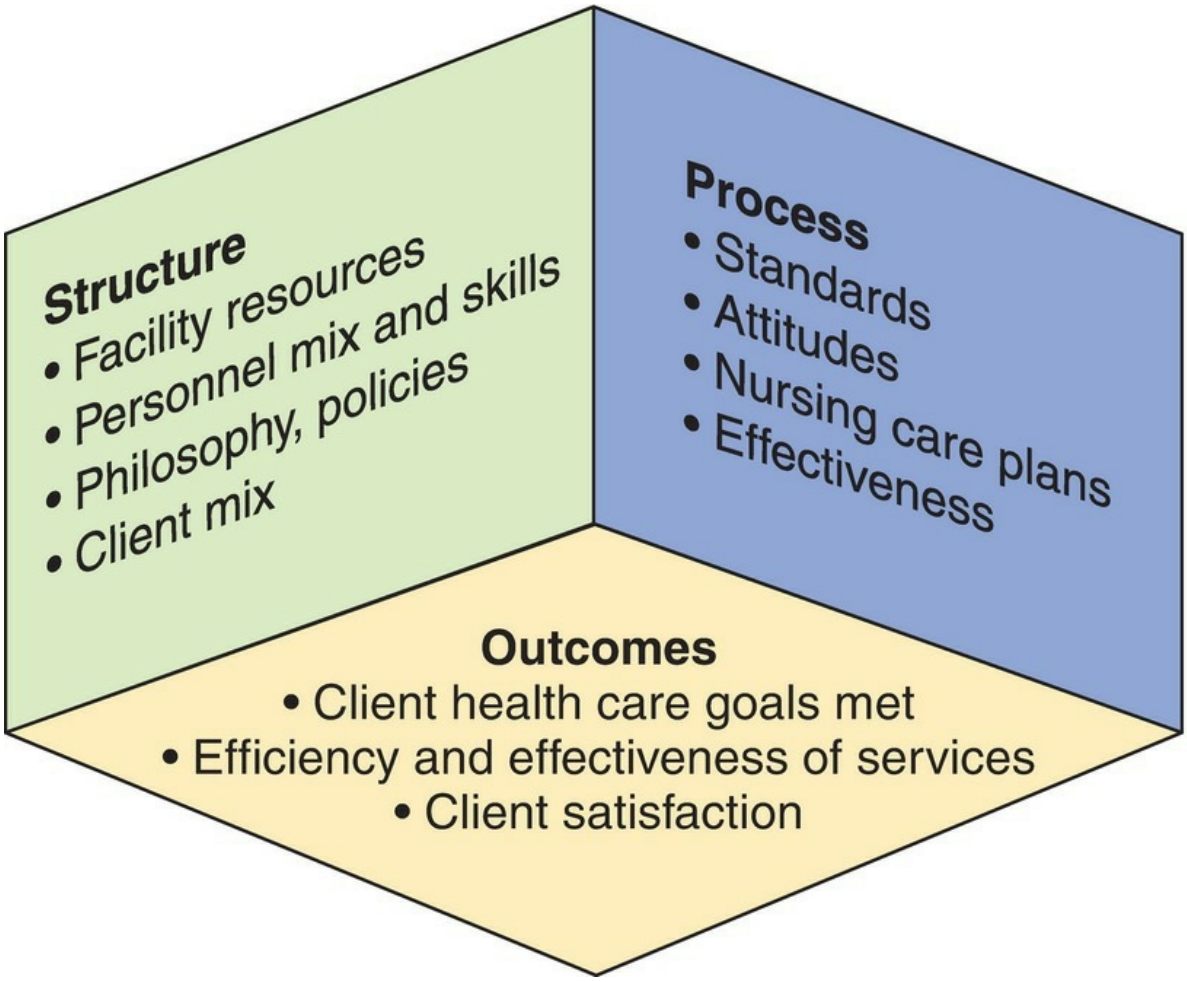

FIGURE 12–5 Structure, process, and outcome of quality model.

Quality Health Outcomes Model

Mitchell, Ferketich, and Jennings (1998) took the time-tested Donabedian model a step further. The Quality Health Outcomes Model includes the client in the model and proposes a two-dimensional relationship among components. Interventions always act through the system and the client, creating a dynamic model. The uniqueness of this model is the postulate that there are dynamic reciprocal relationships, and it has been used in studies as varied as organizing variable choices in acute and community care research, large multistate studies examining nurse skill and staffing mix with adverse patient events, and nursing care/patient satisfaction in several report cards on acute care. Self-care studies in chronic disease management, health-related quality of life, and health promotion studies have also benefited from the use of this model (Mitchell & Lang, 2004). A major criticism of other models is that they do not lend themselves to the population focus of community/public health nursing. However, this model includes community as a client. Cohen and Shang (2015) found that assumptions of reciprocal relationships in the model, as well as its ability for multilevel analysis and culturally sensitive inputs, served to broaden its appeal and applicability in a variety of areas. Figure 12–6 depicts the Quality Health Outcomes Model.

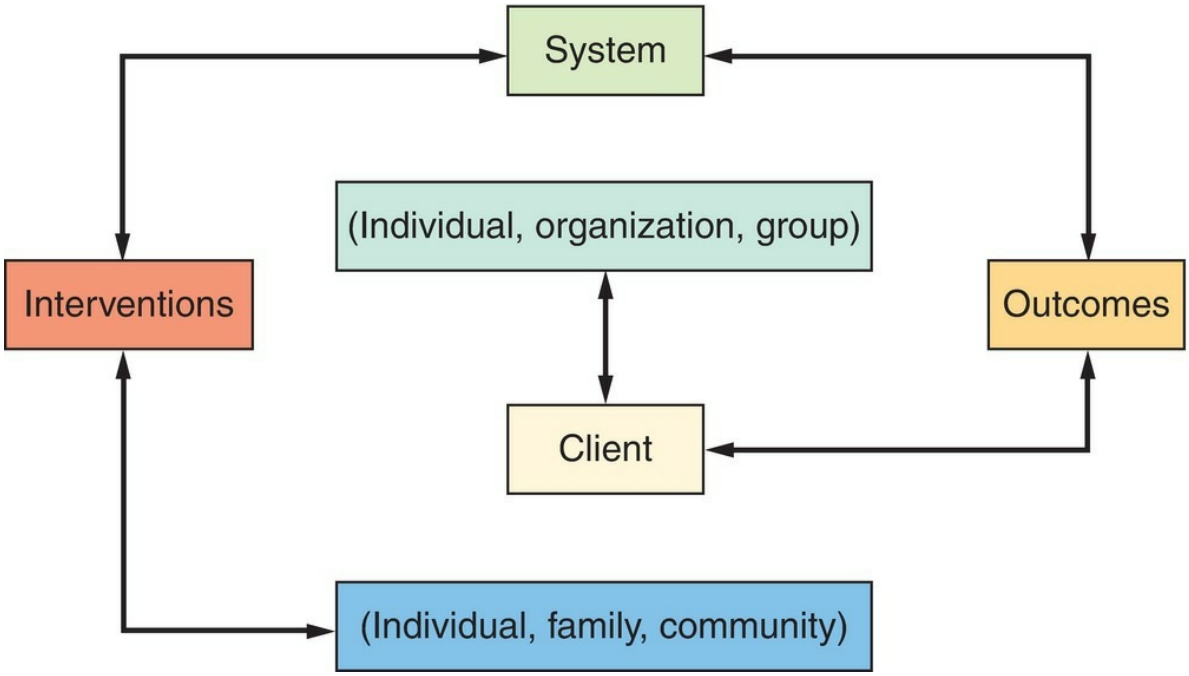

FIGURE 12–6 Quality Health Outcomes Model.

Omaha System

Also discussed in Chapter 14, the Omaha System has measurement approaches that make it a useful model for determining the quality of nursing care provided to individuals, families, and communities. Evaluation focuses on process indicators, client outcome measures, and satisfaction with care (Martin, Leak, & Aden, 1997). With the use of this multifocal approach, measurement of nursing practice becomes comprehensive. Although originally designed to evaluate care to individuals and families, the model has been modified to include the community (Martin, 2005). This revision was prompted by the wider use of the model to document population-based and community-level interventions. Community is defined as "groups, schools, clinics, neighborhoods, or other larger geographic areas that share a common physical environment and ownership of a health-related problem" (Martin, 2005, p. 464). Examples of the application of this model to community settings include a study of public health nursing interventions with at-risk families (Monsen, Radosevich, Kerr, & Fulkerson, 2011b), as well as nurse-managed wellness centers for vulnerable populations (Thompson, Monsen, Wanamaker, Augustyniak, & Thompson, 2012). In this model, outcomes are rated in terms of knowledge (what the client knows), behavior (what the client does), and status (how the client is). This approach allows for quantifying a range of severity, as well as progress either toward or away from optimal health. Ongoing monitoring of these aspects as they relate to individual, family, or community problems allows for evaluation of nursing interventions—a necessary component of both quality assurance and outcome assessment. For instance, individuals enrolled in a 6-week health promotion program on weight management can be assessed initially for their knowledge of healthy eating and exercise, their current behaviors relative to both, and their current health status (e.g., body mass index [BMI]). You can assess program outcomes by measuring those same indicators and then comparing the initially obtained individual and aggregated data with the data collected after the program is concluded. Whereas individual positive changes, such as decreased BMI, are a positive indicator, the impact on the entire group is of even more importance in terms of community-level health status. See From the Case Files I for an example using the Omaha System.

From the Case Files I

Using the Omaha System to Evaluate a Rural Satellite Clinic

A group of county health department public health nurses conducted an assessment of a community's need for a satellite health clinic in a rural part of the county. The nurses gathered data on population needs, age, health status, and accessibility to health care by surveying clients who lived in rural zip code areas and used the main health department. They also conducted a survey by mail of additional residents who were not presently using the health department clinic system for immunizations, screening for tuberculosis or sexually transmitted diseases, or well-baby visits, to see whether these people had unmet needs. After carefully analyzing the data, they began operating three 4-hour clinics during the first week of each month in an empty storeroom of the community pharmacy.

After funding the clinics for 6 months, the health department evaluated the effectiveness of this nursing service. The number of emergency room visits for infants in the area was compared with the number of visits during a similar period before the satellite clinic was established, as was the number of cases of influenza and pneumonia among residents older than 65 years of age. Finally, clients were surveyed in regard to their satisfaction with nursing care and services and were asked if there were any additional services they needed. Survey outcomes were supportive of continuing the clinics and adding an additional well-baby clinic, a dental clinic, and a prenatal clinic. Clients liked the convenience—older residents did not have to drive the 35 miles to the main clinic, parents were able to keep more closely to the recommended schedule for their children's immunizations, and they liked the shorter wait. Follow-up after HIV screening included the formation of an HIV/AIDS support group for clients and families in the rural area, meeting a need that no one had previously identified. The nurses combined clinic responsibilities with home visits in the area on clinic days and were able to do case finding, thus improving the overall health of this rural area.

The nurses were evaluated, and their charts were audited with the use of traditional tools, and clients received the same periodic surveys. Case conferences continued to be held among the nurses serving the rural area, and at times, cases were presented among the larger group of nurses. By utilizing the comprehensive Visiting Nurse Association of Omaha measurement approaches, they met the quality measurement needs of a population.

The Omaha System provides an organized method to assess individual-, family-, and community-level health. With ongoing research efforts, the utility of the model with

respect to program evaluation will be enhanced. Program evaluation studies such as exploring the models utility in nondirect patient interventions by nurse managers (Monsen & Newsom, 2011); use of the system in acute care settings (Monsen, Schenk, Schyeler, & Schiavenato, 2015), as a method of quantifying care coordination (Popejoy et al., 2015); and the body of evidence created from this standardized data (Bowles, 2011) continue to support the broader use of the Omaha System to assess programmatic effectiveness in many settings, including community health.

The Quality Practice Setting Attributes Model

This model, developed by the College of Nurses of Ontario in Canada, provides the foundational framework for a unique quality improvement approach to creating quality practice environments. The College of Nurses of Ontario is the regulatory body for registered nurses and registered practical nurses in the Province of Ontario, Canada; it has functions similar to those of the Board of Registered Nursing in each state in the United States. The Quality Practice Setting Attributes Model is used as a tool to assist in ensuring the quality of nursing practice and the nursing profession by promoting continuing competence among nurses in Canada (MacKay & Risk, 2001). The model provided the framework of the Practice Setting Consultation Program (MacKay & Risk, 2001); later known as the Quality Practice Environment Consultation Program (MacKay, 2007) of the College and Association of Registered Nurses of Alberta (CARNA), the program was developed to assist nurses and agencies in determining and advancing workplace characteristics that support the quality of professional nursing practice and certification (Brookes & Tansey, 2003; Patry, 2006; Saxe-Braithwaite, Carlton, & Bass, 2009).

This nurse-centered model of quality improvement is designed to contribute to the best possible health outcomes for the client, regardless of health care setting. The components of this quality assurance program include reflective nursing practice, practice review, and practice setting consultation. The first two components focus on nurses' individual responsibility for maintaining competence throughout their career; the practice setting consultation focuses on the practice environment in which nursing care is delivered. The governing body for nurses in Ontario, Canada, has relied on the Quality Practice Setting Attributes Model to improve nursing care quality in their province. As mentioned earlier, it also serves as a framework in Alberta (CARNA) in their nursing quality practice program. The model identifies seven key systems attributes in the work environment that create a quality practice setting. Figure 12–7 portrays this model and its components.

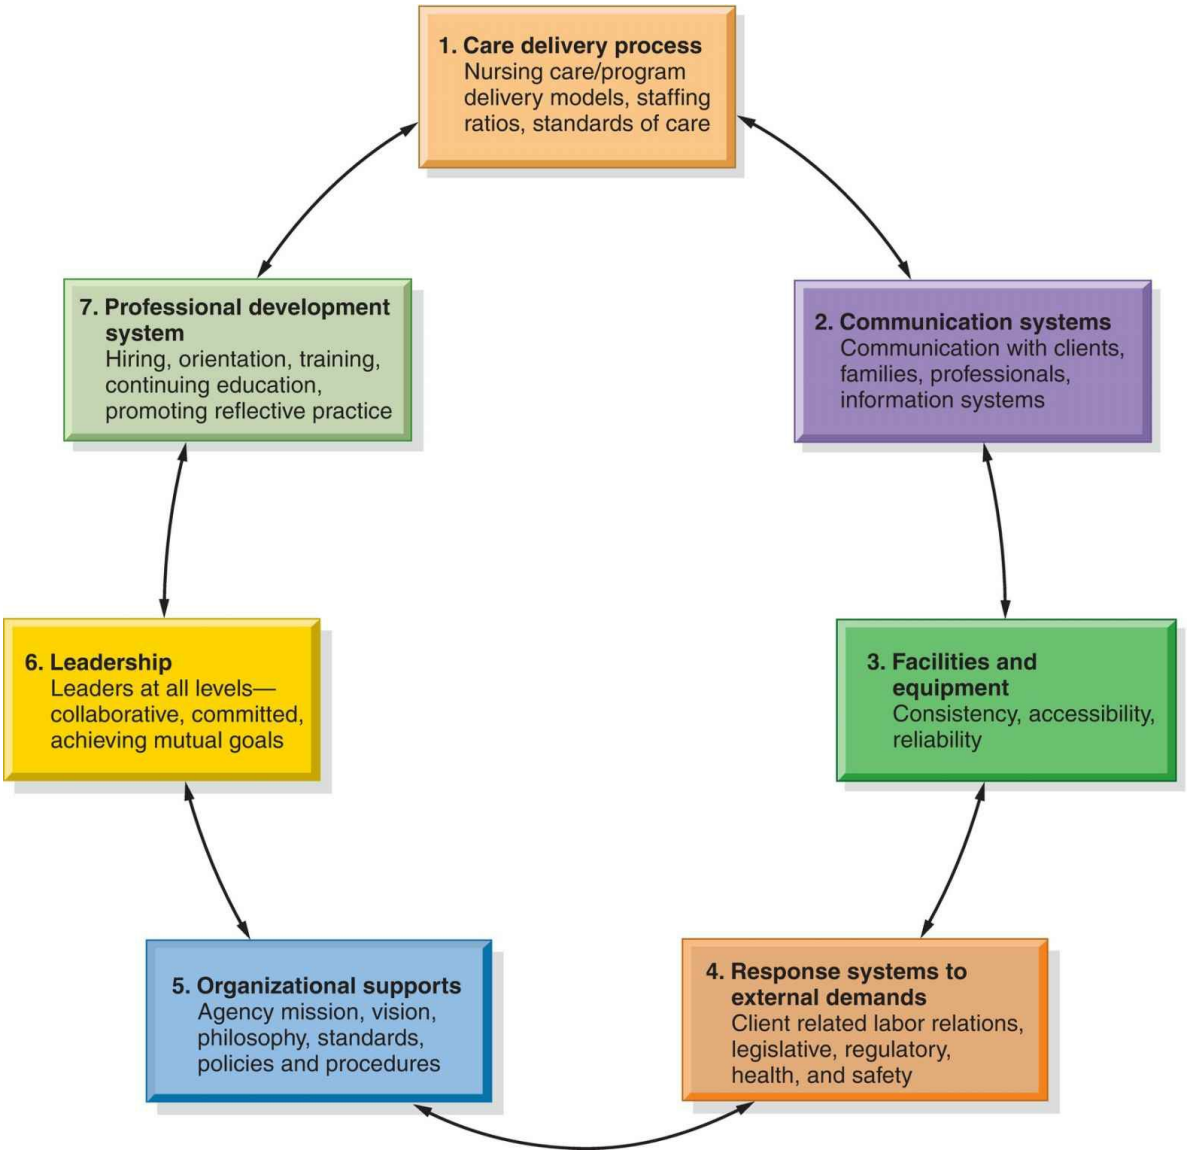

FIGURE 12–7 The Quality Practice Setting Attributes Model.

Quality and Safety Education for Nurses

Both the Magnet Recognition Program and the Pathway to Excellence Program focus on quality outcomes (similar to nurse-centered quality improvement in the Quality Practice Setting Attributes Model just discussed). Magnet hospitals have been shown to provide better work environments for nurses and have better nurse staffing and satisfaction measurements as well as patient satisfaction and outcomes (Dunham-Taylor, 2015; Kutney-Lee et al., 2015). As was mentioned earlier, the issue of quality and safety in health care was brought to the public's attention with the groundbreaking IOM (1999) report on medical errors and the subsequent 2004 report that focused on nursing quality and safety. This recognition promoted the funding by the Robert Wood Johnson Foundation of what has become known as the QSEN project. The purpose of the project is "the challenge of preparing future nurses who will have the knowledge, skills and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems within which they work" (QSEN, 2014, para. 1). Although QSEN is not presented in a diagrammatic form, it is nevertheless a model of quality improvement. Consistent with the taxonomy of educational objectives (Bloom, 1956; Miller, Linn & Gronlund, 2013) as discussed in Chapter 11, the foundational competencies delineated by KSAs can also be described as falling within the cognitive, psychomotor, and affective domains. The KSAs are also similar to the Omaha System outcome measures of knowledge (what the client knows), behavior (what the client does), and status (how the client is). Specific to QSEN (2014, para. 4), the prelicensure KSAs include:

- Patient-centered care
- Teamwork and collaboration
- Evidence-based practice
- Quality improvement
- Safety
- Informatics

Of most relevance to community/public health program assessment is quality improvement, which is defined as the use of data to monitor the outcomes of care and improving methods for changing quality and safety in health care. Barnsteiner et al. (2013) described the diffusion of QSEN competencies in the curricula of nursing schools. Dolansky and Moore (2013) call for these competencies to move beyond the individual to systems of care, bringing in more in line with the population-based focus of public health. The significance to community/public health nursing practice is that the QSEN competencies provide a method of both evaluating individual nurse performance and the use of aggregated data to assess programmatic outcomes. The KSAs can be used across all settings where a nurse may be employed, whether hospital, outpatient center, home care, hospice, or community/public health nursing services.

SOCIAL MARKETING

Each of the five program evaluation models presented provides a mechanism to plan, implement, and evaluate community-based programs and services. Emphasizing the importance of demonstrating quality through measurable outcomes is a crucial aspect of community health. Health promotion and health education programs must demonstrate achievement of stated goals to justify continuation. Likewise, the overall program, be it a health department or a community-based health center staffed by volunteers, is challenged to demonstrate quality outcomes through ongoing evaluation efforts. Community health services are also challenged to provide programs in ways that reach and engage their target populations. In this section, the role of social marketing is explored as an additional tool for community health care professionals to influence health behaviors and lifestyle choices. These methods must be selected carefully and evaluated against the same standards as previously presented, perhaps more so, because of the potentially higher costs of this type of intervention.

When you hear the words "texting and driving," do you think of the stories about the last text message sent by someone before a fatal crash? Or, have you watched the story of the woman showing her high school photo at age 16 when she started smoking and who now walks around her house dragging oxygen tubing because of her COPD? If you remember these, or ones like them, then social marketing has achieved its goal. Businesses have long recognized that providing "catchy" advertisements in a way that is memorable to the potential customer is vital to their success. Marketing can literally make or break their business. If the message is effective, they often have more business; if not, they may lose customers. The military has recognized the effectiveness of these advertising methods (e.g., military video games), using those same techniques in television and print advertising to increase recruitment. Children as young as 3 years have been found to be "branded" with current fast food items and beverages, meaning they recognize and prefer one particular brand or logo over another (Bryner, 2010; McAlister & Cornwell, 2010). The techniques used by some of these businesses and corporations have in many ways contributed to health issues we currently face as a nation (i.e., obesity in children, teenage smoking). A line of research examining knowledge of brands with products high in salt, fat, and sugar among 3- to 6-year-old children found that this brand knowledge was a significant predictor of the child's BMI. Researchers controlled for gender, age, and the amount of television viewing time and concluded that this had policy implications because of exposure to these products and their consumption being tied to higher BMI scores (Cornwell, McAlister, & Polmear-Swendris, 2014).

The public health care sector has also recognized the power of marketing health messages. Although used in some capacity since the 1960s, not until the 1990s—when federal agencies, such as the Centers for Disease Control and Prevention (CDC) spearheaded efforts—did it gain the attention it now has in addressing health issues (Lee &

Kotler, 2016). The term social marketing refers to using marketing principles to influence or advance "a social cause, idea or behavior" (p. 14). Much of this began in the area of public health but has extended into environmental causes, poverty, and community advocacy. The main outcome of social marketing is to improve society's health, by influencing changes in individual health behaviors (e.g., healthy eating), or implementation of policies that impact health behaviors of a population (e.g., seat belt laws). The integration of marketing with public health practice is seen as a useful method to increase the effectiveness of public health practitioners (Resnick & Siegel, 2013).

Concepts that are important in marketing are applicable to social marketing as well (Resnick & Siegel, 2013). These include the following:

- Exchange: An individual gives something to get something; the person weighs the cost and the perceived benefits.
- Self-interest: People act in their own interests in most cases.
- Behavior change: Change in behavior is the focus; thoughts and ideas may also need to change but are not the ultimate goal.
- Competition: Selecting one option (or action) inherently involves giving up another option (or action).
- Consumer orientation: Problem-solving process is directed at the target—the consumer (could be an individual, group, or organization).
- Four P's (product, price, place, and promotion): Also called the marketing mix; each can be altered to increase market share.
- Partners and policy: Other organizations that share similar interests and could provide opportunities to work together; identification of policy changes necessary for behavioral change, those supportive of the change, and those that the organization could help influence.

These principles seem rather straightforward, yet public health practitioners are often at a disadvantage when attempting to implement social marketing campaigns (Resnick & Siegel, 2013). They often lack training in the necessary skills, may be outspent by the competition (e.g., the fast food industry), or have limited access for the distribution of their message (e.g., public service announcements). One example of a very successful social marketing campaign is the *Go Red for Women* initiative begun in 2004 by the American Heart Association (2016). Using a red dress as the symbol of the program, the initiative seeks to raise awareness of heart disease among women. These health issues are equally important, but one has a more broadly recognized campaign; the other was humorous but not necessarily well received. Ultimately, the issue is whether or not behaviors have been changed and health outcomes improved as a result of these social marketing campaigns. Time will be the judge of all these efforts (see Chapter 11; Fig. 12–8).

FIGURE 12–8 *Go Red for Women*, the American Heart Association's social marketing

campaign about heart disease in women, has successfully raised awareness about heart disease among women.

Cates, Ortiz, Shafer, Romocki, and Coyne-Beasley (2012) reported on a qualitative study to explore messaging that was most effective in promoting vaccination for human papillomavirus (HPV) of preteen age boys. Focus groups of parents were conducted and transcripts coded using a constant comparison method to interpret themes. Although the parents knew little about HPV and the vaccine, they supported vaccination of their children, yet did express concern about safety and cost. From a social marketing perspective, the messages that were most motivating focused on infection risk and those that included images of the parents with their sons, providing a visual and more personal link to the parental role (Cates et al., 2012). This study exemplifies the importance of framing health-related messages in a manner that is appealing, relevant to the situation, and acceptable to the audience.

How can social marketing principles be utilized when you have a limited budget, limited time, and limited creativity? See From the Case Files II.

From the Case Files II

Nursing Students and a Social Marketing Campaign

University campuses hold a wealth of often-untapped expertise. For nursing students working on a health promotion program, the substance of the effort (the health issue) is often pretty straightforward, but the presentation is more challenging. Many schools of nursing are providing collaborative experiences for students, supporting partnering with nonnursing students and faculty in addressing health education needs. The following is one example of how collaboration can be effective: Two nursing students recognized that off-campus housing lacked sufficient smoke detectors because of a "loophole" in state and local building codes. This meant that students living in the most high-risk housing for fires (older buildings) might only have one smoke detector in the entire apartment; this was clearly inadequate. After discussing the issue with their faculty member, they sought input from several student organizations. From those discussions, they identified a low level of knowledge about the issue and modest concern by the students present. Recognizing that college students are not prone to worrying about how many smoke detectors they have, the nursing students sought help from the university housing department. The staff of housing agreed that this was an important issue, and they were willing to post information on the housing Web site regarding the need to install additional smoke detectors. The students didn't know how to develop online materials, but based on input from the student groups, they knew that it had to be eye-catching and quickly present a message. In conjunction with their faculty advisor, they contacted the graphic arts department and found an instructor who was willing to include the development of an online smoke detector campaign as part of a class assignment. The nursing students provided the educational information that needed to be included, and the graphic arts students proceeded to develop a campaign within those parameters. In the end, several outstanding examples were submitted, and one was selected and posted on the housing Web site. The campaign was particularly effective with parents who saw the campaign on the Web site as they helped in apartment searches. Many messages were sent to the Web site by the parents regarding the campaign, and the responses were handled by the nursing students. The campaign was not expensive, and it identified the most skilled individuals for each task (health information, nursing students; Web-based campaign, graphic arts students). It also provided much-needed health and safety information to the university students and their parents. Even though they had targeted the college students, the nursing students found that the parents were much more interested in the campaign. The results of this initial effort provided vital information for future campaigns that might target parents, students, apartment management, and the local building code enforcement office.

Can you think of an issue on your university campus that could benefit from

social marketing? Do you recognize any social marketing efforts sponsored by your university or your school of nursing?

When planning for and beginning development of a social marketing approach, there are many resources available to the public health nurse and other public health professionals. The Centers for Disease Control and Prevention offers an excellent Web site, *Gateway to Health Communications and Social Marketing* (CDC, 2016a) that includes links to a wide variety of resources. For instance, one of the social marketing resources, *Social Marketing for Nutrition and Physical Activity Web Course*, is available through the Division of Nutrition, Physical Activity, and Obesity (CDC, 2011). The European Centre for Disease Prevention and Control (2014) offers a comprehensive *Social Marketing Guide for Public Health Programme Managers and Practitioners.* Another very helpful publication is *Using Social Media Platforms to Amplify Public Health Messages* (Ogilvy Washington & the Center for Social Impact Communication at Georgetown University, 2010). Heldman, Schindelar, and Weaver (2013) provide information that goes beyond mass dissemination of public health information and shows the benefits of engaging your targeted audience in "true multiway conversations and interactions" as a means of providing more powerful social media impact (para. 1). There are also downsides to this approach.

The plethora of social marketing campaigns have raised a spotlight on ethical issues that need to be carefully considered when designing, implementing, and evaluating social marketing programs (Carter et al., 2011). The International Union for Health Promotion and Education (2016) is dedicated to seeing optimum health and well-being globally. Their values highlight the importance of ethics in this arena:

- Respect—for the innate dignity of all people; for cultural identity; for cultural diversity; and for natural resources and the environment
- Inclusion and involvement of people in making the decisions that shape their lives and impact upon their health and well-being
- Equity in health, social and economic outcomes for all people
- Accountability and transparency—within governments, organizations and communities
- Sustainability
- Social justice for all people
- Compassion and empowerment (International Union for Health Promotion and Education, 2016, para. 3)

As Carter et al. (2011) point out "the need to integrate evidence and ethics in health promotion becomes especially critical when large-scale intervention for a problem is urged, but guidance for action is limited" (para. 4).

Social marketing is not a panacea, but it does provide techniques that can support health education and health promotion programs. The method can be very expensive and very elaborate, or it can provide simple, straightforward messages. The point is that well-

presented marketing can be the difference in whether behavior changes are made or not. Media messages are not a replacement for a sound health promotion program; they are just one tool that can be used for great impact.

GRANTS

Grants are a reality in public health efforts. They are not easy to locate, easy to secure, or easy to manage once you have one, but they are vital to providing a wide range of programs and services in the community. Many local and county health departments see them as an integral part of their service delivery, even hiring grant writers and grant managers in some cases. For most health departments, community agencies, and volunteer service providers, the task of locating grant funds, writing the grant application, and doing the work stipulated by the grant all falls on the nurses and other professionals within those agencies. On the positive side, it provides an opportunity for community health nurses to explain to others what they can provide to the community in terms of services and programs targeting the community's health. Some basic knowledge about grants can demystify the topic.

Even if you aren't ever required to write a grant, you will likely be involved in some part of a programmatic grant at some point in your career, either in the delivery of services stipulated by the grant (product) or in evaluating the outcomes of the services provided (i.e., satisfaction surveys). You may even be asked to provide ideas for specific services to be included in the grant application; take advantage of these opportunities. The experience you gain will enhance your knowledge of the process and may prove instrumental in future efforts you may be involved with. The grant process, although arduous, provides the opportunity to focus clearly on what you intend to accomplish, why it is needed, and what part you will play in the successful outcome of the project. This is similar to a job interview, in which your prospective employer asks you *"Why should we hire you? What will you contribute to this organization?"* You have a limited amount of time to express your worth. You have to be very specific and concise about what you and your organization or group will be doing to address a specific need. You are making the case that providing you with support is the best choice.

What exactly is a grant? A grant is, very simply, one individual or group providing another individual or group with the support (i.e., money) for a specified purpose. In health promotion and education, it generally means funding for program development or project support. These types of grants fall into the following common categories: planning grants (i.e., initial project development), start-up grants (i.e., seed money), management or technical assistance grants (e.g., for fund raising or marketing), research grants, and facilities or equipment grants (National Institutes of Health, 2016). This money doesn't typically need to be paid back; however, it is a contractual agreement, and the terms and conditions are usually clearly delineated. Federal grants award government funds to implement projects that provide public service and stimulate the economy (Grants.gov, 2016). Federal grants are available from 26 grant-making agencies. The funding categories most applicable to community health include community development, disaster preparation and relief, food and nutrition, and health. Federal grants are available to a wide variety of groups, but typically, health-related grants are available to state or local governments, which include

public health departments, public housing organizations, educational organizations, and nonprofit organizations (Grants.gov, 2016).

What is a *nonprofit organization*? Nonprofit means that the organization was not established to earn a profit. This does not mean that it doesn't generate income, only that there are restrictions on how those funds can be used. Of particular importance to the discussion of grants is the term *501c3*. This is a designation that refers to the Internal Revenue Service (IRS) tax-exempt status granted to certain nonprofit organizations. To be granted this designation, an organization must be organized and operated exclusively for specific purposes, which include charity, science, education, or the prevention of cruelty to children or animals (Internal Revenue Service, Department of the Treasury, 2016). Some grants are only available to 501c3 organizations, and the funders will request proof of this in the grant application. Only corporations, community chests, funds, or foundations can receive this designation; individuals or partnerships do not qualify (Internal Revenue Service, Department of the Treasury, 2016). Essentially, the 501c3 organization can be the provider of the grant funding or the organization seeking the funding.

Grants are available from government sources, private philanthropic sources, and corporations. Federal grants can be found on the Web site www.grants.gov or on individual federal agency Web sites. Private organizations often have sections on their Web sites with information on available grant funding. This is likewise the case with corporations. This broad search approach is not a terribly effective way to find grants; to improve search efficiency, a number of proprietary grant-locating programs are available. These programs are very expensive and, because of cost considerations, often are licensed only to large organizations, such as universities and medical centers. They allow the user the ability to limit the search (e.g., type of funder, health issue, age group, program or research grant, funding limits, and time frame for submission). For the small nonprofit organization seeking funding, one effective approach is to partner with a local university, which allows for more access to grant-locating programs, as well as the expertise offered on the campuses (e.g., content area experts, experienced researchers, statisticians, business plan experts). These partnerships are becoming more attractive, as they meet the needs not only of the nonprofit agency but of the university's school of nursing. An integrative review of over 300 articles on academic-service partnerships found common themes (Beal, 2012). These included:

- Recognize the prerequisites for successful partnerships (e.g., acknowledge difficulty/time-intensiveness, assessment of both individual and mutual opportunities/strengths, base on shared trust/respect/commitment/goals/vision, commit to open/ongoing communication/problem-solving, develop structured leadership and accountability).
- Understand the benefits of partnerships (e.g., nursing esteem and visibility increased, resources maximized, opportunities for nursing student learning/faculty practice, benefits of greater retention/recruitment).

Many grants require proof of some type of interdisciplinary or community involvement. Some grant funders allow letters of inquiry to be submitted prior to an actual full grant application. The letter of inquiry may be by invitation-only or be part of the original advertisement of the grant funding. In any case, this letter is normally only two or three pages in length and includes a concise overview of the project. For example, Karsh and Fox (2014) note that a letter of inquiry would likely include an overview of your organization and its purpose, the reason for the funding request, clearly stated need or problem to be addressed, overview of the proposed project or program, and other funding sources for your project or program (prospective and committed). This letter is brief, yet clearly lays out your plan. Your goal is to be invited to submit a full proposal for consideration. If this approach is successful, you will be asked to complete the organization's application process (the proposal), which can vary in length and complexity depending on the organization.

Crucial to either the letter of inquiry or the full proposal is that you have selected a funder that is a good match for your organization and your program/project. For instance, applying to a faith-based organization that supports abstinence-only educational programs would not be a good fit for your program that seeks to provide contraceptive information in an after-school program for teens. Before you spend valuable time and energy writing a letter of inquiry or a grant application, be sure to do your homework. The Internet provides a quick method for reviewing potential funders, their vision, mission, and types of previous funding. You may even be able to find out the monetary range of grants funded by the organization. Perhaps you have a small grant request and find that the organization you are reviewing only funds large multimillion-dollar projects; it might be best to look for other options. The Web site will likely have contact information; making a phone call can assure you that this organization is a good match for your project and can give you an opportunity to start building a relationship with their staff.

Grants are most often competitive—which means you can expect to have competition from other deserving groups—so be prepared. A well-prepared grant—one that carefully follows the application guidelines specified in the request for proposals (RFPs) and very clearly describes the program you are seeking support for—is more likely to be funded. The request for proposals (RFPs) outlines the specific requirements of the application, the information to include and in what order, and what supplemental forms to include, if any. Submitting a grant after the deadline and not including all required items will mean that your grant application is not likely to be reviewed. If your grant is not selected, make certain to contact the funder to see if they will provide you with a review of your submission; this is common with government-sponsored grants. With knowledge of what hampered your selection, you will be in a much better position to resubmit to this funding source again or to be more prepared for other grant opportunities. Another suggestion for new grant writers is to seek the help of an experienced mentor—someone who has been successful in grant writing—as they can critique your proposal prior to submission and offer suggestions.

The following tips may be helpful as you begin the process of seeking grant funding (Federal Grants Wire, 2016):

- Gain a sound understanding of the grant and specific criteria required, ensuring that your interests and intensions are in line with the grantor agency.
- Seek input from the community that services are meant to benefit.
- Compile all required documents, such as articles of information, tax exemption certificated, etc.
- Organize the proposal to conform to the requirements of the call for applications. The order of contents may vary but in general include a proposal summary, problem statement, project goal and objectives, project methods or designing, project evaluation, and budget.
- Review, proofread, and ensure all requirements met prior to submitting your proposal.
- Ensure the proposal is submitted prior to the deadline.

One reality of grant funding is that experience counts. If you have a proven record in securing grants and completing the requirements specified in those grants, you or your organization will have an easier time securing additional funding. For the new grant seeker, this can be a bit discouraging. So, where to begin? Don't start with the most complicated grants available. Look for small local grants with a proven track record in grant management, and build your reputation. Work with partners. A school of nursing could partner with a home health agency to write a grant to provide worksite wellness programs for uninsured agricultural workers. Or several faith-community groups could partner in a grant application to provide free health screenings for uninsured adults in their area. Finally, be certain that the grant will allow you to meet the mission and goals of your program. The grant funder will also be looking to see if their support will enable you to provide a service that you have both the skill and expertise to accomplish. With limited funds available, funders are looking for proof of the sustainability of your program after their support ends. For instance, a breast-feeding support program sought funding in a high-risk area where there was a clear need. Although the need was demonstrated, the agency had no plan for continuing the program after the funding ended; they did not receive funding. Grant support is often seen as funding to get programs started—not to provide for long-term operations (Karsh & Fox, 2014).

Many courses are available to assist you in understanding how to locate grants, write them, and be successful in your attempts. Your local library is another source of information, and a wide variety of information is available on the Internet. Some examples of helpful Web sites are included in the Internet Resources found on *thePoint*.

SUMMARY

Successful community health programs require that the nurse listen to the target population and not determine the problem and solution without their assistance. Awareness of predisposing, reinforcing, and enabling factors facilitates the assessment of health-related behaviors. Importance and changeability are important considerations when determining priorities among competing behavioral targets. Community-based participatory research is an effective method to increase engagement. An advisory group, with representation from the target and service communities, is an effective tool in helping to identify the problem, select appropriate interventions to address the problem, and evaluate the outcomes of the interventions chosen. Outcome measures should be consistent with the concerns of the community. Evaluation can be facilitated by clearly defined goals that can be measured against actual results.

The multiple models or frameworks on which quality management systems are based include a classic way of looking at programs through organizational structure, process, and outcomes, along with the interrelatedness of each component. The six models presented in this chapter are structured in unique ways that enable them to meet the differing needs of community agencies. Whether quality measurement and improvement techniques are formally or informally practiced, whenever nurses monitor, assess, and judge the quality and appropriateness of care as measured against professional standards, the interests of clients are being served.

Social marketing is one tool that can enhance health promotion efforts in the community. Media messages are particularly helpful in reaching large audiences. The basis of social marketing is similar to product marketing to consumers. The goal of consumer marketing is not necessarily to change the way people think but the way they behave. Social marketing seeks to first change behavior and then to influence how people think about health, lifestyle, and the choices they make every day that influence their health. One example of social marketing is the American Heart Association *Go Red for Women* campaign, which seeks to bring attention to heart disease risk among women. Social marketing, like any consumer-focused marketing, must consider the target population in the design, implementation, and evaluation of the effort. Successful outcomes are imperative for continuation of this type of program, as with any other health promotion campaign.

Grants are increasingly vital to providing health promotion programs and services in the community. Community health nurses frequently are involved in some aspect of a grant program, whether in the writing, in implementation of the program or services stipulated in the grant, or in the evaluation of the outcomes for the grant. Grants are available from government sources, private philanthropic sources, and corporations. Successful grant proposals comply with the instructions provided in the RFPs. Community agencies and academic programs can collaborate in providing community services and

evaluation research that seeks to improve the lives of the target population. Mastering the grant process, from formulating the goal to defining the evaluation methods, is a skill that can benefit all manner of health promotion programs, whether funded or not.

Community/public health nurses are in a key position to plan, implement, and evaluate all types of health promotion/health education programs. Knowledge of the target population and engaging the target population in determining the problem and solutions are vital to successful outcomes. Ongoing use of quality measurement techniques and application of recognized professional standards help assure effective and appropriate service delivery. Social marketing is a tool that can be effective in reaching large audiences with valuable health messages. Finally, the skills gained in working on any portion of a grant effort can be utilized in future programmatic efforts, whether supported through funding or not.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Evaluate examples of community assessments and subsequent program planning and implementation based upon them (from local or state public health departments, community agencies, or the Web site: https://www.healthypeople.gov/2020/LHI/whosleading.aspx). Which *Healthy People 2020* topics and objectives, or leading health indicators, are represented in this assessment/program plan? How were the program objectives achieved? How effective was the program in meeting the assessed needs of the population?
2. A faculty member who teaches acute care nursing approaches a group of nursing students about a problem she has identified. She informs them that there is a high incidence of *Chlamydia* infection in a local community among Spanish-speaking people. The hospital where she and her students have clinical rotations wants to do something to reduce the incidence of *Chlamydia*. The faculty member has found a pamphlet online that describes *Chlamydia* infection, how it's diagnosed, and how it's treated. She thinks it would be a wonderful idea for the student PHNs to translate the pamphlet into Spanish.
   a. Do you feel that this is an appropriate intervention?
   b. What data should be gathered? What literature should be reviewed?
   c. What agencies, organizations, and groups should the students contact?
   d. Who is the target population?
   e. What outreach should be done with this population? What information should be gathered from the population prior to developing any educational materials?
   f. What steps should the students take to ensure that the target population finds the educational materials they develop to be appropriate, acceptable, and understandable?
3. A school nurse works in a rural agricultural community. The main crop is rice. Every year after harvesting the rice, the local farmers burn their rice fields. The school nurse notes a significant increase in absences during this period for respiratory problems, especially asthma. She notes that even the teachers have increasing respiratory problems. She believes that the burning rice fields may aggravate the respiratory problems. She mentions her concerns about the relationship between the fields burning and increased respiratory-related illnesses to the school principal. He responds that while it may be true, the local farmers control the local community—without them, the community would collapse. He states that kids and adults will just have to adjust.
   a. What can the nurse do to determine if the burning rice fields are a threat to the health of children and adults in the local area? (What data should be gathered, what literature should be reviewed, to whom should she talk?) See Chapter 9.

b. What steps should she take to increase interest in addressing this problem?
c. What agencies, organizations, and groups should she contact? Who are the stakeholders?

4. Identify a health-related social marketing campaign that you viewed recently on television, social media sites, or in print. Who is the target audience? What is the main message it is sending? What is the target behavior or problem? Does it reach the target audience? How effective is it?
5. Organize a group of nursing students and meet with other students on campus about public health issues that affect them (e.g., housing, safety on campus, lack of healthy food choices, health issues). Brainstorm possible ways social marketing could be helpful in addressing this issue. Identify who you might work with to address this issue. What message do you want to send and what is the most cost-effective and practical way to do this?
6. Search for examples of social marketing campaigns (e.g., Red Dress campaign) and discuss them in your clinical group. What works? What doesn't seem to be effective? How could you improve on methods to reach the target audience?
7. Talk with PHNs at your local or state public health department. How many and what types of grants do they have? What programs do they fund exclusively from grant writing? How do they manage grant funding and data gathering to justify outcomes for grant funders?

13 CHAPTER

Policy Making and Community Health Advocacy

"Never doubt that a small group of thoughtful citizens can change the world. Indeed, it is the only thing that ever has."

—Margaret Mead

KEY TERMS

Advocacy
Community health advocacy
Distributive health policy
Empowerment
Grassroots
Health policy
Lobbying
Lobbyists
Polarization
Policy
Policy analysis
Political action
Political action committee (PAC)
Politics
Power
Public policy
Redistributive health policy
Regulatory health policies
Special interest groups

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify three measures of population health relevant for national comparisons.
- Describe the relationship between social policy and health outcomes.
- Define health policy and explain how it is established.
- Provide one health-relevant example of each of the four types of policy.
- Discuss policy examples for legislation, regulation, and policy modification.
- Identify a health policy issue for each level of jurisdiction (local, state, national).
- Identify one current health policy issue of interest to public health nursing in terms of the policy problem, the solution, interested parties, and their relative power and influence.
- Describe the five components of the rational framework for policy analysis and identify when it would

be most useful for PHNs.
- Define the three components of Kingdon's framework for policy analysis and identify when it would be most useful for PHNs.
- Identify three possible ways a PHN could engage in policy activism.
- Explain the role of special interest groups in health care legislation and policy making.
- Identify the difference between advocacy and lobbying, as well as the influence of both on policy.
- Discuss power and empowerment and the roles these concepts play in policy development.
- Describe three new Affordable Care Act (ACA) policies that impact the health of the public.
- For each ACA policy, identify one PHN policy-relevant activity that could improve the health of the public.
- Identify two methods of communicating with legislators on advocacy or policy issues.

Behind all legislation and health care regulation lie power struggles. Only the very naive think that others will be persuaded by facts alone. In all legislative activities and reforms, social and political factions are at work—special interest groups, business, and industry each bring their power into play. Because the outcomes of these struggles determine the availability and quality of all health and social services, nurses need to develop a working knowledge of the political process and health policy in order to protect the individuals, families, and communities they serve, as well as their own nursing practice. This chapter examines health policy, the political process involved in determining health policy, and the role of public health nursing in the process. Community health nurses should provide not only input to policy circles through advocacy but also leadership at decision-making tables. Nurses must understand and emphasize their powerful role in providing an essential influence and unique perspective in health care.

Health policy consists of the rules, regulations, legislation, and funding that we, as members of the public, choose to invest in providing, regulating, and researching health care for our fellow Americans. Although we may often be unaware of policy specifics, by virtue of our rights to vote, and the way our governmental system is designed, we are responsible for policy outcomes. For public health nurses, these outcomes affect us personally, but also impact the communities in which we practice —and the health of our neighbors. If we define public health nursing as being related to impacting the health of populations, then the public health nurse needs to understand how health policy impacts health outcomes. In this chapter, we will discuss the current state of the health of Americans, how policy impacts health, how policy is developed, and how PHNs can be involved in health policy formation. We will discuss specific examples of PHN policy involvement and potential action, given the current health care policy changes in the United States.

What do *you* think?

Of all the shocking and inhumane in society; the lack of access to health care is the most

inhumane.

Martin Luther King, Jr. Memorial. (Photo courtesy of NPS.org)

—Dr. Martin Luther King

In the decade or so leading up to President Clinton's attempt at health care reform, the debate about access to health care centered on whether health care was a *right* or a *privilege*. What do you think? Given that so many millions of Americans were without any access to insurance or health care before the Patient Protection and Affordable Care Act (ACA) was passed, should there be some basic rights regarding access to services as found in most other developed nations (e.g., a safety net)? Or is this a privilege that should be earned? What are your thoughts on President Obama's health care reform and how it is being implemented? Has it affected you or someone you know?

HEALTH IN THESE UNITED STATES: HOW HEALTHY ARE WE?

The United States is often touted as having the best health care system in the world. It is recognized worldwide for achievements in the medical and auxiliary sciences that have contributed to the mapping of the genome, advances in biomedical technologies, and increasing numbers of pharmaceuticals that hold promise for addressing the myriad chronic and acute illnesses that affect the world's populations. People often come from other countries to the United States to access our high-quality medical care.

It is well understood that the U.S. health care system is expensive. Current data indicate that the United States spends 17.5% of its gross domestic product (GDP) on health care costs; this is twice as much as the average health care expenditures from countries with similar levels of economic development (Center for Medicare and Medicaid Services [CMS], n.d.; Organization for Economic Cooperation & Development, 2015). High expenditures are not necessarily problematic. Two questions need to be asked: (1) Can the country afford this amount of expenditure for health care? That is, do these expenditures prevent the country from spending resources on other necessities or socially desirable goods? (2) Are the costs worth it? That is, are we getting what we want from these expenditures? The first question is a larger political question, as the nation grapples with where to spend its public funds, because any increase in one area necessarily causes a decrease in another, as resources are never without limits. The government is responsible for debating and deciding these trade-offs, and that debate is not going to be addressed here. However, the second question is relevant to discuss in this chapter. For the amount the United States spends on health care, are we achieving the results we desire? In other words, how healthy is the public? See What Do You Think?

Chapter 6 presented outcomes for health in the United States and comparison countries. As stated earlier, the U.S. health outcomes are very mixed, especially given the cost of the overall health care system. The United States does not compare well to countries at similar levels of economic development in the areas of life expectancy, mortality rates for chronic illnesses, mortality rates for communicable disease, and infant mortality, among other health measures. The recent Institute of Medicine report, *Shorter Lives, Poorer Health* (IOM, 2013), presents additional analyses to explain these disparities in health outcomes. The IOM report corrects the international health outcome comparisons for racial/ethnic diversity, income, and educational levels, among other factors, and proceeds to present additional explanations of why these disparities exist, including environmental, social, and policy factors.

The IOM report also documents areas where the United States compares favorably to other Office of Economic Cooperation and Development countries. These areas include

- Cancer mortality

- Stroke mortality
- Control of blood pressure and cholesterol levels
- Suicide
- Elderly survival
- Self-rated health

Cancer and stroke mortality, and control of blood pressure and cholesterol, are areas of strength for the U.S. health care system, with advances in early diagnosis, and development of new and effective pharmaceutical treatments. In the area of suicide, although the United States does well overall, the one facet of suicide rates where the U.S. population does not compare favorably is suicide using a gun; our numbers far exceed those in our peer countries. Elderly survival is also potentially related to medication therapy and technological advances in old age, so that for those who live to age 75, their odds of living longer are greatly increased. Lastly, self-rated health is high in the United States, possibly because of our technological developments, which provide consumers with the perception of great medical advances from which it is logical to conclude that one's health outcomes are positive.

By comparison, the IOM report cites areas where U.S. health outcomes do not compare favorably with peer countries, including

- Infant mortality and low birth weight
- Injuries and homicides
- Adolescent pregnancy and STIs
- HIV and AIDS
- Drug-related deaths
- Obesity and diabetes
- Cardiovascular disease
- Chronic lung disease
- Disability

These are all conditions that are chronic or have strong behavioral and social components, and where prevention and management of long-term conditions are equally as important as diagnosis and treatment in the improvement of overall health outcomes. The IOM presents a variety of explanations for these health inequities in the United States, including a lack of attention within the current health care system to the social determinants of health, or the challenges with access to health care and social policies that do not address the nonclinical causes of poor health.

From the Case Files I: Obesity in America is an exemplar of the way in which the U.S. health care system addresses the social and nonclinical determinants of health in the area of obesity.

From the Case Files I

Obesity in America

Obesity and overweight are defined as weight higher "than what is considered as generally healthy for a given height," and body mass index (BMI) is a common screening tool to determine if someone is overweight or obese (CDC, 2016, para. 1). Factors related to obesity include "a combination of causes and contributing factors, including individual factors such as behavior and genetics" (CDC, 2016, para. 1). Behaviors can include one's patterns of eating, physical activity or inactivity, and the medications taken, as well as other exposures. In the larger community and society, there are also physical activity and food environments (e.g., access to fast food, safe walking environments), as well as education and how food is promoted and marketed. These latter factors are in large part, public policy issues, as defined earlier in the chapter.

John, a 6-year-old boy, is brought by his mother to see their primary care provider. The nurse practitioner (APRN) notes that John is overweight as defined by the CDC, and talks to his mother about the consequences of being overweight for lifelong health. His mother is interested in helping John achieve a healthy weight, and the APRN provides her with guidance to address John's weight; the mother is asked to return with her son in 6 weeks to see how John is progressing with the changes they discuss. The health care system, in this case, functioned well in that John had access to care, and the primary care provider recognized the potential weight problem early and spent time with John's mother to discuss ways to address helping John achieve a healthy weight. However, when John leaves the clinic, there are additional resources necessary to help his mother implement the plan she discussed with the provider. Does John's family have access to healthy, affordable foods? Such access could be related to where they live, their income level, cultural influences on food choices that also include marketing and advertising, as well as agricultural policy related to food subsidies and what is grown locally or imported and exported. Also, policies on regulating food safety, additives, and labeling, among other thing, have an effect. How does the health care system use its knowledge to influence such policies in ways that promote health?

The APRN also recommends that John increase his physical activity through active play and recreational activities. Does John's family have access to such opportunities? Is it safe to play in their community? Are there recreational opportunities available at school (do they even offer physical education classes)? Does John's family live in a manner where John has time to be outside and active? Are his parents available to supervise his play when necessary, depending on his age? Again, these factors relate to such policy concerns as tax funding for parks and schools, the income and job opportunities available to John's family, and street safety in their wider neighborhood, among other things. How can and should health professionals

be involved in the development or implementation of policies to promote healthy physical activity?

This raises the question that is the focus of this chapter—what is health policy and how it is relevant to community health nursing practice? How are politics and health policy intertwined? If PHNs are to promote and protect the health of populations (APHA, PHN Section, 2013), they need to understand health policy as it relates to the health of the public. Policies affect our daily lives, regardless of whether they are health or work related. So, public health nurses must have an understanding of health policy to better understand the issues affecting the communities they serve. It must be recognized that nurses have differing opinions on health policy, even down to the basic premise of whether nurses should become involved in political issues and the political process. But, according to Plato, "One of the penalties for refusing to participate in politics is that you end up being governed by your inferiors." So it is helpful for nurses to have a better understanding of the political process and health policy. Some questions to ask include the following:

- What do we need to understand about health policy?
- How can it be critical to the overall health of our nation?
- How is policy important in addressing both issues of access to care and of creating and supporting the social conditions that support health?
- What is the relationship of politics and health policy?
- How can nurses become involved in the political process and in promoting meaningful health policies?

In the remainder of the chapter, we will discuss policy, how it is formed, the stages of the policy process, how public health nurses can learn to be policy competent and impact policy in their practice, and the policy changes resulting from the ACA and how they impact public health nursing practice (U.S. Department of Health and Human Services [USDHHS], 2015).

White House forum on health care reform. (Photo courtesy of USA.gov)

We will also discuss the relationship of politics and health policy. Your role as a public health nurse is to be responsive to the needs of the community you serve and its attendant politics. Politics is defined as the art or science of government, or governing of a political entity. It can be and is often defined as the art of using influence to bring about change. However, you may already be aware that politics can represent the machinations in which groups or individuals engage to influence, gain power, or get their way. Politics can also be labeled as the relationships between elected officials and their constituents; it can also be seen as the interplay between staff nurses and their head nurse or nursing supervisor. Politics can be described as the practice of public ethics. A clear example of this is the conflict between individual needs and the needs of a community—such as the debate around assisted suicide or the continuing debate regarding universal health care. Within communities, it may be the debate on whether to have and/or where to locate a family planning clinic or the most appropriate and effective methods to address teen pregnancy issues. As stated by the late Massachusetts Congressman and former Speaker of the House, Tip O'Neill, "*All politics is local*."

HEALTH POLICY ANALYSIS

What Is Policy?

Nancy Milio, a well-known public health nurse, wrote extensively on policy and public health nursing practice, coining the term *healthy public policy*. Milio (1981) defined policy as option setting:

> To bring about the largest improvement in health requires the development of policies that will change the options that organizations and individuals face today. A health-making policy strategy would eliminate or increase the cost of those options that now result in health-damaging situations. It would provide new, easier opportunities, or reduce the cost of current options, in areas that now lack health-promoting resources. It would increase the cost of opportunities where health-promoting resources exist in deleterious excess (p. 76).

From Milio's perspective, public policy was a method for gaining consensus on which options a society would choose in order to meet social goals. Taking this approach, our health care system was guided for most of the 20th century on policy options including:

- Focus on medical treatment
- Fee-for-service financing
- Employment-based insurance
- Significant investment in medical technology and pharmaceuticals
- Limited financial support for prevention and public health

These options differ from what many peer countries select and, according to the Institute of Medicine report, might be a significant factor in U.S. health care disparities. Recent policy changes, primarily the ACA, are changing these options dramatically (USDHHS, 2015), as we shall discuss later in this chapter. Policy analysts define policy as (Anderson, 2015)

- A relatively stable, purposive course of action to deal with a problem or matter of concern
- A set of purposive actions taken over time
- Actions that emerge in response to needs or demands
- Actions that relate to government action, not stated intention
- Actions that can be negative or positive
- Actions that are based on law/regulation
- Actions that are authoritative

This definition focuses attention on purposive action based on law or regulations. We will talk later about how implementation and evaluation of these actions is also a critical component of the policy process. There are also different types of policies (Birkland, 2015). These include

- *Substantive policy*: This refers to policy that involves an action or activity, such as funding for a health program or health-related agency. One example would be federal funding for the Indian Health Service and its activities.
- *Procedural policies*: These involve how something is done, the procedure by which an outcome is sought. An example of this would be voting rights policies, which stipulate the process for voting eligibility.
- *Distributive policies*: Include those that allocate services or benefits to specific groups of people, for example, Medicare, which is also a substantive policy as it distributes resources to people who meet age and/or physical condition criteria.
- *Regulatory health policies*: These put limitations on the activities or behaviors of certain groups or individuals, such as age limits for purchase of alcohol or health professional licensing regulations.

These types can be defined in varying ways and the definitions are descriptive, but not necessarily mutually exclusive.

Policy and Public Health Nursing Practice

Mary Wakefield, PhD, RN, was appointed Administrator of the Health Resources and Services Administration (HRSA) by President Obama in 2009. (Photo courtesy USA.gov).

Now that we have some basic definitions of policy, we can consider how policy is relevant to public health nursing practice. The definition of PHN practice used in this text can be found in Chapter 1. This definition, developed and disseminated by the PHN Section of the American Public Health Association (APHA) in 1996 and reaffirmed in 2013 is as follows:

> Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences (APHA, PHN Section, 2013, para. 5).

The definition is further described as consisting of several key elements: (a) a focus on the health needs of an entire population; (b) assessment of population health using a comprehensive, systematic approach; (c) attention to multiple determinants of health; (d) an emphasis on primary prevention; and (e) application of interventions at all levels—individuals, families, communities, and the systems that impact their health. This definition is very consistent with the earlier discussion on health outcomes in the United States and the need for health care services. It also relates to health and social policies that create conditions in which people can be healthy by addressing the social factors determinants of health in addition to the physiological and behavioral determinants. Assessing and treating the social determinants of health includes working with communities to develop policies that impact living conditions for families and communities. Thus, PHN practice must address policy implications of health needs and conversely look at creating policies to promote and maintain health for communities and populations. A recent movement in public health of interest to nurses is that of *Health in All Policies* (APHA, 2013). The APHA presents this as embedding health considerations into decision-making processes across all sectors.

An example of a *Health in All Policies* approach is a city planning policy for zoning and deciding on a site for a new retirement community for seniors. In the planning phase for the project, a health impact assessment would be done. A health impact assessment (HIA) is a "process that helps evaluate the potential health effects of a plan, project or policy before it is built or implemented. An HIA can provide recommendations to increase positive health outcomes and minimize adverse health outcomes. HIA brings potential public health impacts and considerations to the decision-making process for plans, projects, and policies that fall outside the traditional public health arenas, such as transportation and land use" (CDC, 2016, para. 2). In this case, the HIA would look at health implications of different site options. For example, what are the health implications for the residents if the facility is built just off a major highway? Is the population being served particularly vulnerable to noise or auto exhaust? What about building the facility on the outskirts of a town? Does this population have unique transportation needs? *Health in all Policies* as an approach helps guide decision-making across sectors to maximize health-enhancing options and minimize options that increase health risks for the populations involved.

Policy Competence Integral to PHN Practice

For PHNs to practice to maximum effectiveness, they need to be aware of policy implications of health planning and health-promoting interventions and be prepared to provide data in order to support policy recommendations that enhance the health opportunities of a target group or community. This is called being *policy competent* (Longest, 2016). Policy competence means being able to

- Assess the impact of public policies on one's domain of interest/responsibility
- Understand policy and the policy process sufficiently to be able to exert influence on the process and impact policy
- Exert influence on the policy-making process

For public health nursing practice, this means that the PHN is able to assess which policies are relevant to his/her practice focus and understand the policy process sufficiently to be able to determine where the relevant policy is in the process. The PHN must also be able to determine where action is needed to influence the policy process and determine the role to take in lobbying for new legislation. Depending on the PHN practice role, the nurse (working for a government agency, for instance) may not be able to lobby for new legislation, but may choose to be policy active in private life. Deschaine and Schaffer, in a classic 2003 qualitative study of public health nurse leaders' role in policy development, used Longest's framework to describe political competence. The three areas included policy formulation (defining issues and setting policy agendas), policy implementation (development of potential solutions to identified problems), and policy implementation/modification (creating political circumstances that turn problem-solving into policy action). The study participants identified barriers to development of health policies as political and financial and could often be explained by the public's lack of knowledge about public health and its mission. Having only a few women in politics was also mentioned, along with the need for more in-depth training in policy development for PHN administrators and better access to research materials, trending data, and demographic information. A more recent study of African nurse leaders found that having knowledge of policy and practicing health policy development enhanced nursing's image, whereas a lack of policy involvement promoted a more negative nursing image and promoted processes and structures that excluded nurses (Shariff, 2014). As we shall see later in the chapter, there are many activities relevant to the policy process in addition to lobbying for legislation.

Local, State, and National Level Policy

Policies are laws, regulations, or administrative rulings; when issued by national, state, or local governments, they are called public policy. Health policy refers to specific policies involving health care. The legislative and regulatory process may start with lofty goals, but the final product is usually the result of compromise often encouraged by special interest groups, coalition groups, political realities, or the current economic environment. Although the study of politics has a long history, the systematic study of public policy, on the other hand, can be said to be a 20th-century creation. According to Daniel McCool, in his classic treatise on policy (1995), the study of public policy dates to 1922, when political scientist Charles Merriam sought to "connect the theory and practices of politics to understanding the actual activities of government, which is public policy" (p. 4).

Health policies can be distributive or redistributive. A distributive health policy promotes nongovernmental activities that are thought to be beneficial to society as a whole. An example of a distributive policy is the Nurse Training Act, Title VIII of the Public Health Service Act, which was established in 1965 and provided federal subsidies for nursing education in an effort to address the need for more nurses. A redistributive health policy changes the allocation of resources from one group to another, usually to a broader or different group. Medicare is an example of redistributive policy, in that provisions under Medicare were expanded to provide a broader range of benefits and coverage to needy groups—such as those older than age 65 and the permanently disabled of any age (Frederick, Saguy, & Gruys, in press).

One of the first policy questions to address is that of jurisdiction. Public policy impacts health and well-being at community, state, and national levels, so looking at policy jurisdiction is critical. The first step in understanding a policy issue is to know whether the key decision makers are local policy makers, state policy makers, or national policy makers.

Local Policy

Many policies that impact health care are developed and implemented at the local level, such as tobacco use in public places, availability of facilities for exercise and farmers markets, or access to locally funded health and social services. Although such policies may also be subject to guidelines from other jurisdictions (e.g., state, federal), a hallmark of the U.S. governmental system has been to have robust local policy authority (National League of Cities, 2013). Although the U.S. Constitution specifically talks about state authority, each state also gives powers to local governments, and so the policy-competent PHN needs to know what jurisdiction governs the issue of interest to the health of the community. Such public health–relevant policies as requirements for gun ownership or speed limits on public roads are often made by local level governing bodies. At the local level, these policies are very open to public involvement, because often the legislative and regulatory bodies are close by and composed of neighbors and community residents. The PHN is often able to

collect or interpret data relevant to the health impact of local policies, and can talk directly to these people about local policy concerns.

State Policy

There is a limit to municipal powers and some policies are developed and regulated at the state level. Longest (2016) notes that the role of states in health policy includes being public health guardians (e.g., protect public health and welfare through laws and regulations), health care service purchasers (often in conjunction with the federal level; safety-net providers), and as providers of education and public health laboratory services. Health and related policies such as Medicaid eligibility and services, health professional license regulation and scope of practice, and public health codes including immunization regulations are some of the functions that fall within state powers. With the recent passage of the ACA, participation in the marketplace of insurance plans and expanded federal funding for Medicaid were decisions made by state legislatures and had significant impacts on access to care (Callow, 2015).

National Policy

Funding for the health insurance plan Medicare, the ACA, parts of Medicaid, and health research are all national level policies. This level of policy has the advantage of being broadly applicable across the country, with the potential for significant impact on population health. It is challenging, however, to work at this level because there are a large number of stakeholders and an enormous political and policy bureaucracy for creation of legislation, as well as for implementation and evaluation. However, federal funding and regulatory requirements impact the role and practice of public health nurses, and PHN practice includes being aware of, and in compliance with, federal policies. See Perspectives: Policy Impacts at Local, State, and National Levels.

PERSPECTIVES: POLICY IMPACTS AT LOCAL, STATE, AND NATIONAL LEVELS

Local policy—In January 2016, the mayor of the city of Chicago called for legislation to increase the minimum age for purchasing of tobacco from 18 to 21 years. Teenagers are the largest group of new smokers, and research suggests that increasing the legal age to purchase tobacco is part of an overall strategy to discourage teens from using tobacco products (Rhodes, 2016).

State policy—As of 2015, 22 states and the District of Columbia require that public schools teach sex education; and 20 districts mandate sex education and HIV education. Three states require parental consent before a child can receive instruction. A total of 35 states and the District of Columbia allow parents to opt out on behalf of their children (i.e., if parents sign the form stating that they don't want their child to participate, the school district will exclude them; but, if no form is returned, the child has tacit permission to attend). Clearly, the PHN working in school health needs to be aware of the state policies in this area before planning interventions with school age children on sex education, including HIV education (National Council of State Legislatures, 2015).

National policy—Data indicate that climate change can have detrimental health effects on populations including increased respiratory and cardiovascular disease, injuries and premature deaths related to extreme weather events, changes in the prevalence and geographical distribution of food- and water-borne illnesses and other infectious diseases, and threats to mental health (CDC, 2015a). National policy efforts, implemented by the Environmental Protection Agency (2016), include monitoring greenhouse gas emissions and developing regulatory policies, in conjunction with private sector corporations, to reduce such emission.

LEGISLATIVE PROCESS AT THE NATIONAL LEVEL

How does legislation get passed at the federal level? The federal model for how an idea becomes a bill and how a bill is passed into legislation is relevant across the country. States each have their own mechanism. The first step in becoming policy competent on any issue is to know under which jurisdiction the issue falls (local, state, or federal) and then know how policy is developed and regulated at that level. There are a wide variety of Web sites and descriptions of the legislative process, but the definitive version can be found on the house of representatives Web site: http://www.house.gov/content/learn/legislative_process/. It is estimated that only 5% or less of bills introduced into any session of Congress actually become laws (Braun, 2013). The two session of Congress between 2011 and 2015 only enacted 2% to 3% of bills into law (Civic Impulse, 2015).

How a Bill Becomes a Law

This section will review the process for how a bill becomes a law at the federal level, but the process is very similar at the state level. See Figures 13–1 and 13–2 for state and federal examples.

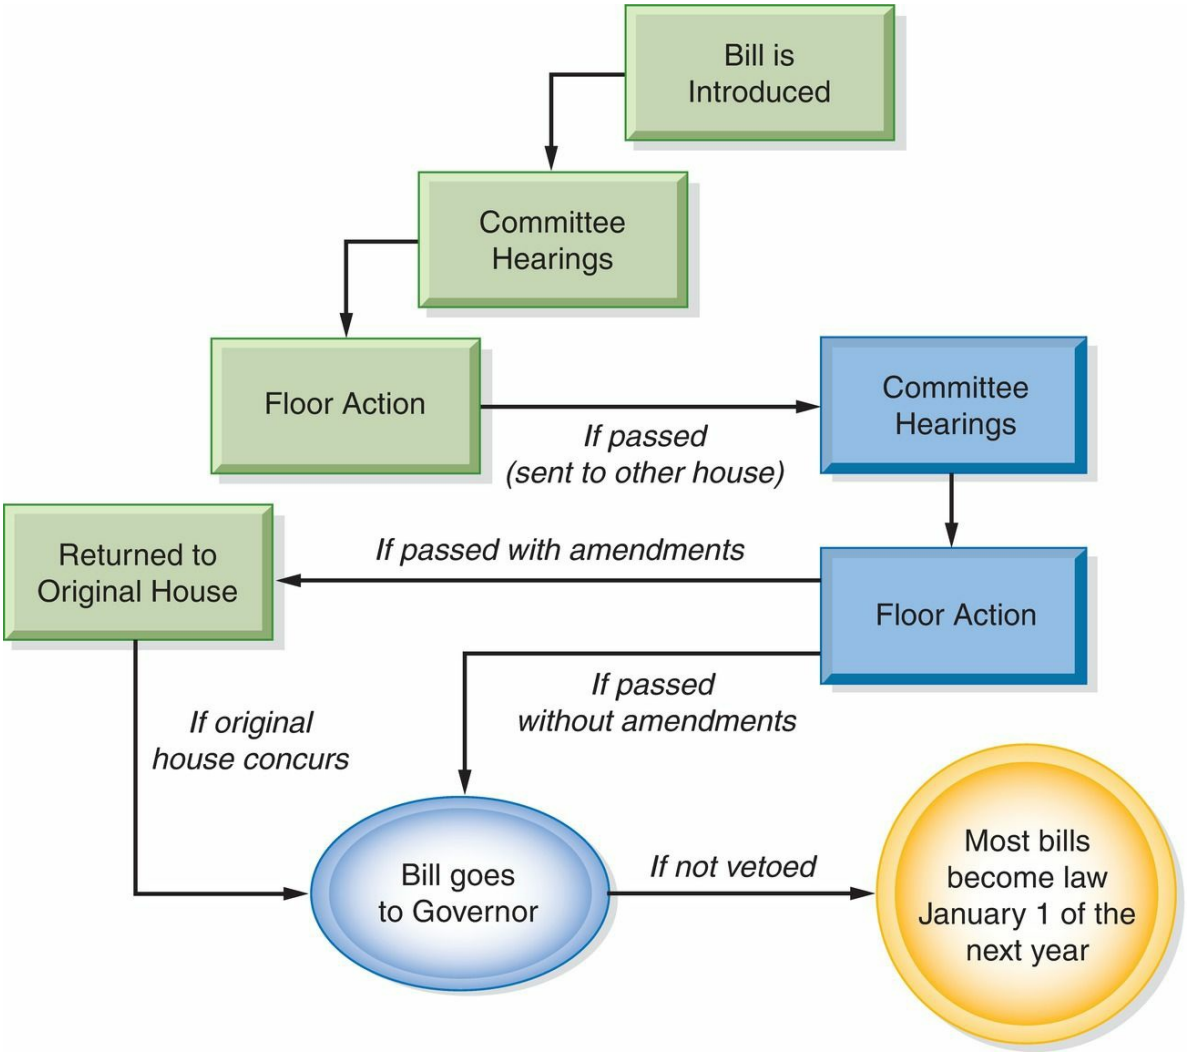

FIGURE 13–1 How a bill becomes a law—state process. The process may vary by state, but generally the schematic shows how the process unfolds. (Source: California Legislative Counsel.)

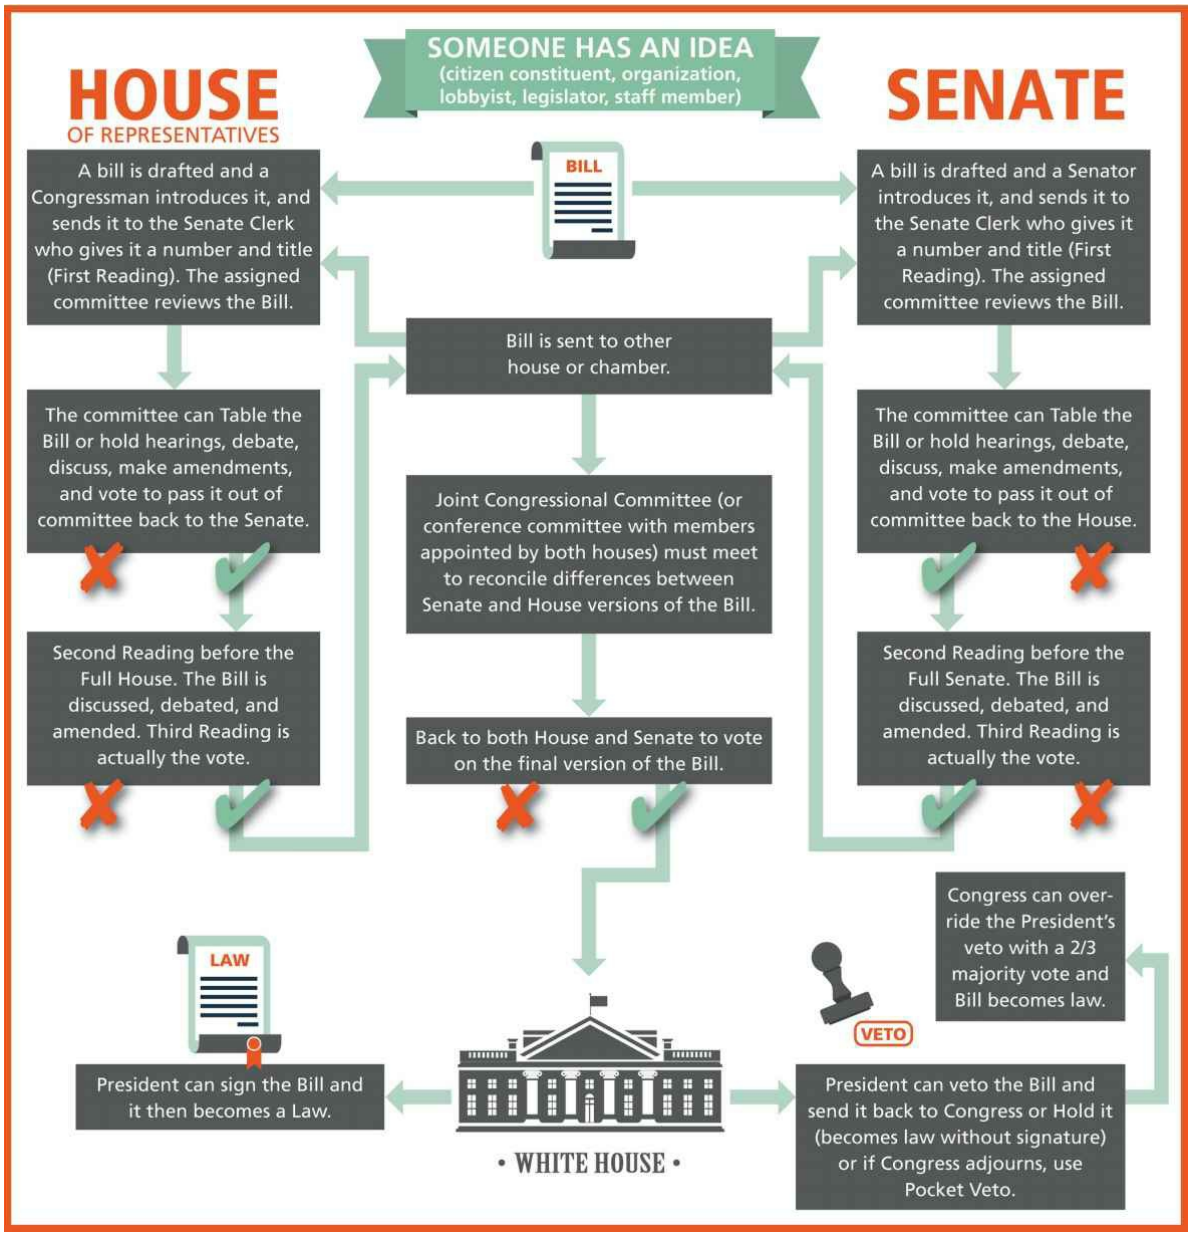

FIGURE 13–2 How a bill becomes a law—federal level. (Adapted from http://beyond5.org/wp-content/uploads/infographics/Bill_to_Law.jpg. Used with permission.)

Ideas for legislation can originate anywhere and be introduced as legislation at the state and federal levels. For federal legislation, the bill is introduced in either the house of representatives or the senate. Individuals or groups may call their local congressman or senator and propose an idea, or lobbyists working for the APHA, for instance, can ask for changes to existing laws that promote their members' interests. Only budget bills must originate in the house of representatives. This was done to keep the budget process closest to the "people's house," the body of the legislature where members represent relatively small numbers of constituents for 2-year terms and thus are thought to be more responsive to their constituents. This structure, built into the U.S. Constitution, was designed to avoid

too much control of government by moneyed classes and to enhance representation of the majority (Jensen, 2011; Longest, 2016). When a bill is introduced to either house, it is assigned to a committee based upon the general area of focus (e.g., appropriations, agriculture). The committee structure is designed to allow members of each house to focus on a smaller number of issues in depth and then vote, as a whole, on issues that are deemed worthy of going before the whole legislature (i.e., going to the "floor") for a vote. Often, bills never leave the committee, stalling there because of lack of interest from the majority party, whose members chair committees and thus set the committee's agenda, in both houses. Some bills have hearings, where experts are brought in to testify to facets of the bill, and answer questions from the committee members. For bills where there is sufficient interest or political will, the bill will be discussed, amended as needed, and voted upon in the committee. If the bill passes in committee, it is sent to the full house for further discussion, possible amendments, and an ultimate vote (Longest, 2016).

If the bill passes the full house, it is sent to the other chamber, and the process begins again. Sometimes, bills are introduced simultaneously to both houses, which can speed the process, as each committee and house reviews and votes on the bill during the same time period. If the bill is passed in each house, but in a slightly different version, a conference committee, composed of members of both houses, is convened to discuss, amend, and vote on the bill. The bill can stall in the conference committee until the session of Congress ends, and then it would need to be reintroduced in the next session, as bills do not carry over from one session to the next. Alternatively, the bill may be passed by the conference committee and then be returned to each chamber for a final vote. At this point, amendments would not be added or the bill would be stalled again and have to go back through the process once again (Longest, 2016; U.S. House of Representatives, n.d.).

After both chambers of Congress pass the same version of a bill, it then goes to the president for signature. The president can sign the bill, in which case it becomes law and is sent to the appropriate administrative agency for rule making, or the president can actively or passively veto the legislation, in which case the bill needs to be sent back to each chamber for a 2/3 vote to override the president's veto, or the bill stalls again, and the process begins anew. In summary, passing legislation is a complex process, designed for maximum debate and representation to avoid frivolous, dangerous, or unnecessary legislation (U.S. House of Representatives, n.d.).

There are other important aspects of the legislative process of which the PHN needs to be aware. These include the rulemaking process, implementation, evaluation, policy modification, and judicial action.

Rulemaking and Implementation

As stated earlier, after a bill is passed and signed into law, it is sent to the appropriate administrative agency to develop rules and processes for implementation. After these rules are developed, they are published in the Federal Register with a designated time period for

public comment. Comments are reviewed and used to revise and edit the rules as needed. Professional nursing organizations monitor rules and legislation that is of interest to their members (ANA, 2016a). The rules are then published, along with an effective date for implementation, and are used to guide organizations and individuals in implementing the policy; rules provide the "who, what, where, when, how, and why" of the law. These rules can be critical to the actual impact of legislation, as they guide how the policy intent will be carried out (Office of the Federal Register, n.d.). For example, the Dodd-Frank Wall Street Reform and Consumer Protection Act of 2010 was intended to reform the abuses that led to the Great Recession. However, "manipulating the minutiae" is the kind of game playing that occurs once legislation is at the rulemaking stage and in the hands of federal agencies, lobbyists, and lawyers who want to slant regulations for self-benefit (Edwards, 2013, para. 9). Subtle changes to one or two words can significantly alter the legislature's intent. Although there are rules that govern the process of rulemaking, Edwards (2013) notes three factors that come into play: (a) asymmetric warfare (e.g., monetary/legal resources for consumer and public interest groups vs. powerful financial institutions to fight objectionable rules), (b) cost–benefit analysis and court rulings (e.g., using competing research and threatening litigation to delay or diffuse implementation), and (c) retroactive congressional attacks (e.g., legislators who opposed the law working to retroactively weaken it). The same strategies were used against the ACA, and some were successful in changing the intent of health care reform.

If you or one of your public health clients suddenly needs a kidney, how do you get one? The Organ Procurement and Transplantation Network (OPTN) allocates kidneys and other organs. Donated-organ allocation provides an example of rulemaking that was not done through a government agency. When organ transplants became more feasible after immunosuppressive medications were developed in the 1980s, the National Organ Transplant Act (PL 98-507) created the OPTN and the Scientific Registry of Transplant Recipients (SRTR) to monitor and "predict the consequences of rule changes" and provide feedback from stakeholders on the consequences of any rule changes (Weimer & Wilk, 2016, p. 2). With such a sensitive issue as shortages or organs available for transplant and deciding who gets one first, legislators wanted to avoid the usual government agency rulemaking that could have their constituents continually badgering them for assistance and chose to go with a more insulating approach using an already existing voluntary network of medical professionals and resorting to "stakeholder rulemaking" (Weimer & Wilk, 2016, p. 4). In other words, the stakeholders, not the governmental agencies, have determined who gets a kidney and how that happens. The stakeholders include hospital transplant centers, physicians, organ procurement organizations, laboratories, and patients. Major rule change proposals are presented during public forums, where feedback is elicited. The OPTN utilizes evidence-based policy making and has made changes based upon their definition of medical effectiveness and the notion that the expertise of their members has been valuable in allocating these vital, but scarce, resources. They have provided an "allocation system that offers both efficiency and greater equity," and stakeholder rulemaking has been considered more successful than the traditional agency rulemaking in this example (p. 27).

Evaluation and Judicial Action

Evaluation of policy is sometimes written into the law and sometimes requested as part of the rulemaking process as a step in implementation. This evaluation data can be used for policy modifications or for modifications of the rules for implementation. Policy evaluation is designed to help the legislature know whether a policy is having the intended impact on the problem or condition it was designed to address. See From the Case Files II for an example of policy evaluation.

From the Case Files II

An Example of Evaluating Policy Changes: California's Safe Patient Handling Legislation

California's Hospital Patient and Health Care Worker Injury Protection Act (or Safe Patient Handling) went into effect in 2012 and directed acute care hospitals to implement policies and procedures for safe patient handling with the hope of reducing musculoskeletal injuries in nurses and other health care workers (State of California, 2012). Researchers completed an epidemiological assessment of 220 nurses with patient handling duties working in California hospitals and found, over a 1-year period, that 69% had musculoskeletal symptoms that were work related. Of those, 37% reported that their hospitals had lift teams, 61% had mechanical lift equipment available, and 22% noted that their hospitals had a "no-lift" policy (Lee, Lee, & Gershon, 2015). Nurses working in hospitals with lift teams had a significantly lower proportion of reported low back pain, and those with ceiling lifts had significantly lower reports of shoulder pain than those working in hospitals without lift teams and ceiling lifts. About 60% of nurses in the study had some knowledge of the new law, and about one third said that their hospitals had made changes regarding patient handling policies and procedures. Lee et al. (2015) concluded that this evaluation of the impact of this legislation and policy change had both positive and "suboptimal" elements and that safe patient handling practices should continue to be monitored.

Do you think nurses are generally aware of legislation that affects their workplace, practice, and patient outcomes? Why? Why not?

How could nurses become involved in the implementation of new laws/regulations and policy evaluation?

Lee, S. J., Lee, J. H., & Gershon, R. R. (2015). Musculoskeletal symptoms in nurses in the early implementation phase of California's Safe Patient Handling legislation. Research in Nursing and Health, 38(3), 183–193

State of California, Department of Industrial Relations. (2012, January 25). Frequently asked questions: Cal/OSHA AB 1136 Safe Patient Handling. Retrieved from https://www.dir.ca.gov/dosh/Safe%20Patient%20Handling%20FAQ.pdf

The judicial branch of government is designed to interpret laws and make sure they comply with the constitution. In some cases, laws are challenged and the challenge works its way through various levels of judicial decision-making. Courts can void a law or require that it be changed in some way to comply with the constitution. If this involves omitting part of the law, this can be done while implementation continues. If such a change negates the intent or desired outcome of the law, the legislative process would have to begin again to make any substantive changes. This process is designed to minimize the power of any branch of government: the legislators who wrote the law, the executive branch who administers the law, or the judicial branch who interprets the law. This is known as the American system of checks and balances (White House, 2016). Policy modification may occur, such as those related to Medicare, and may involve tweaking of regulations to reflect practice changes (Evans, 2013). See From the Case Files III for an example of policy modification.

From the Case Files III

How to Solve a Problem: Pseudoephedrine Legislation and Methamphetamine

Because pseudoephedrine (PSE; a nasal decongestant often used for allergies, colds, and sinus congestion) is a main ingredient in the production of meth (methamphetamine), Congress passed the Combat Methamphetamine Epidemic Act of 2005 to help limit the sale of medications containing PSE. It is now sold only from behind the counter, and daily/monthly limits are mandated. Purchasers are required to show photo identification, and the seller must keep a logbook of customer identification and sales. However, PSE remains an over- the-counter drug, with no prescription necessary for its purchase. Because of the spread of methamphetamine throughout this country, into rural/suburban and urban areas, some states have gone further. Both Mississippi and Oregon have now passed laws requiring that a customer must have a physician's order for any medication containing PSE and have classified these medications as Schedule III. Many other states have introduced legislation requiring prescriptions for PSE-containing medications, some classifying PSE as a controlled substance. Indiana proposed legislation that would have permitted local governments to tighten rules on PSE or allow counties or cities to require prescriptions for PSE or ephedrine products.

Several cities in Missouri and Tennessee have passed laws making PSE medications available by prescription only.

This is an example of policy modification. A federal policy was modified by state and local governments, who chose to tighten regulations on PSE in order to try to control the supply of methamphetamine and better meet the needs of their citizens (Longest, 2016).

Can you think of an example of federal legislation that might be better implemented in your area through policy modification (e.g., environmental, occupational, health/safety)? Or state legislation that should be modified to better serve the needs of your county or city population?

Centers for Disease Control, Office for State, Tribal, Local and Territorial Support Centers for Disease Control and Prevention. (2013, August 17). *Pseudoephedrine: Legal efforts to make it a prescription-only drug*. Retrieved from http://www.cdc.gov/phlp/docs/pseudo-brief112013.pdf.

POLICY ANALYSIS FOR THE PUBLIC HEALTH NURSE

Once the PHN understands how an idea becomes law, and how that law is implemented, she or he can begin to analyze the policy process to determine where they might become involved to create "healthy public policy" (Bowman et al., 2012, p. 2). Policy analysis is the technique of understanding a policy from a variety of perspectives. Such analysis can provide results for better understanding policy, finding ways to impact policy development, understanding the values behind policy, tracking the history of policy in specific areas, and other policy-relevant research and practice questions. Policy analysis can be done using a variety of approaches and methods. Here, we will present policy analysis for practicing PHNs to help them develop policy competence.

Policy competence, as discussed earlier, means understanding policy and the policy process sufficiently to be able to exert influence on the process and impact policy (Longest, 2016). In order to be policy competent, the PHN must be able to assess the impact of public policies on one's domain of interest/responsibility and exert influence on the policy-making process. This can be done at a variety of levels. Because policy sets the context for much of PHN practice, policy competence is particularly important for PHNs, but all nurses should have some concept of how policy affects nurses, patients, and communities. For example, changes in Medicaid funding, at either the national or state level, might directly impact which clients the PHN is allowed to include in certain health promotion/disease prevention programs. Therefore, the PHN should understand this impact, the reasons for the Medicaid changes, and where useful input might be provided. This might be as straightforward as explaining to agency administrators what the impact of these changes will be on individuals in the community, or it may be more complicated and involve policy evaluation mechanisms or development of alternative policy solutions to meet the health goals of the community.

For the purposes of policy competence in PHN practice, we will discuss two frameworks for policy analysis, the rational framework and John Kingdon's framework. These frameworks provide two interrelated mechanisms for looking at the policy process and are combined into a useful diagram by Longest (2016). See Figure 13–3.

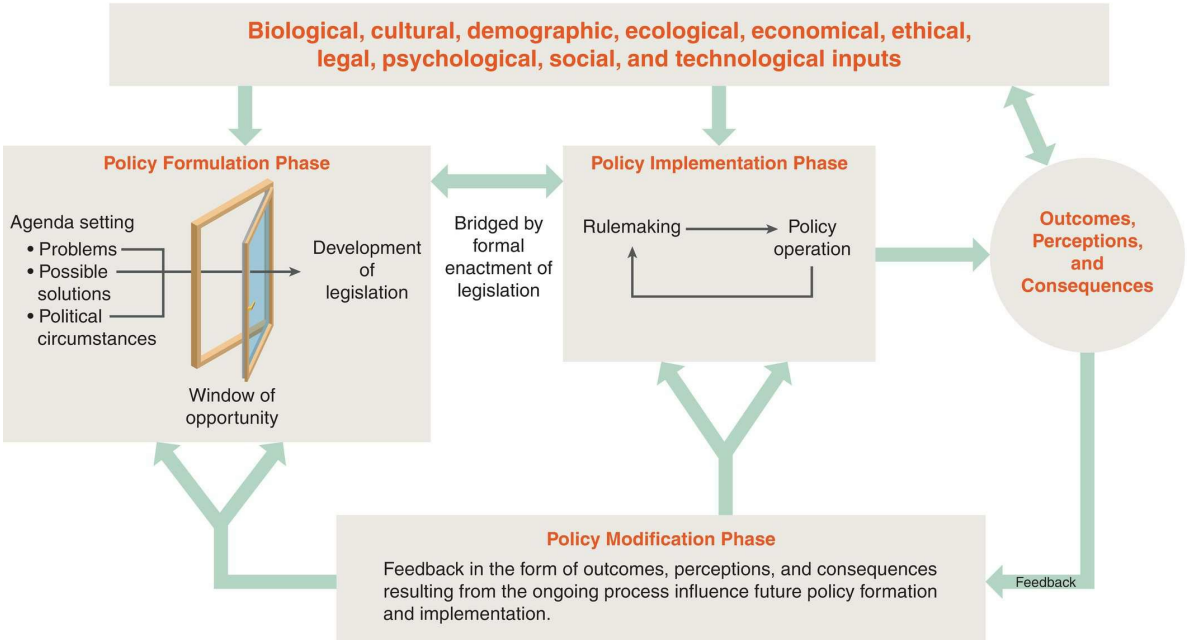

FIGURE 13–3 Longest's model. (Adapted from Longest, B. B. (2016). Health policymaking in the United States (5th ed.). Chicago, IL: Health Administration Press, p. 82, with permission.)

The rational framework is commonly found in policy texts as a straightforward way to comprehend the intent and effect of a particular policy. The framework involves first, defining the policy problem to be addressed. The more clear and measurable this problem definition is, the more specific any policy response can be. The second step in this framework is to understand possible solutions to this policy problem and compare and contrast them to each other in order to determine which is optimal in terms of being politically feasible, easily implemented, and likely to result in the desired outcome. The third step, based on comparing and contrasting the possible policy alternatives, is to select an alternative, after which the alternative is implemented and evaluated for its effectiveness (Kingdon, 2011). This logical analytic framework is very similar to the nursing process, in its structure and components, and as such is easily understood by PHNs (ANA, 2016b). An example from Sri Lanka involves achieving a consensus on the public health problem of high rates of suicide (47 overall and 80 for males per 100,000—the highest in the world at that time). The initial policy change restricted toxic pesticide access and resulted in some reduction in mortality rates. Further reductions were sought, so a presidential committee of experts was convened to examine and make recommendations about the problem, using the rational framework approach. A large proportion of suicides were deemed self-poisoning, and suggestions ranged from reducing access to lethal pesticides, research to decrease the lethality level of pesticides, changing the culture to discourage suicides, repackaging pesticides into nonlethal doses, and increasing access to care to improve survival rates after suicidal poisoning. Once the data and the potential interventions were discussed, policy analysis was used to determine weaknesses, strengths, and costs of options. Interventions that required further political actions, such as taxation, new programs, or private sector self-

interest, were weighed. The influence of expert evidence and data are not sufficient to change policies—political action is needed with an understanding of "context, networks, knowledge, implementation, and impact" (Pearson, Anthony, & Buckley, 2010, para. 37). Understanding of technical feasibility, budgets, marketability, and dominant cultural values are necessary to incorporate, along with evidence and data, in order to exert political influence and change cultural practices.

There are several challenges to using this framework. Again, much like the nursing process, it examines policy as a structured, linear process, and that is often not the case. Challenges in defining the problem or in comparing viable solutions might often influence policy to be formed with insufficient data or based on the power and influence of specific stakeholders, meaning that all elements may not be considered carefully and in the order presented in the framework (Kingdon, 2010, 2011). Additionally, this framework doesn't assist the PHN in addressing the politics involved or in determining why one issue might be addressed when another—equally important to the community—might languish with no policy activity taking place.

The second framework to be discussed here is that developed by John Kingdon (2010, 2011). Kingdon set out in his research to address the question of why some issues came to the forefront in policy development and others did not. Kingdon argued, based on his research results, that policy was enacted when a *window of opportunity* was opened. During the period of this open window, bills could be voted on and new legislation made. The window of opportunity opened when there was a confluence of a *policy problem*, a *viable solution* or solutions, and *political will* on this issue. This confluence opened a window of opportunity for the issue to be acted upon (however briefly). See Figure 13–4, Kingdon's Model of the Policy Process.

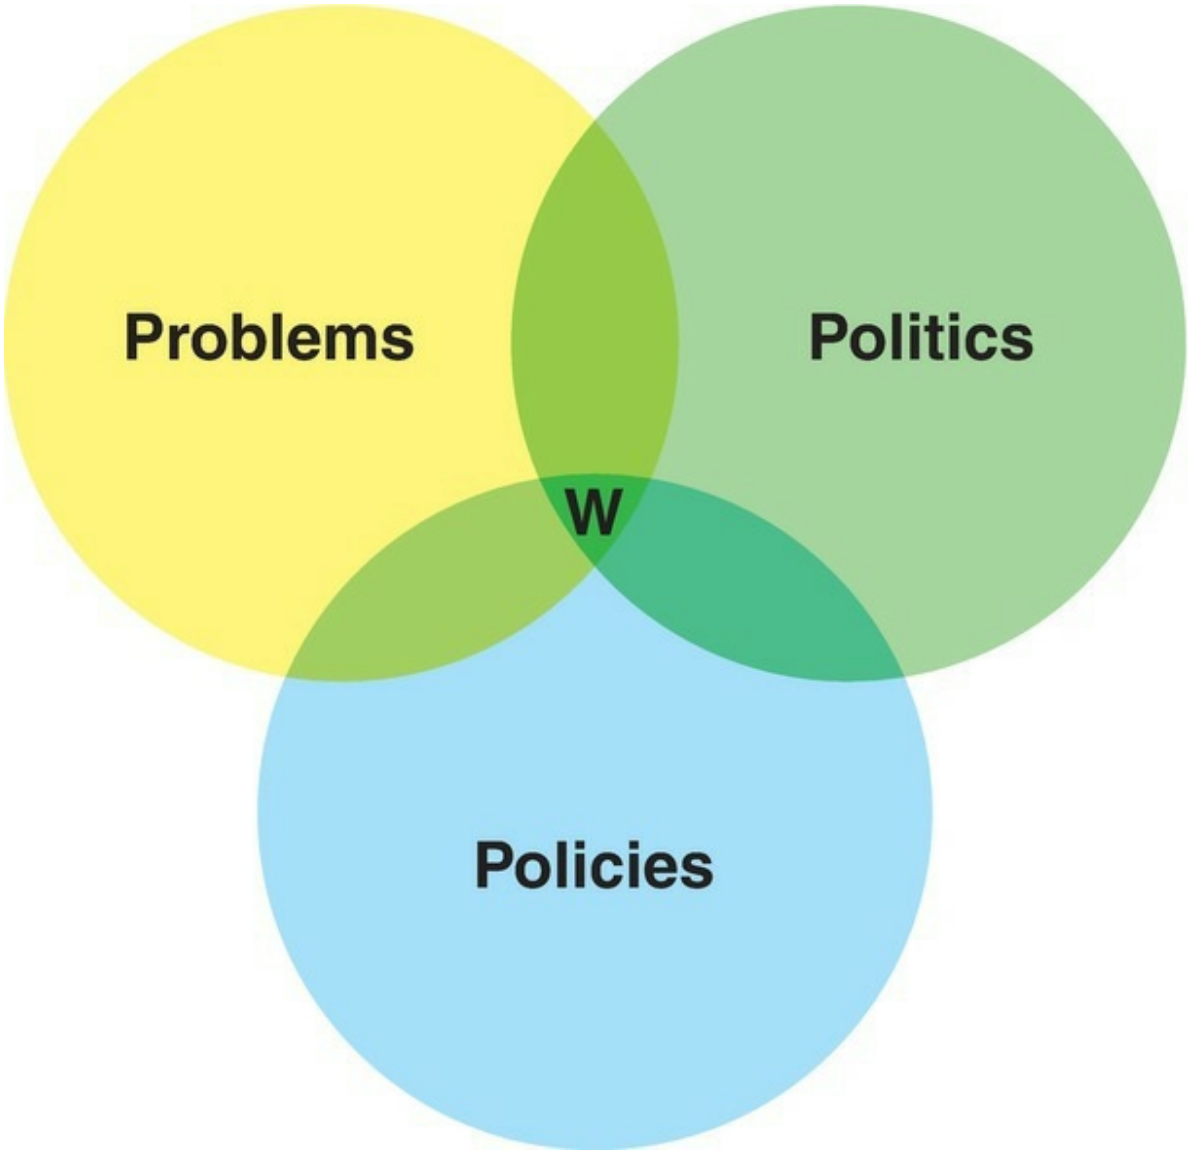

FIGURE 13–4 Kingdon's model of the policy process.

Kingdon presented each component of the framework specifically. The *problem*, he contended, should be defined using *indicators*, that is, data to document its existence. However, he also said problems could be defined by *focusing events*, or attention getting incidents, which highlighted a problem for a large portion of the population. An example of a focusing event would be the terrorist attacks on the World Trade Center and Pentagon in September 2001, which brought national and international attention to the problems of terrorism and airline safety. Kingdon also argued that it was important to understand the problem from multiple perspectives; that is, how would others see the same problem and data? In this way, he contended that the analyst could understand multiple perspectives and how they might impact the solutions and politics (Kingdon, 2010, 2011).

Identifying a *policy solution* was the next component of the Kingdon framework. Kingdon stated that there are always policy solutions floating around in what he called the "policy primeval soup" (2010, para. 10). He provided some parameters for assessing

solutions: Are they technically feasible (can they be implemented)? Are they acceptable in terms of public values? Are they within acceptable costs? Do they comply with the current size and role of government? Would they be considered fair and equitable? He used these questions to compare solutions for those most likely to align with problems and politics (Kingdon, 2011).

When analyzing the *politics* of an issue, Kingdon had several facets to consider. First, what is the political climate at the current time? For example, immediately after the 9/11 terrorist attacks, the U.S. political climate was focused almost entirely on safety and security, and very few other issues were being seriously addressed. Kingdon (2011) also advised looking at stakeholders on both sides of an issue and assessing relative power and influence. This can be done by looking at the numbers of people they represent, resources available for lobbying, and political reputation and past achievements.

When a *window of opportunity* does open, Kingdon (2011) cautioned that it does not remain open forever. Sometimes, other issues arise and take precedence. Sometimes, partial action is taken, and the public perceives the problem has been resolved, at least in the near term. And, other times, a window closes because the public loses interest in unresolved issues that have been around for a long time. In Kingdon's terms, policy activists should look for opportunities to open windows and, when windows are open, should act to capitalize on the opportunity. A global example involves tobacco control. As the United States utilized decades of research and began legislating no-smoking ordinances and tax increases on tobacco products and rates of tobacco-related morbidity and mortality dropped, a window of opportunity opened for countries around the world to enact tobacco control policies (Gneiting, 2016). Employing Kingdon's framework and an international treaty on tobacco control (Framework Convention on Tobacco Control) established by the World Health Organization, the Framework Convention Alliance (FCA) began working globally toward raising awareness of tobacco as a public health threat and utilizing new funding sources (e.g., Gates Foundation, Bloomberg Initiative) to shape national policy agendas. Smoke-free legislation gained the most "advocacy momentum and policy traction," with 120 member countries on board (Gneiting, 2016, p. i80). The tobacco industry has responded by marketing e-cigarettes, influencing trade and governmental partnership agreements, and aggressively lobbying against tobacco tax increases. Some of these measures are not part of the original treaty and now must be addressed. Measures to increase tobacco taxes have not been as successful as smoke-free initiatives. The relative political power of the tobacco industry has been difficult to overcome, but the alliance members continue their work.

Drawbacks to Kingdon's framework include the fact that his framework analyzes policy to the point of passing a bill into law. His framework doesn't address the issue of implementation, evaluation, or policy modification. As mentioned earlier, Longest combined the rational framework and Kingdon's framework into a figure encompassing all facets of policy making.

For the policy analyst, both frameworks present important components of

understanding an issue. The rational framework allows the analyst to look post hoc at an issue and learn from the process as it unfolded. For policy activists, or PHNs who want to use policy effectively in practice (policy competence), the Kingdon framework allows you to examine a current issue in real time and determine if a window of opportunity exists or if one could be created. This helps the PHN, or a public health organization, to prioritize its time and resources and focus policy efforts where they can be most effective.

Policy Analysis for Activism

Now, we will put this altogether—how can a PHN use this information to be policy active in practice? The first step is to select a policy issue to address. What health concern in your community or target population has policy implications or is being impacted by current health policy or the lack thereof? Perhaps there are water quality concerns in the community, or the most recent community assessment has identified an increase in sexually transmitted infections (STIs) among adolescents and young adults. Are these public policy issues? That is, does it involve public decisions about laws and regulations related to funding, services, or rights and behaviors?

The second step, once the PHN has determined that the issue is indeed one of public policy, is to conduct a brief policy analysis using Kingdon's framework initially: What is the *problem*? Are there *solutions*, and are they adequate and appropriate? What are the *politics*—or who are the stakeholders and what is their level of influence? This preliminary analysis will inform the PHN whether this is a new issue on the agenda or whether it is an issue of *implementation* or *evaluation* of existing legislation or regulations.

Given this, what does the PHN want in relation to this issue? And under what policy jurisdiction does the issue fall (local, state, federal)? Perhaps the key concern is the problem: Is it not well defined, or does the definition need to be expanded? Is the main goal to get the issue on the policy agenda via outreach to policy makers? Are better data needed to more clearly define the problem? Is there a viable solution available, or do solutions need to be tested and developed based on practice standards and population needs? Is this an issue of the way a regulation is being implemented, and thus, can change be made by working with legislators to identify the problem and develop implementation modifications? Is there a policy in place that lacks clarity about whether it is working, or if it needs expansion or contraction? Who would be the key stakeholders and target audience for any action?

Once the PHN has answered these questions, then the level of involvement necessary can be determined. And given constraints on time, lobbying, access to data, and the priority of the issue, the level of engagement can then be determined. A number of avenues for activism are available, based on the above criteria. Table 13–1 demonstrates how the analysis framework relates to concerns of the PHN and possible actions in response.

Table 13–1 PHN Practice Mechanisms to Address Policy Issues

Component of Analysis Framework	Action Needed	Mechanisms of Action
Problem	Data to define	• Collect or analyze evaluation data; assessment data • Collaborate with researchers on problem definition
	Expand definition	• Collaborate with researchers on problem definition
Policies/solutions	Develop/pilot possible solutions	• Develop and implement model projects
	Change context to increase solution viability	• Evaluate/collect outcome data on projects to evaluate process of implementation
Politics	Educate public or other stakeholders	• Letters, phone call, e-mails, office visits to key stakeholders • Communicate via letters to the editor or social media • Present program results or assessment results in public forum • Disseminate reports on service outcomes or new conditions to key stakeholders
Implementation	Revise regulations to improve implementation	• Work with regulators to revise regulations and rules
	Expand implementation to others affected	• Work with legislators and/or regulators to expand eligible populations for interventions
Evaluation	Data needed to measure impact	• Evaluate services provided
	Disseminate evaluation results	• Present program results or assessment results in public forum • Disseminate reports on service outcomes or new conditions to key stakeholders
	Policy modification needed (see Problem)	• Collaborate to collect data for problem definition

POLITICAL ACTION AND ADVOCACY FOR PHNS

The definition of PHN practice describes efforts to promote and protect the public's health. When looking at *Healthy Public Policy*, PHN efforts to do so can take many forms from active participation as an informed citizen to actions taken as part of PHN practice to promote *Healthy Public Policy* (Bowman et al., 2012; Gottlieb, Fielding, & Braveman, 2012; National Collaborating Centre for Healthy Public Policy, 2010).

The PHN as an informed citizen, who has valuable knowledge and experience in health and health promotion, can be involved at a basic level by being aware of health policy and using this awareness for informed voting in elections across levels of jurisdiction. Individual PHNs might choose to increase their involvement by serving in a campaign to support a legislator that espouses public policies promoting health and preventing disease. Additionally, the PHN might choose to share their expertise with others, as a means to inform their voting and citizen involvement. The PHN could also choose to be involved in professional organizations or citizen organizations to advocate for *Healthy Public Policies* and the legislators who promote them. PHN practice, looking broadly at health and the social determinants of health, can provide background that is valuable in any number of professional and civic organizations. For example, at the state level, the PHN can ensure that the state nursing organizations maintain a broad-based focus on the health of the public. And locally, PHNs can serve on health boards, but can also provide valuable input into health and education by serving on school boards or parent–teacher organizations. Working toward eliminating health inequities, healthier built environments, HIAs, and sharing knowledge are all worthwhile endeavors for nurses who want to affect population through health policy work (Kostas-Polston, Thanavaro, Arvidson, & Taub, 2015; National Collaborating Centre for Healthy Public Policy, 2010).

PHN researchers can provide policy-relevant input by focusing on research questions related to the social determinants of health or health in all policies and sharing results in a clear and persuasive manner with policy makers and legislators. PHN research might include assessing the impact of public policies on community health outcomes or on evaluating public health promotion efforts in the community (Feetham & Doering, 2015). Lastly, PHNs can provide input by serving on policy-making bodies. A PHN serving on a hospital board could be critical in helping the hospital better understand population health and the role of the hospital in enhancing it. Alternatively, the PHN could serve on state or national advisory groups such as MedPAC (http://www.medpac.gov/home) or the U.S. Preventive Services Task Force (http://www.uspreventiveservicestaskforce.org/Page/Name/home). The organization, Nurses on Boards, is campaigning to put 10,000 nurses on various boards at all levels by 2020. Types of boards may include advisory, elected, appointed, constituency, and regulatory (Rambur, 2015). The organization provides a wide variety of examples across

each state, along with guidance on how to prepare to serve on a board (http://nursesonboardscoalition.org/).

Public Health and Social Justice

The concept of social justice is seen as the very foundation of public health and public health nursing (deChesnay & Anderson, 2016; Donohoe, 2013). The American Association of Colleges of Nursing (n.d.) emphasizes that the guiding values of nursing include social justice at all levels of preparation, and the ANA *Code of Ethics with Interpretative Statements* (2015, preface) states that nurses should "act to change those aspects of society that detract from health and wellbeing." The ANA's *Public Health Nursing: Scope and Standards of Practice* document also highlights the basic value of social justice in community health nursing (2013). The many definitions of social justice depend on the discipline involved; for purposes of this chapter, social justice is a fair allocation of both the costs and rewards of being a member of a group focusing on the processes, perceptions, and roles (Barusch, 2012). This could also be characterized as balancing or equalizing societal costs and benefits. However, nurses are not always consistent in their abilities to fully comprehend or develop strategies to address injustice.

We often want things to be fair, but do not always clearly define what that means, or sufficiently promote specific actions needed to ensure it. We may feel frustrated about situations we see every day, but need to be better equipped to address them (Paquin, 2011). You may be caught in a "Catch-22" situation, working within a market-based system that is inherently unfair and often leads to health and social disparities for ethnic and other disadvantaged groups while having pledged to alleviate suffering within the groups you serve (ANA, 2013, 2015).

As a public health nurse, you are expected to give voice to the disparities found in the communities you serve (e.g., substandard housing, high rates of unemployment, death, and disability)—disparities that often could be prevented or alleviated at early stages. Your efforts through nursing interventions can address not only health issues but also the educational, social, and economic issues that give rise to these disparities (deChesnay & Anderson, 2016; Donohoe, 2013). The Minnesota Department of Public Health Nursing Section has developed a public health interventions model that gives a broad overview of public health nursing. The model is based on the type of intervention and practice levels that allows a range of activities, such as advocacy, community organizing, coalition building, case management, and policy development, which you as a public health practitioner can activate (see Chapter 14). The nexus between social justice, advocacy, and policy is interrelated, complex, and one that will affect every aspect of your community health nursing career.

History of Public Health Nursing Advocacy

Nurses have a long history of action in social justice and advocacy, which can be defined as pleading the case of another or championing a cause (see Chapter 2). Developing policy solutions is a fundamental role for nurses—for the welfare of patients and communities, as

well as the profession (Mason, Gardner, Outlaw, & O'Grady, 2016). To advocate is to try to influence outcomes that affect people, communities, and systems. Additionally, advocacy is a process, not an outcome, one that includes identifying an issue, collecting information, identifying who can be influenced/who can make the decision sought, building support, and taking action. Advocacy can present itself in a variety of ways— self-advocacy, which is advocating for oneself; individual advocacy, which is pleading the case of others; and legislative advocacy, which is changing or modifying state or federal laws. Advocacy also includes litigation and public education campaigns. Finally, advocacy is also the process of empowering those less able to present their views or needs, with the goal of giving them a voice and/or achieving their objectives. Nurses have long been advocates for their patients, and advocacy can and does affect the larger systems of care (deChesnay & Anderson, 2016; Donohoe, 2013; Paquin, 2011). Community health advocacy refers to efforts aimed at creating awareness of and generating support for meeting the community's health needs. Both nurses and communities have a common goal—the best possible health services for all.

The term and concept of *public health nursing* was coined in 1893 by Lillian Wald, who described PHNs as nurses who worked outside the hospital "to provide decent health care" to those people living in poor communities and tenements (Jewish Women's Archive, 2016, para. 2). These nurses specialized in both preserving health and prevention measures as they responded to referrals from patients and physicians and they were only paid if the patient was able to afford payment. In 1893, Lillian Wald and Mary Brewster established the Visiting Nurses Service, and a year later, the famed Henry Street Settlement House was established. Wald's exposure to the plight of newly arrived immigrants to the Lower East Side and the appalling living conditions there spurred her to action. She was determined that these immigrants and other poor people, regardless of ethnicity or religious affiliation, would have access to health care and adequate housing. Wald went on to encourage the establishment of the Department of Nursing and Health at Columbia University's Teachers College through a series of lectures she presented starting in 1910. She also was instrumental in creating the U.S. Children's Bureau in 1912, an agency that oversaw fair child labor laws (see Chapter 2).

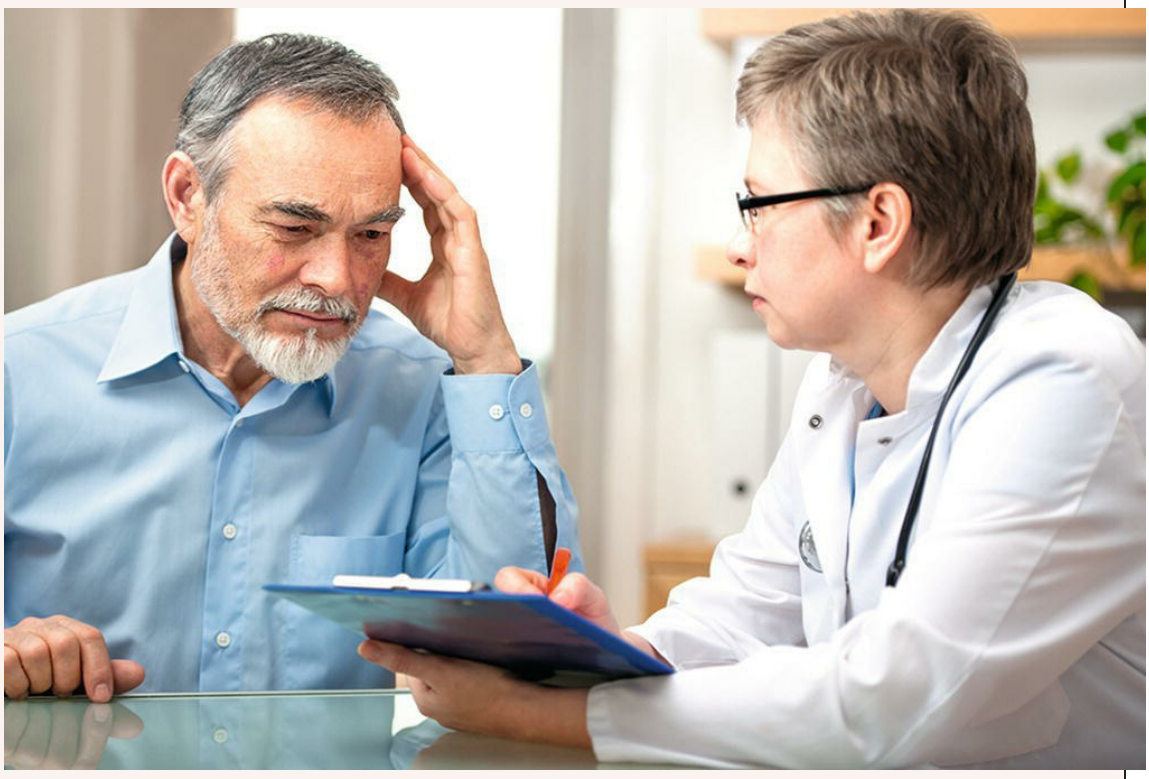
The importance of these nurses—Lillian Wald and her compatriots, Sojourner Truth, Margaret Sanger, Clara Barton, Mary Seacole, Susie King Taylor, Mary Mahoney, and others—is that they wielded influence at a time when women were not even allowed to vote. In fact, many women in the 1800s, regardless of socioeconomic status, did not attend school. African American women in the early 20th century were legally forbidden to learn to read and write (Foreman, 2009; Nickitas, Middaugh, & Aries, 2016). Historically, women—both Black and White—volunteered their services during crises although nursing, as a profession, didn't exist (Whitfield, 2015). For these women to be successful and influential during the 19th century is a tribute to their ability to take on the system in which they lived and to triumph over it. Women during these times rarely, if ever, voiced their opinions about issues affecting their lives, the lives of their children, their families, or

their communities; it was neither expected nor accepted. These early pioneers also are seen as feminists, and the entrance of these women into the political arena opened the way for others, such as Nancy Pelosi, former (and first-ever) Speaker of the house of representatives, and the four women Supreme Court justices (including one retired). In 2016, there 20% of members of the senate were women, and close to that number served in the house. In state legislatures, those numbers were 22.6% and 24.6%, respectively (Rutgers Center for American Women and Politics, 2016).

Professional Advocacy

One of the chief ways in which nurses have been successful in advocating is through membership in their professional organizations. The late 19th century may be seen as the beginning of nurse activism. The Nurses Associated Alumnae of the United States and Canada and the American Society of Superintendents of Training Schools of the United States and Canada were formed in 1890s (ANA, n.d.; National League for Nursing, 2016). Out of these groups came the ANA and the National League for Nursing. However, in the 1980s, with the stratification of nursing into various specialties and organizations, representing an assortment of specialty groups, came the realization that the many nursing groups needed to coordinate efforts in order to be more successful (Cohen et al., 1996). Throughout the next few decades, the nursing organizations realized, regardless of internal differences and competition, that to be politically successful, they must join together to work toward their common political goals. The formation of the following coalitions occurred:

Tri-Council for Nursing—comprising ANA, the American Association of Colleges of Nursing, National League for Nursing, and the American Organization of Nurse Executives



American College of Nurse Practitioners (NPs)—state and national NP groups initially met for a national forum and eventually to influence health policy

Nursing Organizations Alliance (The Alliance)—an alliance of National Federation of Specialty Nursing Organizations and Nursing Organizations Liaison Forum

These and other coalitions permitted the organizations to lobby for common nursing issues (e.g., maintenance of federal funding for nursing education and research) and ultimately the establishment of the National Institute of Nursing Research within the National Institutes of Health (Milstead, 2016). Many of the current state nurse practice acts and expanded responsibilities for NPs are the result of these new coalitions. But more significantly, nursing now has a better understanding that there is a difference between "self-interest" and "selfishness" (Matthews, 2012; Milstead, 2016). One of the most significant outcomes of this time was the development of *Nursing's Agenda for Health Care Reform* (ANA, 1994), this document exemplified the maturing of nursing as a special interest group, but more importantly demonstrated consensus building and collaboration among the more than 60 nursing and various health care provider organizations. Despite nursing's early history of political activism and the fact that nurses are the largest group of health care providers in the United States, widespread political involvement has yet to be fully realized (Nickitas et al., 2016). Nursing has the potential to be a major player in Washington when discussing health care policy. Currently, the call for political action and participation in health policy work among nurses encompasses the global view of "One World, One Health" (Premji & Hatfield, in press, para. 1). For a more recent example of successful professional advocacy, see From the Case Files IV: Nurse Practitioners.

From the Case Files IV

Nurse Practitioners

With full implementation of the Patient Protection and ACA, it is estimated that 32 million more Americans will have access to primary health care; by 2020, there is an expected shortage of 45,000 primary care physicians (Poghosyan, Lucero, Rauch, & Berkowitz, 2012). The demand for nurse practitioners (NPs) or advanced practice nurses (APNs) is increasing; nationally, it is expected to reach an increase of 30% between 2016 and 2020 (Xue & Intrator, 2016). NPs are often thought by patients to be better communicators and provide clearer education about self-management of chronic conditions (e.g., diabetes), but the terms "physician extender," "midlevel practitioner," and "nonphysician provider" are thought to lead to misconceptions about the quality of their care (Poghosyan et al., 2012, p. 147). Many new policies and programs related to the ACA are beneficial to NPs, including

- Graduate Nurse Education funding for demonstration awards to expand NP education programs.
- Increased funds for hiring NPs into the National Health Service Corps; about 1,900 have been hired to practice in medically underserved areas with

increasing levels of retention and extension of their contracts.

- Both Federally Qualified Health Centers (FQHC) and Nurse-Managed Health Clinics (NMHCs) have received increased support, as safety-net providers, to hire NPs to care for their often vulnerable, high-risk clients.
- Medicare beneficiaries with functional limitations and chronic illnesses are able to receive home-based primary care from NPs through a 3-year project, Independence at Home Demonstration (Carthon, Barnes, & Sarik, 2015).

Although these gains have been the hard won result of consistent lobbying and advocacy efforts on the part of professional nursing organizations and individuals, the bright future on the horizon for NPs is at risk because of inconsistent scope of practice laws at the state level (Poghosyan, Boyd, & Clarke, 2016). In 2015, only 21 states and the District of Columbia had full autonomy rules for NPs (e.g., NPs could evaluate/treat patients, order/interpret diagnostic tests, prescribe medications). That leaves 29 states with laws for NPs that restrict or reduce their scope of practice; often, this involves requiring physician oversight or collaboration (Xue & Intrator, 2016). Some states prohibit NPs from certifying home health or long-term care, and limit their admitting privileges to hospitals. This practice leads to barriers to practice and uneven distribution of primary health care providers, with per capita rates for NPs ranging from 1.7 to 8 per 10,000 people in rural areas of the country. Most are working in large cities and urban areas (Xue & Intrator, 2016). Those states with fewer restrictions on NP practice have 30% higher enrollments in advanced practice nursing (APN) programs (Poghosyan et al., 2012).

Another important consideration is the fact that NPs often work with the most vulnerable populations in areas where other health care providers are scarce, and "their active participation in advocating for both health and social policies" for their clients is helpful in promoting health equity in access and quality (Xue & Intrator, 2016, p. 5). Although NPs are achieving success in the area of policy making and expanded practice opportunities, it is still vitally important for them to advocate and politically support health policies that benefit the clients they serve.

Large professional organizations have the resources, relationships with policymakers, success at coalition building, and reputation for the ability to compromise needs to assure viable outcomes. Being a part of your professional organization demonstrates your

professionalism, promotes your organization's viability, and demonstrates your social responsibility to advocate for the needs of your patients. Nurses must take advantage of how the public views the profession. For more than a decade, nurses have ranked highest in a Gallup poll for honesty and ethical standards (Gallup, 2016). Clearly, there is favorable impression of nursing as a profession among the general public. Despite criticism about special interest and professional organizations "protecting their turf," professional nursing organizations demonstrate how a critical mass can be influential and successful in moving the discussion forward on health care and the public's perception of nursing. It is the professional nursing organizations that have elevated nursing professionalism, given voice to the inequities that affect our society, and developed the paradigms that influence and affect public health at the institutional, state, and national level in the 21st century. A united voice on public policy is more powerful than individual nurses pleading with their legislators (Duncan, Thorne, & Rodney, 2015; Taylor, 2016).

The pursuit of personal agendas over the common good results in a piecemeal approach to problems and promotes polarization. Polarization is the process by which a group is severely split into two or more factions over a political issue. Polarization can be so intense that people perceive one another as good or wicked, depending on their ideological opinions. One of the primary goals of a professional nursing association is to build a collective voice for nurses. A strong professional association limits polarization by developing the political skills of its members and ensures that its structure and processes equitably meet the needs of its constituencies. This is the essence of politics: people must listen to each other, learn from others' viewpoints, and compromise to ensure the most positive outcomes from their endeavors (Nickitas et al., 2016).

Nursing's Role in Health Care Reform

Since the 1950s, the ANA has advocated for reforms in health care that will benefit both nurses and their patients. Their involvement in federal health care reform began in the 1960s with the passage of Medicaid and Medicare. In the 1970s, ANA formed a political action committee (PAC). PACs are organizations that raise money to contribute to political parties or candidates, with the understanding that those receiving financial and political support will be sympathetic toward issues of interest to members of the PAC.

In 1991, ANA released *Nursing's Agenda for Health Care Reform: A Call to Action—a* plan so ambitious and forward looking that Senator Kennedy referenced this document when introducing his legislation on health care reform. Even though this legislation failed to pass, ANA and other nursing organizations gained wide recognition for their policy acumen and leadership abilities. During the Clinton-era health care debate, ANA continued to play a key role in the policy and political discussions on health care reform. As research and experience continued to show the need for health care reform, ANA remained steadfast in its advocacy and updated the policy agenda on health care reform and progress toward a more balanced approach incorporating primary care, community-based care, and preventive services. ANA supported the development of a single-payer system. Understanding the time was ripe for health care reform, the ANA-PAC identified those legislators supportive of ANA's legislative and regulatory agenda. They provided financial and political support and increased their grassroots organizing. RNs nationwide responded and through multiple activities (e.g., contacting members of Congress, testifying at hearings, sharing personal stories, participating in high-profile press conferences, attending rallies and events) lobbied for action (see Display 13–1). The frontline nurses also joined ANA's health care reform team, and through these concentrated efforts and collaborations, health care reform became a reality in March 2010 (Lewenson, 2015).

DISPLAY 13.1 AMERICAN NURSES ASSOCIATION (ANA) LOBBYING EFFORTS TOWARD HEALTH CARE REFORM

ANA and its members played a critical role in advocating for health reform. Below is a list of their activities, over a 15-month period:

- Participated in hundreds of media interviews
- Participated in dozens of local media events
- Testified before three Congressional Committees
- Met with White House and Congressional health care reform staff
- Participated in two presidential press conferences at the White House: ANA was one of only 150 representatives invited to participate in the White House Health Care Summit on March 5, 2009
- Participated in the June 25, 2009 rally—*Health Care for America Now*
- Gathered at the July 15, 2009, Rose Garden event where President Obama personally thanked ANA for its involvement in health care reform efforts
- Helped organize America's national-call-in day to Congress in October 2009 (ANA, 2011).

Nurses are increasingly becoming shapers of policy on both the local and federal level; this is occurring because of our experience, perspective, and expertise in health care. The realization that improving conditions for nursing also improves conditions for the communities we serve and the larger society in which we live and work has enhanced our ability to organize. This increases our visibility, access to policy makers, and, more importantly, our capacity to influence the political process (Kostas-Polston et al., 2015). See From the Case Files V: Nurses Lobby Congress.

From the Case Files V

Nurses Lobby Congress

Over 260 nurses came to Washington, DC, in June 2015 to meet and talk with over 200 members of Congress. They learned that legislators want them to participate and share their professional perspective on issues related to health, and Rep. Michelle Lujan Grisham noted that nurses have been "the best champions for health care" and have tirelessly advocated for "long-term care, public health, and greater access to care" (ANA, 2016, para. 6). At the same time, over 1,500 nurses participated in virtual Lobby Day by tweeting, posting on Facebook, and sending e-mails to their members of Congress. Some also visited their local legislator's district offices. The nurses advocated for passing legislation—specifically the Registered Nurse Safe Staffing Act (H.R. 876/S.58), the Veterans Access to Care Act (H.R. 1247), and the Home Health Care Planning Improvement Act (H.R. 2267/S. 227), as well as asking for increased funding for Nursing Workforce Development. Through their earlier efforts, 100 new cosponsors for the nurse staffing and home health bills were found.

This is an annual event sponsored by the American Nurses Association.

Do you know about Lobby Days at your local state capitol? Do nurses participate? Which nursing organizations or groups have lobbyists working with your state legislators?

Look up the three bills mentioned above (www.thomas.gov) and analyze how this legislation might improve nursing care and patient outcomes.

American Nurses Association (ANA). (2016). ANA Lobby Day: Let the advocacy begin. The American Nurse. Retrieved from http://www.theamericannurse.org/index.php/2015/08/31/ana-lobby-day-let-the-advocacy-begin-2/

Nurses represent the largest number of health care practitioners in America—more than 3 million—and are poised at the frontline in patient care to play a major role in implementing of health care reform. Being fully involved in the regulatory framework development (e.g., how the law will be implemented) will further demonstrate the advocacy of nurses as they work to improve the health care delivery system and remove barriers that prevent nurses from providing high-quality, competent, appropriate care. However, to change the existing system, the barriers to competent, quality care (e.g., nursing shortages, faculty shortages, a lack of proper education and training) that prevent nursing from taking its rightful place among the cadre of providers must be addressed. To that end, the Robert Wood Johnson Foundation (2010) in collaboration with the IOM began the activities necessary to "assess and transform" nursing. The document resulting from this evaluation is *The Future of Nursing: Leading Change, Advancing Health* (IOM, 2011). To encourage and assure public participation, three forums were held around the country.

The Future of Nursing is a seminal document that addresses the need to reform the health care and public health system of the 21st century and outlines nursing's pivotal role in this. This is the first time *nurses* are seen as key to "meeting current and future health care needs" (Schultz, 2010, p. 345). In the development of this document, the process was open to all. This allowed nursing to address challenges to the profession while simultaneously putting forth solutions that result in a rationale and a comprehensive approach to the delivery of high-quality health care for all. It also encourages system responsiveness to the needs of those accessing care.

As expected, the nursing organizations were active in the process of developing this document and participated in the National Summit on Advancing Health through Nursing held in late 2010 to discuss the implications of the recommendations for the future of health care and the future role of nurses in America (Robert Wood Johnson Foundation, 2010). Four key messages from *The Future of Nursing: Leading Change, Advancing Health* (IOM, 2011, p. 4) include the following:

1. Nurses should practice to the full extent of their education and training.
2. Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.

3. Nurses should be full partners, with physicians and other health professionals, in redesigning health care in the United States.
4. Effective workforce planning and policy making require better data collection and an improved information infrastructure.

The resulting eight recommendations are

Recommendation 1—*Remove scope of practice barriers*. Advanced practice RNs should be able to practice to the full extent of their education and training (p. 9). Lewenson (2015) notes the historical and current documents that call for nurses to practice to the full extent of their education and to remove barriers to practice.

Recommendation 2—*Expand opportunities for nurses to lead and diffuse collaborative improvement efforts*. Private and public funders, health care organizations, nursing education programs, and nursing associations should expand opportunities for nurses to lead and manage collaborative efforts with physicians and other members of the health care team to conduct research and to redesign and improve practice environments and health systems. These entities should also provide opportunities for nurses to diffuse successful practices (p. 11).

Recommendation 3—*Implement nurse residency programs*. State boards of nursing, accrediting bodies, the federal government, and health care organizations should take actions to support nurses' completion of a transition-to-practice program (nurse residency) after they have completed a prelicensure or advanced practice degree program or when they are transitioning into new clinical practice areas (p. 11).

Recommendation 4—*Increase the proportion of nurses with a baccalaureate degree to 80% by 2020*. Academic nurse leaders across all schools of nursing should work together to increase the proportion of nurses with a baccalaureate degree from 50% to 80% by 2020. These leaders should partner with education accrediting bodies, private and public funders, and employers to ensure funding, monitor progress, and increase the diversity of students to create a workforce prepared to meet the demands of diverse populations across the lifespan (p. 12).

Recommendation 5—*Double the number of nurses with a doctorate by 2020*. Schools of nursing, with support from private and public funders, academic administrators and university trustees, and accrediting bodies, should double the number of nurses with a doctorate by 2020 to add to the cadre of nurse faculty and researchers, with attention to increasing diversity (p. 13).

Recommendation 6—*Ensure that nurses engage in lifelong learning*. Accrediting bodies, schools of nursing, health care organizations, and continuing competency educators from multiple health professions should collaborate to ensure that nurses and nursing students and faculty continue their education and engage in lifelong learning to gain the competencies needed to provide care for diverse populations across the lifespan (p. 13).

Recommendation 7—*Prepare and enable nurses to lead change to advance health*. Nurses, nursing education programs, and nursing associations should prepare the nursing

> workforce to assume leadership positions across all levels, whereas public, private, and governmental health care decision-makers should ensure that leadership positions are available to and filled by nurses (p. 14).
>
> Recommendation 8—*Build an infrastructure for the collection and analysis of interprofessional health care workforce data*. The National Health Care Workforce Commission, with oversight from the Government Accountability Office and the HRSA, should lead a collaborative effort to improve research and the collection and analysis of data on health care workforce requirements. The Workforce Commission and the HRSA should collaborate with state licensing boards, state nursing workforce centers, and the Department of Labor in this effort to ensure that the data are timely and publicly accessible (p. 14).

Nurses are realizing that they are an important force in health care and should be at the table with other stakeholders when important decisions are being made. The IOM report on nursing is a clear hallmark of our growth in the area of health policy and health reform. Health care reform legislation has the potential to transform the current system to be more responsive to the least among us, is more focused on primary care and prevention, and encourages wellness and disease prevention. The resulting system change will be based on research and data collection that fosters better patient outcomes and high-quality care, but more importantly, without the anticipated transformation of nursing, it cannot occur. "Nurses' regular, close proximity to patients and scientific understanding of care processes across the continuum of care give them a unique ability to act as partners with other health professionals and to lead in the improvement and redesign of the health care system and its many practice environments, including hospitals, schools, homes, retail health clinics, long-term care facilities, battlefields, and community and public health centers" (IOM, 2011, p. S-3). This is a mandate for community health nurses to be actively involved in advocacy and influencing the future development of our health care system.

CURRENT U.S. HEALTH POLICY OPTIONS

What does the current health care system look like for PHNs? Earlier in this chapter, we discussed current health outcomes and the need for an increased focus on disease prevention and addressing the social determinants of health. The ACA has changed the policy options for health care on a national level. The United States had a long history of private support for medical care dating back to the early 20th century. Initially, most care was provided in the home, and families paid for any outside services they required. With the development of the germ theory, and the professionalization of medicine and nursing, people began to call on outside professionals to provide health care, primarily financed by individuals and families. As care began to shift to hospitals, and expenses increased, organizations that provided group insurance to cover hospital expenses became more common (Rambur, 2015).

During the First World War, the government recognized that many men of draft-eligible age had health conditions that prevented them from serving in the military. This prompted the first proposal for some type of national health insurance or coverage for health services. This proposal was not successful, but the issue continued to be discussed among policy makers for the next 100 years, with laws passed and regulations developed addressing health insurance coverage and health care regulation along the way. During the New Deal efforts of the Roosevelt administration, national health insurance coverage was originally included, but later bargained away, as part of compromise to get the legislation passed. With the beginning of World War II, the issue was dropped in favor of legislation to keep the country united and prepared for wartime sacrifices. Also during this period, many wartime industries had difficulty finding an appropriate labor source, as so many men were being drafted into the armed services. National cost control measures prevented industries from raising salaries to compete for workers, so industries began to offer benefits to recruit a capable workforce. These benefits included health insurance coverage (Rambur, 2015).

When World War II ended, and servicemen returned to their jobs, they found wartime industries converting to peacetime purposes, but the benefits like health insurance coverage had become an established part of worker benefits. Again, these benefits served to help companies attract and retain the best workers and created an expectation of health care coverage for workers and their families. However, for those who couldn't find work or those who were old enough to retire, there was a question of how their health insurance coverage would be managed. This led to a national policy debate focused on health insurance coverage for the unemployed and poor and for the elderly. This debate culminated in the 1965 enactment of Medicare that provides health insurance coverage for the elderly and Medicaid that offers coverage for the poor and unemployed (CMS, 2015).

Medicare and Medicaid were huge changes in the way health care had been financed. The options for financing were seen as employer-provided insurance, Medicare or

Medicaid, which ideally covered most of the population. And there was consensus on services to be covered. During the first half of the 20th century, medical technology and innovation proliferated—often because of advances in treatment developed during wartime in response to battle injuries and communicable illnesses. Simultaneously, economic prosperity led to improved living conditions and social policy changes, which had beneficial health effects for the population, including the development of vaccines, clean water and sewage treatment extended to most of the country, refrigeration and preservation of food, worker safety policies and the elimination of child labor, development and use of antibiotics, and improved nutrition. These medical and public health advances led to an increase in life expectancy of over 30 years between 1900 and 1965 when Medicare and Medicaid were enacted (CMS, 2015).

Thus, to use Milio's language, the health policy options of the late 1960s were focused on an assumption of continued access to safe water, good food, immunizations, antibiotics, and medical treatment. Medicare and Medicaid were designed to ensure that most American would have access to medical treatment. Once these were enacted, the policy challenges shifted to new and emerging treatments, and coverage under insurance, whether privately or governmentally supported. Physicians were the primary providers of medical treatments, and increasingly, such treatments were provided in hospitals. The policy challenge then came in the form of costs. With new medical technologies, pharmaceuticals, and innovations, along with new coverage for many people, medical costs began to rise. Ethical dilemmas arose, such as, should Medicare coverage be provided for the new procedure of renal dialysis? This issue became very controversial, as it was a policy debate addressing the intersection of costs and ethics. Who should be covered for this procedure? Those who had the greatest need (either medical or financial), or those with the most potential for productive life moving forward? In the end, the policy decision for that issue was that Medicare and Medicaid would cover renal dialysis costs for all eligible clients, which lead to a large number of people surviving end-stage kidney disease who previously would have died and a new and expensive innovation being used for a large number of people, thus increasing costs greatly (Swaminathan, Mor, Mehrotra, & Trivedi, 2012). This scenario arose for numerous new medical procedures and pharmaceuticals leading to a crisis in rising costs.

Other policy concerns addressed included funding for long-term care, for the increase in the population living longer, and debates on specific services to be covered by insurance. Medicare and Medicaid, as the largest insurers with one payer, became the standard setters for such decisions, and big private insurers followed their direction. Medical specialties proliferated to address new care needs brought about by technological advances, driving costs even higher. The policies leading to coverage for medical care spurred technological and pharmaceutical innovations, which had individual impacts on specific diseases, but led to ever-increasing costs. During this time, outcomes were examined for individuals, with dramatic successes of people with previously fatal illnesses, saving infants born earlier, and an increasing demand for high-end, technological services to extend life, despite the cost.

Policy makers talked about providing all Americans with the same access to services that were affordable for the very wealthy, and research funds supported development of increasingly technological, specialized treatments. Additional concerns came about when people lost their jobs and thus lost insurance or had jobs that didn't provide insurance coverage. National health insurance continued to be discussed, but was opposed by a wide variety of groups including fiscal conservatives, those who wanted limited government, some physician provider groups, and insurance companies (Nickitas et al., 2016; Rambur, 2015).

This debate continued until the passage of the ACA, and since its enactment, concerns persist regarding whether this is the best solution to ensuring access and controlling costs of care. However, in the past decade, policy and public health researchers have begun to examine seriously the health outcomes that have derived from the U.S. health care system as configured, with access to care largely through employer-based insurance and a focus on medical treatment. Although the system has spawned innovations in pharmaceuticals and technological innovations, these services have often been effective for a small number of people, in acute need and at a large cost. Thus, the system has developed to be expensive and largely ineffective for the overall population and more widespread disease prevention and chronic disease management needs. As mentioned earlier, the U.S. health care system options included

- Fee-for-service care
- Choice among physician providers
- Employment-based insurance
- Development and use of innovative technological and pharmacological interventions
- Individual responsibility for health promotion
- Prevention not cost-effective for consumers
- Focus on medical treatment

These options have been very successful as measured in terms of education of medical specialists, pharmacological treatments for many illnesses, surgical innovations, and diagnostic technologies. As discussed earlier, however, these options have not led to overall positive health outcomes for the population as a whole. Recent passage of the ACA (Medicaid.gov, n.d.) has led to policy changes designed to address these concerns.

The Affordable Care Act (ACA) and PHN Practice

The Patient Protection and ACA provided a dramatic change in U.S. policy options. Recognizing that the U.S. health care system was not addressing all the factors necessary to improve the health of the public, and that it was costing U.S. taxpayers an ever-increasing and sustainable proportion of the national budget, the Obama administration moved to pass health care reform legislation in 2010. The focus of the ACA, in the minds of the public, was to mandate health insurance coverage for all U.S. citizens, via a required minimal health insurance package, a mandate on employer provision of health insurance or employer contribution to a marketplace of insurance options for individuals to access, and government provision of subsidies for long income people without employer insurance coverage. Indeed, data indicate that the ACA has been successful at insuring those previously uninsured, with a recent Rand Corporation study indicating that the number of newly insured has risen by 16.9 million people as of 2015 (Rand Corporation, 2015). Provisions in health care reform also limit insurance companies from excluding persons because of preexisting conditions and provide for a broader array of coverage for preventive services, such as wellness programs and making nutritional information a requirement for chain restaurants. However, lesser known, but equally critical, changes in options available to people included regulations to improve quality of care provided, cost control mechanisms including future plans for moving from paying for services provided to paying for health outcomes achieved, and beginning efforts to focus health care policy and services on prevention of disease and health promotion (Knickman & Kovner, 2015).

As part of the ACA efforts to move to a culture of disease prevention, the ACA mandated formation of a National Prevention Council, composed of cabinet officials representing the social determinants of health, chaired by the Surgeon General of the United States. The council is charged with development of a National Prevention Strategy (Surgeon General, n.d.a). This strategy was introduced in June 2011 and addressed core strategic directions and priorities for an increased focus on public health and well-being. See Figure 13–5 for the National Prevention Strategy model.

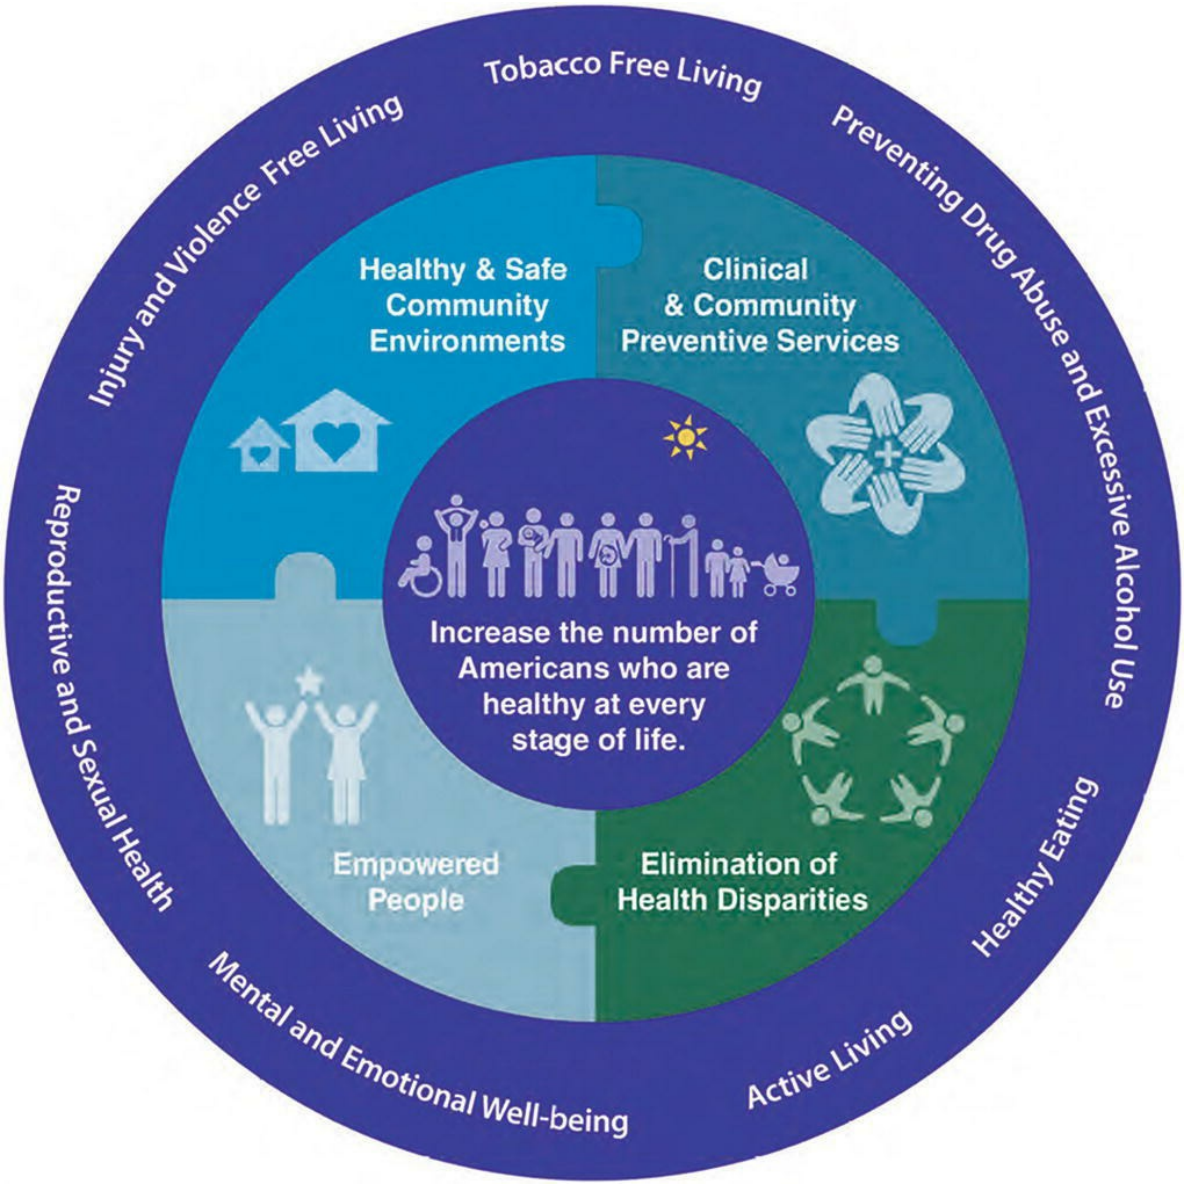

FIGURE 13–5 National Prevention Strategy model. (Adapted from Surgeon General. (n.d.). Retrieved from http://www.surgeongeneral.gov/priorities/prevention/strategy/)

At the core of the strategy is the overall goal of "increasing the number of Americans who are healthy at every stage of life" (para. 5). To achieve this, the strategy outlines four strategic directions, which address health care, health equity, and the social determinants of health and include

- Healthy and safe community environments: This strategy encompasses access to care, community health and development, neighborhood safety, environmental health and all the various social conditions that impact health.
- Clinical and community preventive services: Included in this strategy are those clinical screening and prevention services that are evidence based, with the goal of making these services accessible and affordable for all Americans.
- Empowered people: This addresses the need for community involvement in health

and health care, from the level of schools and businesses being able to see the importance of health to their work to individuals and families being empowered to act to improve their health and well-being.
- Elimination of health disparities: This strategy examines health inequities and recommends beginning prevention efforts in communities where disparities are greatest (para. 7).

Each of these four strategic directions included seven strategic priorities, based on data indicating that two thirds of premature deaths are due to chronic illnesses that can be prevented or controlled with prevention measures. For each strategic direction and priority, evidence-based recommendations are provided for all partners/stakeholders to address, including clinicians, businesses, elected officials and local/state/national government, church leaders and community service providers, educators, and individuals and families, thus highlighting that health promotion and disease prevention are the business of all Americans in every walk of life. The seven strategic priorities include (para. 9)

- Tobacco-free living
- Preventing drug abuse and excessive alcohol use
- Healthy eating
- Active living
- Mental and emotional well-being
- Reproductive and sexual health
- Injury and violence-free living

Subsequent work by the National Prevention Council and the federal advisory group appointed to advise and guide these efforts has included work to disseminate the strategies, document successes and lessons learned, and assist in promotion of model and exemplary interventions and policies to promote health and prevent disease across all levels of government (Surgeon General, n.d.a). The federal advisory group, appointed by the president, includes two nurses, who have worked to disseminate the NPS to PHNs across the country so that it may be incorporated as part of their practice initiatives (Surgeon General, n.d.b).

Additional components of the ACA that have the potential for great changes in health and health policy at the community level include value-based purchasing and accountable care organizations (ACOs), along with the expanded Internal Revenue Service (IRS) requirement for nonprofit hospitals to conduct regular community health needs assessments and develop implementation plans based on this data for improving the health of their communities (Knickman & Kovner, 2015). Nonprofit hospitals have a long history of providing care in the United States as part of a community or charitable mission. Often run by religious organizations, these facilities served communities, often caring for patients with no reimbursement for services. To support and encourage such work, local municipalities provided tax exemptions for such organizations, because of their benefit to

the community. The U.S. Government Accountability Office (GAO) has estimated that tax-exempt status saved hospitals $12.6 billion in federal, state, and local taxes in 2002 ($16.1 billion in 2012 dollars). With implementation of the ACA, medical insurance coverage has been achieved for an additional 16.9 million Americans who previously would have required charity care and now will have their care reimbursed (Rand Corporation, 2015). Hence, the ACA includes new IRS regulations to guide nonprofit hospitals in using their savings from the decrease in uninsured patients to conduct regular community assessments and develop a plan to work with others in their community to improve overall community health (Horwitz & Cutler, 2015). This process has great potential for PHN involvement, to assist local hospitals in conducting such assessments and being involved in planning for implementation of interventions to improve community health. Indeed, this is the cornerstone of public health practice, and PHNs can play key roles in this work.

Value-Based Purchasing and Accountable Care Organizations

The ACA began a movement away from the traditional fee-for-service care where health providers diagnose and treat individuals and are paid for each service provided (e.g., office visits, lab fees, prescriptions, follow-up visits) and that has thought to have led to increasing health care costs (James, 2012). This style of reimbursement for care has had the problem of indirectly encouraging additional care, as each service is reimbursed separately. National health policy has begun to reverse this by mandating no reimbursement for specific services required because of medical error. The ACA expands this with a move toward *value-based purchasing*, or reimbursing a specific amount based on achieving the likely outcome for clients within specific diagnostic categories. For example, instead of fees for office visits, lab fees, and prescriptions, the federal government is proposing paying for achievable health outcomes in a bundled manner based on the client's demographics and diagnosis. A diabetic would not have each service reimbursed, but rather a lump sum reimbursement would be provided upon the client achieving a level of stability in the disease (e.g., lab values for hemoglobin A1c within normal limits). This reimbursement would cover whatever services were required to achieve this outcome, which might be lab tests and medications, but might also include PHN-provided chronic disease self-management training or clinical nutrition counseling. Such a change in reimbursement mechanisms would have a large impact on health care services, as clinical agencies would need to begin looking at what services and providers were most effective at achieving the desired outcomes. This would provide an opportunity for PHNs to demonstrate the effectiveness of their practice interventions in improving health outcomes for individuals and populations (California Directors of Public Health Nursing, 2015; Knickman & Kovner, 2015; Kulbok, 2013; Porter & Lee, 2013; Rambur, 2015; Washington State Nurses Association, 2011). When a national sample of public health nurses were asked about their involvement with components of the ACA, over 65% responded that they were actively involved with integration of public and primary health care, and nearly as many were working in clinical preventive services. Almost 60% noted activity with patient navigation,

care coordination, and establishing public/private collaborations. Slightly fewer mentioned involvement with population health strategies and data, along with community health assessments (Edmonds, Campbell, & Gilder, 2015).

Accountable Care Organizations (ACOs) are another feature of health care reform that is intended to emphasize quality over quantity. Physicians and other health care providers are forming groups, sometimes in conjunction with hospitals, and will be paid based on patient's treatment outcomes (not the number of visits or tests). Thus, duplicative tests or procedures should be avoided, as a more coordinated form of treatment is available. One goal of ACA is to provide 30% of Medicare services to alternative payment models, such as ACOs, and away from fee-for-service models. In addition to cost savings, quality is also a focus. In 2014, Medicare ACOs demonstrated $411 million in cost savings, while 27 out of 33 quality measures were improved between 2013 and 2014 (USDHHS, 2016). Newer types of ACOs not only pay based on quality outcomes but also penalize for negative outcomes, shifting risk to providers and away from the government. The number of ACOs is growing, with 121 new participating groups in 49 states announced in 2016.

Policy Competence as an Integral Part of PHN Practice

The U.S. health care system is undergoing significant changes to improve the health of the public and contain costs. These changes are impacting health care across the system, but are particularly critical for those who work in communities with the increased emphasis on population health and disease prevention. The PHN can be an integral part of these efforts and help lead the way in addressing the social determinants of health and focusing efforts on prevention and long-term health promotion for families and communities. Along with other public health professionals, PHNs need to do this by understanding the policy process and then determining where their efforts would be most effective in improving overall population health (Haughton & Stang, 2012). This is a critical time for nursing in general, and PHN specifically, as the health care system focuses attention on what has always been at the core of PHN concern—health where people live, work, play, and pray.

POWER AND EMPOWERMENT

Eliciting services and programs for underserved populations is a never-ending issue. Citizen participation is never particularly easy in communities that are excluded from political or economic resources. Sherry Arnstein, in her classic 1969 treatise *A Ladder of Citizen Participation*, stated that "citizen participation is citizen power," and without access to information about how the system functions, these populations cannot obtain the resources they need to make their communities livable and nurturing (p. 217). Arnstein goes on to point out that those in power prevent those in need from accessing the process:

> The idea of citizen participation is a little like eating spinach: no one is against it in principle because it is good for you. Participation of the governed in their government is, in theory, the cornerstone of democracy—a revered idea that is vigorously applauded by virtually everyone. The applause is reduced to polite handclaps, however, when this principle is advocated by the have-not Blacks, Mexican Americans, Puerto Ricans, Indians, Eskimos, and Whites. When the have-nots define participation as redistribution of power, the American consensus on the fundamental principle explodes into many shades of outright racial, ethnic, ideological, and political opposition (p. 216).

Although Arnstein writes about the anger that disenfranchised populations feel, she does offer possible solutions that allow each party to "share power through partnership," as outlined by engaging in the process discussed in her treatise (p. 217). See more on this in Chapter 15. Power can be defined as the ability to act or produce an effect, possession of control, or authority or influence over others. As public health professionals, nurses have a commitment to social justice and working with disadvantaged communities. This means that nurses have a responsibility to ensure community participation in issues affecting them, and they must continually examine the relationship and position they hold within these communities. The term empowerment has been used to explain a process of assisting communities to come together to express their values and ideas to those outside the community (Cawley & McNamara, 2011). Generally, the issue of empowerment comes up when outside forces are behaving in a way that the community considers detrimental to its well-being. The various definitions of empowerment and the expansion of the definition of health, which now includes the social, political, and economic determinants of health, have changed our thinking on how best to interact with the communities we serve. Theorists have suggested that if power is the ability to control, predict, and participate in one's environment, then empowerment is the process whereby individuals and communities take power and transform their lives (Baffour, 2012; Petit, 2012; Turner & Maschi, 2015). This also suggests a change in the relationship between professionals and communities—a change from the customary hierarchical patient–provider relationship to one of a partnership. How does the PHN make sure that preconceived ideas about certain communities are not forced on the community in order to meet the goals and objectives of the public health agency? In the past, community health promotion practice often only met the bottom rung of Arnstein's ladder by using the rhetoric of community participation while the professionals working with the community actually set the agenda. Health

promotion may best be facilitated by the use of empowerment and assisting individuals and communities in articulating their problems and solutions. Discovering what is most important to the community and providing access to that information while supporting leadership from within the community and encouraging them to overcome bureaucratic hurdles to action are important parts of community empowerment. This helps to improve problem-solving skills and abilities (Kulbok, Thatcher, Park, & Meszaros, 2012; Piper, 2011; Wong, Zimmerman, & Parker, 2010). Maryland and Gonzalez (2012) note that sharing personal experiences and stories with legislators is one effective method of advocacy. Real stories about clients having problems gaining access to services or resources, not receiving adequate or timely treatment, or about the need for more school nurses who are currently spread so thin that they cannot adequately perform their assigned roles and functions. Firsthand knowledge of how our health care system works (or doesn't work) can be very persuasive when a nurse shares personal examples in a way that demonstrates a passion for clients and communities.

So, how can PHNs influence policies that affect the clients and communities they serve? And, how do we influence policymakers to hear our concerns and act on them? Seasoned advocates have developed skills in influencing policy decisions; ground rules also exist by which to play the game. Some call them the "ten commandments of lobbying." However these steps are described, advocates adhere to the basic ideas inherent in the following:

1. Honesty is the best policy. Being known as someone who has integrity is a lasting virtue. Never mislead a legislator or someone who is likely to support your interests, as it is difficult to regain credibility once you lose it. Speaking beyond your level of expertise gets advocates into trouble. If you don't know the answer, say so; but if you promise to get the answer, then do so. Do not promise what you can't deliver.
2. Start early. Planning always takes longer than you think it will. Your interests are not everyone's interests and convincing others they should be involved always involves time. If you are planning policy change at the state or federal level, it is vital to know the legislative process and the critical time lines.
3. Know what you want. Be aware of all sides of the issue prior to approaching a policy maker, know the pros and cons, and be prepared to answer questions and provide data on both sides of the issue. Understand the role politics plays in getting what you want and how policy makers may respond to your issue. Targeting your story to the goals, emotions, and interests of the legislator is important and may result in a positive outcome. Be *clear* about what you are asking the legislator for—to carry legislation, or to vote no or yes on specific legislation. Asking your legislator to vote a certain way is perfectly legitimate, and if you don't ask, the opposition will.
4. KISS (Keep it simple, stupid). Be able to articulate your issues in a clear and concise manner. Do not confuse possible supporters with complicated arguments. Key issues should be concise and clear and on one page, no more than two. Leave behind an informational packet with pertinent information about the community and/or services

and programs.

5. No permanent enemies, no permanent friends. Political affiliation doesn't always determine what interests a person has or whether they are likely to support your interests. It behooves you to speak with everyone on your issue; if nothing else, you may find out who they are and why they may oppose your concerns. Remember, in politics, there are only permanent interests.
6. Know your opponents. Visit with all possible supporters—just because someone opposed you in the past doesn't mean they won't support you on a current issue. Respectful disagreement keeps the door open for future agreement and compromise.
7. Compromise. Ask for much more than you think you can get. When negotiating, you can give up something without hurting your priorities or your bottom line. In politics, rarely does anyone get all they want, but priority setting is key: What do we expect to accomplish with this activity?
8. There is strength in numbers. The more groups involved, the more likely you are to be successful. Any opportunity for networking is an opportunity to enlarge your coalition. Including disparate groups means you may have accessed conflicting political persuasions. Additionally, it is useful to have groups who can speak with those who are not viewed as "friends." Cross-fertilization of groups is politically expedient, but understand that next time you or they may be in opposition.
9. Work at the local level. Legislators are interested in their constituents—these are the people who elected them to office and who will keep them in office. To be noticed by policy makers, sharing information with them about their constituents is the surest way to capture their attention. Information sharing should occur on issues both in the community where you live and in the one where you work.
10. Thank you. Everyone loves to be told, "Job well done." To maintain your coalitions, always recognize the work of others. Spreading the credit is like sowing seeds: the wider the spread, the more bountiful the crop.

Common methods of generating a conversation with legislators are by e-mail, over phone, or in person. Often, your first contact will be a staff member. It is important to organize your thoughts and carefully craft an "Ask" or what legislation you want the legislator to support that is also something of interest to them and their constituents (Kostas-Polston et al., 2015, p. 12). If possible, you can prepare a "one-pager," with your contact information and credentials listed, along with brief bulleted points on the subject of interest that includes current statistics and research (p. 13). If you meet with a legislator, it is important to remember that they are not allowed to discuss campaign contributions in their legislative offices. Finally, it is important for those new to advocacy to understand that the thing with the most critical influence on policy is *money*. Nurses, even with the passage of the recent health care reform legislation, must become even more actively involved in the process of influencing policy. How many nurses understand that the nurse practice acts, or portions thereof, under which they work are developed by legislators or special interest groups who don't have a background in health care? How many nurses know who their

legislators are at either the state or federal level? How many nurses have written their legislators about pending health care legislation or legislation that affects nursing?

Political Action Committees

One reason why nurses are less politically active can be tied to a lack of money. Nurses don't earn as much money or appear not to have access to as much money as other health care interests (e.g., hospitals, physicians, insurance companies, and health care plans), and as such, there is much less money for nursing organizations to use for lobbyists or to assist chosen candidates. As mentioned earlier, the ANA has a PAC that supports federal candidates on a nonpartisan basis; candidates must demonstrate an interest in and willingness to vote for nursing issues or issues that nurses support. To participate in the PAC, you must be a member of ANA (this also allows your family to contribute to the PAC). By giving to the ANA-PAC, one maximizes their contribution by joining with other nurses—this power in numbers increases our influence with those candidates we choose to endorse. ANA-PAC has the "Race for the Million" campaign to raise money in support of candidates and legislators who back nurses' issues (Song, n.d.). However, giving to your personal legislator can keep you on their mailing list, and it may get you invited to local legislative activities. It also lets your legislator know you are interested in whether she remains in office. Being in regular contact with your legislators provides an avenue for introducing legislation that impacts nursing or other health-related issues, and when you call to ask for a vote "for" or "against" an issue, the legislator is more likely to entertain your request. Aren't you more likely to respond to someone you know, rather than someone who comes to you out of the blue to ask for a favor?

Lobbyists may work for PACs or independently represent various special interests or groups. Lobbying is the process of influencing legislators or other policy makers to make decisions on policy issues. Professional organizations or other special interest groups (individuals who share a common interest and work politically to make their goals a reality) may retain paid lobbyists. Lobbyists are professionals who know the rules governing the state or federal political process, have or develop relationships with policy makers, provide guidance for members of the organizations employing them on how to impact public policy decisions, and work behind the scenes to influence policy discussions and outcomes. States and the federal government have laws and regulations that determine the legal actions of lobbyists as well as the organizations that employ them (Mason et al., 2016; Milstead, 2016). However, some lobbyists are former legislators or staff members who "take lucrative jobs representing the very industries" they formerly regulated, and this "revolving door" lobbying is disconcerting to most citizens as they are often seen as selling their access to current key legislators (LaPira & Thomas, 2014, p. 4).

Volunteering

Money is *not* the only way to build a relationship with your legislator. Volunteering your time can be just as important (see *Perspectives—Voices from the Community*). Candidates for office need people to get things done (e.g., phone banking, stuffing mailers, answering phones, putting up flyers and campaign posters, walking door to door to spread the message, and assisting in the development of issue papers). Candidates develop issue papers to tell their constituents where they stand on key campaign concerns. Nurses have the expertise to assist legislators in developing an agenda on health care policy or at the least to review and comment on issue papers.

PERSPECTIVES VOICES FROM THE COMMUNITY

Volunteer Service for the Long Term

A registered nurse (RN) who had been through what I called the women's legislative career ladder—School Board, City Council, and the County Board of Supervisors—was now posed to run for the state legislature. Because we had had numerous contacts and I believed she would make a good state legislator and a voice for nursing and health care, I volunteered to work in her campaign office. I primarily answered the phones on the evenings I worked, but I met the office staff—many of them were much younger than me. And, even once, she came in while I was there. I talked with the staff about some of my experiences as a lobbyist, and they shared their experiences; many of them were fresh out of college.

She was successful in her run for office, and whenever I needed to meet with her or her staff, I was shown right in. I was also asked my opinion about the hiring of certain staff. Her staff knew me by name—many of them did not work on her campaign, but they were told about me by those campaign staff who were still around. After 3 years in office, she was appointed chairperson of a key committee, and I maintained access to her committee consultants and to her when necessary. We were able to work together quite successfully, and although we didn't always agree on every policy issue, I think the weeks I put in volunteering 3 years earlier really paid off for the clients and the issues I was representing.

—L.B., Professional Lobbyist

Relationships are critical in policy development and in affecting public policy. As demonstrated earlier, being a friend can reap huge benefits when health care policy is on the line. Being involved in local and state elections can take many forms. Voting, for instance, is vital—RNs represent a substantial block of potential voters (Nickitas et al., 2016). Joining your local and state professional organizations is vital to having the voice of nursing heard at all levels. You can become more actively involved by writing legislators about the health care issues that impact the communities, both where you live and work. It is also vital to understand the importance of critically timing those communications. Effective communications with legislators should be tied to times when the issues are being heard in policy committee—thus, you must know when your issue is scheduled to be discussed in committee. For example, it is prudent to send letters on your issue—via fax or regular mail—close to the time of the committee hearing. Holding a press conference or getting other media coverage when the bill is introduced, or on the day it will be heard in committee, is quite effective in drawing attention to your issue. Writing letters to the editor of your local newspaper on health issues and writing articles for various publications are also effective methods of persuading others to back your issue. Other methods for influencing health policy or nursing issues include applying for positions on boards and commissions; each local area has advisory committees for their locally elected officials at the city and county level. The state board of RNs needs nurses willing to sit on their board or to serve on various advisory committees and task forces. At your state capitols, there are usually vacancies on policy committees, or legislators may be looking for new staff—either personal or policy. And, who better to serve in this capacity than a nurse! Who else has more knowledge about health issues than nurses? When all else fails, *run for office*.

SUMMARY

This chapter has reviewed briefly the disparities in health outcomes and discusses the relationship between health policies and population health outcomes. Public health policy is explained, and types of policies (e.g., substantive, procedural, distributive, redistributive, regulatory) are described. Policy competence, or an understanding of policy formulation, implementation, and modification, is important for public health nurses because of the ability to influence both the policy process and the impact of policies on the clients. PHNs need to determine first the level at which policies are considered (e.g., local, state, national). The legislative process (i.e., how a bill becomes law, rulemaking, implementation, evaluation, judicial action) occurs in similar ways at the state and national levels. Policy analysis requires the ability to comprehend policy from various viewpoints, and the rational framework and Kingdon's framework, along with Longest's model, provide guidance in determining windows of opportunity upon which public health nurses may act to initiate policy changes.

The political process is inherent in the development of health policies, and the public health nurse has a role in policy and advocacy within those processes. Lillian Wald, and others like her, provided a rich history of political action and advocacy in public health nursing as they worked to provide a voice for vulnerable and disenfranchised populations. Social justice remains a pillar of our current practice.

Advocacy for our clients is always important, but professional advocacy through affiliation and activity in our professional nursing organizations is also vital so that we, as PHNs, may have a "collective voice." Politics may be uncomfortable and foreign to many of us, yet it provides the methods for needed change through lobbying or influencing legislators. Nurses and special interests groups can gain access to legislators individually or through the services of a professional lobbyist or PACs. Nurses can also serve on various advisory and community boards, and provide input on policy matters by sharing expertise, research/evidence, and personal experiences.

Policies are actions or agendas that can be used to implement important goals and objectives, such as the health objectives found in *Healthy People 2020*, and PHNs can use processes to impact policy formulation, adoption, implementation, and evaluation. Tips on how to influence policy makers were outlined, and nurses may consider volunteering time to a candidate of their choice as a means of gaining greater access to the political process. Nurses' role in health care reform was discussed, along with IOM's *The Future of Nursing* and examples of lobbying efforts. Current U.S. policies, including the ACA and the National Prevention Strategy, provide opportunities for PHNs to improve the health of populations and share with policy makers and legislators the importance of social determinants of health.

Community health nursing is by nature political because we deal with many issues that affect the health and well-being of the diverse populations we serve. Power and

empowerment are important concepts to both public health nursing and politics; Arnstein's ladder provides guidance on citizen participation. Every community health nurse should hone political action and advocacy skills.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Investigate a major health policy system in your community or state, discover how it works, and determine whether public health nurses are represented in this system. Areas to investigate include the boundaries of the system, the authority by which the system generates health policy, how the system receives input (formally and informally), resources the policy system uses and allocates to others, and the system's output over the past few years.
2. Describe a legislative bill related to health at either the state or federal level and the issues involved in it. Identify who is sponsoring the bill, who is opposing it, and why. Determine the population that will be affected by the bill if it passes and in what ways they will be affected. Discuss what you, as a community health nurse, could do to be involved in this bill and then develop a political action plan to support or oppose the bill. E-mail your legislator regarding your position.
3. Attend a meeting of a professional organization, board of directors, government agency, or council when a health policy or health care issue is on the agenda. Analyze the positions of the major interest groups involved and describe to what extent economics comes into the discussion. Describe who controls the discussion and how this is done.
4. What issues or events occurred in the United States that reduced the willingness of nurses to speak out about health care issues? Examine the years starting with the 1930s. What events or issues changed, if any, to reinvigorate nurses serving as political activists?
5. Are nurses the most qualified group to articulate national health care issues? If so, why? If not, why not?
6. Who are your state legislators? What are the critical health issues in your state, and how have your legislators responded to the issues? If there has been health care–related legislation introduced:

   - What is the issue?
   - What political party introduced the bill?
   - At the current time, where is the bill in the legislative process?
   - What groups support or oppose the legislation?
   - What is the reasoning for the groups' support or opposition?

7. How active is your state professional nursing organization in policy issues? Are you a member of the organization? If not, why not? What are the public policy issues the organization is involved in? How successful have they been? Does the group have a paid lobbyist or does it rely on volunteer lobbyists?

Theory

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Discuss three essential characteristics of nursing service when a community is the client: community-oriented, population-focused care and relationship-based care.
- Describe the contributions of at least five models of nursing practice to community/public health nursing practice.
- Describe four programs or initiatives that demonstrate application of the eight principles of public health nursing to community/public health nursing.
- Identify at least five social issues that influence contemporary community/public health nursing care.

When you open the door of a senior center where you will be promoting cardiovascular fitness, advocating for exercise equipment, and suggesting changes in the on-site meal program, how might theories of public health nursing contribute to your success? When you approach your city council about the need to increase staffing for public health services, what models of public health nursing practice might

support your argument? What are *theories, models*, and *principles*, and what is their relevance to day-to-day public health nursing practice? These are the key issues explored in this chapter. First, however, we revisit some of the fundamental characteristics of community/public health nursing that we began to explore in Unit 1.

WHEN THE CLIENT IS A COMMUNITY: CHARACTERISTICS OF COMMUNITY/PUBLIC HEALTH NURSING PRACTICE

Nursing exists to address people's health care needs, and nurses fulfill this purpose through their work in various specialty areas. Specialties are characterized by the unit of care for which the specialty is responsible and by the goal of the specialty. Each specialty requires a particular area of knowledge and a set of skills for excellence in practice.

Public health nursing is a specialty in which the unit of care is a specific community or aggregate, and the nurse has responsibility to promote group health. The goal of this specialty is health improvement of the community. Some of the skills required for excellence in public health nursing practice include epidemiology, research, teaching, community organizing, and interpersonal relational care.

In summary, community/public health nursing is characterized by community-oriented, population-focused care and is based on interpersonal relationships. In the following sections, each of these characteristics is examined in more depth.

Community-Oriented, Population- Focused Care

As was discussed in Chapter 1, a *community* is a group of people who have some characteristics in common, are bounded by time, interact with one another, and feel a connection to one another. For example, members of an Internet-based support group for people with colitis are a community. They share similar experiences and concerns, and they often influence one another's behavior. For instance, they may recommend food choices or complementary therapies to one another. Members of a class of community/public health nursing students are also a community. Because they begin and end their studies in a particular month and year, they are bonded by time, and they most likely share certain values and feel a sense of connection to one another.

Community orientation is a process that is actively shaped by the unique experiences, knowledge, concerns, values, beliefs, and culture of a given community. For example, when an outbreak of hepatitis occurs, the public health nurse does more than simply treat infection in individuals. The nurse also:

- Uses disease investigation skills to locate possible sources of infection
- Determines how the community's knowledge, values, beliefs, and prior experiences with infectious disease may influence its interpretation of the disease, response to the outbreak, and treatment preferences
- Uses knowledge and suggestions gathered from the community to develop, in collaboration with other health professionals, a community-specific program to prevent future outbreaks

A community-oriented nurse who provides education about sexually transmitted diseases to a group of students at a Catholic university includes consideration of community values regarding sexual behavior. Similarly, a community- oriented nurse who provides nutritional counseling to a community of Hispanic seniors considers the meaning of food in this culture, the types of food most commonly consumed, and the cooking methods most commonly used.

A *population* is any group of people who share at least one characteristic, such as age, gender, race, a particular risk factor, or disease. Smokers and breast cancer survivors are two populations. The concept of population may also include delineation by time (e.g., all infants born in the year 2017). The nurse's place of employment commonly limits the population that the nurse serves. For example, a nurse who works for a county health department is limited professionally to caring for the population residing in that county.

A *population focus* implies that a nurse uses population-based skills such as epidemiology, research in community assessment, and community organizing as the basis for interventions. For example, a population-focused nurse employed by an autoworkers' union may study all cases of repetitive-use injury occurring in the auto industry in the United States in the past 5 years, develop a program for reducing repetitive-use injury, and

lobby industry executives for adoption of the program.

Community-oriented, population-focused care employs population-based skills and is shaped by the characteristics and needs of a given community. Public health nurses provide community-oriented, population-focused care when they count and interview homeless people sleeping in a park and, based on these data, help develop a program to provide food, clothing, shelter, health care, and job training for this population.

THEORIES AND MODELS FOR COMMUNITY/PUBLIC HEALTH NURSING PRACTICE

A theory is a set of systematically interrelated concepts or hypotheses that seek to explain or predict phenomena. For example, the "big bang theory" seeks to explain the series of events that occurred during the earliest moments in the history of our universe. A theory is based either explicitly or philosophically on a conceptual model (also referred to as a conceptual framework, a conceptual system, or a paradigm). A conceptual model, as defined by Bigby and Issel (2012, p. 371), is "an integrated set of concepts and relational statements that provide direction for clinical assessment, analysis, planning and evaluation." These concepts are presented in a framework format, used to explain the relationships between variables.

Nurses can enhance their practice in an ever-changing clinical environment by embracing nursing theories and incorporating them with empirical evidence from the research (McCrea, 2012). In response to a wide gap between what was known through research and what was implemented in practice, a movement had begun to implement evidence-based practice (EBP) into nursing care to improve patient outcomes. The Quality and Safety Education for Nurses (QSEN) project identified EBP as one of the six competencies recommended for safe, high-quality nursing care (Case Western Reserve University, 2014). Evidence-based nursing practice brings together empirical evidence obtained through research, nursing expertise, and patient values (Stevens, 2013). Theory plays a critical role in each of these three legs of the EBP triangle. Theoretical frameworks are used to guide the research process. In addition, theory can be used to understand patient values and behaviors, and theory can describe nursing practice.

Nursing theorists have sought to present nursing practice constructs in comprehensive and systematic ways. The evolution of conceptual model and theory development in nursing dominated the last half of the 20th century. The scholarly and creative efforts of those nurse leaders and researchers sought to explain what nursing is and how it influences individuals, families, or communities and provide a basis for building nursing knowledge. From those early efforts came more testable theories, many from those same nurse researchers; those theories are typically referred to as middle-range theories. Although less abstract than conceptual models, the need for an even more practical approach to theory use and testing led ultimately to practice-based theories (Alligood, 2014; McCrea, 2012).

To more fully understand the elements inherent in a nursing theory and the underlying conceptual model, a pictorial representation, or graphic model, is often used. These models provide a visual means to understand the relationships between, for instance, the nurse and the environment, the nurse and the client, or the client and stressors. However complex these models are, comprehension of the entire work can only be derived from reading the theorist's descriptions of the conceptual models, the theories, and the

subsequent research testing those theories. Concepts, when fully defined, related/linked, and measured, describe the building blocks of the theory. Both theories and conceptual models have been developed to describe, clarify, and guide nursing practice (Alligood, 2014). Theories and conceptual models that have particular relevance to the practice of community/public health nursing are described here.

Nightingale's Theory of Environment

Florence Nightingale's environmental theory has great significance to nursing in general and to public health nursing specifically, because it focuses on preventive care for populations. While organizing and supervising a nursing service for soldiers in the Crimean War, Nightingale kept meticulous records. Her observations suggested that disease was more prevalent in poor environments and that health could be promoted by providing adequate ventilation, pure water, quiet, warmth, light, and cleanliness. In fact, 420 soldiers per 1,000 died within the first 2 months of Nightingale's arrival, and she was able to reduce that rate to 22 per 1,000 soldiers within 6 months time. The crux of her theory was that poor environmental conditions were bad for health and that good environmental conditions reduced disease (Johnson & Webber, 2015; Nightingale, 1859/1992).

As current-day public health practitioners look upstream to identify the root causes of poor health, physical, social, and economic factors have been identified as influencing health outcomes. Where people live, work, and play impacts their overall health (U.S. Department of Health and Human Services [USDHHS], 2016d). Examples of these determinants of health include segregation, the design of a home or a community, the availability of green spaces and light, access to healthy foods, and much more. These same observations were made generations ago by Florence Nightingale as she provided care to those living and dying in unhealthy environments.

A more expansive list of social and physical determinants of health can be seen in greater detail in Displays 14–1 and 14–2 (USDHHS, 2016d). As you think about services included in Display 14–1, it is useful to consider:

DISPLAY 14.1 EXAMPLES OF SOCIAL DETERMINANTS OF HEALTH

- Availability of resources to meet daily needs (e.g., safe housing and local food markets)
- Access to educational, economic, and job opportunities
- Access to health care services
- Quality of education and job training
- Availability of community-based resources in support of community living and opportunities for recreational and leisure-time activities
- Transportation options

- Public safety
- Social support
- Social norms and attitudes (e.g., discrimination, racism, and distrust of government)
- Exposure to crime, violence, and social disorder (e.g., presence of trash and lack of cooperation in a community)
- Socioeconomic conditions (e.g., concentrated poverty and the stressful conditions that accompany it)
- Residential segregation
- Language/literacy
- Access to mass media and emerging technologies (e.g., cell phones, the Internet, and social media)
- Culture

From U.S. Department of Health and Human Services. (2016). Healthy People 2020: Social determinants of health. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/overview.aspx?topicid=39

DISPLAY 14.2 EXAMPLES OF PHYSICAL DETERMINANTS OF HEALTH

- Natural environment, such as green space (e.g., trees and grass) or weather (e.g., climate change)
- Built environment, such as buildings, sidewalks, bike lanes, and roads
- Worksites, schools, and recreational settings
- Housing and community design
- Exposure to toxic substances and other physical hazards
- Physical barriers, especially for people with disabilities
- Aesthetic elements (e.g., good lighting, trees, and benches)

From U.S. Department of Health and Human Services. (2016). Healthy People 2020: Social determinants of health. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/overview.aspx?topicid=39

- Why these services were created?
- Who benefits from the services?
- Who pays for the services?
- What is the cost to the people using the services?
- What is the public perception of the services?

For example, if ventilation in a city's homeless shelter is inadequate, the public health nurse who plans to advocate for capital improvements to the shelter needs to consider who pays for the shelter as well as the public's perception of the shelter.

One contemporary example of the utility of Nightingale's theory is the work done by public health nurses in Cook County, Illinois. These nurses used geographic information system (GIS) technology to create maps that indicated the level of walkability in low-income neighborhoods. Features that were identified included availability of sidewalks and accessibility to grocery stores and health services (DeGuzman & Kulbok, 2012). Using the evidence that demonstrates the link between environment and poor health, these nurses were able to advocate for changes to be built into those communities identified as having poor walkability. Nightingale's influence on the way nurses approach health issues that impact the communities of today remains a powerful force, as noted by Zborowsky (2014) in a study about the influence of Nightingale's theory on nursing research.

Orem's Self-Care Model

Dorothy Orem (1914–2007), a nurse administrator and educator, focused on the concept of *self-care*—learned, goal-oriented actions to preserve and promote life, health, and well-being. She described people who need nursing care as those who lack ability in self-care and discussed three systems of self-care: fully compensatory system where the nurse needs to provide care as the patient is unable to do any self-care, partially compensatory system where both the patient and the nurse work together in care provision, and the supportive–educative system where the nurse reinforces the patient's self-care efforts (Johnson & Webber, 2015; Orem, 2001). If a demand for self-care exceeds the client's ability, the client experiences a self-care deficit, and nursing intervention becomes appropriate. The goal of nursing action is to help people recognize their self-care demands and limitations and increase their self- care ability. Nursing care also functions to meet clients' self-care needs until they are able to care for themselves. Orem further described three types of requirements that influence people's self-care abilities:

- Universal requirements are activities common to all human beings, which are essential to meet physiologic and psychosocial needs.
- Developmental requirements are activities necessary to help people progress developmentally.
- Health-deviation requirements are activities needed to help people deal with a diminished level of wellness.

Although Orem's model focused primarily on individuals, it can be applied to public health nursing practice. Populations and communities can be considered to have a collective set of self-care actions and requirements that affect the well-being of the total group. If an aggregate's demands for self-care exceed its ability, the aggregate experiences a self-care deficit, and public health nursing intervention is indicated. According to this interpretation, the goal of nursing is to promote a community's collective independence and self-care ability. Kagan expanded on Orem's interpretation of self to reflect a more unitary link between humans and their environment; considering human–environment as one entity. With this worldview, she emphasized that nurses "can learn new information, make ethical and political decisions, and act to take care of the environment including regulation of human interaction with, and impact on, the environment" (Kagan, 2011, p. 73).

Green (2013) described how Orem's Self-Care Deficit Theory can be applied at the population level by school nurses who develop care plans for children with disabilities to help them meet their self-care requisites. Orem's constructs of conditioning factors and universal self-care requisites correlate to the public health concepts of social determinants of health and the World Health Organization's (2016) definition of health, not as the absence of disease, but as physical, mental, and social well-being. Orem's basic conditioning factors can be related to the compounding effect that overlapping factors of inequality such as

access issues, discrimination, and racism present. This is known as intersectionality (Green, 2013). Children with disabilities are an example of a vulnerable population because of accessibility challenges, discrimination, and their young age, which is further compounded by health risks related to their preexisting medical condition. Health outcomes are likely to differ between students even though they may have similar diagnoses. One child may be from a mainstream culture and have a stable, middle-income family, whereas another may be a minority, experiencing racism and living in poverty. To ensure optimal health for all, school nurses must be mindful that children may experience confounding factors beyond their physical disability that further threaten their self-care agency to ensure health (Green, 2013).

Neuman's Health Care Systems Model

Betty Neuman, a leader in mental health nursing and nursing education, proposed a systems model first used in a graduate community mental health clinical specialist program (Neuman, 1982; Neuman & Fawcett, 2011) and can be adapted to view clients as aggregates. In this model, people are seen as open systems that constantly and reciprocally interact with their environments. Each system is greater than the sum of its parts, and wellness exists when the parts of the system interact in harmony with each other and with the system's environment. Four sets of variables, or influences, make up each system's "whole." These are physiologic, psychological, sociocultural, and developmental variables. Given these variables, each system has a unique response to environmental stressors and to those tension-producing stimuli that may cause disequilibrium or illness (Alligood, 2014; Johnson & Webber, 2015).

A system's response to stressors may be envisioned as a series of concentric circles (Fig. 14–1). In the center is a core of basic survival abilities, such as a community's ability to make the best use of its natural resources. Surrounding this core are three boundaries. The innermost boundary is a flexible line of resistance that encompasses internal defenses, such as a community's collective sense of responsibility for raising healthy children. The second boundary is the system's normal line of defense, such as a community's police force or voluntary fire brigade. The third boundary is a dynamic, flexible line of defense, a buffer that prevents stressors from invading the system's normal line of defense (Alligood, 2014; Johnson & Webber, 2015). An example is regular maintenance of a community's roads and bridges.

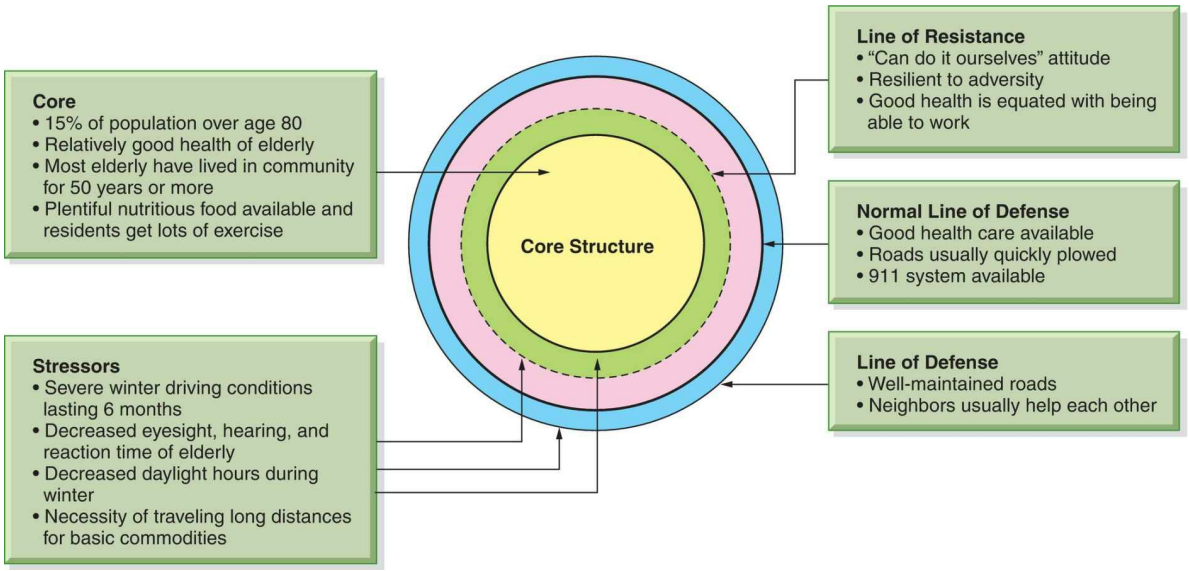

FIGURE 14–1 Neuman's Health Care Systems Model applied to a rural county regarding traffic safety issues concerning the elderly by D. Block. (From Allender, J., & Spradley, B. (2001). Community health nursing: Concepts and practice (5th ed.). Philadelphia, PA: Lippincott, with permission.)

In Neuman's model, stressors can originate from the internal environment or the external environment. Examples of internal stressors include a high proportion of low-income residents or an inadequate system of water purification. External stressors might include natural disasters, war, or a downturn in the global economy. The role of public health nursing, then, is to assist communities in remaining stable within their environments.

Olowokere and Okanlawon (2015) used the concepts from Neuman's Healthcare Systems Model to guide population-level interventions for school children in Nigeria. Neuman's model is a good fit for population-level nursing interventions because it provides a systems perspective on the relationships between people, the environment, nursing care, and health. This intervention focused on addressing the psychosocial needs of children who had chronic illnesses such as HIV/AIDS, had one or both parents die, were victims of abuse or traumatized by conflict, or were in need of legal protection or alternative care. The nurses caring for the children had little time and no training to provide psychosocial support to these children. Neuman's model provided the framework for public health nurses to help the students develop a line of resistance to prevent stress (primary prevention) or to help them cope with the stressors they faced (secondary prevention) to protect their inner core. Examples of resistance resources included participation in support groups and resilience training (Olowokere & Okanlawon, 2015). Public health nurses also helped develop protective resources within the family and the community by serving as case managers to help the children access needed resources. At the tertiary level, the nurse facilitated access to needed services such as counseling to prevent regression (Olowokere & Okanlawon, 2015).

Rogers' Model of the Science of Unitary Human Beings

Martha Rogers (1914–1994) created the Science of Unitary Human Beings Model. She had a strong public health nursing background. She worked as a public health nurse in 1937 to 1939 and was on staff as a home visiting nurse from 1940 to 1945 and established the first visiting nursing service in Arizona in the mid-1940 to 1951; it was one of the first in the nation (American Nurses Association [ANA], 2016; Tomasson, 1994). In 1954, she obtained a public health master's degree from Johns Hopkins University (ANA, 2016). A nursing administrator and long-time nurse educator, Rogers is responsible for modern nursing's emphasis on the whole person. In 1970, she developed a nursing conceptual model based on systems theory. Her model emphasized that the individual and environment should be viewed as one unit; that is, focusing on the individual without examining their environment, or examining parts of a community, such as its health care or housing, does not provide an adequate picture of its totality in relation to the person (Johnson & Webber, 2015).

Rogers also incorporated developmental theory into her model by describing the development of "unitary" persons or systems according to three principles: (1) life proceeds in one direction along a rhythmic spiral, (2) energy fields follow a certain wave pattern and organization, and (3) human and environmental energy fields interact simultaneously and mutually, leading to completeness and unity (Rogers, 1990). Not typically linked with community/public health nursing practice, this model can be useful for the public health nurse in promoting holistic and healthful community–environment interactions. Using this model, the public health nurse can focus on community–environment interaction; the community functions interdependently with others and with the environment. Utilizing Rogerian concepts, Jarrin (2012) described how environment affects both the nurse and the patient, explaining that caring in nursing is situated in "space, place, and time, shaped by the internal and external environments of both the nurse and the patient/client" (p. 15). Jarrin further notes that nursing needs to provide evidence about our care environments to policymakers in order to effect meaningful changes.

Rogers' work continues to influence nursing care decades after her death. Reis and Alligood (2014) used patterning concepts from Rogers' theory in their study of 27 pregnant women from a public health prenatal clinic and a private practice who participated in a 6-week prenatal yoga class. They used baseline measures for optimism, power, and well-being, as defined by Rogers, and then retested participants at the end of the class. The 21 participants who completed the program had higher, statistically significant scores on all three measures at the conclusion of the yoga classes that were viewed by the researchers as a "holistic practice" consistent with a "holistic Rogerian view" (p. 35).

Guided by Rogers' concepts of human–environment and the effect of environmental stressors on human–environment energy field, Greene and Greene (2012) provided Internet-based guided imagery to a convenience sample of adults. Guided imagery uses

visual stimuli and a calming story or fantasy journey that encourages relaxation and may integrate "suggestion and affirmations" (p. 152). It has been found to be helpful with chemotherapy patients and those patients experiencing pain. This pilot study provided a 7-minute session that was available on demand to participants by accessing a specific Web site. No limits were set on the number of times a person could participate in the guided imagery session, and participants took a brief pretest as a baseline measure of stress and anxiety and then completed a posttest. Researchers found participants by sending email invitations to known subjects, who in turn forwarded the email invitations to others (e.g., a snowball sample). Results revealed a significant difference in pre- and posttest scores, indicating reduction in self-reported levels of stress. This research has implications for population health, especially for those living in remote areas.

King's Theory of Goal Attainment

Imogene King (1923–2007), nursing scholar and educator, was one of the early nurse theorists to provide a conceptual model of nursing (Messmer & Palmer, 2008). Her groundbreaking work *Toward a Theory for Nursing* (1970) and the subsequent *A Theory for Nursing: Systems, Concepts, Process* (1981) were both designed to "promote conceptual learning in undergraduate and graduate nursing programs" (1981, p. vii) and can be utilized by the public health nurse to define the nurse–client relationship. From the original general systems model that demonstrated the interrelationship between social, interpersonal, and personal systems (Killeen & King, 2007), King formulated the Theory of Goal Attainment. The theory focuses on the personal and interpersonal systems of the conceptual model. The basis of the theory is that, in any nurse– client encounter, both the nurse and the client come to the situation with their own goals and expectations. Optimal success at goal achievement is only possible when the nurse and the client work together to set goals, thus recognizing the expectations of both parties rather than the preeminence of one over the other. For instance, a public health nurse may have planned to speak to a teen mother about birth control on a home visit. The teen, however, has nearly run out of formula and has exhausted all her cash. In this instance, the teen's priorities are to locate formula or the resources to obtain formula, whereas the nurse may be concerned that the teen has resumed sexual activity and may become pregnant again. The immediate priority would clearly be the formula, but the nurse can also provide birth control information within that context after the teen is aware that a solution to the formula issue can be found. King's theory is a reminder of the importance of the reciprocal relationship between the nurse and the client. Negotiation is a skill inherent in the theory; only through recognition of the perceived needs and goals of the client can the public health nurse help maintain or improve the client's health and well-being.

Another example is seen with Housing First programs where the primary focus is on housing those who experience chronic homelessness, rather than on enforcement of strict abstinence rules among those who struggle with addition (Collins et al., 2012). The traditional abstinence-only programs were found to not be in alignment with the needs of this population. Collins et al. (2012) sought to understand the barriers to abstinence and identified that chronic alcohol use served to hold off withdrawal symptoms, was used as self-medication for psychiatric conditions, and also served as a social convener. Through the program, instead of only recognizing total abstinence, any positive change was rewarded. Ultimately, residents reported that having housing allowed them to have control over their own goals and most were able to reduce their substance use (Collins et al., 2012). The results of this program serve as a reminder of the importance of treating the client as an equal partner in their own goal setting.

Community engagement and empowerment are key concepts in international public health practices as well. An example of the importance of this approach can be seen during an Ebola outbreak where community participation can play a critical role in the control of

this disease (Shrivastava, Shrivastava, & Ramasamy, 2015). Fear and lack of information contribute to the rapid spread of this deadly disease. Culturally sensitive approaches are needed to counter misunderstandings about the disease, ineffective treatments through traditional healers, and exposures to reservoir species (e.g., bats). Community-based approaches where public health nurses and community members are working toward common goals can result in collaboration in contact investigations, improved cooking methods, and even changes in funeral practices (Shrivastava et al., 2015). These and many other examples demonstrate the utility of King's work to current practice in public health.

Parse's Theory of Human Becoming

Rosemarie Rizzo Parse developed her theory, initially called the "man-living-health" theory, in 1981. In 1992, she changed the name to Human Becoming Theory to better reflect all people. The theory posits quality of life from each person's own perspective as the goal of nursing practice (Johnson & Webber, 2015). The theory is structured around three themes (Parse, 1981, 1998):

Meaning. People coparticipate in creating what is real for them through self-expression by living their values in their own chosen way.

Rhythmicity. The unity of life encompasses apparent opposites in rhythmic patterns of relating. While living moment to moment, one shows and does not show the self, creating both opportunities and limitations that emerge as moving with and moving apart from others.

Transcendence. Viewed as moving beyond the moment and forging a unique personal path for oneself in the midst of ambiguity and continuous change.

These three themes apply effectively to the community. The nurse must know what the community means to its inhabitants, identify and be aware of the rhythmicity of the people as attempts are made to create positive health changes in the community, and realize the transcendence that occurs when people work in the presence of ambiguity and continuous change, characteristics inherent in a community. Use of this theory as a guide enhances the ability of community members to work together to accomplish identified goals. Examples of the use of the theory most applicable to public health nursing practice include nursing's engagement in health policy (Poirier, 2012), the act of being "present" in professional practice (Zyblock, 2010), and supporting caring– healing–sustainable nursing practices (Clark, 2012).

Building on her research, Parse has developed what she terms a Human Becoming Community Model (Parse, 2012). The model emphasizes the change concepts of moving–initiating, anchoring–shifting, and pondering–shaping. She clarifies the significance of community such that "when people come together as a group, the individual communities bring their histories to the emerging now, and this creates an entity of coevolving histories, which confirms individual as community and group as community" (pp. 44–45). The work of Parse and others brings a unique and holistic perspective to community/public health nursing practice.

This theory can serve as a guide for nurses advocating for health care policy change. Milton (2015) noted that the constructs of freedom and choice are often overridden when policies and protocols are implemented in health care settings. People often become labeled as noncompliant if they do not agree with set protocols. However, Parse's theory described freedom and choice as woven into the fabric of being human (Milton, 2015). Milton called for nurses to honor the importance of freedom and choice when creating and implementing policies rather than dehumanize the health care process.

Pender's Health Promotion Model

As we have noted throughout this text, health promotion is a priority in community/public health nursing practice. Pender defined health promotion as actions that are directed toward increasing the level of well-being and self-actualization in individuals or groups (Pender, Murdaugh, & Parsons, 2015). It is a proactive set of behaviors in which people act on their environment rather than react to stressors arising from the environment.

Pender's *Health Promotion Model* seeks to explain this proactive behavior. The model, based on social learning theory, stresses cognitive processes that help regulate behavior such as perceptions people have that directly influence their motivation to begin or continue health-promoting behaviors. These include, for example, perceptions of control of health, health status, benefits of health-promoting behaviors, and barriers to engaging in health-promoting behaviors (Pender et al., 2015; Sakraida, 2014).

Five types of modifying factors influence people's perceptions about pursuing health-promoting behaviors:

- Demographic factors, such as age and race
- Biologic characteristics, such as height and weight
- Interpersonal influences, such as the expectations of others
- Situational factors, such as availability of healthful foods
- Behavioral factors, such as stress-coping patterns

Using Pender's model, a public health nurse might interview the residents of a low-income housing project to determine their perceptions about improving health and safety. Research of demographic, situational, and other factors that might influence the residents' motivation and ability to change their circumstances could then be conducted.

Pender's model was validated as a motivational model during a program that incorporated exercise and physical activity for people with spinal cord injuries (Keegan, Chan, Ditchman, & Chiu, 2012). People who have sustained a spinal cord injury are at a greater risk of secondary health complications and chronic conditions related to inactivity. Nurses designed exercise and physical activity plans taking into consideration the four predictor variables described in Pender's model including individual factors, interrelational and situational factors, behavior-specific cognition, and commitment to the plan (Keegan et al., 2012). Self-efficacy and sense of control were found to be strong predictors of commitment resulting in engaging in health-promoting behavior. Beliefs about control and support and encouragement from family and friends were also linked to increased motivation. Perceived barriers had a low prediction correlation. To promote long-term health among people with spinal cord injuries, rehabilitation plans should include these factors to increase motivation (Keegan et al., 2012).

Although pertinent to public health nursing practice, the model is not strictly speaking of a conceptual model of nursing, as was discussed earlier in this chapter. The

metaparadigm concepts of patient/client, health, and environment are present, but the model does not stipulate that the provider of health educational services be a nurse and can in fact be from other disciplines. Pender's model is further discussed in relation to client education in Chapter 11.

FIGURE 14–2 Sister Callista Roy. (Courtesy of Christopher Sold.)

Roy's Adaptation Model

Sister Callista Roy's model describes people as open and adaptive systems that experience stimuli, develop coping mechanisms, and produce responses. These responses, which may be adaptive or maladaptive, provide feedback that influences the amount and type of stimuli that can be handled in the future. Nursing works, using four modes (i.e., basic physiologic needs, role mastery, self-concept, interdependence) to bring about environmental changes that permit the client to adapt (Andrews & Roy, 1991; Johnson & Webber, 2015; Roy, 2009; Roy & Andrews, 1999). This model helps the public health nurse understand how a community's ability to adapt to stressors will affect the health of the community (Fig. 14–2).

Roy describes two response processes. In the *regulator* or focal stimulus process, stimuli from the internal and external environments are received, and this combination of information is then processed to produce a response. In the *control* or contextual stimulus process, perceptions, learning, judgment, and emotion are considered in formulating a response to stimuli. An example of the regulator process might begin with a community's desire to keep adolescents from smoking (internal stimulus) and new state regulations prohibiting the sale of tobacco products to minors (external stimulus). These combined stimuli lead to a city ordinance that prevents the sale of cigarettes to minors (coping mechanism), resulting in reduced levels of smoking (response) among this population. A regulator process might begin with the stimulus of heavy rainfall in a riverside community. Residents' perceptions of the amount of rainfall, memories of past floods, insights about preventing or managing floods, and the level of anxiety all contribute to their plans for evacuation, sandbagging, and soliciting county or state assistance (Phillips & Harris, 2014).

In applying Roy's conceptual model to public health nursing, it is important to remember that a community is made up of many parts and is influenced by many variables. The community's collective adaptation level is constantly changing. The public health nurse must assess a community's coping mechanisms and help its members use these collective abilities in adapting to challenges. For example, if a community is doing nothing to respond to the increased number of obese children, nursing actions can be designed to encourage more healthful coping patterns and adaptive responses.

Roy's Adaptation Model is well designed to help guide public health nursing practice as demonstrated with nurses working with newly diagnosed HIV/AIDS clients. Perrett and Biley (2013) found the model constructs of adaptation to be applicable. The diagnosis serves as the stimulus, triggering a level of uncertainty. Adaptation was not a passive event, rather it was noted to be a conscious effort. Factors such as the optimism gained from the availability of antiretroviral medications and new relationships triggered steps toward adaptation. Ineffective adaptation would present as anxiety, powerlessness, and loneliness (Perrett & Biley, 2013). Nurses need to assess the client's sense of self, including their perception of their health and their role within society. This can guide nursing

interventions to support clients as they move toward effective adaptation (Perrett & Biley, 2013).

Salmon's Construct for Public Health Nursing

Marla Salmon, a leader in public health nursing administration, nursing education, and public health policy in the United States, has proposed a model to specifically guide community health nursing practice. In *Construct for Public Health Nursing*, Salmon (1982, 1993) described public health as an organized societal effort to protect, promote, and restore the health of people and public health nursing as focused on achieving and maintaining public health.

The model describes three practice priorities. These priorities are prevention of disease and poor health, protection against disease and external agents, and promotion of health. There are three general categories of nursing intervention:

- Education that is directed toward voluntary change in the attitudes and behavior of the subjects
- Engineering that is directed at managing risk-related variables
- Enforcement that is directed at mandatory regulation to achieve better health

The scope of practice spans individual, family, community, and global care. Interventions target determinants in four categories: human/biologic, environmental, medical/technologic/organizational, and social.

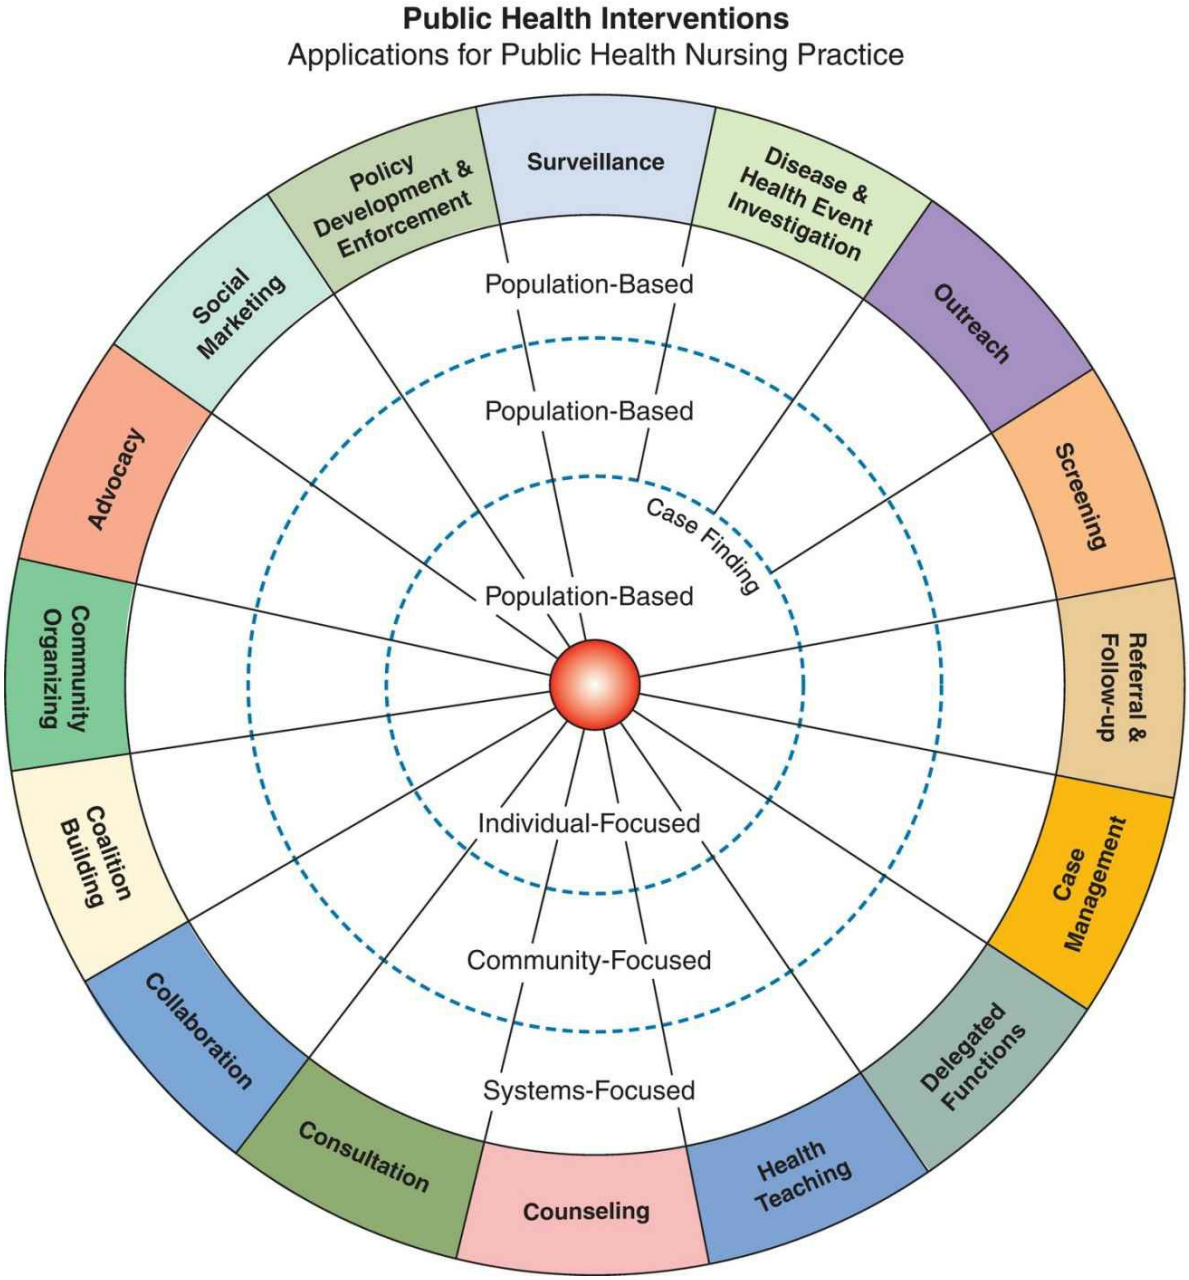
The Centers for Disease Control and Prevention included the three E's in the 2012 National Action Plan for Child Injury Prevention. In their work to prevent drowning among young children, public health nurses could engage in education outreach to families with small children about potential risks of drowning and safety measures they could implement. In addition, nurses could advocate for policies mandating fences around pools and natural bodies of water. Finally, nurses can help families find affordable fencing resources if they were struggling to pay for a fence installation (CDC, 2012). These examples of client advocacy on several levels are an important component of public health nursing and represent the types of activities common to early nurses who saw social problems resulting in poor health and worked on local and national levels to address them (see Chapter 13 for more on advocacy and policy making). Kelley, Connor, Kun, and Salmon (2008, p. 4) described social responsibility as a foundational professional duty that is "woven into the fabric of nursing's history."

Using Salmon's approach, a public health nurse attempting to reduce the transmission of tuberculosis would use education, engineering, and enforcement in working with the population of affected individuals and families. Strategies could include collaboration with the client community on a variety of interventions, from mandating isolation precautions to providing education about medications and connecting the client and their family to social support: all in an effort to prevent further disease in the community and to promote global health.

PUBLIC HEALTH PRACTICE MODELS

Minnesota Wheel—The Public Health Interventions Model

The Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section, devised a model that depicts public health interventions and applications for public health practice. In the form of a wheel, the model presents 17 different interventions within three levels of public health practice: population-based community-focused practice, systems-focused practice, and individual-focused practice. The "Minnesota Wheel" (Public Health Nursing Section, Minnesota Department of Health, 2001) is depicted in Figure 14–3.



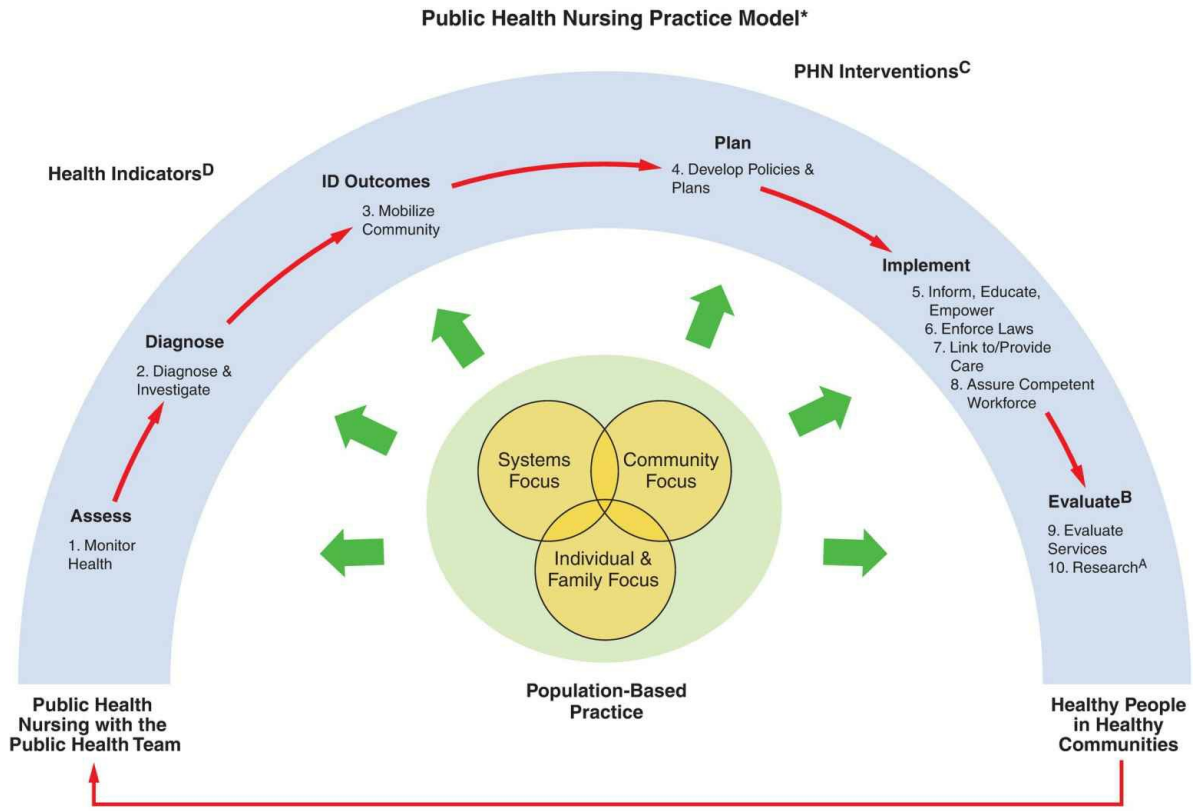


FIGURE 14–3 The Minnesota Wheel. (Source: Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section.)

The intervention wheel was first proposed in 1998 (Keller, Strohschein, Lia-Hoagberg, & Schaffer, 1998) as a practice model for population-based public health nursing. It presents public health nursing as a specialty practice within the field of nursing (Public Health Nursing Section, Minnesota Department of Health, 2001). It can be applied in a variety of venues including public health practice, nursing education, and management. Keller and colleagues emphasized that the "use of the Wheel has empowered nurses to explain in a better way how their practice contributes to the improvement of population health" (Keller, Strohschein, Lia-Hoagberg, & Schaffer, 2004, p. 454). The wheel is useful for public health nurses because it visually depicts the comprehensive list of interventions

nurses must consider in the scope of practice. Schaffer, Anderson, and Rising (2015) described how school nurses using the interventions presented within the model in their day-to-day work. Including nurses who were not even aware of the model, school nurses identified screening, referrals, and case management as the interventions they most commonly implement (Schaffer et al., 2015). This example shows how well the model describes and guides community health nursing interventions.

Public Health Nursing Practice Model

The Los Angeles County Public Health Nursing Practice Model (LAC PHN Practice Model) was developed in response to an identified need for a model that could blend public health nursing practice and the principles of public health, which could be applicable to both the generalist nurse and nurses working in specific programs (Smith & Bazini-Barakat, 2003). Public health nurses at the Los Angeles County Department of Health Services (LAC-DHS) created the model, with input from the California Conference of Local Health Department Nursing Directors (CCLHNDN) Southern Region and other public health nurse leaders. The LAC PHN Practice Model (Public Health Nursing, Los Angeles County Department of Health Services [PHN, LAC-DHS], 2013) integrates foundational nursing and public health guiding documents including the Public Health Nursing Standards of Practice, the 10 Essential Public Health Services, the 12 Leading Health Indicators from *Healthy People 2020*, and the Minnesota Public Health Nursing Interventions Model. The LAC PHN Practice Model provides a "conceptual framework that assists in clarifying the role of the public health nurse and presents a guide for public health practice applicable to all public health disciplines" (Smith & Bazini-Barakat, 2003, p. 42). It establishes that public health nursing is population based and was created to "describe the building blocks of PHN practice and to delineate their relationship to each other" (PHN, LAC-DHS, 2013, para. 1).

As described by Smith and Bazini-Barakat (2003) and Public Health Nursing (PHN, LAC-DHS, 2013), the principles of population-based practice are included in the LAC PHN Practice Model. Public health nurses integrate assessment, policy development, and assurance into their work. The three levels of population-based practice—individuals and families, community, and systems—are addressed, with the nursing process applied throughout the model. The 17 interventions, as first presented in the Minnesota Public Health Nursing Model described above, are also incorporated into the LAC PHN Practice Model. The LAC PHN Practice Model promotes the concepts of an interdisciplinary public health team working together, with an emphasis on primary prevention. It also recognizes the importance of active participation of the individual, family, and community (PHN, LAC-DHS, 2013; Smith & Bazini-Barakat, 2003). See Figure 14–4 for a depiction of the LAC PHN Model.

Omaha System

The Omaha System is a multidisciplinary standardized interface that incorporates documentation of nursing assessment and interventions (Thompson, Monsen, Wanamaker, Augustyniak, & Thompson, 2012). It was developed and refined during four research projects conducted between 1975 and 1992 with the Omaha Visiting Nursing Association. It was designed to increase the effectiveness and efficiency of nursing practice in the agency (Bowles & Naylor, 1996; Martin, Leak, & Aden, 1992). The system is now finding increasing utility in facilitating EBP, documentation, and information management, all of which are critical to contemporary public health care systems. It is a comprehensive system, including the following components (Martin, 2005):

- *Problem classification scheme* that offers nurses a holistic, comprehensive method for identifying clients' health-related concerns. It includes domains, problems, modifiers, and signs/symptoms. Problems can be identified at the individual, family, or community level.
- *Intervention scheme* that provides a framework for documenting plans and interventions in the client record in the areas of health teaching, guidance, and counseling; treatments and procedures; case management; and surveillance.
- *Problem rating scale* for outcomes that consists of a Likert-type scale that is a systematic and recurring method used to document the progress of clients in the record and in case conferences during their time of service in the agency. It is used in conjunction with any problem in the Problem Classification Scheme. Central to problem rating is quantifying outcomes in three dimensions: knowledge (what the client knows), behavior (what the client does), and status (how the client is).

The Omaha System is based on universal principles of nursing practice. The model was judged to be consistent with the Nightingale model of environmental health (Zurakowski, 2005). Citing some variations in language use, Griffin and Landers (2014) found that Orem's model of self-care was also consistent with the premises of the Omaha System. The *Omaha System Model of the Problem-Solving Process* (Fig. 14–5) shows the interrelationship between the practitioner and the client in addressing health problems. The model guides the nurse through the six steps in the process: (1) collecting and assessing data, (2) stating the problem, (3) identifying the problem rating on admission, (4) planning and actual interventions, (5) identification of interim or dismissal problem rating, and, finally, (6) evaluating the problem outcome. The model is applicable to individuals, families, and communities and provides a mechanism to evaluate both individual and group change over time. With ongoing pressure for public health program funding, outcome data is vital and can be achieved through the application of the Omaha System.

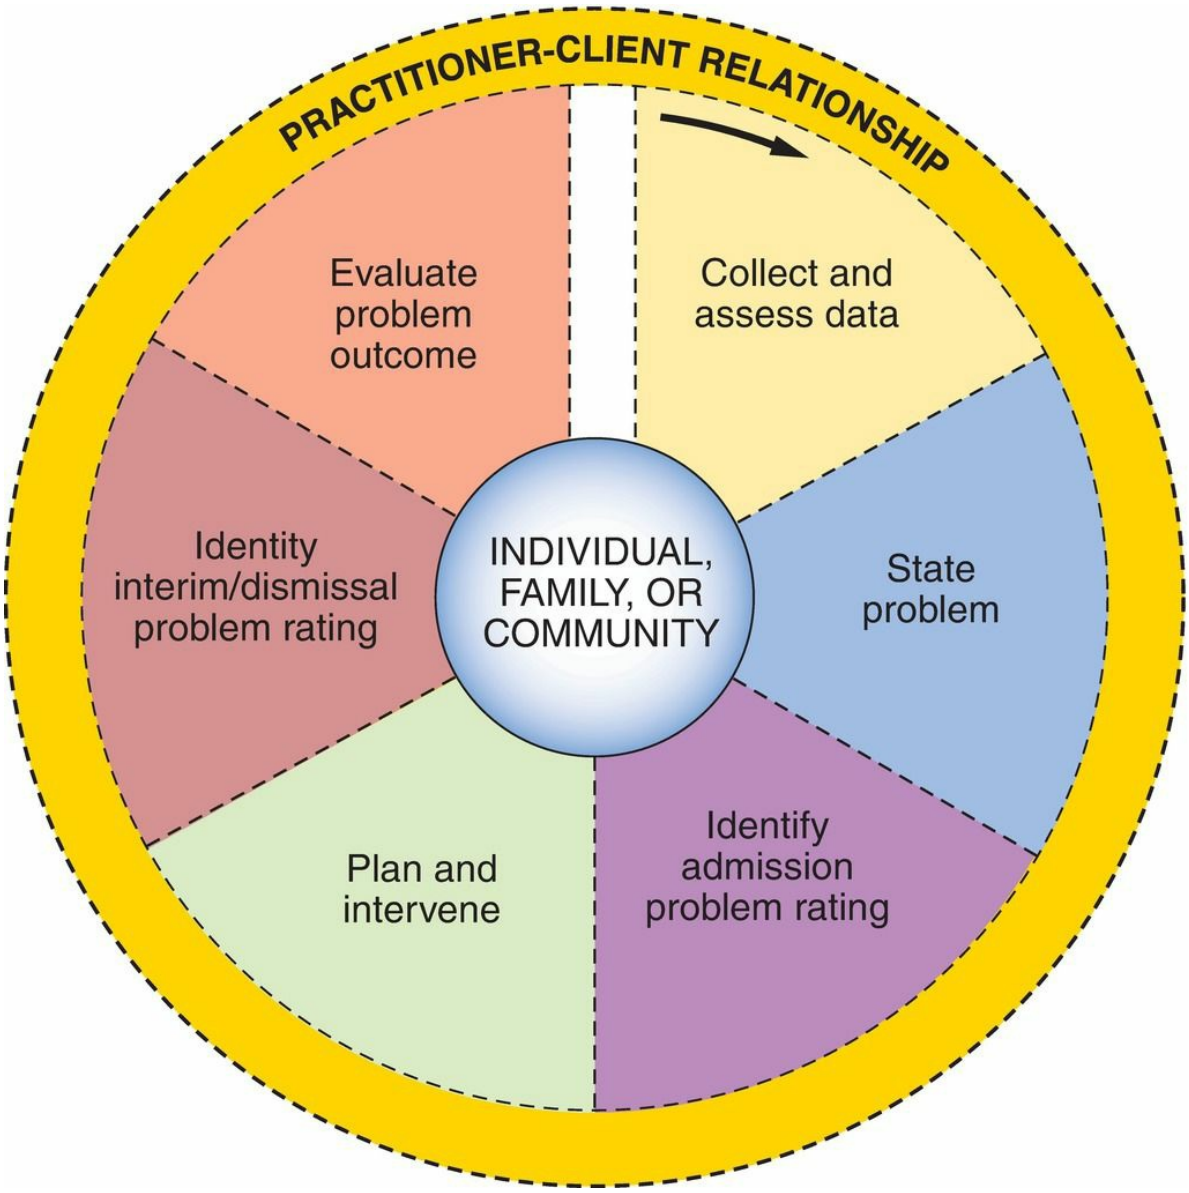

FIGURE 14–5 Omaha System Model of the Problem-Solving Process. (From Martin, K. S. (2005). The Omaha System: A key to practice, documentation, and information management (2nd ed.). Omaha, NE: Health Connections Press, with permission.)

Research regarding the contribution of the Omaha System to program evaluation has included. This model was used by Thompson et al. (2012) to assess the outcome of public health nurse interventions provided through a nurse-managed wellness center. In a practice-related approach, health promotion lifestyle profiles and quality of life in Turkish women were explored using the Omaha System (Erci, 2012). The findings of this study demonstrated that application of system interventions improved measurements of self-actualization, health responsibility, interpersonal support, and stress management. Thompson et al. (2012) utilized the Omaha System to gather data regarding the effectiveness of a nurse-managed wellness center. Students documented their interventions in the system that allowed the researchers to access and analyze the data. The results

indicated that the nurse-managed center saw improved outcomes, justifying the value and effectiveness of the work being done there (Thompson et al., 2012). These are but a few of the examples of research adding to the body of knowledge regarding the role of the Omaha System in affecting individual and group change and providing a reliable measure of programmatic effectiveness.

PRINCIPLES OF COMMUNITY/PUBLIC HEALTH NURSING

Public health nursing, as defined by the ANA (2013), is "…evidence-based and focuses on promotion of the health of entire populations and prevention of disease, injury, and premature death" (p. 3). The key elements of this practice include population-level focus on issues including health inequities and the needs of special vulnerable populations, a comprehensive and systematic assessment with particular attention to the determinants of health, a focus on primary prevention, and implementation of interventions of primary-, secondary-, and tertiary-level prevention (ANA, 2013). The ANA recognizes that public health nurses function as part of an interdisciplinary team from various organizations and agencies as well as collaborate with members of the communities they serve and recommends a baccalaureate education for entry-level public health nurses. The Public Health Intervention Wheel and the 10 Essential Public Health Services serve as guides to the public health nurse's activities (ANA, 2013).

The word principle can be defined variably as a "rule or code of conduct" or an underlying aptitude or ability (Merriam-Webster, n.d., para. 2). Whatever the definition, there are universals in practice that can guide public health nursing practice in a way that can help achieve the most beneficial outcomes. The goals of public health nursing, to promote and protect the health of communities, are facilitated by adhering to eight principles identified by the ANA (2013) for public health nursing practice. These principles are summarized in Display 14–3 (ANA, 2013).

DISPLAY 14.3 PRINCIPLES OF PUBLIC HEALTH NURSING

1. Focus on the Community. The client or unit of care is the population.
2. Give Priority to Community Needs. The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.
3. Work in Partnership with the People. The processes used by public health nurses include working with the client as an equal partner.
4. Focus on Primary Prevention. Primary prevention is the priority in selecting appropriate activities.
5. Promote a Healthful Environment. Public health nursing focuses on strategies that create healthy environmental, social, and economic conditions in which

populations may thrive.

6. Target All Who Might Benefit. A public health nurse is obligated to actively identify and reach out to all who might benefit from a specific activity or service.
7. Promote Optimum Allocation of Resources. Optimal use of available resources to ensure the best overall improvement in the health of the population is a key element of the practice.
8. Collaborate with Others in the Community. Collaboration with a variety of other professions, populations, organizations, and other stakeholder groups is the most effective way to promote and protect the health of the people.

Adapted from American Nurses Association. (2013). Public health nursing: Scope and standards of practice (2nd ed., pp. 8–9). Silver Spring, MD: Nursesbooks.org.

Principle 1: Focus on the Community

The first principle reminds us that the ultimate responsibility of public health nursing is to direct services to the population as a whole. Even though public health nurses may intervene to address individual, family, or group needs, the entire community is the client (Kulbok, Thatcher, Park, & Meszaros, 2012).

Principle 2: Give Priority to Community Needs

The second principle deals with the ethical obligation of the public health nurse to give priority to the needs and preferences of the whole community over those of one individual. This means that the nurse must consider interventions that will lead to the greatest good for the most people (Rushton & Broome, 2015). For example, programs that make mammograms for early detection of breast cancer available to all women regardless of income level are given priority over those that provide bone marrow transplantation for women with advanced metastatic breast cancer.

Principle 3: Work in Partnership with the People

The third principle requires the public health nurse to work in partnership with the community. The nurse and the community members (or groups) each bring their own values, beliefs, and expertise to the partnership (Kulbok et al., 2012). Policy development and assurance are more likely to be accepted and applied if there is mutual consideration of and respect for these elements. Developed policies need to be communicated in language that reflects an understanding of the community. For these reasons, an essential part of establishing a partnership with a community is getting to know the members and groups within that community.

Principle 4: Focus on Primary Prevention

The fourth principle of public health nursing underscores the importance of primary prevention in promoting the health of people. Most fields of medicine, including acute care nursing, are primarily concerned with illness and with efforts to prevent complications from and reoccurrence of the illness. In contrast, public health nursing has an obligation to prevent health problems and to promote a higher level of wellness. Public health nurses take the initiative to seek out high-risk groups, potential health problems, and situations that contribute to health problems. They then institute preventive programs (Kulbok et al., 2012). For example, if community assessment revealed a large number of new mothers with postpartum depression, public health nurses would address secondary prevention by establishing mental health programs. Equally as important, they would attend to primary prevention by working to change the conditions in the community that increase the risk for postpartum depression.

Principle 5: Promote a Healthful Environment

The fifth principle recognizes the importance of ensuring that people live in conditions conducive to health. Therefore, it is aligned with Nightingale's Environmental Theory of Health. People are less likely to be healthy if they live in a community with high unemployment, crowded housing, and dirty air or where it is difficult to obtain inexpensive, healthful food. They are also less likely to be healthy if the community's norms include acceptance or even encouragement of activities such as smoking, binge drinking, drug use, or unsafe sex. To change these conditions requires commitment, perseverance, patience, resourcefulness, and a long-range view. Public health nurses, along with other public health professionals, understand the effects of social determinants of health and work to improve them (Braveman & Gottlieb, 2014).

Principle 6: Target All Who Might Benefit

The sixth principle involves outreach strategies to meet the obligation to serve all people who might benefit from an intervention. This tenet requires that the nurse examine policies or programs to determine whether they are accessible and acceptable to the entire population in need and advocate for change if necessary (Maryland & Gonzalez, 2012).

Public health nurses can advocate for clients on many levels. For instance, for those clients who have limited economic resources and need regular medications to maintain normal blood pressure and other common health problems, PHNs can recommend a program available through Walmart stores that offers 30-day supplies of medications for as low as $4.00 (Maryland & Gonzalez, 2012). They can also work with local, state, and national legislators to promote health and necessary services for vulnerable populations.

The questions in Display 14–4 can help the nurse evaluate a planned program's success in reaching people who might benefit. These questions should guide the design, implementation, and evaluation of outreach strategies.

DISPLAY 14.4 DETERMINING WHETHER PROGRAMS SERVE INTENDED POPULATIONS

- Is the service offered in a manner that encourages utilization?
  Are the services located conveniently?Do the hours of the service fit with the work or school life of the people?Are the services offered in a manner that is respectful of the values, beliefs, mores, and traditions of the people?What kind of marketing strategies has been used to inform the people of the service?
- What is the satisfaction level of users of the service?
- Why are some people not using the services?

Principle 7: Promote Optimum Allocation of Resources

The seventh principle addresses resource allocation decisions. In most communities, the available resources are not sufficient to meet all the needs of all the people. The nurse must ensure that the community is using limited resources in ways that lead to the greatest improvement in health (Bekemeier, Chen, Kawakyu, & Yang, 2013). To promote optimum allocation of resources, the nurse must:

- Know the latest research on the effectiveness of various programs in addressing needs
- Collect information about the short- and long-term costs of programs
- Evaluate existing programs and policies for ways to improve or discontinue them
- Communicate this information to community decision makers, so that they can make resource allocation decisions that are most likely to improve the community's health.

In current research on resource allocation in public health agencies, the majority of agencies in one study reported little impact resulting from public input, but more influence from boards of health. Most agencies did not conduct needs assessments or use economic analyses in their decision making about how to allocate resources (Baum, DesRoches, Campbell, & Goold, 2011). The realities of constrained budgets and mandated and categorically determined services, along with workforce capacity and local stakeholder input, had greater influence than EBP research and recognized community needs. What "should" happen and what "does" happen are often at odds, as noted in one Washington state study of quantitative data and interviews with public health leaders (Bekemeier et al., 2013). Public health nurses should continue to work on all levels to promote greater funding for public health programs and more effective allocation of resources.

Principle 8: Collaborate with Others in the Community

The eighth principle underscores the importance of collaboration with other nurses, health care providers, social workers, educators, spiritual leaders, business leaders, and government officials within the community. This interdisciplinary collaboration is essential to establish and maintain effective programs. Programs that are planned and implemented in isolation can lead to fragmentation, gaps, and overlaps in health services (Kulbok et al., 2012). For instance, without collaboration, a well-child clinic may be started in a community that already has a strong developmental screening program but does not have community prenatal services. Without collaboration, programs may also fail to be effective. Another example, a Saturday-morning cardiovascular fitness program designed without consultation with spiritual leaders may be totally ineffective in a devout Jewish community, where members devote Saturdays to religious observances.

SOCIETAL INFLUENCES ON COMMUNITY-ORIENTED, POPULATION-FOCUSED NURSING

Society is constantly changing, and these changes influence a community's health, either positively or negatively. For this reason, public health nurses need to continually alter their strategies to respond to these changing conditions. An example is international air travel combined with reduced levels of immunizations among school-age children, which increases risk for transmission of measles at a world-renowned amusement park (Halsey & Salmon, 2015). Public health nurses must be proactive in developing strategies to control the spread of communicable disease through primary prevention interventions such as launching an immunization campaign. Social changes may also affect the availability of resources necessary to ensure that effective intervention strategies are available, for example, mistrust of vaccines and communities of under- or unvaccinated children.

Contemporary public health nurses must be especially aware of the mutual interaction between nursing and technology. The term technology refers to the application of science to change processes of production or industry or simply the practical application of knowledge (Merriam-Webster, n.d.). Ideally, technologic innovations lead to improvements in processes for creating products or services. The 20th century was filled with technologic innovations that simultaneously disrupted old patterns of production and created new opportunities to increase production, but new technology also presents new challenges. Two technologic changes that are highly relevant to contemporary public health nursing are communication technology and genetic engineering (Fig. 14–6).

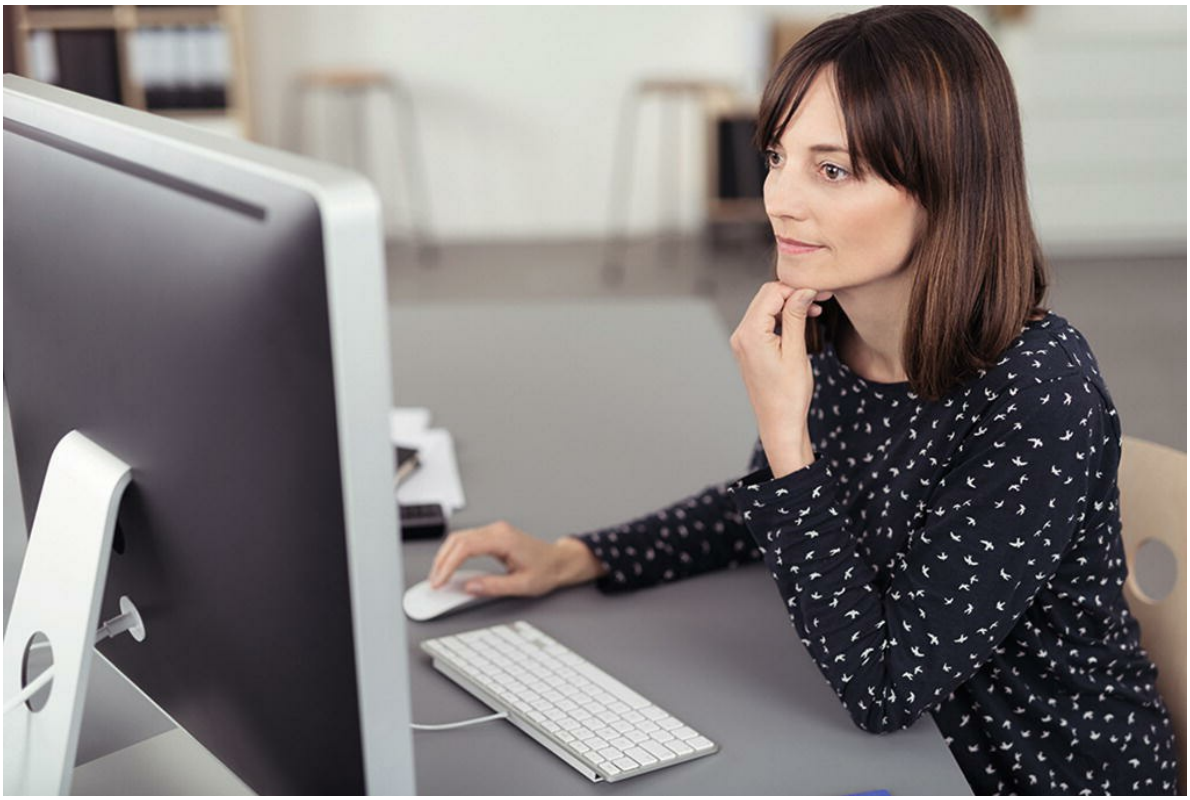

FIGURE 14–6 Communication technology offers many benefits for population health.

Communication Technology

The rapid changes in communication technology present new opportunities and challenges for community- oriented, population-focused care. Because of advances in satellite and telecommunications technology, communication is possible anywhere in the world where resources are available to purchase equipment and services. This means that a public health nurse, whether working in the Australian outback or at a public health clinic in Anchorage, Alaska, can contact clients, consultants, and agencies worldwide, if resources are available to take advantage of the technologies. Community members can become more involved in the decision-making process on issues that impact them or their communities, self-management tools can be personalized, clients can access online support networks and resources, health literacy can increase, and culturally isolated populations may be more readily accessed (USDHHS, 2016a).

In addition, Internet technology has made it possible to access local, state, national, and international data for community assessment, planning, and evaluation. Nurses who require data for a new intervention strategy, for example, can search the Internet for information from consumer groups, researchers, and other experts worldwide. To keep apprised of emerging issues and trends in public health, the nurse can join numerous Internet-based electronic discussion groups or LISTSERV (electronic discussions distributed by way of email). The challenge to the nurse is to manage the volume of information and to critically evaluate the validity and credibility of this information.

Health care consumers face similar opportunities and challenges. Most diseases and disabilities can be researched online; information is available on the Internet, and consumers are increasingly searching the Net for health-related data. Certainly, the validity and reliability of information on the Internet can vary widely. Research is needed to understand how people decide what information to use from the Internet, how they use it, and how its use affects their health. As health educators, public health nurses can provide guidelines to help people decide how to use health information found on the Internet (Display 14–5). At the same time, public health nurses need to be actively involved in creating technology resources, such as Internet sites, to provide health information specific to their targeted communities. Public health nurses must bear in mind that disparities exist among those who have access to new technology and those who do not. This could present a barrier to accessing critical information to protect and promote health (USDHHS, 2016a). Alternate modes of information sharing need to be in place. See Chapter 10 for more on technology.

DISPLAY 14.5 DETERMINING WORTH OF HEALTH INFORMATION ON THE INTERNET

- What are the credentials and affiliation of the author?
- Is it easy to determine who is the publisher or sponsor of the Web site? Evaluate how the publisher or sponsor might gain economically through your use of the information.
- Is the date of publication of the Web site included? Is the information current?
- Are both sides of an issue described? Does the author discuss pros and cons of information presented?
- What references are included to substantiate the information in the article?

The Internet is a superb vehicle for rapidly tracing the international spread of infectious diseases. For example, the World Health Organization has an Internet site for countries to report epidemiologic and laboratory data on influenza. The Centers for Disease Control and Prevention (CDC) offers current data on communicable diseases through the online publication *Morbidity and Mortality Weekly Report*. In addition, many local health departments and health agencies have their own Web sites that can provide information and resources specific to the needs of the local communities. In addition, health care providers are integrating electronic medical records into their practices. Between 2007 and 2013, the number of medical practices that implemented electronic health records increased by 175.6% (USDHHS, 2016c). This can improve health care efficiency and care delivery, increase health care quality and safety and support clinical and consumer decision making (USDHHS, 2016b). See Chapter 8 for more on communicable diseases.

New forms of technology continue to be introduced. Today, forms of communication can range from cell phones and text messages to instant messaging and social networking. This new technology provides innovative ways to enhance health communication and social marketing. Nurses can utilize social media such as Web blogs, Facebook, and Twitter to disseminate health messages to specific target populations (CDC, 2015). Health messages distributed through a variety of modalities including mass media such as television and radio, small media such as brochures, social media such as computer networking, and interpersonal communication such as face-to-face interactions increase the exposure of the message to a wider swath of the population (CDC, 2015).

As technology advances, nurses must keep up to date on new ways information can be

shared. In addition, the lines between professional recommendations and peer advice can become blurred, leading to the risk of decisions being made on information that is not based on empirical evidence (USDHHS, 2016b).

Genetics, Genomics, and Genetic Engineering

Genetics, the science of heredity and genomics, the study of the entire genome, are terms that have gained increased attention from nurses over the past decade. An outgrowth of this knowledge is genetic engineering, which can be defined as "the group of applied techniques of genetics and biotechnology used to cut up and join together genetic material and especially DNA from one or more species of organism and to introduce the result into an organism in order to change one or more of its characteristics" (Merriam-Webster, n.d., para. 2). The development of the field was made possible by the discovery of certain enzymes that can "cut" DNA from two or more different sources into pieces that can be recombined in a test tube. Gene manipulation also required the development of methods for inserting these recombinant DNA molecules into cells by the use of so-called *vectors* such as viruses (Fig. 14–7).

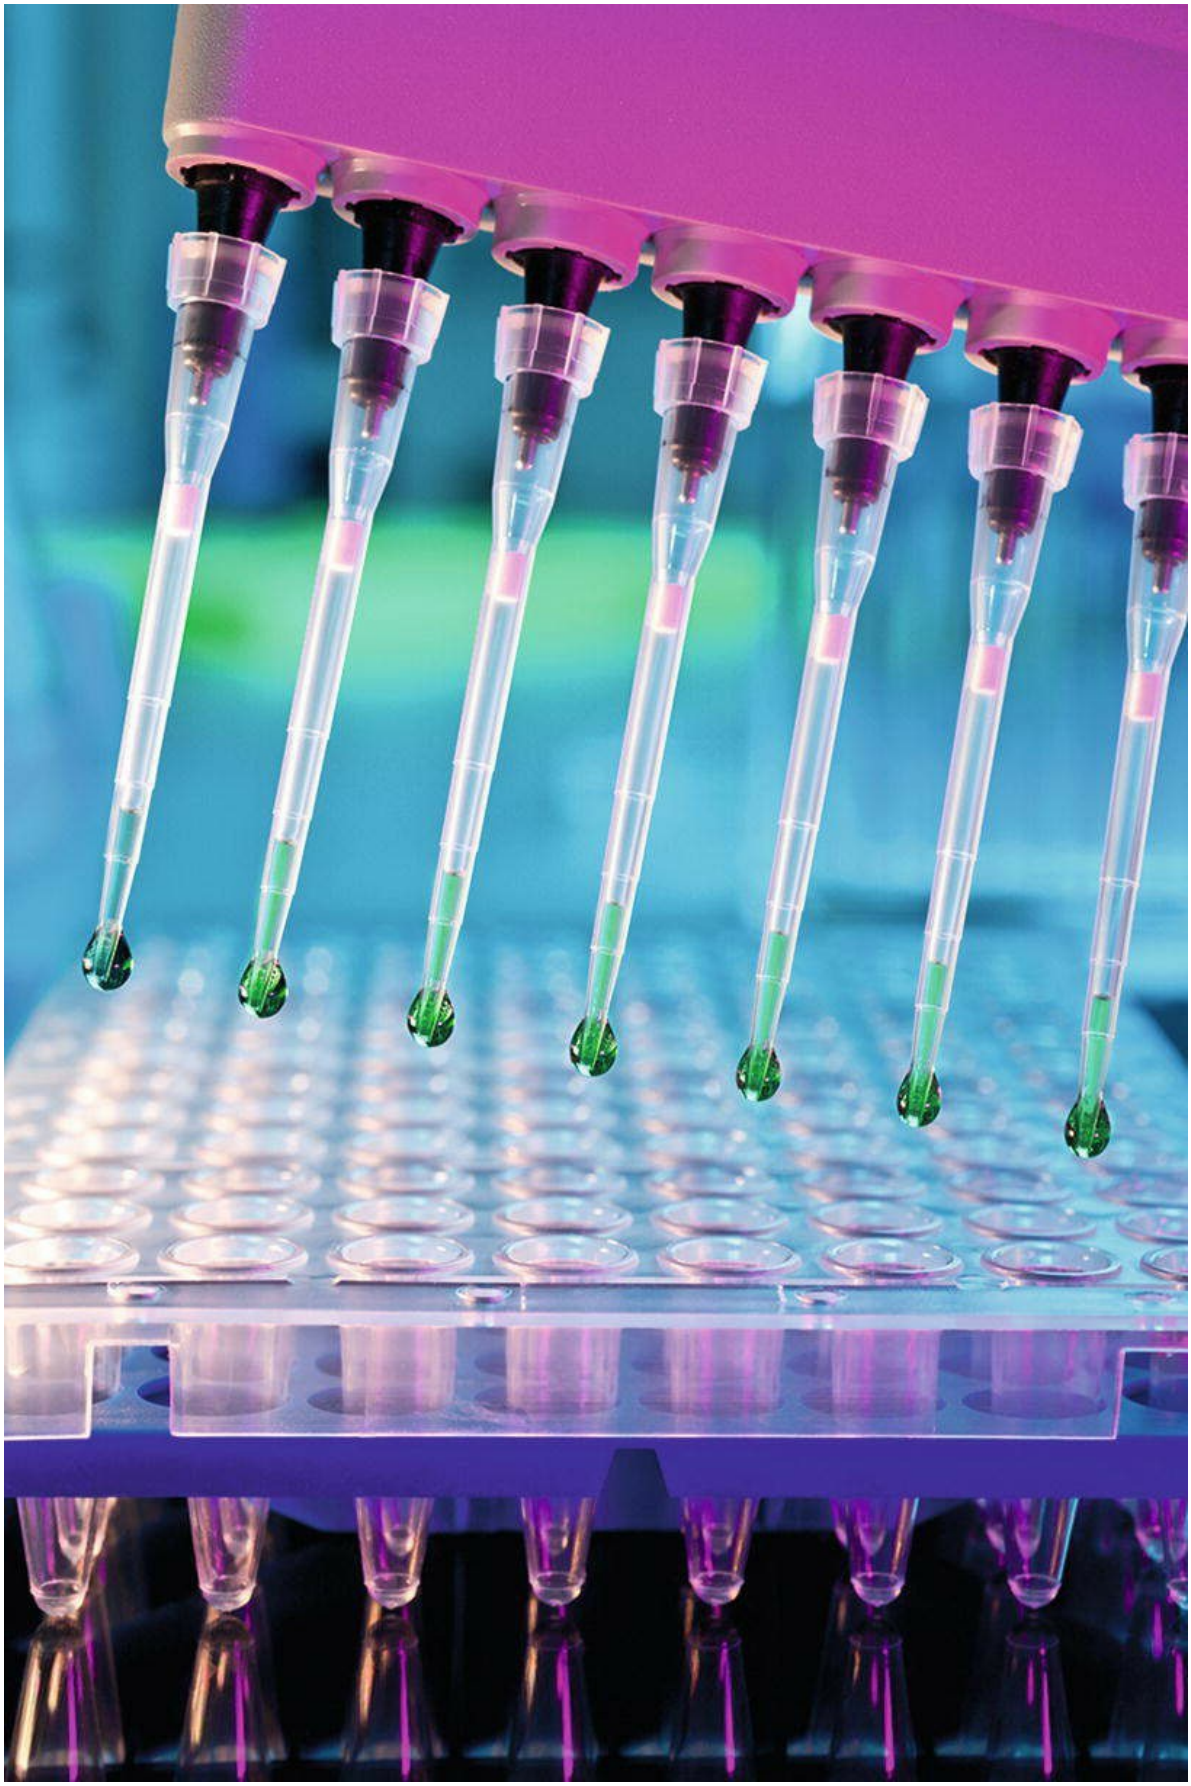

FIGURE 14–7 DNA discoveries have changed health care.

The topic of genomics is a new area that included *Healthy People 2020*. This topic was added because genomics is associated with nine of the 10 leading causes of death. Genetic testing might help to reduce the risk for certain types of cancer (USDHHS, 2016a). *Healthy People 2020* objectives currently include two recommendations related to genomics. The first genomics recommendations are for women at increased risk for breast, ovarian, tubal, or peritoneal cancer to receive genetic counseling and obtain information about BRCA-12 testing options. The second recommendation is for people who are newly diagnosed with colorectal cancer to receive counseling and information about genetic testing (USDHHS, 2016a).

Genomics is another rapidly changing field. There is a lull of research regarding genetic tests and family health history tools and the risk versus benefits of using genomics in health care decision making. This is an area that needs further exploration. Issues of future exploration include assuring privacy and confidentiality of information acquired through genomics, including this information in electronic health records, implementation of testing, and exploration of how practitioners can use this information for patient education and recommendations (USDHHS, 2016a).

The Human Genome Project has opened dramatic possibilities for health and well-being, as well as created ethical challenges in the near future. The potential scientific capacity to alter methods of human reproduction raises concerns about creating unintended consequences for the human race. Another source of concern is that science is "playing God." For some people, the possibility of being able to select the gender, intelligence, or eye color of a child raises concerns about interfering with nature and creates conflict with religious or ethical views. In addition, genetic screening could be used to deny rights and opportunities to people. For example, someone who is found to carry a gene that increases the risk for heart disease might be denied health insurance coverage. Another source of concern has been the distrust many people have of government, large commercial enterprises, and the scientific community. Some people believe that they are not being told the truth about scientific or other issues.

In dealing with these concerns, it is the public health nurse's responsibility to be aware of the latest scientific information when educating communities, so that the decisions made best fit the community's value system. Advocating for the highest scientific rigor in genetic engineering research is another important role of public health nurses. Public health nurses need to advocate for research that not only maps DNA but also identifies interventions that can change the outcome for people at risk for genetic disorders. Nurses need to balance what is good for the community as a whole against potential costs to people at risk, advocating for policies and regulations that ensure such a balance. The *Essentials of Baccalaureate Education for Professional Nursing Practice* (American Association of Colleges of Nursing, 2008) emphasized the impact of advances in genetics and genomics. Specifically, Essential VII: Clinical Prevention and Population Health stresses that the graduate be prepared to (1) "Assess protective and predictive factors, including genetics, which influence the health of individuals, families, groups, communities, and populations"

and (2) "Conduct a health history, including environmental exposure and a family history that recognizes genetic risks, to identify current and future health problems" (p. 24).

Global Economy

The global economy has grown exponentially over the past half century. It expanded six times more than the world's population. Per capita income tripled while the population doubled in size (Executive Summary, 2015). The rapid rate of growth is attributed to two factors, a growing labor force and increased productivity. The labor force grew due to reductions in high fertility rates, infant mortality rates, and expanded life expectancy. This resulted in a bulge of people of working age from 58% in 1964 to 68% in 2014 (Executive Summary, 2015). Productivity varied between countries with productivity in developed countries five times higher than those of developing countries. Employment rates are beginning to peak and downturns are appearing. Germany, Russia, Italy, and Japan have already begun to experience this downturn, it is expected to hit China and Korea within the next decade, and other countries will follow over the next half century (Executive Summary, 2015). Steps have been identified by economists to boost the world's economy, they include enabling catch-up through transparency and competition, especially in emerging markets; using incentivizing innovation to push the frontier; mobilizing labor, particularly among women and young people; and allowing cross-border economic flow for goods and trade services (Executive Summary, 2015). Figure 14–8 depicts a European Central Bank.

FIGURE 14–8 European Central Bank in Frankfurt, Germany.

The United Nations adopted the Millennium Development Goals (MDGs) in an effort to counter the impact of global poverty and hunger. Interventions would focus on universal primary education, improved maternal and child health, address gender inequalities, promote environmental stability, and reduced rates of HIV/AIDS and other communicable diseases. Progress on these goals varied, and areas such as the sub-Saharan African and South Asian regions did not experience much progress at all (Sridhar et al., 2013). In 2015, the 2030 Agenda for Sustainable Development was developed as an extension of the MDGs (WHO, 2015). This initiative focuses on economic, social, and environmental issues with 17 Sustainable Development Goals (SDGs). Financing for global health and shifts in governance have potential to impact these goals. Rising economies are developing in Brazil, China, and India. These countries have the potential to assume more influence in global governance. Countries that have traditionally held dominance, such as the United States and European countries, may not hold the same influence. These shifts in influence can

impact global health decisions. Health issues have dropped off the agenda of international meetings such as G8 and G20. Historically, the G8 meetings resulted in global strategies on tuberculosis and HIV/AIDS. These topics are no longer part of the conversations. Universal goals may be needed to address the interests of emerging economies (Sridhar et al., 2013). Shifts have occurred in funding at the World Health Organization and World Bank. Funding through these organizations has flattened and is earmarked for special project. New funding organizations have emerged, such as the Global Fund and the GAVI Alliance. The Global Fund is becoming the largest donors at $3.2 billion in 2010. The Bill and Melinda Gates Foundation and other private sector and nongovernmental organizations have voting rights on this board. They narrow down on a few health topics such as immunizations, bed netting, or access to antiretroviral medication. They also measure their success based on outcomes on specific topics rather than a wide range of countries around the globe. Their funding is more discretionary and based on donations rather than through government funds. Unfortunately, donations have been dropping (Sridhar et al., 2013). Philanthropic organizations are becoming more of a force in global health issues. It is important that these various organizations align goals and work together rather than having competing projects (Sridhar et al., 2013). For more on global health, see Chapter 16.

The increase in noncommunicable diseases impacts social and economic opportunity and result in greater inequality (Sridhar et al., 2013). More than 80% of noncommunicable diseases are occurring in middle- to low-income countries. For example, the increased consumption of high-sugar beverages in low-income nations results in increased chronic illnesses and more years lost to disability while rates of heart disease is dropping in the United States. Other factors impacting chronic illness are climate change and increased numbers of people living in urban settings (Sridhar et al., 2013).

Universal health coverage (UHC) is another economic issue that impacts the global economy. In 2012, the United Nation General Assembly voted to adopt a resolution on UHC that would encourage governments to move forward with promoting this initiative for affordable access to quality health care. The risk is that various countries may interpret differing meanings to the term UHC (Sridhar et al., 2013). The World Health Organization is moving toward promoting UHC globally rather than a state level; however, this is very difficult to achieve as every situation is different, requiring individual solutions (Sridhar et al., 2013). See Chapter 16 for more on global health issues.

Migration

Migration is the act of moving from one region or country to another, temporarily, seasonally, or permanently. Throughout history, people have migrated from place to place to seek improved opportunities or to escape intolerable conditions in their home countries. In the late 20th century and the early years of the 21st century, a dramatic increase occurred in the number of *refugees* who migrated from their homes to escape invasion, oppression, or persecution (WHO, 2012). For example, recent displacement of Syrian refugees who are escaping civil unrest and violence has impacted neighboring countries. The crisis in Syria began in 2011, and as of October of 2014, more than 3.2 million refugees had entered Lebanon, Turkey, and Jordan (Doocy, Lyles, Delbiso, & Robinson, 2015). These refugees are poor and vulnerable. The receiving countries have limited resources to assist them. As new refugees enter, their needs differ from those who have been already in the country for 1 to 4 years. The type of violence that they escaped can also impact their specific needs (Doocy et al., 2015). This type of ongoing mass exodus puts extraordinary strain on resources and requires ongoing assessment of needs (Doocy et al., 2015). See Chapter 16.

We also saw an increased reliance on migrant farmworkers, people who move from one region to another seasonally, following the crops. The health care needs of migrants and migrant refugees are enormous. Environmental factors are a primary reason for compromised health and include inadequate waste disposal, crowded and unsanitary living conditions, lack of access to healthful foods, and air pollution from an increased concentration of vehicles used for moving refugees. Compounding these problems are language and cultural barriers, as well as distrust and fear that may interfere with meeting the needs of these vulnerable populations. The potential detriments to health associated with migration require that public health nurses ensure that surveillance systems able to detect emerging health problems are in place; programs to prevent health problems and treat existing conditions also need to be developed (Ruiz-Casares et al., 2013). See Chapter 29 for more on migrant health issues.

Terrorism and Bioterrorism

Terrorism is one way in which a small number of people who perceive that they have been unfairly treated can exert influence on a larger group or nation. Groups wishing to harm other countries need sophisticated skills and coordination for most conventional weapons. Terrorists may also use unconventional weapons when highly motivated, such as flying planes into buildings, strapping bombs to their bodies, or even allowing bombs to be implanted in their bodies.

Some methods of bioterrorism may be even cheaper and easier to use. Bioterrorism is the use of living organisms, such as bacteria, viruses, or other organic materials, to harm or intimidate others, in order to achieve political ends. Some of the possible biologic agents used include *Bacillus anthracis*, smallpox virus, *Brucella*, and botulinum toxin (see Chapters 8 and 17). The federal government has adopted an increasingly proactive approach to reduce the risk of both natural-occurring and deliberate outbreaks of disease. This approach requires a melding of biodefense needs with an increased emphasis on biosecurity, balancing both public health and national security interests (Koblentz, 2012).

Because of escalating concerns about bioterrorism, public health workers increasingly recognize the need for skills in dealing with a bioterrorist attack. They need to engage in emergency preparedness activities and be prepared to initiate response activities in the event of an actual bioterrorism attack (CDC, 2011). Preparedness includes the following:

- Establish relationships with mutual aid partners.
- Conduct hazard vulnerability and risk assessment.
- Identify resources.
- Acquire resources.
- Develop objectives and a plan.
- Put plans into place to mass casualties.
- Develop plan for communicating with members of the community.
- Train personnel.
- Conduct training exercises and engage in after-action reviews.

Response includes the following:

- Assess the situation.
- Activate key personnel.
- Develop objectives and action plan.
- Participate in the Emergency Operations Center (EOC).
- Coordinate with the safety officer to identify hazards.
- Communicate with key partners.
- Deploy resources.
- Respond to health-related requests.

- Communicate with the public.
- Involve legal counsel.
- Document all activities.

Engagement in ongoing public health response duties incorporates:

- Surveillance
- Meeting the needs of the community
- Addressing needs of special populations
- Engaging in the recovery phase

Perhaps more importantly, public health nurses need to be involved in primary prevention of bioterrorism through advocating for the elimination of biologic weapons and addressing the root causes of terrorism, such as poverty, hunger, poor housing, limited educational opportunities, lack of clean water, and inadequate or no health care. See Chapter 17.

Climate Change

Climate change can be considered societal changes because they may be influenced by economics. Since the Industrial Revolution, increased amounts of carbon dioxide, methane, and nitrous oxide created by manufacturing industries, automobile emissions, and consumer products have been introduced into the earth's atmosphere. These increases have contributed to climate changes that are expected to affect sea level; the production of food, fiber, and medicines; and the spread of infectious diseases. Conversely, significant increases in fuel efficiency and efforts to reduce pollution could avoid millions of deaths around the world. Population-focused nurses need to educate the public about the potential dangers of continuing to contaminate the environment and to advocate for changes in public policy that reduce air and water contaminants. In 2008, the American Nurses Association's House of Delegates passed a Global Climate Change initiative that encourages nurses to "advocate for change on both individual and policy levels; to support local public policies that endorse sustainable energy sources and reduce greenhouse gas emissions; and … to support initiatives to decrease the contribution to global warming by the healthcare industry" (ANA, 2012). This built on elements of the 2007 Public Health Nursing: Scope and Standards of Practice most notably in terms of ethics in practice, challenging nurses to contribute to "resolving social and environmental issues and barriers to healthy living conditions" (p. 34). Chapter 9 explores health-related environmental issues in more detail.

SUMMARY

Public health nursing is a community-oriented, population-focused nursing specialty that is based on interpersonal relationships. The unit of care is the community or population rather than the individual, and the goal is to promote healthy communities.

Theories and models of community/public health nursing practice aid the nurse in understanding the rationale behind community-oriented care. Florence Nightingale's environmental theory emphasizes the importance of improving environmental conditions to promote health. Orem's self-care model provides a framework, within which the public health nurse can promote a community's collective independence and self-care ability. Neuman's Health Care Systems Model describes the nurse's role as one of assisting clients to remain stable within their environment, whereas Rogers' model of the science of unitary man focuses on client–environment interaction and holistic health. King's Theory of Goal Attainment reminds nurses to work in partnership with clients to achieve the best health outcomes. Parse's Human Becoming Theory posits quality of life from each person's own perspective as the goal of nursing practice. Pender's model focuses on the promotion of health behaviors in people; the goal of nursing is to enhance the likelihood that people will engage in health-promoting behaviors by assessing and influencing perceptual and modifying factors. Roy's adaptation model describes the nurse's goal as one that promotes healthful coping mechanisms and adaptive responses to stressors. Salmon's construct for public health nursing prescribes education, engineering, and enforcement with individuals, families, communities, and nations. Finally, the models used in public health nursing practice, the Minnesota Intervention "Wheel," the Los Angeles County–Public Health Nursing Practice Model, and the Omaha System Model of the Problem-Solving Process provide a mechanism for public health nurses to assess, plan, intervene, and evaluate the care they provide in their communities.

The eight principles of public health nursing applied to community/public health nursing practice provide a framework within which the nurse works to promote and protect the health of populations. They emphasize the primacy of prevention, the need for outreach, and the importance of working in collaboration for the greatest good of the greatest number of people.

Nurses must anticipate and adapt to societal changes in order to fulfill their mission of promoting the health of all people. Contemporary societal influences on public health nursing include communication technology, genetic engineering, the global economy, migration, terrorism, and climate changes.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Search your local public health agency's Web site to determine what population-focused programs are offered in your locality. Talk with the public health nursing director or a program manager to explore nursing's role in the assessment, development, implementation, and evaluation of these programs. Discuss how public health nurses might expand their population-focused interventions.
2. Describe a situation in community/public health nursing practice in which the use of an educational intervention would be most appropriate. Do the same with engineering (Salmon) and enforcement interventions. Discuss your rationale for matching each situation with that intervention.
3. Assume you have been asked to make a home visit to a 75-year-old man, living alone, whose wife recently died. In addition to assessing his individual needs, what factors should you consider for assessment and intervention that would indicate an aggregate- or community-focused approach?
4. Select one of the societal influences on a community or population. How would the theories or models for community/public health nursing practice that were discussed in this chapter guide your practice concerning that societal issue? Choose three models or theories to apply and examine main concepts in relation to your chosen issue. Search for current research studies that utilize this model or theory and critique its applicability.
5. Search online to explore one of the societal influences on community or population. Using the information in Display 14–5, try to determine the worth of the information available on several Internet sites.
6. Select five or six conceptual models used in nursing research with a community/public health focus. Develop a chart showing how each model defines the nursing metaparadigm concepts: nurse, client/patient, health, and environment. Which of these conceptual models include all of these concepts? In instances where the provider of services is defined, can public health nurse be substituted for another provider of services?

15 CHAPTER

Community as Client: Applying the Nursing Process

"A community needs a soul if it is to become a true home for human beings. You, the people, must get it this soul."
—*Pope John Paul II* (1920–2005)

KEY TERMS

Assets assessment
Coalition
Community as client
Community development
Community diagnoses
Community assessment
Community subsystem assessment
Comprehensive assessment
Descriptive epidemiologic study
Evaluation
Familiarization assessment
Goals
Implementation
Interaction
Key informants
Location variables
Objectives
Outcome criteria
Partnerships
Planning
Population variables
Priority setting
Problem-oriented assessment
Social class
Social determinants of health
Social system variables
Survey
Windshield survey

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the characteristics of a healthy community.
- Describe the meaning of community as client.
- Articulate three specific considerations of each of the three dimensions of the community as client.
- Explain methods the community health nurse might use to interact with the community.
- Discuss methods of community health assessment.
- Compare and contrast five types of community assessment.
- Delineate five sources of community data.
- Describe the role of the community health nurse as a catalyst for community development.

By this point in your nursing education, you are familiar with the use of the nursing process in caring for individuals in the acute care setting. It is a new experience to think of an entire community as your focus of care, but similar principles apply. Although community health nursing practice involves the care of individuals, families, and populations, the care of communities is vital to promoting health and preventing disease. The term community has been well defined in the nursing literature. A community is a collection of people interacting with one another because of geography, common interests, characteristics, or goals. These interactions include social institutions, such as schools, government agencies, and social services. The concept of community as client refers to a group or population of people as the focus of nursing service (Anderson & McFarlane, 2015). As described in Chapter 1, understanding the concept of the community as client is a prerequisite for effective service at every level of community nursing practice. In this era of increased emphasis on population health and public health improvement, the demand for related skills is increasing (Michener, Koo, Castrucci, & Sprague, 2015). It is this population-focused practice that distinguishes community health nursing from other nursing specialties (American Nurses Association [ANA], 2013; American Public Health Association, Public Health Nursing Section, 2013).

WHAT IS A HEALTHY COMMUNITY?

What is a healthy community? Just as health for an individual is relative and will change, all communities exist in a relative state of health. A community's health can be viewed within the context of health being more than just the absence of disease and including things that promote the maintenance of a high quality of life and productivity. A key vision for healthy communities is presented in *Healthy People 2020*, the national health promotion and disease prevention agenda published by the U.S. Department of Health and Human Services (USDHHS). Its four overarching goals for the health of the nation are

- To attain high-quality, longer lives free of preventable disease, disability, injury, and premature death
- To achieve health equity, eliminate disparities, and improve the health of all groups
- To create social and physical environments that promote good health for all
- To promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, 2016, para. 5)

The 42 topic areas and 1,200 objectives are discussed in more detail elsewhere (see Chapter 1 describing *Healthy People 2020*). These objectives and targets provide guidelines for communities to follow in order to promote the health of their members. By encouraging collaboration across communities, empowering individuals to make better choices, and measuring progress toward set benchmarks, *Healthy People 2020* can be used as a road map for achieving longer and healthier lives for all Americans.

The National Prevention Strategy (NPS), largely based on *Healthy People 2020* priorities, was developed in 2011 to further national health improvement efforts. The NPS aims to guide national efforts in the most effective and achievable means for improving health and well-being. The strategy prioritizes prevention by integrating recommendations and actions across multiple settings in order to improve health and save lives. To realize this vision and achieve this goal, the strategy identifies four strategic directions and seven targeted priorities (National Prevention Council, 2011).

The *strategic directions* provide a strong foundation for all of our nation's prevention efforts and include core recommendations necessary to build a prevention-oriented society. They include

- Healthy and safe community environments: Create, sustain, and recognize communities that promote health and wellness through prevention.
- Clinical and community preventive services: Ensure that prevention-focused health care and community prevention efforts are available, integrated, and mutually reinforcing.
- Empowered people: Support people in making healthy choices.
- Elimination of health disparities: Eliminate disparities, improving the quality of life

for all Americans.

Within this framework, the *priorities* provide evidence-based recommendations that are most likely to reduce the burden of the leading causes of preventable death and major illness, and include

- Tobacco-free living
- Preventing drug abuse and excessive alcohol use
- Healthy eating
- Active living
- Injury- and violence-free living
- Reproductive and sexual health
- Mental and emotional well-being

The NPS serves as a road map for community health nurses collaborating with stakeholders and community partners, to address priority areas such as healthy eating, active living, and tobacco control through the prioritization of prevention and integration of recommendations and actions across multiple settings. By working on shared priorities, community health nurses can serve as a valuable partner in identifying community health needs and connecting communities with available resources (Jarris & Schneider, 2013). Nurses can also serve as community educators, empowering people with information to make healthy choices while working to create environments where healthy choices are more accessible and affordable, which is the ultimate intent of the strategy (Lushniak, Alley, Ulin, & Graffunder, 2015).

Healthy communities promote productivity and a good quality of life for their residents.

DIMENSIONS OF THE COMMUNITY AS CLIENT

The health of a community can be characterized through a number of perspectives. Donabedian's classic theory of structure, process, and outcomes provides unique insight into the health status of the community (Donabedian, 2005).

Status/people is the most common measure of the health of a community. It typically comprises morbidity and mortality data identifying the physical, emotional, and social determinants of health (SDH). Physical and social indices include vital statistics, leading causes of death and illness, suicide rates, and rates of drug and alcohol addiction. Social determinants can be identified by crime rates and functional ability level or by high school dropout rates or average income levels. Other demographic characteristics, such as single, female-headed households, are also helpful status measures. Informal leaders and resource persons can impact the health of communities outside the formal health care system.

Structure of a community refers to its services and resources. Community associations, groups, and organizations provide a means for accessing needed services. Adequacy and appropriateness of health services can be determined by examining patterns of use, number and types of health and social services, and quality measures. Classification as a medically underserved area is indicative of a lack of sufficient health care providers (e.g., nurses, physicians, dentists) and is determined by the federal government (Health Resources & Services Administration [HRSA], 2014). Demographic data, such as socioeconomic and racial distribution, age, gender, and educational level, are also important indicators of community structure. These measures provide key information and correlate to health status.

Process reflects the community's ability to function effectively. It includes processes within the community (collaboration between subsystems of education and health, for instance) and between the community and the state or national levels. Social capital (i.e., the networks of relationships among people who live and work in a particular society, enabling that society to function effectively) is a key component to the process dimension (Murayama, Fujiwara, & Kawachi, 2012). Just as nurses assess the strengths and limitations of clients when working with individuals, the community health nurse must assess the strengths and limitations of the community when working with the community as client. Strengths must be enhanced and limitations addressed to achieve agreed-upon goals. Communities with social capital are able to:

- Collaborate effectively in identifying community needs and problems
- Achieve a working consensus on goals and priorities
- Induce collective action to implement agreed-upon goals
- Collaborate effectively to take the required actions

These characteristics are discussed in more detail later in this chapter under the discussion on "Planning to Meet the Health Needs of the Community." See Chapter 1 for more information on healthy communities.

Addressing community health by examining the process, in addition to the structure and status dimensions, provides a broader view into the complexities of community health and community actions for change. It is key not only to examine health outcomes but also to consider how the interactions between processes and structure impact health outcomes (Public Health Accreditation Board, 2013).

Another perspective identifies the community as having three features: a location, a population, and a social system. Figure 15–1 presents a visual interpretation of this perspective. Each of these features has several components that need to be addressed and represents further information that must be collected and analyzed when assessing the health of a community. These are detailed in Tables 15–1 to 15–3.

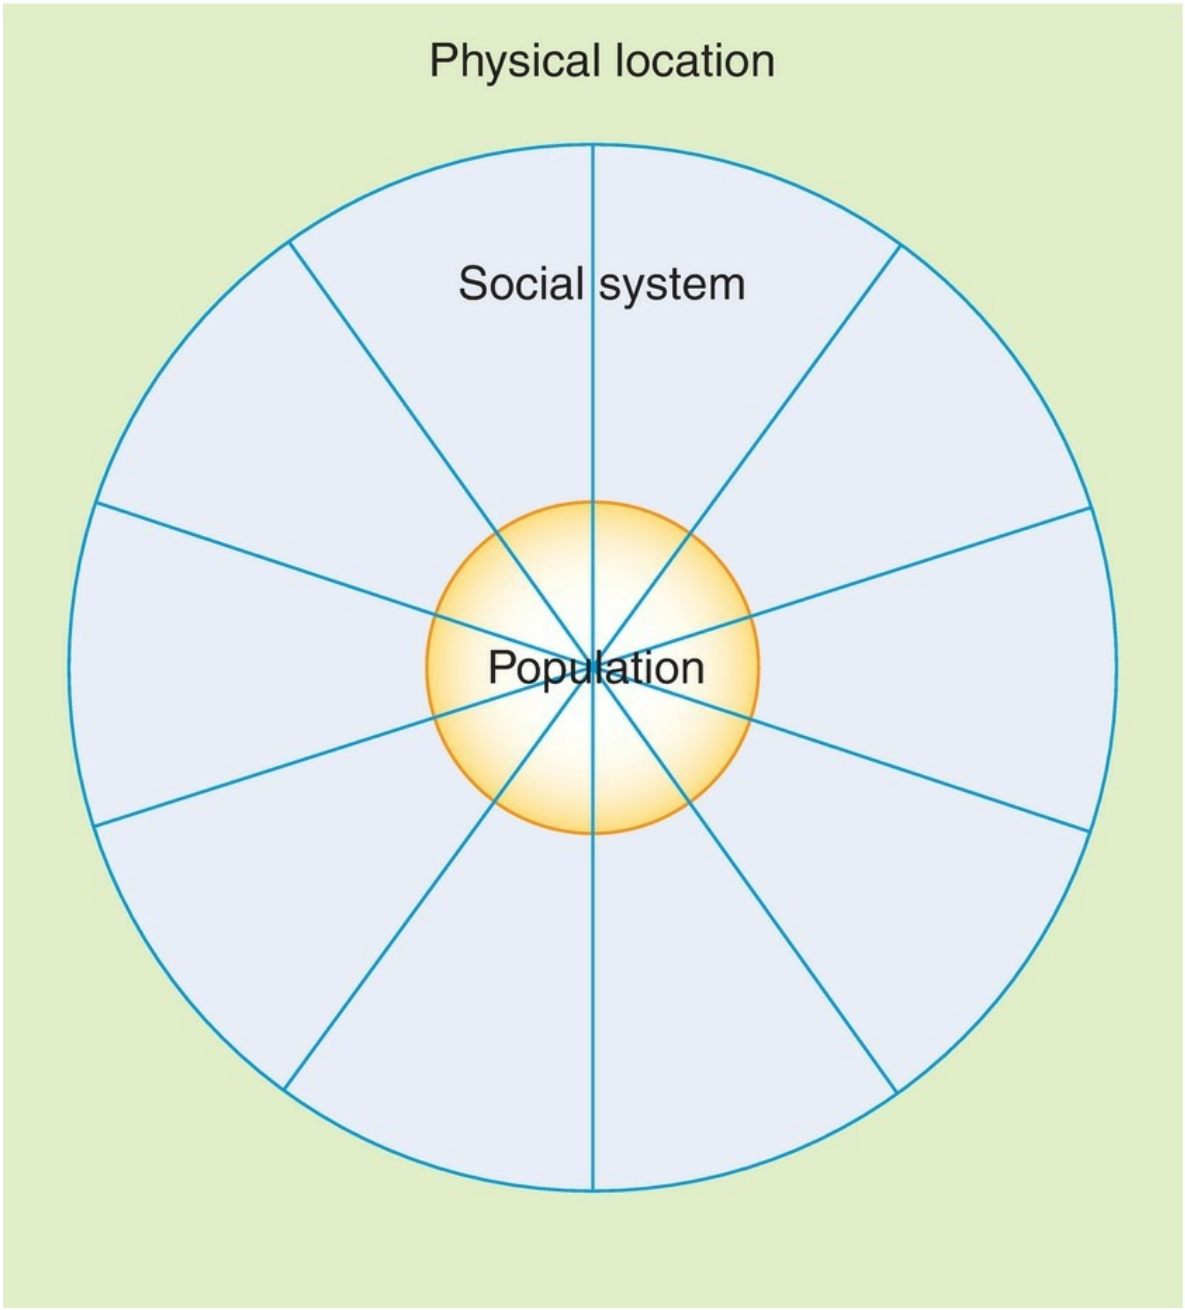

FIGURE 15–1 Three features of a community. The community has (1) a physical location, represented here by the square boundary; (2) a population, shown here by the central circle; and (3) a social system, divided here into subsystems.

Table 15–1 Community Profile Inventory: Location Perspective

Location Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All–Various Internet Sites)
Boundary of community	Community boundaries serve as basis for measuring incidence of wellness and illness and for determining spread of disease.	Where is the community located? What is its boundary? Is it a part of a larger community? What smaller communities does it include?	Atlas State maps County maps City maps Telephone book City directory Public library
Location of health services	Use of health services depends on availability and accessibility.	Where are the major health institutions located? What necessary health institutions are outside the community? Where are they?	Telephone book Chamber of commerce State health department County or local health departments Maps Public library
Geographic features	Injury, death, and destruction may be caused by floods, earthquakes, volcanoes, tornadoes, or hurricanes. Recreational opportunities at lakes, seashore, and mountains promote health and fitness.	What major landforms are in or near the community? What geographic features pose possible threats? What geographic features offer opportunities for healthful activities?	Atlas Chamber of commerce Maps State health department Public library
Climate	Extremes of heat and cold affect health and illness. Extremes of temperature and precipitation may tax community's coping ability.	What are the average temperature and precipitation? What are the extremes? What climatic features affect health and fitness? Is the community prepared to cope with emergencies?	Weather atlas Chamber of commerce State health department Maps Local government Weather bureau Public library
Flora and fauna	Poisonous plants and disease-carrying animals can affect community health. Plants and animals offer resources as well as dangers.	What plants and animals pose possible threats to health?	State health department Poison control center Police department Emergency rooms Encyclopedia Public library
Human-made environment	All human influences on environment (housing, dams, farming, type of industry, chemical waste, air pollution, and so forth) can influence levels of community wellness.	What are the major industries? How have air, land, and water been affected by humans? What is the quality of housing? Do highways allow access to health institutions?	Chamber of commerce Local government City directory State health department University research reports Public library

Table 15–2 Community Profile Inventory: Population Perspective

Population Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All–Various Internet Sites)
Size	The number of people influences number and size of health care institutions. Size affects homogeneity of the population and its needs.	What is the population of the community? Is it an urban, suburban, or rural community?	State health department Census data Maps City or town officials Chamber of commerce
Density	Increased density may increase stress. High and low density often affects the availability of health services.	What is the density of the population per square mile?	Census data State health department
Composition	Composition of the population often determines types of health needs.	What is the age composition of the community? What is the sex composition of the community? What is the marital status of community members? What occupations are represented and in what percentages?	Census data State health department Chamber of Commerce U.S. Department of Labor Statistics
Rate of growth or decline	Rapidly growing communities may place excessive demands on health services. Marked decline in population may signal a poorly functioning community.	How has population size changed over the past two decades? What are the health implications of this change?	Census data State health department
Cultural differences	Health needs vary among subcultural and ethnic populations. Utilization of health services varies with culture. Health practices and extent of knowledge are affected by culture.	What is the ethnic breakdown of population? What racial groups are represented? What subcultural populations exist in the community? Do any of the subcultural groups have unique health needs and practices? Are different ethnic and cultural groups included in health planning?	Census data State health department Social and cultural research reports Human rights commission City government Health planning boards
Social class	Class differences influence the utilization of health services. Class composition influences cost of public health services.	What percentage of the population falls into each social class? What do class differences suggest for health needs and services?	State health department Census data Sociological reports
Mobility	Mobility of the population affects continuity of care. Mobility affects availability of service to highly mobile populations.	How frequently do members move into and out of the community? How frequently do members move within the community? Are there any specific populations, such as migrant workers, that are highly mobile? How does the pattern of mobility affect the health of the community? Is the community organized to meet the health needs of mobile groups?	State health department Census data Health agencies serving migrant workers Farm labor offices Program serving transients and the homeless
Education level	Education disparities may lead to health disparities.	What percentage of the population has less than high school education? What is the literacy rate?	State data Local data (schools)
Unemployment rate	Health insurance is often tied to employment. Lack of regular income can be a family stressor. Both can lead to health disparities.	What is the rate of unemployment? How variable is this rate?	U.S. Department of Labor State data Local data
Population by age	A high proportion of children and elderly can overburden health care and social systems.	What is the dependency ratio? Has this rate changed dramatically? What is the trend?	Census data State data Local data
Health status	Community members' status relative to the 10 Leading Health Indicators can impact overall community health.	What is the rate of obesity/overweight? What are the rates of tobacco use and substance abuse? What is the immunization rate? What are rates of injury and violence? What are the STD and HIV/AIDS rates?	State data Local data Centers for Disease Control and Prevention (CDC) data Vital statistics—numbers of births, deaths, marriages, and infant mortality rate. (Compare local to state data; state to national data.)
Environmental health status	Poor environmental health (e.g., presence of coliform bacteria in well water, toxic chemicals, or poor air quality) can lead to increased incidence of communicable or chronic diseases.	What are rates of communicable or chronic diseases (e.g., *E. coli* infections, asthma)? What is the Toxic Release Inventory?	CDC data State data Local data

Table 15–3 Community Profile Inventory: Social System Perspective

Social System Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All–Various Internet Sites)
Health system Family system Economic system Educational system Religious system Welfare system Political system Recreational system Legal system Communication system	Each system must fulfill its functions for a healthy community. Collaboration among the systems to identify goals and problems affects health of community. Undue influence of one system on another may lower the health of the community. Agreement on the means to achieve community goals affects community health. Communication among organizations in each system affects community health.	What are the functions of each major system? What are the major subsystems of each system? What are the major organizations in each subsystem? How well do the various organizations function? Are the subsystems in each major system in conflict? Is there adequate communication among the major systems? Is there agreement on community goals? Are there mechanisms for resolving conflict? Do any parts of the total system dominate the others? What community needs are not being met?	Chamber of Commerce Telephone book City directory Organizational literature Officials in organizations Community self-study Community survey Local library Key informants

Location

Every physical community carries out its daily existence in a specific geographic location. The health of a community is affected by location, because placement of health services, geographic features, climate, plants, animals, and the human-made environment are intrinsic to geographic location. The location of a community places it in an environment that offers resources and also poses threats (Nykiforuk et al., 2012; Thomas, DiClemente, & Snell, 2013). The healthy community is one that makes wise use of its resources and is prepared to meet threats and dangers. In assessing the health of any community, it is necessary to collect information not only about variables specific to location but also about relationships between the community and its location. Do groups cooperate to identify threats? Do health agencies cooperate to prepare for an emergency such as a flood, tornado, or earthquake? Does the community make certain that its members are given available information about resources and dangers? Table 15–1 describes the location perspective of the Community Profile Inventory, including the six location variables: community boundaries, location of health services, geographic features, climate, flora and fauna, and the human-made environment.

Community Boundaries

To talk about the community in any sense, one must first describe its boundaries (Schildkraut, 2014). Measurements of wellness and illness within a community depend on defining the outer geographic limits of the unit under consideration and also the more informal boundaries that are present (Swarts, 2011). Nurses need to be clear, for example, that a target community of the elderly includes a description of age and location (e.g., all persons age 65 and older in a given city or county). Some communities are distinctly separate, such as an isolated rural town, whereas others are closely situated to one another, such as the suburbs of a large metropolis. Therefore, it is important for the nurse to know the nature of each location and clearly define its boundaries.

Location of Health Services

If the members of a town must travel 200 miles to the nearest clinic or dental office, the health of the community will be affected. When assessing a community, the community health nurse needs to identify the major health centers and know where they are located (Barnett, 2012). For example, an alcoholism treatment center for indigent alcoholics was located 30 miles outside one city. This location presented transportation problems and profoundly affected the length of time they remained at the center and the willingness of clients to voluntarily seek treatment there. If a well-baby clinic is located on the edge of a high-crime district, parents may be deterred from using it. It is often helpful to plot the major health institutions, both inside and outside the community, on a map that shows their proximity and relationship to the community as a whole.

Geographic Features

Communities have been constructed in every conceivable physical environment, and environment certainly can affect the health of a community (see Chapter 9). A healthy community is one that takes into consideration the geography of its location, identifies possible problems and likely resources, and responds in an adaptive fashion (Kindig & Isham, 2014). For example, Anchorage, Alaska, and San Francisco, California, are both located on a geologic fault line and are subject to major earthquakes. In such places, the health of the community is determined, in part, by its preparedness for an earthquake and its ability to cope and respond quickly when such a crisis occurs.

Soil and water pollution pose a serious threat to food safety, and both represent an important threat to human health. Concerns of this kind have become increasingly problematic in China, where a combination of pollution and an increasing food safety risk has affected a large part of the population. Clean water shortages in the country have forced residents to use wastewater irrigation to fulfill the water requirements for agricultural production. Water shortages, coupled with the overapplication of pesticides and chemical pollutants, have caused serious agricultural land and food pollution leading to increased health risks for those living in affected areas (Lu et al., 2015; Starks et al., 2011).

Climate

Winter weather patterns are expected to become more variable as average global temperatures continually increase. Research findings indicate that there is a relationship between temperature variability and health outcomes, including cardiovascular, respiratory, cerebrovascular events, and all-cause morbidity and mortality. Epidemiologic studies indicate that the populations most vulnerable to variations in cold winter weather are the elderly, rural, and, generally, populations living in moderate winter climates (Conlon, Rajkovich, White-Newsome, Larsen, & O'Neill, 2011).

The intense summer heat of a location such as Phoenix, Arizona, can create many health problems (e.g., heatstroke, heat exhaustion). Skin cancer incidence is associated with unprotected sun exposure, which increases the risk for people who live in warm, sunny regions (Townsend et al., 2011). Asthma and other lung diseases are exacerbated in the Central San Joaquin Valley of California because mountains surround this area and create an air inversion, trapping vehicle and agricultural by-products in what can be described as a "large bowl," causing smog during many months of the year. Asthmatic children in densely populated areas of Baltimore, Maryland, have been found to experience exacerbations of asthma symptoms in both the summer and winter months (Teach et al., 2015). Climate can also affect infectious disease rates (McMichael, 2015). A healthy community encourages physical activity among its members, but the climate affects this activity. Although long, cold winters can restrict activity, one community, St. Paul, Minnesota, holds an annual Winter Carnival. Sporting events, parades, ice sailing, dog sledding, a treasure hunt, and hot air balloon races bring thousands of Minnesotans outdoors at a time

when they might otherwise be confined by the weather.

Flora and Fauna

Plant and animal populations in a community are often determined by location. The way a community responds to these populations, whether wild or domesticated, can affect the health of the community. More than 26 million American children and adults live with asthma. Evidence of a connection between asthma attacks and community environments has been demonstrated both in the United States and abroad (Iqbal, Oraka, Chew, & Flanders, 2014). Inner-city children have been shown to demonstrate higher rates of asthma, and research has shown strong allergic reactions, especially to rat and cat allergens (Rao et al., 2015).

Public health officials note chronic environmental factors as a possible cause for increased asthma cases: pollution from high-traffic areas, secondhand smoke in homes, and poor living conditions characterized by dust mites, mold, industrial air pollution, mouse and cockroach droppings, and animal dander. However, research completed at Johns Hopkins University in 2015 counters that claim. Researchers examined records for 23,065 children living in 5,853 census tracts and found asthma prevalence of 12.9% for inner-city children and 10.6% for those living outside of inner cities. When they statistically adjusted for age, gender, region, and race/ethnicity, no statistical difference was found. They noted that poverty increased the risk of asthma for children (Keet et al., 2015).

For 2015, the city named "asthma capital" of the United States was Memphis, Tennessee (Asthma and Allergy Foundation of America, 2015). Many of the asthma capitals that year were in the South, largely because of the lack of smoke-free legislation in many tobacco-producing states, along with poor air quality and high pollen counts. To further make the case for a connection between environment and asthma, in Atlanta, the 1996 Olympics brought an unexpected benefit: a 42% reduction in asthma-related emergency room visits. With the Olympic congestion downtown, Atlanta restricted traffic and thus improved air quality. The same outcomes were experienced with the Beijing Olympics. Internationally, Singapore also noticed a reduction in emergency room visits for asthma after it restricted automobile traffic in its central business district (Li et al., 2011).

Poison oak, ivy, and sumac can be found across the United States, and these plants produce an allergic contact dermatitis in many people who come in contact with it (Petersen, 2011). In the Sierra foothill communities of central California, black widow and tarantula spiders, scorpions, and rattlesnakes are resident populations that pose potential health threats. The poison from a single snakebite may cause serious injury or death (Gras, Plantefève, Baud, & Chippaux, 2012). In the south–central Midwest, the bite of the brown recluse spider injects a toxin that can lead to necrotic skin ulcers as well as systemic symptoms (Quan, 2012). In the Northeast and Mid-Atlantic states, increased deer populations—and consequently deer ticks—bring with them an increased incidence of Lyme disease (Tran & Waller, 2013).

Public health nurses need to know about the major sources of danger from plants and animals affecting the community under study. Are there community agencies that provide educational information about these dangers? Does the populace understand their significance? Are emergency services, such as a poison control center, available to community members?

The Built Environment

Every community is located in the midst of an environment created and transformed by human ingenuity. People build houses and factories, dump wastes into streams or vacant lots, fill the air with gases, and build dams to control streams. All of these human alterations of the environment have important implications for community health (Trowbridge & Schmid, 2013). A Public Health Nursing (PHN) might improve the health of a community by working with community members, legislators, and stakeholders to improve the design of the built environment to promote health and well-being. Such initiatives have become an emerging priority within public health, particularly as the ongoing epidemics of childhood and adult obesity persist (Trowbridge et al., 2013). Evidence-based environmental design guidelines and evaluation tools are available to promote physical activity and healthy eating.

The promotion of walking has become a common and effective intervention for increasing physical activity, both as recreational exercise and as a daily activity to prevent and control obesity (Trowbridge & Schmid, 2013). Other modifications of the built environment that have been found effective in promoting healthy behaviors include the designation of exercise areas and building safe walking and biking paths (Simiyu, Njororai, & Jivetti, 2015).

Population Characteristics

When one considers the community as the client, examining the health status of the total population in a given community is a critical component. The population consists not of a specialized aggregate but of all the diverse people who live within the boundaries of the community. The health of any community is greatly influenced by the attributes of its population. Various features of the population suggest health needs and provide a basis for health planning (Nguyen, Knight, Roughead, Brooks, & Mant, 2015; Schoenbaum, Schoen, Nicholson, & Cantor, 2011). A healthy community has leaders who are aware of the population's characteristics, know its various needs, and respond to those needs. Community health nurses can better understand any community by knowing about its population variables: size, density, composition or demography, rate of growth or decline, cultural characteristics, social class structure, and mobility. Table 15–2 presents the population perspective section of the Community Profile Inventory.

Size

Dover, Delaware (with about 35,000 people), and the city of Los Angeles, California (with around 4 million people), have radically different health problems. If a single case of *Salmonella* poisoning occurred in Dover, health officials would probably quickly learn of it. It would be relatively easy to trace the course, check the few restaurants in town, and interview people about sanitation practices. However, many cases might occur in Los Angeles without the health department's knowledge. Moreover, once the cases were discovered, tracing the source of contamination might involve a long and complicated search. This is only one small way in which population size can affect the health of a community. The size of a community also influences the presence of inadequate housing, the heterogeneity of the population, and almost every conceivable aspect of health needs and services (Nauenberg, Laporte, & Shen, 2011). Knowing a community's size provides community health nurses with important information for planning. See Chapter 29 for issues related to rural and urban population health.

Density

In some communities, thousands of people are crowded into high-rise apartment buildings. In others, such as farm communities, people live great distances from one another. Population density, or the number of people residing within a square mile area, is used to describe how many people live within a community. Using our example of Dover, Delaware, at 1,566 people per square mile, and the greater Los Angeles area with 23,557 people per square mile, it is readily apparent which one is more densely populated. The full impact of living in high-density communities is being researched, and some research has already shown that crowding affects individual and community health. Motor vehicle exhaust from highways has been shown to be associated with higher risk of asthma and reduced lung function in children, as well as higher pulmonary and cardiac mortality in

adults (Cesaroni et al., 2013). When compared with rural populations, urban populations in some countries have a higher incidence of allergic diseases and respiratory symptoms, thought to be associated with higher air pollution levels (Shpakou, Brożek, Stryzhak, Neviartovich, & Zejda, 2012).

A low-density community, however, may have problems. When people are spread out, provision of health care services can become difficult. There may not be enough resources in the form of taxes to support public health services. Rural communities often suffer from inadequate distribution of health care personnel, including private physicians and community health nurses. A national study of rural–urban health disparities found a higher prevalence of poverty, premature death, and all-cause mortality in rural areas than in more densely populated metropolitan areas (Singh & Siahpush, 2014). Artnak, McGraw, and Stanley (2011) noted "quality health care services in rural communities for the chronically ill and dying remain problematic" (p. 140). One large study found that populations using critical access rural hospitals had higher mortality rates for acute myocardial infarction (MI), congestive heart failure, and pneumonia when compared with patients at nonrural hospitals (Joynt, Harris, Orav, & Jha, 2011). Other rural health risks include greater rates of injuries from traffic accidents (Burrows, Auger, Gamache, & Hamel, 2013) and illnesses related to agricultural pesticide exposure. Recent studies have also found an association between increasing pesticide exposure and attention-deficit hyperactivity disorder (ADHD) that may be stronger for hyperactive–impulsive symptoms compared to inattention and in boys compared to girls. Given the growing use of pesticides, these results may be of considerable public health importance (Wagner-Schuman et al., 2015).

A healthy community takes into consideration the density of its population. It organizes to meet the differing needs created by its density levels (e.g., it recognizes differences in density between the inner city and the suburbs and allocates services accordingly). See Chapter 29 for more on health risks specific to rural and urban areas.

Composition/Demographics

Communities differ in the types of people who live within their boundaries. A retirement community in Florida whose members are mostly older than age 65 has one set of interests and concerns, whereas a city with a large number of women in their childbearing years will have another set of concerns. A healthy community is one that takes full account of the needs of its constituents and provides for their differences. Age, sex, educational level, occupation, and many other demographic variables affect health concerns (Zheng, Tumin, & Qian, 2013). In communities with a high proportion of low-income families, considerations must be made to accommodate the needs of the poor (Lee et al., 2011). Occupation can also affect health. For example, in a town where 75% of the workers are employed in a textile mill, the community lives with the threat of brown lung disease, which is caused by cotton dust. In areas where tobacco is the main source of income and a large proportion of the population is engaged in its production, green tobacco sickness—or acute nicotine poisoning—is a concern because workers can absorb nicotine through the

skin, and precautions must be taken to prevent this from happening (Fassa et al., 2014). Understanding a community's composition is an important early step in determining its level of health.

Rate of Growth or Decline

Community populations change over time. Some grow rapidly. The growth of Las Vegas, Nevada, as a popular place to live has placed extreme demands on the environment, along with the provision of health care and other services. Other populations may experience a decline because of economic change, for example, those areas of the United States where steel and auto manufacturing have declined. Any significant fluctuation in population size can affect the health of the community, much like the size of a hospital is often correlated with rates of drug-resistant infections (Kouyos, Wiesch, & Bonhoeffer, 2011). As people leave to find new employment or better living conditions, consumption of goods and services drops. Community morale may suffer, and community leadership may decline. Even a stable community can have problems (e.g., members may resist needed change because they notice little fluctuation in their population; commercial and residential properties may be abandoned or left vacant).

Cultural Characteristics

A community may be composed of a single cultural group, such as Ojibway Indians on their reservation in Wisconsin, or it may be made up of many cultures or subcultures. For instance, if a city has a large Hispanic population, along with a group of Native Americans living in the inner city and a cluster of Vietnamese refugees, the cultural differences among these members will influence the health of the community. These differences can create conflicting or competing demands for resources and services or create intergroup hostility. A healthy community is aware of such cultural differences and acts to promote understanding among cultural subgroups (Spector, 2013). See Chapter 5 for more about transcultural nursing in the community.

Social Class and Educational Level

Social class refers to the ranking of groups within society by income, education, occupation, social class, or a combination of these factors. There is no absolute agreement on income levels or other criteria to designate social class categories (upper, middle, lower), other than the government formula used to compute poverty level (USDHHS, 2015). Although class distinctions are not clearly defined, class rankings based on occupation, education, and wealth (income plus assets) seem to correlate with many different health outcomes and are used frequently in research (Mondal & Shitan, 2014). Occupational level, in particular, has historically and consistently proven to be a reliable measure, with surprisingly similar rankings among all societies for which data exist (Adcock & Brown, 1957). This classic research has shown that people with higher occupational levels generally have higher incomes and education, exert greater political influence, and are more highly

esteemed by others. More recent research, linking educational attainment with mortality, indicates that income (linked to education and occupation) is often the best predictor for mortality (Hummer & Hernandez, 2013; Lantz, Golberstein, House, & Morenoff, 2010). *Healthy People 2020* identified the relationship between these factors and others by defining social determinants of health:

> Social determinants of health reflect social factors and the physical conditions in the environment in which people are born, live, learn, play, work, and age. Social and physical determinants of health impact a wide range of health, functioning, and quality of life outcomes. (USDHHS, 2016, para. 10)

For example, socioeconomic conditions (e.g., poverty), resources to meet daily needs (e.g., opportunities for quality education and employment; access to healthy food), social norms and attitudes (e.g., segregation, discrimination), public safety and transportation (e.g., crime, violence, sanitation, mass transit), and social support/interactions (e.g., cell phones, mass media, families/friends) are part of the larger construct of SDH. Physical determinants of health include things like the natural environment (e.g., climate, plants), the built environment (e.g., transportation, buildings), housing and neighborhoods (e.g., density, condition), exposure to hazards (e.g., physical, toxic), barriers (e.g., being disabled), and aesthetic elements (e.g., green belts, lighting). While health promotion and preventive health services can be beneficial to all social and economic groups, low-income groups and people with fewer years of education who are most likely to be affected by health disparities can gain particular benefit from targeted community health improvement efforts. Frieden's (2010) influential Health Impact Pyramid has as its base socioeconomic factors (or SDH), as these can have the greatest impact on populations, followed by changing context to make default decisions more healthy (e.g., when most people don't smoke, it is easier to be a nonsmoker), then protective interventions that are long lasting (e.g., immunizations, colonoscopies), and finally clinical interventions (e.g., ongoing monitoring for chronic conditions like heart disease) and counseling/education (e.g., health education to improve diet/exercise) (see Fig. 15–2).

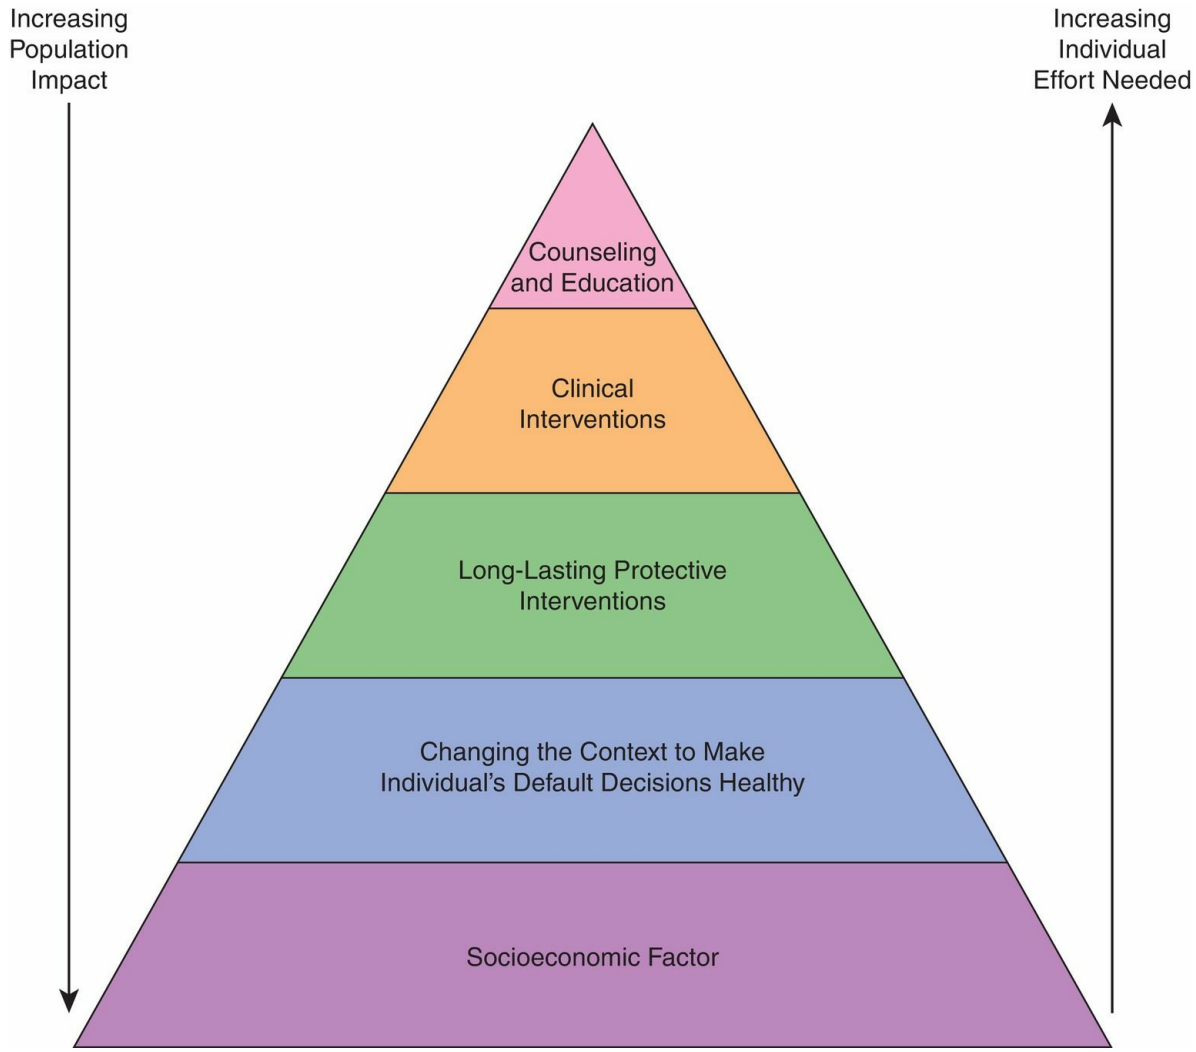

FIGURE 15–2 Health Impact Pyramid. (Source: http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2836340/figure/fig1/)

It is generally known that different social classes have different health problems, as well as a variety of resources for coping with illness and diverse ways of using health services. A healthy community recognizes these differences and creates health care services to meet these varied needs.

Mobility

Americans are a mobile population. Between the 2007 to 2009 period of recession and the 2010 to 2012 postrecession period, 15.7% of Americans moved. However, that is a record low compared to 20.2% in 1985, and these fluctuations have been linked to social and economic factors (U.S. Census Bureau, n.d.). People move to go to college, take a new job, join other family members or friends, or seek a new climate after retirement. This mobility has a direct effect on the health of communities (Gushulak & MacPherson, 2011). If the population turnover is extensive, continuity of services may suffer. Leadership for improving the health of the community may change so frequently that concerted action

becomes difficult. High turnover may necessitate special attention to health education about local conditions.

Population groups may arrive and depart in seasonal swings; fluctuations in the number of migrant farm workers, tourists, or college students can affect a community. Border health issues are of special concern, as people continually move across borders, bringing with them health issues such as vaccine-preventable diseases and chronic illnesses (Matthews et al., 2015). Immigrants and refugees may represent a significant population subgroup in many areas of a country, and public health officials must meet their unique needs. The community health nurse also needs to identify those populations that are seasonally mobile. These subgroups present special health needs and place an added burden on a community (e.g., migrant workers). If a town of 3,000 people has an annual influx of 10,000 students who disappear in the summer, residents must prepare to meet this population instability. The small towns of the San Juan Islands in Puget Sound, Washington, can command such high prices for accommodations in the summer that some low-income, year-round residents camp in tents during those months because they are unable to pay the high rents. Thus, the lives of many families are disrupted each year. A healthy community neither ignores nor overreacts to this kind of mobility. Rather, it identifies the nature of the population change, determines the needs created by such change, and organizes to meet those needs.

Social System

In addition to location and population, every community has a third feature—a social system. The various parts of a community's social system that interact and influence the health of a community are called social system variables. These variables include health, family, economic, educational, religion, welfare, political, recreational, legal, and communication. Whether assessing a community's health, developing new services for the mentally ill within the community, or promoting the health of the elderly, the community health nurse needs to understand the community as a social system. A community health nurse working in a tiny village in Alaska needs to understand and work with the social system of that village no less than a nurse practicing in New York City. Table 15–3 guides the nurse in assessing a community's social system variables.

The Concept of a Social System

A social system is an abstract concept and can be more readily understood by first considering the people who make up the community's population. Each person enacts multiple roles, such as parent, spouse, employee, citizen, church member, and/or political volunteer. People in certain roles tend to interact more closely with others in related roles, such as a nursing supervisor with a staff nurse or a customer with a sales clerk. The patterns and communication that emerge from these interactions form the basis of organizations. Some organizations are informal (e.g., an extended family group). Other organizations, such as a city police department or a software business, are more formal. However, all organizations are constructed from roles that are enacted by individual citizens. Organizations, in turn, interact with one another, forming linkages. For example, a medical equipment company and a laboratory establish contracts (linkages) with a home care agency. When a group of organizations are linked and have similar functions, such as all those providing social services, they form a community system or subsystem (Fig. 15–3). The various community systems have a profound influence on one another. Because this interaction among parts determines the health of the whole, it is the total social system that concerns community health nurses.

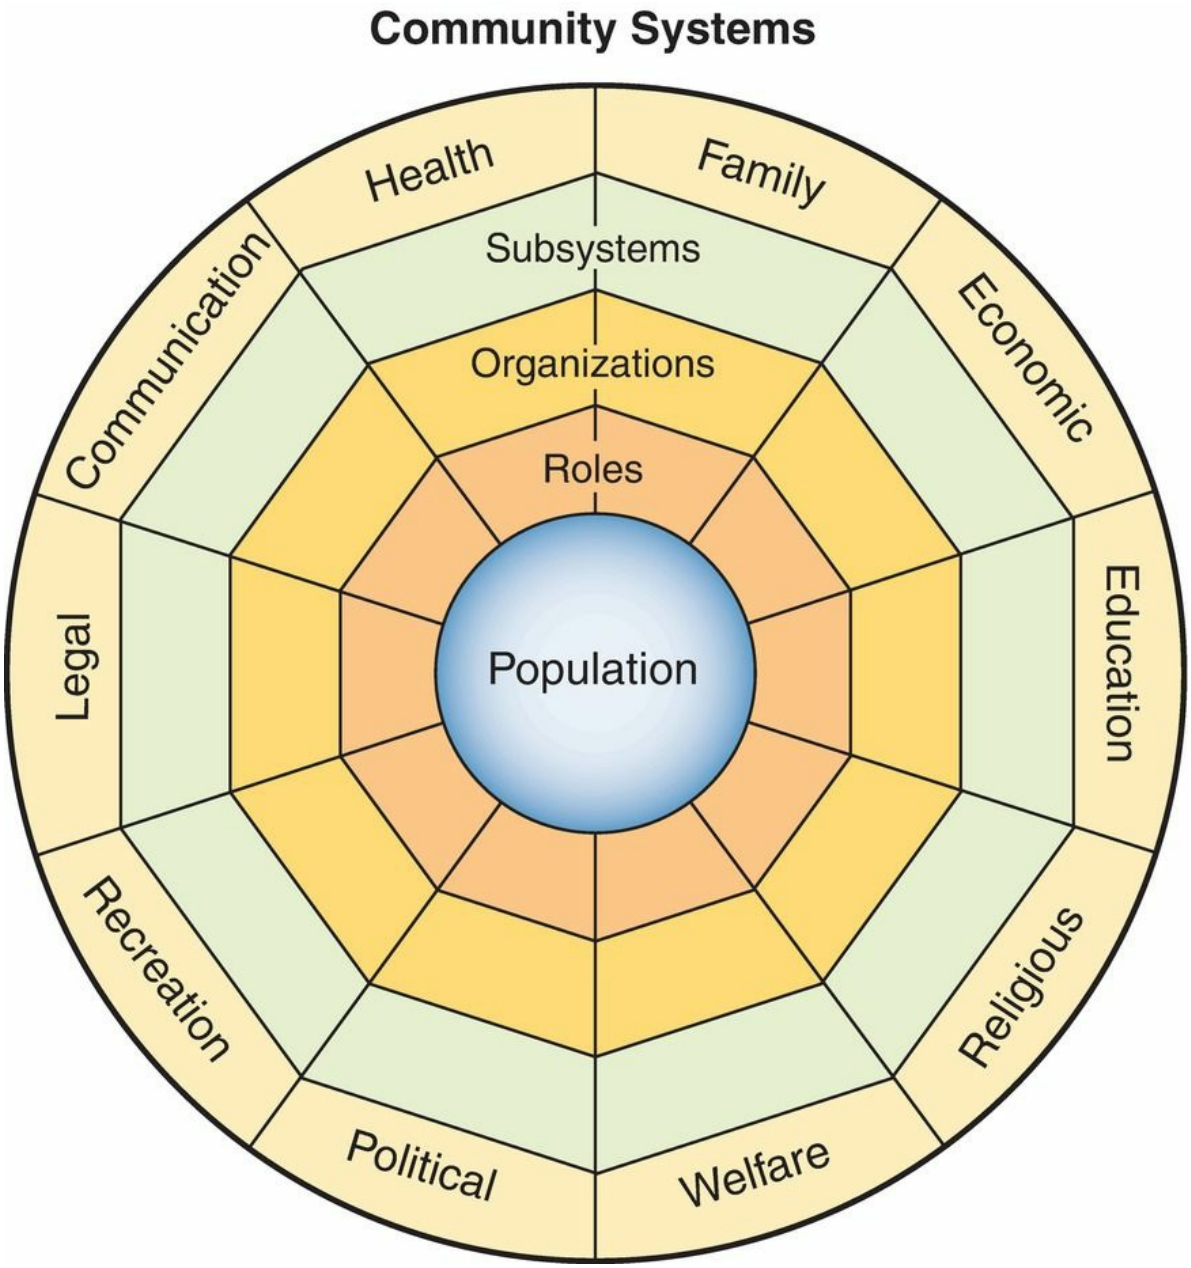

FIGURE 15–3 The community as a social system. Each of the 10 major systems of a community includes a number of subsystems that are made up of organizations. Members of the community occupy roles in these organizations.

The Health Care Delivery System as Part of the Social System

Although community health nurses must examine all the systems in a community and must understand how they interact, the health system is of particular importance. The major function of the health system is to promote the health of the community. Community assessment asks not only whether but also how well the system is functioning. What is the level of health promotion carried out by the health system of a community? To answer this question—one that can be applied to any system—the PHN needs a clear notion about the subsystems, organizations, and roles that make up the system. Any evidence of inadequate

functioning becomes a warning signal for more careful assessment. For example, a high rate of teenage pregnancies in a city may signal inadequate functioning of several systems (e.g., family, educational, religious, health), so a closer look is in order. What community values influence sexual behavior among adolescents? What sex education programs are available to this population? Does the health system provide information and counseling?

The components of the health system, described in Figure 15–4, include eight major subsystems—each with one or more organizations. Although the community health nurse must be aware of all the systems in a community, the health system is of central importance. Figure 15–4 represents an organizational view of health system components.

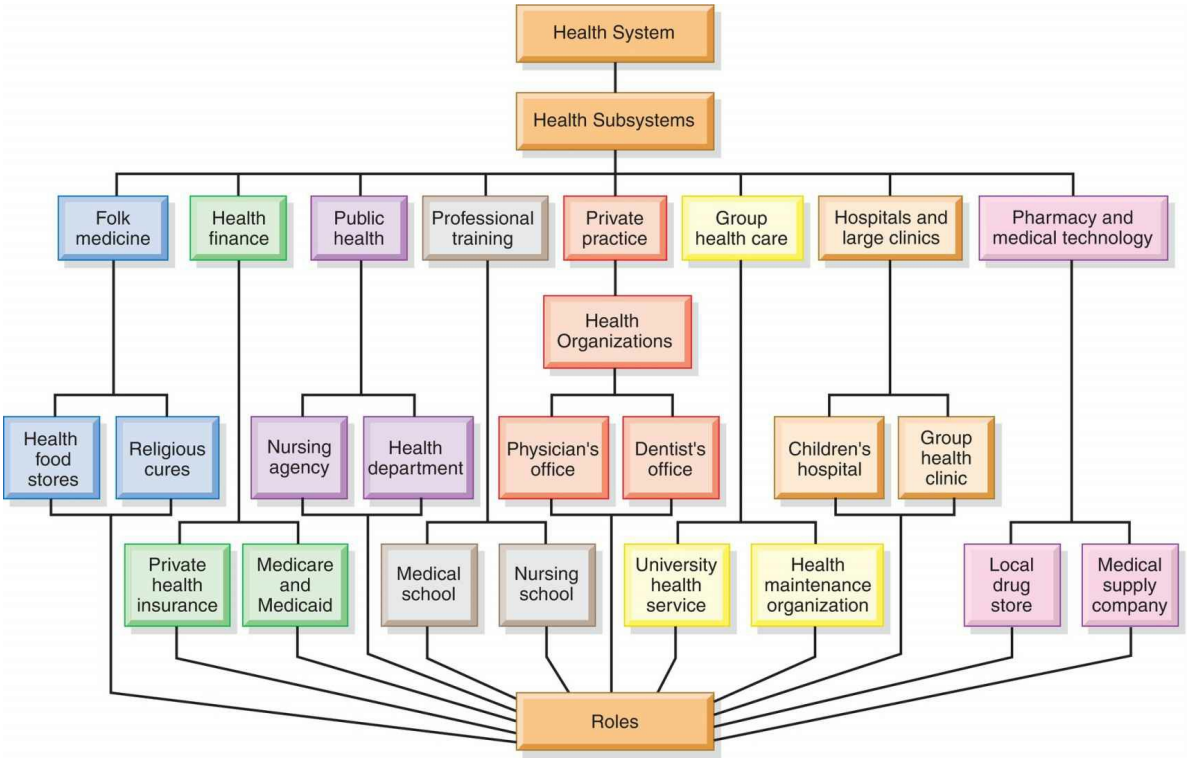

FIGURE 15–4 FIGURE 15–4Components of the health system. This figure shows some representative types of organizations for each of the major subsystems. In turn, each of these organizations also has members with many different roles, and the health of the entire system depends, in part, on how well these roles are carried out.

THE NURSING PROCESS APPLIED TO THE COMMUNITY AS CLIENT

Consisting of a systematic, purposeful set of interpersonal actions, the nursing process provides a structure for change that remains a viable tool employed by the community health nurse. This chapter examines the use of the nursing process as applied at the aggregate or community level. Five components—assessment, diagnosis, planning, implementation, and evaluation—give direction to the dynamics for solving problems, managing nursing actions, and improving the health of communities and community health nursing practice.

Three characteristics support the use of the nursing process in community health nursing. First, the nursing process is a problem-solving process that addresses community health problems at every aggregate level with the goals of preventing illness and promoting public health. Second, it is a management process that requires situational analysis, decision-making, planning, organization, direction, and control of services, as well as outcome evaluation. As a management tool, the nursing process addresses all aggregate levels. Third, it is a process for implementing changes that improve the function of various health-related systems and the ways that people behave within those systems. A representation of nursing process characteristics used in community health nursing is seen in Figure 15–5.

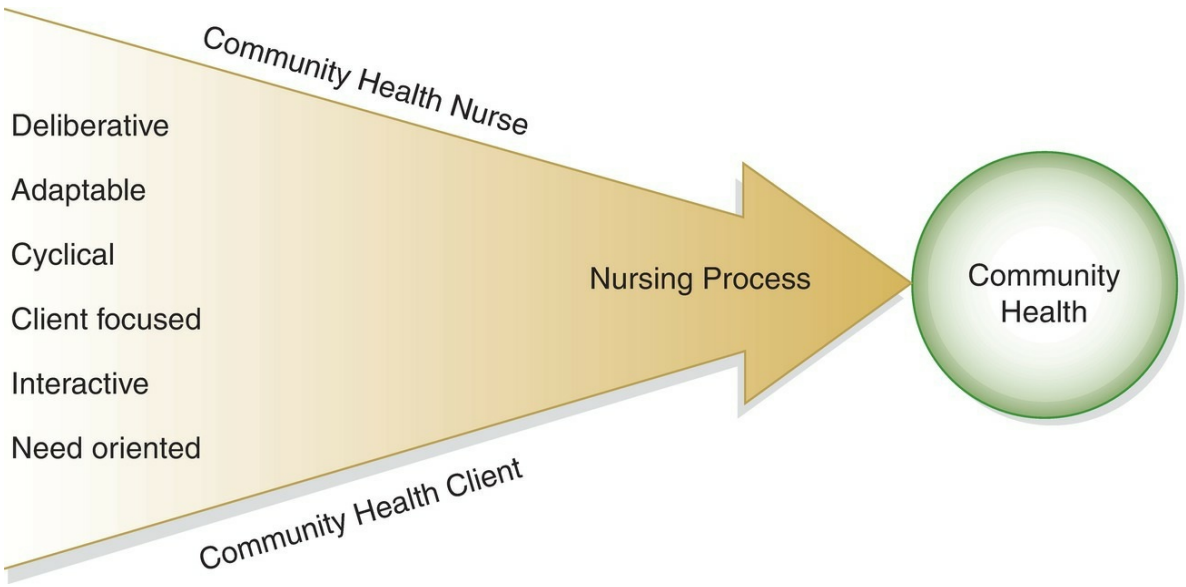

FIGURE 15–5 FIGURE 15–5Nursing process characteristics emphasized in community health.

The nursing process provides a framework or structure on which PHN actions are based (ANA, 2013). Application of the process varies with each situation, but the nature of

the process remains the same. Certain characteristics of that process are important for community health nurses to emphasize in their practices. The Quad Council of Public Health Nursing Organizations, building on the work of the Council on Linkages Between Academia and Public Health Practice (CoL) developed a list of "Core Competencies for Public Health Nurses." These competencies have helped clarify the role of the community health nurse within the context of community as client (Quad Council, 2011) (see Display 15–1).

DISPLAY 15.1 QUAD COUNCIL CORE COMPETENCIES OF PUBLIC HEALTH NURSING (2011)

Tier 2 Community Based, Population Focused

1. Analytic and Assessment Skills

- Assesses health status of populations and related determinants of health and illness. Partners with populations, health professionals, and other stakeholders to attach meaning to collected data.
- Develops PHN diagnoses for individuals, families, communities, and populations. Uses a synthesis of nursing, public health, and system science/theory when characterizing population-level health risks. Assures that assessments identify population assets and needs, values and beliefs, resources, and relevant environmental factors. Derives population diagnoses and priorities based on assessment data, including input from populations.
- Utilizes a wide variety of relevant variables to measure health conditions for a community or population.
- Develops a data collection plan using models and principles of epidemiology, demography, and biostatistics, as well as social, behavioral, and natural sciences to collect quantitative and qualitative data on a community or population. Uses methods and instruments for collecting valid and reliable quantitative and qualitative data.
- Uses multiple methods and sources when collecting and analyzing data for a comprehensive community/population assessment. Assures that assessments are documented and interpreted in terms that are understandable to all who were involved in the process, including communities.

- Critiques validity, reliability, and comparability of data collected for communities/populations.
- Identifies gaps and redundancies in data sources used in a comprehensive community/population assessment. Examines the effect of gaps in data on PH practice/program planning.
- Assures the application of ethical, legal, and policy principles in the collection, maintenance, use, and dissemination of data and information.
- Synthesizes qualitative and quantitative data during analysis for a comprehensive community/population assessment. Uses various data collection methods and qualitative and quantitative data sources to conduct a comprehensive, community/population assessment.
- Incorporates an ecological perspective when analyzing data from a comprehensive community/population assessment. Partners with groups, communities, populations, health professionals, and stakeholders to review and evaluate data collected.
- Utilizes information technology effectively to collect, analyze, store, and retrieve data related to care of communities and populations.
- Practices evidence-based PHN to promote health of communities and populations.
- Collects data related to SDH and community resources to plan for community-oriented and population-level programs. Analyzes those data. Incorporates the results of those analyses into program planning.

2. Policy Development/Program Planning Skills

- Identifies valid and reliable data relevant to health policies targeted to communities and populations. Conducts and uses policy analysis to address specific public health issues.
- Plans population-level interventions guided by relevant models and research findings.
- Conducts and uses policy analysis to address public health issues. Incorporates a wide range of policy options into the planning and delivery of health services and interventions to groups, communities, and populations.
- Plans population-level interventions guided by relevant theories, concepts, models, policies, and evidence. Uses planning models, epidemiology, and other analytical methods in evaluating population-level interventions. Critiques the evidence for population-level interventions. Conducts and uses policy analysis to address specific public health issues.
- Selects an appropriate method of decision analysis for an issue relevant to an identified group, community, or population. Uses planning models, epidemiology, and other analytical methods in the development and implementation of population-level interventions.

- Manages the delivery of community/population-based health services. Evaluates and ensures compliance with public health laws and regulations.
- Develops plans to implement programs and organizational policies. Works as part of an interdisciplinary team to implement relevant policies into community/population-level interventions.
- Manages the implementation of organizational policies and programs for areas of responsibility.
- Designs an evaluation plan that addresses multiple variables, includes both process and outcome measures, and uses multiple data collection methods. Conducts evaluation of care delivery to communities and populations served by the organization. Provides feedback on the organization's quality improvement program. Establishes methods to utilize technology to collect data to monitor and evaluate the quality and effectiveness of programs for communities and populations.
- Identifies a variety of sources and methods to access public health information for a community/population. Utilizes technology to collect DISPLAY 15–1Quad Council Core Competencies of Public Health Nursing (2011) (Continued)data to monitor and evaluate the quality and effectiveness of programs for populations.
- Develops quality improvement indicators and core measures as part of the process to improve public health programs and services. Utilizes quality improvement indicators and core measures as part of the process to improve public health programs and services.

3. Communication Skills

- Assesses the health literacy of communities/ populations served.
- Communicates effectively in writing, orally, and electronically. Communications are characterized by critical thinking and complex decision-making.
- Solicits input from community/population members and stakeholders when planning health care programs.
- Utilizes a variety of methods to disseminate public health information tailored to communities/populations.
- Demonstrates presentation of targeted health information and outcomes of evidence-based practice (EBP) to multiple audiences, including community and professional groups.
- Communicates effectively with community groups, partners, and interprofessional teams.
- Articulates role of public health within the overall health system to internal and external audiences.

4. Cultural Competency Skills

- Utilizes social and ecological determinants of health to develop culturally responsive interventions with communities and populations.
- Uses epidemiological data, concepts, and other evidence to analyze the SDH when developing and tailoring population-level health services. Applies multiple methods and sources of information technology to better understand the impact of SDH on communities and populations.
- Plans health services to meet the cultural needs of diverse communities and populations.
- Explains the interplay of multiple forces contributing to cultural diversity.
- Serves as an advocate to build a diverse public health workforce.
- Uses evidence and awareness of cultural models to tailor interventions to diverse populations. Evaluates current population health programs for evidence of cultural tailoring. Evaluates staff development needs related to cultural competency.
- Uses evidence and cultural models to tailor program level interventions.

5. Community Dimensions of Practice Skills

- Utilizes an ecological perspective in health assessment, planning, and interventions with communities and populations.
- Provides population health expertise for community-based participatory research (CBPR) teams.
- Identifies need for community involvement and partners to create community groups/coalitions.
- Identifies mechanisms for enhancing collaboration among stakeholders in population-focused health interventions. Develops partnerships with key stakeholders and groups.
- Partners effectively with key stakeholders and groups in care delivery to communities/populations.
- Identifies areas for community involvement in agency programs and initiatives. Critiques the evidence on approaches to fostering community partnerships and involvement. Uses evidence-based guidelines and effective group processes to partner with community members and groups.
- Explains to community groups and partners the role of government and the private and nonprofit sectors in the delivery of community health services.
- Utilizes community assets and resources to promote and deliver care to communities/populations.
- Uses input from a variety of community/aggregate stakeholders in development of public health programs and services.
- Advocates for public health policies, programs, and resources that better serve populations.

6. Basic Public Health Sciences Skills

- Utilizes public health and nursing science to practice at population and community level.
- Describes the influence of sentinel events on current PHN practice.
- Uses EBP to assure population-level programs contribute to meeting core public health functions and the 10 essential services.
- Uses descriptive and analytical methods and public health sciences to design, implement, and evaluate interventions at community and population level.
- Synthesizes research across disciplines related to public health concerns and population-level interventions.
- Identifies gaps in the scientific evidence related to public health issues, concerns, and population-level interventions.
- Identifies a wide variety of sources and methods to access public health information, for example, geographic information system (GIS) mapping. Identifies gaps and inconsistencies in research evidence for practice.
- Incorporates the requirements of patient confidentiality, human subject protection, and research ethics into data collection and processing.
- Disseminates theory-guided and/or EBP outcomes in peer-reviewed journals and national level meetings. Facilitates research projects with organizations.

7. Financial Management and Planning Skills

- Collaborates with relevant public and/or private systems for managing programs in public health.
- Supervises the operations of health programs within federal, state, tribal, and local public health agencies.
- Develops partnerships with communities and agencies within federal, state, tribal, and local levels of government that have authority over public health situations, such as emergency preparedness.
- Implements the judicial and operational procedures of the governing body and/or administrative unit designated with oversight of public health organizational operations.
- Develops a programmatic budget.
- Manages care delivery to communities/populations within current and forecasted budget constraints.
- Develops strategies for determining budget priorities based on financial input from federal, state, tribal, and local sources.
- Assesses impact of organizational budget priorities on PHN programs and practice. Establishes organization PHN resource priorities that assure effective PHN practice.
- Designs evaluation plans for population-focused programs. Implements evaluation plans for population-focused programs.

- Leads revisions to population-focused programs based on formative and summative evaluation results.
- Develops proposals for funding from external sources.
- Applies basic human relations and conflict management skills in interactions with direct reports, other professionals, and health care team members.
- Identifies opportunities to use health care technologies and informatics to improve public health program and business operations. Incorporates health care technology and informatics to improve public health program and business operations.
- Assists in the development of contracts and other agreements for the provision of services.
- Describes how cost-effectiveness, cost–benefit, and cost–utility analyses affect programmatic prioritization and decision-making. Employs cost-effectiveness, cost–benefit, and cost–utility analyses for programmatic prioritization and decision-making.
- Participates in implementation and evaluation of performance management systems.

8. Leadership and Systems Thinking Skills

- Addresses ethical issues related to the PHN care of communities/populations.
- Applies system theory to PHN practice with communities and populations.
- Leads team and community partners in identifying vision, values, and principles for community action.
- Analyzes internal and external factors that may impact the delivery of essential public health services. Implements strategies to assure quality, collaboration, and coordination in delivery of PHN services.
- Leads interprofessional team and organizational learning opportunities. Provides leadership in staff development.
- Implements opportunities to mentor, advise, coach, and develop peers, direct reports, and other members of the public health workforce.
- Uses evidence-based models to design and implement quality initiatives. Establishes indicators to monitor organizational performance.
- Adapts program delivery to communities/populations in consideration of changes in the public health system and larger social, political, and economic environment. Assesses outcomes of current health policy relevant to public health/PHN practice.

Note: Tier 1 competencies cover generalist PHNs, and tier 2 competencies cover PHNs with program implementation and supervisory/management duties that may include clinical services, home visiting, and community-based and population-focused programs. Tier 3 competencies refer to senior management or executive level PHNs in administrative/leadership roles at public health agencies or organizations.

Refer to the complete document for a total list of competencies at all three levels.

From Swider, S., Krothe, J., Reyes, D., & Cravetz, M. (2013). The Quad Council practice competencies for public health nursing (pp. 525–536). Public Health Nursing, 30(6), 519–536. Used with permission.

Deliberative

The nursing process, like the research process in EBP (evidence-based practice), is deliberative—purposefully, rationally, and carefully thought out. It requires the use of sound judgment that is based on adequate information. Community health nurses often practice in situations that demand the ability to think independently and make difficult decisions. Furthermore, thoughtful, deliberative problem solving is a necessary skill for working with the community health team to address the needs and problems of aggregates in the community. The nursing process is a decision-making tool to facilitate these determinations.

Adaptable

The nursing process is adaptable. Its dynamic nature enables the community health nurse to adjust appropriately to each situation and to be flexible in applying the process to aggregate health needs. Furthermore, its flexibility is a reminder to the nurse that each client group and each community situation is unique. The nursing process must be applied specifically to the individual situation and group of people. Based on assessment and sound planning, the nurse adapts and tailors services to meet the identified needs of each community client group.

Cyclical

The nursing process is cyclical and in constant progression. Steps are repeated over and over in the nurse–aggregate client relationship. The nurse engages in continual interaction, data collection, analysis, intervention, and evaluation. As interactions between nurse and client group continue, various steps in the process overlap with one another and are used simultaneously. The cyclic nature of the nursing process enables the nurse to engage in a constant information feedback loop: The information gathered and lessons learned at each step of the process promote greater understanding of the group being served, the most effective way to provide quality services, and the best methods of raising this group's level of health.

Client Focused

The nursing process is client focused; it is used for and with clients. Community health nurses use the nursing process for the express purpose of addressing the health of populations. They are helping aggregate clients, directly or indirectly, to achieve and maintain health. Clients as total systems—whether groups, populations, or communities—are the targets of the PHN's nursing process (ANA, 2013).

Interactive

The nursing process is interactive, in that nurse and clients are engaged in a process of ongoing interpersonal communication. Giving and receiving accurate information is necessary to promote understanding between nurse and clients and to foster effective use of the nursing process. Furthermore, because of the movement toward informed use of health care, demands for clients' rights and the concept of self-care have gained emphasis. Client groups and community health nurses have increasingly joined forces to assume responsibility for promoting community health. The nurse–aggregate client relationship can and should be a partnership, a shared experience by professionals (nurses and others) and client groups (Tucker, Arthur, Roncoroni, Wall, & Sanchez, 2015).

Need Oriented

The nursing process is need oriented. A long association with problem solving has tended to limit the focus of the nursing process to the correction of existing problems. Although problem solving is certainly an appropriate use of the nursing process, the community health nurse can also use the nursing process to anticipate client needs and prevent problems. The nurse should think of nursing diagnoses as ranging from health problem identification to primary prevention and health promotion opportunities. This focus is needed if the goals of community health—to protect, promote, and restore the people's health—are to be realized.

Interacting with the Community

All steps of the nursing process depend on interaction, reciprocal exchange, and influence among people. Although nurse–client interaction is often an implied or assumed element in the process, it is an essential first consideration for community health nursing (see Chapter 10 for more details). Listening to a group of elderly people, teaching a class of expectant mothers, lobbying in the legislature for the poor, working with parents to set up a dental screening program for children—all these involve relationships, and relationships require interaction. Mutual give and take between nurse, clients, and community stakeholders—whether a family, a group of mothers on a Native American reservation, or representatives from resource agencies within the community—is an expected and much needed skill that should be integrated throughout the nursing process (see Fig. 15–6).

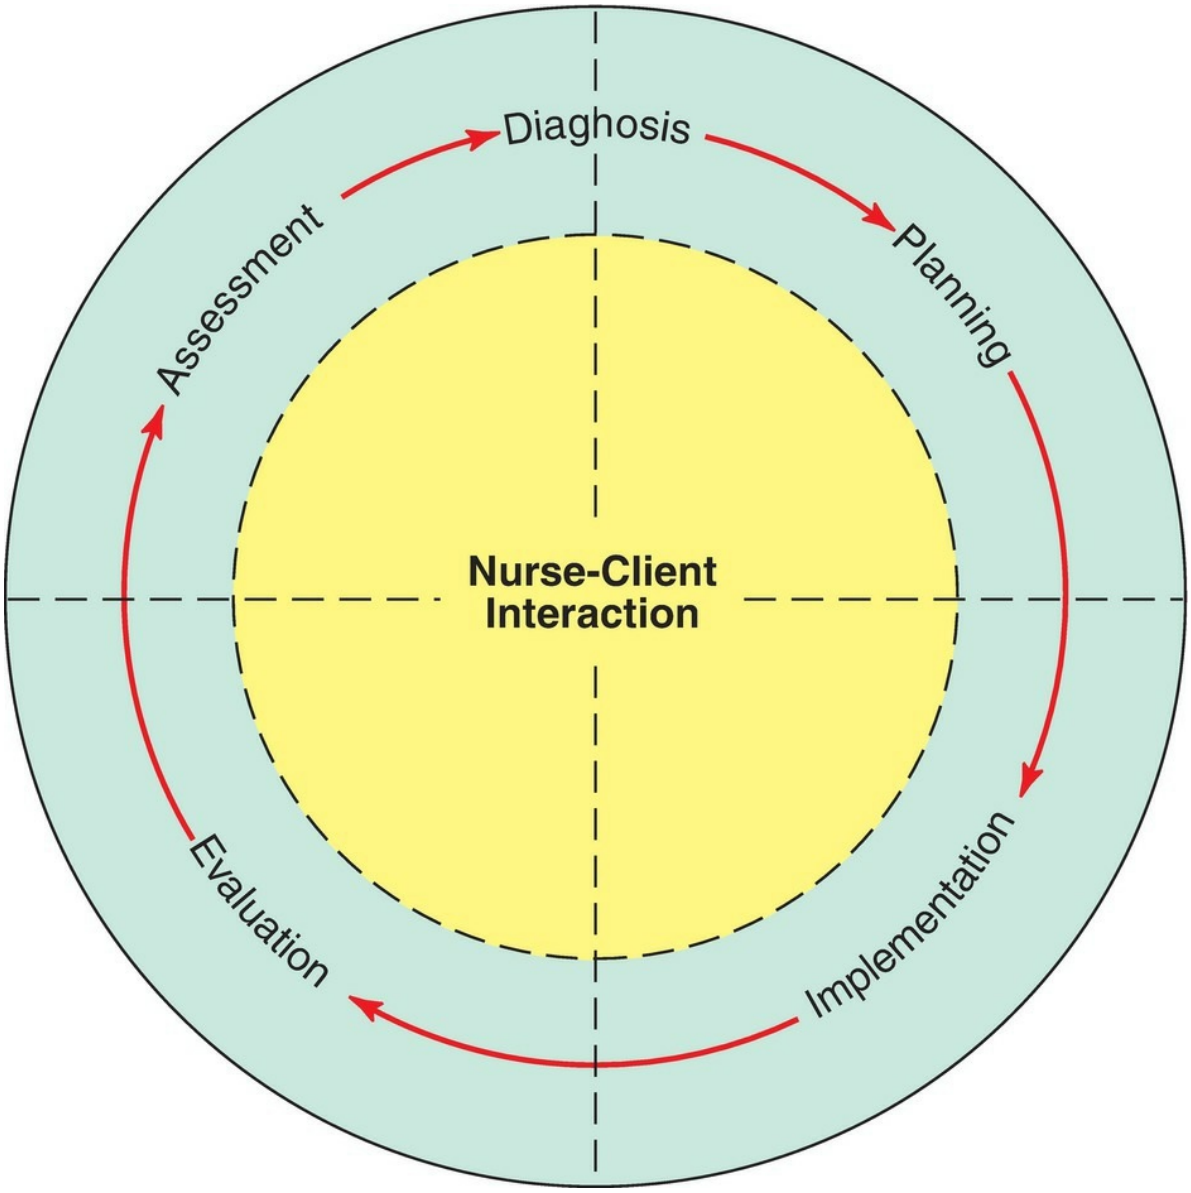

FIGURE 15–6 NURSING process components. Nurse–client interaction, a preamble structure, forms the core of the process. As a nurse and client maintain a reciprocal exchange of information and trust through interaction, they can effectively assess client needs, diagnose needs, and plan, implement, and evaluate care.

Need for Communication

When a community health nurse initially contacts a group of community leaders, for example, any information the nurse may have in advance can give only partial clues to that group's needs and wants. Unless everyone involved talks and listens, the steps of the nursing process will go awry (LeBan, 2011). PHNs can serve as effective liaisons—facilitating communication between stakeholders and clients to ensure that health needs both identified and adequately addressed (University of Michigan Center of Excellence in Public Health Workforce Studies, 2013).

Interaction and Effective Communication

Through open and honest sharing, the nurse (and others on the health team) will begin to develop trust and establish lines of effective communication. For instance, the nurse explains who he is and why he is there. The nurse encourages the group members to talk about themselves. Nurse and group members together discuss their relationship and clarify the desired nature of that alliance (Pavlish & Pharris, 2012). Does the group want help to identify and work on its health needs? Would its members like this nurse to continue regular contacts? What will their respective roles be? Effective communication, as a part of interaction, is essential to develop understanding and facilitate a free exchange of information between nurse and client.

Interaction is Reciprocal

Sharing of information, ideas, feelings, concerns, and self goes both ways. Nurses must avoid the temptation either to do all the talking or merely to listen while a few group members monopolize the conversation (Rost & Wilson, 2013). A dynamic exchange must exist between two systems. The community health nurse (and other collaborating health professionals) represents one system and the client group represents the other. Health care professionals tend to prioritize based on their own perspective and many times neglect to take the clients' wishes into account. Whether the client is a parent group, a homeless population, or an entire community, this exchange involves a two-way sharing between the nurse and client group. The key elements of interaction are mutuality and cooperation.

Consider the following example: Members of a disadvantaged community met for several weeks at a community center to discuss disease management, physical activity, and healthy diets. After their agreed-upon goals had been accomplished, the nurse wondered whether further meetings were needed. After several discussions, the residents verbalized concern about unsafe conditions within the neighborhood that limited physical activity of the residents and the lack of fresh food availability within the community. These external conditions would limit the residents' ability to adopt the healthy behaviors they had learned in the group. The nurse initially felt unprepared to address these issues, but after consulting with other support agencies within the community, she realized that resources were available and was able to work with community members and local agencies to develop a feasible physical activity plan for residents. Engagement with community members and communication were the first step in reapplying the nursing process and allowed goals for the group to be accomplished.

Interaction Paves the Way for a Helping Relationship

As nurse and client interact, each learns about the other. A test period occurs before trust can be fully established (Summach, 2011). For the female school nurse working with

middle school students about health education and human sexuality, establishing interaction was more difficult at the time of the initial contact with the boys than with the girls. They had been reluctant to talk and felt embarrassed to discuss personal subjects with an adult they did not know. Nonetheless, their interests in bodybuilding and personal appearance were strong enough to them to these optional sessions. Interaction began with a friendly exchange on nonthreatening topics and gradually deepened, as the boys seemed ready to discuss personal subjects. Eventually, it was relatively simple to talk about a new "problem" (and start the nursing process over again), because a helping relationship had already been developed. The nurse had a track record. The boys trusted, respected, and liked the nurse, so they were happy to interact around a newly stated need.

Aggregate Application

As noted in earlier chapters, community health practice focuses largely on the health of population groups; therefore, interaction goes beyond the one-on-one with individual patients. The challenge that the community health nurse faces is a one-to-aggregate approach. A group of parents concerned about teenage alcohol abuse, physically disabled people needing access ramps, and a neighborhood's older adult population frightened by muggings and thefts are all aggregates or clients with different concerns and opinions. As defined in Chapter 1, an aggregate refers to a mass or grouping of distinct individuals who are considered as a whole and who are loosely associated with one another. Each person in an aggregate is influenced by the thoughts and behavior of other group members. Nursing interaction with an aggregate client demands an understanding of group behavior, group dynamics, and group-level decision-making. It requires interpersonal communication skills applied at the group level. Interaction is more complex with an aggregate than with an individual, but it also can be challenging and rewarding. Once community health nurses acquire an understanding of aggregate behavior, they can capitalize on the potential of group influence to make a far-reaching impact on the health of the total community (see Perspectives for an example of a public health nurse partnering with law enforcement to provide preventive health care to gang youth). Chapter 10 more closely examines communication and interaction with groups.

Forming Partnerships and Building Coalitions

Another important consideration in community-level nursing practice requires teamwork. The job of planning for the health of an entire community or a community subsystem requires that the nurse collaborate with other professionals. Usually, the nurse is part of an organized team, separate from the agency that employs the nurse. The team is brought together with the goal of improving the health of the community. Each group member brings expertise and a particular view of the problem. These interprofessional work groups are often formed as either partnerships or coalitions (Wyer, Umscheid, Wright, Silva, & Lang, 2015).

Partnerships are agreements between people (and agencies) that support a joint purpose (Beal, 2012). A partnership can be large (e.g., a multinational corporation and several high schools; a city government and the county jail system), or it can be a more modest endeavor (e.g., a group of senior citizens and a preschool program; a Girl Scout troop and a community recycling program). Community-wide partnerships require more planning and coordination than do small partnerships. For example, because of increased student enrollment, a college may need two additional temporary and part-time faculty members who can teach the PHN course. The county public health department is interested in more new graduate nurses coming to work in the agency. The nursing program and the health department form a partnership and design a plan to solve both problems. The health department selects two staff nurses who have master's degrees and are qualified to teach undergraduate clinical courses in PHN one day a week for two semesters. The benefits for everyone are numerous. The nursing program solves a temporary staffing problem; the nurses from the health department share their expertise with students, enhancing their practice and the students' learning experience; and the health department successfully introduces a pool of students, who may be potential staff members, to the agency and the services that it provides for the community.

A coalition is an alliance of individuals or groups that work together to influence the outcomes of a specific problem (Clark et al., 2011; Trinh-Shevrin et al., 2011). Coalitions are an effective means to achieve a collaborative and coordinated approach to solving community problems (Anderson, Adeney, Shinn, Krause, & Safranek, 2012). Steps to coalition building include defining goals and objectives, conducting a community assessment, identifying key players or leaders, and identifying potential coalition members (CDC, 2015c). Once these steps have been accomplished, the leader needs to keep the coalition active. This is best done by knowing and staying in touch with the coalition members, running effective meetings, and keeping every participant involved. An example of a successful coalition is an Asian American hepatitis B program using CBPR as a means of community assessment and providing pooled resources for this community in New York City (Trinh-Shevrin et al., 2011).

Sound public health practice depends on pooling resources—including people—in

ways that will best serve the public. Whether health service is aimed at families, groups, subpopulations, populations, or communities, the consumers of that service are equally important members of the team. In planning for a community's health, the community (represented by appropriate individuals and agencies) must be involved. Community health nurses cannot lose sight of the need for client involvement at all levels and in all stages of community health practice (see Perspectives: Voices from the Community).

PERSPECTIVES
VOICES FROM THE COMMUNITY

Public Health Nurse

I am a public health nurse, married to a Los Angeles–area police officer. His job with a juvenile diversion program for 13- to 18-year-old offenders (gang youth or those at risk of gang involvement) includes organizing a semester-long course to build confidence and self-esteem, as well as physical training and education in a classroom setting. Various officers teach the course, and they invite guest speakers. I ended up being a guest speaker for three 3-hour sessions and loved it! In order to prepare, I examined statistics and other assessment information about gangs as an aggregate. I noted that they have been found to have higher drug and alcohol use, earlier sexual initiation, and unsafe sexual practices with attendant higher rates of STIs (sexually transmitted infections). Higher rates of mental disorders, drug-related crime, and violent victimization are also hallmarks of gang membership. Basically, they are more likely to engage in high-risk behaviors, and I wanted to try to reach this aggregate that often has little access to health care. I thought this was a great opportunity to reach a vulnerable population and generate a discussion with them on health-related issues. I wanted it to be interactive and used examples they could identify with; I also spoke with some of their slang terms. The first session addressed major causes of morbidity and mortality among their age group. I showed them a photograph of a car involved in a crash due to driver texting and discussed the dangers of racing cars, driving drunk, and driving while distracted (as this driver had done). I started a discussion with them about homicide statistics and asked how this has personally affected them. I also gave them information about suicide and hotline numbers.

At the second session, I wanted to focus on major health issues (e.g., obesity, drug use, mental and sexual health) and addressed each by highlighting the health consequences, behaviors that needed to change, and how they could prevent problems and access care when needed. We discussed obesity, and I brought examples of food nutrition labels, especially from fast food restaurants they frequented. They were amazed at the calories and fat levels, so we discussed healthier alternatives. At the last session, I focused on health promotion and risk prevention. I emphasized testicular and breast self-exams (yes, there were girls) and encouraged medical screening for STIs, with information on free clinics in their areas.

Although no formal evaluation of the program was done, I got great feedback from parents of the youth involved, who reported that their child's attitudes improved. Also, a good number of graduates of the program came back to work as student volunteers with subsequent cohorts. I felt a sense of accomplishment, having reached this difficult yet vulnerable population. I think that my openness and frankness in answering their questions and comfortable use of their slang terms developed rapport with them and permitted me to reach them with health information that they really needed to hear. I would encourage you to look for opportunities to do the same!

Alisha, BSN

Types of Community Needs Assessment

After considering the importance of community partnerships and coalitions, the community health nurse is ready to determine the community's health status, resources, and needs. Assessment is the key initial step of the nursing process. Assessment for nurses means collecting and evaluating information about a community's health status to discover existing or potential needs and assets as a basis for planning future action (Anderson & McFarlane, 2015). Assessments are also a critical requirement for public health department accreditation (Public Health Accreditation Board, 2013) and are now a requirement for nonprofit hospitals under the Affordable Care Act, or health care reform, a program supported by nurses (Rice et al., 2014; ANA, 2014).

Several models or frameworks can be used for assessment. Three such models are Mobilizing for Action through Planning and Partnerships (MAPP) and Protocol for Assessing Community Excellence in Environmental Health (PACE EH). These models have been developed through partnership with the Centers for Disease Control and Prevention (CDC) to improve community assessment in relation to Healthy People goals (CDC, 2015a). An earlier tool, the Planned Approach to Community Health (PATCH), was developed to assist communities in assessing health promotion and chronic disease prevention programs (NACCHO, 2012). The *Healthy People 2020* website also provides planning tools and toolkits to assist local communities (see Internet Resources on *thePoint*). These are all valuable resources that provide specific guidelines focusing on local-level strategies to improve the health of communities.

Assessment involves two major activities. The first is collection of pertinent data, and the second is analysis and interpretation of data. These actions overlap and are repeated constantly throughout the assessment phase of the nursing process. While assessing a community's ability to enhance its health, the nurse may simultaneously collect data on community lifestyle behaviors and interpret previously collected data on morbidity and mortality.

Community health assessment is the process of determining the real or perceived needs of a defined community. In some situations, an extensive community study may be the first priority; in others, all that is needed is a study of one system or even one organization. At other times, community health nurses may need to perform a cursory examination or windshield survey to familiarize themselves with an entire community without going into any depth (Anderson & McFarlane, 2015).

Familiarization or Windshield Survey

A familiarization assessment is a common starting place in evaluation of a community. Familiarization assessment involves studying data already available on a community and then gathering a certain amount of firsthand data in order to gain a working knowledge of the community. Such an approach may utilize a windshield survey—an activity often used

by nursing students in public health courses and by new staff members in community health agencies. Nurses drive (or walk) around the community of interest; find health, social, and governmental services; obtain literature; introduce themselves and explain that they are working in the area; and generally become familiar with the community and its residents. This type of assessment is needed whenever the community health nurse works with families, groups, organizations, or populations. The windshield survey provides knowledge of the context in which these aggregates live and may enable the nurse to better connect clients with community resources (Table 15–4). See an example in From the Case Files I.

Table 15–4 Community Familiarization (Windshield) Survey

This is often done to help you become familiar with a new community or public health service area. Walking/driving around neighborhoods and interacting with community members can provide a context for further community assessment. You might begin at the local Chamber of Commerce or government building to determine history, current statistics, and demographics and to access maps and further resources for data you might use for a more formal community health assessment.

Physical

- Look at the age and conditions of the buildings, the density (apartments, houses on large lots) and materials used (bricks, plywood), and the zoning and maintenance of yards/empty lots. What clues does that give you about the community as a whole?
- How similar are the houses (are some neighborhoods very rich, others very poor)? Are there abandoned vehicles, piles of excess trash, large numbers of stray animals/for sale signs, or vacant houses?
- Are there open spaces (parks, agricultural areas, public/private areas like golf courses) and are they being used; by whom?
- Are there boundaries separating the community (e.g., natural boundaries like rivers, economic boundaries, commercial/residential boundaries)?
- What about air/water quality, signs of pollution?

Economic

- Does the area look like it is a thriving community?
- Are there areas where homeless gather? Soup kitchens?
- Is there adequate shopping (e.g., grocery stores, shopping centers)?
- Does it appear that food stamps are accepted/welcomed?
- Are there businesses, industries, manufacturing, and adequate places for employment? What is the unemployment rate?

Services

- Are there schools (how many, in what condition)? School nurses? What are the main concerns or problems with the educational system here (e.g., dropout rates)?
- Are there libraries? Do they provide additional services (e.g., Internet)? Are they well used?
- Are there recreational facilities (e.g., gyms, playgrounds, soccer fields, baseball diamonds)? Are these being used and by whom?
- How many churches do you see? What denominations?
- Is there adequate health care? Does the community have a hospital? Are there adequate health care services (e.g., physicians, clinics, nurses, mental health/substance abuse facilities, PH department services, nursing homes, traditional health care providers)? Is it a medically underserved area or a health professions shortage area?
- What types of social services are available (e.g., welfare/social workers, shelters, mental health counseling)? Do you see one main location for social services (e.g., government center) or are they dispersed around the community?
- What types of public/private transportation are available? Are highways and roads crowded with traffic? Accident rate? Are there bike paths/trails and adequate sidewalks? How is transportation access for the disabled?
- Does the community "feel" safe to you? Is there adequate fire and police protection? What is the crime rate? What are the most common types of crimes?
- Are there signs of political activity (e.g., posters, notices of meetings, predominant party affiliations)? Do people feel that they can be involved in decisions made by their local government?

Social

- Are there common "hangouts" (e.g., teen gathering spots, chess playing for older adults)? What about local newspapers, radio, and TV (e.g., satellite dishes)?
- Who do you see on the streets? Are there indications of homogeneity or diversity of ethnicities, languages spoken, SES (socioeconomic status), and occupations? How are people dressed?
- How do people feel about living in this community? What problems or concerns do they express? What strengths do they note? How "healthy" is their community?
- What are your impressions of this community?

From the Case Files I

The Angelo Family and a Familiarization Assessment

A community health nurse named Jean visited the Angelo family on the outskirts of Philadelphia. During the initial visit, she gathered information, learning that the family was Italian American and that there were four children, ranging in age from 15 to 3. The father had been out of work for 6 months; the mother worked on weekends as a maid in a motel; the oldest boy had been in trouble with the juvenile authorities; the 13-year-old girl was deaf; and their house appeared rundown. Jean assessed this family, trying to determine its coping ability and its level of health. Furthermore, because community health nursing is population focused, her concern was not only for the Angelo family but also for the population of families with similar problems that this family represented.

However, the nurse's assessment was almost impossible without further knowledge of the community. Was theirs an Italian American neighborhood with specific cultural influences? What was the extent of unemployment in this city? What were the services for the deaf? Were all the houses in this part of town old and in need of repair? Once the nurse began working with the family, familiarity with the community became even more imperative. She discovered that, as a result of the Angelos' low income, family conflicts were intense. The family members seldom got out; they made almost no use of the community's recreational system. Before she could help them make use of it, however, the nurse had to find out what resources were available. As she familiarized herself with the community, she discovered Friends of the Deaf, which sponsored a group for parents of deaf children. The nurse could now help Mr. and Mrs. Angelo become part of that group. A quick survey of the religious system in the community revealed two job-transition support groups, one of which would welcome Mr. Angelo. In the meantime, the nurse chose to find out about the public assistance or welfare system and how this family and other similar families could benefit from its services. Even her own attitude changed as she studied the community. For instance, she discovered that a strike had closed down the plant where Mr. Angelo worked for 20 years and could view his and others' unemployment from a broader perspective. Using a familiarization assessment helped this nurse to enhance her practice.

Whatever role nurses play in community health promotion, they will want to be making a continuous study, an ongoing assessment. Whether nurses become client advocates, work with the local government, or operate from a nursing agency serving

the elderly, a familiarization assessment is prerequisite for their work.

Windshield surveys are a quick way to become familiar with a new community and its residents.

Problem-Oriented Assessment

A second type of community assessment, problem-oriented assessment, begins with a single problem and assesses the community in terms of that problem. Suppose that Jean, the nurse who explored services available for the Angelo family's deaf child in From the Case Files I, had discovered that there were none. Confronted with this problem—one family with one deaf child—she could make a problem-oriented community assessment. Her first step would be to discover the incidence of childhood deafness, both in the community and in the state. Second, she might begin interviewing officials in the schools and health institutions to find out what had been done in the past to assist deaf children. She could do an Internet search to locate available resources on the subject of deafness. Are there interpreters available for people who use sign language? How do hospitals and courts approach deafness? Are there any clubs or other organizations for deaf people? Are there school programs for the deaf, and if so, where are they located?

The problem-oriented assessment can be used when familiarization is not sufficient and a comprehensive assessment is not feasible. This type of assessment is responsive to a particular need and should also seek to describe contextual issues associated with the need. The data collected can support community efforts to address specific problems. Data should address the magnitude of the problem to be studied (e.g., prevalence, incidence), the precursors of the problem, and information about population characteristics (e.g., community resources, strengths, and weaknesses), along with the attitudes and behaviors of the population being studied (Kirst-Ashman, 2014).

Community Subsystem Assessment

In community subsystem assessment, the community health nurse focuses on a single dimension of community life. For example, the nurse might decide to survey churches and religious organizations to discover their roles in the community. What kinds of needs do the leaders in these organizations believe exist? What services do these organizations offer? To what extent are services coordinated within the religious system and between it and other systems in the community? For example, churches and other cultural leaders were instrumental in providing information to address a public health department's concerns. A small county health department worked with the nearby university PHN clinical instructor and her students to determine why two specific racial/ethnic groups were not using the health department's free women's health clinics. One group of students led by a Black student met with local pastors from several Black churches, and the other group, who was led by a Hmong student, met with Hmong leaders. Students attended the local Black churches on a particular Sunday and met with the congregation after the services to ask them about their knowledge and use of the health department's clinics. The students let

them know about the available health services and answered questions. The health department followed up with the pastors, and it was determined that most of the members of the congregations were unaware of the services provided through the county health department. PHNs and other staff made efforts to regularly meet with members of the congregations to encourage their attendance at various clinics. For the Hmong population, students met with a local clan leader and several members of the community to inquire about the lack of attendance at the women's clinic. They were told that, with the Hmong culture, husbands generally accompanied their wives when getting prenatal care or family planning services. Also, they felt more comfortable with Hmong health care personnel than those from outside their group, and there happened to be a Hmong physician available to them in a larger neighboring county. The health department staff later met with members of the Hmong community to discuss their concerns, and it was determined that this population felt more comfortable not using health department services for women's health but would participate in well-child and immunization clinics. Working with and through these subsystems facilitated this process.

Community subsystem assessment can be a useful way for a team to conduct a more thorough community assessment. If five members of a nursing agency divide up the ten systems in the community and each person does an assessment of two systems, they could then share their findings to create a more comprehensive picture of the community and its needs.

Comprehensive Assessment

Comprehensive assessment seeks to discover all relevant community health information. It begins with a review of existing studies and all the data presently available on the community. A survey compiles all the demographic information on the population, such as its size, density, and composition. Key informants are interviewed in every major system—education, health, religious, economic, and others. Key informants are experts in one particular area of the community or they may know the community as a whole. Examples of key informants would be a school nurse, a religious leader, key cultural leaders, the local police chief or fire captain, a mail carrier, or a local city council person. Then, more detailed surveys and intensive interviews are performed to yield information on organizations and the various roles in each organization. A comprehensive assessment describes the systems of a community and also how power is distributed throughout the system, how decisions are made, and how change occurs (Anderson & McFarlane, 2015; LeBan, 2011).

Because comprehensive assessment is an expensive, time-consuming process, it is not often undertaken. Performing a more focused study, based on prior knowledge of needs, is often a better and less costly strategy. Nevertheless, knowing how to conduct a comprehensive assessment is an important skill when designing smaller, more focused assessments (see Perspectives: Public Health Nursing Instructor).

PERSPECTIVES
PUBLIC HEALTH NURSING INSTRUCTOR

I have worked for many years in community and public health settings. I had been teaching community health nursing at a state university for 5 or 6 years when I decided to break from the "usual procedure" of having students do a comprehensive type of community assessment (all subsystems, vital statistics, etc.). This information did not change dramatically from the previous semester or the prior 2 to 3 years for that matter. Students hate busy work and I do, too! They had complained to instructors about this repetitive assignment (a classic learning activity in PHN coursework) for many years, and some were tempted to just repackage previous groups' assessments. I felt it would be more meaningful, but still have a population focus, if we could actually gather data and information for the small country health department where we were assigned. I asked several department heads to come up with ideas of aggregate or population assessment data that they needed (often related to grants they were writing or state-directed program evaluations). Several of them "pitched" these ideas and projects to our student group. The students then voted on the one they found most interesting or viable, and we set about creating our own community assessment template, usually drawing from standardized assessment tools. Each semester was different, depending upon the need. They would gather data, analyze it, and present it to the department head. From that assessment, they would create a project (often an educational intervention) that could be completed and evaluated within their time frame. They were excited to gather this information; it was like a bunch of detectives chasing down leads! They problem-solved and worked together to achieve their goals. They worked with other agencies and NGOs; they spoke with local health care providers and members of the community. Once, the program director for a teen pregnancy program asked them to help with getting questionnaires distributed to local teens to gather information on sexual activity and attitudes. At that time, the county had the highest rate of teen

pregnancies in the state, and one of the large universities in a metropolitan area was developing a survey to gather data on teen pregnancy and sexual activity in the state. This was a conservative county, and many parents opposed *Sex Ed*. However, students were able to gather information and statistics on teen pregnancies in this county and compared it with state and national data. They investigated best practices for teen pregnancy prevention programs. Forming into smaller work groups, some met with school officials, high school students, teachers, and parents in order to educate them about this project. Others worked with the program director and local school nurses and counselors. They were able to convince one school superintendent to distribute this survey to high school students in his district. The nursing students strategized about the best methods for distributing and collecting the surveys. The day came for the survey, and it was a rousing success, with no major roadblocks. They felt that their community assessment and project were worthwhile and very meaningful to this community. The health department and the university heartily agreed! I never went back to the "usual procedure," and I always encourage other instructors to try this approach.

Debbie, PHN Instructor

Community Assets Assessment

The final form of assessment presented here is assets assessment, also known as asset mapping. This method of assessment focuses on the strengths and capacities of a community rather than its problems (Jakes, Hardison-Moody, Bowen, & Blevins, 2015) and evaluates variables such as the needs that exist, the goals to be achieved, and the resources available for carrying out the study. Although it is difficult to determine the type of assessment needed in advance, understanding the various types of community assessment in advance helps to facilitate your decision. Based on a classic model developed by McKnight and Kretzmann in the 1980s (Kretzman & McKnight, 1993), the assets assessment provides a framework for conducting a complete functional community assessment and serves as a guide to the community for the nurse, as well as the foundation for community development. The previously mentioned methods are needs oriented and deficit based—in other words, they are *pathology* models, in which the assessment is performed in response to needs, barriers, weaknesses, problems, or perceived scarcity in the community. This may result in a fragmented approach to solutions for the community's problems rather than an approach focused on the community's possibilities, strengths, and assets. The assets assessment also provides the community the ability to "identify a variety and richness of skills, talents, knowledge, and experience of people" and "provides a base upon which to build new approaches and enterprises" (p. 4).

Assets assessment begins with what is present in the community (Jakes et al., 2015). The capacities and skills of community members are identified, with a focus on creating or rebuilding relationships among local residents, associations, and institutions to multiply

power and effectiveness. This approach requires that the assessor look for the positive or see the glass as half full. The nurse can then become a partner in community intervention efforts, rather than merely a provider of services. Assets assessment includes three levels (Kramer, Seedat, Lazarus, & Suffla, 2011):

1. Specific skills, talents, interests, and experiences of individual community members such as individual businesses, cultural groups, and professionals living in the community.
2. Local citizen associations, organizations, and institutions controlled largely by the community such as libraries, social service agencies, voluntary agencies, schools, and police.
3. Local institutions originating outside the community controlled largely outside the community such as welfare and public capital expenditures (p. 14).

The key, however, is linking these assets together to enhance the community from within. The community health nurse's role is to assist with those linkages.

COMMUNITY ASSESSMENT METHODS

The health status of the community may be assessed using a variety of methods. Regardless of the assessment method used, data must be collected. Data collection in community health requires the exercise of sound professional judgment, effective communication techniques, and special investigative skills. Four important methods are discussed here: surveys, descriptive epidemiologic studies, community forums or town meetings, and focus groups.

Surveys

A survey is an assessment method in which a series of questions is used to collect data for analysis of a specific group or area. Surveys are commonly used to provide a broad range of data that will be helpful when used with other sources or if other sources are not available. To plan and conduct community health surveys, the goal should be to determine the variables (selected environmental, socioeconomic, and behavioral conditions or needs) that affect a community's ability to control disease and promote wellness. The nurse may choose to conduct a survey to determine such things as health care use patterns and needs, immunization levels, demographic characteristics, or health beliefs and practices. The survey method involves self-report, or response to predetermined questions, and can include questionnaires, telephone, or in person interviews (Polit & Beck, 2014). Survey findings can be combined with other health data in order to better understand the health status of the community and the determinants of health. These data include reports of health risks and outcomes by zip code (Agarwal, Menon, & Jaber, 2015; Wang, Ponce, Wang, Opsomer, & Yu, 2015) and CDC Environmental Health Tracking Network reports of local environmental health exposures (Charleston, Wilson, Edwards, David, & Dewitt, 2015). Consideration of these data along with survey results allows for a more comprehensive understanding of the communities health status and the conditions impacting health.

Descriptive Epidemiologic Studies

A second assessment method is a descriptive epidemiologic study, which examines the amount and distribution of a disease or health condition in a population by person (Who is affected?), by place (Where does the condition occur?), and by time (When do the cases occur?). In addition to their value in assessing the health status of a population, descriptive epidemiologic studies are useful for suggesting which individuals are at greatest risk and where and when the condition might occur. They have also long been known to be useful for health planning purposes and for suggesting hypotheses concerning disease etiology (Merrill, 2013). Their design and use are detailed in Chapter 7.

Geographic Information System Analysis

In Chapter 10, the concept of GIS was introduced as a health information technology. GIS technology is an integration of research methods and analytic techniques from both medical geography and spatial epidemiology. It has been well documented as a tool that can collect, organize, and display public health data (Graham, Carlton, Gaede, & Jamison, 2011), and it is widely used in assessment and research of health disparities, resources availability, and health-related behaviors (Auchincloss, Gebreab, Mair, & Roux, 2012).

Harvard's T.H. Chan School of Public Health offers a Web site designated to the use of GIS in public health, including particular research studies. For instance, one line of research examines effects of air pollution on MI rates within the community of Worchester and spatial mapping of incidence and levels of pollution. Researchers are also working on developing a predictive model for pollution's effect on death rates in Eastern Massachusetts. A prospective study of normative aging began with data collected from healthy cohort of 2,500 individuals in the 1970s; and GIS data on exposure is used to estimate cumulative exposure to pollution and its association with COPD, MI, and death (Harvard University, 2013). Earlier research has been useful in identifying air pollutant risk exposure (Hammond et al., 2011), and another common use of GIS is in planning for disaster response and support (Kawasaki, Berman & Guan, 2013; Wheeler & Basch, 2014).

FIGURE 15–7 A town hall meeting in Vermont.

Community Forums and Social Media

The community forum or town hall meeting is a qualitative assessment method designed to obtain community opinions (Fig. 15–7). It takes place in the neighborhood of the people involved, perhaps in a school gymnasium or an auditorium. The participants are selected to participate by invitation from the group organizing the forum. Members come from within the community and represent all segments of the community that are involved with the issue. For instance, if a community is contemplating building a swimming pool, the people invited to the community forum might include potential users of the pool (residents of the community who do not have pools and special groups such as the Girl Scouts, elders, and disabled citizens), community planners, health and safety personnel, and other key people with vested interests. They are asked to give their views on the pool: Where should it be located? Who will use it? How will the cost of building and maintaining it be assumed? What are the drawbacks to having the pool? Any other pertinent issues the participants may raise are included. This method is relatively inexpensive, and results are quickly obtained. A drawback of this method is that only the most vocal community members, or those with the greatest vested interests in the issue, may be heard. This format does not provide a representative voice to others in the community who also may be affected by the proposed decision.

This method is used to elicit public opinion on a variety of issues, including health care concerns, political views, and feelings about issues in the public eye, such as school safety. Frequently, local cable television channels air important city government or school board meetings. Local news programs may hold town meetings, soliciting public opinion on regional issues. Other methods of opinion gathering include e-mailing (e.g., to a television news program) to support a particular view, Web-based survey sites (e.g., Survey Monkey), and using a toll-free phone number set up especially for text messaging a Yes or No vote on an issue.

Social media sites, like Facebook and Twitter, are also popular forums for opinion sharing. Digital media is often used to elicit grassroots opinions from local community members and has been utilized by many entities to enable political organization, including those in favor of health care reform and other social and political agendas (Howard & Parks, 2012; Gil de Zúñiga, Jung, & Valenzuela, 2012). See more ideas on the use of social media in Chapter 10.

Focus Groups

This fourth assessment method, focus groups, is similar to the community forum or town hall meeting in that it is designed to obtain grassroots opinion. However, it has some differences. First, only a small group of participants, usually 5 to 15 people, is present (Polit & Beck, 2014). The members chosen for the group are homogeneous with respect to specific demographic variables. For example, a focus group may consist of female community health nurses, young women in their first pregnancy, or retired businessmen. Leadership and facilitation skills are used in conjunction with the small group process to promote a supportive atmosphere and to accomplish set goals. The interviewer guides the discussion according to a predetermined set of questions or topics. The best use of focus group data includes not only an analysis of verbal messages but also behavioral data such as facial expressions (Stewart & Shamdasani, 2014). Major advantages of focus groups are their efficiency and low cost, similar to the community forum or town hall meeting format. A focus group can be organized to be representative of an aggregate, to capture community interest groups, or to sample for diversity among different population groups. One example is a research study involving adult e-cigarette users. Eleven focus groups were held to determine perceptions of e-cigarette efficacy in smoking cessation (Barbeau, Burda, & Siegel, 2013). Whatever the purpose, however, some people may be uncomfortable expressing their views in a group situation (Polit & Beck, 2014).

The choice of assessment method varies depending on the reasons for data collection, the goals and objectives of the study, and the available resources. It also varies according to the theoretical framework or philosophical approach through which the nurse views the community. In other words, the community health nurse's theoretical basis for approaching community assessment influences the purposes for conducting the assessment and the selection of methodology. For example, Neuman's health care systems model forms the basis for the "community-as-partner" assessment model developed by Anderson and McFarlane (2015). Additional resources on methodologies for assessing community health (e.g., list of Internet resources, selected readings) are available on *thePoint*.

SOURCES OF COMMUNITY DATA

The community health nurse can look in many places for data to enhance and complete a community assessment. Data sources can be primary or secondary, and they can be from international, national, state, or local sources. Websites for many primary and secondary data sources are included in Internet resources on *thePoint*.

Primary and Secondary Sources

Community health nurses make use of many sources in data collection. Community members, including formal leaders, informal leaders, and community members, can frequently offer the most accurate insights and comprehensive information. Information gathered by talking to people provides primary data, because the data are obtained directly from the community. Secondary sources of data include people who know the community well and the records such people create in the performance of their jobs. Specific examples are health team members, client records, community health (vital) statistics, census bureau data, reference books, research reports, HEDIS measures, and community health nurses. Because secondary data may not totally describe the community and do not necessarily reflect community self-perceptions, they may need augmentation or further validation through focus groups, surveys, and other primary data collection methods.

International Sources

International data are collected by several agencies, including the World Health Organization (WHO) and its six regional offices and health organizations, such as the Pan-American Health Organization. The WHO publishes an annual report of their activity, and international statistics for diseases and illness trends can be found on the Internet (WHO, 2015). The WHO also publishes health statistics by country and information about specific diseases and health measures in their annual Global Health Observatory. This report tracks progress toward Millennium Health Goals that include poverty reduction, education improvements, and increased access to safe drinking water (WHO, 2014). Information from these official sources can give the nurse in the local community information about immigrant and refugee populations he serves. More information on international health agencies can be found in Chapter 16.

National Sources

Community health nurses can access a wealth of official and nonofficial sources of national data (see Chapter 6 for more information). Official sources develop documents based on data compiled by the government. The following are the major official agencies:

- USDHHS. This is the main agency from which data can be retrieved, and the National Center for Health Statistics (NCHS) at the Centers for Disease Control and Prevention (CDC) was specifically established under its auspices for the collection and dissemination of health-related data. This agency is the nation's principal health statistics agency, compiling data from many sources. These data provide information for many functions, including health status for various populations and subgroups, identification of disparities, monitoring trends, identifying health problems, and supporting research.
    - USDHHS also developed *Healthy People 2020* (USDHHS, 2016), designed to focus America's attention on the major national health problems, including realistic goals for national, state, and local agencies to work toward over one decade. Data from *Healthy People 2010* is available for analysis. Other data sources available through the CDC include Health Indicators Warehouse, Health Data Interactive, Surveillance Resource Center, Community Health Status Indicators, and VitalStats (CDC, 2015b).
- U.S. Census Bureau. This agency undertakes a major survey of American families every 10 years, gathering data on health, socioeconomic, and environmental conditions. This information is available on the Web or on a CD-ROM, allowing numerous variables to be viewed in combination, for easier development of a community profile (U.S. Census Bureau, n.d.).
- National Institutes of Health (NIH). This system of 27 institutes and centers, a part of the USDHHS, focuses on improving the health of the nation. An emphasis is placed on discovery of new cures or treatments and preventing disease. Employees of these agencies prevent, diagnose, and treat diseases and conduct research and disseminate research findings (NIH, 2015).

Nonofficial agencies have data sources generated from research they conduct that focuses on the population, disease, or condition they were developed to serve. Each agency collects data at the national level; however, the more accessible arm for services functions at state, county, and local levels. Examples of these agencies are the American Cancer Society (ACS), American Heart Association (AHA), the American Association of Retired Persons (AARP), Mothers Against Drunk Drivers (MADD), and Students Against Drunk Drivers (SADD). The Public Health Foundation (n.d.) offers information on many areas of interest to PHNs: teams toolbox, critical thinking tools, population heath driver diagrams, and other quality improvement tools for public health. The Kaiser Family Foundation and the RAND Corporation have a variety of fact sheets and compilations of data from various

sources. The Gallup Poll provides national survey information on various topics, including health. Information from such national sources allows community health assessment teams to compare local data with national and state statistics and trends—a very valuable function. The Robert Wood Johnson Foundation's (2015) County Health Rankings and Roadmaps is based on a model of population health that emphasizes the many factors that, if improved, can help make communities healthier places to live, learn, work, and play. Proprietary data sources include the American Hospital Association, the American Medical Association, or various health insurance companies. See Chapter 6 for a list of data collection systems.

State and Local Sources

For nurses, the most significant state source of assessment data comes from the state health department. This official agency is responsible for collecting state vital statistics and morbidity data. The Behavioral Health Surveillance System (BRFSS) is the world's largest telephone health survey that monitors health risk at the state level (CDC, 2012). Supported by the CDC, the information is used at various levels to identify risk and prevent disease. As a resource to local health departments, the state health department provides invaluable support services, and it is the main source of health-related data on the state level. Nonofficial agencies have state chapters or headquarters and compile their information at the state level. Local nonofficial agency chapters have documents of compiled state and national data on the population, disease, or condition they address.

State and county budgets or public health agency Web sites may also provide helpful information. All states collect vital statistics (e.g., births, deaths), and many collect information on hospitalization and morbidities related to infectious diseases, cancer, or cardiovascular disease. State departments of education may have school-based data on immunizations and overall school health. Information on traffic accidents, mental health, and environmental hazards are often available at the state level. States may also organize their statistics by county level, making it easier to compare your county's data with others.

Many sources of information may be obtained at the local level. Some key sources are the local visitor's bureau, city chamber of commerce, city planner's office, health department, hospitals, social service agencies, county extension office, school districts, universities or colleges, libraries, clergy, business and service organizations, and community leaders and key informants. Some of these sources compile their own statistics, but all have views of the community particular to their discipline, interest, or knowledge base. Some agencies at the local level develop city or county directories. These are updated periodically and are valuable resources for community health assessment teams and community health nurses. More detailed information on national, state, and local health agencies, and information available from them, can be found in Chapter 6.

Data Analysis and Diagnosis

This stage of assessment requires analysis of the information gathered, so that inferences or conclusions may be made about its meaning. Such inferences must be validated to determine their accuracy, after which a nursing diagnosis can be formed.

The Analysis Process

First, the data must be validated: Are they accurate, complete, representative of the population, and current? Several validation procedures may be used (Northwest Center for Public Health Practice, n.d.):

- Data can be rechecked by the community assessment team.
- Data can be rechecked by others.
- Subjective and objective data can be compared.
- Community members can consider the findings and verify them.

Validated data are then separated into categories such as physical, social, and environmental data. In many instances, data spreadsheets are used to provide a structure for data organization. Next, each category is examined to determine its significance. At this point, there may be a need to search for additional information to clarify the meaning of the data. Only then can inferences be made and a tentative conclusion about the meaning of the data be reached (Anderson & McFarlane, 2015).

Some computer programs are designed to analyze community assessment data. For large, complex, or ongoing community assessment plans, this may be the best method. For smaller, one-time assessments, the paper-and-pencil method may be sufficient and less unwieldy. Some communities may hire an outside professional assessment service. These teams often use the latest technology when analyzing data. Not all communities can afford such a service, and if key leaders become familiar with assessment, analysis, and diagnostic processes, an investment in a computer program may be worthwhile. GIS technology, as noted earlier, is proving very useful in community assessment. These tools are becoming more user friendly and cost-effective and have been used to pinpoint incidences of various diseases, display environmental risks, note the location of health care facilities, and determine accurate community boundaries (Auchincloss et al., 2012; McEntee & Agyeman, 2010). Regardless of the analysis method used, data interpretation remains a critical phase of the process.

In data interpretation, the ever-present danger exists of making inaccurate assumptions and diagnoses. The importance of validation cannot be overemphasized. Before making a diagnosis, all assumptions must be validated: Are they sound? Community members should participate actively in validation efforts by clarifying perceptions, explaining the circumstances surrounding the situation, and acting as sounding boards for testing assumptions. Other resources, such as the health team members and community leaders, are used to explore and confirm inferences. Data collection, data interpretation, and nursing diagnosis are sequential activities, with validation serving as the bridges between them (Fig. 15–8). When performed thoroughly, these steps lead to accurate diagnoses.

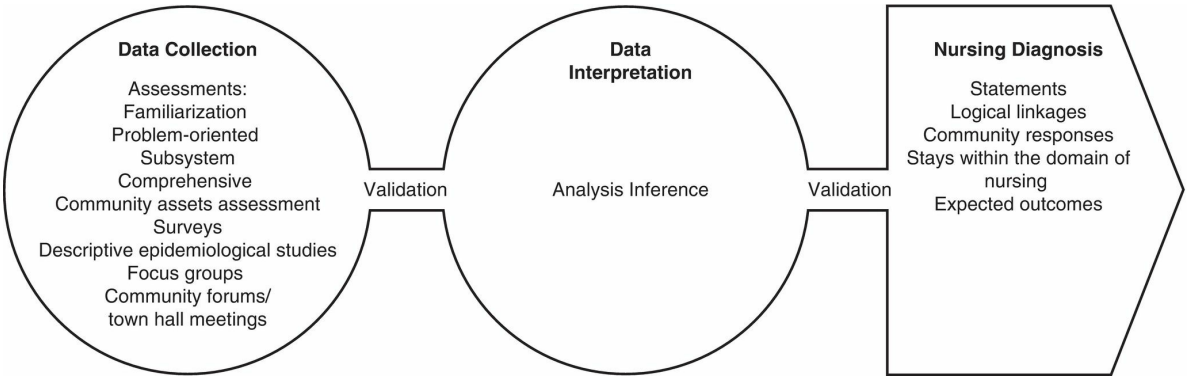

FIGURE 15–8 Assessment and Diagnosis Phases of the Nursing Process. Interpretation of data leads to diagnosis of a community's needs, the community responses, and expected outcomes.

Community Diagnosis Formation

The next step of the nursing process, after analysis, is the development of the community diagnosis. Community diagnoses stems from analysis of assessment data. The diagnosis "describes a situation" and "implies a reason" or etiology focusing on a specific community (Anderson & McFarlane, 2015). Various taxonomies and classification systems are used in nursing to describe specific nursing problems, and each one has its limitations when dealing with community-level diagnoses. The North American Nursing Diagnosis Association (NANDA) is much more oriented to nursing diagnoses of individuals and families than to community-level problems. Nursing Outcomes Classification (NOC) is also generally individual oriented. The Omaha System, originally designed by the Omaha Visiting Nurse Association, is again primarily used in nursing diagnoses of individuals, families, and small groups, and some community health applications have been developed (Omaha System, 2015).

This chapter discusses nursing diagnosis as characterized by Neufeld and Harrison (1996), based on the classic work of Mundinger and Jauron (1975). These authors proposed the use of nursing diagnoses in the community by substituting the term *client, family, group*, or *aggregate* for the word *patient*. Their definition of a nursing diagnosis is (Neufeld & Harrison, 1996, p. 221)

The statement of a [client's] response which is actually or potentially unhealthful and which nursing intervention can help to change in the direction of health. It should also identify essential factors related to the unhealthful response.

Neufeld and Harrison (1996, p. 221) built on this work to form a wellness diagnosis by using the phrase *healthful response* instead of *unhealthful response*. Their definition of a wellness diagnosis is

> …the statement of a client's [or community's] healthful response which nursing intervention can support or strengthen. It should also identify the essential factors related to the healthful response.

In 1996, Stolte developed a manual dedicated solely to nursing wellness diagnosis. Carpenito (2012) incorporated both community diagnosis and wellness diagnosis into her well-known handbook on applying nursing diagnosis to clinical practice. By substituting the term *community* for client, family, group, or aggregate, the nursing or wellness diagnosis can be applied to the community as a whole. These diagnoses identify the conclusion the nurse draws from interpretation of collected data and describe a community's healthy or unhealthy responses that can be influenced or changed by nursing interventions. Change comes about through collaboration with other community and health team members.

In community health, nurses do not limit their focus to problems; they consider the community as a total system and look for evidence of all kinds of responses that may influence the community's level of wellness (as shown in Fig. 15–6). Responses encompass the whole health–illness continuum, from specific deficits, such as a lack of senior centers

or day care programs, to opportunities for maximizing a community's health, such as promoting farmer's markets for better access to fresh fruits and vegetables or improving the safety of the roadways. The statement of community response—the diagnosis—can focus on a wide range of topics.

Community Diagnoses

Data have been gathered from a variety of sources and have been validated by several means. The data have been recorded, tabulated, analyzed, and synthesized, so that patterns and trends can be seen. The use of charts, graphs, and tables assists in visualizing the synthesized data. The community assessment team should present their findings to peers and colleagues and use their expertise to assist in the formulation of the community diagnoses. Inferences are drawn from the data, and these statements refer to *actual* or *potential* problems. Additional statements involve *etiology*, by stating that this condition is *related to* certain conditions or problems. There may be a number of these statements, involving several subsystems, for every one diagnosis. Signs and symptoms of the diagnosis relate to the *magnitude* or *duration* of the problem, usually documented "as manifested by" (Anderson & McFarlane, 2015).

Continuing with the nursing process format, nursing diagnoses for the community are developed. Community diagnoses refer to nursing diagnoses about a community's ineffective coping ability and potential for enhanced coping. The statements about the community should include the strengths of the community and possible sources for community solutions, as well as the community's weaknesses or problem areas. Using the standard nursing diagnosis format, community-level diagnoses can be developed (Carpenito, 2012). These diagnoses are used as tools as the community begins to plan, intervene, and evaluate outcomes. Diagnostic categories for individuals (e.g., knowledge deficit of senior services, high risk for injury or falls) can often be applied at the community level. Community-level nursing diagnoses should portray a community focus, include the community response, and identify any related factors that have potential for change through community health nursing. These may also include wellness diagnoses, which indicate maintenance or potential change responses (due to growth and development), when no deficit is present. Community nursing diagnoses must also include statements that are narrow enough to guide interventions, have logical linkages between community responses and related factors, and include factors within the domain of community health nursing intervention.

Examples of wellness and deficit community nursing diagnoses and several diagnoses for a specific community follow:

1. *Wellness nursing diagnosis for an assisted living community of elders*. The senior residents of an assisted living center (*community focus*) have the potential for achieving optimal functioning related to (*host factors*) their expressed interest in exercise, diet, and meaningful activities and to (*environmental factors*) their access to exercise opportunities, nutritional information, and social outlets.
2. *Deficit community nursing diagnosis for a rural farmworker community*. The inhabitants of (*name of the town*) in (*name of the state*) are at risk for illness and injury related to (*host factors*) exposure to pesticides, lack of motivation to add or use safety devices on

farm machinery, lack of safety knowledge, choice to take unnecessary risks (*environmental factors*), lack of family income to purchase newer equipment, and long hours of work that lead to stress and exhaustion.

3. *Community diagnoses for Anytown, Kansas*. Anytown, Kansas, is experiencing an increase in crime, a problem compounded by the small size of the police force and an influx of many new community members. The community has worked together constructively in the past, communicates well, and has strong recreational outlets for community members. The community:

- Has expressed vulnerability and feels overwhelmed related to threats to community safety
- Has failed to meet its own expectations related to inadequate law enforcement services
- Has expressed difficulty in meeting the demands of change related to an influx of new community members
- Has a successful history of coping with a previous crisis of teenage pregnancy
- Has positive communication among community members
- Has a well-developed program for recreation and relaxation

Such diagnoses can guide communities toward maximizing or improving their health as they plan, implement, and evaluate changes to be measured by established outcome criteria. Broad goals can form the basis for planning interventions. From these goals, more specific activities, interventions, and targeted programs can be designed. Measurable objectives can be written and evaluated (Anderson & McFarlane, 2015; Issel, 2014). Outcome criteria are measurable standards that community members use to measure success as they work toward improving the health of their community. Outcome-based or evidence-based nursing practice applies to aggregates in the community as well as to patients in acute care settings.

Nursing diagnoses change over time because they reflect changes in the health status of the community; therefore, diagnoses need to be periodically reevaluated and redefined. The changing diagnosis can be a useful means of moving a community toward improved health because it gives community members a clear standard against which to measure progress.

PLANNING TO MEET THE HEALTH NEEDS OF THE COMMUNITY

Planning is the logical decision-making process used to design an orderly, detailed series of actions for accomplishing specific goals and objectives. Planning for community health is based on assessment of the community and the nursing diagnoses formulated, but assessment and diagnosis alone do not prescribe the specific actions necessary to meet clients' needs (Anderson & McFarlane, 2015; Minnesota Department of Health, n.d.a). Knowing that a group of mothers at the well-child clinic need emotional support does not tell the nurse what further action is indicated. A diagnosis of culture shock (adjustment deficit to a contrasting culture) for a family newly arrived from Cuba does not reveal what action to take. The nurse must systematically develop an appropriate plan (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

The Problem of Child Abuse

SITUATION: Desire to reduce the incidence of child abuse in a given community by 50% within 2 years.

GOAL: Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and the fullest possible potential is restored.

TERTIARY PREVENTION		
Rehabilitation	**Primary Prevention**	
	Health Promotion and Education	*Health Protection*
• Establish rehabilitation programs for abused children, including safe home placement, physical and emotional treatment, and self-esteem building • Rebuild the family unit if appropriate or possible	• Provide family life education programs for families • Develop resources to support health promotion programs	• If unable or inappropriate to rehabilitate the abuser or family, keep abuser away from victim through incarceration or court order

SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
• Develop early detection programs through schools, clinics, and physicians' offices • Promote enforcement of child protection laws	• Establish programs to provide prompt treatment for abused children and abusing parents

PRIMARY PREVENTION	
Health Promotion and Education	**Health Protection**
• Assess factors contributing to child abuse • Institute family life education programs through schools and community groups • Develop community resources to support health protection programs	• Identify families in the community who are at greatest risk (e.g., parents with history of child abuse, families under great stress) • Develop community resources to support health promotion programs

Tools to Assist with Planning

A wide variety of tools are available to enhance community health improvement planning; these include activity descriptions, templates, and models (Minnesota Department of Health, n.d.a; NACCHO, 2015). Such tools help prioritize health issues, develop goals and objectives, specify interventions, and anticipate client outcomes. Tools that assist with planning also enable the nurse to test ideas and adjust solutions before actual implementation. Finally, the use of standardized tools enhances the planning process and promotes effectiveness of services, as well as professional standards of practice.

In addition to using tools, a systematic approach guides the community health nurse in the development of a feasible plan that adequately and appropriately addresses the needs of the community (Anderson & McFarlane, 2015). As they do in the rest of the nursing process, community health nurses collaborate with clients and other appropriate professionals throughout each of these planning activities.

The Health Planning Process

The health planning process is a four-stage system used to design new health-related programs or services in the community. The process is often used by health educators when designing educational programs or by administrators in community health agencies when initiating new services. The nursing process is similar to the health planning process (Table 15–5). Each model helps to promote service effectiveness in addition to maintaining standards of practice. Community health nurses familiar with both the health planning process and the nursing process should be able to work collaboratively with community health professionals using either model.

Table 15–5 Comparison Between the Health Planning Process and the Nursing Process

Health Planning Process	Nursing Process
1. ASSESSMENT STAGE Determine data needed and collect data. Interpret data and identity needs. Set goals based on needs.	**1. ASSESSMENT** Determine data needed and collect data. Interpret data and identity needs. Set goals based on needs.
2. ANALYSIS AND DESIGN Analyze findings and set specific objectives. Design alternative interventions. Analyze and compare pros and cons of various solutions.	**2. DIAGNOSIS** Analyze findings and set specific objectives. Design alternative interventions. Analyze and compare pros and cons of various solutions. Formulate nursing diagnoses.
Create a plan.	**3. PLANNING** List needs in order of priority. Establish goals and objectives. Write an action plan.
3. IMPLEMENTATION STAGE Describe how to operationalize the plan. Design a method for monitoring progress.	**4. IMPLEMENTATION** Describe how to operationalize the plan. Design a method for monitoring progress.
4. EVALUATION STAGE Examine costs and benefits of proposed solution. Judge the potential outputs, outcomes, and impact of plan. Modify to achieve the best plan. Present plan to sponsoring group or agency. Obtain acceptance (and funding).	**5. EVALUATION** Examine costs and benefits of proposed solution. Judge the potential outputs, outcomes, and impact of plan. Modify to achieve the best plan. Present plan to sponsoring group or agency. Obtain acceptance (and funding).

Setting Priorities

Priority setting involves assigning rank or importance to the identified needs to determine the order in which goals should be addressed. There are numerous ways to set priorities in the planning process. Many have identified useful criteria that can guide ranking problems for order of action (CDC, n.d.; Issel, 2014; McGregor, Henderson, & Kaldor, 2014; National Association of County & City Health Officials, n.d.; Office of the Assistant Secretary for Planning and Evaluation, n.d.; Public Health Institute, 2012). They are presented here as a combination of criteria:

1. Significance of the problem or the number of people affected in the community
2. Level of community awareness of the problem
3. Community motivation to act on the problem (or, Is this important to the community?)
4. Nurse and partnership's ability to reduce risk and/or influence the solution
5. Cost of risk reduction in terms of financial, social, and ethical capital
6. Ability to identify a specific target population for an intervention
7. Availability of expertise to solve the problem within the partnership, coalition, or community
8. Severity of the outcome if left unresolved or the consequences of inaction
9. Speed with which the problem can be resolved

A common test for priority setting is called PEARL, an acronym for "propriety, economics, acceptability, resources, and legality" (Public Health Institute, 2012, p. 50). A priority matrix may also be developed, but decisions must not be unilateral and should include input from all stakeholders, including community members. For example, a community assessment revealed that a group of elderly residents living within a specific zip code were fearful of crime, but also identified the lack of public transportation as issues to be addressed. Using the above criteria, the community health nurse working in this community identified that 85% of residents of the community had fears about crime but did not see transportation as an issue. The residents saw crime as an important concern and were also motivated to act on the crime issue, but were not willing to explore the transportation issue at the current time. The nurse, along with the community coalition partners, would be better able to influence the crime problem by helping to form town watch groups and getting the local police district to provide increased patrols during evening hours when robberies were more likely to occur. However, the partners had little influence to extend the hours of operation on buses or influence the creation of new bus routes. Members of the coalition included the local police chief and chamber of commerce director. If the crime problem was left unchecked, more people could be adversely affected, including businesses, because people would not be willing to leave their homes to shop or might even be forced to move away. Finally, these initiatives could be put in place rather quickly and inexpensively after the formation and training of volunteer town watch groups.

There certainly are no adverse social, economic, or ethical consequences attached to addressing this problem. Therefore, it would seem that the crime issue would take priority over the transportation issue. It is important to remember that each community diagnosis is examined separately and then compared. Priorities for action are discussed, ranked, and then prioritized for action (Hauck & Smith, 2015) (Fig. 15–9).

FIGURE 15–9 A team meeting held to develop goals and objectives.

Establishing Goals and Objectives

Goals and objectives are crucial to planning and should be feasible, specific, and measurable (Anderson & McFarlane, 2015; CDC, n.d.). The diagnosis that identifies needs must be translated into goals to give focus and meaning to the nursing plan. Goals are broad statements of desired outcomes. Objectives are specific statements of desired outcomes, phrased in behavioral terms that can be measured. Target dates for expected completion of each objective are also stated. Objectives are the stepping-stones to help one reach the end results of the larger goal. For the elderly group concerned about crime in the neighborhood, the need, the goal, and the objectives were defined as follows:

- *Need*: The group of elderly people has altered coping ability related to their fear of crime.
- *Goal*: Within 6 months, this group of elderly people will feel comfortable to walk the streets of their neighborhood without experiencing any incidents of criminal assault.
- *Objectives:*
  1. By the end of the first month, a safety committee (composed of senior citizens, nurses, police, and other appropriate community members) will be established to study the crime patterns in the neighborhood.2. The safety committee will develop strategies for crime reduction and elder protection, which will be presented to the city council for approval by the end of the third month.3. Safety strategies, such as increased police surveillance, town watch patrols, and escort services, will be implemented by the end of the fifth month.4. By the end of the sixth month, nursing assessment will determine that senior citizens feel free to walk about the neighborhood.5. By the sixth month, there will be fewer reported incidents of criminal assault.

Development of objectives depends on a careful analysis of all the ways in which one could accomplish the larger goal. PHNs should first select the course of action that is best suited to meet the goal and then build objectives. For the group of elderly people, other alternatives, such as staying indoors or always walking in pairs, were considered and rejected. The ultimate choice was to find a way to make their environment safe and enjoyable.

Some rules of thumb are helpful when writing objectives. First, each objective should state a single idea. When more than one idea is expressed—as in an objective to both obtain equipment and learn procedures—it is more difficult to measure the completion of the objective. Second, each objective should describe one specific behavior that can be measured. For instance, the fourth objective from the list states that the seniors will report feeling free to walk outdoors within 6 months. It describes a behavior that can be measured at some point in time. One can more readily evaluate objectives that include specifics—such as what will be done, who will do it, and when it will be accomplished. Then it is clear to everyone involved exactly what has to be done and within what time frame. Writing

measurable objectives makes a tremendous difference in the success of planning. See Chapter 11 for more information on writing behavioral objectives.

The acronym SMART is another useful guideline when writing objectives (Minnesota Department of Health, n.d.b). SMART objectives are

- Specific: Concrete, detailed, and well defined so that you know where you are going and what to expect when you arrive.
- Measurable: Numbers and quantities provide means of measurement and comparison.
- Achievable: Feasible and easy to put into action.
- Realistic: Considers constraints such as resources, personnel, cost, and time frame.
- Time bound: A time frame helps to set boundaries around the objective.

Planning means thinking ahead. The nurse looks ahead toward the desired end and then decides what intermediate actions are necessary to meet that goal. Sometimes, an objective itself describes the intermediate actions. At other times, an objective may be further broken down into several activities. For example, the second objective states that the safety committee will be charged with developing strategies, presenting them to the city council, and gaining their approval. Good planning requires this kind of detail.

Making decisions is an important part of planning. Decisions must be made during the process of establishing priorities. Decisions are necessary for selecting goals and for choosing the best course of action from many possible courses. Further decision-making is involved in selecting objectives and taking action to accomplish the objectives.

To facilitate planning and decision-making, the community health nurse involves other people. Clients must be included at every step because they are the ones for whom the planning is being done. Without their insight and cooperation, the plan may not succeed. Additionally, the involvement of other nurses may be important. Team meetings, nurse–supervisor conferences, and nurse–expert consultant sessions are all useful resources for planning. In addition, it is essential that you confer with members of other health and professional disciplines (e.g., teachers, social workers, mental health professionals, hospital representatives, city planners). Interdisciplinary team conferences are valuable for gaining a broader perspective and enlisting wider support for the evolving plan.

IMPLEMENTING HEALTH PROMOTION PLANS FOR THE COMMUNITY

Implementation is putting the plan into action. The nurse, other professionals, or clients carry out the activities of the plan. Implementation is often referred to as the action phase of the nursing process. In community health nursing, implementation includes not just nursing action or nursing intervention, but collaboration with clients, stakeholders, and other professionals. When bringing about change in a community organization, implementation involves the greatest commitment of time and planning. This often includes an implementation timetable, as well as funding or organizing physical/informational/staff/management resources, collaboration with outside agencies, training staff and working with community volunteers as needed for program implementation, and actually putting into action those interventions created during the planning phase (Anderson & McFarlane, 2015; Issel, 2014; Public Health Institute, 2012). Certainly, the nurse's professional expertise and judgment provide a necessary resource to the client group. The nurse is also a catalyst and facilitator in planning and activating the action plan. However, a primary goal in community health is to help people learn to help themselves in achieving their optimal level of health. To realize this goal, the nurse must constantly involve clients in the deliberative process and encourage their sense of responsibility and autonomy. Other health team members may also participate in carrying out the plan. All are partners in implementation.

Preparation

The actual course of implementation, outlined in the plan, should be fairly easy to follow if goals, expected outcomes, and planned actions have been designed carefully. Professionals and clients should have a clear idea of *who*, *what*, *why*, *when*, *where*, and *how*. Who will be involved in carrying out the plan? What are each person's responsibilities? Do all understand why and how to do their parts? Do they know when and where activities will occur? As implementation begins, nurses should review these questions for themselves, as well as for clients. This is the time to clarify any doubtful areas, thereby facilitating a smooth implementation phase. An operations manual may be needed, as well as organizational charts, clear budgets, and social marketing plans (Anderson & McFarlane, 2015; Issel, 2014).

Even the best planning may require adjustments. For example, some nurses who planned a health fair for seniors discovered that the target group would not have transportation to the site because the volunteering bus company had withdrawn its offer. To smoothly implement the plan, the nurses arranged for volunteers from local churches to pick up the seniors, bring them to the health fair, and deliver them afterward to their homes. Implementation requires flexibility and adaptation to unanticipated events.

Activities or Actions

The process of implementation requires a series of nursing actions or activities:

- The nurse applies appropriate theories, such as systems theory or change theory, to the actions being performed.
- The nurse helps to facilitate an environment that is conducive to carrying out the plan (e.g., a quiet room in which to hold a group teaching session or solicitation of support from local officials for an environmental cleanup project).
- The nurse and other health team members prepare clients to receive services by assessing their knowledge, understanding, and attitudes and by carefully interpreting the plan to clients. This interaction nurtures open communication and trust between nurse and clients. Professionals and clients (or representatives if the aggregate is large) form a contractual agreement about the content of the plan and how it is to be carried out.
- The plan is carried out, or modified and then carried out, by professionals and clients. Modification requires constant observation and interchange during implementation, because these actions determine the success of the plan and the nature of needed changes.
- The nurse and the team monitor and document the progress of the implementation phase by process evaluation, which measures the ongoing achievement of planned actions (Anderson & McFarlane, 2015; Issel, 2014).

EVALUATING IMPLEMENTED COMMUNITY HEALTH IMPROVEMENT PLAN

Evaluation is usually seen as the final step, but because the nursing process is cyclic in nature, the nurse is constantly evaluating throughout the entire process. For instance, in the assessment phase, the nurse must evaluate whether the collected data are sufficient and appropriate to beginning planning. Evaluation methods must be addressed during the planning phase as goals and objectives as well as interventions are identified (Anderson & McFarlane, 2015; Issel, 2014). Evaluation refers to measuring and judging the effectiveness of goal or outcome attainment. Too often, emphasis is placed primarily on assessing client needs and on planning and implementing service. The nursing process is not complete until evaluation takes place. Ideally, the nursing process should be observed as cyclical instead of linear, and when this occurs, it is obvious that evaluation guides the next assessment (Issel, 2014). The Community Toolbox (2015) provides suggestions for participatory evaluation that includes examination of the process (e.g., how the assessment was conducted), implementation (e.g., how the program was designed and executed), and outcomes (e.g., if desired results were accomplished). Appropriate questions include the following: Was all potential information assessed? How effective was the service provided? Were client needs truly met? How has health status changed? Professional practitioners owe it to their clients, themselves, and other health service providers to fully and effectively evaluate a program (see From the Case Files II).

From the Case Files II

Evaluating Outcomes of a Home Care Postpartum Program

As a nurse working as the liaison between Capitol City Hospital and its home health agency, you are given the job of reviewing your early postpartum discharge program. Your program has been in effect for 18 months. Client satisfaction is high. The program has increased revenue for the hospital as many clients choose to deliver at Capitol City Hospital because of the early discharge program.

The protocol for your early discharge program includes a postpartum home visit by an RN from the home health agency. These visits are provided as a service to the client. In some cases, visits are billable to insurance companies. Medicaid authorizes payment for one postpartum visit.

You have gathered the following information about the early discharge program:

I. Protocol: Standard is one visit within 48 hours after discharge, which includes

A. Education:

1. Newborn care
2. Breast-feeding
3. Warning signs warranting follow-up (mother and baby)

- Infection
- Hemorrhage

4. Comfort
5. Parenting
6. Sexuality

- Resumption of sexual activity
- Contraception

7. Community resources
8. Nutrition
9. Well and sick baby care

B. Assessment:

1. Infant: Jaundice (heel stick performed if necessary)
   Mother: Hemorrhage, perineal lacerations, hematomas
   Both: Nutrition

- Weight
- Hydration
- Breast-feeding

2. Elimination

II. Cost:

A. Fully reimbursed by some insurance companies.

B. All mother/baby dyads receive postpartum visits, regardless of insurance coverage.

C. Optional or additional methods of reimbursement have not been explored by the agency.

D. Agency makes money on reimbursed visits, loses money on nonreimbursed, but additional revenue generated by clients choosing the hospital because of the

positive public perception. The program is thought to balance out cost of nonreimbursed visits.

Outcomes of postpartum early discharge with accompanying home visit (as compared to traditional length of postpartum stay):

I. Positive:

A. Higher percentage of successful (at least 2 months) breast-feeding
B. Higher rate of immunization compliance
C. Fewer inappropriate emergency room visits
D. High client satisfaction
E. Lower levels of maternal stress reported to pediatricians

II. Negative:

A. Higher incidence in jaundice in babies whose mothers participated in the early discharge program

1. What, if any, additional information do you need to make a recommendation regarding the program?

- How will you obtain this information?

2. As the nurse making a recommendation for the continuation or termination of the postpartum early discharge program, what are your recommendations?

- Should the program be abandoned?
- Should the program be maintained?

3. What, if any, alterations would you make in the following areas:

- Funding
- Protocol
- Client education
- Assessment
- Timing of visit

4. Outcome measurements are critical to demonstrate the efficacy of this program.

- What will you evaluate?
- How often?
- Why?

As stated earlier, evaluation is an act of appraisal in which one judges value in relation to a standard and a set of criteria. Evaluation requires a stated purpose, specific standards, and criteria by which to judge and judgment skills.

Types of Evaluations

To determine the success of their planning and intervention, community health nurses use two main types of evaluation: formative and summative evaluation. The focus of *formative* evaluation is on process during the actual interventions. *Summative* evaluation focuses on the outcome of the interventions: Did you meet your goals? In formative evaluation, performance standards are developed and used to determine what is and is not working throughout the process. These could include the physical and organizational structure of the agency, as well as resources that provide a foundation for any interventions. Formative evaluation essentially looks at the step-by-step process of program implementation (Green, Sim, & Breiner, 2013). Could I do anything better or differently to increase my desired outcome? An example would occur when looking at the poor attendance at two sessions of an evening health promotion class for senior citizens. The nurse identifies the reason for poor attendance as being seniors' reluctance to attend an evening class because they either don't drive at night, have low vision at night, or fear coming out in the dark. The class is rescheduled for midmorning, and the attendance dramatically increases.

Summative evaluation examines outcomes of the interventions. The *effect*, or degree to which an outcome objective has been met, informs the agency or program leader of the program's impact on clients' health. As an example, one manufacturing company had an 80% adherence rate for employees who were supposed to wear proper protective devices (goggles, safety shoes, and hard hats) in the plant. Noncompliance on the part of some workers was a concern to union representatives, the health and safety team, and the company management. They were concerned that 20% of their employees were at risk for injury that would cause pain, suffering, loss of work time, disruption to the manufacturing process, and reduced profitability. The occupational health nurse along with the safety officer began a month-long safety campaign that included safety miniclasses, posters, and incentives for departments with 100% safety equipment adherence. Three months after the program, 95% of the employees were adhering to the safety regulations. This 15% increase was attributed to the effect of the safety program.

The *impact* of a program determines how close it comes to attaining its goals. In the earlier example, the objective of the safety campaign was to increase safety equipment use, and use was significantly increased as a result of the program. However, if the goal of the program had been to decrease accidents and save the company money, the result could be determined only with additional information. Were there fewer injuries caused by accidents? Were there fewer days lost to injuries? Did the company save money as the direct result of employee safety adherence? What was the cost–benefit ratio? Depending on the answers to these questions, the overall goal of the program may or may not have been met, even though the objective of the program was met. The full impact of the program cannot be determined without additional data. See Chapter 12 for more on program evaluation.

Community Development Theory

An outcome of effective community-level nursing practice is community development. Community development is the process of collaborating with community members to assess their collective needs and desires for positive change and to address these needs through problem solving, collaboration with community stakeholders, and resource development (Leigh & Blakely, 2013). A community development perspective assumes that community members participate in all aspects of change—assessment, planning, development, delivery of services, and evaluation. With this approach, the focus is on healthful community changes generated from within the community, as a partnership between health care providers and inhabitants, rather than a commodity dispensed by health care providers. The community as partner model exemplifies this approach (Anderson & McFarlane, 2015). Chapter 11 details community change theory.

The outcomes are more positive when community members have a sense of ownership in the health programs and services that address their needs. This enhances empowerment among members of the community and enables them to more effectively control and participate in transforming their environment and their personal circumstances. This implies that health care agency infrastructures are appropriate additions to services that are planned and delivered in an acceptable manner to the community (see Fig. 15–10, Arnstein's Ladder). This empowerment leads to greater resilience and ultimately, wellness (RAND Corporation, 2015) (see Chapter 13).

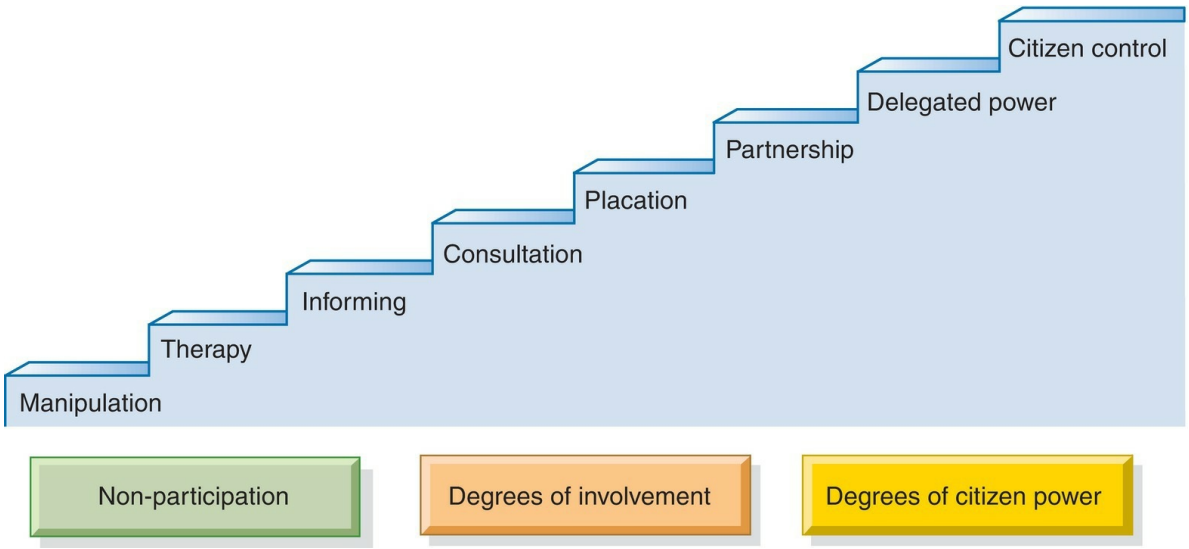

FIGURE 15–10 Arnstein's Ladder—Eight steps of citizen participation. (Adapted from Arnstein, S. R. (1969, July). A ladder of citizen participation. Journal of the American Institute of Planners, 35(4), 217–224.)

When applying community development theory, the agent of change (often the public health nurse) is considered a partner rather than an authority figure responsible for the

community's health. To achieve acceptance as a partner, the nurse must listen and learn from the community members, because they are the experts with respect to their health care needs, culture, and values (Michener et al., 2012). They have mastered adaptation to the community, and they have firsthand knowledge of prevention methods and interventions that are appropriate to their lifestyles. For example, a randomized controlled trial with 285 women having chronic health conditions and receiving Temporary Aid for Needy Families (TANF), and utilizing a CBPR approach, found that 9 months of PHN case management improved health outcomes for those in the intervention group (Kneipp et al., 2011). Medicaid knowledge and skills improved for both the intervention and control groups, but those in the intervention group had improved depression and functional status; they were also more likely to have a new mental health visit (Kneipp et al., 2011). The PHNs developed rapport with their clients and formed a partnership with them. The principles of CBPR involve this type of partnership (see Chapters 4, 13, and 25 for more information on CBPR). Members of the community are engaged as coresearchers, and time is spent building trust and developing collaborative relationships with community members, stakeholders, and neighborhood health care providers. The expertise of community members is valued and can be useful in designing recruitment strategies, as well as in data analysis (Perry & Hoffman, 2010). This experience can enrich the community as a whole, as well as the actual participants.

The outcomes of the services provided by any organization can be benchmarked against those of other groups. *Benchmarking* involves comparing an organization's outcomes against those of a similar organization or an organization that is known for its excellence in a particular area of client care (Haustein et al., 2011). Information from this comparison can be used to identify an organization's areas of weakness and to focus attention on specific outcomes. The establishment of *best practice* activities entails constant comparisons between high- and low-performance programs and interventions (Ettorchi-Tardy, Levif, & Michel, 2012).

From a global perspective, the Conference on Primary Health Care held at Alma-Ata in 1978 concluded that people have little control over their own health care services and that the emphasis should be on health problems identified by the members of the community in their attempts to attain a state of wellness (WHO, 1998). Since that time, the WHO, along with other agencies and groups, has been providing leadership in the use of community development methods to improve global health, based on the following concepts (Brennan, Birdger, & Alter, 2013):

- Promote active, representative participation to influence decisions affecting community members' daily lives
- Engage community members in economic, social, political, environmental, psychological, and other issues that impact them
- Interest them in learning more about alternative courses of action
- Incorporate diverse cultures, ethnic and racial groups, and varied interests in the

process of community development
- Refrain from supporting efforts that are likely to adversely affect disadvantaged members of the community
- Actively work to build leadership capacity of community leaders and groups, and individuals
- Work toward long-term sustainability and community well-being

SUMMARY

Characteristics of healthy communities include those elements that enable people to maintain a high quality of life and productivity by increasing health and decreasing disease and disparities in health and health care delivery. The effectiveness of community health nursing practice depends on how well the nursing process is used as a tool to enhance aggregate or population health. The nursing process involves appropriate application of a systematic series of actions with the goal of helping clients achieve their optimal level of health. The components of this process are assessment, diagnosis, planning, implementation, and evaluation.

The concept of community as client refers to a group or population of people as the focus of nursing service. The community's health is reflected in its status (e.g., morbidity and mortality rates, crime rates, educational and economic levels), structure (availability, use, and quality of services and resources), and processes (how well it functions in regard to its strengths and limitations). The dimensions of a community's health may be seen in regard to its location (e.g., climate, vegetation, boundaries), population (e.g., diversity or homogeneity, old, young, pregnant, addicted, or academic members), and social systems (e.g., schools, businesses, communications, health care, and religious organizations, among others).

Interaction is deeply integrated in the nursing process. Because nurse and clients must first establish a relationship of reciprocal influence and exchange before any change can take place, interaction could be considered the most essential step in the process. Effective communication is inherent in assessing needs and establishing trust between nurse and clients as partners in the nursing process. The first steps in interacting involve understanding group behaviors and dynamics, followed by interpersonal communication at the group level in the form of listening, teaching, building trust, seeking client involvement, sharing, and collaborating to build partnerships and teams.

Assessment for community health nurses means collecting and evaluating information about a community's health status to discover existing or potential needs and assets as a basis for planning future action. Assessment involves two major activities. The first is collection of pertinent data, and the second is analysis and interpretation of that data.

Community health nurses may use various assessment methods to determine a community's needs. They include *familiarization assessments*, such as windshield surveys, which involves studying data already available on a community; *problem-oriented assessment*, which focuses on a single problem and looks at the community in terms of that problem; *community subsystem assessment*, by which the community health nurse focuses on a single dimension of community life; a complicated and often time-consuming *comprehensive assessment*, to discover *all* relevant community health information; or an *assets assessment* that focuses on the strengths of a community as opposed to its deficits. Combinations may also prove useful (e.g., problem oriented and assets assessments).

Community data may be provided by many means—surveys, descriptive epidemiologic studies, community forums, and town meetings. Focus groups as well as primary and secondary sources (e.g., people who are familiar with the community and its character and history) are also common sources of data, along with Web sites, and government departments and agencies that compile statistics (e.g., U.S. Census Bureau, state or county health departments). Sources can include national, international, state, county, and local agencies, as well as business and social organizations.

Using the nursing process in the community would not be complete without looking at the role of the public health nurse as a catalyst for community health improvement. Community development theory is the foundation that supports citizen empowerment and use of key players in the community to plan for the health and safety of that community.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Explain to a nonnursing friend why it is important to understand and work with the community as a total entity, in addition to individuals and families.
2. How does defining the community as the client change the community health nurse's practice? List some specific examples of how this concept can be applied.
3. If you were part of a health planning team concerned about the health needs of senior citizens in your community, what are some location, population, and social system variables you would want to assess? Name some of the sources from which you might collect the data.
4. Discuss under what circumstances you might choose to conduct a problem-oriented community health assessment. What method would you consider using to conduct this assessment, and how would you carry it out?
5. If possible, interview someone from your state or local health department or from a nonprofit hospital who has recently conducted a community health assessment survey. Or, access one on a state or hospital Web site. Analyze the process used, and compare it with the steps for conducting a survey described in this chapter. How are they similar? Different?
6. Critically reflect on the community in which you were raised. Who were the "haves" and "have-nots" in your community? What characterized them as that (e.g., money, education/position, race/ethnicity)? Verify this by examining current vital statistics by income, education, and ethnicity. How has your community changed since you were in grade school? Speak with a few people from older generations about their views on the community (e.g., causes of morbidity/mortality, general population health). How do their views differ from your? How are they similar? Compare current vital statistics with those of your birth year. Do the results follow the expected patterns based upon your interviews? Compare your community to a peer's community. Which one might be seen as healthier? Why?

16 CHAPTER

Global Public Health Nursing: Population Health Around the Globe

"When it comes to global health, there is no 'them'… only 'us.' "

—*Global Health Council* (2010)

KEY TERMS

Community health worker (CHW)
Control
Disability-adjusted life year (DALY)
Elimination
Era of Chronic, Long-Term Health Conditions
Era of Infectious Diseases
Era of Social Health Conditions
Eradication
Global burden of disease (GBD)
Global nursing
Health for All
Integrated management of childhood illness (IMCI)
Jakarta Declaration
Multilateral agencies
Oral rehydration therapy (ORT)
Ottawa Charter for Health Promotion
Pluralistic health care systems
Primary health care (PHC)
Universal imperatives of care
World Bank (WB)
World Health Assembly (WHA)
World Health Organization (WHO)
World Health Organization Collaborating Centers

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe a context and framework for delivering community-based nursing within the context of international community health nursing.
- Describe the major health care conditions currently affecting the world's populations and the types and preparation of health care workers addressing them.
- Describe the community health nursing interventions and strategies commonly used within an

international context.

- Recognize the factors that influence populations' perceptions of health and health status and their receptivity to community health nursing programs.
- Describe the personal and professional perceptions and biases you bring to providing community health nursing interventions within an international context.
- Identify the major international, national, regional, and local organizational structures and organizations that affect the ways in which community health nursing is practiced.
- Locate relevant resources as a basis for planning the assessment, implementation, and evaluation of community health nursing within an international context.

Let us suppose that you have completed your schooling and are ready to embark on a career in global community health nursing. Global nursing can range from providing clinical services to policymaking at an international level. Perhaps you engaged in several years of successful clinical practice and are interested in pursuing an international opportunity to practice nursing in another country. You undertake a search of the Internet, you talk to professional colleagues, and you read articles in nursing and other professional and popular journals.

You quickly realize that researching health care is a rather awesome undertaking, and the search for health care opportunities within a global context yields a plethora of Web sites, universities, and organizations going global. We can connect to almost anyone, anywhere, by computer or cell phone. We can access ancestral records that are centuries old, talk to colleagues in the far reaches of Africa or Asia, and instantly learn about global health issues occurring on the opposite side of the globe.

You also learn that community health care is complex and that it affects and is affected by multiple factors that have to do with geography, history, politics, culture, religion, and a nation's wealth. Your searches will be informative. You will notice that some countries' data are difficult to access, and you realize that this may be because a country has been involved in a long, protracted civil war or has experienced continuous cycles of disasters or financial collapse.

In your search, you also find that people's conception of health, wellness, and illness varies from culture to culture and that the ways in which they view nurses and other health care providers is affected by their attitudes toward women, their culture, and belief systems. You will also notice patterns of privilege across countries and regions regarding who lives, who dies, the way people function on a day-to-day basis, the health care decisions they make, and the cost of the care they receive.

In your search, you also will learn a great deal about the health care providers that countries look to for nursing care and medical treatment. You will notice a disparity between the health status and health conditions of people in a country, as well as the kind of health care providers who are educated practicing in that country. For example, if you were to travel to mountainous areas, such as Nepal, you would see medications and treatments being administered without questions asked about the provider's credentials. The closest primary health care (PHC) station might be 20 miles away, and any relief from pain is welcome.

You may become sensitized to the difference between your kind of nursing education and that of the nurses in countries different from your own. The ways in which one is recruited and educated varies from country to country, as does legislation regarding licensure and entry to practice. For example, midwifery in the United States is based on a baccalaureate degree in nursing, whereas in Denmark, students have been admitted directly into a midwifery program without a nursing background and foundation. In France, midwives are aligned with the field of medicine and see their practice from that standpoint rather than from a nursing perspective.

You will come across hundreds of references to international, national, and regional agencies that work in health care internationally. These references will be organized according to international agencies, national governments, universities, churches, and nongovernmental organizations (NGOs), including those with religious affiliations and those that are nondenominational.

Most importantly, you will become aware of your own approach to community health nursing. The ways in which practice takes place in an international context are influenced by all these factors and by your own personal background, your religious beliefs and attitudes, your orientation toward the theory of community health nursing practice, as well as your values and cultural beliefs. These factors and issues constitute a global framework for community health nursing, and they are the foci of this chapter. The question arises: How to put all of this in perspective, to apply a way of thinking to assist you in achieving your goal of an international nursing experience?

This chapter begins with a framework you can use to organize your thinking and around which you can structure your search as you expand your repertoire of knowledge and understanding. Those of us who work abroad need a framework in which to place our searches, professional dialogues, and readings. We need a compass to guide us as we conduct these searches to help match us with the people we hope to serve. We also need a way of thinking about the communities, regions, or countries of the world and about the kinds of community health nursing interventions a country may need, given the elements described here.

A FRAMEWORK FOR GLOBAL PUBLIC HEALTH NURSING

The Three P's

To guide your thinking, consider a global framework that includes three parts, the three "P's": the population, the provider, and the procedure. In community health nursing, our focus is on populations rather than individual patients. The provider refers to the health care team, which may include a community health nurse, a physician, a midwife, an "injector" (someone who is trained to only give injections), or a community health worker (CHW). The procedure refers to the interventions health care providers implement for or with populations.

In this global framework, alongside the three P's, think about three *eras* of health and health conditions, as described in a classic article by Breslow (2006). During our ancestors' time, populations of people died from the plague, tuberculosis (TB), puerperal fever, and other infectious diseases. Entire populations were sometimes eliminated through these infections. During this first era, families had many children, as they knew that most children would die before adulthood, and without any form of social security, children were their parents' only source of livelihood. Sons were preferred over daughters as sons ensured the family's livelihood and were capable of defending the community from enemies. This is referred to as the Era of Infectious Diseases. With the advent of antibiotics, people survived common infections. The lifespan of children was longer than that of their parents, but often, they suffered from chronic, long-term illnesses such as heart disease, cancer, and debilitating arthritis (Remington & Brownson, 2011). This is referred to as the Era of Chronic, Long-Term Health Conditions. Despite changes and advances in health care, people continued to produce large families because of the cost or absence of birth control measures, persistent religious beliefs that influenced families regarding birth, and the intent of countries—such as Romania (before 1989)—to increase their populations for financial reasons. More recently, a new array of health conditions is affecting world populations, including addictions and obesity, and social conditions such as prostitution, sexual abuse, and deviant behavior. These are examples from the Era of Social Health Conditions. The popular press has exposed many of these conditions through documentaries on the effects of methamphetamine on entire communities, the abuse of prescription painkillers, the obesity epidemic sweeping countries throughout the world, and the exploitation of children.

Continuing Emerging Health Conditions

Today, the communities of the world are experiencing all three eras of health conditions simultaneously. In one community, a population may be dealing with the Ebola virus, heart disease, cancer, adolescent prostitution, and mental illness. Some of these health

conditions have been present for many years, some for thousands of years, and some are relatively new. Although significant progress has been made in controlling infectious diseases, the recent globalization of our world has increased opportunities for the spread of known and emerging infectious diseases (Centers for Disease Control and Prevention, [CDC], 2015c). This trend is attributed, in part, to the increase in travel, the massive migration of populations occurring because of wars and civil uprising, and the economic situation forcing people to leave their home countries for employment. This chapter examines the context where these conditions occur, the health care providers who work with them, and the ways in which interventions are applied through the work of many sponsoring global health organizations.

Universal Imperatives of Care

In addition to the three P's and the three eras of health conditions, community health nurses need to consider the current status of health in the community of interest. One useful paradigm is the universal imperatives of care. When we ask the question, how many nurses does a community need, part of answer has to do with these imperatives. These imperatives include mortality, morbidity, daily functioning, decision-making, and cost of and access to health care. This paradigm underscores the notion of *first things first*. That is, one must be alive and well before interventions can focus on functioning or decision-making (Fig. 16–1).

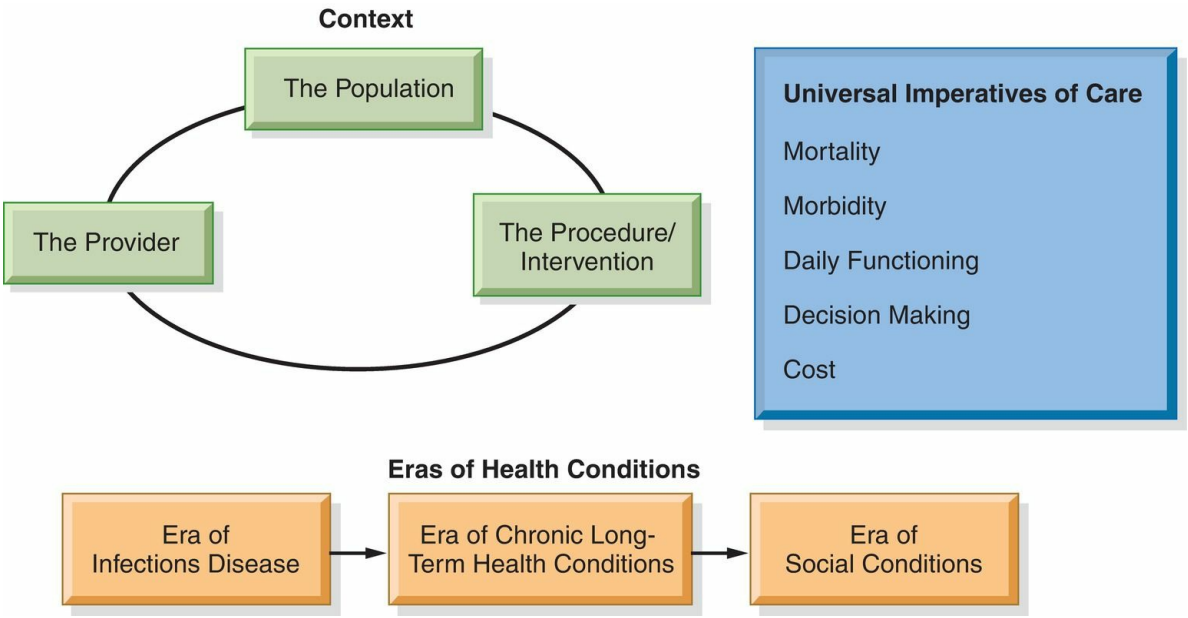

Figure 16–1 Framework for global community health nursing. (M. Farrell, 2012.)

Mortality

A government's first priority is to keep its population alive and free from illness. This is critical if a country is to survive, protect itself, and feed its population. In this regard, community health nurses may be frustrated that the disabled are going without community resources, programs are not created to help couples make informed decisions about abortion and birth control, or the mentally ill have no possibilities for therapy. However, when countries are poor, they will focus on preventing mortality and the evidence-based interventions that will ensure the survival of the people (World Bank, 2014). The health care team member required when mortality is a priority is the physician.

Morbidity

When people are not dying, a country can focus on its population's morbidity—the conditions that make people sick—and will look to physicians and nurses for assistance.

Sickness derives from infectious diseases, long-term chronic health conditions, and the social conditions introduced above and will be discussed in more detail in upcoming sections.

Daily Functioning

In many countries, the ability to care for oneself—to bathe, secure food, and carry out other activities of daily living for fragile elderly or the disabled—is the purview of nurses, physical therapists, social services, and social workers. However, in some countries, certain health care team members that nurses in the United States take for granted do not exist. Caring for an autistic child or a severely disabled parent is left entirely to the family. This is not because the government is negligent. It is because the universal imperatives in a country with constrained resources must focus on the necessities first.

Decision-Making

In order to choose, one needs options. In countries with only one health care delivery system, there are no other options. As countries have expanded to include privatization, and as people increasingly have access to the Internet, they have generally evolved in their decision-making processes about the providers they will use and the sources of their health information.

Cost

In many countries in the past, the state provided all health care, and all costs were the burden of the community. Increasingly, these health services are being rationed, restricted, or placed under insurance schemes. Nations are forced to weigh the cost of managing some health conditions over others. Most of the time, they opt for those that can be addressed with the least input and the maximum benefit. This is, in part, the reason that the Era of Social Conditions is not being addressed in many countries. The interventions that will reduce the incidence of these conditions are often unknown, and the knowledge and research needed to access them are well beyond many countries' resources, thus encouraging these countries to work increasingly with the international community. Many countries do not have the resources to support the necessary research and programming to address the issues that may involve them and their border nations. In some countries with national health services that purport to provide all of a family's needs, a strong underground of health products and services is available to those who can afford to pay for them (Lohman, 2015).

Access

Increasingly, a major concern is not only having the health services available to populations but that the health services are accessible to the people. Access to health care refers to the ease with which an individual can obtain needed (health care) services. Several factors

influence access worldwide. For example, people who speak the language, people who have insurance, and those who are part of the military establishment may have priority in some countries. Most often, the particular groups who go wanting include the poor, the illiterate, those living in rural or remote areas, and, in some places, women (because of religious taboos).

THE CONTEXT

A Context of Interdependency

The context of community health nursing suggests considering one planet of interdependent nations. This interdependence relates to virtually all areas of life, including health. As of July 2015, the world's population reached 7.325 billion, with an estimated 8.501 billion by 2030 and 9.925 billion by 2050 (United Nations, Department of Economic and Social Affairs, Population Division, 2015). As systems theory suggests and Friedman (2005) reiterates in his definitive book, "The World Is Flat," what happens in one country affects many others in important ways. For example, air travel can transport health problems from a country halfway around the world to new communities in less than a day.

> On our one Earth, "water tables are falling, soil is eroding, glaciers are melting, and fish stocks are vanishing. Close to a billion people go hungry each day. Decades from now, there will be most likely two billion more mouths to feed, mostly in poor countries. There will be billions more people wanting and deserving to boost themselves out of poverty. If they follow the path blazed by wealthy countries—clearing forests, burning coal and oil, freely scattering fertilizers and pesticides—they too will be stepping hard on the planet's natural resources" (p. 43).

In addition to the number of people, the location and movement of populations is a major consideration. The number of migrants internationally has doubled over the past 25 years to 231 million people (United Nations Department of Economic Affairs, Population Division, 2013), and Goldin, Cameron, and Balarajan (2011) predict this will define the future more than environmental or weather patterns affecting the globe. These migrants sometimes settle in the country to which they have moved, and others return to their native homeland. During the Syrian civil war, thousands of refugees have poured into neighboring countries as well as into European countries, straining their economies and systems of health care (Doocy, Lyles, Akhu-Zaheya, Burtob, & Weiss, 2016).

One example of a deadly migration involves the international spread of a virus. In New York, in the fall of 1999, 61 severe cases and seven deaths were reported from a mysterious viral illness later identified as the West Nile virus (WNV), which had not previously been reported in the United States. Researchers now speculate that the virus may have traveled to the United States in smuggled exotic birds. The virus was closely related genetically to strains found in the Middle East. At its peak in 2003, a reported 9,862 cases related to WNV and 264 deaths had occurred in 46 states (CDC, 2015e, 2015f). By 2014, over 2,200 total cases were reported (CDC, 2015f). A new threat emerged in 2015; the Zika virus was found in Brazil and travelers returning to the United States were reported to have cases of the virus, known to be a danger for pregnant women because of its link with birth defects (CDC, 2016).

The globalization of food commodities and food safety also affects health. For example,

researchers suggest that a causal relationship exists between ongoing outbreaks in Europe of bovine spongiform encephalopathy, or *mad cow disease*, and the human disease called new variant Creutzfeldt-Jakob disease (vCJD). Of the worldwide total of 153 vCJD cases, 143 have occurred in the United Kingdom. Cattle are considered the only source of the disease (CDC, 2011).

The 2014 Ebola outbreak in West Africa was bigger and more extensive than any prior Ebola epidemic. Numerous responders from a variety of disciplines, including nursing, rushed to help as teams tried to contain the spread of the deadly virus. Responders later reported tales of challenges and ingenuity as they struggled to overcome hardships and obstacles. Visit the following Web site for further stories of what it is really like to work under harsh conditions in the face of deadly epidemics (http://www.cdc.gov/about/ebola/overcoming-challenges.html).

It wasn't long before the virus reached U.S. soil, including two imported cases and two locally acquired cases among health care workers (CDC, 2015b). Standard screening protocols are now in place in the United States to guide screening and management of travelers from West Africa with suspected symptoms (see Fig. 16–2).

Ebola Virus Disease (Ebola)

Algorithm for Evaluation of the Returned Traveler

FEVER (subjective or ≥100.4°F or 38.0°C) or compatible Ebola symptoms* in a patient who has resided in or traveled to a country with wide-spread Ebola transmission** in the 21 days before illness onset

* headache, weakness, muscle pain, vomiting, diarrhea, abdominal pain, or hemorrhage

NO

Report asymptomatic patients with high- or low-risk exposures (see below) in the past 21 days to the health department

YES

1. Isolate patient in single room with a private bathroom and with the door to hallway closed
2. Implement standard, contact, and droplet precautions
3. Notify the hospital Infection Control Program and other appropriate staff
4. Evaluate for any risk exposures for Ebola
5. IMMEDIATELY report to the health department

HIGH-RISK EXPOSURE

Percutaneous (e.g., needle stick) or mucous membrane contact with blood or body fluids from an Ebola patient

OR

Direct skin contact with, or exposure to blood or body fluids of, an Ebola patient

OR

Processing blood or body fluids from an Ebola patient without appropriate personal protective equipment (PPE) or biosafety precautions

OR

Direct contact with a dead body (including during funeral rites) in a country with wide-spread Ebola transmission** without appropriate PPE

LOW-RISK EXPOSURE

Household members of an Ebola patient and others who had brief direct contact (e.g., shaking hands) with an Ebola patient without appropriate PPE

OR

Healthcare personnel in facilities with confirmed or probable Ebola patients who have been in the care area for a prolonged period of time while not wearing recommended PPE

NO KNOWN EXPOSURE

Residence in or travel to a country with wide-spread Ebola transmission** without HIGH- or LOW-risk exposure

Review Case with Health Department Including:

- Severity of illness
- Laboratory findings (e.g., platelet counts)
- Alternative diagnoses

Ebola suspected ⟷ **Ebola not suspected**

TESTING IS INDICATED

The health department will arrange specimen transport and testing at a Public Health Laboratory and CDC

The health department, in consultation with CDC, will provide guidance to the hospital on all aspects of patient care and management

TESTING IS NOT INDICATED

If patient requires in-hospital management:

- Decisions regarding infection control precautions should be based on the patient's clinical situation and in consultation with hospital infection control and the health department
- If patient's symptoms progress or change, re-assess need for testing with the health department

If patient does not require in-hospital management:

- Alert the health department before discharge to arrange appropriate discharge instructions and to determine if the patient should self-monitor for illness
- Self-monitoring includes taking their temperature twice a day for 21 days after their last exposure to an Ebola patient

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

> *"…Creativity is possibly just as valuable as all the hard facts and materials. When there is no money, people are working beyond exhaustion and options are limited, thinking creatively can be the thing to pull you through."*—Leisha Nolen, Ebola responder, Sierra Leone

Global health issues become everyone's concerns when they spread within or beyond one's borders, when we commit resources to a country in need, when we make a personal commitment to improve the health of a population beyond our shores, and when we import or export food.

These trends and examples underscore both the ways in which people are being exposed to the health conditions, food, and environmental effects that may originate in one part of the world and to the uniqueness of local communities with their own geography and environment, history, cultural traditions, religion, and ideas about health, wellness, disease, and death. The notion to *think globally and act locally* captures the essence of this seeming dichotomy. Each of these elements constitutes entire disciplines of study and requires years of interacting with people to understand the ways in which they affect health care in a particular country.

Geography and Environment

The environment in which people live includes air, climate, soil, and water, and each of these may undergo changes that turn natural elements into hazardous ones. Humans are exposed to pollutants in two basic ways: by exposure to the source or by release of the pollutant into air or water. See Chapter 9 for more on environmental health issues.

Air pollution in China. (Photo courtesy of CDC Photo Image Library.)

When people use streams and rivers to dispose of body wastes and then use the same body of water for cleaning and washing their clothes, they expose themselves to infections from those waters. For example, countries such as India, Indonesia, and Bangladesh—countries with large populations—have no choice as sewerage and clean water sources are not available in some parts of these countries. When people in villages build their homes around sources of water, they also invite mosquitoes that carry malaria, for instance. In this environment, community health nurses' interventions might include teaching people the steps to preventing malaria, such as placing netting around a bed during the night, cleaning pools of stagnant water around the home, and covering the body with light cotton clothes (Amoran, 2013), and advising on the placement and maintenance of latrines. See From the Case Files: Addressing Malaria in the Community.

From the Case Files I

Addressing Malaria in the Community

Background: The Kenya Strategy for Community Health 2014 to 2019 includes an objective to "enhance community access to health care in order to improve

productivity and thus reduce poverty, hunger, and child and maternal deaths, as well as improve education performance across all stages of life" (Kenya Ministry of Health, 2014, para. 1). In other words, it aims to empower Kenyan communities to take charge of improving their own health. One of the ways the community strategy intends to improve the health status of communities is by building the capacity of the community health extension workers (CHEWs) and community-owned resource persons (CORPs) to recognize and respond to emerging trends in the community.

Case: Atieno is a community nurse engaged as a CHEW in Siaya County. Over the past 3 months, she has observed a rise in the number of malaria cases involving children. In some cases, she herself made referrals during home visits in response to fever-related complaints. Though the county is a malaria endemic area, Atieno is concerned about the trend and begins to have conversations with the mothers/guardians. She soon learns that most of the patients are from a particular location in the community.

During one of the facility staff meetings, she raises the issue and proposes an explorative visit to the location by the extension team. During the visit, the team observes that almost every home compound has freshly dug pits that subsequently formed small, stagnant ponds. Some of the homes also have furnace-like structures. They learn that the local administration had recently hosted an organization promoting brick making as an income-generating venture. The venture had modest returns and was gaining popularity.

The team also noted that the start of the long rainy season had recently begun, which was accompanied by a steady rise in the number of children 0 to 5 years of age with fever-related symptoms. Some of the locals attribute the fever cases to the children playing in the stagnant ponds and catching cold. The team sought permission to check sleeping areas and realized that most do not have bed nets, and even for those who do, parents don't ensure that their children sleep under the net. The extension team heads back to their station to review their findings and discuss the next course of action.

In liaison with the local administration and the CHWs, the team participates in a community "*baraza*" (public meeting) to highlight the worrying trend in malaria morbidity and the findings of the explorative visit.

Together, the team and the community discuss the link between the findings and malaria morbidity. The community acknowledges that the brick-making venture has contributed to increase in stagnant water pools that have turned into breeding grounds for malaria-transmitting mosquitoes and that households have not adhered to protection measures to control malaria transmission. A number of immediate actions to address the problem without compromising their newfound source of income were identified:

- Draining stagnant water around the homesteads

- Monitoring fever, particularly in the children
- Seeking immediate medical attention at the local dispensary

Through collaboration, the community identifies and agrees on further steps to stem the problem:

- A community leader agrees to advocate for the distribution of free insecticide-treated bed nets, especially to households with pregnant women and children <5 years of age, because these are the most vulnerable.
- In the meantime, households were advised to buy locally available bed nets and treat them with approved insecticides.
- The household heads commit to identifying other areas for harvesting soil for brick making that would be away from the immediate home compounds.
- The local administration leader promises to work with the dispensary officials to access approved insecticides to fumigate the existing breeding grounds.
- The CHEW commits to providing ongoing community-based health services including health education, outreach services, and effective community–facility referrals
- One of the community nurses provides information on the causes, symptoms, and the importance of early treatment of malaria and demonstrated how to properly treat and use bed nets.

This case demonstrates highly effective, community-owned action, all spurred by one community nurse's observations and follow-up actions.

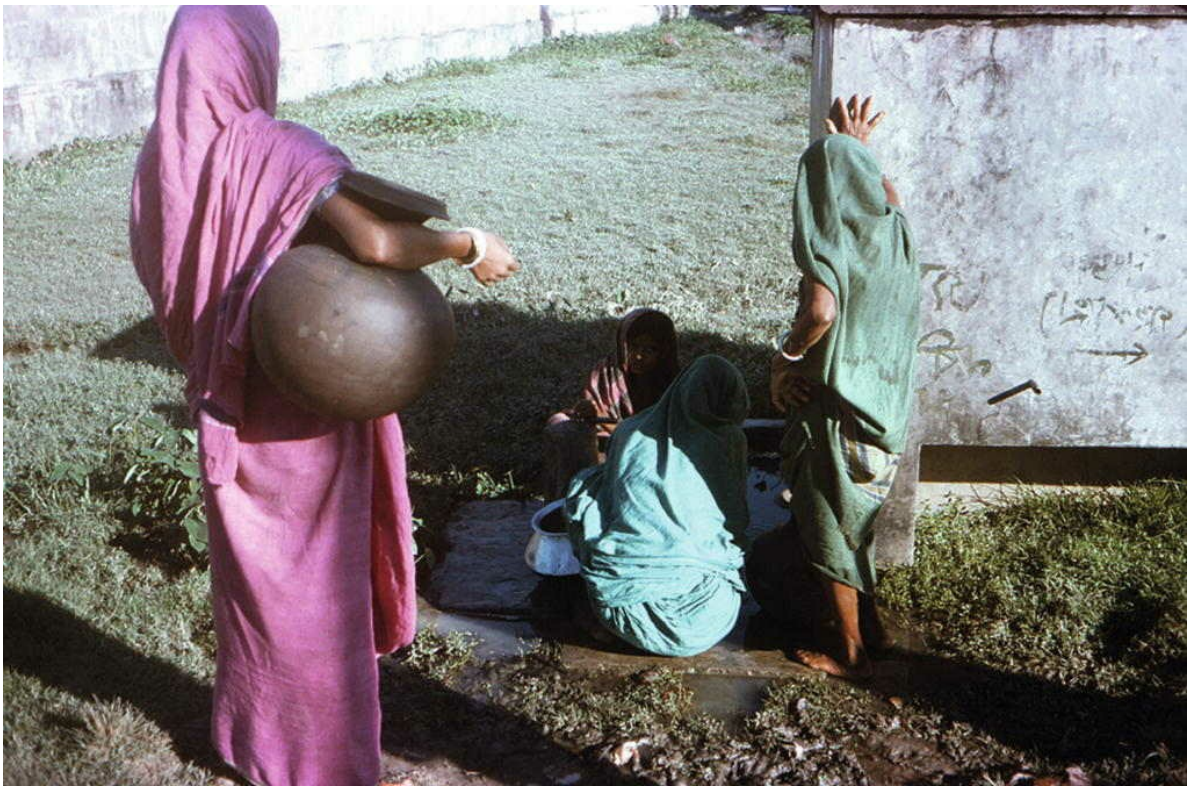
People throughout the world are affected by the impact of major developments that may occur in their communities over which they have no control. For example, populations in Ethiopia were moved from one part of the country to another as colonial rulers developed crops for their own use. In the process, they displaced farmers to other areas to grow crops about which they knew little and which were not appropriate for the soil and weather conditions. In the aftermath of a 6.9 magnitude earthquake in Armenian Soviet Socialist Republic (SSR), Union of Soviet Socialist Republics (USSR), an Italian corporation built temporary housing in the available surrounding areas. The government provided basic metal enclosures for housing that later were destroyed to provide long-term structures and roads, along with many other donations of goods and services from countries around the world (ReliefWeb, 2011).

Environmental experts have focused on these and other issues, such as the effects on communities when climate changes occur or when weather conditions affect entire regions.

The volcano eruption in Iceland, the tsunami and subsequent damage to the nuclear reactors in Japan, the tsunami in Asia, and Hurricane Katrina in the United States are examples where entire communities were swept away (National Geographic Daily News, 2011). Over the past 5 years, the international meeting on the environment held in Copenhagen, Denmark, brought these issues to the forefront as did former United States Vice President and Nobel Prize winner, Al Gore, in his focus on global warming through his provocative and moving film, *An Inconvenient Truth*. In that film, Gore examined the ways in which our current habits and beliefs are affecting the world's temperature and environmental conditions (Parker, 2014; Takepart, n.d.).

Sometimes, change is intentional and is made in the interests of survival and daily functioning. For example, when governments address energy concerns for transportation and industry, they may move to nuclear sources of that energy—clearly as an effort to secure a local resource but also with some risk. The people in New Orleans experienced the aftermath of an oil rig disaster in the Gulf of Mexico as did the people of Chernobyl who found their homes a wasteland when the nuclear plant disaster polluted the region with cesium and iodine (Boston Globe, 2011). In a follow-up meeting to the Chernobyl accident, held a few years later in the Netherlands, representatives spoke of the population's fears and actions, including possessing machines that would measure the radioactivity near their homes. This accident prompted the discussion of disaster-preparedness strategies to evacuate entire cities of people after a nuclear environmental accident.

Environmental Hazards



Environmental health is about human health as determined by physical, chemical, biological, social, and psychosocial factors in the environment. Environmental risk factors are of increasing importance and have been influences by increased urbanization, a rise of employment in informal sectors, growth of the chemical industry, increased oil consumption, and climate change (WHO, 2011). Broad categories of environmental hazards include water, sanitation, and hygiene, chemical exposure, occupational health hazards, radiation exposure, air pollution, and climate change (Maxwell, 2014). Our job, as public health nurses, is to assess, correct, control, and prevent factors in the environment that have potential adverse effects.

Water and Sanitation

Worldwide, 780 million people lack access to safe water and 2.5 billion do not have improved sanitation; the implications for health are considerable (CDC, 2015f). Up to 90% of wastewater in developing countries is discharged untreated, polluting rivers, lakes, and coastal areas (Fuhrmeister, Schwab, & Julian, 2015). In places such as Peru, Egypt, Bangladesh, India, Indonesia, and Thailand, raw sewage is released into rivers that are used for drinking and bathing. In Western Africa, parts of the ocean are contaminated with raw

sewage. Such practices often result in diarrheal diseases, including cholera. The International Centre for Diarrhoeal Diseases Control Research (ICDDR) in Bangladesh specializes in those illnesses, including cholera that results from these practices, for which residents know of no alternative.

Six to eight million people die annually from illnesses linked to unsafe drinking water, poor household hygiene, and improper human and animal waste disposal. Diarrheal diseases are the second leading cause of death in children >5 years of age, predominantly in developing countries (World Health Organization [WHO] Media Centre, 2013) (see Display 16–1, Environmental-Related Killers in Children Under Age 5). Half of the population in the poor countries of the world suffers from one or more of the five main diseases associated with water and sanitation—diarrhea, ascariasis, hookworm, schistosomiasis, and trachoma—and 35% of the world's population is without access to improved sanitation (CDC, 2015b).

Women in a Bangladeshi village getting water from a communal well. (Photo courtesy of CDC Photo Image Library.)

Millions of people worldwide are infected with neglected tropical diseases, many of which are water and/or hygiene related. Diseases such as Guinea worm disease, Buruli ulcer, trachoma, and schistosomiasis thrive where there is unsafe drinking water, poor sanitation, and insufficient hygiene practices. Improving water, sanitation, and hygiene has the potential to prevent 9.1% of the disease burden globally. Improved water sources alone can reduce diarrheal morbidity by 21%. Improving sanitation reduces diarrheal morbidity

by 37.5% (CDC, 2015e). In short, prevention is a key intervention for the public health nurse. See Display 16–1 about environmental-related child deaths.

DISPLAY 16.1 ENVIRONMENTAL-RELATED KILLERS IN CHILDREN UNDER AGE 5

- Diarrhea kills 1.6 million children each year (mainly because of unsafe water and poor sanitation).
- Indoor air pollution kills 1 million children each year as a result of acute respiratory infections (because of use of biomass fuels for indoor cooking and heating).
- Malaria kills around 1 million children, mostly in Africa (exacerbated by poor management and storage of water, deforestation, and inadequate housing).
- Unintentional physical injuries account for 300,000 annual deaths due to drowning, fires, falls, poisoning, traffic accidents, and other causes (often related to community or household hazards).

Climate Change

There is a growing body of evidence supporting global warming. Data indicate that the global average combined land and ocean surface temperature has warmed by 0.85°C between 1880 and 2012. Climate change, and the resulting variations in weather patterns, has the potential to impact our health. Predicted extreme weather events and longer-term impacts of drought are likely to lead to malnutrition and an increase in the spread of some infectious diseases such as malaria and dengue fever. Not surprisingly, the poorest and most vulnerable population are likely to experience the most dramatic impacts, often worsened by forced migration, unplanned urbanization, and contamination of air and water. Those of us in the health sector need to ensure that health facilities have access to clean energy and play our part in lowering the climate footprint of the health sector in developed countries (WHO, 2015a).

The Ozone Layer

As the challenge of a depleted ozone layer is addressed, the incidence of cataracts and cancer (especially melanoma and basal cell carcinoma) is reduced. It is believed that human activities are contributing to the depletion of the ozone layer; these activities include the use of chlorofluorocarbons (CFCs) (used in the manufacture of air conditioners, refrigerators, aerosol propellants, and other products) and methyl bromides (found in pesticides and herbicides). Efforts are under way to phase out CFCs in 13 countries, including the United States (Ozone Hole, n.d.). While the hole is still present, new ways of measuring ozone in the atmosphere and some weather changes have caused it to shrink slightly over Antarctica, thought to be a normal phenomenon of waxing and waning. But scientists are now hopeful that it may close entirely by 2070 (Heffernan, 2013).

History

If you have tea with a group of health care providers in Moscow, the conversation inevitably turns to the devastating effects of the major historical event that faced that country—World War II, or the Great Patriotic War. Despite the fact that this war occurred over 60 years ago, it remains in the collective memory of the Russian people, their leaders, and many others in Eastern Europe, as 20 million Russians died along with thousands of people in other countries. That war, and the war that involved Bosnia–Herzegovina and Serbia, will affect the health of people for decades to come and will influence the ways in which the health care systems of these countries will partner and collaborate with each other in the future (Ringdal & Ringdal, 2016).

The ways in which mental health was viewed historically was strongly influenced in England by leprosy as a reminder of death and the need to rid the community of those infected with this disease. Like lepers, the mentally ill were cast out of society. The response was to rid the community by first sending the insane outside the gates of the cities, then on ships out to sea (Ships of Fools), only later to be turned over to doctors and housed in buildings referred to as "madhouses," through a process of incarceration enforced by the law. In this way, the mentally ill became inextricably linked to law enforcement (as described in the classic book by Foucault, 1965), and this link persists today (Shimmon, 2011). This form of power was expressed through laws that controlled not only the mentally ill but the poor and the unemployed.

Throughout the past century, other forms of power and control occurred throughout the world as countries were colonized and sometimes purged of their wealth. The relationship between those colonized and their colonizers persists today. These political relationships also affect the ways in which community health nurses might be recruited and practice. For example, given a country's history, health care providers with particular nationalities or religious backgrounds might not be acceptable to a country. Whereas people in one country might consider these biases unacceptable, they remain as policy in other places, determining whether or not care providers of a particular nationality are allowed to enter and work in a country. These biases are often unexpected and may be puzzling. At first glance, one may wonder why Italy might want to support a disaster-

preparedness program in Ethiopia. But a review of the historical relationship between Italy and Ethiopia reveals a relationship that preceded the program initiative. In a similar way, for example, Chad has a past relationship with France, Mozambique with Portugal, the Congo with Belgium, Albania with Italy, and Indonesia with the Netherlands, to name just a few (MacQueen, 2014). In addition to past relationships with other countries, communities also develop within the context of other relationships as well.

Public health nurses are involved in designing and implementing projects in collaboration with international governmental organizations and NGOs. In summary, the historical context of a country is paramount as people are selected for international positions and projects, for interventions that a community is willing to adopt, and organizations are chosen to intervene in a region.

Language

Often, a language connection exists between countries, and this linkage prompts health officials to seek nurses who speak the same language. For example, common history and language often connect Mozambique, Portugal, and Brazil, which are all Portuguese-speaking countries. Many people from Mozambique immigrated to Portugal during the 1970s, and the shared historical past affects current perceptions about the two countries' relationship with each other (MacQueen, 2014). Knowing that a shared language exists among countries may suggest ways of learning about cultural practices and about gathering existing health-related teaching and learning materials and can reduce the costs of production and language validation.

Political, Cultural, Religious Practices, and Context

A country's political orientation and practices affect the ways in which community health nurses are educated and function daily. For example, in some countries, nurses and midwives were not exposed to the emerging knowledge and practices concerning the HIV/acquired immunodeficiency syndrome (AIDS) epidemic. This happened, in part, because countries whose economies depended on tourism were fearful that public knowledge of high numbers of HIV-infected people would frighten away tourists. In other countries with closed borders and totalitarian regimes, health authorities were left out of the latest information on the epidemiology of diseases. In some countries, tribal practices took precedence over protection from the virus, and in other countries, the custom of visiting brothels resulted in epidemic rates of the virus. Consequently, national health policies and announcements denied the presence of the virus, people by the hundreds were infected, and nurses and midwives were not protected as they collected blood samples, administered injections, and delivered babies. One large international study examined the differences in national response to HIV/AIDS and also noncommunicable diseases among four countries (Haregu, Setswe, Elliott, & Oldenburg, 2014). Two countries considered as upper middle-

income (South Africa, Malaysia) and two lower-income countries (Sri Lanka, Ethiopia) were evaluated for prevalence of HIV (17.3% South Africa, 0.4% Malaysia, 0.1% Sri Lanka, 1.4%, Ethiopia) and diabetes (6.5% South Africa, 11.7% Malaysia, 7.8% Sri Lanka, 3.4% Ethiopia). Researchers noted differences in process and internal constituents.

The culture and religion of a community represent the frame within which people understand who they are, why they are on the earth, and what their purposes are in life (Spector, 2013). Culture and religion influence the knowledge, attitudes, and practices of people about what they think will kill them or make them sick, will help them function or make decisions, or will affect their financial status. People in different cultures manage these in ways that may seem peculiar, ill advised, immoral, or even criminal to someone outside the society. For example, Illyes (1979), in the classic book *People of the Puszta*, discussed the cultural practice of suicide in a part of Hungary, the Puszta, where people are characterized as "dirt poor." Yet, suicide is not a socially accepted option for people in other cultures. In the Philippines, some prostitutes see their activities as simply their "daily work," not as a moral act. Efforts to dismantle the country's prostitution business have met with negative reactions from the prostitutes themselves, as this is their way of feeding their children and caring for their families. However, as younger females are becoming more involved, often as unwilling victims, there is more momentum to address this problem (Tupas, 2015).

Community health nurses will face their own beliefs when confronting female circumcision, the use of nonlicensed personnel to carry out medical treatments, and the use of Western interventions used simultaneously with local treatments. For example, in Chad, clients in a Chadian hospital received Western-style medical treatment and nursing care through the interventions of French physicians and nurses whereas lines wound around the grounds of the hospital to the offices of the two Chinese acupuncturists. In rural villages in India, untrained midwives, or *dais,* may fail to treat a fever in women during the postpartum period regardless of its etiology. Some of these alternatives are deemed helpful, whereas others have garnered mixed reviews in research studies (Das et al., 2012).

Cultural issues are of concern when individuals and groups of a particular background from one country are often fiercely committed to "helping" their homeland. Here, both donors and recipients need to understand each other and their reasons for entering collaborative relationships. When this is thought through, the results can be most positive. In this regard, Armenian communities benefited enormously from the fund-raising efforts of U.S. community health nurses and physicians who knew well the Armenian communities in Boston, parts of Canada, and Los Angeles. Similarly, the American Albanian community was mobilized after the economic collapse of Albania in 1991. The same thing occurred after the "Arab Spring" uprisings in Egypt, with calls for wealthy Egyptian Americans to help support postrevolution Egypt (Eishinnawi, 2011).

Women and Culture

Women in most societies are viewed in ways that require close scrutiny. Historically, women in Western society during the Middle Ages and the Renaissance had an incentive to marry early as they had no legal status before the courts and had to generally be represented by a male proctor (Blanton, 2014). These practices persist today in some European countries and in other parts of the world. For example, in Saudi Arabia, a male family member must accompany a female going to receive health care. Historically and today, poor women were and are particularly marginalized because of few opportunities for work. They were raised to produce children and were kept relatively secluded until marriage. If their spouses died, they had few options; typically, they entered a nunnery or prostituted themselves.

Women are seen as Madonnas, superheroes, warriors, nurturers, slaves, income producers, objects of sexual desire, concubines, negotiators, angels of mercy, and assistants. Although these characterizations may be repulsive to some, to others, women in their communities have played these roles for so long that they are considered immutable and acceptable. In many countries, nurses are exclusively women and experience these projections as they carry out their daily work. In some places, women have no or little voice and are viewed as weak or ineffectual, despite their physiological hardiness and ability to survive above their male counterparts. Kirk and Okazawa-Rey (2013) have documented the harmful economic, social, and military policies that they suggest have been imposed on the South and have wreaked havoc on U.S. working class and poor people of color as well as immigrant communities.

Community health nurses may perceive themselves as excellent practitioners with excellent theoretical and clinical backgrounds and expect to be respected for these qualities. Yet, in another country, their nursing notes may be torn up (who will read them?), their projects taken over by others (a nurse can't possibly lead a project), and their research may be published under someone else's name (anyone can write hypotheses, so what makes these so special?). In some countries, women (and nurses) are not expected to argue with authority, assume a team leadership role, or attend important meetings at high levels. In some circumstances, women have learned to succeed by the use of "feminine charm" in the workplace or to combine friendly approaches and a degree of flirtation (Kray, Locke, & Van Zant, 2012).

Globally, nurses strive for autonomy, and this is especially true when working in resource-limited settings. Research has shown the profession of nursing is viewed differently in different cultural settings. Some nurses perceive a wide hierarchical distance from physicians that promotes subservience on the part of the nurse. Other factors that have been reported as having a negative impact on professional relationships are generational differences and gender biases (Ng'ang'a & Byrne, 2015).

These are challenging situations, some of which become teachable moments. Some may be events that alter the duration of one's assignment or provide an opportunity to reframe interactions with others of differing persuasions, beliefs, and practices. Community health nurses need to determine their own position on these issues and come to terms with being

placed in subservient positions or in roles that detract from their level of academic preparation, expectations for learning and developing, and, ultimately, their sense of self. Yet, as noted below, women have played critical activist roles in the situations of crisis, conflict, and genocide.

Women carry the culture of a society, and they are inextricably linked with a country's history, conflicts, and their solutions. Here, women's issues intersect with issues of armed conflict, militarism, and their activism. In this section of this chapter, as in their lives, women provide a link between a society's culture and the wars in which the society engages. For example, Gallimore (2008) notes "women all over the African region have not only participated in, survived and resisted violent conflict, but played key roles in facilitating negotiations and peace-brokering efforts" (p. 6). Women have also joined together to campaign for an end to all violence against women and girls (Raab & Rocha, 2011).

Armed Conflict, Uprisings, Wars, and Humanitarian Emergencies

An armed conflict is defined as major if the number of deaths has reached 1,000. Increasingly, conflicts are internal rather than between states. In their quest for economic and political power, the combatants target the lives and livelihoods of civilians associated with opposing factions (Themnér & Wallensteen, 2013). Typically, armed conflicts and uprisings initially cause governments and agencies to place a high priority on health care, but their ability to sustain health care is reduced as time goes on. Countries engaged in armed conflict form internal factions, including those supporting the government and those in conflict against them. Most conflicts occur between states for economic and political power. Currently, the world is experiencing another sea change as rebel forces in Egypt, Libya, Yemen, Syria, and other countries reject the existing regimes in power. Sometimes, outside nations support a country's factions, and fighting escalates and continues until the supporting powers win, lose interest, change their political orientation, or exhaust their financial sources (Critchlow, 2015). In this regard, community health nurses need to be aware of those involved in the immediate situation and of those who are influencing the situation from abroad. In turn, funding and sustaining nursing projects may depend ultimately on a variety of factors, not the least of which is being able to participate in situations that may be a threat to the nurse's safety and survival.

Countries that have long-standing conflicts suffer as current health care needs are unaddressed, and the long-term health status of an entire country may be affected—sometimes for decades. For example, Mozambique had endured a national conflict for over two decades. Two generations of young people had no formal education and were prepared only to fight. Children were forced to be soldiers and prompted to commit horrible atrocities within their communities and often within their own families. Countries in conflict deflect resources to the battlefield, and those fighting, identified as the males in the society, receive whatever resources are available despite the fact that women and children experience extreme devastation during these times. These conflicts are extremely complex social phenomena, for which the most rooted causes are inequity, cultural and religious intolerance, and ethnic discrimination (Ringdal & Ringdal, 2016).

The health infrastructure during conflicts and uprisings becomes vulnerable because of the instability. Often, opposing factions raid hospitals and clinics. For example, during the 1989 Romanian uprising, health providers told of instances in which the underground secret police feigned injury, transported themselves in rigged ambulances, and entered the emergency room areas of the capitol's major hospitals, all in an effort to kill or wound the hospitals' health care providers. Also, refugees fleeing war-torn areas are often unable to receive adequate health care, shelter, and other necessities of life (Doocy et al., 2016).

The community interventions that nurses develop are informed by the situation and the layers of conflict that have occurred in the past and those that may be continuing (see

From the Case Files I). During national conflicts, health services become disorganized and experience decreased resources. Outside help is needed in these instances, and international help is often available. For example, during the Romanian uprising, members of WHO/EURO international disaster-preparedness team, along with the country's health officials, established an Interim Ministry of Health and identified key areas that required attention. Members of the team, including the Regional Nursing Advisor, met with NATO and COMECON ambassadors in the capitol and communicated the health needs of the population. They remained in Romania and established a WHO office, participating with groups, universities, and organizations to assist the country during this difficult period. These actions have been repeated in numerous other areas over the years as conflicts have emerged. See Perspectives: WHO Regional Advisor.

PERSPECTIVES WHO REGIONAL ADVISOR

During the war in Yugoslavia, Bosnians and Serbs worked with the European Regional Office of the World Health Organization (WHO/EURO) in Copenhagen, Denmark, to develop interventions for women and children's health. WHO/EURO developed the training program to be held in Denmark but was not certain that the roads between Sarajevo and the coast would be open and safe for travel, as snipers continued to operate out of the mountains surrounding Sarajevo and along the roads to the country's borders. The workshop the nurses, physicians, and midwives attended in Copenhagen included both Bosnians and Serbs in the breakout sessions, but the facilitator had to ensure separate dining spaces, as the workshops occurred during the latter part of the war—a time during which communications were difficult and awkward.

Marie, WHO Regional Advisor

During wars and other man-made disasters, epidemics are almost inevitable. As conflict goes on, the health care needs of the combatants often take priority over those of civilians; consequently, thousands of children may be injured, orphaned, and at risk for disease. Additionally, conflict disrupts food cultivation, harvest, and distribution, leaving populations at risk for malnutrition and setting the stage for disease. In the Syrian conflict, 6.5 million have been displaced, and infection outbreaks have increased in Syria and its neighbor countries (Sharara & Kanj, 2014). Refugees from such events have special health and social needs. Often, refugee camps are developed by international organizations on the fringe of such conflicts to temporarily assist refugees with shelter, food, and the rudiments

of health care. Such camps place a strain on the resources of neighboring countries, as illustrated during the recent conflicts in the Middle East and the civil war in Syria (Doocy et al., 2016). It is estimated that by the start of 2015, over 3.7 million Syrians had fled and another 11.6 million were considered displaced (Ostrand, 2015). Sweden and Germany had accepted the largest proportion of refugees, and many other countries also opened their borders to them.

All of these factors can lead to complex humanitarian emergencies. The CDC describes complex humanitarian emergencies as situations that involve large civilian populations and factors related to war or civil strife, shortage of necessities such as food, and the dislocation of local populations. These situations and these factors result in mortality beyond that expected under normal circumstances (United Nations High Commissioner for Refugees, 2010).

Recovery after war is a long-term project. Any postwar recovery effort must deal with the disabled, the mentally ill, prisoners, widows, orphans, abandoned children, homeless and displaced persons, refugees, and the unemployed (Levy & Sidel, 2015). In addition, livestock and domestic animals must be cared for or their carcasses buried or incinerated. These issues are complex; for example, in some African countries, if a family loses its land and its members cannot plant and harvest crops, the family has no source of food and may become malnourished—leading to death. During the long conflict in that region, many women lost their husbands and their land. They required care from others who had very little to offer them. At times, the rebel forces in conflict countries are poorly equipped and have experienced severe injuries, and they require interventions from a population also under siege.

Health Promotion

It is not enough to strive to protect individuals from disease or adverse events, but health promotion is also vital. This paradigm shift was exemplified in the Ottawa Charter for Health Promotion. The first international conference on health promotion took place there in 1986, and prerequisites were outlined: peace, shelter, food, income, education, a stable ecosystem, sustainable resources, and social justice/equity (WHO, 2016o). The participants acknowledged that individuals create their health each day as they care for themselves and others. The conference ended with this pledge to:

- Move into the arena of healthy public policy and to advocate a clear political commitment to health and equity in all sectors
- Counteract the pressures toward harmful products, resource depletion, unhealthy living conditions and environments, and bad nutrition and to focus attention on public health issues such as pollution, occupational hazards, housing, and settlements
- Respond to the health gap within and between societies; to tackle the inequities in health produced by the rules and practices of these societies; to acknowledge people as the main health resource; to support and enable them to keep themselves, their families, and friends healthy through financial and other means; and to accept the community as the essential voice in matters of its health, living conditions, and well-being
- Reorient health services and their resources toward the promotion of health and to share power with other sectors, other disciplines, and, most importantly, people themselves
- Recognize health and its maintenance as a major social investment and challenge and to address the overall ecological issue of our ways of living (WHO, 2016o, p. 3)

At the fourth international conference on health promotion in 1997, the Jakarta Declaration on Leading Health Promotion Into the 21st Century was developed (WHO, 2016i). This was the first health promotion conference held in a developing country (Jakarta, Indonesia). Participants acknowledged "health is a basic right and is essential for social and economic development" (p. 1). They noted that comprehensive approaches are most effective, that specific settings (e.g., workplaces, schools, cities, health care facilities) are best for implementation of these strategies, and that individual participation is critical and can be facilitated by proper information and education. Priorities for 21st century health promotion include the following:

- Promote social responsibility for health.
- Increase investments for health development.
- Consolidate and expand partnerships for health.
- Increase community and empower the individual.
- Secure an infrastructure for health promotion (p. 3).

Governments were called on to promote health within their own countries and work together to create alliances, and this was again emphasized at the Global Conference on Health Promotion (8GCHP) held in Helsinki, Finland, in 2013. This conference promoted the concept to *health in all policies*: a drive to inspire countries to think about health as they refine policies within all sectors.

Many countries have agencies that promote health within their boundaries and assist in health and development in other countries (e.g., Canadian International Development Agency [CIDA], National Primary Healthcare Development Agency [NPHCDA] in Nigeria, U.S. Centers for Disease Control and Prevention [CDC]). NGOs from many countries also work together to promote health and assist in community development (e.g., Aga Khan Development Network, Oxfam, Project HOPE).

Health Care Systems

Countries throughout the world have developed health care systems that they organize and structure in particular ways. When community health nurses find themselves in locations different from their own, they notice differences immediately, and their ability to practice within the context of these different ways of delivering health care services is critical to their success. The capacity to reflect on one's consciousness is an essential skill as one considers the ways in which people expect to govern others, provide people with what they need, determine who gets served and who does not, establish lines of authority and communication, and establish payment systems for health care services.

Important questions arise as one delivers community health nursing services within a country's health care system. For example, if a client has to wait 6 months for elective surgery, what does he or she do in the meantime? If a government provides all prenatal and obstetrical services but will not instruct couples on birth control, how do couples manage, and how do health authorities deal with prevalent practices that result in an abortion rate that is three times the birth rate (as documented in a classic article by Farrell et al., 1994) or that allow *under the table* reimbursement for these services? If a ministry of health is administered through a centrally governed model of decision-making, how do decisions get made that require local rather than district or national answers? If a local nursing group is interested in developing community health nursing standards of practice, and yet all nursing actions are reviewed by only a medical board of physicians, on what are the nursing standards based?

Pluralistic health care systems are found in many countries (see Chapter 6). They often consist of traditional healing systems, lay practices, household remedies, transitional health workers, and practitioners of Western medicine (Davis, Stremikis, Squires, & Schoen, 2014). Traditional healing may be all that is available to populations in some rural areas and in some cities.

Western medicine was introduced to some countries during colonial times, and systems were operated either by colonial administrations or by missions. After independence, health systems tended to vary in their development. Some continue their colonial practices; others followed tax-financed government insurance or socialist health care systems (Davis et al., 2014).

During the second half of the 20th century, curative health care expanded rapidly in urban areas, and the level of health care was raised in those areas. In the late 1970s, many countries adopted the PHC approach and the WHO regions of the world developed their own set of targets, for example, in the United States, *Healthy People 2000*, followed by *Healthy People 2010*, and now *Healthy People 2020* (USDHHS, 2016); through regional consultation, WHO (2016m) member states developed objectives and targets for its *Health 2020*. Throughout the world, countries used this approach to serve their urban and rural populations. Four major types of health care systems are currently operational throughout

the world. These systems are entrepreneurial, welfare-oriented, comprehensive, and socialist systems.

- *Entrepreneurial health care systems*. A country's health care system is based, in part, on its political economy. An entrepreneurial health system is typically found in industrialized countries with free-market economies, abundant resources, large amounts of money allocated to health care, and decentralized governments. These countries operate from a highly individualistic perspective. For example, the health care system in the United States is typical of the entrepreneurial system (Shi & Singh, 2016).
- *Welfare-oriented health care systems*. Statutory programs drive these systems that support the cost of health care for all, or almost all, of the population through their "national health insurance." In these, half of the health-related expenditures are covered by government sources, but most physicians and dentists remain in private practice. Western Europe, Japan, and Australia subscribe to welfare-oriented health care systems (Davis et al., 2014).
- *Comprehensive health care systems*. These systems are a step away from the welfare-oriented types in that substantial modifications exist in delivery and financing that result in universal entitlements. These systems abandon the separate and complex sources of financing found in the previous two systems. The Scandinavian countries, Great Britain, and New Zealand use a comprehensive health care delivery system (Davis et al., 2014).
- *Socialist health care systems*. These systems came about through social revolutions that abolished free-market economies and replaced them with socialism, in which the health care system is also socialized. The first overthrow of capitalism was in Russia in 1917, followed by Eastern Europe, Albania, Bulgaria, Czechoslovakia, Hungary, Poland, Romania, and later China, Cuba, and Korea. In these systems, health services were viewed as a social entitlement and a government responsibility. They emphasized prevention and engaged in central planning for health resources and services with one central health authority. They also prioritized special groups, such as industrial workers and children, and based health care work on scientific principles. Nonscientific and cultist practices were not permitted. Many of these countries have begun the process of democratization and redesign of their administrative and health care systems (Liebert, Condrey, & Goncharov, 2013).

The four health systems described above apply to industrialized countries. The renowned health system researcher Roemer (1993) used the same typology for transitional and very poor countries. Countries that are in the process of development are referred to as "transitional." Such countries and their health care systems are moving effectively toward economic and social development. The global median gross domestic product (GDP) of these countries was $1,500 per capita. It should be noted that some might object to this classification system that considers being financially poor synonymous with being socially

underdeveloped. This suggests a bias in thinking and a Western perspective that determines what is "developed" and what "needs developing."

Very poor countries are even less economically developed and have lower per capita GDPs than do the industrialized or transitional countries. Areas classified by the World Bank Group (2016) as poor have a large proportion of their population living on $1.90 or less per day. Some countries in sub-Saharan Africa have almost 43% of their population that meets this standard, as do almost 40% of people living in areas of conflict. South Asian regions have almost 19% of the population falling into this category.

Trends Affecting Health Care Systems

Health care systems are affected by major social factors such as urbanization, industrialization, education, government structure, international trade, and demographic changes. Many national health systems have undergone major changes during the last few decades of the 20th and into the 21st century. Specifically, these health care systems have changed the way they organize and are managed. For example, in England, health care has traditionally been provided through the National Health Service. People who can afford to pay for services outside the system are becoming more prevalent. Some health care systems that were totally funded by national health services are moving toward privatization of their services, whereas the United States has moved toward health care reform. See Chapter 6 for more on health care systems.

Health care systems also expanded their resources and added personnel, facilities, and equipment. Meanwhile, populations grew, migrated, and became more educated. They demanded more and better health care services. Over the past decade, hospitals worldwide have shifted to outpatient services and home care, expanding the roles and positions of community health nurses. Currently, in the United States, this trend has resulted in the closing of small community hospitals, to the consternation of many residents of smaller towns and rural areas (Tribble, 2011).

Hospitals in Denmark benefited from a surgical procedure for hip replacement that would allow a patient to be discharged from hospital to home in a much shorter time period than previously experienced. This meant that home care had to be ready to accept the patient within an abbreviated time frame, thus requiring innovations in discharge planning and teaching protocols. In addition to these advances, the PHC movement supported efforts to reduce the number of hospital buildings and to increase community-based nursing services (Husted et al., 2011).

Technological advances occurred to support this move, and ways of thinking about health promotion emerged with a variety of quality measures and, more recently, evidence-based practices that support nursing interventions on an outpatient basis and at lowered costs. The depopulation of some communities and the increasing number of empty beds has also been related to these closings.

Most importantly, people have begun to educate themselves through the use of the

Internet. Ministries of health are training community care workers in communication, observation, and technical skills for telehealth systems that link remote areas to academic health centers. For example, a health center in Almaty, Kazakhstan, is now connected through the Internet, even though it began as a relatively isolated center in what was referred to as Alma-Ata. Now, groups with relatively rare health care conditions can receive support and information from others in parts of the world formerly unknown to them. See Chapter 10 for more on technology and telehealth.

THE POPULATION

The populations that community health nurses serve are complex and include clients' concerns, values, beliefs, physical symptoms, and health history. As described earlier, the framework that provides some boundaries for considering these issues focuses on context, the three eras of health conditions, and the universal imperatives of care.

Era of Infectious Diseases

Infectious diseases and conditions have killed people, made them sick, altered their daily functioning, influenced their decision-making, and affected the costs of care. Thus, these infections and infectious processes involve all the universal imperatives of care but do so differently, depending on a variety of factors (Davies, 2012). These factors include the climate, geography, and other conditions infectious organisms need to survive and thrive and the populations the infectious agents invade–often infants and children. Surveillance and response networks are key to containing infectious diseases, and this can be difficult for countries with underfunded health systems to accomplish. Thus, it is not surprising that 83% of all worldwide deaths in children younger than 5 years are due to infectious diseases, nutrition, or neonatal conditions. A good percentage of the almost 6 million deaths in children below the age of 5 in 2015 were due to infectious diseases (WHO, 2014b, 2016e). Three of the ten leading causes of death are communicable diseases that largely affect children. Most of these are preventable.

Almost 200 nations, and all member states of the World Health Organization (2016n), agreed to International Health Regulations (IHRs) regarding surveillance and notification about infectious diseases that may spread globally. Public Health Emergencies of International Concern (PHEIC) procedures clarify steps countries need to take in order to comply with the IHRs. Some of these include not only controlling borders but containing the source of infectious diseases and all public health threats, as well as allowing for adaptive responses (Davies, 2012). Three categories of concerns include:

1. Cholera, pneumonic plague, yellow fever, viral hemorrhagic fevers (Ebola, Lassa, Marburg), West Nile fever, and others of specific regional concern (e.g., dengue fever, Rift Valley fever, meningococcal disease)
2. Unusual or unexpected outbreaks and especially the following diseases: poliomyelitis, SARS, new human influenza subtype, and smallpox (all require immediate notification)
3. Novel outbreaks of diseases not noted above (Davies, 2012, p. 698)

The major preventive measure, immunization, is described here, followed by brief descriptions of some of the major infectious diseases. (See Display 16–2 for global death rates by selected causes worldwide.)

DISPLAY 16.2 GLOBAL DEATH

RATE PER 100,000: SELECTED CAUSES, 2013

Causes	2013 Death Rate	Median % Change From 1990
All Causes	879.7	–24.2
Communicable, maternal, neonatal, and nutritional diseases	172.2	–40.5
Diarrhea, lower respiratory infections, and other common infectious diseases	72.4	–49.4
Malaria and neglected tropical diseases	13.9	–24.9
Noncommunicable diseases	637.5	–18.6
Neoplasms	133.8	–14.7
Cardiovascular disease	293.2	–22.0
Chronic respiratory diseases	73.0	–30.4
Neurological disorders	35.0	2.3
Behavioral health disorders	4.0	–5.7
Diabetes, urogenital, blood, and endocrine diseases	48.3	14.4
Injuries	70.0	–21.0

Adapted from Global Burden of Disease Mortality and Causes of Death Collaborators. (2015). Global, regional, and national age-sex specific all-cause and cause-specific mortality for 240 causes of death, 1990–2013: A systematic analysis for the Global Burden of Disease Study, 12013. Lancet, 385, 117–171.

Immunization

The CDC estimates that vaccines prevent 2.5 million deaths among children younger than 5 years of age every year. Regardless, one child dies every 20 seconds from a disease that could have been prevented by a vaccine (CDC, 2015d). Vaccines are one of the most cost-effective interventions found in public health. Today, almost 75% of the world's children are being reached with essential vaccines, but many barriers make it difficult to maintain high levels of immunization in low- and middle-income countries. Scaling up vaccines in 73 of the poorest countries by 2020 could have 6.4 million lives and $6.2 billion in treatment costs and $145 billion in productivity losses (UNICEF, 2014).

Historically, a lot has been accomplished: smallpox has been eradicated; polio is close to being eradicated; measles deaths have declined by 75% since 2000; and deaths from maternal/neonatal tetanus dropped by 90% over the past 20 years.

Barriers persist and include limited finances, lack of trained health care workers, physical obstacles to reaching remote areas, and civil wars; these factors have prompted the development of an interagency vaccine initiative, which is now called GAVI—The Global Alliance (formerly the Global Alliance for Vaccine and Immunization). This initiative seeks to protect every child against vaccine-preventable diseases (WHO, 2016d). Strategies include funding, research, development, distribution of vaccines, and program sustainability. These approaches are expected to result in more immunized children and to move newer vaccines into developing countries more quickly. See Chapter 8 for more on vaccine-preventable diseases.

Measles

Measles is a vaccine-preventable communicable disease. In 2014, the number of measles deaths was 114,900. The largest number of deaths—95%—occurred in low-income countries with inadequate health infrastructures (WHO Media Centre, 2015e). The intervention considered to have the greatest impact in reducing measles is the integrated management of childhood illness (IMCI). This intervention promotes wide immunization coverage, rapid referral of serious cases, prompt recognition of secondary conditions, improved nutrition including breast-feeding, and vitamin A supplementation. Three main foci include improving health systems and case management skills, along with community and family health practice improvement. A WHO/UNICEF Measles Mortality Reduction and Regional Elimination Strategic Plan sought a 50% reduction in measles mortality worldwide by 2005—hoping eventually to eradicate the disease. Measles deaths actually fell worldwide by 79% between 2000 and 2014 worldwide (WHO Media Centre, 2015e).

Poliomyelitis

In 1988, there were 350,000 cases of poliomyelitis (polio) in the world. By 2013, there were only a total of 407 cases worldwide (CDC, 2014). Polio is now almost eliminated worldwide, even in densely populated and war-torn countries. Since the inception of the Global Polio Eradication Initiative, cases have fallen dramatically and there are now only three polio-infected countries remaining: Afghanistan and Pakistan (Global Polio Eradication Initiative, 2016). Still, as long as a single child remains infected with polio, children worldwide are at risk. The CDC, WHO, UNICEF, and many national governments support the Global Polio Eradication Initiative.

Pandemic Influenza

The World Health Organization, in cooperation with many other agencies, prepared for the 2009 to 2020 H1N1 influenza pandemic. The United States has a pandemic influenza plan (see http://www.hhs.gov/pandemicflu/plan/) that outlines public health and medical support, guidance for state and local health departments, and an operational plan for the U.S. Department of Health and Human Services. The response to this novel virus may have seemed too many to be an overreaction— this was simply "the flu." But an H1N1 virus was responsible for the 1918 influenza pandemic that killed over 50 million people worldwide (much more than the 16 million lost in World War I), and it appeared without warning in late spring. It surfaced again in fall and was much more virulent, with some victims dying "within hours of their first symptoms" (National Archives and Records Administration, n.d., para 3). Young adults, along with children and the elderly, were most susceptible to complications and U.S. life expectancy "dropped by 12 years" during 1918 (para 4).

Because of this earlier pandemic experience with H1N1, WHO issued worldwide

cautions and preparations, and scientists raced to produce enough specific vaccine to meet global demand. Researchers ran statistical models to predict transmissibility and control measures. Even though more recent reexaminations of preserved lung tissue samples from soldiers who died of influenza in 1918 found a majority of deaths due to bacterial pneumonia secondary to the flu, it was deemed important to take precautionary measures. This bacterial agent is commonly found in the nose and throat, but as H1N1 obliterated cells lining the bronchial tubes and lungs, it invaded the lungs causing pneumonia (Kash et al., 2011). Although we now have antibiotics to combat influenza complications, a pandemic of influenza can still wreak havoc on economies and societies. While WHO noted almost 18,500 laboratory-confirmed deaths from the 2009 to 2010 H1N1 flu epidemic, many believe that the actual number of deaths was closer to over 200,000 or more (Knox, 2013). The numbers are confusing, and this pandemic behaved very differently from most others; it had very varied responses in countries around the world. Whereas high numbers of deaths were not reported in Europe, Australia, and New Zealand, countries in the Americas were hit fairly hard. Even neighboring countries, like Chile and Argentina, had very different levels of severity and researchers have a difficult time explaining these regional variations. What was apparent, however, were the unusually high number of deaths among pregnant women and otherwise healthy children, teens, and young adults (Knox, 2013).

Diarrheal Diseases

Diarrhea is defined as the passage of more than three loose or liquid stools during a 24-hour period for individuals older than 3 months of age. The incidence of diarrheal diseases is somewhat elusive because it depends on the definition of diarrhea used, the frequency of surveillance, and the population. Sometimes, public health professionals use the term *diarrhea* to mean dysentery, although the latter is usually characterized by the presence of blood in the stool, with or without looseness or specified frequency. Diarrheal disease is the second leading cause of death in children <5 years of age even though it is preventable and treatable. The actual cause of death is generally severe dehydration and fluid loss. Children who are malnourished or immunocompromised are most at risk. The risk is highest among infants who are not breast-fed, and 88% of deaths associated with diarrhea poor sanitation, unsafe water supplies, or inadequate sanitation. Acute diarrhea due to rotavirus is responsible for 40% of hospitalizations for diarrhea in children under age 5 (CDC, 2015f). Each year, an estimated 1.2 million children die from diarrhea and related illnesses (Rehydration Project, 2016).

Reductions in mortality rates have occurred, and many international agencies and groups are working to make water safer to drink and to provide rotavirus vaccines for at-risk populations. One international nonprofit agency, PATH, has worked collaboratively with communities to provide low-cost rotavirus and pneumococcal vaccines and low-cost water treatment and storage products to low-income populations in India and Africa (and other countries) who have a higher burden of diarrheal diseases, pneumonia, and

malnutrition (PATH, 2015). Actions need to prevent diarrheal disease include community programs that promote personal and domestic hygiene (especially hand washing), water supply and sanitation facility improvements, promotion of breast-feeding and improved weaning practices, zinc treatment, and immunizations for cholera, measles, and rotavirus (PATH, 2015). Oral rehydration therapy (ORT), or the use of oral rehydration salts (ORS) are used to prevent or correct dehydration (not to treat the source of the diarrheal illness). A program to provide services of CHWs in three Indian states resulted in over 3 million children between 2 and 59 months reported and 84% were treated with both ORS and zinc. Researchers felt that CHWs could deliver timely care and appropriate supplies to deal with diarrheal illness (Kumar, Roy, & Dutta, 2015). ORS packets are available, but you can also make it yourself. See Display 16–3 for more information on this.

DISPLAY 16.3 HOW TO PREPARE HOMEMADE ORAL REHYDRATION SOLUTION (ORS)

- If ORS sachets are available: dilute one ORS sachet in 1 L of safe water.
- Otherwise, make your own:
- Use 1 L of safe water (clean or boiled and then cooled)—about 5 cups—and add:
  Salt—2.6 g (1/2 level teaspoon)Sugar (anhydrous glucose)—13.5 g (2 3/4 teaspoons)Potassium chloride—1.5 g (1/3 teaspoon)Trisodium citrate, dehydrate—2.9 g (1/2 teaspoon)
- Home remedy for watery diarrhea:
  ½ to 1 cup precooked rice baby cereal (or 1½ tablespoon granulated sugar)2 cups water½ teaspoon salt

Note: Solutions should not taste saltier than human tears. Extra liquids are needed until diarrhea ceases.

From Rehydration Project. (2016). Oral rehydration therapy. Retrieved from http://rehydrate.org/ors/ort.htm

Wide implementation of seven preventive interventions: improved water sources; improved sanitation and household water treatments; exclusive breast-feeding for the first 6 months; hand washing with soap; good personal and food hygiene; health education; and rotavirus vaccination. Treatment interventions include oral rehydration salts, zinc supplements, rehydration with intravenous fluids in cases of severe dehydration, nutrient-

rich foods, and seeking early treatment from a health professional (WHO Media Centre, 2015d).

Acute Respiratory Tract Infections

The most common illness in the world and a leading cause of mortality is acute respiratory tract infection (ARI). Pneumonia is the leading cause of death in children under 5 years of age, claiming nearly 1 million children annually. It is treatable, especially when caught early, and simple interventions such as vaccines, good nutrition, safe hygiene practices, and improved indoor air quality can help reduce the impact (Nair et al., 2013). Risk factors include low birth weight, poverty, crowding, lower educational levels, poor nutrition, inadequate childcare practices, a lack of health education about ARI, and delays in seeking treatment. Additional risk factors include smoking and indoor and outdoor air pollution. Indoor air pollution is much higher among villages in poor areas than in homes in those countries of the world where people smoke. The source of pollution is largely indoor cook stoves that use organic fuel. Indoor cooking stoves kill 2 million people annually more than malaria (Sheridan, 2011). The risk of pneumonia is doubled with exposure to indoor air pollution (Burki, 2011). A threat to the reduction of pneumonia, however, is the increase in drug-resistant organisms. Measures to better control ARI include immunizations, birth spacing, and improvement in nutrition and living conditions (including use of smokeless cooking stoves). A global commitment to reduce ARI was realized by a resolution at the World Summit for Children in 1990 that called for a one-third reduction in deaths from the condition. The current trend is addressing community education to encourage mothers to seek care and treatment early and to empower CHWs to diagnose and treat signs of pneumonia early.

Human Immunodeficiency Virus Infection and Acquired Immunodeficiency Syndrome

HIV has claimed the lives of more than 34 million people so far. An estimated 36.9 million people worldwide are living with HIV by the end of 2014, with 1.2 million people dying from HIV-related causes globally. Sub-Saharan Africa accounts for nearly 70% of global new infections, with 25.8 million people living with HIV in 2014 (WHO Media Centre, 2015a).

Although there remains no cure for HIV infection, effective treatment can control the virus so people can live productive lives. Treatment also helps prevent transmission. Current trends in HIV prevention, treatment, and care focus on early testing, so people know their status and can take measure to either remain HIV negative or take measure to prevent transmission. HIV is diagnosed through rapid diagnostic tests that provide results the same day. Once HIV-positive status is known, treatment with antiretroviral therapy (ART) is initiated. Nearly 16 million people living with HIV were receiving ART globally as of mid-2015. Concurrent assessment and treatment for possible TB infections and

prevention of mother-to-child transmission are also important interventions that have proved successful in improving health outcomes and reducing transmission to newborns. New HIV infections fell by 35% between 2000 and 2015, with 7.8 million lives saved as a result of global initiatives implementing evidenced-based practices (WHO Media Centre, 2015a).

The virus attacks young adults in productive age groups, requiring older people to care for and support their terminally ill adult children and, later, their orphaned grandchildren. Often, these elders are themselves impoverished and in poor health and are left without caregivers when they require assistance in their later years. For a time, the HIV/AIDS epidemic upset and destabilized entire societies in Africa, until medications were made available to make this more of a chronic illness than a death sentence (Kincaid, 2012; Smith, 2012). Reduced productivity of adult workers and early death are counterproductive to economic and social development.

LEVELS OF PREVENTION PYRAMID

SITUATION: Prevent acute respiratory tract infections (ARIs) in children in developing countries.

GOAL: Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest possible potential is restored.

TERTIARY PREVENTION		
Rehabilitation	**Primary Prevention**	
	Health Promotion and Education	*Health Protection*
• Restore child to optimal level of functioning through the recovery period.	• Continue to promote educational programs and individual teaching regarding practices that promote health and prevent diseases among family members.	• Educate on the prevention of recurrence and spread of disease.

SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
• Get a prompt diagnosis of an acute ARI.	• Collaborate with families to combine the best of folk and home remedies with established Western medical practices. • Diagnose and treat early • Provide culturally appropriate symptomatic care. • Teach caregiver signs and symptoms of complications.

PRIMARY PREVENTION	
Health Promotion and Education	**Health Protection**
• Promote general health education among community members. • Good prenatal care • Advocate breast-feeding, child spacing, and adequate nutrition. • Teach good hygiene and childcare practices. • Teach when to seek medical attention. • Eliminate poverty and household crowding.	• Administer appropriate immunizations. • Eliminate indoor contaminants such as smoke from cook stoves without chimneys and cigarette, cigar, or pipe smoking. • Ventilate rooms to eliminate indoor smoke and allow fresh air in.

Tuberculosis

TB is an infectious disease caused by the tubercle bacillus. The disease has been known for hundreds of years and was commonly referred to as *consumption*. The causative organism has become resistant to the medications used to treat it, and currently, a worldwide TB epidemic is under way. One third of the world's population is thought to be currently infected, but only 5% to 10% of those become ill or can spread this to others within their lifetime. In 2014, 9.6 million people fell ill with TB and it is estimated that 1.5 million people died from TB, with the highest number of deaths in Africa (50 per 100,000). TB is one of the illnesses that disproportionately affects poor people around the world, and it is estimated that the largest number of new cases of TB in 2008 were in Southeast Asia (WHO Media Centre, 2015h). Drug-resistant TB is a problem around the world. Globally, 480,000 people developed multidrug-resistant TB and the CDC estimates that there are a half a million new cases each year. In December 2015, President Obama announced the National Action Plan for Combating Multidrug-Resistant Tuberculosis, which provides urgent guidance for rapid, focused action. Although great progress has been made in tackling TB, MDR-TP threatens to reverse this progress and is a growing global health concern (CDC, 2016). WHO began the Stop TB Strategy in 2006, and 41 million people have been treated using drug-observed therapy (DOTS). The newly adopted Sustainable Development Goals seek to end the TB epidemic by 2030 (WHO, 2013c).

Tuberculosis and Human Immunodeficiency Virus

TB alone is a pernicious illness. When TB and HIV occur in one individual, the combination is lethal, with each speeding the other's progress. TB is the leading cause of death among people who are HIV positive (WHO Media Centre, 2015h). In 2015, TB was the cause of one in three deaths among HIV-positive populations.

Malaria

Malaria is a disease caused by the presence of the protozoan parasite *Plasmodium* in human red blood cells; the parasite is usually transmitted to humans by the bite of an infected female *Anopheles* mosquito. Fifty percent of the world population lives in malaria endemic areas. About 214 million new cases and 438,000 deaths occur per year because of malaria, most are among African children; however, mortality rates dropped by 66% over the last 15 years in all age groups from this region (WHO Media Centre, 2015i). As we have seen with other diseases, sub-Saharan Africa carries a disproportionately high share of the global burden, with 89% of malaria cases and 91% of malaria deaths in 2015 (WHO, 2015b). Those most at risk are young children, pregnant women, and people living with HIV. Malaria is resistant to multidrug therapy (MDT), and the mosquito, its tenacious vector, persists. Malaria is highly endemic in some areas, and its eradication depends on pesticides such as DDT. In addition, human and economic resources are not available to fully implement a malaria program. Perhaps, the major contributors to lack of success have been failure to integrate the malaria eradication effort into basic health services, inadequate efforts to exploit the effective involvement of communities, and the absence of political will. Also, climate has been shown to exacerbate malaria prevalence in one area of East Africa. Using predictive models, researchers found larger observed changes in malaria cases beyond the number expected by their predictive model and noted that climate change had an impact (Alonso, Bouma, & Pascual, 2011).

Current strategies to control malaria include community education programs, vector control (indoor and outdoor spraying to destroy mosquitoes and larvae), source detection through surveillance, early treatment-seeking behaviors, and reducing contact with mosquitoes through protective clothing and sleeping under insecticide-treated mosquito nets. In 2015, it was estimated that 55% of the population in sub-Saharan Africa were sleeping under the protection of these nets, up from 2% in the year 2000. Also, better and quicker diagnostic testing helps to discern malarial versus other nonmalarial fevers so that treatment can begin quickly; Artemisinin-based combination therapies (ACTs) have been used for the past decade and been found to be highly effective against the most common form of malaria. ACT, along with residual spraying inside homes and insecticide-treated mosquito net, have been the most impactful in preventing new cases—estimated at about 68% (WHO Media Centre, 2015i).

Over 500 partners, along with WHO, launched an initiative entitled the Roll Back Malaria (RBM) Program, which coordinates a worldwide action plan against malaria, and

in 2015, a new 15-year plan for control of malaria in endemic regions was launched. Fifteen countries, largely in Africa, have the highest rates of malaria deaths (78%), and malaria cases and deaths have been slower to drop in these countries often due to health systems that are less than highly effective (WHO Media Centre, 2015f). There is currently no licensed malaria vaccine, but one research vaccine is being evaluated in seven African countries (WHO, 2015b). As with TB, malaria disproportionately affects the poor, and it has damaging effects on the economies of many poor countries.

West Nile Virus

WNV (*flavivirus: Flaviviridae*) is considered the most widespread *arbovirus* worldwide and is most often transmitted to humans through the bite of an infected mosquito (Moser, Lim, Styer, Kramer, & Bernard, 2015). This virus may cause a fatal neurological disease, but most of those individuals infected do not demonstrate any symptoms. In those that develop West Nile fever, symptoms often are comprised of fever, body aches, nausea and vomiting, headache, fatigue, and sometimes skin rash and enlarged lymph nodes. The severe disease, often termed West Nile encephalitis, is characterized by symptoms of headache, stiff neck, stupor, high fever, disorientation, coma, tremors, paralysis, and seizures. WNV can cause severe illness and death in horses, and contact with infected animals, their tissue or blood, can also be a source of transmission. It was first identified in the West Nile area of Uganda in 1937 and is commonly found in Africa, the Middle East, Europe, West Asia, and now North America. Birds are natural hosts (crows and jays may become ill and die), and mosquitoes most often transmit the infection from birds to humans. Sites for outbreaks are often on major migratory routes for birds (CDC, 2015e, 2015f, 2015g).

No vaccine is available for humans, but there is one for horses. Treatment is most often supportive in nature (e.g., IV fluids, hospitalization). Active animal surveillance and early warning from veterinarians and public health officials are being used to prevent transmission. Education and reducing mosquito transmission (e.g., use of nets, spraying, eliminating mosquito breeding sources) are also being used (WHO Media Centre, 2011). Research continues to find treatment for this illness and other mosquito-borne viruses such as yellow fever and dengue fever (Brecher et al., 2015).

Leprosy

Leprosy is a chronic granulomatous infection caused by *Mycobacterium leprae* (Hansen's bacillus). It affects various parts of the body including the skin of the face and the eyes and causes progressive and permanent damage even though it is not easily transmitted (WHO Media Centre, 2015b). In 2013, the prevalence was 180,618 cases for all types of leprosy. The World Health Organization (WHO Media Centre, 2015b) provides multidrug therapy (MDT) for this condition free of charge to all those infected. People with leprosy have had access to this free effective drug treatment since 1995. Communities can help eradicate this disease through proper diagnosis and treatment and provision of care without stigma or isolation. A change in the image of leprosy, so that people with the condition will

more readily present themselves for treatment, is essential. Leprosy was considered eliminated around the world in 2000, because the prevalence rate of leprosy was <1 case per 10,000 persons globally. Over the past 20 years, nearly 16 million cases have been cured with MDT (WHO Media Centre, 2015b).

Guinea Worm Disease (Dracunculiasis)

Dracunculiasis, or guinea worm disease, is a parasitic disease that is transmitted to humans when a person drinks water containing a worm's intermediate host, a water flea that can ingest and harbor guinea worm larvae. Once in a human body, the larvae migrate through the tissue and the mature adult worm attempts to emerge, usually from the lower leg. Farmers are the most commonly affected. Although there is no cure, once the larvae are ingested, the eradication strategy includes interruption of transmission, surveillance, health education, and certification (Carter Center, 2016).

Guinea worm disease is nearly eradicated with incidents of Guinea worm reduced by more than 99.99% with only 22 cases in 2015. The Carter Center is an organization dedicated to the complete eradication of guinea worm and continues to work in the four remaining endemic countries of Chad, Ethiopia, Mali, and South Sudan (Carter Center, 2016).

Era of Infectious Disease and the Universal Imperatives of Care

The infectious diseases and processes carry the potential for death, illness, and compromised functioning but when addressed promptly can be prevented. When left unmanaged, they can result in sickness and lifelong consequences to daily functioning. Some of these conditions involve decision-making. For example, when national governments do not provide clear national policies or funding for immunization programs, entire populations are at risk for the consequences of diphtheria, pertussis, typhoid, measles, and polio. When families and communities are living in areas with infectious agents, or do not clear their land as needed, their members are exposed to malaria (Kremer, Leino, Miguel, & Zwane, 2011). When community health programs do not include sanitation and the building of latrines, the result is diarrheal diseases that affect an entire community (Turley, Saith, Bhan, Rehfuess, & Carter, 2013).

Eradication, Elimination, and Control of Communicable Diseases

The primary global health goals related to communicable disease are eradication, elimination, and worldwide control. Eradication means interruption of person-to- person transmission and limitation of the reservoir of infection so that no further preventive efforts are required; it indicates a status whereby no further cases of a disease occur anywhere. At times, the term elimination is used when a disease has been interrupted in a defined geographic area. In 1998, disease elimination was first defined as a reduction of prevalence in a certain area to zero, and disease eradication as a permanent worldwide incidence of zero (WHO, 2016b). In contrast, the term control indicates that a specific disease has ceased to be a public health threat. Control programs are aimed at reducing the incidence and prevalence of communicable and some noncommunicable conditions.

Although eradication is always the desired effect, extensive funding and much international cooperation are usually required to achieve such a goal (see What Do You Think?). The successful eradication of smallpox from the world came about because of the leadership of the WHO, and it was a tremendous accomplishment in public health. In 1959, several countries proposed the global eradication of smallpox, but progress was slow. The Intensified Smallpox Eradication Programme began in 1967, when smallpox was endemic in 31 countries, with 10 to 15 million individuals infected. Through enhanced surveillance and *ring vaccination* to prevent transmission between humans and control epidemics, progress improved. New cases were quickly identified and quarantined, and their close contacts were vaccinated and quarantined. Remarkably, by 1980, there were no cases in the world (Global Alert and Response, 2010). Clearly, if global eradication programs are to be successful, collaboration and partnerships are essential. The Global Outbreak Alert and Response Network helps to coordinate responses and deal with

outbreaks (Mackenzie et al., 2014). Control of river blindness (onchocerciasis—the chief cause of blindness in many African countries) joined the growing list of global public health accomplishments (WHO, 2016k). These programs are dependent on commitment from involved governments, international bodies, NGOs, and the affected communities themselves. Global eradication and elimination programs that are close to meeting the goal include poliomyelitis and guinea worm disease. Eradication programs for measles are continuing. Additional major efforts have increased to reduce, control, and prevent malaria, TB, HIV/AIDS, diarrheal diseases, and respiratory infections. Unfortunately, international terrorism threatens to reintroduce smallpox through acts of bioterrorism; in some instances, smallpox vaccination programs will need to be reestablished in order to protect health workers and the populations at risk (Adalja, Toner, & Inglesby, 2015).

New and Emerging Infectious Diseases and Conditions

Despite the advances made, new and emerging diseases, conditions, and syndromes have appeared in parts of the world. Health authorities thought that some of these were under control. Over the past 20 years, a number of previously unknown diseases have emerged, resulting in pandemics, economic losses, and travel restrictions. Among these emerging infectious diseases are severe acute respiratory syndrome (SARS), HIV/AIDS, H5N1 and H7N9 (bird flus) and H1N1 (swine flu) influenzas, Middle Eastern respiratory syndrome (MERS), and variant Creutzfeldt-Jakob disease, commonly known as mad cow disease (Kaiser Family Foundation, 2014; WHO, 2016p). See Table 16–1.

Table 16–1 Examples of Emerging Pathogens Identified Since 1973

Agent	Microbe	Disease
V	Rotavirus	Major cause of infantile diarrhea globally
V	*Cryptosporidium parvum*	Acute and chronic diarrhea
V	Ebola virus	Ebola hemorrhagic fever (Africa)
B	*Legionella pneumophila*	Legionnaires' disease/pneumonia
V	Hantaan virus (Sin Nombre virus)	Hemorrhagic fever with renal syndrome
B	*Campylobacter jejuni*	GI infections (infants/children) globally
V	Human T-lymphotropic virus 1 (HTLV-1)	T-cell lymphoma and leukemia globally
B	Toxin producing strains of *Staphylococcus aureus*	Toxic shock syndrome
B	*Escherichia coli 0157:H7*	Mild to severe diarrhea, hemorrhagic colitis, hemolytic uremic syndrome (beef)
V	HTLV-II	Hairy cell leukemia and paraparesis globally
S	*Borrelia burgdorferi*	Lyme disease
V	Human immunodeficiency virus (I and II)	Acquired immunodeficiency syndrome (AIDS) worldwide
B	*Helicobacter pylori*	Peptic ulcer disease
V	Hepatitis C	Hepatitis, cirrhosis, carcinoma globally
V	Guanarito virus	Venezuelan hemorrhagic fever
V	Junin virus	Argentine hemorrhagic fever
B	*Vibrio cholerae 0139*	New strain associated with epidemic cholera
B	*Bartonella henselae*	Catscratch disease, bacillary angiomatosis
V	Sabia virus	Brazilian hemorrhagic fever
V	Machupo virus	Bolivian hemorrhagic fever
V	Human herpesvirus 6, 7, 8	Roseola infantum/mononucleosis in adults, febrile childhood illness, Kaposi's sarcoma in AIDS patients
V	Norovirus	Acute vomiting, cramps, diarrhea
V	Parvovirus B19	Fifth disease, arthropathy, anemia worldwide
V	Nipah virus	Encephalitis, coma, seizures
V	Hendra virus	Severe pneumonitis/meningitis
V	Marburg virus	Microvascular leakage/hemorrhages (Africa)
B	*Clostridium difficile*	Severe infections—toxic megacolon, sepsis, death (asymptomatic in healthy neonates, nosocomial adults)
V	Coronaviruses	Severe acute respiratory syndrome (SARS) and Middle Eastern respiratory syndrome (MERS)
V	Nairovirus *Bunyaviridae*	Crimean Congo hemorrhagic fever (India) and Rift Valley fever (Africa)
V	Lassa virus *Arenaviridae*	Fever, mild to severe (Africa)
V	Dengue virus	Fever, headache, rash, bleeding, low white cell count (tropics/subtropics, Texas outbreak)
V	West Nile virus	Fever, headache, myalgia, rash (United States 48 states)

The development of antimicrobial-resistant organisms, mainly as a result of the overuse and misuse of antibiotics, has fueled a resurgence of some diseases that were under control, such as TB. Medication-resistant TB (MDR-TB) is now estimated to comprise almost 4% of new TB cases worldwide, and in previously treated patients, that proportion increases to 20% of cases (WHO, 2013c). Antimalarial medicines have become ineffective in some countries, and WHO (2013) estimates that 60% of the half million new cases of MDR-TB are in Russia, South Africa, Brazil, India, and China. About 9% of cases are classified as extensively drug-resistant TB (XDR-TB) and do not respond to two other classes of medication. A case–control study in Addis Ababa noted that first-line drug side effects, not using DOTS, and missing a daily dose of medication or a treatment lasting 2 to 7 months were all factors that were associated with MDR-TB (Hirpa et al., 2013). The easy availability of global air travel and subsequent rapid transmission of microbes pose real health threats. Despite the problems with MDR-TB, almost half of patients treated in 2009 were successful in their treatments (WHO, 2013c).

Another factor related to emergence of new and recycling conditions is migration (as discussed earlier in this chapter) and urbanization, which serves to concentrate large numbers of people in small geographic areas. With urbanization, deforestation continues, and the two phenomena may permit the infestation of microbes into human populations, as humans who move into the cleared forests may encounter previously unknown pathogens. Changes in agricultural practices, such as new dams and irrigation schemes, also present potential factors in transmission. The ability of microbes to change and adapt rapidly is a persistent threat as well.

Era of Chronic Long-Term Health Conditions

Despite the programs of control, many infectious diseases persist, but people survive and live on to experience chronic, long-term conditions. These conditions, while averting mortality, persist through their ongoing etiology and affect people's daily functioning, decision-making, and cost. Adding to the burden is the escalating sale of tobacco and the use of cigarettes by young populations in developing countries. The long-term effects of these practices for people in these countries will undoubtedly follow a similar trajectory as has occurred in developed countries with increases in lung cancer, heart disease, and other illnesses related to tobacco use (WHO Media Centre, 2015g). Thus, the longevity that has resulted from meeting the challenges of the Era of Infectious Diseases compounds the more recent emergence of chronic diseases in the many countries. Here, a transition occurs. As infectious diseases decrease, life expectancy lengthens and the population experiences the degenerative diseases seen in developed countries.

The concept of epidemiologic transition explains the replacement of infectious disease morbidity and mortality with that of chronic disease. The ways in which people in remote areas will manage their heart disease or cope with the long-term effects of diabetes and cancer are yet to be understood. Formerly, those with mental illness, inborn genetic disorders, disabilities, or compromised activities of daily living were cared for by the family and were often hidden from the community. This was often because of religious and cultural beliefs, lack of knowledge, the availability of health providers with specialized expertise, and dedicated health care facilities or services for those chronic illnesses. However, it is difficult to gather precise statistics in many areas of the world. For instance, research on the global prevalence of mental illness is difficult, as many poorer nations do not conduct research in this area and definitions of various mental health conditions vary across regions (Baxter, Patton, Scott, Degenhardt, & Whiteford, 2013). The impact of mental illness on families and caregivers is also very difficult to ascertain.

As families change their composition, members of families migrate to seek employment; the care of those who require daily assistance will also have to change. It will require a change in the response of the health care system in terms of provision of care, planning, and allocation of resources. Addressing these concerns is considered a cost-effective investment in a nation's human capital (Yach, Mensah, Hawkes, Epping-Jordan, & Steyn, 2012).

Era of Social Health Conditions

The WHO researchers suggest that overall, dramatic changes in health-related needs will occur within the next 20 years. There is evidence that noncommunicable diseases are rapidly replacing infectious diseases as the major causes of disability and premature death. Noncommunicable diseases account for 8 of every 10 deaths in higher-income countries, compared with 6 of every 10 deaths worldwide (WHO Media Centre, 2016a; Yach et al., 2012). See Display 16–4 for differences in ranked causes of death between developed and developing countries.

DISPLAY 16.4 RANKING OF 10 LEADING CAUSES OF DEATH WORLDWIDE: DEVELOPED AND DEVELOPING COUNTRIES, 2013

Developed Countries	Developing Countries
1. Ischemic heart disease	1. Lower respiratory infections
2. Stroke	2. Ischemic heart disease
3. Lung cancer	3. Stroke
4. Self-harm	4. Diarrhea
5. Alzheimer's disease	5. HIV/AIDS
6. Cirrhosis	6. Preterm birth
7. COPD	7. Malaria
8. Colorectal cancer	8. Road injuries
9. Lower respiratory infections	9. Neonatal encephalitis
10. Road injuries	10. Congenital

Adapted from Global Burden of Disease Mortality and Causes of Death Collaborators. (2015). Global, regional, and national age-sex specific all-cause and cause-specific mortality for 240 causes of death, 1990–2013: A systematic analysis for the Global Burden of Disease Study, 12013. Lancet, 385, 117–171.

Maternal and Perinatal Morbidity and Mortality

The WHO estimates that almost 303,000 women died in 2015 from complications of pregnancy and childbirth. Ninety-nine percent of these deaths are in economically poor countries. Pregnant women living in rural areas and adolescent mothers face higher mortality rates. The death of a mother profoundly affects the well-being of the entire family. Between 1990 and 2015, global rates of maternal mortality dropped by 44%

(WHO Media Centre, 2015c).

Early pregnancy, high fertility, and close child spacing are common in developing countries and are known to be major determinants of poor health for mothers and children. Poverty, illiteracy, poor nutrition, and low weight gain in pregnancy are also risk factors. The leading causes of maternal death include severe bleeding and infections after childbirth, complications from delivery, high blood pressure during pregnancy, and unsafe abortions (WHO Media Centre, 2015c). As noted above, the added burden of long protracted civil wars has exacerbated these conditions, as have the factors associated with migration. As men leave home to seek employment abroad, women remain behind to care for children, often managing heavy workloads along with their pregnancies.

Prevention strategies include better general health for women through poverty alleviation, education, family planning guidance, prenatal care including food supplementation, immunization, local and regional care with referrals for complications, training of traditional birth attendants (TBAs), and effective postpartum care. One pilot program in Malawi instituted community-linked maternal death reviews as a way to better understand causes of maternal death and implement community-planned actions to prevent them (Bayley et al., 2015). Researchers noted that 67% of district hospital and 65% of health centers completed actions to improve maternal care and reduce mortality rates. Another study examined strategies that had been developed and implemented by women's groups in an effort to improve maternal–child health and decrease mortality rates in Malawi (Rosato et al., 2012). Common strategies included birth attendant training, health education classes, cultivation of vegetable gardens, using bicycle ambulances, and distributing insecticide-treated bed nets.

Maternal and perinatal morbidity and mortality are important global issues addressed by

the World Health Organization. (Photo courtesy of CDC Photo Image Library.)

Mental Health Conditions

Mental illness has been thought of in a variety of ways over the centuries through drastic measures including exclusion from society, ridicule, and incarceration, as outlined in the classic book by Foucault (1965) and the writings of Shimmon (2011). In one review of 174 studies conducted in 63 countries, researchers found almost 18% of survey respondents met criteria for some type of common mental disorder within last year, and almost 30% had one at some point in their life (Steel et al., 2014). The recent civil wars and popular uprisings and the major wars in Iraq and Afghanistan have taken their toll on members of the armed forces resulting in posttraumatic stress among soldiers as well as the inhabitants who have experienced war (Levy & Sidel, 2013; Litz & Orsillo, 2015). These events and the recent financial downturn in the economies of the world have affected the mental health of people as they struggle to manage the multiple social, financial, and cultural issues facing them, not the least of which are the effects of unemployment and financial ruin for families throughout many parts of the world.

Tobacco

Over 100 million deaths were attributed to tobacco in the 20th century. Tobacco accounts for one death every 6 seconds in the world or about 6 million people annually. Without some form of intervention, this trend will continue ultimately resulting in over 8 million annual deaths by 2030 and over 1 billion deaths within the 21st century. Most of the world's 1 billion smokers live in low-income or mid-income countries where premature death and the burden of disease prevent economic growth (WHO Media Centre, 2015g). The statistics are startling when one considers the lifelong smoker who is as likely to die from tobacco as he/she is from all other causes of death combined (Schaffer Library of Drug Policy, 2011). Yet, it is difficult for smokers to stop smoking. With medication and counseling, however, the chances of success in quitting smoking are doubled (WHO Media Centre, 2015g).

PERSPECTIVES
A NURSE–MIDWIFE IN SUDAN

I am a nurse–midwife in South Sudan. My husband, who works with local pastors, and I are Seventh-Day Adventist missionaries based out of Uganda. One evening, I got a call about a lady in labor. I had not seen her for prenatal care, and there was a terrible

rainstorm that night. I was told this was a first baby for the young woman, and she had been in labor for more than 24 hours. They wanted to take her to a hospital but could not get a vehicle to transport her there. The dirt roads are slippery and awful in this area, and the girl was 11 miles away from me (5 miles were dirt roads). I rode my bike in the rain, watching children on the sides of the road trying to capture ants to eat. They were beating on tin cans to lure them out of the ant holes, in order to gather the fat, winged ants that are considered tasty treats. As my assistant and I got close to the girl's thatched hut, we noticed groups of people gathered nearby. Villagers were often concerned about mothers and babies, but we were quickly told that the baby had just been born and was dead. I went into the hut and noticed a limp baby girl. I began to examine the baby and felt a faint heartbeat on the umbilical cord (still connected to the mother). I grabbed my bag and mask and began resuscitating the baby. The baby was on the mat covering the dirt floor, and I finally found an oral airway to keep the baby's mouth open, as the air did not seem to be getting through. Air finally began going into the lungs, and I checked the heartbeat (normal). I kept bagging the baby and watched the tiny chest rise and fall. The tiny hut was filled with concerned neighborhood women who had been wailing because they thought the baby had died. Now, they sat quietly, speaking softly to one another as they watched me intently. Other women were crowded around the doorway to the hut and still more sat outside. I looked over at the mother, who seemed to be alright, not bleeding too much. I asked the women for hot water so I could keep the baby warm, and I kept bagging the baby. Then, I tried shocking the baby with colder water, so that she would begin to breathe on her own. We went back and forth like this a few times, and the baby would take an occasional breath. I inserted a nasogastric tube to remove any excess air that may have accumulated, and her color improved and muscle tone increased. After awhile, the baby began to breathe on her own. I checked the mother for any tearing (none apparent) and stayed with them for several hours to make sure there were no further signs of respiratory distress or other problems. Because the next day was market day, the word about the baby's condition spread very fast. I don't know what will happen tomorrow, but I am grateful for the blessings of today!

Kristina, Nurse–Midwife

The WHO Framework Convention on Tobacco Control took effect in 2005. The treaty's signatory parties (over 170 representing 87% of the world population) agreed to implement comprehensive tobacco control programs and strategies. WHO introduced a tobacco control package, MPOWER, to help implement the provisions of the treaty. The six components are as follows:

- Monitor tobacco use and prevention policies.
- Protect people from tobacco use.
- Offer help to quit tobacco use.

- Warn about the dangers of tobacco.
- Enforce bans on tobacco advertising, promotion, and sponsorship.
- Raise taxes on tobacco (WHO Media Centre, 2015g, para. 33).

This legally binding treaty and international effort represents an important step in global public health and is expected to reduce the impact of tobacco use in the decades to come.

Given that tobacco eventually kills about half of its users, this important global public health initiative should help save lives, improve standards of living and world economies, as well as improve global health.

Population Health of LGBT Globally

Amnesty International highlights the growing problems associated with the criminalization of homosexuality around the globe and the resulting systematic discrimination that compounds the risks and disadvantages already faced by lesbian, gay, bisexual, and transgender (LGBT) people (Amnesty International, 2015). In Uganda, for example, recently enacted, highly controversial, legislative bills have resulted in heightened repression and discrimination based on sexual orientation. According to a recent report, women believed to belong to the LGBT community based on their dress alone were attacked, stripped, and beaten, whereas other members of the community were "evicted from their homes, lost their jobs, and faced challenges accessing healthcare" (Amnesty International, 2014, para 5). As it is, LGBT individuals face poorer health outcomes than the general population globally, including higher risks for sexually transmitted infections and HIV for gay men; higher risks of obesity and breast cancer for lesbian, bisexual women; institutionalized prejudice, antihomosexual hatred, and violence; social exclusion and widespread stigmatization within health systems; and increased isolation for the aging LGBT population (U.S. Department of Health and Human Services [USDHHS], 2015; WHO, 2013a). The true extent of the problem is hard to measure, because there is limited health research on this population; but we do know that the LGBT community faces numerous barriers in accessing health care. These barriers include outright denial of care, substandard care, and fear of discrimination or criminal penalties. Moving forward, we, as nurses, need to engage in more rigorous research on the realities of discrimination toward the LGBT community globally and how this impacts their ability to achieve and maintain their full health potential. In addition, we need to contribute to the development of health standards and curricula that is designed to provide adequate training of health care professionals in the care of LGBT people (WHO, 2013a). Both populations we serve and health care professionals deserve respect in their choices. See Perspectives: One Nurse's Experiences Overseas.

PERSPECTIVES
ONE NURSE'S EXPERIENCES OVERSEAS

From an early age, I was exposed to nursing. My mother was a nurse, and I saw firsthand how she cared for us as a family and how she cared for her friends when they were in need. I also listened intently when she talked about the patients she helped over the years. Furthermore, I witnessed how she integrated her own faith with her nursing practice in the simplest of forms: genuine service to others. After I became a nurse, I also felt a deep calling to use my nursing skills in volunteer ways to serve others.

My first volunteer experience was in the rural mountains of Guatemala where I worked with indigenous women to improve birth practices. I thought I was going there to teach them how to safely deliver babies. But after spending 2 months caring for women during pregnancy and childbirth, they actually taught me more about the miracle of birth than I ever learned in my hospital-based experiences. We shared our knowledge with each other and both came away from the experience with a deeper understanding of what it means to become a mother.

Later in life, I met a nurse with the same deep passion for service to others. She was preparing to move to West Africa to serve women with childbirth injuries. She and I had both been raised within the same Christian faith and we both felt our nursing practice was very integrated into our values and beliefs. Then, we fell in love with each other. This was a challenging time for us, as we navigated the minority of being in a same-sex relationship within the Christian community. We struggled as some of our friends and family made it clear they did not approve of our relationship. But we also found new friends and family in the journey as well who were willing to see the greater value of who we were together.

In addition to navigating our home-front challenges, we also had to negotiate our relationship abroad. My wife was working for a faith-based organization in a predominately Muslim country, both of which do not condone same-sex relationships. In order for me to visit with her, to spend time together, and to also offer myself for service when I was there, we had to be silent about the depth of our relationship. We acted only as friends, with no public displays of affection. This was a compromise we both felt committed to in order to make a difference in the lives of the nurses and the women we cared for. Although some might find this compromise too costly, we continue to be grateful for the opportunities we had to serve and would do it again in a heartbeat.

Global Burden of Disease

If a member of your family dies, what does it cost? What does it cost if you miss a month of work or school because of an illness? What does it cost a country when the majority of adults smoke a package of cigarettes a day or when adults eat betel nut several times a day? These questions are often irritating and are sometimes considered in poor taste. Yet, insurance companies, governments, and community members do ask these questions—as they must carry the financial burden for them. But how does one go about putting a value on a life? Or how can value be placed on the cost of a disability? To capture these concerns, the WHO coined the term the *global burden of disease* (GBD).

The World Health Organization's GBD studies numerically verified numerous long-held assumptions about disparities in the burden of disease worldwide, especially in regard to children, through landmark studies that revealed startling statistics:

- 33% of worldwide deaths from neonatal encephalopathy occur in one country—India.
- 50% of diarrheal deaths in children/adolescents are in five countries—Ethiopia, Democratic Republic of Congo, India, Nigeria, and Pakistan (Global Burden of Disease Pediatrics Collaboration, 2016).

As more people around the world are living longer, the number of years lived with disability (YLD) increases. Low back pain and depression are the most commonly cited causes of disability in countries worldwide, and most of increases in YLD are due to "musculoskeletal, mental, and substance use disorders, neurological disorders, and chronic respiratory distress" (Global Burden of Disease Study 2013 Collaborators, 2015, p. 743). In sub-Saharan Africa, the leading driver is HIV/AIDS. In addition to causes of mortality, the GBD study quantified the burden of disease with a measure that is used for cost-effectiveness analysis. To compare across conditions and risk factors, researchers developed a measure called the disability-adjusted life year (DALY), which is the combination of years of life lost because of premature mortality and years of life lived with disability adjusted for the severity of disability (WHO, 2016j). The 2012 GBD study ranked the leading risk factor causes of DALYs overall (see Table 16–2). Another measure, years of life lost (YLL), is ranked by category of disease or condition (WHO, 2016g). Almost 40% are due to communicable diseases (e.g., TB, HIV/AIDS, diarrheal diseases) along with nutritional, maternal, and perinatal causes. Noncommunicable diseases are responsible for 47% (e.g., cardiovascular disease, diabetes, neoplasms).

Table 16–2 Worldwide Ranking of 20 Leading Risk Factor Causes of Disability-Adjusted Life Years (DALYs), 2012

Rank	Cause	DALYs (000s)	% DALYs	DALYs per 100,000 Population
	All causes	2,743,857	100.0	38,780
1	Ischemic heart disease	165,717	6.0	2,342
2	Lower respiratory infections	146,864	5.4	2,076
3	Stroke	141,348	5.2	1,998
4	Preterm birth complications	107,210	3.9	1,515
5	Diarrheal diseases	99,728	3.6	1,409
6	COPD	92,377	3.4	1,306
7	HIV/AIDS	91,907	3.4	1,299
8	Road injury	78,724	2.9	1,113
9	Unipolar depressive disorders	76,500	2.8	1,081
10	Birth asphyxia and trauma	74,600	2.7	1,054
11	Diabetes mellitus	59,258	2.2	838
12	Malaria	55,111	2.0	779
13	Back and neck pain	53,920	2.0	762
14	Congenital anomalies	52,532	1.9	742
15	Iron deficiency anemia	47,627	1.7	673
16	Tuberculosis	43,650	1.6	617
17	Falls	42,466	1.6	600
18	Neonatal sepsis and infections	39,646	1.4	560
19	Self-harm	39,358	1.4	556
20	Trachea, bronchus, and lung cancers	38,535	1.4	545

From World Health Organization. (2016). DALY estimates, 200-2012: Global summary estimates. Retrieved from http://www.who.int/healthinfo/global_burden_disease/estimates/en/index2.html

The leading causes of death worldwide can be broken down by income level. For instance, the five most common cause of death among low-income countries are:

- Lower respiratory tract infections, HIV/AIDS, diarrheal diseases, stroke, and ischemic heart disease

Among lower middle-income countries, the top five are:

- Ischemic heart disease, stroke, lower respiratory tract infections, COPD, and diarrheal diseases

For upper middle-income countries, stroke, ischemic heart disease, and COPD remain, but lung cancer and diabetes are now in top five.

For high-income countries, the top five causes of death include:

- Ischemic heart disease, stroke, lung cancer, Alzheimer's/other dementias, and COPD (WHO, 2016f).

About 44% of deaths in children occur during the neonatal period, and about 6.6 million children died in 2012. The major causes of death for those under age 5 were prematurity, birth trauma/asphyxia, pneumonia, and diarrheal diseases. Malaria is responsible for 15% of child deaths in sub-Saharan Africa (WHO, 2016e). See Table 16–3 for more on global monitoring of risk factors.

Table 16–3 Comprehensive Noncommunicable Disease Global Monitoring Framework, Risk Factors, Targets, and Indicators

Framework Element	Target	Indicator
Premature Mortality From Noncommunicable Disease	25% reduction in mortality from cancer, cardiovascular diseases, diabetes, chronic respiratory diseases	Unconditional probability of dying between ages 30 and 70 from these causes Cancer incidence per 100,000
Behavioral Risk Factors		
Harmful Use of Alcohol	10% reduction in harmful use of alcohol within national standards	Total alcohol consumption per capita; prevalence of heavy episodic drinking; alcohol-related morbidity/mortality
Physical Inactivity	10% reduction in physical inactivity prevalence	Prevalence defined as <60 min moderate to vigorous activity/day for adolescents; <150 min/wk for over 18 years
Sodium Intake	30% reduction in mean population intake of sodium	Mean population intake of sodium chloride in g/d for >18 (age standardized)
Use of Tobacco	30% reduction in current tobacco use prevalence in people over age 15	Prevalence of adolescent tobacco uses; prevalence of age-standardized tobacco use over age 18
Biological Risk Factors		
Hypertension	25% reduction in prevalence of hypertension, depending on national conditions	Prevalence of systolic blood pressure of ≥ 140 mm Hg systolic and/or ≥ 90 mm Hg diastolic blood pressure means
Obesity and Diabetes	Halt the rise in obesity and diabetes	Prevalence of fasting plasma glucose 126 mg/dL or on blood glucose medication (over age 18); prevalence of school-age and adolescent overweight and obesity per WHO growth reference; for adults ≥25 kg/m² for overweight and ≥30 kg/m² for obese
National Health Systems		
Availability of medications and treatments for risk factors	50%–80% availability	Proportion of those over age 40 with 10-year CVD risk ≥30% with access to medication and counseling; access to affordable medications and technologies for noncommunicable diseases

Adapted from World Health Organization (WHO). (2014). Global status report on noncommunicable diseases, 2014. Retrieved from http://apps.who.int/iris/bitstream/10665/148114/1/9789241564854_eng.pdf

The information obtained from the GBD and its analysis guides current decisions related to investments in health, research, human resource development, and physical infrastructure. Reassessment of global and regional information on diseases and injuries is expected to occur periodically.

PROVIDERS OF HEALTH CARE

The implications for community health nursing concerning the three eras of health conditions are many. The health provider most appropriate when death is a common occurrence, as it was during the Era of Infectious Diseases, is a physician. This category of health worker is best suited for saving lives and for delivering the medical interventions that keep people alive. Nursing and nursing personnel are health care providers who have traditionally served populations that experience long-term chronic illnesses. Nursing personnel worldwide serve populations in nursing homes, long-term care facilities, and community-based programs for the elderly and disabled. The nursing services in Slovenia and Germany are excellent examples of the latter practice in Europe.

The caregiver needed for the Era of Social Conditions is evolving. For example, community health nurses and primary care physicians are developing new competencies for HIV/AIDS prevention among adolescent prostitutes, but also needed is a host of other interventions that require collaboration with other social service. In addition, some communities, because of their former political persuasion and cultural beliefs, have viewed the state as the provider of all health care services. For example, during the earthquake in Armenia, international workers recognized the need for social supports for those whose homes and community had been destroyed. At that time, these social structures, as they existed in North America, were not available to that population. Although alcoholism has been rampant in parts of Eastern Europe, organizations such as Alcoholic Anonymous were not available. In other areas, such as South America, close-knit family structures are vital. Yet, few if any services are available to families living between the era of the close-knit family structure and one that requires outside help for emerging third era conditions.

In the future, community health care will be increasingly collaborative and experienced as participatory partnerships with clear shifts in ownership and leadership. Formerly, international workers and consultants went to a country as outsiders and delivered their ideas, programs, and projects. The philosophy, beliefs, practices, and values of this dominant group of outsiders prevailed, and the recipient groups were considered a success to the extent that they adopted the dominant group's ways of being, living, and caring for their health.

In the future, partnerships that are sensitive to the dynamics of power and oppression, and which honor the need for local groups to be in control of their own projects and the resources that are used to implement them, will prevail. Pablo Freire's (1970) well-known advocacy for using *generative themes* that support education and critical consciousness has been adopted as collaborative projects demonstrate innovative ways of learning and conducting research. For example, in many countries, local experts and community members are forming partnerships with outside consultants and are insisting on striking changes in responsibility, authority, and ownership of data and innovations. In these emerging models, action research projects are being adopted over positivist, empirical

studies, where the community becomes the initiator of action. See more on community-based participatory research in Chapter 4.

Health Providers at District Levels

In earlier forms of PHC, the locus of decision-making was at the village level. However, after many years of effort, the WHO and other organizations realized that the power to sustain change required more than village-level involvement. Thus, the move to the district level of implementation is currently being practiced in many places.

Regardless of level, however, the essential point is the adage: Think globally, act locally. Specifically, this means that expertise is needed from those at international, national, regional, and district levels, but the ways in which communities interpret the issues and actually decides to use the solutions belong to them. In local areas, communities adopt the health centers or organizations created to address community concerns. For example, in one Greek community, a local mayor sat through a week of deliberations on ways to bring PHC to his island. He heard the comments of members of the local community, its health workers, and an international WHO PHC team. Ultimately, the mayor realized that rooms for health providers would be needed, and he declared the community's full support to provide these rooms to further the work of the health center. In this way, his community was fully active and responsible for its own health status.

Community Health Workers

In some countries, particularly those in which professional health providers are scarce, the community identifies a local, respected, responsible person most often called the CHW. This person is selected from the village and is approved by the committee to serve the village people in health matters. CHWs usually provide 1 to 2 hours of health service per day, for which they may or may not be compensated by the community. In Ethiopia, refugees in camps erected after disasters identify responsible adults to serve as their kind of CHWs; these adults are known to and are trusted by newly established communities.

The CHW is trained in the fundamentals of promoting health and preventing and treating the most common health care conditions. This includes basic first aid, advice and assistance on simple treatments, and health teaching on personal hygiene, safe water supplies, safe disposal of human waste and refuse, and nutrition. Community health nurses often serve as consultants to the CHW and, in some places, are expected to supervise their work and provide ongoing education. These CHWs, as noted above, have demonstrated their effectiveness in controlling communicable diseases (e.g., malaria treatment) and promoting health (e.g., cervical cancer/mammography screenings) in this country and around the world (Perry & Zulliger, 2012).

Village Midwife

The village midwife provides basic antenatal, intrapartum, and postnatal care and makes referrals as required. In India, the village midwife is referred to as a trained *dai*. These are most often older women who may have had training from professional nurses and who are expected to call on professionals when needed. However, they often make their own decisions even though they have a referral source to professionals. Many times, adverse effects occur because cultural practices take precedence over knowledge-based practices that require collaborative decision-making. In Africa and Sudan, village midwives deliver a good percentage of babies, often in isolated villages. In Indonesia, village midwives expanded these services to also provide family planning services and contraceptives (Weaver et al., 2013). In Sudan and other areas, training is provided and encouraged in order for midwives to perform infant resuscitation and other skills more effectively (Me Arabi et al., 2016).

In some countries, traditional health practitioners receive formal training and return to their villages to continue their services with new knowledge and skills to enhance their effectiveness. Countries such as Bangladesh implemented programs to train workers who would practice in ways similar to the "barefoot doctors" of China (Shah et al., 2014; Xu et al., 2014). WHO advisors examined the work of these barefoot doctors as the Ministry of Health in Bangladesh was challenged in its efforts during the 1980s to provide health care to rural population. Because of cultural taboos, women were not allowed to leave their homes for training and, if they did, would rarely want to be posted in a village other than their own. This was because women were viewed as wayward if they were not with their families in their home environments. This issue also occurred in Indonesia, when community health nurses were placed in villages away from home. They did not have the respect of the local community, were not seen as experts, and were considered to be of dubious moral standing. This cultural barrier presents challenges to nursing education programs that focus on community rather than hospital-based experiences.

Midwives are considered an important resource in the effort to end preventable maternal deaths (Bergevin, Fauveau, & McKinnon, 2015). A recent systematic review found that women who used the services of midwives who provided "continuity models of care" were more satisfied and have fewer interventions than women who received "other models of care" (Sandall, Soltani, Gates, Shennan, & Devane, 2015, para. 10). The researchers also noted that care provided by midwives was often the only available maternal care in many areas of the world.

Community Health Nurses

Background and Age at Entry to Nursing Education

When community health nurses join their colleagues in a country other than their own, they often assume that "a nurse is a nurse, is a nurse." Nothing could be further from the truth. The ways in which women and men are socialized, recruited into, advanced through, and graduated from nursing programs vary considerably from country to country. So does the age at entry, the exposure that nursing students have to the social and behavioral sciences, the theoretical and clinical applications studied, and the kind and extent of supervision they receive. For example, in some countries, young people begin their study of nursing at age 15, studying nursing in programs designed, sequenced, and financed by the government. These graduates are expected to practice as fully experienced community health nurses by age 18. In some countries, the extent of responsibilities placed on these relatively young practitioners is beyond their ability or maturity levels; however, the expectations persist because the number of prepared health care personnel is often at a premium. Some American universities have relationships with students and health care professionals from other countries and work with them to provide additional skills and education (Anft, 2013).

Curricula of Nursing Programs

In the United States, curricula in nursing are designed to serve the community in which the nursing program is based. Thus, a community prone to hurricanes, for example, would provide enhanced curricula for delivering nursing care in this kind of natural disaster. However, in some countries, nursing education curricula are conceived and designed at national levels and, in this way, are not responsive to local situations. The opportunity this model provides is consistency of teaching and learning and the possibility to produce teaching–learning materials in a uniform way and in the language of the country. The risks are that local conditions are not included, and care practices essential for a region of a country may not be addressed. For example, during an earthquake in Armenia, a WHO European Regional Advisor requested that content related to earthquakes and disaster preparedness be added to the curriculum. Authorities declined, showing the consulting team and local nurse leaders the detailed content and hours developed for the curriculum designed in Moscow. No opportunities, at that time, were possible for this content to be added, despite the fact that 25,000 people had lost their lives in this natural disaster.

Around the world, nursing educational programs may still be based in hospitals or technical schools or offered in universities. Specialty areas may be introduced as part of the basic curriculum, as is the practice in Denmark where midwifery is a basic program offered and is seen as a discipline different from nursing. In France, midwifery is aligned with medicine. This design differs from other countries in which nursing is the basic preparation upon which mental health, midwifery, and other areas are built and considered as advanced

practice. In some countries, mental health is not included as part of the basic curriculum. For the graduates of these programs, moving to and working in countries that require mental health theory and practice requires additional schooling before the candidate is allowed to sit for the licensing examination.

The World Health Organization (2013d) has developed guidelines to improve for health professions education and training that address the requirements for faculty and students, as well as the need for better educational pathways, accreditation, and interprofessional education. Also, there has recently been a focus on including curriculum that provides meaningful opportunities for students to learn about global health and cultural competency through study abroad courses. Often, these courses involve an emersion experience, whereby students learn the realities of health care challenges and about delivering culturally appropriate care in diverse settings. See Perspectives: From Faculty and Students.

PERSPECTIVES FROM A NURSING PROFESSOR ON LEARNING ABROAD

As a public health nurse for many years and then as a Professor of Nursing in community health nursing, I have become aware of the need for a culturally competent nursing workforce. For the last 10 years, I have had the privilege of teaching nursing students in a 3-week cultural immersion course in Mexico and then in Ecuador. It is my belief based on the Essentials of Baccalaureate Education for Professional Nursing Practice (American Association of Colleges of Nursing, 2008) that learning abroad allows health care members to immerse themselves in cultures different from their own as a means to challenge beliefs and attitudes about cultures and better understands cultural differences. The aim of this class is to assist students in developing an awareness, understanding, and appreciation of the cultural factors and views that underlie a person's health and way of living. The course's goal is to assist and help increase the nurse's ability to make in-depth assessments of the cultural influences on individuals' health care and develop the ability to deliver culturally sensitive, safe, and effective care. Through study abroad, students gain knowledge, skills, and principles that will enable them to generalize to other cultural groups.

A cultural immersion experience for students adds to the effectiveness of the transfer of knowledge in cultural competent health care delivery. I believe that this teaching strategy assists students of all learning styles to gain knowledge in culturally appropriate care and is

needed in light of the increasing population of Hispanics and in California and the United States in general. Students have come back from these experiences with renewed cultural understanding. Here is a sample of student comments after the immersion experience:

- *"Currently I work in a hospital setting, but I anticipate working in the community setting in the future. I hope that I will have more awareness of the Mexican culture with Spanish-speaking patients, and I will definitively have more empathy with potential language barriers and use a translator more readily."*
- *"I will most definitely appreciate the circumstances of health care in America and most definitely better understand the rationale of my Mexican patients."*
- *"A broader understanding of where they are coming from and what they deal with before we see them in the health care setting."*
- *"In many ways! I have a better understanding of habits and practices."*
- *"Oh—I'll always think twice when caring for <u>all</u> of my patients and consider culture in their care."*

As health professionals, we are always on the learning curve of cultural competency. The immersion experience is one very effective tool in teaching and assisting nursing students toward the goal of a more culturally competent workforce.

Judith Keswick, RN, PHN, MSN,
Associate Professor of Nursing

From American Association of Colleges of Nursing. (2008). Essentials of baccalaureate education for professional nursing practice. Washington, DC: Author.

PERSPECTIVES
STUDENT NURSE IN ECUADOR

I never thought I would study abroad, but when the opportunity to take one of my nursing classes in Cuenca, Ecuador, arose, I decided to embrace it, expecting a great learning experience. Little did I imagine that it was going to be anything short of life changing. Simply stated, it was humbling to be a guest in a host family's home, accepted like family, and it was awesome to become immersed in a culture so different from our own. During our 1-month stay, our itinerary was packed with school as well as experiences in hospitals, clinics, school, and even an orphanage.

I recall a particular hospital where I assisted a compassionate nurse in giving bed baths with limited resources. I ripped three pairs of small-sized latex gloves before

managing to keep a pair on my large hands. I learned that being a good nurse was not dependent on the availability of supplies but rather in maximizing the potential to deliver compassionate care in any circumstance.

I am happy I made the decision to study abroad. In addition to the learning experience, I gained insight, respect, humility, and gratitude for life and for others. It is as if I have become aware of what living fully is, something unattainable without the smells, sights, sounds, and interactions I encountered abroad.

Jaime Morga, SN

International Migration of Nurses

Although this chapter often focuses on U.S. nurses working in other countries, another, sometimes ominous component of global nursing is the migration of nurses from less-developed nations to more industrialized countries offering higher wages. Conditions in sub-Saharan Africa are very problematic. Having an already weak and poorly developed health system, countries in this region are now facing a serious crisis due to nursing shortages and migration of nurses to South Africa or other countries within the region where a better standard of living exists. Although sub-Saharan Africa represents 25% of the global disease burden, it receives about 1% of the global financial resources and only 1.3% of the world's trained health care workers live in that area (Li, Nie, & Li, 2014). Filipino nurses are the largest group migrating to the United States, with nurses from the Caribbean, India, Korea, and other countries following. In fact, about 70% of nurses graduating from programs in the Philippines go abroad for higher-paying work (Li et al., 2014). Canada and the United Kingdom often recruit nurses from outside their countries, while at the same time losing Canadian nurses to the United States. The United States, with its history of nursing shortages and a large health care system, has often relied on foreign graduates of nursing schools to meet its demands. This has caused concern among other nations and exemplifies the uneven balance in economic and political might, along with questions of ethics.

Forces That Support Nursing Development

In many places, nursing has yet to distinguish itself with its own body of research, knowledge, managerial practices, standards of practice, and ethical tenets. In Saudi Arabia, only about 29% of the nursing workforce are citizens, and even though nursing education has existed for over 40 years there, no postgraduate advanced practice programs are offered there and very few advanced practice nurses work there. In Israel, limited programs and regulations have been developed for specific nurse specialists (e.g., palliative care, geriatrics, wound care), bur nurses practicing in a rural area kibbutz may function as a nurse practitioner when no physician is available (Kleinpell et al., 2014). However, it appears that nursing has thrived as a respected discipline in countries where, overall, women are respected and where those in leadership positions understand the value of the caring process

and are willing to champion nursing at all levels, including at the national level. For example, Turkey stands out as a country with physicians that sponsored nurses so that they were able to pursue higher education through the doctoral level of preparation. Nursing has developed in unusual ways in other countries as well. In the United Kingdom, home of Florence Nightingale, no national certification or regulations for advanced practice nursing exists, although many nurses and midwives practice in this capacity because of the "permissive approach to the scope of practice" there (Kleinpell et al., 2014, para. 16). In Australia, nurse practitioner practice is, at the present time, much less organized, despite a national board and standards, than what we have in the United States.

A major challenge to community health nurses who have undergone theory and clinical experiences as learners is working with nurses who have not had community health experience. As is well understood, functioning well in a fully equipped hospital is different from working in a community or village where resources are not easily available. Exploring these differences is an essential part of one's own needs assessment as one embarks on an experience with a team from locations other than one's own.

THE PROCEDURES/INTERVENTIONS

Community health nurses consider the population as their patient or client. A population might refer to all those living in a catchment area, in a neighborhood, village, a district, or city. Countries might refer to their populations at national, regional, or international levels. Regardless of location or level, community health nurses practice within the context of some kind of health care system or organization.

Nurses and midwives constitute a majority of the qualified workforce in many national health care systems, and they represent a powerful force for bringing health care to all populations. Nurses provide the spectrum of PHC services and conduct health research, and as the global population ages, average age of nurses is increasing; this further intensifies nursing shortages according to the most recent data from the International Centre for Human Resources in Nursing (ICHRN, 2008).

The interventions that community health nurses provide depend on the context in which they are working and on the population, its health status, and the health conditions it presents. These interventions also depend on the ways in which nursing is practiced in a country and on the organizations in which community health nurses are employed or with which they are collaborating. A key issue here is that community health nurses need to know the mission of the agencies with which they are working and the kinds of services and resources their employing organizations provide. This section describes selected organizations that provide interventions to address community health care issues and the ways in which community health nurses work within them.

Providing an intervention that "works" constitutes an achievement. Providing an intervention in community health constitutes a remarkable achievement. This is because interventions are complex and often costly and involve considerable knowledge, planning, and expert execution and evaluation skills. This section also focuses on the interventions community health nurses provide in a context different from their own within the context of a sponsoring organization.

As noted, the first step is to understand what the community's health needs are, who is involved in addressing them, the roles they play, and the contributions they are able to bring to the issue. Again, knowing the context in which one is working and understanding the population and their health status and health conditions are also critical elements (and have been addressed earlier). A second but often overlooked step is to understand the reasons the interventions are being delivered and one's reasons for being involved. Specifically, what does the sponsoring agency believe is its mission and why now, why here? What does the community have to say? Does the community see itself as a recipient of donations or as partners and collaborators? How do they see the intervention? Did they identify the need and ask for assistance? Have the recipients been involved in identifying the issue, in planning strategies for the intervention? Are they committed to the issue and to the outcome? What is their level of involvement in the issue?

These are complex questions. In some countries, the number and seriousness of challenges may be overwhelming, and despite outsiders' authoritative view of what should be tackled first, the community's perspective will often determine the intervention's effectiveness. For example, in Chad, of all the health information that the country could collect, Harvard University international consultants worked with the Ministry of Health and established an essential list that its people would find the most useful. At times, one's own interests may not be the ones the community needs to tackle.

Questions you need to ask yourself are the following: Why are you there? What motivates you and what is your commitment? How does this fit with the scope of the work you will be undertaking, and will your time commitment see the project through, and if not, what effect will your leaving have on its success? In some places, a custom has been established of exchanges where the international project staff is accommodated and where the local staff expects the same when they join the international staff in their home country. This commitment may represent a time and financial commitment you are not prepared to make. You will want to examine this issue before you commit to a project and its occasionally unwritten expectations.

Criteria for Support of Interventions

Sustainability. One of the most important criterions for donor support is sustainability: Can the recipient unit, a village health center, a regional health office, and a district hospital administer the projects after external funds are no longer available? For example, in one project slated for an African country, one consultant was instructed to avoid any project under $5 million, as the donor agency did not want to manage what they considered "small projects."

Absorptive capacity. Although many communities need support for their interventions, they often lack the personnel, structures, or processes to actually use the support. For example, in the project described above, the country's department requesting funding, although in dire need of help, was staffed at the national level with one full-time and one half-time person, with virtually no computer capability and no delivery system. In many countries, particularly after national disasters, well-intentioned donors flood a country with clothing, supplies, and equipment that go into warehouses as the infrastructure to receive, sort, transport, and deliver the goods are simply not functional.

Transferability. Many donor organizations and countries support pilot projects to assess their use in other places in the region, country, or throughout the world. For example, one country committed to its history of medicine requested funds from an international donor agency. The request was denied as this agency saw itself as promoting creative ideas and projects that might be applied to other places in the world.

When considering a project's funding, these questions need to be asked. Other questions need to be asked as well—about gender, political, and cultural issues. For example, if an organization plans to support the elimination of the practice of female circumcision, how will that be seen by the population? If a donor agency insists on a democratic process of decision-making, how do leaders implement this process when they have no background or skills in the democratic process and their positions are tied to their ability to make decisions without team input? How do CHWs implement sanitation programs that place farm animals in places segregated from humans when villagers see their cows as sacred and want to have them in the family compound? How does the community health nurse reduce the malaria fever of a newly delivered woman when the village midwife, the untrained *dais*, insists "you sponge her only on day three"? How do you provide international education for a country's highly intelligent practicing nurses when local physicians view the nurses as their assistants?

These and many other questions challenge the underlying assumptions about the process of change and the unplanned effects a well-intentioned intervention is designed to deliver. Yet another question relates to the way community health services are organized.

The most commonly involved organizations that provide health-related interventions and support are described here. An overall umbrella agency is the United Nations (UN). Most people know of the UN's work in peacekeeping. This body also focuses on working

conditions through the International Labor Organization (ILO), educational issues through the United Nations Educational Scientific and Cultural Organization (UNESCO), and health issues, specifically, through WHO and UNICEF.

The World Health Organization

The leading global agency that focuses specifically on health is the World Health Organization (WHO, 2016q). The organization has regional offices in six parts of the world with its headquarters in Geneva, Switzerland (WHO, 2016s). The six regional offices include WHO Regional Office for Americas (PAHO), WHO Regional Office for the Eastern Mediterranean (EMRO), WHO Regional Office for Europe (EURO), WHO Regional Office for Southeast Asia (SEARO), WHO Regional Office for Africa (AFRO), and WHO Regional Office for the Western Pacific (WPRO).

The WHO, Its History, and Its Work

The UN began in 1945, and discussions about the need for a global health organization began. The WHO developed its own constitution that went into effect on April 7, 1948, although it has been closely associated with the UN since its inception. It is responsible for its own programs, funded by regular and extra budgetary funds, and also for health-related initiatives sponsored and funded by UN agencies and other international bodies. The WHO carries out its work through the policies it creates with its member states throughout the world. It provides leadership and technical support, monitors health trends, sets norms and standards, and helps to spur research worldwide (WHO, 2016h). It does this initially at its annual May meeting, the World Health Assembly (WHA). World Health Day is celebrated annually on the anniversary of the WHO's inception (April 7th).

The World Health Assembly

The WHA is the highest governing body within the WHO and includes 193 member countries. Representatives from each of the world's regions attend this assembly and bring the policies and recommendations to their respective regional offices for implementation and expression at regional and local levels. Staff members at the regional offices then work with their member countries through their annual September Regional Committee Meeting held each year after the WHA (WHO, 2016s; WHO Media Centre, 2016b).

The WHO provides technical support and advises member states on strategies to meet their health care needs. The WHO serves as a catalyst to mobilize the resources of national governments, financial institutions and endowments, and bilateral partners for health development. Its six-point agenda includes promoting development, fostering health security, strengthening health systems, harnessing information/evidence/research, enhancing partnerships, and improving performance through its ongoing reforms (WHO, 2016a). The WHO is not the organization of choice when vehicles, equipment, and medicines are required; the WHO can help a member state determine the drugs that are essential and will assist in developing health policy, project plans, and programs.

The WHO employs many types of professionals, including nurses. However, the organization does not focus on professional issues to support the development of particular

health-related practitioners, such as nurses, midwives, social workers, or physicians. Nurses interested in these types of issues should explore opportunities with the International Council of Nurses (ICN) or nursing organizations at national or state levels. In the United States, these would include the American Association of Colleges of Nursing, the American Nurses Association, or National Council of State Boards of Nursing.

The WHO does focus on providing technical support related to the interventions these health professionals deliver, and for these, considerable effort is expended on developing nursing, midwifery, social work, and physician-related knowledge and skills that are basic to these interventions. However, the WHO works closely with the ICN and with national nursing organizations on policies and programming issues.

WHO Collaborating Centers

The WHO generally uses a 5-year planning cycle that is divided into 2-year cycles of projects, documentation, publications, and the development of information systems. Community health nurses are employed at the international level in Geneva, and they hold regional level positions as Regional Nursing Advisors. However, one or two Regional Nursing Advisors cannot possibly carry out the work of a region that might be the home to thousands of nursing personnel. To address this issue, WHO developed a network of World Health Organization Collaborating Centers; these centers focus on specific areas of expertise and carry out the work of the member countries in these areas. For example, the collaborating center network in nursing of the European Region has focused on PHC and information systems. The European Regional also developed a collaborating center network on disaster preparedness that included a 30-member international team of experts, including the Regional Advisor for Nursing, Midwifery, and Social Work. The network in the United States has worked through universities in their respective areas of excellence. In the United States, early pioneer universities included the University of Illinois, the University of Pennsylvania, the University of Texas, the University of Alabama, and the University of California. Student nurses in these universities have the opportunity to participate in the research, nursing projects, and other international activities their universities sponsor, both in the United States and in their partnering countries. About 11% of WHO collaborating centers are in the United States. Sometimes, these collaborating centers represent the WHO and their countries at national and international meetings. They provide critical services that are recognized by but cannot be funded or staffed by the WHO. They also bring credibility to projects, as they come from the communities they represent, and they know the issues and interventions that have the greatest chances of succeeding (WHO, 2014a).

WHO and Its Collaborators

The WHO works closely with national governments, its collaborating center network, its universities, research centers, and NGOs. Experts from member countries are recruited throughout the year to deliberate on global health and health-related issues. For example,

during the Chernobyl disaster, WHO/EURO called five internationally recognized nuclear experts to an emergency meeting to examine the issues and assist the member countries with next-step actions to protect their populations, livestock, and agricultural industries. Historically, the WHO has collaborated with centers of excellence throughout the world, including the CDC in the United States.

WHO as a Multilateral Agency

The WHO and other UN agencies are sometimes referred to as *multinational* or multilateral agencies. They support development efforts of governments, organizations, and universities in countries throughout the world. The WHO regional offices also collaborate with each other to address issues on which they can partner and provide resources. For example, during the civil wars in Africa, Chad, Angola, and Mozambique, WHO/AFRO and WHO/EURO collaborated to develop projects on rehabilitation for the countries with few nursing programs, no medical schools, and no comprehensive programs for the disabled. The WHO intervenes through its own staff's efforts and through those of its partnerships. In another example, the WHO's health-promoting schools is a collaborative effort with UNESCO and UNICEF. Still, another example is the Human Reproduction Program, a global research program on reproductive health. It collaborates with two programs of the UN as well as the World Bank (WB). Similarly, the WHO has joined with several other organizations to fight hunger and improve food standards and has collaborated with UNICEF, the WB, and other agencies on *Deliver Now for Women + Children*, a program launched in 2007 to promote advocacy for women and children in South America, Tanzania, India, and other areas of the world (WHO, 2016c).

Health for All: A Primary Health Care Initiative

In its earlier years, the WHO personnel watched as hospitals and costly health establishments were built throughout the world. One of the world's leading economists, Dr. Brian Abel Smith, noted that countries could not afford to erect costly buildings, nor could they add large numbers of health professional to their cadres of personnel. Rather, he suggested that the health personnel available work with the population to manage their health care needs. His major assertion is that health care needs and wants may expand infinitely, but resources do not, and all must manage with the resources currently available. Many health leaders throughout the world recognized the trends emerging and believed that a major change in thinking and practice was needed. They met together in Alma-Ata, Kazakhstan, in the former Soviet Union and created a sweeping set of declarations that became the *Declaration of Alma-Ata* (see Chapter 1) or Health for All. The world body of 134 countries called on all members to reframe their expectations and implement PHC. In Europe, the 32-member countries developed its 38 regional targets for health. In the United States, health care professionals launched *Healthy People 2000*. After the year 2000, *Healthy People 2010* became the blueprint, and now, the *Healthy People 2020* document outlines our goals and objectives for the future (USDHHS, 2016).

PHC is sometimes called a philosophy, a movement, a way of thinking, a way of working, a setting for health services, or a set of principles. Making it operational at the national level, however, meant that communities would focus on health care services at the local level rather than building large, tertiary hospitals that cater exclusively to urban, financially secure populations. This also meant that the education of health care providers would be located at this level with a de-emphasis on high-cost medical interventions and technology available only to relatively few in the population.

Health for All emphasizes PHC that is affordable, culturally acceptable, appropriate, accessible, and delivered through partnerships between national health services system and local communities. The communities take the leading responsibility for identifying their own priority health concerns and planning and implementing their own PHC service. These PHC services include prevention, health promotion, and curative and rehabilitative care provided by the people themselves (WHO, 2012). See Figure 16–3 for an illustration of the organizational pattern of community-based PHC.

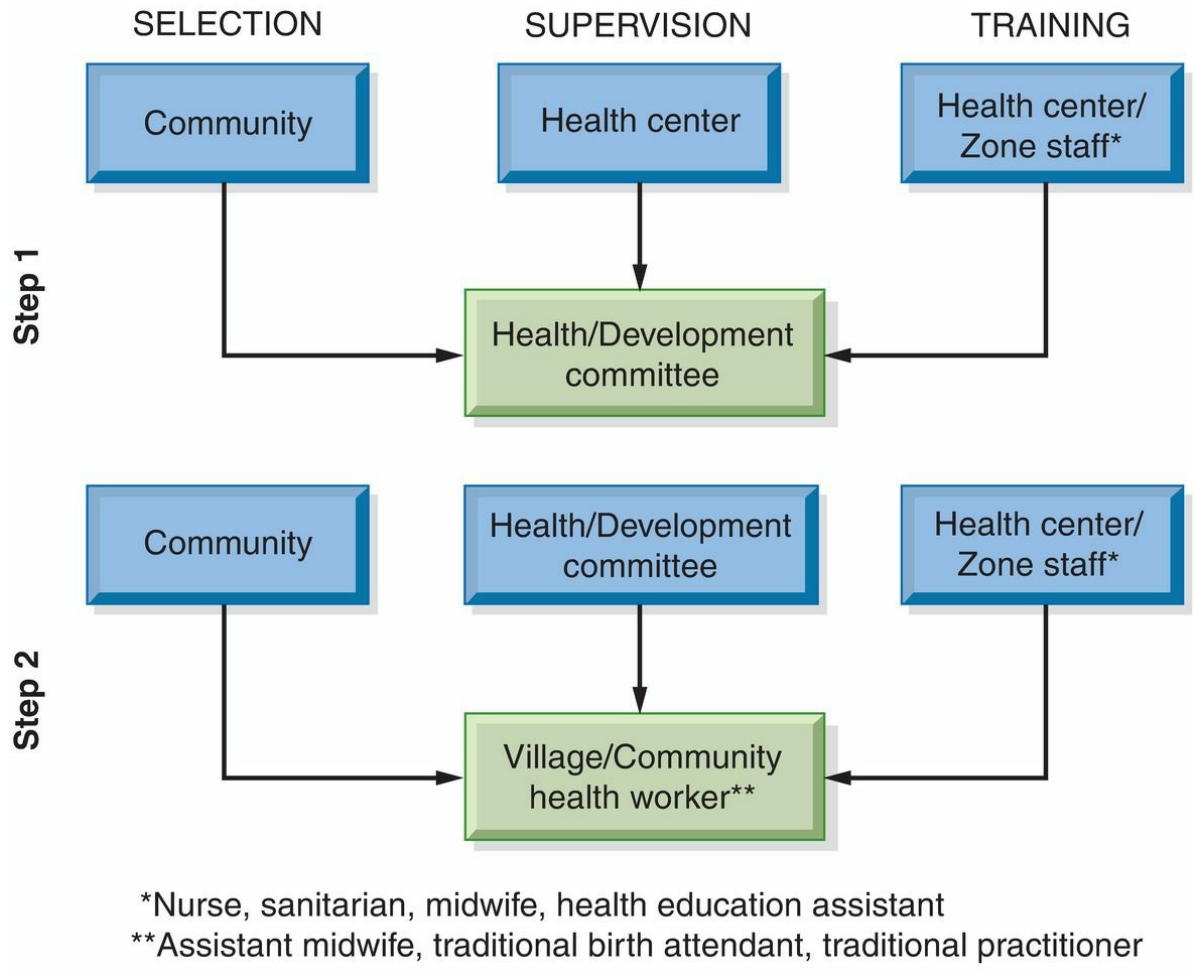

Figure 16–3 Community-based primary care.

Functions of Primary Health Care

In 1978, Article VII of the *Declaration of Alma-Ata* (now Almaty) lists the eight basic elements of PHC (WHO, 2016r):

1. Education concerning prevailing health problems and the methods of preventing and controlling them
2. Promotion of food supply and proper nutrition
3. An adequate supply of safe water and basic sanitation
4. Maternal and child health, including family planning
5. Immunization against major infectious diseases
6. Prevention and control of locally endemic diseases
7. Appropriate treatment of common diseases and injuries
8. Provision of essential drugs

Public health care also involves related sectors concerned with national and community development, including agriculture, animal husbandry, food, industry, education, housing,

public works, and communication (Article VI, Section 4). Health for All by the year 2000 was the goal, but the majority of global deaths occur in developing countries. Much assistance is needed there. Some have called for wealthy countries to devote a small percentage of their GDP to assist poor countries with their health issues. Also, low-income countries have been encouraged to devote a reasonable percentage of their own budgets to health. Access to PHN is also vital. Working with countries in various regions to address the social determinants of health through collaborative development of policies and priorities has shown some promise. This type of "intersectoral" approach to health problems has gained international support (WHO, 2013b, p. 3).

Deterrents to Primary Health Care

Fostering a PHC approach is one thing, implementing it is another. Initially, political reactions from professional groups, who felt threatened by a potential loss of income due to the shift away from specialists and tertiary hospitals in favor of primary care providers, were not supportive. Universities and teaching institutions lacked the experience of working in communities and did not know how to educate professionals for PHC. Textbooks were based on education for treating diseases and assumed the backup of well-equipped and, in some places, technically advanced hospital environments. Nursing faculty in developing countries adopted community health nursing textbooks from North America but did not understand the problems of placing student nurses in remote clinical areas with no faculty. Faculty was virtually nonexistent in rural areas and, if they were available, clients were not. Stationing young women in villages without supervision was seen in some countries as ill advised, and clients refused to appear at these health centers. In addition, populations in some rural areas were used to traditional methods and indigenous practitioners, and even when available, professional nurses or midwives were not consulted. Inadequate supervision and follow-up led to misapplication of theory learned, and those in rural areas were not prepared for the situations they faced daily. Health care workers did not understand their responsibilities for maintaining, restocking, and securing medical supplies on a regular basis, and many had no knowledge of community-based principles of case finding, record keeping, community monitoring of immunizations, prenatal care, disease prevention, health promotion, and basic measures to ensure community sanitation. For example, in one rural health center in Southeast Asia, this author observed barrels of antibiotics, medicated creams, lotions, and other medications spoiled from running solutions that had not been sorted, shelved, or refrigerated.

In many places, referral systems to nearby hospitals were not effective, and health care workers were reluctant to place themselves in responsible positions without backup and accessible secondary and tertiary facilities. In one rural community in Spain, a nurse–physician pair who worked closely together confided that they worried that the distance between them and the nearest tertiary facility would threaten their success in securing help for those during periods of emergencies.

Natural environmental phenomena such as rain, floods, and poor or absent communication facilities periodically isolated areas and prevented transport of patients to nearby facilities. Other problems arose when expensive drugs were dispensed in place of less-expensive generic brands (or in some cases were given first to the family and friends of the health care workers) and when health centers failed to refer patients back to the referring CHW. See Evidence-Based Practice for comparison of physician-led and nurse-led patient care.

EVIDENCE-BASED PRACTICE

Substituting Physicians With Nurses

Researchers conducted a systematic review and meta-analysis of published randomized controlled trials (RCTs) that assessed nurse-led care with care by primary care physicians, on hospital admissions, costs of health care, mortality, quality of life, and patient satisfaction. Results from 28,974 participants across the 24 RCTs that met criteria for inclusion in the meta-analysis showed that "nurse-led care seems to have a positive effect on patient satisfaction, hospital admission, and mortality" (Martínez-González et al., 2014, para 4). Nurses in these studies worked in a variety of settings including general practice, health care agencies, nurse clinics, community clinics, and nurse clinics.

This evidence is significant because of the growing concern about the global shortage of heath care providers, especially physicians. Many lower-income countries rely on nurses to provide some or most primary care to meet the growing demands of the aging population in health care environment where physicians are scarce.

From Martínez-González, N. A., Djalali, S., Tandjung, R., Huber-Geismann, F., Markun, S., Wensing, M., & Rosemann, T. (2014). Substitution of physicians by nurses in primary care: A systematic review and meta-analysis. Retrieved from http://www.biomedcentral.com/1472-6963/14/214

Achievements of Primary Health Care

In the almost 40 years since the 1978 proclamation of *Health for All* by WHO, there have been acknowledged significant global accomplishments. Childhood immunization rates have improved, as has the provision of safe water and sanitation. But the access to essential health care is still not available worldwide. Economic barriers, the shortage of health care personnel, and the worldwide HIV/AIDS epidemic have made it more difficult to achieve this worthwhile goal. One example of expansion of comprehensive services to their full population is Portugal (Waddington, 2008). Portugal organized Family Health Units

(FHU), where groups of physicians, nurses, and staff work to provide care to patients and families and make decisions together with them about health needs. Since the 1970s, Portugal's infant mortality rate has dropped by 50% every 8 years; the 2006 rate was 3 per 1,000. Life expectancy jumped 9.2 years in one generation. Patients register for government-sponsored health services through a family physician, and MD/RN salaries are based on productivity and performance (Waddington, 2008). Although Portugal has achieved provision of health care to most of its population and improved vital statistics, it still has a high out-of-pocket expenditure (about 22%). High-risk groups (e.g., pregnant women, children, people with diabetes) are exempt from these co-payments.

Many other nations need to achieve *Health for All* by making health care a right for all citizens and expanding services to meet the needs of rural populations and high-risk groups. Future action regarding PHC calls for strengthened collaboration among governmental agencies and NGOs in both the public and private sectors. Only then will the world have a realistic chance of achieving all the goals set out in the *Declaration of Alma-Ata* (WHO, 2016r).

The Way Forward

One of the greatest achievements of the WHO has been the eradication of smallpox. In 1967, this disease threatened 60% of the world's population. It is projected that 20 million people would have died in the next two decades if smallpox had not been eradicated. In 2010, a statue was erected to commemorate the 30th anniversary of smallpox eradication (WHO Media Centre, 2010). The WHO's other accomplishments include reduction of malaria, standardization of data collection systems, adoption of international standards for the control and reporting of morbidity and mortality, and publication of classic works for the prevention and management of disease. They have also partnered with Rotary International and UNICEF to provide measles, polio, and DPT immunizations to the world's children. In 1990, they reached the 80% mark. In addition, the WHO has been credited with preventing hundreds of millions of cases of tropical diseases. As the 21st century begins, new eradication/elimination programs are under way for polio, guinea worm disease, and measles. Other initiatives include:

1. Reducing transmission and incidence of HIV/AIDS
2. Launching the *RBM* program
3. Stopping the transmission of TB
4. Increasing access to essential pharmaceuticals
5. Improving the poor quality of some pharmaceuticals
6. Preventing and treating iron deficiency
7. Reducing maternal morbidity and mortality
8. Promoting healthful lifestyles for all age groups, including elders (WHO, 2016l)

Dr. Gro Harlem Brundtland, former Director General of WHO, characterized the 20th century as one encompassing the biggest social transformations of history. Living

conditions, she noted, have dramatically improved for the large majority of human beings, and she identified health as the key to improving the productivity of people and nations. She noted the persistence of excess mortality and morbidity that disproportionately affect poor people and underscored the need to focus on those interventions that can achieve the greatest health gains possible using available resources.

International Governmental Organizations With National Governments

Sometimes, the WHO is the first to describe a health-related situation requiring international support. It then contacts other groups or organizations with the requisite expertise, assembling members of its international disaster-preparedness teams from governmental organizations that represent various nations. Organizations such as church-related groups, universities, researchers, and governments provide international assistance.

Countries throughout the world are structured to fund within-country health issues and to contribute to the international agenda. The United States contributes internationally through its United States Agency for International Development (USAID). Some other countries' international arms include Denmark's DANIDA and Italy's Italian Cooperation. The European Union (EU) is an organization that provides funding for many health-related projects.

United States Agency for International Development

The USAID is an independent, bilateral agency of the executive branch that is under the guidance of the Secretary of State. It works to enhance long-term and equitable economic growth and to advance U.S. foreign policy by supporting countries in their efforts to recover from disaster, escape poverty, and engage in democratic reforms. The agency provides support to developing countries for economic development, agriculture and trade, global health, democracy, conflict prevention, and humanitarian assistance and does this through its collaboration with many governmental and private agencies to implement its programs (Nichols, 2011). This agency also hires nurses and other health care providers and often provides workshops to brief grant writers on the interventions currently under exploration.

The Centers for Disease Control and Prevention

The CDC's Center for Global Health is a leading player in addressing global challenges such as HIV/AIDS, malaria, emergency and refugee health, noncommunicable diseases, injuries, and more. The center strives to protect and improve health globally through science, policy, partnership, and evidence-based public health action and has four broad goals:

Goal 1: Health Impact: Improve the health and well-being of people around the world

Goal 2: Health Security: Improve capabilities to prepare and respond to infectious disease or emerging health threats and public health emergencies

Goal 3: Health Capacity: Build country public health capacity

Goal 4: Organizational Capacity: Maximize potential of CDC's global program to achieve impact

The core of CDC's strength lies in its technical expertise and scientific rigor while working with partners around the globe to address pressing and emerging public health challenges (CDC, 2015a).

American International Health Alliance

The USAID often collaborates with other organizations to implement its programs. The American International Health Alliance (AIHA) is one of these and operates under a cooperative agreement with USAID. It establishes and manages hospital partnerships between health care institutions in the United States and their counterparts in Central and Eastern Europe and in the newly independent states of Central Asia. The AIHA is reportedly the U.S. hospital sector's most coordinated response to health care issues in those areas. AIHA manages programs and research in partnerships with countries in Eurasia (Central and Eastern Europe, Central Asia), Africa, Asia, and the Caribbean (AIHA, 2012).

World Bank

The World Bank (WB) is an agency that focuses on economic development, and it includes a health component (e.g., projects related to child health and health system performance). It partners with countries, the WHO, and other organizations to address poverty, build capacity, transfer knowledge, provide resources, and forge partnerships in the public and private sectors (World Bank Group, 2016). See Display 16–5.

DISPLAY 16.5 WORLD BANK

The fight against poverty is not a fight for glory. It is about equity and social justice, about the environment and resources we all share, and about peace and security. It is a fight for a better life for all of us and for our children who will live in this very interconnected world.

From Wolfensohn, J. D., & Kircher, A. (2005). Voice for the world's poor: Selected speeches and writings of World Bank President James D. Wolfensohn, 1995–2005. Washington, DC: The World Bank. Quote excerpted from p. 167.

Nongovernmental Organizations

Countries throughout the world provide interventions through formal governmental organizations and through NGOs. These organizations are not under government sponsorship or control. In the United States, they are designated as private voluntary organizations (PVOs) that focus on humanitarian and professional issues related to global health. Examples of PVOs are the Global Health Council (GHC), the Center for International Health and Cooperation, Cooperative for American Remittances to Europe (CARE), the Carter Center, and the ICN.

These organizations contribute in their particular areas of expertise and work with other international organizations, research centers, and universities. Some focus on children, such as Save the Children and the International Society of Prevention of Child Abuse and Neglect (SPCAN); some on medically focused interventions, such as Doctors Without Borders; and some on logistics and supplies, such as Direct Relief International (DRI).

Global Health Council

The GHC (formerly known as the National Council for International Health) is the world's largest membership alliance dedicated to saving lives by improving health throughout the world. The GHC advocates for needed policies and resources, builds networks and alliances among those working to improve health, and shares innovative ideas, knowledge, and best practices in health (GHC, 2015a).

The GHC's membership includes hundreds of private and public organizations around the world, as well as several thousand professionals involved in global health. A multidisciplinary, cross-cultural board of directors, health professionals, student interns, volunteers, and members comprise its staff. Its mission is to "improve health globally through increased investment, robust policies and the power of the collective voice" (GHC, 2015a, para. 2).

Center for International Humanitarian Cooperation

The Center for International Humanitarian Cooperation (CIHC), founded in 1992, promotes peace and healing in countries shattered by war, regional conflicts, and ethnic violence, as well as natural disasters. Its belief is that health and other basic humanitarian actions often provide the only common ground for initiating dialogue and cooperation among warring parties. The center provides training in mental health issues, disaster management, and negotiation, as well as books on topics ranging from civil strife to epidemics (CIHC, n.d.).

CARE

The CARE was founded in 1945, when 22 American organizations joined together to rush lifesaving *care packages* from individual American citizens, churches, clubs, and businesses to survivors of World War II. Millions of CARE packages followed in the next two decades. In the 1950s, CARE expanded its program to developing nations, using surplus American food to feed the hungry. In the 1960s, it pioneered PHC. Now renamed the Cooperative for Assistance and Relief Everywhere, CARE is affiliated with foundations and other organizations, as well as the UN and the European Union (EU). CARE intervenes by responding to famines and disasters worldwide with emergency food, supplies, and rehabilitative efforts. It delivers programs in education, health, population, water and sanitation, agriculture, environmental preservation, economic development, and community building in over 90 countries (CARE, 2016).

The Carter Center

Former United States President, Jimmy Carter, and his wife, Roselyn, founded the Carter Center in 1986. The Carter Center intervenes in disease prevention and agriculture throughout the world and cites its fundamental mission as "human rights and alleviation of human suffering" (Carter Center, 2016, para 1). It is aligned with Emory University, and the particularly successful interventions include the guinea worm disease eradication program and the program to eradicate river blindness, as well as trachoma and schistosomiasis control. Lymphatic filariasis elimination, malaria control, and mental health issues, along with an international task force on disease eradication, are also components of its health program.

Bill & Melinda Gates Foundation

Bill Gates, the force behind popular computer software giant, Microsoft, and his wife Melinda operate a global foundation that provides assistance for those living in hunger and poverty. The foundation provides vaccines to prevent the spread of infectious diseases like malaria, polio, and HIV. They also work to improve maternal–child health and nutrition (Bill & Melinda Gates Foundation, 2015).

International Council of Nurses

As noted earlier, the ICN represents the global interests and concerns of the nursing profession. ICN's mission is to maintain the role of nursing in health care through its global voice. Its current membership includes nursing organizations from 130 countries representing 13 million nurses (ICN, 2014).

National Governments Working Alone

Individual nations have considerable experience working across agencies and organizations, and they have traditions that they honor as they intervene. For example, the Federal Republic of Germany has one of the largest voluntary sectors in the world and is known for its work with the International Red Cross. The Finnish Nursing Organization has an outstanding international reputation for its work during the Armenian earthquake and in other international efforts throughout Europe. The Danish Nurses Organization has provided funds, leadership, and expertise to numerous projects in collaboration with the WHO and with the ICN.

At times, however, governments facing a crisis or disaster prefer to operate alone, without international assistance. This position must be respected, and because of this expectation, international organizations will not appear in a country until a formal request is received from representatives of the country in crisis. Furthermore, some countries are more receptive to certain kinds of assistance than others. Some countries do not welcome foreign professionals, as they believe they have enough of their own. They may prefer help in the form of equipment, transport, medications, or vital supplies, such as water and food. Those in disaster preparedness are well aware of what some refer to as the "second disaster," when well-intentioned groups send in truckloads of used clothing and articles that are useless in some environments. The recent disasters in Haiti lead to an outbreak of cholera that was brought into the country by international workers. This experience has added another layer of concern for those involved in relief work. Further, these disasters have also spurred the removal of children from affected countries; some of these are characterized as rescue missions, some are reported to arise out of groups dedicated to religious objectives, and some have been shown to occur out of financial interests (receiving payment for couples wishing to adopt children). At times, governments would prefer to work alone but do not have the resources to do so, nor can their authorities provide the personnel to sort the kinds of contributions donors provide during emergencies.

Organizations With Religious Affiliations

Many religious groups sponsor organizations, and some of them include a religiously oriented agenda along with their interventions. Others, however, do not. Often, the work of these groups is similar to those with a nonreligious focus, and the source of funding for a particular project may be the only overt connection to any religious group. Catholic Charities and other Christian organizations provide critical interventions, as do Muslim, Jewish, and other religiously oriented organizations. These organizations often recruit community health nurses and other health care providers for short- and long-term assignments. See Perspectives: One Nurse's Experience Overseas.

PERSPECTIVES
ONE NURSE'S EXPERIENCE OVERSEAS

I had always wanted to be a nurse and work in a foreign country, so when I heard of an organization that sent health workers overseas, I got involved while I was in college. The experiential cross-cultural training that my husband and I received before we left made all the difference in preparing us to have a positive transition. We learned that our goal would be to become "servant learners," serving the local population and learning from them rather than coming in to solve their problems with our superior ways of doing things. This was a hard lesson to learn, and we kept coming back to it in our 18 years abroad as we searched for the rationales behind customs that puzzled us. I also had to find a balance between "going native" in each new culture and keeping the parts of my own identity that were valuable.

When we first arrived, it was like nothing I expected. No one met us at the airport as planned, we did not speak the language, a luggage cart hit me from behind and cut my leg, and it was hot, crowded, and dirty. This was not a complete surprise as I had been prepared for the actual experience to differ from my expectations, but adjusting took conscious effort. I expected to go to a delta town and work in an established hospital. We were asked to go to a major seaport city and teach English! We did find an opportunity to work in community health with the goal of "working ourselves out of a job" by training national workers who would be far more effective in their country than we could ever be.

Flexibility, comfort with ambiguity, being able to laugh at ourselves, and patience when results seemed few and far between were essential skills. I learned much about myself and grew in my ability to cross cultures. I learned to actually prefer other ways of doing and being. My faith deepened, and I learned to depend upon it like I never had before.

We were accepted by people, who brought us into their culture, and treated us like family members. I consider that the most valuable part of the whole experience as I look back upon our time there. Our children were born overseas and grew up feeling at ease in many settings and with a particular sensitivity to differing perspectives. I know what it is to live with war, to celebrate life in impossibly difficult circumstances, and to stand truly in another's shoes—experiences I would never have had at home but which expanded my life. Although I had no idea when I first got off that airplane that I would spend most of my adult life in foreign countries, I am so grateful for the opportunity I have had to live my dreams.

Karin Urso, RN, PHN,
Missionary Nurse

COMMUNITY HEALTH NURSING OPPORTUNITIES

Let us suppose that, after reading this chapter and some of its references, you have decided to work in a location other than your own. You are not alone.

Global health programs are becoming increasingly prevalent at academic health centers. These programs range in scope from comprehensive, multidisciplinary, multiprofessional initiatives—with patient care, research, and education components—to individual courses. The larger initiatives may involve collaborative efforts among schools of medicine, public health, nursing, and dentistry and may have alliances with schools outside the health professions. This growth in the number of programs is accompanied by a surge of interest in every facet of global health among health science students and trainees (Pinto et al., 2014).

If you decide to pursue work abroad, you might begin your work at a local level, at a local health center in a village. You would be aware of your own issues and reasons for wanting this experience, and you would have selected the location because of some factors that draw you to it. How then might you go about preparing for the experience? In what kind of activities might you be involved? What might be the expectations and commitments you would make regarding the assignment?

Community health nurses, as shown in this chapter, carry major responsibility for managing health services in health centers, clinics, schools, workplaces, and community settings that range in population density and complexity from remote areas to major centers in large metropolitan areas. This work includes providing education, guidance, and professional supervision to other cadres of health care providers.

Before you travel, conduct your own preliminary needs assessment. You can use the logic of the thinking process developed in this chapter and move through the framework as a guide. Begin, as this chapter suggests, with a review of the context. Here, you would examine the location, climate, temperatures, weather conditions, travel routes, living arrangements, languages spoken, cultural patterns, religious beliefs, and religious holidays. Locate novels and literature from the country, as this source of data is often more revealing than many of the statistical charts and information available from official sources. Interacting with people from the country often provides valuable insights not available from reading materials. In all probability, you will find enclaves of people living in the United States from the country in which you plan to work. For example, Armenian communities are located in Watertown, Massachusetts, and Los Angeles, California. There are many Ethiopian communities in Atlanta, Georgia; New York City, New York; and Los Angeles, California. There are groups and organizations of Albanian Americans, Polish Americans, Hungarian Americans, Romanian Americans, Indian Americans, Ethiopian Americans, and Mexican Americans. These groups maintain close contact with their

mother country and receive and give support to their family members and organizations in those countries.

Next, examine the population's health status, at the regional levels (e.g., Europe, Asia, Africa), the country level (e.g., Chad, Nepal, India), and at the local level (e.g., Tete Provinces and villages in Tete Provinces, Mozambique). Here, you would review the data to identify the universals of care, that is, the causes of mortality and morbidity, the level of functioning in the community, decision-making (if available), and cost of health care.

Then, move on to review evidence of the three eras of health conditions in the country and determine the age of the population and the health conditions they experience, given their history, location, and experiences with natural or man-made disasters. Look at birth rates, death rates, infant mortality rates, and maternal mortality rates, asking the following: How many infants are born? How many of these die at birth, during the first month of life, during the first year of life? How long do people live? What kills them? What makes them sick? How do people function everyday? What kinds of decisions do they have to make and how do they make them? What community supports exist to help people with these processes? What is the average income per capita? What do people buy with their money?

Review the conditions and diseases that account for the three eras of health conditions as described in this chapter and determine the prevailing health conditions that you will encounter. Review the kinds of health conditions that are reported both in the professional literature and in the popular literature and media.

Next, it's helpful to review the organization with which you will be associated. Examine its philosophy, its mission, its ways of working, its relationship to the community of interest, and the ways in which community health nurses are considered, placed, and function. Query the nature of the health care team of which you would become a member, those to whom you report, and those who would report to you. Review their scope of practice, the interventions they provide, and their ways of delivering health services.

It is helpful to identify the international governmental and NGOs working in the area and obtain their publications for review and their addresses and contact numbers (when you arrive in the area, visit these organizations and request a briefing). Review the projects currently under way, and examine their track record for the factors that suggest ill-conceived outcomes and evidence of those that produced successful outcomes.

If you are considering further education, you will find many opportunities available to you. Universities throughout North America have developed partnerships with universities, governments, and agencies in other countries. The major universities and colleges that specialize in community health most often include schools of public health and graduate programs in nursing. Harvard's School of Public Health, Johns Hopkins University, Wayne State University, Duke University, the University of Illinois, the University of Pennsylvania, to name just a few, provide scholar practitioner education to those wishing to work toward providing access to health care, develop community partnerships to ensure health care for the uninsured, and serve as researchers, teachers, practitioners, community

health administrators, or health information specialists. A world of challenges and a world of opportunity and self-learning are waiting—when you are ready.

Following this review, identify and remediate gaps in your knowledge of theory and practice. Most importantly, take the time to plan and to take care of yourself and your health, as your own health status is critical to your functioning in what may be a very different context from your own.

To explore specific opportunities, contact the organization of interest (see the listing of selected organizations at the end of the chapter). Some of the larger organizations, such as the WHO, require graduate education and at least 5 years of experience, but many organizations do not. Nurses can participate in numerous smaller organizations that are involved in health programs. Among such groups seeking nurses are the U.S. Peace Corps, religious and lay organizations, and private and governmental agencies, societies, and foundations. Health Volunteers Overseas (HVO) is an example of a private, nonprofit organization that seeks to improve health care quality and access in developing countries through education. Twelve professional organizations sponsor HVO, including the American Association of Colleges of Nursing (HVO, 2011). The GHC provides information on career opportunities in global health for community health nurses and others. It also offers career seminars and provides suggestions from global health experts for nurses interested in entering the field, as well as a newsletter (GHC, 2015b). University student nurses can also contact their campus office of global affairs for opportunities available overseas (see Perspectives: Voices From the Community).

PERSPECTIVES Voices From the Community

You cannot build a strong country on the backs of sick people.

—Dr. Mohammad Akhter, Executive Director, American Public Health Association

Nurses and midwives play a crucial and cost-effective role in reducing excess mortality, morbidity, and disability and in promotion of healthy lifestyles.

—Dr. Gro Harlem Brundtland, former Director General, World Health Organization

Global health nurses always receive far more than they give.

—Cydne, former Peace Corps nurse

The developing world may be poor materially, but it is rich in hope and spirit.

—Edith, missionary nurse

Nurses working in foreign lands make a big difference through their training and support of local nurses and others. Their professional dedication to quality health care and promotion of healthful living among their patients, families, and communities serves as an effective role model and has a profound impact on the well-being of the people they work with.

—Tom, physician

Living overseas for many years was a challenging and rewarding experience. Raising a family was not always easy, but our six children, now adults, value the exposure they had to other cultures and the many interesting friendships they made.

—Inez, spouse of a global health administrator

Nurses play an important role ministering to the health care needs of not only the indigenous population but also the sometimes-sizable population of expatriates and their families.

—Jennifer, teacher

There is nothing so powerful as seeing a community that has changed through individuals taking responsibility for themselves and their own community.

—Lydia, volunteer PHN with Medical Ambassadors

SUMMARY

Community health nursing is practiced throughout the world and can be considered within a useful, worldwide framework. This framework considers first the context within which the population, the provider, and the procedures interact.

The context reflects a location's geography, history, weather, culture, religious patterns, and belief systems. This context is a critical element that community health nurses appreciate for its influences on the populations, the providers, and the interventions they are able to deliver.

Community health nurses work with populations that vary from country to country, and to serve them appropriately requires an understanding of the ways in which the context in which they are located interacts with their health status and health histories. In this regard, an examination is required to assess the universal imperatives of care, to identify the population's current health status, and to determine the focus of nursing interventions. That is, when a population is experiencing high mortality, the interventions must be targeted to that level and not, say, at the level of functioning.

Community health nurses also examine the population to assess the kinds of health conditions they experience, and the three eras are helpful guides in this assessment. These are the Era of Infectious Diseases, the Era of Chronic Long-Term Health Conditions, and the Era of Social Conditions. The three P's (population, providers, and procedures) relate to the interventions community health nurses deliver as they serve populations and are informed by the organization with which the community health nurse works. A number of international, national, and local organizations intervene in communities. Some of these agencies are intergovernmental and multilateral, such as the UN and WHO; others are bilateral, such as the USAID and the Peace Corps. Many NGOs (or PVOs) also assist with global health.

The focus remains on delivering PHC to populations throughout the world. The world's communities deliver health care in different ways, depending on their political economies. The entrepreneurial, welfare-oriented, comprehensive, and socialist systems provide for the health of their citizens in unique ways.

Variations of these systems exist, depending on whether the country is considered industrialized, transitional, or very poor. The GBD study has provided important quantifiable information about morbidity and mortality in the world, as well as disability measurements. Primary global health concerns include the eradication, elimination, or control of communicable disease, as well as immunization, maternal and perinatal morbidity and mortality, tobacco-related diseases, chronic disease, environmental illness, and malnutrition. In addition to these age-old health problems, there are new, emerging, and reemerging diseases. Armed conflicts and political upheavals also adversely affect health; this is an important consideration because of the number of major armed conflicts

occurring at any given time.

Community health nursing services are critical to the ultimate health of a community. They provide important primary, secondary, and tertiary levels of care and prevention throughout the world. In the future, community health nurses will continue as major contributors to global health.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. What infectious diseases are most commonplace around the world? What is being done to combat them?
2. Which of the worldwide leading risk factors also impact the United States? Why? What can you, as a public health nurse, do to address these risk factors?
3. Identify a country or community in which you would like to practice community health nursing. Before you begin a review of this country or community, write down your own knowledge, attitudes, and beliefs about the country or community, the people, and the culture. Examine your own reasons for wanting this experience. Identify the way you might feel if you were the recipient rather than the donor of the services you plan to provide.
4. Conduct your own needs assessment using the framework provided in this chapter. Given what you have found, what would you prioritize as the major focus of a community nursing intervention for that community? Provide your rationale for your choices.
5. Given what you have found, what organizations, groups, or references would you access before you left on your assignment?
6. Based on your examination, what questions would you want to ask of the employing agency before you left on your assignment? What additional actions would you take to protect yourself and your health, given the review you conducted?
7. What sources of information appear to be most informative? What data are you seeking that are not reported? Why do you think this is the case?

17 CHAPTER

Being Prepared: Impact of Disaster, Terrorism, and War

"In this dangerous world that we live in, where hatred and violence and natural disasters sometimes collide to almost overwhelm us, we each can help in some way."

—*Marsha Blackburn* (1952), American Politician

"I have an almost complete disregard of precedent, and a faith in the possibility of something better. It irritates me to be told how things have always been done. I defy the tyranny of precedent. I go for anything new that might improve the past."

—*Clara Barton*, Nurse Founder of the American Red Cross

KEY TERMS

Biologic warfare
Casualty
Chemical warfare
Complex emergency
Crisis intervention
Critical incident stress debriefing (CISD)
Directly impacted by disaster
Disaster
Disaster planning
Displaced persons
Incident command system
Indirectly impacted by disaster
Intensity
Man-made disaster
Mass-casualty incident
Moulage
Natural disaster
Nuclear warfare
Posttraumatic stress disorder (PTSD)
Refugee
Resilience
Scope
Shelter in place
Terrorism
Triage

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe a variety of characteristics of disasters, including causation, number of casualties, scope, and intensity.
- Discuss a variety of factors contributing to a community's potential for experiencing a disaster.
- Identify the four phases of disaster management.
- Describe factors involved in disaster planning.
- Describe the role of the community health nurse in preventing, preparing for, responding to, and supporting recovery from disasters.
- Use the levels of prevention to describe the role of the community health nurse in relation to acts of chemical, biologic, or nuclear terrorism.

What would you do if your local news station broadcasts an announcement that your community was directly in the path of a hurricane that earlier in the day had caused extensive damage and loss of life in a neighboring state? What would you do if you were shopping at a local mall, suddenly heard an explosive noise followed by shouts and cries for help, and then noticed that a pungent odor was filling the air? In March of 2011, were you glued to your television watching live coverage of the earthquake and tsunami in Japan? When you hear news of riots and the civil war in Syria or other violence in the Middle East and bombings in Belgium or terrorist attacks in Paris or San Bernardino, do you think of it as a disaster? Even today, the impact of the 2005 hurricanes Katrina and Rita on the Gulf Coast continues to affect the lives of the residents of those communities devastated by the storms. This is also true for residents of New Jersey after Hurricane/Superstorm Sandy in 2012. As distant as some of these scenarios might seem from your own life, natural disasters and terrorism are ever-present possibilities, and nurses and other health care professionals have an obligation to respond appropriately. This chapter increases your understanding of the community health nurse's role in preparing for, responding to, and recovering from natural disasters and terrorism.

DISASTERS

A disaster is any natural or man-made event that causes a level of destruction or emotional trauma exceeding the abilities of those affected to respond without community assistance. The crash of a private plane over the Pacific Ocean in which no bodies are recovered and no environmental impact is felt is not a disaster by this definition, because no specific community-based response is required or even possible. Such a tragedy may, however, be felt for a lifetime by family members and friends who need emotional support and possibly long-term financial assistance. If a plane with 150 passengers crashes over land, destroying several homes in its path, the community affected is unable to cope with the resulting injuries, deaths, and property destruction without assistance; by the definition used here, this constitutes a disaster.

The geographic distribution of disasters varies because certain types of disasters are more common in some parts of the world. For example, California, Alaska, and Tennessee are associated with earthquakes and the Gulf Coast with hurricanes and oil spills. Similarly, it is not surprising to hear of drought in Ethiopia, floods in India during the monsoon season, or bombings in Afghanistan. When certain types of disasters are anticipated, communities are usually more prepared for them. For instance, California has strict building codes to prevent destruction of structures in the event of earthquakes, but most California homes lack the basements and insulation that characterize homes in Iowa and Oklahoma that are often visited by tornados or severe winter storms. Similarly, residents of Germany, Austria, and Russia are better prepared for blizzards than for heavy rain, which explains in part the devastation caused in some communities by floods there in 2002.

Because the local media in the United States do not typically report on disasters unless there are mass casualties, one may be unaware of the frequency and variety of both natural and technologic disasters worldwide. Here is a brief sampling of major disasters that occurred from 2007 to 2016 (Chuck & Kwong, 2015; Infoplease, 2008, 2009, 2012; International Charter, 2008; Littleton, Axsom, & Grills-Taquechel, 2009; Press Information Bureau, Government of India, 2008):

April 2007

- *Virginia*: Worst mass shooting in U.S. history at Virginia Tech University ended with 33 dead and 17 seriously wounded.

August 2007

- *Minnesota.* An eight-lane interstate bridge packed with cars broke into sections and collapsed into the Mississippi River, killing at least nine and injuring at least 60.

October 2007

- *California*: Wildfires burned more than 516,000 acres in Southern California. Seven died, and nearly ninety people were injured. Over 500,000 people were forced to evacuate their homes; 2,000 homes were destroyed.

November 2007

- *Bangladesh*: Cyclone killed nearly 3,500 people in southern Bangladesh; millions of people were left homeless.

January 2008

- *Kenya*: After an election, violent riots between tribes killed 300 people, and thousands of houses, farms, and businesses were burned.

February 2008

- *U.S. South*: Violent tornados struck Kentucky, Tennessee, Alabama, Mississippi, and Arkansas with little warning, resulting in 54 deaths and hundreds of injured, with widespread damage reported.

May 2008

- *China*: Earthquake struck eastern Sichuan, northwest of Chengdu. The tremor was felt throughout the region, with the death toll exceeding 65,000.

November 2008

- *India*: Terrorists attacked Mumbai with 10 coordinated bombings and attacks across the city. Terrorists killed 164 people and wounded over 300.

April 2009

- *International:* H1N1, also known as Swine Flu, outbreaks in more than 70 countries. CDC (2009) reported between April and October that 22 million Americans had contracted the virus, 98,000 required hospitalization, and about 3,900 people died from H1N1-related causes.

January 2010

- *Haiti*: Earthquake struck Port-au-Prince, Haiti. The tremor was felt throughout the region, with the death toll exceeding 222,570.

March 2011

- *Japan*: Earthquake and tsunami struck Pacific coastal areas of northeastern Japan.

Estimates of over 9,000 dead and 18,000 missing.

October 2012

- *Hurricane Sandy*: Struck the east coast, killing 132 people and causing an estimated $82 billion dollars in damages to New York, New Jersey, and Connecticut.

December 2012

- *Newtown, Connecticut*: Sandy Hook Elementary School shooting, 26 people killed, including 20 children between the ages of six and seven. The lone gunman shot his mother prior to the school shooting.
- *U.S. Nationwide:* Meningitis outbreak traced back to contaminated steroid medication shipped to 23 states killed 36; 500 cases reported.

July 2012

- *Aurora, Colorado:* Mass shooting at a movie theater, 12 killed, 58 wounded. Lone gunman sentenced to life in prison after unsuccessful insanity defense.

March 2014

- *West Africa:* The largest outbreak of Ebola in history, with multiple countries affected (Liberia, Sierra Leone, and Guinea).

August to October 2015

- *Washington:* Wildfires and mudslides in the state of Washington killed three firefighters and damaged or destroyed hundreds of homes.

October 2015

- *United States:* Severe storms cause serious flooding in North and South Carolina, leading to 25 deaths and billions of dollars in property damage. Just prior to this, severe flooding in Kansas, Oklahoma, and Texas was responsible for 43 deaths and much destruction.

November 2015

- *Paris, France:* A coordinated, multisite terrorist attack kills 130 people and injures over 350 people. Earlier, in January, terrorists attacked offices of a magazine and a Jewish market, killing 17.

January 2016

- *United States:* Blizzard affected the northeast, mid-Atlantic, and southeast sections of the United States, killing 38 people.

March 2016

- *Belgium*: Coordinated terrorist attacks at the airport and metro system killed 35 and injured over 250 people.

Characteristics of Disasters

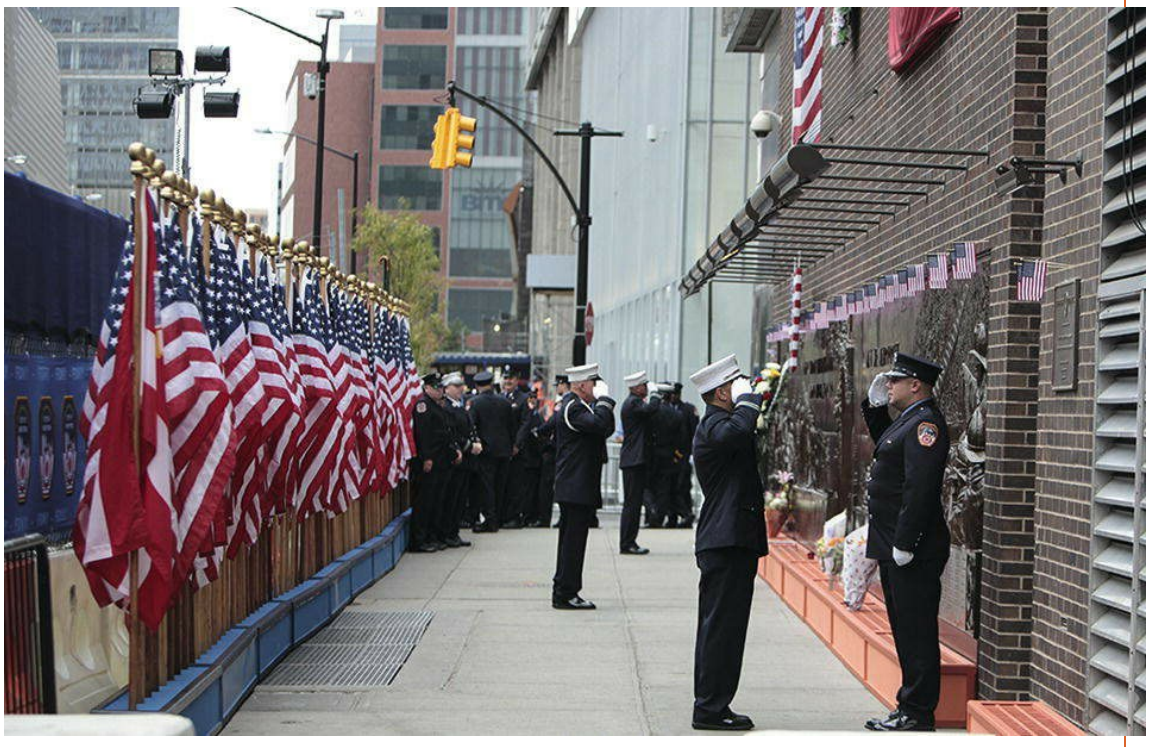
Disasters are often characterized by their cause. A natural disaster is caused by natural events, such as the earthquake and tsunami in Japan in 2011. A man-made disaster is caused by human activity, such as the 2008 shootings at Virginia Tech, the bombing of the World Trade Center in New York City in 2001, the displacement of thousands of Kosovars during their war with Serbia in 1999, or the riots in Kenya in 2008. Other man-made disasters include nuclear reactor meltdowns, industrial accidents, oil spills, construction accidents, and air, train, bus, and subway crashes. In fact, man-made disasters can and frequently do follow natural disasters, as occurred with the nuclear reactors in Japan following the earthquake and tsunami in 2011. A complex emergency is a multifaceted "humanitarian crisis in a country, region or society where there is a total or considerable breakdown of authority resulting from internal or external conflict and which requires a multi-sectorial, international response" (United Nations Inter-Agency Standing Committee, 2008, p. 9). Complex humanitarian emergencies disproportionately impact women and children.

A casualty is a human being who is injured or killed by, or as a direct result of, an accident or natural disaster. Although major disasters sometimes occur without any injury or loss of life, the number of casualties involved increases the likelihood of wider news coverage. If casualties number more than two people but fewer than 100, the disaster is characterized as a *multiple-casualty incident*. Although multiple-casualty incidents may strain the health care systems of small or midsized communities, a mass-casualty incident —often involving many casualties—can completely overwhelm the resources of even large cities. Preparedness for mass-casualty incidents is essential for all communities.

The possibility of being prepared is another characteristic that varies with different types of disasters. For instance, the path and time of landfall of a hurricane can be tracked, so that residents in the storm's path can be evacuated and families and businesses can be protected. Communities can also minimize devastation from flooding by building reservoirs or refusing to grant building permits in flood-prone areas and by reinforcing areas around waterways with sandbags during rainy weather. In fire-prone areas, communities can post notices to heighten awareness of fire danger and enforce regulations to cut back vegetation near structures in forested areas.

On the other hand, some disasters strike without warning. For example, the terrorist attacks in New York City caught thousands of civilians by surprise. They were trapped in buildings with limited escape routes and very little time to retreat to safety. For survivors of the 2015 Paris terrorist attacks, survival depended on being in the right place at the right time. Coworkers were trapped in a building during the 2015 San Bernardino terrorist attack. A total of 14 were killed and 27 were injured as a married couple sprayed them with automatic weapons fire. The number of wildfires across California in 2015 was not completely unanticipated, but was uncharacteristically large, and control was hindered by

drought conditions, along with heat and high winds. Some residents were barred from reentering their communities for weeks, without any knowledge of whether they would have homes when they were allowed to return. The shootings at Virginia Tech in 2007 and in Tucson in 2011, which resulted in six deaths and seriously wounded Rep. Gabrielle Giffords, occurred without warning and were both the result of a mentally unstable individual acting alone. Some disasters, like the natural gas leak in a southern California community during 2015 to 2016, are at first unknown to the public. After residents began noticing headaches, nosebleeds, respiratory problems, and other symptoms, the Southern California Gas Company acknowledged that a deep well gas leak had occurred in a difficult-to-reach canyon miles away. The company assured the public that the leak did not pose an imminent health risk, although it had been occurring for months and would take several more months to stop. Many residents voluntarily moved their families to other areas because of the effects of the gas fumes. It was estimated that over 30,000 kg/hour of methane was released into the atmosphere, and the area became a no-fly zone per the Federal Aviation Administration (Reilly, 2016). It was finally stopped and "permanently sealed" in late February 2016 (Pamer, Wynter, & McDade, 2016, p. 4).



The scope of a disaster is the range of its effect, either geographically or in terms of the number of people impacted. The collapse of a 500-unit high-rise apartment building has a greater scope than the collapse of a bridge that occurs while only two cars are crossing.

The intensity of a disaster is the level of destruction and devastation it causes. For instance, an earthquake centered in a large metropolitan area and one centered in a desert may have the same numeric rating on the Richter scale yet have very different intensities in terms of the destruction they cause.

Persons Impacted by Disasters

Because disasters are so variable, there is no typical person impacted in a disaster. Nor can anyone predict whether he or she will ever become impacted by a disaster. Directly impacted by disaster are the people who experience the event, whether fire, volcanic eruption, war, or bomb. They are the dead and the survivors, and even if they are without physical injuries, they are likely to have health effects from their experience. Some may be without shelter or food, and many experience serious psychological stress long after the event is over (Display 17–1).

DISPLAY 17–1 DIRECTLY AND INDIRECTLY IMPACTED PEOPLE—HOW A DISASTER'S INFLUENCE LIVES ON

Anniversary observance of World Trade Center terrorist attack.

On September 11, 2001, almost 3,000 people died in the terrorist attacks on the World Trade Center in New York City. Although all of the employees and visitors in

the two buildings were directly impacted by this disaster, the entire population of Manhattan can be considered indirectly impacted. Hotels, businesses, and apartments for blocks surrounding the Twin Towers suffered structural damage, blown-out windows, and interiors covered with inches of powdered cement and other debris. A year after this disaster, many residents in the surrounding areas still were unable to return home.

Many rescue workers who were survivors have lasting psychological effects from their own survival experiences and from losing close friends and colleagues. In addition, many rescuers inhaled the dust in the air for days and now are suffering from respiratory damage, which changes their status from indirectly impacted to directly impacted by the disaster.

All people working in or visiting Manhattan that day were affected by the closing of the bridges and tunnels and were stranded in New York City until transportation routes opened again, thus becoming indirectly impacted. Other indirectly impacted persons included were children attending school and living within sight of the Twin Towers. They received counseling in school for months, and in some cases years, after the disaster.

For 1 year after the attack, volunteer construction workers and rescue workers who lost fellow police officers, paramedics, or firefighters worked 24 hours a day. First, the efforts were geared to find survivors. Shortly after, workers knew that they were looking for the bodies or body parts of victims while removing thousands of tons of building pieces. Thousands of people involved in the recovery efforts can still be considered indirectly impacted.

Family members of the 2,980 deceased victims, who have been affected for a lifetime, also are indirectly impacted. Thousands of children lost a parent, some parents lost multiple children, and, in some cases, both spouses were lost because both the husband and wife were working in the World Trade Center. The ripples of tragedy extended beyond the borders of the United States, because hundreds of people from different countries were working in the Twin Towers whose family members remain indirectly impacted.

Depending on the cause and characteristics of the disaster, some direct survivors may become displaced persons or refugees. Displaced persons are forced to leave their homes to escape the effects of a disaster. Usually, displacement is a temporary condition and involves movement within the person's own country. A common example is relocation of residents of flooded areas to schools, churches, and other shelters on higher ground. Typically, the term refugee is reserved for people who are forced to leave their homeland because of war or persecution. For example, the catastrophic earthquake in Haiti in 2010 killed an estimated 316,000 people, and more than a million people were left homeless. Over 60,000 Haitian refugees reside in the United States today (Comas, 2013) escaping poverty and

devastation. Returning refugees can place economic and social strains on the county of origin. Along with needs for employment and shelter, these influx situations raise concerns, especially regarding early or forced marriages, child labor, and human trafficking (United Nations Refugee Agency, n.d.). Whether the displacement of refugees is permanent or not, the lasting impact to both the country of origin and the host country is significant.

Indirectly impacted by disaster are the relatives and friends of persons directly impacted by disasters. Although these people do not experience the stress of the event itself, they often undergo extreme anguish from trying to locate loved ones or accommodate their emergency needs. If bodies cannot be found or are unidentifiable, indirectly impacted persons experience even greater anguish and may not be able to accept that a loved one has died. Family members of those killed on 9/11 in New York City worked with architects to develop a complex of buildings and a memorial that meets the expectations of most of those indirectly impacted by the attack and honors their loved ones. This effort, along with the Flight 93 National Memorial in Shanksville, PA, and the Pentagon Memorial, helps with the long healing process. They also serve as a reminder of the impact that day had on each of our lives.

Factors Contributing to Disasters

It is useful to apply the host, agent, and environment model (epidemiological triad) to understand the factors contributing to disasters, because manipulation of these factors can be instrumental in planning strategies to prevent or prepare for disasters.

Host Factors

The *host* is the human being who experiences the disaster. Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and even socioeconomic factors. For instance, elderly residents of a mobile home community may be unable to evacuate independently in response to a tornado warning if they can no longer drive. Impoverished residents of a low-income apartment complex in a large city may notice that their building is not compliant with city fire codes, but may avoid alerting authorities for fear of being forced to move to more expensive housing.

Agent Factors

The *agent* is the natural or technologic element that causes the disaster. For example, the high winds of a hurricane and the lava of an erupting volcano are agents, as are radiation, industrial chemicals, biologic agents, and bombs. The Station nightclub fire and the apartment deck collapse in Chicago (both in 2003) demonstrated that the irresponsibility of contractors and inspectors and failure to adhere to safety policies can act as agents of disaster, resulting in death and destruction (Pemberton, 2013).

Environmental Factors

Environmental factors are those that could potentially contribute to or mitigate a disaster. Some of the most common environmental factors are a community's level of preparedness; the presence of industries that produce harmful chemicals or radiation; the presence of flood-prone rivers, lakes, or streams; average amount of rainfall or snowfall; average high and low temperatures; proximity to fault lines, coastal waters, or volcanoes; level of compliance with local building codes; and presence or absence of political unrest.

Agencies and Organizations for Disaster Management

In 1803, just 10 years after the Treaty of Paris, the United States first recognized the need to prepare for emergencies through law and dedicated organizations. The first law was written as a direct response to a major disaster, the Portsmouth, New Hampshire, fire of 1803. The majority of subsequent legislation was also in response to specific crises and created many different agencies to respond to those disasters. From 1803 until the passage of the Disaster Relief Act of 1950, there were 125 pieces of legislation related to disaster assistance and many of these pieces of legislation changed the roles and responsibilities of government agencies. The one constant was that the response of the federal government to disasters remained more reactive than proactive and was ad hoc in nature, only becoming coordinated with the establishment of the Federal Emergency Management Agency (FEMA) in 1979 and the passage of the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 (Haddow, Bullock, & Coppola, 2014). George Washington University has an Institute for Crisis, Disaster and Risk Management (n.d.) and offers resources and publications on this topic, as well as degrees in this area.

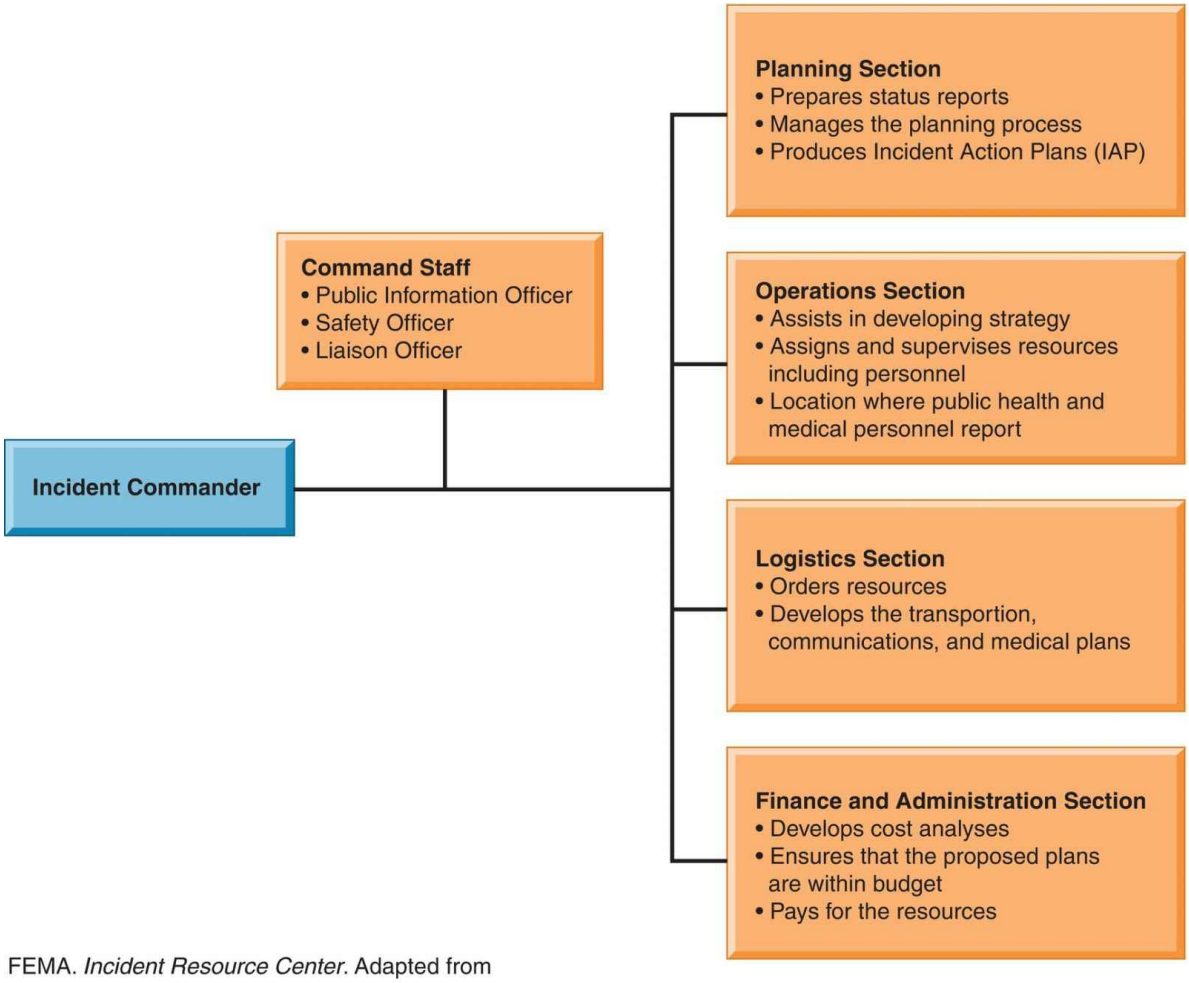
In response to World War II and the specter of all-out nuclear war with the Soviet Union, the United States created Civil Defense, a series of programs and agencies designed to protect the population from "counter-value" nuclear strikes and increase the survivability of a nuclear war. The Department of Health, Education, and Welfare (USDHEW) created the *Handbook for Civil Defense Emergency Planning in Welfare Institutions*, which was a guide to protect individuals and help staff prepare for fallout from a nuclear event (USDHEW, 1961). Significant in this handbook was the attention given to family responsibilities and the likelihood that staff, including nurses, would choose family responsibilities over professional responsibilities. To help alleviate the problems associated with absenteeism as a result of the nurses' conflicting responsibilities, the handbook recommended (1) reminding staff of their responsibility as public servants, (2) providing shelter for families within the institution, (3) planning for getting families to the shelter, and (4) planning for families to assist the staff during a crisis (USDHEW, 1961).

Under the 1950 version for the United States Civil Defense Plan, health services were to remain under the control of existing health agencies to avoid unnecessary duplication of services, but would now also be subject to the rules and regulations of civil defense. The U.S. Public Health Service was responsible for providing staffing for civil defense offices and would work for the state health officer who would have the lead. The roles have been in continual transition since that time, but the basic principles remain the same.

Public health has become recognized as a critical component of emergency planning, preparedness, and response. National public health response requires coordination with state and local authorities, to include nongovernmental agencies (CDC, 2011).

Among disaster-relief organizations, perhaps none is as famous as the Red Cross, which is referred to as the American Red Cross in the United States and the Red Crescent

Societies in Islamic countries. The American Red Cross was founded in 1881 by Clara Barton and was chartered by the U.S. Congress in 1905. It is authorized to provide disaster assistance free of charge across the country through its more than half a million volunteers and staff. The duties assumed by the Red Cross in the event of a disaster are to provide shelter, food, basic health and mental health services, and distribution of emergency supplies (American Red Cross, n.d.). Even the role of this historic disaster response organization changed after September 11, 2001.



President George W. Bush sought to consolidate the roles and responsibilities of agencies and organizations involved in disaster response and to align them with the Emergency Support Functions (ESFs) (see Table 17–1). The Department of Homeland Security (DHS) was organized in 2002 and incorporates many of the nation's security, protection, and emergency response activities into a single federal department. In 2003, the Federal Emergency Management Agency (FEMA), along with parts of 23 agencies, became part of the DHS. The FEMA, established in 1979, is the federal agency responsible for assessing and responding to disaster events in the United States. It also provides training and guidance in all phases of disaster management. The DHS includes other widely known agencies including the Transportation Security Administration (TSA), U.S. Customs and Border Protection, U.S. Immigration and Customs Enforcement (ICE), U.S. Citizenship and Immigration Services (USCIS), U.S. Coast Guard, and U.S. Secret Service (DHS, 2006, 2011, 2015).

Table 17–1 Emergency Support Functions (ESF) Responsibilities

ESF	Scope	Coordinating Agency
1. Transportation	Transportation modes management and control Transportation safety Stabilization/reestablishment of transportation infrastructure Movement restrictions Damage and impact assessment	Department of Transportation
2. Communications	Coordination with telecommunications and information technology industries Reestablishment/repair of telecommunications infrastructure Protection, reestablishment, and sustainment of national cyber and information technology resources Oversight of communications within the federal response structures	Department of Homeland Security (DHS)—National Communications System
3. Public works and engineering	Infrastructure protection and emergency repair Infrastructure reestablishment Engineering services and construction management Emergency contracting support for lifesaving and life-sustaining services	Department of Defense—U.S. Army Corps of Engineers
4. Firefighting	Support to wildland, rural, and urban firefighting operations	U.S. Department of Agriculture—U.S. Forest Service and DHS, FEMA, U.S. Fire Administration
5. Information and planning	Incident action planning Information collection, analysis, and dissemination	Department of Homeland Security—Federal Emergency Management Agency
6. Mass care, emergency assistance, temporary housing, and human services	Mass care Emergency assistance Disaster housing Human services	Department of Homeland Security—Federal Emergency Management Agency
7. Logistics	Comprehensive, national incident logistics planning, management, and sustainment capability Resource support (e.g., facility space, office equipment and supplies, contracting services)	General Services Administration and Department of Homeland Security, Federal Emergency Management Agency
8. Public health and medical services	Public health Medical surge support including patient movement Behavioral health services Mass fatality management	Department of Health and Human Services
9. Search and rescue	Structural collapse (urban) search and rescue Maritime/coastal/waterborne search and rescue Land search and rescue	Department of Homeland Security—Federal Emergency Management Agency
10. Oil and hazardous materials response	Environmental assessment of the nature and extent of oil and hazardous materials contamination Environmental decontamination and cleanup	Environmental Protection Agency
11. Agriculture and natural services	Nutrition assistance Animal and agricultural health issue response Technical expertise, coordination, and support of animal and agriculture emergency management Meat, poultry, and processed egg products safety and defense Natural and cultural resources and historic properties protection	Department of Agriculture
12. Energy	Energy infrastructure assessment, repair, and reestablishment Energy industry utilities coordination Energy forecast	Department of Energy
13. Public safety and security	Facility and resource security Security planning and technical resource assistance Public safety and security support Support to access, traffic, and crowd control	Department of Justice—Bureau of Alcohol, Tobacco, Firearms, and Explosives
14. Long-term community recovery	National Response Framework superseded by *National Disaster Recovery Framework*	Department of Homeland Security (FEMA)
15. External affairs	Public affairs and Joint Information Center Intergovernmental (local, state, tribal, and territorial) affairs Congressional affairs Private sector outreach Community relations	Department of Homeland Security

From The Department of Homeland Security. (2013). National response framework, pp. 32–35. Retrieved from http://www.fema.gov/media-library-data/20130726-1914-25045-1246/final_national_response_framework_20130501.pdf

FEMA provides oversight of the National Incident Management System (NIMS), developed to allow responders from different jurisdictions and disciplines to work more cohesively in response to natural disasters, emergencies, and terrorist acts. The benefits of NIMS lie in its unified approach to incident management, standard command and management structures, and emphasis on preparedness, mutual aid, and resource management (FEMA, 2015). NIMS approach provides a proactive response system to terrorist attacks, natural disasters, and other emergencies (CDC, 2011). Among the elements of disaster preparedness that nurses must understand is the incident command system (ICS) that was created in the 1970s after catastrophic wildfires in California resulted in many deaths (see Fig. 17–1). Nurses and other health care professionals must understand this system and are encouraged to take courses dealing with the ICS; these courses are available free online from FEMA Emergency Management Institute at http://www.training.fema.gov/EMI/. The most important courses for a nurse are (1) IS-100.HCb introduction to the ICS for health care/hospitals, (2) IS-700.a introduction to the NIMS, and (3) IS-800.b introduction to the nation response framework.

FEMA. *Incident Resource Center*. Adapted from http://training.fema.gov/EMIWeb/IS/ICSResource/index.htm

FIGURE 17–1 Incident command system.

The USDHHS is the lead federal agency for public health and medical services during a public health or medical disaster. Supplemental services are provided to state, local, and territorial governments (USDHHS, 2014). The services may include Disaster Medical Assistance Teams (DMAT), U.S. Public Health Service officers, epidemiological personnel from the CDC, and veterinary support to name a few. The Assistant Secretary for Preparedness and Response leads the USDHHS preparedness and response efforts for public health and medical emergencies, and the Office of the Assistant Secretary for Public Health and Science leads recovery efforts. The USDHHS efforts to support human services needs, including disaster case management, are led by the Administration for Children and Families (n.d.). The surge of unaccompanied children (over 50,000) apprehended by DHS immigration officials in the summer of 2014 was an extraordinary challenge for law enforcement and health care providers. The children's safety and well-being was assured while their nutritional and basic human needs were immediately addressed upon apprehension by the Administration for Children and Families (Park, 2014).

When natural or man-made disasters are accompanied by civil disturbance, looting, or violent crime, the resources of local police departments in this country may be

overwhelmed. In such cases, the National Guard is often called in to restore order. This action is typically accomplished within each individual state, under the jurisdiction of the governor.

The World Health Organization's (WHO) Emergency Relief Operations provide disaster assistance internationally, the Pan American Health Organization works to coordinate relief efforts in Latin America and the Caribbean, and the U.S. Agency for International Development (USAID) serves as the U.S. government agency responsible for directing contributions to nonprofit partners and international organizations that respond to disasters around the world. In addition, various international nongovernmental organizations (such as Doctors Without Borders, the International Medical Corps, and Operation Blessing), religious groups, and other volunteer agencies provide needed emergency care (see Chapter 16) (Fig. 17–2).

FIGURE 17–2 Mobile hospitals are often deployed during disasters.

Governments often send their military personnel and equipment in response to international disasters. For example, in May 2008, the U.S. Navy attempted for 3 weeks to provide much-needed supplies to the cyclone survivors in Myanmar (Burma). With limited options, the Navy had helicopters and landing craft on standby to deliver food, water, and medical supplies to the most remote areas of the country. The military junta in Myanmar refused to allow the shipments, further risking the lives of the millions of survivors. U.S. military planes were eventually allowed to land with supplies in the country's largest city, Rangoon (Kazmin, 2008). The government conducted the transport of vital supplies to the

rural areas, and results were questionable.

In this situation, political agendas prevented the aid typically accepted by countries experiencing catastrophe. Fortunately, the Commissioned Corps of the U.S. Public Health Service (USPHS) was allowed to provide aid for the tsunami and earthquake survivors in Indonesia and Haiti. The USPHS has also worked collaboratively with the U.S. Navy to provide nursing and other medical care on combined humanitarian missions to South America and the South Pacific and was sent to Africa to assist with the Ebola crisis (USPHS, 2014). Chapter 30 contains additional information about the role of the USPHS Commissioned Corps Nurses and their role in emergency preparedness.

Phases of Disaster Management

In developing strategies to address the problem of disasters, it is helpful for the community health nurse to consider each of the four phases of disaster management: prevention, preparedness, response, and recovery. Additionally, some knowledge of the language typically used in disaster preparedness may be helpful and is included in Display 17–2.

DISPLAY 17–2 COMMON TERMS USED IN EMERGENCY PREPAREDNESS AND RESPONSE

All-hazards preparation: Preparedness for domestic terrorist attacks, major disasters, and other emergencies

Chain of command: A series of command, control, executive, or management positions in hierarchical order of authority

Credential: A health volunteer's qualifications. Credentials are used to determine a health volunteer's emergency credentialing level (i.e., nursing license).

Designated equivalent source: Selected agencies that have been determined to maintain a specific item or items of credential information that is identical to the information at the primary source

Disaster, major (federal): Any natural catastrophe, or, regardless of cause, any fire, flood, or explosion, in any part of the United States, which in the determination of the president causes damage of sufficient severity and magnitude to warrant major disaster assistance to supplement the efforts and available resources of states, local governments, and disaster relief organizations

Emergency declaration: Refers to the state (or local) government's capacity to declare a general emergency or public health emergency, or state of disaster

Emergency Management Assistance Compact (EMAC): An interstate mutual aid agreement that allows states to assist one another in responding to all types of natural and man-made disasters

Hospital emergency incident command system (HEICS): An emergency management system that employs a logical management structure, defined responsibilities, clear reporting channels, and a common nomenclature to help unify hospitals with other emergency responders

Incident command system (ICS): The combination of equipment, facilities,

communication, personnel, and procedures that operates within a common organizational structure, designed to aid in the management of resources during incidents

Just-in-time training: Concise, targeted training, normally provided on-site after a disaster or emergency has occurred. It provides a minimum level of exposure for volunteers regarding select issues in disaster response. Examples could be use of self-protection equipment, documentation, mental health triage, or registration of casualties.

National Electronic Disease Surveillance System (NEDSS): A CDC initiative promoting the use of data and information systems standards to improve disease surveillance systems at federal, state, and local levels

National Incident Management System (NIMS): The single all-hazards incident management system required by Homeland Security that governs the management of the National Response Plan

Public Health Information Network (PHIN): A framework providing the basis for information technology projects for CDC-funded programs including NEDSS, Health Alert Network (HAN), and others that improve public health

Shelter-In-Place: Used as alternative to evacuation; people may be asked to remain indoors in homes, businesses, schools, or public buildings (especially if there is limited time to react to a threat). People should plan on having 72 hours' worth of food, water, and medical supplies in order to remain indoors.

Strategic National Stockpile: A national cache of drugs, vaccines, and medical supplies that can be deployed to areas struck by disasters, including bioterrorism, in a matter of 12 to 36 hours

Surge capacity: The accommodation by the health system to a transient sudden rise in demand for health care following an incident with real or perceived adverse health effects or in some cases a more prolonged demand

Adapted from Blanchard, B. W. (2008). Guide to emergency management and related terms, definitions, concepts, acronyms, organizations, programs, guidance, executive orders, & legislation: A tutorial on emergency management, broadly defined, past and present. Retrieved from https://www.training.fema.gov/hiedu/docs/terms%20and%20definitions/terms%20and%20definitions.pdf

Prevention Phase

During the *prevention phase*, no disaster is expected or anticipated. The tasks during this phase are to identify community risk factors, to develop and implement programs to prevent disasters from occurring or mitigate their impact, and to train personnel and educate citizens. Task forces typically include representatives from the community's local government, health care providers, social services providers, police and fire departments, major industries, local media, schools, and citizens' groups. Programs developed during the prevention phase may also focus on strategies to mitigate the effects of disasters that cannot

be prevented, such as earthquakes, hurricanes, and tornadoes (CDC, 2015).

The United States has strengthened the preparedness phase of disaster management since September 2001. This is most visible to the average citizen at airports, where airline passengers must now go through a more rigorous security screening before boarding the plane. Nonpassengers cannot go beyond the security area. Photographic identification is required at two or more points before boarding. Strict limits have been placed on liquids that can be in carry-on baggage. Random searches of hand-carried luggage occur, and passengers may be screened with advanced imaging technology. At more than 450 airports, over 1.8 million passengers are screened daily (TSA, 2012). In some airports, luggage is tested for radioactive material, police officials with trained dogs patrol the airport, or some people have credentials prescreened and are permitted to wear shoes and light jackets as part of the screening process. All of these measures have been initiated to prevent a terrorist attack.

Preparedness Phase

Disaster *preparedness* involves improving community and individual reaction and responses, so that the effects of a disaster are minimized. Disaster preparedness saves lives and minimizes injury and property damage. It includes plans for communication, evacuation, rescue, victim care, and recovery. Any plan must also address acquisition of equipment, personnel, supplies, medicine, and even food, clean water, blankets, and shelter. Semiannual disaster drills and tests of the Emergency Broadcast System are examples of appropriate activities during the preparedness phase (CDC, 2015).

Disaster preparedness activities occur locally, regionally, and nationally. A town keeps its warning system working and tests it each month. Sections of the country coordinate larger warning systems to notify communities in the path of a tornado or hurricane, and the country has a plan to stockpile vital pharmaceuticals such as smallpox vaccine for mass immunization. The Centers for Disease Control and Prevention (CDC, 2015) reports that the Strategic National Stockpile (SNS) contains doses of vaccines, medical countermeasures, and needed medical supplies stored around the country in various strategic locations. The CDC reports the SNS contains enough medications and medical supplies to manage a large public health emergency and protect the American public (CDC, 2016).

Response Phase

The *response phase* begins immediately after the onset of the disastrous event. Preparedness plans take effect immediately, with the goals of saving lives and preventing further injury or damage to property. Periodic notification drills are held, and 45-minute response time targets were recently met by 83% in the first drill, and 94% in the second drill of 2013 (CDC, 2015). Focused response teams (e.g., behavioral health, mortuary, social work) facilitate an effective, comprehensive response effort. Activities during the response phase

include rescue, triage, on-site stabilization, transportation of injured, and treatment at local hospitals and clinics. Response also requires recovery, identification, and refrigeration of bodies, so that notification of family members is possible and correct, even weeks after a disaster. This care of the dead is demanding and time-consuming work that is often overlooked by people unfamiliar with disaster response. Persons trained in mortuary services are an essential part of any emergency planning efforts. The mortuary teams always have pastoral personnel with them to ensure that remains are always treated with respect and in accordance with religious traditions. Supportive care, including food, water, and shelter for survivors and relief workers, is also an essential element of the total disaster response. The extent of care provided for animals is an additional area of concern that should be addressed in the overall plan. Veterinarian response teams are able to address the acute and long-term needs of the animals impacted by the disaster. Many shelters will not accept pets; those that do need to be identified as soon as possible to avoid unnecessary confusion and delays in sheltering (Fig. 17–3).

FIGURE 17–3 Victims of Superstorm Sandy receiving assistance at a temporary shelter.

Recovery Phase

During the *recovery phase*, the community takes actions to repair, rebuild, or relocate damaged homes and businesses and restore health, social, and economic vitality to the community. Psychological recovery must also be addressed. The emotional scars from witnessing a traumatic event may last a lifetime. Both survivors and relief workers should be

offered mental health services to support their recovery (see Perspectives: Voices From the Community). The Substance Abuse Mental Health Services Administration (SAMHSA) offers guides and a disaster kit for managing stress in crisis for both professionals and victims (SAMHSA, 2015).

PERSECTIVES
VOICES FROM THE COMMUNITY

It was 5:00 PM on October 17, 1989, in Santa Cruz, CA—a day that would change my view of life forever. I had just fed my newborn son and was rocking him in a soft, comfortable chair when the house began to shake. Without even thinking or being aware of what I was doing, I jumped up with my baby in my arms and headed for the nearest doorway, as I had done so many times before in an earthquake. I stood there holding my son in one arm and braced myself against the doorjamb with the other one as the house continued to shake all around us. It was not until the shaking stopped that I began to feel fear and worry as I surveyed the damage to my house.

In my kitchen, all of the cupboard doors were flung open and their contents spilled onto the floor, which was now a mess of spilled food, sticky sauces, dented tin cans, and broken glass. Tears came to my eyes as I saw my son's infant seat, where he had been seated only moments before the quake, covered with glass shards and fallen tin cans. I realized he could have been killed, and I had no control over it. I became afraid for the safety of my 10-year-old daughter, who was at dancing lessons across town. Fortunately, when I got to her, she was safe.

The next few days continued to be very stressful. We had no gas or electricity and no running water that was safe to drink. I went to the drug store in a panic to buy premixed formula to feed my son, since I could not boil the water to mix with the powdered formula. Both the drug store and the grocery store were "trashed," all of the items were thrown off of the shelves and laying on the debris-strewn floors. The grocery store was giving away the ice cream because they had no power to keep it frozen. But who could eat ice cream?

There was something about seeing my favorite grocery store in such a disastrous condition that made me realize how little control I had over the consequences of what insurance companies call "acts of God." I couldn't just run to the grocery store for what I needed; it wouldn't be there for me. My family and I felt very unsafe as we all huddled together in the master bedroom at night. My son was in his bassinet at the foot of the bed and my daughter slept with me until she felt safe enough to return to her own room. I was

attempting to regain control of my life as I cleaned up my house and waited for the water and electricity to be restored. Of all the losses, the greatest loss was the illusion of safety and the illusion that I had control over my life.

Over the next week, I experienced the loss of many services and products that made up my comfortable and safe lifestyle: homes were damaged, with their chimneys strewn across front lawns, there was no phone service for days, and a normal 10-minute drive took an hour and a half on clogged highways provided as an alternative route to highways and bridges damaged by the quake. As a community mental health nurse, I wanted to volunteer to help others who were experiencing the same feelings as I was, but I was told that they were not taking mental health volunteers from the immediate area because we, too, were victims of the disaster and needed to care for ourselves first. I think they were right, since I had many feelings that took a long while to heal and I have lost the illusion of control forever.

Nancy, age 32

During the recovery phase, special attention should be given to the needs of children who are approximately 25% of the population in the United States and even higher in many countries. The Substance Abuse and Mental Health Services Administration has resources available for specific populations to assist with managing disasters (SAMHSA, 2015). One example is *Tips for Talking With and Helping Children and Youth Cope After a Disaster or Traumatic Event: A Guide for Parents, Caregivers, and Teachers.*

Role of the Community/Public Health Nurse

The public health nurse has a pivotal role in preventing, preparing for, responding to, and supporting recovery from a disaster (Association of Public Health Nurses [APHN] Public Health Preparedness Committee, 2013). After a thorough community assessment for risk factors, the community health nurse may initiate the formation of a multidisciplinary task force to address disaster prevention and preparedness in the community.

Preventing Disasters

Disaster prevention may be considered on three levels: primary, secondary, and tertiary. These are applied to a natural disaster in the Levels of Prevention Pyramid.

LEVELS OF PREVENTION PYRAMID

SITUATION: A natural disaster—tornado

GOAL: By using the three levels of prevention, negative health conditions are avoided, promptly diagnosed, and treated, and/or the fullest possible potential is restored.

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Remain safe during the immediate recovery period • Accept help from others—friends, family, and community services • Rebuild family lives through counseling and other services to reestablish stable life physically, emotionally, spiritually, and financially	• Educate community members about the need to enhance planning against damage from future natural disasters, based on experiences with the current disaster	• Keep recommended immunizations current • Community physical structures need rebuilding, with infrastructure planning and supports that improve ability to withstand natural disasters

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Remain in your position of safety until a community all-clear warning signal is sounded or until rescued • Leave a damaged building cautiously, if able and not seriously injured, and do not return until it is declared safe	• Rescue individuals promptly and get appropriate care for those injured as soon as possible • The infrastructure of the community becomes/remains intact, keeping community members safe from hazards such as live wires, broken gas lines, and fallen debris

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Increase community awareness • Increase community preparation through education • Each person is as prepared as possible both physically and emotionally	• Community members know what to do and where to go, whether at home, work, school, or elsewhere in the community • Get to safety before the impact—southwest corner of a home's basement or an interior room away from windows and under heavy furniture

Primary Prevention

Primary prevention of a disaster means keeping the disaster from ever happening by taking actions that completely eliminate its occurrence. This is the first aspect of primary disaster prevention. Although it is obviously the most effective level of intervention, both in terms of promoting clients' health and containing costs, it is not always possible. Tornadoes, earthquakes, terrorist attacks, and other disasters often strike without warning, despite the use of every available technologic device for prediction and tracking.

If possible, primary prevention of disasters can be practiced in all settings: in the workplace and home with programs to reduce safety hazards and in the community with programs to monitor risk factors, reduce pollution, and encourage nonviolent conflict resolution (CDC, 2015). Primary disaster prevention efforts should take into account a community's physical, psychosocial, cultural, economic, and spiritual needs. The community health nurse has a role in each of these areas. As a teacher, the community health nurse educates people at home, at work, at school, or in a faith community about safety and security focused on preventing a disaster. The community health nurse can teach community members how to protect themselves from the effects of a natural disaster. The nurse can be a part of a safety team, if working as a school nurse or occupational health nurse. If working for a health department, the PHN can determine during home visits

whether a family has a personal disaster plan and help them develop one if none exists. Nursing students can work with low-income community–dwelling elders to ensure that they have enough food, water, and medical supplies to shelter in place for at least 72 hours. There are many actions the nurse can initiate (APHN Public Health Preparedness Committee, 2013).

The second aspect of primary disaster prevention is anticipatory guidance. Disaster drills and other anticipatory exercises help relief workers experience some of the feelings of chaos and stress associated with a disaster before one occurs (CDC, 2015). It is much easier to do this when energy and intellectual processes are at a high level of functioning. Anticipatory work can dissipate the impact of a disastrous event. The community health nurse has a role in these disaster drills through committee membership, organization of drills at the place of employment, or activism at the grassroots level to assist in holding community-wide disaster drills on a regular basis (see Quality and Safety Education for Nurses [QSEN] feature). In addition, the community health nurse could lead or participate with community health assessment programs seeking an understanding of the community needs predisaster and provide preventive education and preparation guidance.

Secondary Prevention

Secondary disaster prevention focuses on the earliest possible detection and treatment. For example, a mobile home community is devastated by a tornado. After the disaster, the local health department's community health nurses work with the American Red Cross to provide emergency assistance. Secondary prevention corresponds to immediate and effective response. For example, in a post-Katrina study of the emergency planning and response by home health providers serving the poor in New Orleans during the emergency, the successes and challenges of these providers were identified (Kirkpatrick & Bryan, 2007). Agencies that provided early evacuation, identified shelters for special-needs patients outside the high-risk area, implemented volunteer cascading communication systems, and conducted pre-event mock evacuation plans and those that included volunteers in their disaster plan were most successful. Recommendations to improve response include identification of patients who may be reluctant to evacuate, the provision of adequate security at special-needs shelters, and, most importantly, practice drills (DHS, n.d.). With appropriate planning, sound and easily understood emergency response can provide optimal care and services to those impacted by the disaster. New Orleans has developed a citywide preparedness program entitled *Are you Ready?*; this aims to inform, prepare, and ensure residents are ready for any type of man-made or natural disaster (City of New Orleans, 2016). Similar examinations are conducted after other disasters, for instance, after Hurricane/Superstorm Sandy (Ladislaw, Kostro, & Walton, 2013) and the Nepal earthquakes (Government of Nepal, National Planning Commission, 2015).

Tertiary Prevention

Tertiary disaster prevention involves reducing the amount and degree of disability or damage resulting from the disaster. Although it involves rehabilitative work, it can help a community recover and reduce the risk of further disasters. In this sense, it becomes a preventive measure.

An example from September 11, 2001, comes from a nurse living in the Boston area who, after that date, began to lose a sense of hope for her future. She often found it difficult to assist her patients with their needs because of her own insecurities and fears. She and a peer responded to a request from the Logan Airport Employee Assistance Program (EAP) asking for help with crisis counseling for United Airlines survivors of 9/11. The planes used in the attacks were from American and United Airlines, and the community of employees felt like survivors because they lived while fellow employees were lost in the disaster. Employees were in turmoil and their ability to function was affected. The most important intervention the nurses could provide was a listening ear and validation that what the employees were feeling and experiencing was normal, and often essential, for healthy grieving. Some employees needed to talk about good times, others were quiet and sad, and others expressed a fear of flying again but did so with the support of family and friends. All demonstrated courage and an ability to continue their lives with a sense of strength and hope. Since 9/11, the American Psychiatric Nurses Association has developed a profile that assists psychiatric nurses by providing clearer information for targeted assessments of those with significant emotional trauma (White, 2002) and provides access to many resources for nurses dealing with traumatic events (American Psychiatric Nurses Association, 2016).

Preparing for Disasters

Disaster planning is essential for a community, business, or hospital. It involves thinking about details of preparation and management by all involved, including community leaders, health and safety professionals, and lay people. A disaster plan need not be lengthy. Two weeks after the April 1995 Oklahoma City bombing of the Murrah Federal Building by two American citizens, one hospital distilled its 44-page manual into a 5-page disaster response guide. Despite many disaster drills and numerous iterations of disaster plans before Hurricane Katrina, some hospitals in New Orleans were better prepared for terrorism events than for the hurricanes and flooding that are not uncommon to this area. Memorial Medical Center was hit with massive flooding and electrical outages after Katrina, and their backup generators were in the basement and soon underwater (Fink, 2013). Unlike the Memorial disaster plan, the Oklahoma hospital plan was concise. Such a concise plan should still contain information on the elements discussed in this and the following section. Public health nurses can be very instrumental in disaster preparedness (APHN Public Health Preparedness Committee, 2013) (see Display 17–3 for a summary of these elements).

DISPLAY 17–3 ELEMENTS OF A DISASTER PLAN

A disaster plan should address all of the following:

- Chain of authority
- Lines of communication
- Routes and modes of transport
- Mobilization
- Warning
- Evacuation
- Rescue and recovery
- Triage
- Treatment
- Support of survivors and families
- Care of dead bodies
- Disaster worker rehabilitation

Personal Preparation

The preparation of a disaster plan for a community should be preceded by the need for all nurses to address their own personal preparedness to respond in a disaster. From the Case Files describes the tragic outcome of one nurse's lack of preparation when she attempted to provide nursing care at the scene of the Oklahoma City bombing (see From the Case Files I).

From the Case Files I

Nurses at Disaster Sites—Help or Hindrance?

On April 19, 1995, 37-year-old Rebecca Anderson, a registered nurse working in Oklahoma City, after hearing a televised report of the bombing of the Federal Building, went to the site wearing jeans and a sweatshirt. Along with firefighters and other rescue workers in hard hats and other protective gear, she was allowed to enter the scene. Within a short time, Rebecca was struck on the back of the head by a concrete slab that fell from the building's wreckage. She died 5 days later of massive cerebral edema. Nurses can learn the following lessons from this tragedy:

- Never enter a disaster scene unless you are directed to do so by an emergency medical technician, firefighter, or law enforcement official.
- Contact local hospitals and clinics to offer your help; your medical expertise is more useful in the clinical environment.
- Take courses in first aid and emergency care. Contact your local Red Cross for a list of courses.
- Contact your local health department to learn more about your community's disaster plan and how you can contribute in the event of a disaster in your area.

From McGuigan, P. B. (2010). Resolution honors nurse rescuer killed in the bombing's aftermath. Retrieved from http://www.capitolbeatok.com/reports/resolution-honors-nurse-rescuer-killed-in-the-bombing-s-aftermath

Personal preparedness means that the nurse has read and understood workplace and community disaster plans and has developed a disaster plan for his or her own family (San Diego County Office of Emergency Services, n.d.). The prepared nurse also has participated in disaster drills and knows cardiopulmonary resuscitation and first aid. Finally, nurses preparing to work in disaster areas should bring copies of their nursing license and driver's license, durable clothing, and basic equipment, such as stethoscopes, flashlights, and cellular phones. In the event of an emergency, many who are unprepared or untrained often present at the site of a disaster or at local hospitals to volunteer. These "spontaneous volunteers" can be an additional burden to those in charge.

To increase understanding of and the ability to work within an emergency situation, every nurse should become familiar with the NIMS. The NIMS "is a systematic, proactive approach to guide departments and agencies at all levels of government, nongovernmental organizations, and the private sector to work together seamlessly and manage incidents involving all threats and hazards— regardless of cause, size, location, or complexity— in order to reduce loss of life, property and harm to the environment" (FEMA, 2015, p. 3). In essence, it provides a framework for management of incidents in support of the national preparedness system, using common language for disaster response, to reduce confusion as much as possible. Free online courses are offered through FEMA (see Display 17–4).

Additionally, every nurse should have up-to-date vaccinations; many biologic threats have the same initial presentations, and reducing susceptibility to common illnesses such as influenza can help with initial identification.

Assessment for Risk Factors and Disaster History

As noted earlier in the chapter, the public health nurse is uniquely qualified to perform a community assessment for risk factors that may contribute to disasters (APHN Public Health Preparedness Committee, 2013). In addition, the nurse should review the *disaster history* and preparedness plans of the community. Have earthquakes, tornadoes, hurricanes, floods, blizzards, riots, or other disasters occurred in the past? If so, what (if any) were the warning signs? Were they heeded? Were people warned in time? Did evacuation efforts remove all people in danger? What were the community's on-site responses, and how effective were they? What programs were put in place to rehabilitate the community?

Establishing Authority, Communication, and Transportation

In addition to assessing for preparedness, the effective disaster plan follows the NIMS

model and establishes a clear chain of authority, develops lines of communication, and delineates routes of transport. Establishing a clear and flexible chain of authority is critical for successful implementation of a disaster plan (CDC, 2015). Usually, the chain is hierarchical, with, for example, the community's governmental head (e.g., mayor) initiating the plan, alerting the media to broadcast warnings, authorizing the police to begin evacuations, and so on. Within each level of the organization, the hierarchy continues. For example, at the local hospital, the hospital administrator may be responsible for alerting nurse managers to call in additional personnel. Flexibility is essential, because key authority figures may themselves be survivors of the disaster. If the home of the chief of police is destroyed in an earthquake, his or her second-in-command must have equal knowledge of the community's disaster plan and be able to step in without delay.

Effective communication is often a point of breakdown for communities attempting to cope with major disasters. After the terrorist attacks in Oklahoma City and New York City, phone lines were damaged and cellular sites were overwhelmed, making communication difficult. Communication was possible only through handheld radios or by way of couriers on foot. At times of heightened chaos and stress, as well as after physical damage to communication facilities and equipment, misinformation and misinterpretation can flourish, leading to delayed treatment and increased loss of life.

Again, clarity and flexibility are the watchwords for establishing lines of communication. How will warnings be communicated? What backups are available if the normal communication systems are destroyed in the disaster? How will communication between relief workers at the disaster site, hospital personnel, police, and governmental authorities be maintained? What role will local media play, both in keeping information flowing to the outside world and in broadcasting needs for assistance and supplies? Significant forms of communication have developed since the 9/11 terrorist attacks. Social media has become a critical method of communicating important health and safety information to the public since the 2001 terrorist attacks. Social media and disaster communication leaderships have collaborated and formed a partnership under the guidance of the FEMA Regional Interagency Steering Committee (2011). Finally, how will friends and family members be informed of the whereabouts or health status of loved ones? The characteristics of effective communication during disasters are summarized in Display 17–5.

DISPLAY 17–5 EFFECTIVE COMMUNICATION DURING DISASTERS

To be effective, communication during disasters must elicit action. Communication that elicits action provides information that is

- Believable
- Current
- Unambiguous
- Authoritative
- Predictive of the probability of future events (what is going to happen next?)

Effective communication is

- Interactive—it allows for and addresses questions
- Conclusive—it eliminates room for speculation and *catastrophizing*
- Urgent—conveys seriousness without resorting to fear tactics
- Clear, simple, and repetitive
- Characterized by solutions and suggestions for success
- Personal—it uses people's names if possible and addresses their real and perceived needs

Finally, because rumors can hinder effective action or provoke premature action, effective communication includes rumor control. It provides suggestions for constructive activity, reducing time and energy spent on rumor generation and perpetuation.

Closed or inefficient routes of transportation can also increase injury and loss of life. For example, if a single, narrow mountainous road is the only means of transporting firefighters to or evacuating residents from the scene of a forest fire, then disaster planners should propose widening the road or clearing a second road. Disaster planners must also consider what routes emergency vehicles will take when transporting disaster survivors to local and outlying hospitals or health care workers to the disaster site. What if the chosen routes are inaccessible because of floodwaters, advancing fires, mountain slides, avalanches, or building rubble? Are alternative routes designated? Also, how will people move about after the disaster? After the Japanese earthquake and tsunami in 2011, Nakanishi, Matsuo, and Black (2013) examined planning methodologies and future hypothetical disaster scenarios to help answer these types of questions.

Mobilizing, Warning, and Evacuating

In many natural disasters, local weather service personnel, public works officials, police officers, or firefighters have the earliest information indicating an increasing potential for a disaster. These officials typically have a plan in place for providing community authorities with specific data indicating increased risk (CDC, 2015). They may also advise the mayor's

office or other community leaders of their recommendations for warning or evacuating the public. Additionally, they may recommend actions the community can take to mitigate damage, such as spraying rooftops in the path of fires, sandbagging the banks of rising rivers, or imposing a curfew in times of civil unrest.

Disaster plans must specify the means of communicating warnings to the public, as well as the precise information that should be included in warnings (CDC, 2015). Planners should never assume that all citizens can be reached by radio or television or that broadcast systems will be unaffected by the disaster. Broadcast media may indeed be a primary means of communicating warnings, but alternative strategies, such as social media or police and volunteers canvassing neighborhoods, should be considered. Social media options such as Facebook, Twitter, and blogs are reliable methods used by news stations and public health agencies that must not be ignored. Over 20 million tweets were sent by utilities after Hurricane Sandy, and Google's Web application, *Person Finder*, was especially helpful during the Boston Marathon bombings (Maron, 2013). In multilingual communities, messages should be broadcast in multiple languages. Not only homes but also businesses must be informed. Information that should be communicated includes the nature of the disaster; the exact geographic region affected, including street names if appropriate; and the actions citizens should take to protect themselves and their property.

An evacuation plan is an essential component of the total disaster plan (CDC, 2015). The plan should include notification of the police, local military personnel, or voluntary citizens' groups of the need to evacuate people, as well as methods of notifying and transporting the evacuees. A plan should also be made for responding to citizens who refuse to evacuate. For example, will police authorities forcibly remove an elderly citizen from his home to a shelter? Will evacuation plans include household pets? If farms or ranches are in the path of fires or floods, will animals be evacuated? How? Who will do this and where will they be taken/sheltered?

Responding to Disasters

At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue, triage, and treat disaster survivors. One of the first obligations of relief workers is to remove survivors from danger (Fig. 17–4).

FIGURE 17–4 Rescue of Hurricane Katrina victim.

Rescue

The job of rescue typically belongs to firefighters and urban search and rescue teams that have personnel with special training in search and rescue. Depending on the disaster agent, protective gear, heavy equipment, and special vehicles may be needed, and dogs trained to locate dead bodies may be brought in (Fig. 17–5). Sometimes, the immediate disaster site is not the best place for the disaster nurse, who can be far more effective in triage and treatment of survivors. The PHN's population-based approaches are needed, as well as knowledge of community resources and particularly vulnerable aggregates (APHN Public Health Preparedness Committee, 2013).

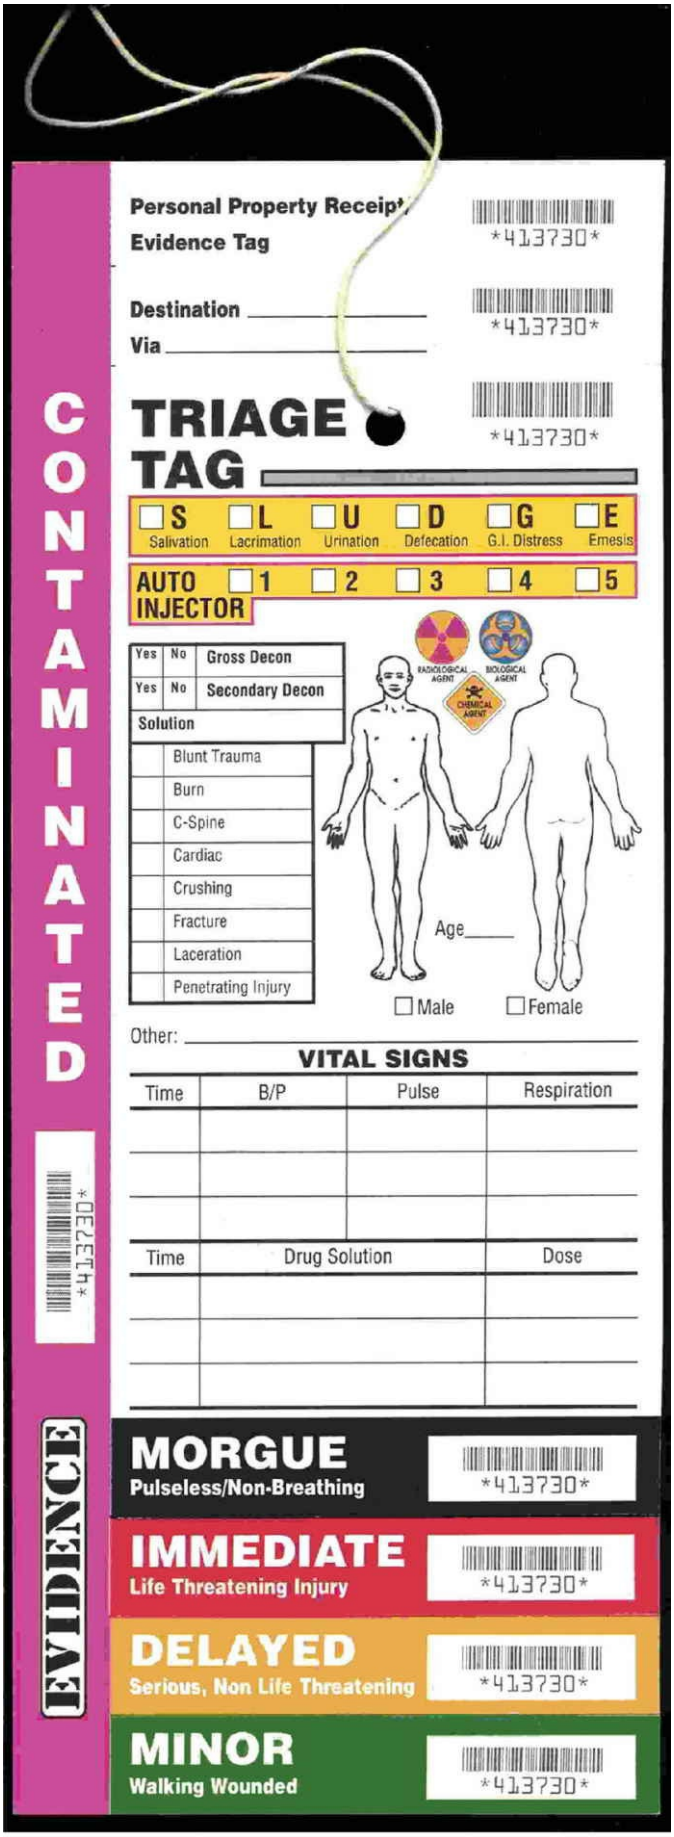

FIGURE 17–5 Hazardous materials suit used by the military and most fire departments. (Photo by Cynthia Tait.)

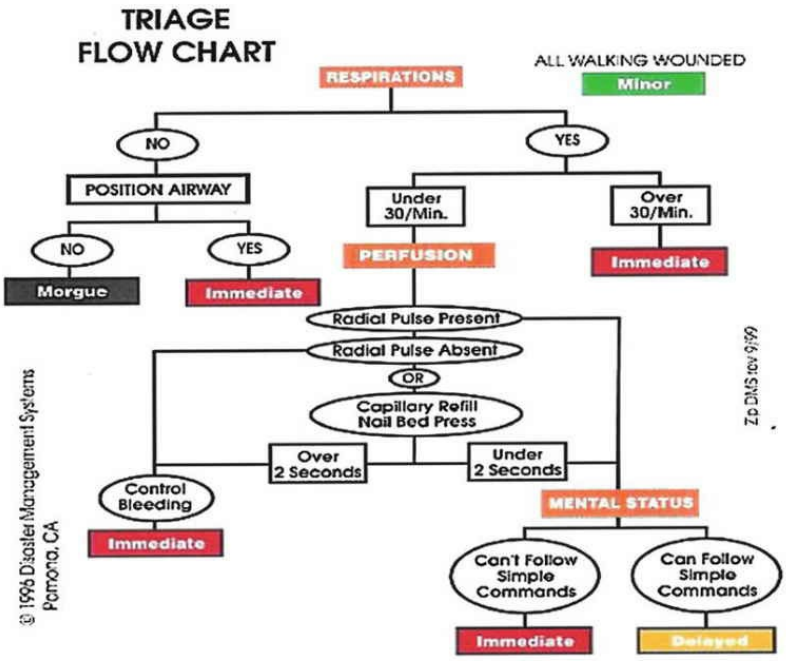
Rescue workers face the logistically and psychologically difficult task of determining when to cease rescue efforts. Some factors to consider include increasing danger to rescue workers, diminishing numbers of survivors, and diminishing possibilities for survival. For example, after a plane crash on a snowy mountain, rescue efforts may cease if it is deemed that anyone who might have survived the crash would subsequently have died of exposure.

Triage



Whereas emergency nurses daily determine which clients require priority care, the community health nurse may be at a loss as to where to start when faced with multiple persons impacted by a disaster. Knowing the principles and practice of triage allows the nurse to offer nursing skills most effectively (Wagner & Dahnke, 2015). Triage is the process of sorting multiple casualties in the event of a war or major disaster. It is required when the number of casualties exceeds immediate treatment resources. The goal of triage is to affect the greatest amount of good for the greatest number of people. Figure 17–6 shows the four basic categories of the international triage system, as well as a triage tag. The most common method of triage used by first responders at a mass-casualty incident in the United States is the simple triage and rapid treatment (START) for adults and JumpSTART for pediatric patients. START and JumpSTART are forms of triage used to sort victims into four categories (immediate, delayed, minor, or morgue/deceased) and are consistent with (Fig. 17–6).

B

A and B.Example of a victim triage tag. Radio frequency identification (RFID) technology may be used, so that victim tags (barcodes) may be scanned with RFID readers in order to reduce triage time and provide better tracking of incident casualties. Four basic categories are applied when a medical system is overwhelmed with persons impacted by the incident: (1) *Red*: Urgent/Critical. Victims in this category have injuries or medical problems that will likely lead to death if not treated immediately (e.g., an unconscious victim with signs of internal bleeding). (2) *Yellow*: Delayed. Victims in this category have injuries that will require medical attention; however, time to medical treatment is not yet critical (e.g., a conscious victim with a fractured femur). (3) *Green*: Minor/Walking Wounded. Victims in this category have sustained minor injury or are presenting with minimal signs of illness. Prolonged delay in care most likely will not adversely affect their long-term outcome (e.g., a conscious victim with superficial cuts, scrapes, and bruises). (4) *Black*: Dead/Nonsalvageable. Victims in this category are obviously dead or have suffered mortal wounds because of which death is imminent (e.g., an unconscious victim with an open skull fracture with brain matter showing). Lifesaving heroics on this group of victims will only delay medical care on more viable victims. (From the U.S. Department of Homeland Security. (2013). System assessment and validation for emergency responders (SAVER). Retrieved from https://upload.wikimedia.org/wikipedia/commons/9/97/Deconference-2002-triage-tag.jpg)

Prioritization of treatment may be very different in a mass-casualty event as opposed to an average day in a hospital emergency department. Under normal circumstances, a person presenting to a hospital emergency department with a myocardial infarction and showing no pulse or respirations would receive immediate treatment and have a chance of recovery. At a disaster site, a person without a pulse or respirations would most likely be placed in the nonsalvageable category.

The term *mass casualty* refers to a number of persons impacted that is greater than that which can be managed safely with the resources the community has to offer, such as rescue vehicles and emergency facilities available to serve disaster survivors while also meeting the needs of the rest of the community (Culley & Svendsen, 2014; Lee, 2010). Frequently, in mass-casualty occurrences, the broader community needs to become involved, which necessitates calling in rescue vehicles, firefighters, and police officers from neighboring towns or the use of neighboring hospitals. This adds another layer of disaster management coordination that must be considered.

Immediate Treatment and Support

Disaster nurses provide treatment on-site at emergency treatment stations, at mobile field hospitals, in shelters, and at local hospitals and clinics (see Display 17–6). In addition to direct nursing care, on-site interventions might include arranging for transport once survivors are stabilized and managing the procurement, distribution, and replenishment of

all supplies. Disposable items might be in short supply, requiring resterilization procedures that may be unfamiliar to a nurse not accustomed to fieldwork. These procedures may pose a challenge even to an experienced nurse because of the field environment. The nurse may also manage provision or distribution of food and beverages, including infant formulas and rehydration fluids, and arrange for adequate, accessible, and safe sanitation facilities, either on-site or in a shelter. Finally, the nurse often must also arrange for psychological and spiritual care of survivors of disasters (APHN Public Health Preparedness Committee, 2013).

DISPLAY 17–6 MOBILE FIELD HOSPITAL

On August 25, 2007, California featured the first state-owned mobile field hospital in a statewide disaster-training exercise. The tent hospital is one of three 200-bed hospitals purchased by California and prepositioned around the state in the event of a major emergency. The hospital can be deployed and on-site within 72 hours and comes equipped for 7 days of full patient care. Used together, the hospitals can be reconfigured into a 400- or 600-bed hospital, if needed. This is the same type of mobile field hospital used by the military, and it was modeled after the hospitals used by the Air Force and Navy. The various units within the hospital mirror services provided in any modern facility including emergency room, surgical suite, laboratory, x-ray, surgical intensive care, and even a pediatric unit.

Because of California's subsequent budget crisis, all three mobile hospitals were in a Northern California storage facility. As funding became available again, one mobile hospital was moved to Southern California because of the history of earthquakes and other potential disasters there. Members of the public and other concerned stakeholders supported funding for these hospitals, as they will be very important to care for victims of future disasters and emergencies.

From Rodriguez, F. (2014, May 28). Assembly approves $1.9 million to restore California's mobile field hospitals. Retrieved from http://asmdc.org/members/a52/news-room/press-releases/assembly-approves-1-96-million-dollars-to-restore-californias-mobile-field-hospitals

Some survivors who seem physically uninjured may, in fact, be suffering from major injuries but be unable to relate their symptoms to a relief worker because of shock or anxiety. For instance, a father pulling debris away from his collapsed house after a tornado may be so worried about a missing child that he does not realize that he has a broken arm.

Other survivors may be so emotionally traumatized by a disaster that they act out, disrupting efforts to assist them and other survivors and even engaging in dangerous activities. This may cause relief workers to focus on emotional care; however, such survivors must be assessed for head trauma and internal injuries, because their behavior may have a physical cause. If they are physically able, such survivors may be given a simple, repetitive task to perform, which serves as both a distraction and a means to restore, to a small extent, their sense of control over their environment.

Care of Bodies and Notification of Families

Identification and transport of the dead to a morgue or holding facility are crucial, especially if contagion is feared though this is rare in mass-casualty situations. Toe tags make documentation visible and accessible. Records of deaths must be made and maintained, and family members should be notified of their loved ones' deaths as quickly and compassionately as possible. If feasible, a representative from each of the area's faith communities should be available to assist families awaiting news of missing loved ones. As stated earlier, a family's recovery from loss is often delayed when notification of relatives (indirectly impacted) is not possible because the persons' bodies are badly damaged or not found.

Supporting Recovery from Disasters

Disasters do not suddenly end when the rubble is cleared and the survivors' wounds are healed. Rather, recovery is a long, complex process. It often includes long-term medical treatment, physical rehabilitation, financial restitution, case management, and psychological and spiritual support (APHN Public Health Preparedness Committee, 2013; CDC, 2015).

Long-Term Treatment

Long-term treatment may be required for many survivors of disasters, straining the local rehabilitative care facilities and resources. Children who are survivors may have to deal with lifelong disabilities or scars from their ordeal, and families may be without adequate financial support for their child's medical care. Elderly citizens who had been in excellent health but who sustained serious injuries in the disaster might suddenly find that they can

no longer live independently and must move to a long-term care facility. After floods, landslides, fires, or earthquakes, extensive property damage may cause some residents or businesses to relocate rather than rebuild on land they now deem to be disaster prone. A disaster that creates numerous persons impacted in a small community may alter the entire social fabric of that community permanently.

Long-Term Support

Disaster survivors may need funding to repair or rebuild their homes or to reopen businesses, such as stores, restaurants, childcare facilities, and other services needed by the community. Insurance settlements, FEMA funding, and private donations may assist in financing community rehabilitation. Health care workers may be required to provide case management and assist survivors with necessary paperwork (CDC, 2015). Immediately after a disaster, some survivors may be unable to concentrate on anything beyond fulfilling their immediate needs and those of their family.

Psychological support is often required after a disaster, both for survivors and for relief workers. Some individuals may experience posttraumatic stress disorder (PTSD) (discussed later). Many survivors, especially elderly persons displaced from their homes, may quietly lose their will to live and drift into apathy and malaise. Individuals whose belief in God was unshakable before the incident may now question their faith, wondering how a loving God could have let this happen, especially if they lost a loved one. These survivors often require not only empathetic listening but also long-term skilled spiritual counseling. In assessing a community's citizens for counseling needs after a disaster, the nurse should not forget to include children. Often, children do not have words to express their feelings or fears and may act out in ways adults find difficult to understand, unless age-appropriate psychological intervention is provided. Major depression and grief, along with PTSD, may be found among the survivors and the emergency workers and health care personnel (Cherry, Sampson, Nezat, & Galea, 2014; McFarlane & Williams, 2012).

Long-term support must be considered when assessing a community and planning for disasters. Each community may be unique in their needs, and different disasters require a unique array of services and planning. Although many communities may be efficient in providing services in quick response to a disaster, they often do not factor in the long-term needs and provide the structure and support (McFarlane & Williams, 2012).

Need for Self-Care

Self-care, including stress education for all relief workers after a disaster, is a common practice and actively encouraged in many communities. Proponents report that stress education helps to reduce anxiety and put the situation into proper perspective. Critical incident stress debriefing (CISD) provides relief workers with professional debriefing in small groups or individually and becomes a mechanism for emotional reconciliation (Davis,

2013). CISD is generally provided between 24 and 72 hours after the disaster event. Proponents of CISD claim that it typically produces positive effects by:

- Accelerating the healing process
- Equipping participants with positive coping mechanisms
- Clearing up misconceptions and misunderstandings
- Restoring or reinforcing group cohesiveness
- Promoting a healthy, supportive work atmosphere
- Identifying individuals who require more extensive psychological assistance

A CISD addresses all components of the human response to trauma, including physiologic effects, emotions, and cognition (Pack, 2012). The research on CISD has been mixed, but Mitchell (n.d.) reports that if the personnel providing the intervention are well trained and follow acceptable CISD practice standards, the outcomes are more positive. Based on the conflicting research studies, nurses should be cautious about CISD, but should also be knowledgeable about it because it is so prevalent following a disaster. It can take years to end a popular practice even when it has been shown to be ineffective.

Self-care comes in many forms and is part of a prescription for emotional healing after a traumatic event. Self-care is not just for rescue workers; it is for everyone touched by trauma (Wall, 2012).

Psychological Consequences of Disasters

In addition to physical injury, potential loss of life, and destruction of property that can occur from a disaster, people affected by the disaster can also suffer from psychological consequences, such as acute stress disorder, depression, and PTSD (Cherry et al., 2014). The community health and community mental health nurses, through education, screening, assessment, and referral, have an important role in the primary, secondary, and tertiary prevention of psychological disturbances due to a disaster.

Primary Prevention

Although a disaster, by its very nature, is often unforeseen, people's ability to cope with the disaster can be determined in part by their previous level of coping and the resources available to help them. Stuart (2012) explains that primary prevention in behavioral health care has two basic objectives:

- To help people avoid stressors or cope with them more adaptively
- To change the resources, policies, or agents of the environment so that they no longer cause stress but rather enhance people's functioning

A community health nurse can engage in many activities to promote mental health and strengthen adaptive coping skills in individuals and the community. She or he can teach health education classes in positive stress adaptation, positive ways of coping, self-efficacy, and resilience, an important quality that enables people to cope with disaster. The American Psychological Association (2016) describes resilience as a process of behaviors, thoughts, and actions. The term resilience describes the personal and community qualities that enable us to rebound from adversity, trauma, tragedy, threats, or other stresses—and to go on with life with a sense of mastery, competence, and hope. We now understand from research that resilience can be a protective asset that may reduce the risk of mental health conditions (Mayo Clinic, n.d.). The building of competency or resilience is an important primary prevention strategy, since a competent person or community can make informed decisions based on availability of resources and problem-solving skills. Boscarino, Hoffman, Pitcavage, and Urosevich (2015) noted the importance of the mental health team's alertness for psychological trauma behaviors after any type of disaster.

Community health nurses can contribute to primary prevention in the face of disaster by being active advocates for improving the social structure of the community, including housing, work, schools, child care, and economic conditions for community members. At a time when governments are reducing spending and services, it is important for the community health nurse to advocate for the resources necessary for the community to meet both the physical and psychological challenges of a disaster. Community disaster training must include information on resiliency and resources to support individual and community resilience (APHN Public Health Preparedness Committee, 2013).

Secondary Prevention

Despite community education and intervention, people involved in a disaster often feel anxious and overwhelmed. They are in a *mental health crisis*, defined as a state when people's usual coping mechanisms no longer are effective in the face of the overwhelming disaster (Stuart, 2012). A crisis or disaster, an event that is out of the ordinary in magnitude and personal experience, is called an *adventitious crisis*. Examples of adventitious crises are natural disasters, such as floods, earthquakes, and fires, and national disasters such as terrorist attacks, war, riots, mass shootings, and airplane crashes (Varcarolis & Halter, 2014). When the stress of these disasters causes overwhelming anxiety, *crisis intervention* is a secondary prevention intervention that the trained community health or community mental health nurse can employ to minimize the psychological consequences of the disaster (American Psychiatric Association, 2016).

Crisis intervention is a short-term intervention, no longer than 6 weeks, designed to return an individual or community to its predisaster level of functioning and solve immediate psychological problems. Interventions are provided on several levels: environmental manipulation, general support, generic approach, and the individual approach (Stuart, 2012). *Environmental manipulation* results in the change of a person's physical or interpersonal situation, providing situational support to relieve stress. An example of environmental manipulation is when a community health nurse coordinates the reunification of family members separated by the disaster. *General support* is defined as the caring, warmth, and concern the community health nurse conveys to the client as he or she delivers services (Stuart, 2012).

The *generic approach* is an aspect of crisis intervention that is particularly well suited to the community health nurse. This approach is designed to reach high-risk individuals and large groups who have experienced the same disaster, teaching them about the expected emotional reactions to the type of disaster they have experienced and promoting adaptive responses. Grief reactions follow a known pattern, and large groups can be taught what to expect in the face of severe loss while giving individual members of the group an opportunity to express their feelings of loss. This generic approach is sometimes called *debriefing*. Individual crisis intervention is reserved for high-risk individuals who need special treatment because of the severity of their symptoms and is best provided by nurses trained in mental health treatment and crisis intervention (Stuart, 2012).

Tertiary Prevention

People who have experienced or witnessed a disaster and have been unable to adequately cope with its consequences can develop long-term effects, such as *acute stress disorder* or posttraumatic stress disorder (PTSD). According to the fifth edition of *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5), text revision (American Psychiatric Association, 2013), both acute stress disorder and PTSD can occur after any traumatic event to which a person responds with intense fear, helplessness, or horror; this may be an

actual or threatened death or serious injury to oneself or others. Both natural and man-made disasters fit into this definition.

The DSM-5 (American Psychiatric Association, 2013) defines PTSD more clearly as a traumatic or stress-related disorder activated by exposure to actual or threatened death or serious injury or social violation. The new diagnostic criteria includes "history of exposure to a traumatic event that meets specific stipulations and symptoms from each of four symptom clusters: intrusion, avoidance, negative alterations in cognitions and mood, and alterations in arousal and reactivity. The sixth criterion concerns duration of symptoms; the seventh assesses functioning; and, the eighth criterion clarifies symptoms as not attributable to a substance or co-occurring medical condition" (U.S. Department of Veterans Affairs, 2015, p. 3). It is important for the community health nurse to be aware of the symptoms of these disorders so that she or he can refer the client for treatment to the advanced practice mental health nurse and other mental health professionals.

TERRORISM AND WARS

At the start of the 21st century, the world is a global community. This is particularly evident with the increased incidence and sophistication of terrorist threats and acts around the world. Incidents occurring on U.S. soil, such as the initial bombing of the World Trade Center in 1993 and its destruction on September 11, 2001, alerted us to our vulnerability and dramatically emphasized the need for increased preparedness within our communities.

The July 2005 bombings in London that struck multiple transportation system sites and killed 56 while injuring over 700; the February 2008 bombings in Baghdad, by remotely controlled bombs carried by two mentally disabled women, that killed 98 and wounded 200; and the 2007 bombings in Karachi, Pakistan, that killed 136 and injured 387 all confirm that our vulnerability exists in many areas of the world. The Paris, France, and San Bernardino, California, terrorist attacks, mentioned earlier, also remind us of the global scope of this problem. Biologic, chemical, and nuclear terror attacks are tragically possible.

History of Terrorism

The U.S. Federal Bureau of Investigation (FBI, n.d.) has defined terrorism in three ways—international terrorism, domestic terrorism, and the federal crime of terrorism. Generally, these involve dangerous acts, violating laws, and are injurious to human life. They also involve a type of coercion or intimidation that affects government (U.S. Department of Justice, 2011). A terrorist is overzealous and obsessed with an idea. Terrorism and terrorist acts are not new. The term *terrorism* can be traced to 1798, and the use of terrorist tactics precedes this date. A highly organized religious sect called the *Sicarii* attacked crowds of people with knives during holiday celebrations in Palestine at about the time of Christ. During the French and Indian War of 1763, British forces gave smallpox-contaminated blankets to Native Americans. During World War I, the German bioweapons program developed anthrax, glanders, cholera, and wheat fungus as weapons targeting cavalry animals. In World War II, the Japanese tested biologic weapons on Chinese prisoners, and the Nazi's conducted medical experiments with Jews forced into concentration camps (Spendlove & Simonsen, 2013).

Bioterrorism, Nuclear, and Chemical Warfare

Three major countries operated offensive bioweapons programs in recent years: the United Kingdom until 1957, the United States until 1969, and the former Soviet Union until 1990. Iraq started its bioweapons program in 1985 and continued to develop weapons until 2003. Bioweapons include mustard gas, sarin, and VX gas, as well as anthrax (Spendlove & Simonsen, 2013). Terrorists typically use biologic or chemical agents, explosives, or incendiary devices to deliver the agents to their targets.

Nuclear warfare involves the use of nuclear devices as weapons and can take several forms. Terrorists who gain access to nuclear power plants could cause a chain of events that lead to a meltdown of the nuclear core, thereby releasing radioactive particles for hundreds of miles around the site. Nuclear accidents have occurred, but no known terrorist attacks have yet involved the use of nuclear power plants as weapons (Spendlove & Simonsen, 2013). A terrorist attack using nuclear weapons or destruction of a nuclear plant would cause multiple and prolonged deaths with extensive damage and negative effects for decades.

Chemical warfare involves the use of chemicals such as explosives, nerve agents, blister agents, choking agents, and incapacitating or riot-control agents to cause confusion, debilitation, death, and destruction. Sarin and chlorine have been used most recently in Syria. They may be known as the "poor man's bomb" because of them being relatively inexpensive to create (Esfandiary, 2014, p. 1). Terrorists in the Middle East, willing to murder others and knowing they will be committing suicide, strap bombs to their bodies and detonate the explosives in or near targets. Others plant explosives at large outdoor events like the 2013 Boston Marathon (CNN Library, 2015) or crash vehicles loaded with explosives into crowds of people or into a building.

The aircraft used on September 11, 2001, were incendiary devices because they were carrying thousands of tons of jet fuel. The success of the mission depended on the surprise of the attack, severe damage to recognizable buildings, and the deaths of many people. Disaster responders and government officials did not expect the collapse of the buildings. If the planes had been low on fuel, the damage would have been less severe. The liquid fuel burned at such a high temperature that the internal structures of the buildings were weakened (National Institute of Standards and Technology, 2008).

Biologic warfare involves using biologic agents to cause multiple illnesses and deaths. Biological agents are graded as category A, B, or C by the CDC (see Table 17–2). Typical biologic agents are anthrax, botulinum, bubonic plague, Ebola, and smallpox. These agents could be used to contaminate food, water, or air. Deliberate food and water contamination remains the easiest way to distribute biologic agents for the purpose of terrorism (American Academy of Pediatrics, 2015; CDC, 2011).

Table 17–2 Categories of Biologic Agents

Category	Definition	Agents/Diseases
Category A	• Pose highest risk to national security/ public health: • Can be easily disseminated or transmitted from person to person • Result in high mortality rates and have the potential for major public health impact • Might cause public panic and social disruption • Require special action for public health preparedness	• Anthrax (*Bacillus anthracis*) • Botulism (*Clostridium botulinum* toxin) • Plague (*Yersinia pestis*) • Smallpox (variola major) and other pox viruses • Tularemia (*Francisella tularensis*) • Viral hemorrhagic fevers Arenaviruses (e.g., Lassas, Junin) Bunyaviruses (e.g., Hantaviruses) Flaviviruses (Dengue) Filoviruses (e.g., Ebola, Marburg)
Category B	• Second highest risk to national security: • Are moderately easy to disseminate • Result in moderate morbidity rates and low mortality rates • Require specific enhancements of CDC's diagnostic capacity and enhanced disease surveillance	• Q fever (*Coxiella burnetii*) • Brucellosis (*Brucella* species) • Melioidosis (*Burkholderia pseudomallei*) • Psittacosis (*Chlamydia psittaci*) • Ricin toxin (*Ricinus communis*) • Epsilon toxin of *Clostridium perfringens* • *Staphylococcus* enterotoxin B (SEB) • Typhus fever (*Rickettsia prowazekii*) • *Food and waterborne pathogens:* *Bacteria* (e.g., Diarrheagenic *E. coli*, Pathogenic Vibrios, Shigella species, salmonella, *Listeria monocytogenes, Campylobacter jejuni, Yersinia enterocolitica*) *Viruses*: (e.g., Calicviruses, Hepatitis A) *Protozoa*: (e.g., *Cryptosporidium parvum, Cyclospora cayetanensis, Giardia lamblia, Entamoeba histolytica, Toxoplasma gondii, Naegleria fowleri, Balamuthia mandrillaris*) *Fungi*: (Microsporidia) *Mosquito-borne encephalitis viruses*: (e.g., West Nile virus, LaCrosse/ California encephalitis, Venezuelan/Eastern/Western equine encephalitis, Japanese/St. Louis encephalitis virus)
Category C	• Third highest priority agents include emerging pathogens that could be engineered for mass dissemination in the future because of: • Availability • Ease of production and dissemination • Potential for high morbidity and mortality rates and major health impact	• Nipah and Hendra viruses • Additional hantaviruses • Tick-borne hemorrhagic fever viruses • Tick-borne encephalitis complex flaviviruses • Yellow fever virus • Tuberculosis, including drug-resistant TB • Influenza virus • Other Rickettsias • Rabies virus • Prions • Chikungunya virus • Coccidioides spp. • SARS or MERS corona viruses • Antimicrobial resistance

From The U.S. Department of Health and Human Services, National Institute of Allergy and Infectious Disease. (2016). NAIAD emerging infectious disease/pathogens: Category A, B, and C priority pathogens. Retrieved from https://www.niaid.nih.gov/topics/biodefenserelated/biodefense/pages/cata.aspx.

The United States is very concerned about the possibility of biologic warfare or bioterrorism, as nations should be. The anthrax infections and deaths that occurred after September 11, 2001, added to these concerns. It was years before the government investigation led to a scientist at Fort Detrick as the cause of this terroristic act. Although charges were never filed because of the individual's suicide, the FBI believes that he was solely responsible for this act of domestic terrorism (FBI, 2008). Regardless of the source of terrorism, the outcomes are the same: fear, death, and destruction.

The Trauma of Warfare

Nurses, or men and women acting in that capacity, have provided comfort and care to

soldiers long before Florence Nightingale arrived in the Crimea during the mid-19th century (see Chapter 2). Nurses helped during the Civil War and were part of the armed services during both World Wars; their influence has expanded with other conflicts and continues today (Brooks & Hallett, 2015; Judd & Sitzman, 2014). Military nurses often saw and experienced many sad and traumatic events. Nurses who have served in the military are themselves veterans and may experience some of the effects of this trauma long after their service (Aloi, 2011). Amputations, head injuries, and other physical problems are common in war. For Iraq and Afghanistan veterans, those who had early amputations had better psychological and physical outcomes than those who waited and had later amputations (Melcer, Sechriest, Walker, & Galarneau, 2013). For all combat veterans, the trauma of warfare can be devastating and may continue to affect them for many years after their active service (Magruder et al., 2016). Exposure to new traumatic events can cause additional problems for them (Hamblen & Sione, 2015). Studies have shown that many years after the close of the Vietnam conflict, PTSD prevalence for those over age 60 was close to 17% (Goldberg et al., 2016). It is estimated that about 271,000 Vietnam veterans (both men and women) currently suffer from PTSD, and about 33% have major depressive symptoms (Marmar et al., 2015). Others have noted that PTSD among this population of veterans is a risk factor for coronary heart disease (Vaccarino et al., 2013). Community health nurses should be aware of the needs of veterans, especially during disasters, terrorist attacks, and other traumatic events that may bring these past experiences to the forefront again. It is also important to know about services available to veterans and treatments that are effective (Jain et al., 2016). See From the Case Files II.

From the Case Files II

Missed Opportunities for an Older Veteran

Tom Walton is a 70-year-old retired salesperson from an equipment manufacturer and a Vietnam veteran who served in the U.S. Navy. He has been a widower for the past year, and his adult children live out-of-state. Tom's health has declined dramatically since his wife's death, and he is struggling to control his hypertension and diabetes. Tom is noncompliant with medications and diet restrictions, and he seems to have more frequent outbursts of anger than usual.

Sadly, Tom's case is not one that is rare or unusual. I work at a Veterans Administration (VA) clinic, and I often see cases like Tom's in our clinic. Many veterans do not deal with the traumas they experienced during warfare, and when support systems are weakened or they are no longer busy with work and family, these long-repressed feelings begin to reemerge. For Tom, his case could easily result in a deteriorating health care spiral that will ultimately lead to multiple hospitalizations or his demise. But, as a veteran, Tom may be a candidate for posttraumatic stress disorder (PTSD) treatment, mental health care treatment programs, or other proven treatment modalities offered by the VA. Unfortunately, many of our nation's veterans fail to take advantage of this resource or even acknowledge that they may have this type of problem. In this case, having a working knowledge of the resources available to veterans in your community provides an opportunity for you, as a public health nurse, to assist Tom in accessing services that meet his health care needs and may prolong his life.

—Bryan, VA Clinic Manager

Factors Contributing to Terrorism

Political factors are the most common contributors to terrorism. Anti-American sentiment runs high in many foreign countries, especially those that perceive the United States as a threat to their military, economic, social, or religious self-determination. Terrorist acts against American military installations abroad, in airports, in airplanes, at American embassies, and even on American soil targeting civilian populations have occurred frequently in the last decade as an expression of political unrest. The war in Iraq in 2003 was based on information about suspected bioterrorism weapons and reports that Iraq was harboring anti-Western terrorists; these two pieces of information resulted in the toppling of the Saddam Hussein political regime. However, hundreds of military lives were lost and many thousands of civilians were killed, and no weapons of mass destruction were found. As of February 2016, more than 6,881 U.S. military and civilian personnel have lost their lives during conflicts in the Middle East. There have been 2,215 killed in Afghanistan and 4,411 killed in Iraq (U.S. Department of Defense, 2016a). Many more have been wounded —to date, over 22,229 in Iraq (U.S. Department of Defense, 2016b). Additionally, there have been approximately 165,000 Iraqi civilian deaths due to "direct war-related violence" since the beginning of Operation Iraqi Freedom through 2015 (Watson Institute for International & Public Affairs, 2015, p. 1).

Within the United States, violence-prone members of militia movements, violent antiabortion activists, racial desegregation advocates, and other radical groups have committed terrorist acts, such as the bombing of health clinics offering abortions and bombings and shootings at Black churches. The variety of methods used is raising the level of fear in everyday lives of the average American citizen (Galhotra, 2012).

Role of the Community Health Nurse

Community health nurses need to be prepared for the possibility of terrorist activity. They have a role in primary, secondary, and tertiary prevention.

Primary Prevention

Community health nurses are in ideal situations within communities to participate in surveillance. They must look and listen within their communities for antigroup sentiments, for example, antireligion, antigay, or antiethnic feelings. The nurse should report any untoward activities accordingly.

Nurses should be alert to signs of possible terrorist activity. Specific indicators of possible chemical or biologic terrorism include unusual numbers of dead or dying animals; unexplained serious illnesses or deaths; an unusual liquid, spray, vapor, or odor; and low-lying clouds or fog unrelated to weather. Unusual swarms of insects might also indicate the use of biologic agents for terrorism. "It is imperative that each nurse acquire a knowledge base and minimum set of skills to enable them to plan for and respond to a disaster in a timely and appropriate manner" (Veenema, 2013, p. 17). Cox (2008), in a seminal article, presents a historical overview of terrorism and relating these to the current state of affairs that have become increasingly concerning for our government agencies as well as citizens. In addition, recommendations for pre- and postdisaster planning to include critical, specific nursing competencies and evidence-based practices are provided. The American Nurses Association (2016) has developed policies, resources, and educational opportunities for nurses on disaster preparedness acknowledging the importance of nurse preparation before a critical event (Fig. 17–7).

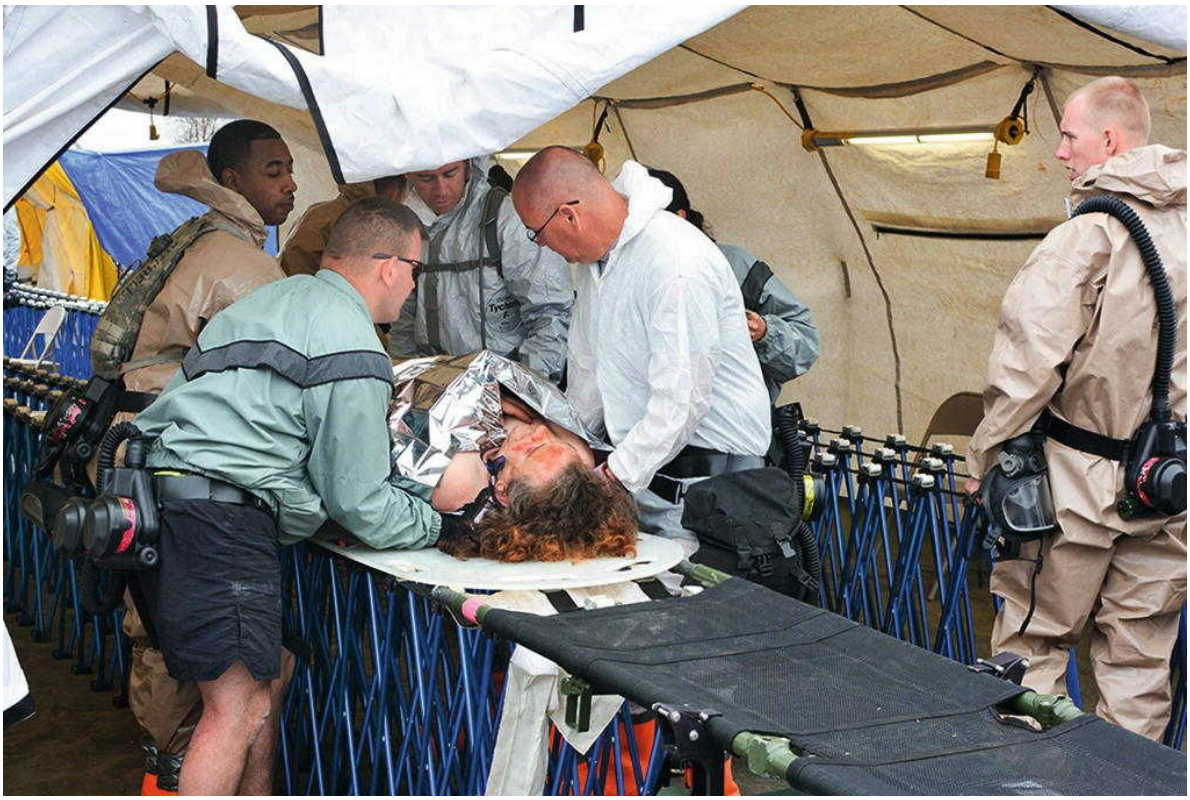

FIGURE 17–7 Disaster drills help prepare communities and health care workers.

Secondary and Tertiary Prevention

Although prevention of terrorist incidents is primarily the responsibility of the Department of Defense, the DHS, and public health and law enforcement agencies, community health nurses must be ready to handle the secondary and tertiary effects of such attacks. Knowing the lethal and incapacitating chemical, biological, and radiological weapons that may be used by terrorists is important. Many of the communicable disease organisms that could be used by terrorists were discussed in Chapter 8.

Realizing that terrorist attacks may result in large numbers of casualties, the public health nurse must be prepared to act safely, access information rapidly, and use resources effectively. Specifically, the community health nurse may be called on to provide direct care to survivors, to volunteer as a hospital–community liaison, to set up and administer mass immunizations, to support shelters, to make home visits to affected families, to establish a case management system for survivors, or to serve on committees responding to terrorist acts. Formulating, updating, and following a disaster plan is one of the most effective community-based strategies to minimize injury and mortality from terrorism. However, recent survey research among working nurses and nursing students found that most participants were not very confident in their abilities related to disasters or managing violent or serious events. Prior experience with disasters and those who worked in emergency departments, especially during night shifts, resulted in higher scores on measures of disaster nursing competence (Baack & Alfred, 2013; Nilsson et al., 2015).

Most community health nurses will not be on the front line of uncovering or immediately responding to terrorist activities, but their skills will be needed with groups, families, or individuals who experience a terrorist-related event. Some of the activities listed earlier in this chapter to help people deal with the aftermath of a disaster would also be appropriate if terrorism is the cause of the disaster. In addition, community health nurses may work with people who need help coping or who want to do something to help. After experiencing a traumatic event such as a terrorist attack, people do not know how to cope. We are warned to expect more attacks. We are told to be vigilant. The terror we are fighting is often our own. This is a new experience for most people, and assistance from the community health nurse can help them cope effectively. Smith and Segal (2016) offer advice for those affected by traumatic events, such as disasters:

- Feeling scared, anxious, and worried about the future are common reactions to this type of stress.
- Deal with these feelings by taking care of yourself (acknowledge them, be patient with yourself, feel them without guilt or shame, try to reduce stress/promote relaxation and sleep, seek help).
- Recognize that people react to disasters and traumas in very different ways.
- Be aware of repetitive, obsessive thoughts about the incident and try to deflect them or find something to do that engages your mind in other ways (e.g., reading, watching a movie, visiting with family/friends).
- Understand that you will need to deal with your feelings and emotions regarding the event and that permitting yourself to feel these emotions will help you in the healing process.
- Talking about the experience, like dealing with your emotions, is also healing, as is expressing them through art or writing a journal.
- Seek comfort and support by establishing a routine, connecting with others, and challenging your sense of helplessness (e.g., comforting others, donating blood).
- Try to minimize your family's extended exposure to media coverage of the event (this is especially true for children).
- Provide support for children and opportunities for them to talk about the incident and their feelings and concerns.

Community health nurses can make major differences in grassroots efforts to bring about change, but on a day-to-day basis, the little things they say and do with peers and clients can make just as big a difference. For example, providing information on foods to avoid and nonmedical treatment options such as support groups, hypnosis, and biofeedback are a few examples of how nurses can assist with coping mechanisms.

Current and Future Opportunities

There are many ways in which nurses, especially nursing students, can prepare themselves both personally and professionally for emergency events in their own communities. Various governmental and educational programs have been developed to provide free online training covering a broad range of topics. A summary of some of those training opportunities is provided in Display 17–4. For the novice nurse, or nursing student, an important issue is your role, if any, in your local response plan. Many schools of nursing have now begun to formalize their emergency preparedness plans in coordination with local hospitals, public health departments, or faith institutions. Take some time to discuss with your faculty what role you have in the event of a local emergency. If no organized plan exists, then perhaps you can work with the nursing faculty or your local student nurses association to prepare one (Halstead, 2013).

Knowing your role in an emergency will give you the peace of mind of knowing where you should go and what you are expected to do. Doing a little extra work by completing some of the online courses listed will help you to feel more involved and less fearful if the unimaginable were to happen. FEMA offers four particular courses within the incident command system (ICS 100, ICS 200, IS 700, & IS 800B); these are recommended for all health care personnel. Students who are also employed at local hospitals as interns or salaried employees should find out what role they have in the hospital's emergency plan. Finally, make sure you have a family plan to reconnect with and care for children, spouses, and parents.

FIGURE 17–8 Moulage is often used to provide a more realistic experience for health care workers and "victims."

Increasingly, communities are conducting emergency preparedness exercises (e.g., mass-casualty exercises and tabletop exercises; see Display 17–7) in response to the need to prepare local resources to coordinate emergency response efforts for maximum effectiveness (CDC, 2016). As a student, you may be asked to participate in one of these exercises as a "victim." Take the opportunity; the knowledge you gain from this experience will enhance your understanding of the process, and you may be able to help identify gaps in services or areas in need of improvement. With your expertise in nursing, you are a much greater asset to the exercise than untrained individuals. You may be asked to have moulage applied to simulate injuries, and you will likely be given a brief description of your trauma (see Display 17–8 and Fig. 17–8). Your assigned health problem may be emotional and not physical, allowing you utilize your understanding of behavioral health issues and crisis intervention. Whatever your capacity, the experience will provide as close to a realistic event as possible. Just as immunizations help fight against infections, participating in an emergency preparedness drill can build your tolerance for responding appropriately in a real event.

DISPLAY 17–7 POPULATION FOCUS ON DISASTERS: USING A TABLETOP EXERCISE TO PLAN FOR POPULATION CARE

A tabletop exercise is an interactive drill typically used by emergency planners and responders. It is designed to allow personnel to gather in a semiformal setting, so that they can participate in open discussions regarding their role in the event of an emergency situation in their community. Participants typically assume their own role, but may be required to assume other key positions. A simulated disaster/emergency event that affects their population is used, called the *scenario*. A facilitator keeps participants on track with their scripts and any accompanying videos or other media. This type of activity:

- Does not require complete plans and procedures
- Allows for practice in coordinated emergency problem-solving
- Permits brainstorming gaps and discussion of response capabilities and plans

- Prepares personnel for larger, more costly exercises (i.e., mass-casualty exercises)
- Helps multidisciplinary teams to plan for services affecting their entire community, with attention given to specific vulnerable populations who are at risk

From the Federal Emergency Management Agency (FEMA). (2015). Emergency planning exercises. Retrieved from https://www.fema.gov/emergency-planning-exercises

DISPLAY 17–8 WHAT IS MOULAGE?

Pronounced *mü-läzh*, the term *moulage* comes from the French word *mouler*, which means "to mold." In emergency preparedness training, moulage refers to the art of applying mock injuries for use in mass-casualty exercises. These injuries can be very simple or more complex, depending on available resources and the skills of the person applying the moulage. The use of moulage typically provides a more realistic experience for personnel participating in mass-casualty exercises.

Of the many online resources for information regarding equipment needed and how-to advice, one such Web site is Community Emergency Response Team (CERT) Los Angeles: *Step-by-Step Moulage Instructions* at http://www.cert-la.com/education/moulage.htm

Many organizations, both private and governmental, are seeking volunteers. As a student, you have more limited options; however, two major opportunities are available to you. Both require initial and ongoing training, but if you wish to become more active in emergency preparedness volunteer efforts, the American Red Cross and your local Medical Reserve Corps are two options. You can continue your relationship with these organizations after you receive your nursing license, and your role with them will likely evolve.

With your registered nurse license in hand, many more options are open to you. Each state is developing plans for a database of licensed health care providers who may be willing to volunteer in the event of local, state, or national emergencies. The exact criteria being developed for registration by each state may vary slightly, but as a licensed health care professional you may add your name to the registry along with your specialty training and contact information. Registration does not obligate you to any service; you agree only to be contacted if the need arises. The guidelines for these state-run databases were generated by

the U.S. Department of Health and Human Services and can be reviewed in the document *Emergency Systems for Advance Registration of Volunteer Health Professionals* (ESAR-VHP; USDHHS, 2011). The professional volunteer registry in Wisconsin is named WEAVR (*Wisconsin Emergency Assistance Volunteer Registry*). Using similar guidelines, California launched its version of the registry (*Disaster Healthcare Volunteers*). Mississippi has the *Volunteers in Preparedness Registry* (VIPR), and Arkansas nurses can register with the *Arkansas Volunteer Registry*. Check with your state's office of emergency preparedness and response for the link to your particular registry or information on availability.

As you progress in your career, many other high-intensity efforts are available for your involvement. At both the national and state level are DMAT, groups of highly trained health professionals who can rapidly respond to emergencies within a state or nationally. The DMATs operate as part of the National Disaster Medical System (NDMS). Each DMAT has a sponsoring organization (i.e., major medical center, public health agency, nonprofit organization). Check to see if your organization has sponsored a DMAT; if so, you might want to interview one of the members to learn more about his training and experiences (Murray, 2012).

The APHN Public Health Preparedness Committee (2013) position paper, *The Role of the Public Health Nurse in Disaster, Preparedness, Response, and Recovery,* is based on the earlier work of Jakeway, LaRosa, Cary, Schoenfisch, and Association of State and Territorial Directors of Nursing (2008). They developed specific core competencies for public health nurses related to emergency preparedness, and these can serve as a guide for students and practicing public health nurses. These include the following:

1. Describe the public health role in responding to a range of likely emergencies.
2. Describe the agency's chain of command in emergency response.
3. Identify and locate the agency's emergency response plan.
4. Describe one's functional roles and responsibilities in emergency response and demonstrate those roles in regular drills.
5. Demonstrate the correct use of equipment (including personal protective equipment) and the skills required in emergency response during regular drills.
6. Demonstrate the correct use of all equipment used for emergency communication.
7. Describe communication role(s) in emergency response.
8. Identify the limits of one's own knowledge, skills, and authority, and identify key system resources for matters that exceed these limits.
9. Apply creative problem-solving skills and flexible thinking to unusual challenges within one's functional responsibilities, and evaluate the effectiveness of all actions taken.
10. Recognize deviations from the norm that might indicate an emergency and describe appropriate action.
11. Participate in continuing education to maintain up-to-date knowledge in areas relevant to emergency response.

12. Participate in planning, exercising, and evaluating drills.

An adapted version of the 2013 position paper's table of disaster phases and corresponding nursing process actions is found in Display 17–9. Many options are available to you as both a student and a practicing nurse. What is important is that you are prepared. Assuring that you understand the role you may assume in the event of a local disaster or emergency situation is critical to your own welfare as well as to your community. You decide your level of participation, but resources are available for you to become as prepared as possible.

DISPLAY 17–9 PHN USE OF THE NURSING PROCESS DURING DISASTERS

Disaster Cycle	Definition	Assessment	Planning	Implementation	Evaluation
PREPAREDNESS	Includes: Prevention, protection, mitigation What is needed to prevent a disaster or reduce the impact of one (lives lost, property damage)?	Do you have specific populations in your service area that are vulnerable and at risk because of problems with access and functional needs during disaster (e.g., physically/mentally disabled, those with Alzheimer's, frail elderly)? Determine any hazards or threats that pose risks.	Plan for additional assistance and accommodations for those at-risk and vulnerable populations during disasters or other emergencies. Work with other stakeholders to meet their needs and the needs of your service area population (e.g., sheltering in place, evacuation, mass-casualty surge capabilities)	Conduct drills, trainings, and exercises regarding care of individuals, families, and communities during disasters. Focus on at-risk and vulnerable populations you have identified previously (e.g., physically/mentally disabled, those with Alzheimer's, frail elderly).	Evaluate the drills, trainings, and exercises in regards to care of at-risk and vulnerable populations. Identify gaps and any residual needs. Conduct evaluation of operational plans (e.g., preparedness, response, recovery for at-risk and vulnerable populations).
RESPONSE	Includes: Lifesaving Protection of property Meeting basic human needs post disaster What services and personnel are needed to save lives and protect property in a disaster? What services and personnel are needed immediately after the disaster to meet basic needs?	Using population-based triage, assess the impact of any communicable disease outbreak. Who is susceptible? Who has been exposed? Who is infected?	Work with stakeholders to develop or choose triage plans and methods of patient flow based on present symptoms and known history (e.g., COPD).	Work to organize PHNs and other trained personnel to provide care per triage plans. Perform ongoing rapid needs assessments during this phase, and ensure planning for community care support.	During the disaster, take part in continuing response planning and service planning. Ensure that necessary PHN care is provided.
RECOVERY	Includes assistance in recovery after a disaster What core skills and capacities are needed to ensure effective recovery?	Continue intermittent rapid needs assessment to ascertain health status and capacity for critical resources after the disaster (e.g., floods).	Together with stakeholders, make plans for any identified long-term health concerns, and pinpoint key resources needed for recovery.	Contribute to restoration of critical community services and sustaining the social and health infrastructures. Work to help the community achieve stabilization after the disaster.	Help with evaluation of disaster's long-term impact on the community. Through the work of PHNs, promote essential public health services.

Adapted from the Association of Public Health Nurses, Public Health Preparedness Committee. (2013). The role of the public health nurse in disaster, preparedness, response, and recovery: A position paper (2nd ed.). Retrieved from http://www.achne.org/files/public/APHN_RoleOfPHNinDisasterPRR_FINALJan14.pdf.

Healthy People 2020

Healthy People 2010 focused upon increasing quality and years of healthy life and to eliminating health disparities. Formulated in the years before January 2000, many disasters, both natural and man made, had yet to occur. The United States had not yet faced the national failures in the response to the hurricanes Katrina and Rita. We would also learn 18 months after the publication of *Healthy People 2010* that our nation was not immune from acts of terrorism. The objectives of *Healthy People 2020* directly address issues of emergency preparedness and response under the new topic of *Preparedness*. Additional topics also include preparedness activities, such as the objectives for public health infrastructure. In the ensuing years, many of these objectives will help focus public's attention on health care during a disaster. The goal of the new topics and objectives are to improve our "ability to prevent, prepare for, respond to, and recover from a major health incident" (USDHHS, 2016, p. 1; see Display 17–10). Those specific objectives provide the support needed to enhance public health surveillance activities, laboratories, training, development of professional competencies, and performance standards for public health organizations.

DISPLAY 17–10 HEALTHY PEOPLE 2020

PREP-1 (Developmental): Reduce the time necessary to issue official information to the public about a public health emergency.

PREP-2: Reduce the time necessary to activate designated personnel in response to a public health emergency.

> Baseline indicates that 66 minutes were needed for personnel to report to duty in 2009.

PREP-3: Increase the proportion of Laboratory Response Network (LRN) laboratories that meet proficiency standards.

PREP 3.1 (Developmental) Proportion of LRN biological laboratories that meet proficiency standards for category A and B threat agents

PREP 3.2 Proportion of LRN chemical laboratories that meet proficiency standards for chemical threat agents

PREP-4: Reduce the time for state public health agencies to establish after action reports and improvement plans following responses to public health emergencies and exercises.

Baseline indicates that it took state public health agencies 46 days to establish after action improvement plans in response to a public health emergency in 2009.

From the U.S. Department of Health and Human Services (USDHHS). (2016). Healthy People 2020 topics & objectives: Preparedness. Retrieved from https://www.healthypeople.gov/2020/topics-objectives/topic/preparedness/objectives

SUMMARY

A disaster is any event that causes a level of destruction that exceeds the abilities of the affected community to respond without assistance. Disasters may be caused by natural or man-made/technologic events and may be classified as multiple-casualty incidents or mass-casualty incidents.

The scope of a disaster is its range of effect, and its intensity is the level of destruction it causes. Persons impacted by disasters include those directly impacted (those injured or killed) and indirectly impacted (the loved ones of directly impacted). Displaced persons are those who are forced to flee their homes because of the disaster, and refugees are those who are forced to leave their homelands, usually in response to war or political persecution.

Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and socioeconomic factors. The disaster agent is the fire, flood, bomb, or other cause. Environmental factors are those that could potentially contribute to or mitigate a disaster.

In developing strategies to address the problem of disasters, it is helpful for the community health nurse to consider each of the four phases of disaster management: prevention, preparedness, response, and recovery.

Primary prevention of disasters means keeping the disaster from ever happening by taking actions to eliminate the possibility of its occurrence. Secondary prevention focuses on earliest possible detection and treatment. Tertiary prevention involves reducing the amount and degree of disability or damage resulting from the disaster.

In addition to assessing for preparedness, an effective disaster plan establishes a clear chain of authority, develops lines of communication, and delineates routes and modes of transport. Plans for mobilizing, warning, and evacuating people are also critical elements of the disaster plan. At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue survivors from further injury, triage survivors by seriousness of injury, and treat survivors on-site and in local hospitals. Care and transport of dead bodies must also be managed, as well as support for the loved ones of the injured, dead, or missing. Long-term support includes both financial assistance and physical and emotional rehabilitation.

Physical injuries resulting from disasters are not the sole consequence; people also suffer psychological trauma that can affect them for life. The importance of prevention, early crisis intervention, and ongoing treatment for those in need is evident. The community health nurse plays a key role in assessing individuals for symptoms of psychological trauma and intervening to prevent long-term consequences. Self-care, including stress education for all relief workers after a disaster, helps to lower anxiety and put the situation into perspective. CISD provides relief workers with a mechanism for emotional reconciliation and healing.

Terrorism is the unlawful use of force or violence against persons or property to intimidate or coerce a government or civilian population in the furtherance of political or social objectives. Terrorism may be nuclear, biologic, or chemical and may involve the use of nerve agents and explosive devices. The community health nurse should be alert to signs of possible terrorist activity and prepared to address the secondary or tertiary effects of such attacks. Preparation includes knowledge of the effects of specific biologic or chemical agents and how to help people cope with the terror they personally feel. Around the world, wars and conflicts are a daily occurrence. Nurses have provided care and comfort in many conflicts. It is important for PHNs to understand both the physical and mental consequences of combat and the other traumatic events associated with conflicts. Many veterans continue to suffer from PTSD and other physical and mental conditions, even years after their participation in combat may have ended.

Many opportunities are available for both student nurses and experienced community health nurses to become involved in emergency preparedness and response efforts. Agencies such as the American Red Cross and the Medical Reserve Corps are options available to students and at a higher level of involvement, once licensed. Natural and man-made disasters are a too frequent occurrence. It is the obligation of all nurses to be involved in emergency preparedness and to seek training that will enable them to provide the best possible service if the unthinkable happens. With the development of *Healthy People 2020*, ongoing efforts to help communities prepare for disasters and emergencies will require more nurses willing and able to respond to a call for action.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Think about your own community and its residents. What are some host factors that might increase its risk of experiencing a disaster? What environmental factors might be significant? In each case, identify the likely agent. What interventions could be included in a disaster plan to reduce these risk factors?
2. Current news sources show that at least 200 people have been injured in an explosion in a neighboring community. At the disaster site, survivors are still being recovered from the wreckage, and local hospitals are overwhelmed with patients who have fractures, lacerations, and burns. You want to offer your assistance as a registered nurse. How should you go about volunteering your services?
3. Think about your state and any sites that might be a target of terrorism. What is your state doing to address these issues? Examine Web sites (e.g., U.S. Homeland Security, Centers for Disease Control and Prevention, World Health Organization) for strategic planning or documents that could be helpful in assessing terror threats and preventing attacks. If an attack does occur, what should health professionals do to be most effective?
4. Check with your local and state health department. Are there plans in place for large-scale disasters or terrorist attacks? How often are they updated? Who is involved in the planning?
5. Check with your local hospital about their disaster plan. Do they collaborate with your local health department and other agencies in designing and executing this plan? How often do they hold "disaster drills"? Who is involved in these? How many types of emergency situations do they cover?
6. As a community health nurse practicing in an area with a high concentration of veterans, what knowledge and skills do you think are necessary to provide culturally competent, evidence-based care to this segment of the population? To become more familiar with this population, do the following activities:

- *Talk to veterans* to find out what is meant by military culture or veteran culture. How does this relate to other aspects of culture for the individual, family, or population group?
- *Contact your state or county Veterans Commission* to find out about the veteran population in your community. In what ways are the members of this population similar, and how might they be different? Consider age, gender, exposure to combat, type of service (regular active duty, guard/reserve duty), physical or mental injury, trauma, sexual orientation, lifestyle, and other factors. Think about how gender plays a role in other areas of diversity for this population. What are some common assumptions about veterans or stereotypes that might impact the way veterans are viewed in the community?

- *Access the U.S. Department of Veterans Affairs Public Health Web site to learn more about public health issues for the veteran population* (http://www.publichealth.va.gov/PUBLICHEALTH/about/index.asp).

What health risk factors are common among this population? What are the health conditions and the accompanying risk factors and how does the local community address these needs? What facilitating actions or barriers do you see? How do health issues in the veteran population impact the community as a whole, or other individuals within the community? Based on the risks identified for this population, what would you anticipate to be important primary prevention strategies for a community with a large veteran population? What might be the most important health promotion and population health strategies for this community?

5 UNIT

THE FAMILY AS CLIENT

18 CHAPTER

Theoretical Basis for Promoting Family Health

"Family is who they say they are."

—*Wright and Leahey* (2013, p. 55), Family Nurse Theorists

KEY TERMS

Family
Family culture
Family functions
Family health
Family life cycle
Family structure
Family system boundaries
Foster families
Gay and lesbian families
Homeless families
Roles

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Define family health nursing.
- Analyze definitions of family.
- Discuss characteristics all families have in common.
- Identify the stages of the family life cycle and the developmental tasks of a family.
- Discuss how a family's culture influences its values, behaviors, and roles.
- Describe the functions of a family.
- Analyze the role of the community health nurse in promoting the health of the family.

Community health nurses are intimately involved with families. The family plays a critical role in the health of its members. Health habits such as preventative care, diet, exercise, and physical activity are developed in the context of family. Health beliefs, genetic influences, and care of the ill family member all take place within the family environment. The community health nurse is in a unique position to influence and promote family health.

Definition of family varies by organization, discipline, and individual. These definitions are certainly changing with recent recognition of same-sex marriage laws.

> Many family theorists suggest that a family consists of two or more individuals who share a residence or live near one another; possess some common emotional bond; engage in interrelated social positions, roles, and tasks; and share cultural ties and a sense of affection and belonging (Kaakinen, Coehlo, Steele, Tabacco, & Hanson, 2015; Titelman, 2014). There are many definitions of family. One definition that seems the most inclusive and yet the simplest is "family is who they say they are" (Wright & Leahey, 2013, p. 55).

Today's community health nurse needs to understand and work with many types of families, each of which has unique health needs. For example, a young, single mother who is homeless seeks help in caring for her sick infant. A 55-year-old grandfather provides care for his elderly mother, who was recently discharged from the hospital after a stroke. A family from El Salvador needs instruction on the purchase and preparation of food. Why is it important for the community health nurse to understand and respect the unique characteristics, cultures, structures, and functions of each of these families? Do families have characteristics that affect the type of community health nursing intervention? The answer is an unqualified yes. The effectiveness of the community health nurse depends on knowing how to work with all kinds of families.

This chapter explores the nature of families and family health. It draws from various theories to strengthen the student's understanding and appreciation of families as clients. This information will promote the effectiveness of interventions with families at the primary, secondary, and tertiary levels of prevention. See Levels of Prevention Pyramid.

LEVELS OF PREVENTION PYRAMID

SITUATION: The family will provide the emotional and material resources necessary for its members' growth and well-being.

GOAL: Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed, and treated, and/or the fullest possible potential is restored.

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• After the family suffers a crisis, the members recognize the need for help and accept that help • Families draw on personal resources to rebuild relationships and heal the family unit	• The family continues using resources that enhance the growth and well-being of individuals and the family as a unit	• Engage in family strengthening practices to protect the family from possible inhibitors to growth and well-being

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Identification of a family member's personal problems that affect the family as a whole • Early recognition that problems exist in the relationship among or between family members	• The family seeks out the appropriate resources that brings the family to the highest level of wellness possible

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Adults are well prepared for the responsibilities of their union • Adults enter the relationship with the personal resources necessary to promote the growth and development of their family unit	• Adults are able to provide for basic needs (housing, nutrition, safety)

FAMILY HEALTH

Kaakinen et al. (2015) define family health as a "dynamic changing state of wellbeing, which includes the biological, psychological, spiritual, sociological, and culture factors of individual members and the whole family system" (p. 5). Family health is concerned with how well the family functions together as a unit. It involves not only the health of the members and how they relate to other members but also how well they relate to and cope with the community, outside the family. In fact, family health, like individual health, ranges along a continuum from wellness to illness. A family may be at one point on that continuum now and at a much different point 6 months from now. Family health refers to the health status of a given family at a given point in time (Kaakinen et al., 2015).

WHAT IS FAMILY HEALTH NURSING?

There are multiple ways that community health nurses can approach families. Nurses can provide care to individuals within the family or to the family as the client (family as context) or to the family as a system. Some nurses view family nursing as part of other specialties such as public health nursing, maternal child nursing, or behavioral health nursing. However, some nurses view family nursing as its own distinct specialty, rich with its own body of literature and research. Each of these approaches with families has their own distinct set of beliefs (Fig. 18–1).

FIGURE 18–1 Community health nurses work with families and individual family members.

Nurses work with individuals within families every day. Most often, the individual is the recipient of care. While assessing the needs of the individual, the nurse needs to include the family in the assessment, as the family is the pivotal provider of care. This may represent family as context. How does the family assist the individual family member? What are their available resources (physically, emotionally, and spiritually)? Nurses working with families as a system view the family as part of a larger suprasystem that includes many subsystems. The family becomes greater than the sum of all of its parts. A change within the family system affects not only the individual member but all of the family members (Wright & Leahey, 2013). When visualizing a family as a system, it may help to compare it

to a mobile. Think of all the pieces suspended freely by a string. If you pull lightly on one piece, all the pieces move, just as a change in one member's health affects the entire family. Can you think of some examples of this in your own family?

Examples of Level of Care

How can this make more sense to us? A nurse receives a referral to visit a new adolescent mother in her home. The baby girl (Rose) is currently 2 weeks old. Her mother (Zoe) is 15 years old. Zoe lives with her mother and three other siblings (13, 11, and 9 years of age). On the referral, Rose is listed as the client and the recipient of care. The nurse assesses Rose's feeding, sleeping, and interaction with her mother. The focus is clearly on the needs of the infant and intervening with any information that may be needed to meet the needs of Rose.

The nurse on the same visit includes information about the family on the assessment from the perspective of the family as context. How would the birth of Rose change the family? Who assists in the care of Rose? Will Zoe remain in school? Who takes care of Rose while she attends school?

The nurse includes information on the assessment looking at the family as a system of care. The nurse would observe Rose and Zoe as members of a family. How are they adjusting to their new roles within the family? How has the birth of Rose changed Zoe's role in the family? Does Zoe's mother interact with her differently? What has changed in the family with the birth of Rose? It would be important to ask each of the family members their answers to these questions.

DEFINITIONS OF FAMILY

Throughout history, the family has been the most basic unit. One of the first steps of the nurse is to define the family. How nurses define a family influences the care that they provide and how they interact with the family. What comes to mind when you hear the word family? How would you define your own family? Is your grandmother a member of your family? Your niece? Your neighbor? A friend? A family pet?

What do *you* think?

DEFINITION OF FAMILY

How do you define family? How would you define your own family?

Who do you include as family members? What are your first memories of family?

Most of us were raised in families and spent a good portion of our lives within families. Our first experiences with others are from our families. Often, how we interact with others is determined by how we were taught within our family. So we come to our nursing practice with ideas about families based on our own experiences. As the nurse begins working with families, it is important to first reflect on our own definition of a family. Bell (2013) asserts that the way we interact with families actually comes from how we define family so it is important to spend some time looking at this, because it will shape our care.

The United Nations (UN) defines family "as the basic unit of society" (n.d., para. 1). They recognize that there have been many changes in families in the last 50 years due to societal forces such as delayed marriage and childbearing, smaller family size, increases in divorce rates, and migration (UN, n.d.). In regard to demographic statistics, the UN defines family as "those members of the household who are related, to a specified degree, through blood, adoption, or marriage," acknowledging that the term "related" varies worldwide (2014, para. 3). The U.S. Census Bureau (Vespa, Lewis, & Krider, 2013) views family as people living together and related by birth, adoption, or marriage. Kaakinen et al. (2015) defines family as "two or more individuals who depend on one another for emotional, physical, and economical support. The members of the family are self-defined" (p. 5).

UNIVERSAL CHARACTERISTICS OF FAMILIES

Several observations can be made about families in general. First, each family is unique, with its own distinct set of strengths. As a nurse you want to look first at the family's strengths. When you approach the door of a house to begin your visit with a family, you cannot be sure of what they will be like. You will have to gather information about the family in order to provide the best nursing care possible. Starting with their strengths will only assure your success.

Families share universal characteristics with every other family. These characteristics provide an important key to understanding each family's uniqueness. Five of the most important family characteristics for community health nurses to recognize are as follows:

1. Every family is a small social system.
2. Every family moves through stages in its life cycle.
3. Every family has its own cultural values and rules.
4. Every family has structure.
5. Every family has certain basic functions.

No matter how many families a nurse may visit over the course of a year, each one will have universal features; it is important for PHNs to know each family's unique set of characteristics and their effects on family health. These five universal characteristics of family life, which provide the framework of this chapter, are based on systems theory, sociology, and family development.

Families as Social Systems

Many Americans fall into the habit of viewing families merely as individuals. This may be caused partly by our strong cultural emphasis on individualism. This error also occurs because families are often encountered through the individual members. When a community health nurse sits in a living room talking with a family about their adolescent son who has significant cognitive delays, it is important to keep in mind that all the family members are present by way of their influence. Systems theory offers some insights about how families operate as social systems (Titelman, 2014). Knowing the attributes of living systems or open systems can help strengthen understanding of family structure and function. There are five attributes of open systems that help explain functions of families: (1) families are interdependent, (2) families maintain boundaries, (3) families exchange energy with their environments, (4) families are adaptive, and (5) families are goal oriented.

Interdependence Among Members

All the members of a family are interdependent; each member's actions affect the other members, and what affects the family system affects each family member. For example, consider the changes a father might make to treat his hypertension. If he cuts back on working overtime, the family's income will be reduced. If he begins to eat different foods, food preparation and eating patterns in the family will be altered. If he starts a new exercise program three evenings a week, this may upset other family routines. Even his ability to carry out his usual roles as husband and father may be affected if, for instance, he has less time to help his children with their homework or share household chores with his wife.

Family Boundaries

Families as systems set and maintain boundaries that can include outside influences (permeable) or not (limiting) (Wright & Leahey, 2013). These boundaries result from shared experiences and expectations and link family members together in a bond that excludes the rest of the world. Also, a greater concentration of energy exists within the family than between the family and its external environment, thereby creating a family system boundary.

Energy Exchange

Family boundaries are semipermeable; although they protect and preserve the family unit, they also allow selective linkage with the outside world. To function adequately as open systems, families exchange materials or information with their environment (Friedman, Bowden, & Jones, 2003; Titelman, 2014). This process is called energy exchange. This exchange promotes a healthy ecologic balance between the family system and the environment that is its immediate community.

DISPLAY 18–1 THINK OF YOUR OWN FAMILY

How do you help your family? What kind of tasks do you do to maintain your family's equilibrium? Do you care for younger siblings or aging family members? Clean? Cook? Give money to the family? What are some of the roles/tasks that other family members have? Be specific.

Adaptive Behavior

Families are adaptive, equilibrium-seeking systems. Families never stay the same. They shift and change in response to internal and external forces (Titelman, 2014). The family composition changes as new members are added. Roles and relationships change as members advance in age and experience. With each new set of pressures, the family shifts and accommodates to regain balance and maintain a normal lifestyle.

Goal-Oriented Behavior

Families as social systems are goal directed. Families exist for a purpose—to establish and maintain a milieu that promotes the development of their members (Titelman, 2014; Wright & Leahey, 2013). To fulfill this purpose, a family must perform basic functions, such as providing love, security, identity, a sense of belonging; assisting with preparation for adult roles in society; and maintaining order and control. In addition to these functions, each family member engages in tasks to maintain the family as a viable unit. See What Do You Think?

Family Life Cycle

Many of the characteristics and defined developmental stages of individual growth also apply to families. For example, families change continuously. Families grow and develop as the individuals within them mature and adapt to changes. A family's composition, set of roles, and interpersonal relationships change with time (Friedman et al., 2003; Wright & Leahey, 2013). Families vary with each stage of the family life cycle. See Display 18–1 for some questions to ask yourself about your own family. At what stage are you and your own family?

Consider the following example. The Jordan family, a young married couple, concentrated on learning their new roles of husband and wife and building a mutually satisfying marriage. With the birth of their first child, Ben, the family composition and relationships changed and role transitions occurred. The Jordan family consists of not only a husband and wife but also a father, mother, and son; the family added three new roles. Within the next 4 years, two daughters, Lisa and Tiffany, were born. The introduction of each new member not only increased family size but also significantly reorganized family living. As Duvall and Miller (1985) first pointed out and later Plomin and Daniels (2011) reaffirmed, no two children are born into precisely the same family. The children entered school; Mrs. Jordan went back to work, and soon, Scott was leaving for college. The Jordan family, like every family, is moving through a predictable and sequential pattern of stages known as the family life cycle.

PHNs who are knowledgeable about this cycle can provide anticipatory guidance to families. For instance, while teaching prenatal care to the Jordan family, the nurse can help the soon-to-be parents to anticipate the responsibility and costs of raising her child by helping them calculate child care needs. The nurse can assist the family in figuring out the monthly costs of breast-feeding versus buying formula, disposable diapers versus cloth or a diaper service, and the clothing, equipment, and medical costs of infant care. When working with middle-aged parents of an adult son who has had a brain injury, the nurse can discuss what arrangements the parents have made for their son's care after they are older and unable to provide care themselves or after one or both of them die.

Stages of the Family Life Cycle

There are two broad stages in the family life cycle: one of expansion as new members are added and roles and relationships are increased, and one of contraction as family members leave to start lives of their own or age or die (Wright & Leahey, 2013). Within this framework of the expanding–contracting family are more specific phases, such as launching of children and retirement of parents. In some families, expansion and contraction are repeated as various members are added, return home with their children and perhaps a partner, or leave home permanently.

Family Developmental Tasks

To progress through the stages of the life cycle, a family must carry out its basic functions and the developmental tasks associated with those functions. Unlike developmental tasks, which are specific to each age level, family developmental tasks are ongoing throughout the life cycle. All families, for instance, must provide for the physical needs of their members at every stage. The manner and degree to which each function is carried out varies depending on how well members accomplish individual developmental tasks and meet the demand of a particular stage (Rasheed, Rasheed, & Marley, 2011). Physical maintenance, for example, affects the parents' ability to accept responsibility and procure the necessary resources to provide food, clothing, and shelter for their children. At early stages, children are dependent on their parents for meeting these needs; at the school, teenage, and launching stages, children may increasingly contribute to home management and family income. The responsibility for these tasks shifts from just the parents to other family members as well.

Some functions require greater emphasis at certain stages. Socialization, for example, consumes much of a family's time during the early years of child development. These same functions and their associated developmental tasks can be further broken down into actions specific to certain stages. While carrying out its function of maintaining controls, a family sets clearly defined limits for children at the preschool stage: "Do not cross the street"; "You may have dessert only after you finish your meal"; or "Bedtime is at 8 o'clock." During the school stage, control activities may center on allocating responsibilities and division of labor within the family: "Feed the dog"; "Clean your room"; or "Take out the trash." When a family reaches the teenage stage, its control function increasingly focuses on the relationships between family members and outsiders. The family may regulate some activities by setting limits: "Be home by midnight." In areas such as moral conduct, controls may involve family values and therefore be more imperceptible. A family at this stage must recognize the need for young people to assume increasing responsibility for their own behavior and acknowledge its own diminishing control over members who are exploring independence. Duvall and Miller (1985) described these activities as "stage critical" family developmental tasks that must be completed before moving onto the next stage. Others have echoed the concept of critical stages and tasks in family development (Rasheed et al., 2011). Sample community health nursing actions with the family at different stages are presented in Table 18–1.

Table 18–1 Stage Critical Family Developmental Tasks

Stage of Family Life Cycle	Family Position	Stage Critical Family Developmental Tasks	Role of the Community Health Nurse
Forming a partnership	Female partner Male partner	Establishing a mutually satisfying relationship	Interact with family where they are at
Childbearing	Partner–mother Partner–father Infant child(ren)	Adjusting to pregnancy and the promise of parenthood Fitting into the kin network Having and adjusting to infants and encouraging their development Establishing a satisfying home for both parents and infant(s)	Assist them in developing strong relationships
Preschool age	Partner–mother Partner–father Child, siblings	Adapting to the critical needs and interests of preschool children in stimulating, growth-promoting ways Coping with energy depletion and lack of privacy as parents	Assist in preparing for family expansion through education and anticipatory guidance
School age	Partner–mother Partner–father Child, siblings	Fitting into the community of school-age families in constructive ways Encouraging children's educational achievement	Encourage time for each other as adults in a relationship separate from parenting role
Teenage	Partner–mother Partner–father Child, siblings	Balancing freedom with responsibility as teenagers mature and emancipate themselves Establishing outside interests and careers as growing parents	Provide anticipatory guidance for the school-aged children as they grow into adulthood
Launching center	Partner–mother–grandmother Partner–father–grandfather Child, sibling, aunt or uncle	Releasing young adults into work, military service, college, marriage, etc., with appropriate rituals and assistance Maintaining a supportive home base	Provide anticipatory guidance for the contracting family as children leave home
Middle-aged parents	Partner–mother–grandmother Partner–father–grandfather	Rebuilding the relationship Maintaining kin ties with older and younger generations	Prepare adults for grandparenting role
Aging family members	Widow or widower Partner–mother–grandmother Partner–father–grandfather	Adjusting to retirement Coping with bereavement and living alone Closing the family home or adapting it to aging	Assist aging adults with emotional and financial security, as they approach retirement Prepare the aging adults with ways to cope with the losses of old age, including changes in space, work, health, status, and loss of friends and family members

Adapted from Duvall, E. R., & Miller, B. C. (1985). Marriage and family development. New York, NY: Harper & Row; and

Wright, L. M., & Leahey, M. (2013). Nurses and families: A guide to family assessment and intervention (6th ed.). Philadelphia, PA: F. A. Davis.

Family Culture

Family culture is an acquired knowledge that family members use to interpret their experiences and generate their behaviors that in turn influence their actions. The concept of family culture arises from a significant body of literature in the social and behavioral sciences. Culture explains why families behave as they do (McGoldrick, Garcia-Preto, & Carter, 2016; Pender, Murdaugh, & Parsons, 2015). Family culture also gives the community health nurse a basis for assessing family health and designing appropriate interventions. Three aspects of family culture deserve special consideration: (1) family members share certain values that affect family behavior, (2) certain roles are defined for family members, and (3) a family's culture determines its distribution and use of power.

Shared Values and Their Effect on Behavior

Although families share many broad cultural values drawn from the larger society in which they live, they also develop unique characteristics. Every family has its own set of values and rules for operation that can be considered as family (McGoldrick et al., 2016). Some values are explicitly stated: "Family issues and problems must always stay within the family." Such values may give rise to specific operating rules: "Don't tell anyone about our problems." Values such as these may make it difficult for families to ask for help.

Like all cultural values, many family values remain outside the conscious awareness of family members. These values, often not verbalized, become powerful determinants of what the family believes, feels, thinks, and does. Family values include those beliefs transmitted by previous generations, religious influences, immediate social pressures, and the larger society. Values become an integral part of a family's life and are difficult to change. A family that values free expression for every member engages comfortably in loud, noisy debates. Another family that values quietness, order, and control does not tolerate its members raising their voices. One family uses birth control based on beliefs about human life and parental responsibility; another family chooses not to use birth control because the members may feel it is against their religion. How a family views education, health care, lifestyle, courtship, marriage, child rearing, sex roles, or any of the countless other issues requiring choices depends on the cultural values of the family.

Roles

Roles, the assigned or assumed parts that members play during day-to-day family living, are bestowed and defined by the family (Kaakinen et al., 2015). For instance, the father role may be assigned as an authoritative one that includes establishing rules, judging behavior, and administering punishment for violation of rules. In another family, the father role may be defined primarily as that of a breadwinner and supporting the mother's decisions in day-to-day child rearing. If there is an absence of a male parent, a grandfather, uncle, friend, or even the mother may take over the father role. Selection of specific roles to be played in any

given family varies depending on the family's structure, needs, and patterns of functioning. In a single-parent family, the parent may need to assume the roles of mother, father, and breadwinner, as well as others.

Families distribute among their members all the responsibilities and tasks necessary to conduct family living. The responsibilities of breadwinner and homemaker, with their accompanying tasks, may belong to husband and wife, respectively, or may be shared if both husband and wife have jobs outside the home. Older children may help younger ones with homework, entertain them, or care for their basic needs. This releases parents for other tasks and increases the responsibility of older children.

Family members may play several roles at the same time. This can be taxing. A woman may play the role of wife to her husband, daughter to her mother, and mother to each of her children. The mother role may involve taking on several additional roles and responsibilities and varies with each child's needs. Parents may care for their children and also have some responsibility for aging parents. This situation characterizes the sandwich generation, and those experiencing this newly coined phenomenon feel the squeeze both in overloaded schedules and financial burden (Parker & Patten, 2013). A single parent often takes on the role of both father and mother but may distribute responsibilities and tasks more widely. A grandmother or a child may assume responsibility for some chores and thereby relieve some of the demands on the single parent. Among families, there is great variation in expectations for each role and in the degree of flexibility in divisions of roles. An example may be specific tasks given to girls versus boys within the family. Girls may be given child care or kitchen responsibilities and boys given yard tasks. Confusion and conflict can develop unless roles are clarified.

Other roles of family may extend beyond the immediate family. There may be extended family members nearby who interact with the family on a regular basis or only on special occasions like birthdays. If both parents are employed, they may have an expansive network of folks within the neighborhood. Friendships are often made with the parents of children's friends, particularly if the children participate in the same activities. Many families enjoy the fellowship of organized religious or cultural groups. This fellowship can be a source of support or comfort, as well as an additional role function for the family members. Family members can also participate in roles outside the family. These may involve local or regional politics, community improvement, volunteerism for nonprofit groups, or other groups outside the home that the community may offer. These diverse role relationships should enrich and energize the participants. However, many people become overcommitted, creating an imbalance of role responsibilities that is draining and causes friction and stress. The community health nurse may work with families to help them achieve a balance of activities that promote family health.

Distribution and Use of Power

Power is the possession of control, authority, or influence over others—assuming patterns

in each family. In some families, power is concentrated primarily in one member; in other families, it is distributed on a more egalitarian basis (Perelberg & Miller, 2011). The traditional patriarchal family, in which the father holds absolute authority over the other members, is rare in American society. However, the pattern of husband as head of the household and dominant member of the family is still frequently seen. The dominant power, whether male or female, holds the majority of the decision-making power, particularly over more important family matters such as employment, finances, and health care. Other areas of decision-making, including choices about vacations, housing, leisure activities, household purchases, and child rearing, may be shared or delegated. With changing societal influences, however, the present trend among American families is toward egalitarian power distribution (Fig. 18–2).

FIGURE 18–2 Families exist in many different forms.

Family Structures

Globally, families—in all varied forms—are the basic social unit (Wright & Leahey, 2013). The meaning of family among the Hmong of northern Laos may include hundreds of people who make up a clan. In Mexico, families remain close, are large, and extend into multiple generations. In Germany and Japan, families are small and tend to the needs of their elders at home. In the United States, where families come from many cultural groups, many variations coexist within communities.

For many people in the United States, the term family used to evoke a picture of a husband, wife, and children living under one roof, with the man as breadwinner and the woman as homemaker. In the past, this nuclear family structure was often seen as the norm for everyone. Changes in social values and cultural lifestyles (i.e., women working outside the home) combined with acceptance of alternative lifestyles have changed the definition of family. Today, definitions of a family include unmarried adults living together with or without children, single-parent households, divorced couples combining households with children from previous marriages (the blended family), and gay couples with or without children.

Families come in many shapes and sizes. McGoldrick et al. (2016) find changes in family structure related to societal changes such as increased divorce rates and remarriage rates, changing roles for women, increase in LGBT couples and families, lower birth rates, rise in single-parent families, increase in single-parent adoptions, high rates of unwed childbearing, two-income households, and a greater physical distance among members.

It is a privilege to gain entry into a family's home. This is a uniquely private space belonging to the family. The people who are members of this household interact, care for one another, and bond in ways that may never be fully understood by anyone outside the family. Therefore, being granted entrance into this system gives the community health nurse an opportunity to work with the family that few other professionals experience. Each type of household requires recognition and acceptance by community health nurses, who must help families achieve optimal health.

Family Functions

Families in every culture throughout history have engaged in similar functions: families have produced children, physically cared for their members, protected their health, encouraged their education or training, given emotional support and acceptance, and provided supportive and nurturing care during illness. Some societies have experimented with separation of these functions, allocating activities such as child care, socialization, or social control to a larger group (e.g., government, social systems). In U.S. society, certain social institutions help perform some aspects of traditional family functions. Schools, for example, help in child socialization, professionals supervise health care, and religious organizations influence values.

Six functions are typical of American families today and are essential for the maintenance and promotion of family health: (1) providing affection, (2) providing security, (3) instilling identity, (4) promoting affiliation, (5) providing socialization, and (6) establishing controls (Duvall & Miller, 1985; Titelman, 2014; Wright & Leahey, 2013). See Table 18–2 for a list of tasks associated with these functions.

Table 18–2 Family Functions

Functions	Tasks
Providing affection	1. Meeting physical needs (food, shelter, clothing, health care) 2. Provides dependability
Providing security and acceptance	1. Provide need fulfillment 2. Offers a safe retreat
Instilling identity and satisfaction	1. Teaching roles 2. Instilling values and goals
Promoting affiliation	1. To give a sense of belonging 2. Provide a connection to a family
Providing socialization	1. Transmit their culture 2. Learn roles within the family
Establishing controls	1. Maintain order 2. Learn right and wrong 3. Teach division of labor

SOCIAL CLASS

As a community health nurse, it is important to include social class of families you are visiting in your assessment. Social class often shapes a family's access and choices to work, educational, and health care opportunities (McGoldrick et al., 2016). Their overall health is often determined by their class position. The biggest predictor of health is your level of wealth (Unnatural Causes, 2008). How healthy we are and how long we live are often related to our social standing. The neighborhoods families choose to live in, and the schools their children attend, are often determined by social class. These decisions/choices have lifelong implications and shape the history of families. See Chapter 25 on social determinants of health and the socioeconomic gradient.

TRADITIONAL FAMILIES

Traditional families are those that are likely most familiar to us. They include the nuclear family—husband, wife, and children living together in the same household. In nuclear families, the workload distribution between the two adults can vary. Both adults may work outside the home; one adult may work outside the home, whereas the other stays at home and assumes primary responsibilities for the household; or partners may alternate, constantly renegotiating work and domestic responsibilities.

In 2012, according to the U.S. Census Bureau, for the first time, only 48% of American households consist of a married couple with or without children (Vespa et al., 2013). In 2014, 64% of children under the age of 17 years lived with two-parent families (ChildStats.gov, 2015). The percentage of children living in two-parent families continues to decrease.

A nuclear dyad family consists of two adults living together who have no children or who have grown children living outside the home. A single adult family is one in which one adult is living alone by choice or because of separation from a spouse or children or both. Separation may be the result of divorce, death, or distance from children.

Sometimes, in close-knit ethnic communities, families form a kin network, in which several nuclear families live in the same household or near one another and share goods and services. They may own and operate a family business, sharing work and child care responsibilities, income and expenses, and even meals. Variations of this trend are increasing among all groups as children postpone leaving home because of economic conditions, educational plans, or student loans. The number of young adults who continue to live with their parents is on the rise. Nineteen percent of men and ten percent of women between the ages of 25 and 34 years continue to live with their parents (Vespa et al., 2013).

CONTEMPORARY FAMILIES

The traditional nuclear family has been a fundamental part of our cultural heritage shared by many Americans and reinforced by religion, education, and other influential social institutions. Variations from this pattern often were treated as deviant and abnormal. Walsh (2012) describes the continued diversity in types of families and foresees the possibilities of normality and healthy functioning in each of these diverse family types. McGoldrick et al. (2016) fosters the importance of putting a positive spin on the families that make up our world. The nurse is in a unique position to assess families in a strength-based model rather than viewing certain families as deviant. Society has begun to accept contemporary definitions of family.

Divorce

Divorce changes family structures. Half of all marriages now end in divorce (the rate is higher for teen mothers), and the median duration of marriages is approximately 7 years. In the United States, the marriage rate is reported as 6.9 per 1,000 and the divorce rate as 3.6 per 1,000 in 2014 (Centers for Disease Control and Prevention [CDC], 2016). Seventy percent of divorced individuals remarry (McGoldrick et al., 2016). See Table 18–3.

Table 18–3 When Families Divorce

Phase	Emotional Responses	Developmental Issues
1. Stressor leading to marital differences	Reveal the fact that the marriage has major problems	Accepting the fact that the marriage has major problems
2. Decision to divorce	Accepting the inability to resolve marital differences	Accepting one's own contribution to the failed marriage
3. Planning the dissolution of the family system	Negotiating viable arrangements for all members within the system	Cooperating on custody visitation and financial issues Informing and dealing with extended family members and friends
4. Separation	Mourning loss of intact family Working on resolving attachment to spouse	Develop coparental arrangements/relationships Restructure living arrangements Adapt to living apart Realign relationship with extended family and friends Begin to rebuild own social network
5. Divorce	Continue working on emotional recovery by overcoming hurt, anger, or guilt.	Giving up fantasies of reunion Staying connected with extended families Rebuild and strengthen own social network
6. Postdivorce	Separate feelings about ex-spouse from parenting role Prepare self for possibility of changes in custody as child(ren) get older; be open to their needs Risk developing a new intimate relationship	Make flexible and generous visitation arrangements for child(ren) and noncustodial parent and extended family members Deal with possibilities of changing custody arrangements as child(ren) get older Deal with child(ren)'s reaction to parents establishing relationships with new partners

Adapted from McGoldrick, M., Garcia-Preto, N., & Carter, B. (2016). The expanding family life cycle: Individual, family, and social perspectives (5th ed.). Upper Saddle River, NJ: Prentice Hall.

Adjusting to divorce involves a series of transitions and reorganizations for all family members. For children, it may require coping with a new geographic location and a new school, as well as adjusting to changes in the mental and physical health of family members. In addition to the normal growth and developmental changes, children of divorce may face an absent father or mother, interparental conflict, economic distress, parental adjustment, multiple life stressors, and short-term crises.

Blending

Another variation in family composition is the blended family. In this structure, single parents marry and raise the children from each of the previous relationships together. They may be custodial parents who have the children except during planned visits with the noncustodial parent, or they may share custody, so that the children live in the blended arrangement only part time or possibly live in two separate blended homes. The family may include children from the couple, in addition to the children brought into the relationship. Not all divorced adults stay single; most remarry or cohabitate with another adult, who may or may not have children. This new couple may have children from their union, creating an even more complex family. Merged or blended families require considerable adjustment and relearning of roles, tasks, communication patterns, and relationships.

Identifiable phases occur in divorce, remarriage, and the blending of families; each phase has its own emotional transitions and developmental issues. We all come to new relationships with our own history from the past.

Because this emerging family pattern has become so prominent in such a short period, it is very possible that the community health nurse is familiar with this pattern or lives in such a family. The Pew Research Center (2011) found that 4 in 10 Americans currently have at least one step-relative, and 3 in 10 have a step or half sibling. Thirteen percent of adults have at least one stepchild. Stepfamilies are less common among those with college educations and higher-income levels. Survey respondents showed higher levels of feeling very obligated to give assistance to biological parents, grown children, and siblings over those with stepparents, stepchildren, or step/half sibling relationships (85% vs. 56%, 78% vs. 62%, and 64% vs. 42%, respectively).

Nursing skills that are needed when working with divorced or blended families include the ability to listen and be empathetic, as well as a nonjudgmental attitude. The nurse can be a rich resource for the family. Support groups for adults and children are excellent resources and provide invaluable services at a time of emotional instability in the family. Peer support groups for children and adolescents and support from within the schools should be used, if available, or started if they do not exist. The community health nurse can have a significant role in community-wide planning if services are needed but unavailable. See Table 18–4.

Table 18–4 Remarriage and Blending Families

Phase	Emotional Responses	Developmental Issues
1. Meeting new people	Allowing for the possibility of developing a new intimate relationship	Dealing with child(ren)'s and ex-family members' reactions to a parent "dating"
2. Entering a new relationship	Completing an "emotional recovery" from past divorce Accepting one's fears about developing a new relationship Working on feeling good about what the future may bring	Recovery from loss of marriage is adequate Discovering what you want from a new relationship Working on openness in a new relationship
3. Planning a new marriage	Accepting one's fears about the ambiguity and complexity of entering a new relationship such as: New roles and responsibilities Boundaries: space, time, and authority Affective issues: guilt, loyalty, conflicts, unresolvable past hurts	Recommitment to marriage and forming a new family unit Dealing with stepchild(ren) as custodial or noncustodial parent Planning for maintenance of coparental relationships with ex-spouses Planning to help child(ren) deal with fears, loyalty conflicts, and memberships in two systems Realignment of relationships with ex-family to include new spouse and child(ren)
4. Remarriage and blending of families	Final resolution of attachment to previous spouse Acceptance of new family unit with different boundaries	Restructuring family boundaries to allow for new spouse of stepparent Realignment of relationships to allow intermingling of systems Expanding relationships to include all new family members Sharing family memories and histories to enrich members' lives

Adapted from McGoldrick, M., Garcia-Preto, N., & Carter, B. (2016). The expanding family life cycle: Individual, family, and social perspectives (5th ed.). Upper Saddle River, NJ: Prentice Hall.

Single-Parent Family

One of the most common contemporary family structures is the single-parent family mostly headed by a woman. Sometimes single women choose to adopt or have children without being married. Sometimes pregnancy without marriage creates this family unity. In 2013, births to single women remain relatively stable at 41% of all births (ChildStats.gov, 2015). Twenty-four percent of all children live only with their mother, 4% of children live with their father, and 4% live with neither parent. Most of these children live with their grandparents (ChildStats.gov, 2015).

Over time, this form of family has become more accepted by society. It is important for community health nurses to view the strengths of single-parent families. Building on their current strengths can be most helpful in terms of meeting the challenges that they may face. See Population Focus on Families.

POPULATION-FOCUS ON FAMILIES

How Much Time Do Mothers Need to Spend With Children?

One of the biggest concerns for single mothers is how to best care for their children while at the same time making a living and maintaining a home. Many single mothers feel guilty spending time at work and not having enough time to spend with their young children and adolescents. And early research in this area often touted the need for intensive mothering, spawning the tension between mothers who chose to work versus those choosing to stay home—hence the "Mommy Wars." Many child support structures emphasize the need for mothers of young children to stay home and not work. A study by Milkie, Nomaguchi, and Denny (2015) examined the amount of time mothers spent with their children (ages 0 to 19) on child outcomes of academic performance, as well as emotional and behavioral problems. The data came from two waves of a "nationally representative longitudinal survey of families" (p. 359). The overall findings revealed that none of the measures of maternal time with children were significantly associated with their outcome behaviors. They did find that mother's level of education and family income level were significantly associated with school performance with some subject matter (e.g., reading, math).

When compared with children from two-parent homes, those from stepfamilies had greater behavioral problems, and ones from single-mother families had greater emotional problems. For adolescents, the only differences were behavioral problems for those from single-mother homes. Having time with both parents was beneficial to teens. They noted that the amount of time a mother spends with her 3- to 11-year-old children does not show a significant difference in their outcomes. However, there was some difference noted for adolescents. Time spent in "focused interactions" with adolescents was significantly associated with decreased delinquent behaviors (p. 368). Mother's work hours were negatively associated with their teenager's scores in math. Children and adolescents with a "warmer" mother had better outcomes (p. 369). The researchers noted the limitations of their study, and that mothers often provide engagement with their children in alternative ways (e.g., through proxies [extended family, neighbors, friends], networking with resources [e.g., after-school programs], phone calls) that were not measured in this study. They do encourage mothers to not simply focus time on younger children but to build in quality time with their adolescents.

Do you agree with these findings?

You need more evidence. Where could you find similar research studies that may show differing results?

How could you use this information in your work with single-mother families?

From Milkie, M. A., Nomaguchi, K. M., & Denny, K. E. (2015). Does the amount of time mothers spend with children or adolescents matter? Journal of Marriage and Family, 77(2), 355–372.

Adolescent Parents

Statistics indicate that teenagers are increasingly heads of single-parent families; some of these teen head of households become pregnant in junior high school. The birth rate among teens 15 to 19 years old has continued a steady decline, but teen birth rates in the United States remain the highest among those in developed countries. Specific factors related to teen birth rates are poor performance in school, growing up in a single-parent family, having parents with lower levels of education, living in poverty, lack of access to contraception, and being sexually active (Ventura, Hamilton, & Mathews, 2014).

Infants born to teen mothers are at risk for low birth weight, developmental delay, and death before 1 year of age. The infant mortality rate among mothers younger than 15 is twice as high as for women between the ages of 20 and 24 years, and 20% higher among teens between ages 15 and 19 years than from women in their twenties (Ventura et al., 2014). Of all births in 2013 to 15 to 17 year olds, 95% were to unmarried mothers (ChildStats.gov, 2015).

Teen fathers are often left out of the loop for services that communities provide for the teen mother and infant. However, paternal involvement contributes positively to the physical, social, and cognitive development of children. Children with absent fathers are at increased risk for behavioral difficulties and poor academic performance. Longitudinal research found lower birth weights and lower cognitive and behavioral scores at age two and poorer health for children of adolescent fathers when compared with those of adult fathers. Most children of teen fathers live in lower SES households and their mothers frequently do not marry their fathers (Mollborn & Lovegrove, 2011). A father who is emotionally supportive of the mother and provides child care and financial support directly and indirectly affects the well-being of his child.

The implications for the role of the PHN are greatest with the adolescent parent population. For example, nurses work with young teens through schools, clinics, or home-visiting programs to ensure healthy pregnancies and teach parenting skills to the parents and grandparents. Nurses can also ensure that the infant receives immunizations and primary care health services and can provide family planning information to the new parents. SmithBattle, Lorenz, and Leander (2013) suggest that teen mothers respond positively to community health nursing interventions. On a broader scale, community health nurses should collaborate with other professionals to make sure that the community has resources for all levels of prevention, with a focus on primary prevention. By initially approaching the teen parent in the hopes of developing a relationship, positive changes may be set in motion to assist the family in their child-rearing activities (SmithBattle et al., 2013). See Chapter 22.

Cohabitating Couples

Another form of nontraditional families includes couples that form a family alliance outside of a legal marriage. Cohabitating couples may range from young adults living together to an elderly couple sharing their lives outside of marriage to avoid tax penalties or inheritance issues. Cohabitating couples may be heterosexual or gay/lesbian; they may or may not share a sexual relationship. In some instances, these couples have their own biologic or adopted children. Kuperberg (2014) studied age at "coresidence" and found that a good portion of later marital dissolutions occurred in younger couples with a history of prior cohabitation.

Gay and Lesbian Families

Although the exact number of gay and lesbian families is not known, this emerging family type is increasing. It is estimated that there are 600,000 to 4 million children with gay or lesbian parents in the United States (Vespa et al., 2013). Gates (2013) reports there are over 8 million American adults identifying themselves as lesbian, gay, bisexual, and transgender (LGBT), and 3 million of them report having had a child. Six million American children and adults state that they have at least one parent who is LGBT. Almost one half of LGBT women are raising a child and about one fifth of LGBT men. Foster and adopted children are often being raised by LGBT couples, and over 25% of same-sex couples are raising siblings, grandchildren, or other related/nonrelated children. About half of the children living with same-sex couples are non-white (Gates, 2013).

One of the new topic areas established by *Healthy People 2020* is Lesbian, Gay, Bisexual, and Transgender (LGBT) Health, and this speaks to the importance of understanding the discrimination and oppression that LGBT families have faced (Display 18–2). Although much progress has been made in accepting people with values and beliefs different from those of the mainstream, pervasive homophobia and heterosexism persist (U.S. Department of Health and Human Services, 2016).

Gay and lesbian families have many of the same hopes regarding parenting that any family may have. In addition, they experience the stress that accompanies being stigmatized by much of a society. Lack of acceptance from their families and communities may have negative implications on their own family. Brown (2013) reports that 21% of LGBT participants surveyed have experienced workplace discrimination. Other markers of discrimination (e.g., rejected by family/friend, been a subject of jokes/slurs, threatened or physically attacked, poor service at business, hotel, restaurant) have shown decreases from past year to current year; this indicates that some progress has occurred. But annual family income is lower (39% vs. 38% earning < $30,000; 20% vs. 34% earning < $75,000) for LGBT families than for overall U.S. population.

The nurse can become a valued resource for the family. Through education and anticipatory guidance, the nurse can assist the family to successfully navigate the developmental stages of their children as well as the varied issues faced by families. Research has shown that the psychosocial development of the children of gay or lesbian parents is similar to that of children with heterosexual parents (American Academy of Pediatrics, 2015). The nurse can work with parents to anticipate what questions to expect from their children about their family (Table 18–5).

Table 18–5 Questions to Expect from Children About Their Family

Developmental Stage	Concern	Approach
Preschool children	Curious about background of family and meeting other children's parents, or about an absent parent	Answer questions simply and honestly. Talk to your children. Have fun together. Find other families like yours.
School-aged children	Have a better understanding of how their family may be different from other families; may have more questions about family background as they are introduced to other families through peers	Be honest. Talk to your children. Teach your schools. Show unconditional love.
Young and older teens	Know that their family is unique; may become embarrassed by parents. Also may begin to question own sexual orientation	Talk more about your life choices and sexual orientation when asked. Continue to show unconditional love and support.

Adapted from American Academy of Pediatrics. (2015). Questions to expect. Retrieved from https://www.healthychildren.org/English/family-life/family-dynamics/types-of-families/Pages/Gay-and-Lesbian-Parents.aspx

Older Adults

Elderly individuals are the fastest growing segment of the population. In 2010, 40 million people in the United States were over the age of 65 years or 11% of the total population. This is projected to double by 2030 (AgingStats.gov, 2015). Many older adults live independently well into the eighties and maintain healthy contacts with family and friends. Others feel isolated because of chronic health problems that limit mobility, thereby reducing or eliminating the ability to interact or contribute meaningfully in society (Fig. 18-3).

FIGURE 18–3 Older adults constitute a growing population.

The community health nurse needs to understand the complex dynamics of such situations and offer support and encouragement as family members work through chronic health problems. Often, a nurse serves an entire community of elders in a senior apartment complex, an assisted living center, or a mobile home community, for whom maintaining wellness is the focus. Keeping physically active, eating healthy meals, receiving appropriate medical care and immunizations, and establishing and maintaining social contacts are some of the tasks elders should focus on to stay healthy well into old age; these are some of the areas in which the community health nurse can intervene (Touhy & Jett, 2014). See Chapter 24.

DISPLAY 18–3 HEALTHY PEOPLE 2020 OBJECTIVES

Selected Healthy People Goals and Objectives Related to Family Health

Family Planning

Goal: Improve planning and spacing of pregnancies and prevent unintended pregnancies.

Overview: "Family planning is one of the 10 great public health achievements of the 20th century" (para 2). Family planning services can improve outcomes for families, women, infants, and children.

FP-1	Increase the proportion of adolescents who are connected to a parent or another positive adult caregiver.
FP-5	Reduce the proportion of pregnancies conceived within 18 months of a previous birth.
FP-6	Increase the proportion of females at risk of an unintended pregnancy or their partners who used contraception at most recent sexual intercourse.
FP-8	Reduce pregnancy rates among adolescent females.
FP-9	Increase the proportion of adolescents aged 17 years and under who have never had sexual intercourse.
FP-13	Increase the proportion of adolescents who talked to a parent or guardian about reproductive health topics before they were 18 years old.

Adolescent Health

Goal: Improve the healthy development, health, safety, and well-being of adolescents and young adults.

Overview: Adolescents (ages 10 to 19) and young adults (ages 20 to 24) make up 21% of the population of the United States. The behavioral patterns established during these developmental periods help determine young people's current health status and their risk for developing chronic diseases in adulthood.

AH-3.1	Increase the proportion of adolescents who have an adult in their lives with whom they can talk about serious problems.
AH-3.2	Increase the proportion of parents who attend events and activities in which their adolescents participate.
AH-4	Increase the proportion of adolescents who transition to self-sufficiency from foster care.
AH-4.1	Increase the proportion of adolescents in foster care who exhibit positive early indicators of readiness for transition to adulthood.

Maternal, Infant, and Child Health

Goal: Improve the health and well-being of women, infants, children, and families.

Overview: Improving the well-being of mothers, infants, and children is an important public health goal for the United States. Their well-being determines the health of the next generation and can help predict future public health challenges for families, communities, and the health care system. The objectives of the Maternal, Infant, and Child Health topic area address a wide range of conditions, health behaviors, and health system indicators that affect the health, wellness, and quality of life of women, children, and families.

Morbidity and Mortality

MICH-1	Reduce the rate of fetal and infant deaths.
MICH-8	Reduce low birth weight (LBW) and very low birth weight (VLBW).

Infant Care

MICH-21	Increase the proportion of infants who are breast-fed.
MICH-22	Increase the proportion of employers that have worksite lactation support programs.

Health Services

MICH-30	Increase the proportion of children, including those with special health care needs, who have access to a medical home.
MICH-31	Increase the proportion of children with special health care needs who receive their care in family-centered, comprehensive, coordinated systems.

From U.S. Department of Health and Human Services, Office of Disease Prevention and Health Promotion. (2016). Healthy People 2020: Topics and objectives. Retrieved from http://www.healthypeople.gov/2020/topics-objectives

Homeless Families

Children make up 39% of the homeless population and 42% of the children are under 6 years of age. Families with young children now account for 40% of the nations' homeless population (National Law Center on Homelessness and Poverty, 2015). On any given night in the United States, 2.5 million children are homeless; this translates into 1 in 30 children. This actually represents an 8% increase from the previous year. Of the adults in homeless families, 29% are working (Bassuk, DeCandia, Beach, & Berman, 2013). You can check your state rates at http://www.homelesschildrenamerica.org/.

Typically, homeless families are young single mothers with two children. Ninety-two percent of these women have experienced physical and/or sexual abuse. One in four women is homeless because of violence committed against them. They typically have poorer health than other women and suffer from posttraumatic stress disorder (PTSD) at three times higher rates than other women; one half have a recent history of major depression and one third have a chronic physical condition (National Center on Family Homelessness, 2015).

Homeless families present the PHN with unique challenges. Primarily, the family is in crisis often not being able to provide for its most basic needs. A PHN's knowledge of the resources available in the community is an important first step in providing the family with the help to deal with the crisis and assist in the provision of ongoing shelter, food, health, employment, and schooling needs. See Chapter 28.

Foster Families

Many children are removed from their families because of maltreatment due to abuse, violence, or neglect. In most communities, these children are placed with families known as foster families (Gonzalez, 2014). These families take a variety of forms, but all foster families have formal training to accept unrelated children into their homes on a temporary basis, while the children's parents receive the help necessary to reunify the original family. Although this arrangement is not ideal, most foster families provide safe and loving homes for these children in transition. Often, foster children have emotional and physical health problems, and they may never have experienced the positive structure that foster families provide. These problems, which can cause stress for everyone involved, are typically ones that the community health nurse may help to alleviate See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

Parenting Programs for Incarcerated Parents and Their Children

Recognizing the significant public health implications of parents who are in prison and their children was the impetus for a literature review of programs targeting these vulnerable families. Newman, Fowler, and Cashin (2011) cited the intergenerational nature of criminal activity and delinquency as leading to poor choices made by these children during childhood and into their adult years. The risk that these children will themselves develop poor parenting skills and engage in criminal activity is well documented. Families with one or more parents incarcerated are a growing problem in Australia, the United States, and England, with nearly 2 million children in the United States alone having a parent in prison. The authors reviewed the literature on 11 prison programs designed to deliver some level of parenting support using a variety of methods, both short and longer term. These programs were seen to vary in both delivery methods and evaluation; most significantly, few looked at the long-term impact of the programs. Using educationally based approaches covering areas of child development, communication, play skills, child safety, and discipline, they ranged from as few as 5 hours to a program lasting 24 weeks. The potential for improving child–parent relationships through increased contact and facilitation of that contact were seen as essential to both the child's well-being and the recidivism of the parents. The authors stress that addressing this growing public health problem requires assurance that evidence-based approaches are used and evaluation of

effectiveness is ongoing.

A more recent study by Whalen and Loper (2014) examines an impact on children when a parent is unable to care for them because of incarceration. The researchers analyzed data from 12 waves of survey data from a U.S. longitudinal study of youth and found that girls who had a household member incarcerated had more family and demographic risk factors present than did those who did not. Using advanced statistical methods, they were able to demonstrate that teen pregnancy could be predicted by the additional variable of household incarceration in addition to basic family and demographic variables. They noted that prevention programs should be developed for at-risk teenage girls who have household members incarcerated along with other family dynamic risk factors.

1. As you will see in Chapter 30, many public health nurses are employed in state and federal prisons; what challenges might they face in providing parenting support to these populations?
2. How could long-term evaluation of these programs be achieved?
3. What challenges from the prison system, the public health care system, schools, and politicians would the public health nurse face in the implementation of programs such as these? What sources of support could be identified?
4. Aside from the literature, what other sources might provide information on parenting support (or lack of) in the prison system?

From Newman, C., Fowler, C., & Cashin, A. (2011). The development of a parenting program for incarcerated mothers in Australia: A review of prison-based parenting programs. Contemporary Nurse, 39(1), 2–11;

Whalen, M. L., & Loper, A. B. (2014). Teenage pregnancy in adolescents with an incarcerated household member. Western Journal of Nursing Research, 36(3), 346–361.

IMPLICATIONS FOR COMMUNITY HEALTH NURSES

The variety of family structures raises three important issues for consideration. First, community health nurses can no longer hold to a myth that idealizes the traditional nuclear family. They must be prepared to work with all types of families and to accept them. Unless the PHN can accept the full array of family lifestyles and address the special needs of each, it is questionable that they will be able to fully help the family and may even create additional difficulties.

Second, the structure of an individual's family may change several times over a lifetime. A girl may be born into a nuclear family and then become part of a single-parent family when her parents are divorced. As she matures, she may become a single adult living alone and then become a part of a cohabitating couple. Still later, she may marry and have children in a nuclear family. After the death of her husband as a senior citizen, she may have a relationship outside of marriage and choose not to remarry. For the individual, each family form involves changes in roles, interaction patterns, socialization processes, and links with external resources. The community health nurse must learn to address clients' needs throughout these life changes equipping people with the skills needed to deal the inevitability of changing structures.

Finally, each type of family structure creates different issues and problems that, in turn, influence a family's ability to perform basic functions. Gottlieb (2013) recommends a strength-based approach by getting to know families for "what they do best" (p. 1). Wright and Leahey (2013) discuss the need for nurses to identify and develop strengths with families in planning nursing care. This should be a community health nurse's starting point. What are the family strengths? How does the family see their strengths? All families have strengths, although sometimes these are not easily recognized. It is important for the nurse to identify these with the family's collaboration (Display 18–3).

DISPLAY 18–4 QUESTIONS THE NURSE MAY ASK THE FAMILY

1. What are your strengths as a family?
2. If you had to tell me your three most favorite things about your family what would they be?

3. Name one quality about your mother that you really respect. About your father? Your partner? Your child?
4. What is your best memory of your family?

SUMMARY

The family as the unit of service has received increasing emphasis in nursing over the years. Today, family nursing has an important place in nursing practice, particularly in community health nursing. Its significance results from recognizing that the family itself must be a focus of service, that family health and individual health strongly influence each other, and that family health affects community health. A community health nurse's effectiveness in working with families depends on an understanding of family theory and characteristics.

Every family on the globe is unique; its needs and strengths are different from those of every other family. At the same time, each family is alike because of certain shared universal characteristics. Five of these universal characteristics have particular significance for community health nursing: every family is a small social system, has its own cultural values and rules, has structure, has certain basic functions, and moves through stages in its life cycle.

Family patterns influence the role of the community health nurse. The single adolescent parent needs the community health nurse's knowledge of family developmental theory. More complex interaction patterns and living arrangements are created by divorce, remarriage, the blending of families, and the unique relationships these arrangements create. Gay and lesbian families with children may also have special needs calling for a sensitive understanding of society's reaction to their family. Understanding families different needs will help the nurse provide appropriate services.

The chapter ends as it begins with several important points to consider when working with families. The nurse begins where the family is and accepts the family's own definition of who their family is and listens to the family's ideas about the direction of visits and time together. The nurse and the family become partners in providing health care. The nurse should begin the work assessing the family's strengths, which will begin to build a positive relationship between the nurse and the family. This is the essential starting point in the community health nurse's work.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Get together with a small group of your peers. Ask each of your peers to define family and then compare each of your definitions. How similar or different are each of the definitions? What in each person's own experience may account for the way they view families?
2. Analyze two families you know well (other than your own) and answer the following questions:

- If the major breadwinner in this family was unable to work or lost his or her job, how would the family most likely respond immediately and in the long term?
- What developmental stage is this family currently in and how does that affect their functioning?
- What are the strengths of the family?
- How could a nurse most effectively intervene in this situation?

3. More LGBT couples are becoming parents. What are some of the characteristics they have in common with other parents? What could be some concerns they might have?
4. Talk with members of a blended family and discuss with each member his or her relationships with stepchildren, stepparents, or siblings. What strengths can they identify in their family? How has this helped them adapt to their blended family?
5. Read through the new topic areas of *Healthy People 2020* that relate to family health at http://www.healthypeople.gov/2020/topics-objectives.

- What do the new areas reflect about changes in our society?
- How do social determinants relate to family?
- *Healthy People 2020* calls for more research in the areas of LGBT parenting issues throughout the life course. What do you think are potential areas of needed research? Back up your position with current research and statistics.

Interactional framework
Outcome evaluation
Population
Referral
Resource directory
Strengthening
Structural–functional framework

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the components of the nursing process as they apply to enhancing family health.
- Identify the steps in a successful family health intervention.
- Describe useful activities and actions when intervening on family health visits.
- List at least six specific safety measures the community/public health nurse should take when traveling to a home or making a home visit.
- Describe the effect of family health on individual health.
- Describe individual and group characteristics of a healthy family.
- Identify five family health practice guidelines.
- Describe three conceptual frameworks that can be used to assess a family.
- Describe the 12 major assessment categories for families.
- List the five basic principles the community/public health nurse should follow when assessing family health.

- Discuss the two foci of family health visits: education and health promotion.
- Describe the three types of evaluations that are necessary after family health interventions.

Chapter 18 explored the theoretical basis of family formation and the variety of family structures. Other chapters have stressed that families come in all sizes, consist of members of many ages and biologic relationships, and experience the world filtered through their unique cultures. There are many theoretical approaches and roles to consider when caring for families. This chapter explores the nursing process as it applies to community/public health nurses working with families, the "core unit of service," in the promotion of health and wellness, illness prevention, and overall improved health of the population.

The delivery of care to families occurs in various community settings (i.e., their homes, their work settings, classrooms, clinics and outpatient departments, neighborhood centers, and homeless shelters). Although caring for the family, as a unit of service, is an effective way to treat the population in the communities, a gap often exists between family nursing theory, development, and practice. The problem, in part, is derived from a health care system that tailors services to an individual and not a family and/or a community. This is evident in many third-party payer and reimbursement policies that impose limits to the kinds of services funded, in public health agencies' tendencies to organize services around individuals, and in government requirements that agencies keep statistics for specific diseases or service categories that reflect individual rather than family or aggregate data.

By focusing on the health needs of the core unit of service, the family, public health nurses address the health needs of the communities for the treatment of the population (American Nurses Association [ANA], 2013). Through legal changes, public health nurses are the leaders in using the accessible health care services to prevent illnesses and promote health in families (ANA, 2014; American Public Health Association, 2013; Davis & Gustafson, 2014). Therefore, family health has become the cornerstone for community and population health, making the family the focus of health care and related services.

The family is the basic element of a community and a population. A family refers to a group of individuals whose behaviors, actions, health conditions, and interrelationships impact the health of the group and the individuals (Smith, 2013a). A community relates to a set of people in families that share a common purpose with a sense of belonging and place (ANA, 2013). A population encompasses the total number of persons in families within communities at a specific geographic location (ANA, 2013). Based on the above definitions, providing the family with a positive experience when accessing health services means improved health for the community that leads to a healthier population. With that premise in mind, it is important for families to have equal access to optimal health care, social services, and community resources in a supportive and healthy environment. For example, immunization programs exist for infants and children. Parks, recreational services,

organized team sports, and social centers exist for the physical and emotional well-being of families. Pregnant women can attend childbirth education classes and receive medical care throughout the entire pregnancy from their health care providers (Aston et al., 2015; Parthasarathy, Dailey, Young, Lam, & Pies, 2014). Growing families can access parenting classes and support groups for help with developmental crises and in the management of chronic illness (Bahramnezhad, Asgari, Zolfaghari, & Afshar, 2015). Senior centers exist for the older adults in families, and myriad social and recreational activities offer senior discounts. What all these clients have in common is that they are members of families. Maintaining the health of the family is a way to influence the health and wellness of the population.

Think about how your family has influenced you. Did family members impact your choice for a career or the schools you attended? What impact did your family have on your value system, understanding of right or wrong, or your view of health? What role did the family play in the friendships you've formed? How different would your choices for food be if you had grown up with vegetarian parents or parents that annually hunted deer? Clearly, family members influence each other as well as the family as a whole, making it a unique unit of service.

Just as each family is unique, so too are their homes. Some families live in homes that look very much like yours, where you will feel comfortable almost immediately upon entering it. Other families may live in places that may not feel so comfortable to you. Families live in a variety of structures or buildings that define a home (e.g., mobile homes, high-rise inner-city apartments, rural cabins, cardboard boxes, farm labor camps). To a novice public health nurse, it can be daunting to enter a home that is a small and cluttered apartment, a sparsely furnished single room, or a makeshift structure in disrepair. Each home can bring its own set of unique challenges, as well as strengths, to the families you are visiting. These challenges can also influence the way the public health nurse perceives and interacts with the community to promote health, prevent illnesses, and reduce risk.

Family-level problem-solving techniques are needed to deal with important health issues including health promotion, pregnancy and childbirth, acute life-threatening illness, chronic illness, substance abuse, domestic violence, and terminal illness (Aston et al., 2015; Ayala et al., 2014; Bahramnezhad et al., 2015; Dennis, 2014; Kulbok, Thatcher, Park, & Meszaros, 2012; Parthasarathy et al., 2014; Prichard, Lee, Hutchinson, & Wilson, 2015). The first step is to complete a detailed assessment of the family with emphasis on both internal and external influences (ANA, 2013). This is foundational to the development of a database on which, to formulate a family diagnosis, an essential step before planning, implementation, and evaluation of services can occur. It is important for the novice public health nurse to understand how to execute their practice within the nursing process. With that in mind, this chapter is structured on addressing the *family* health needs through the nursing process: assessing, diagnosing, planning, implementing, and evaluating to enhance family health.

NURSING PROCESS WITH FAMILIES AS CLIENTS

The nursing process (assessing, diagnosing, planning, implementing, and evaluating nursing care) includes steps used to deliver care to clients in acute care settings and in the extensive clinic system. These same steps are used with families and aggregates in community health settings. The difference is the context and client focus (the family) and the consideration of external variables that have not been encountered in other contexts.

For public health nursing, the nursing process is executed with the family at the center of each step, knowing that addressing the health needs of the core unit of service will always transition into the health needs of the community and the population. As shown in Table 19–1, the context and application of each step are tailored to the needs of the population by focusing on the core unit of service (ANA, 2013).

Table 19–1 The Nursing Process

	Client = Individual	Client = Family in Community
Step 1	Assessment—gather information, subjective and objective, from interviewing client	Assessment—collect detailed health information about families from observations, interactions, and inferences in a systematic and continuous process to understand population's health status
Step 2	Diagnosis—identify problems of concern specific to client and assign action-based categories	Diagnosis and priorities—analyze assessment data to identify patterns of behavior, constraints to health, potential risks, actual risks, and unhealthy routines within and outside family relationships and their interactions
Step 3	Planning—identify interventions and plan of care for client with targeted outcomes and goals	Outcomes identification—in collaboration with the family, determine what the expected outcomes and goals will be for a detailed plan of care Planning—document the plan of care with clearly defined prescriptive interventions and strategies uses resources within the family and community
Step 4	Implementation—execute the interventions for the targeted goals and outcomes with the client	Implementation—work with the family to fulfill the interventions and strategies in the plan of care, which involves, but is not limited to: • Organizing the care • Educating the family about ways to prevent illnesses and promote health • Advising on how to use internal and external resources • Collaborating for health promotion activities
Step 5	Evaluation—review goals and outcomes achieved by the client and determine if further actions are needed	Evaluation—with the family, systematically and continuously review the process in achieving the targeted outcomes with the family and plan for future steps to promote and maintain the health of the family with internal and external services

Family assessment refers to a detailed collection of information from the public health nurse's observations about the family and external factors (e.g., family members, extended family, friends, neighbors). This assessment includes verbal and nonverbal cues, what is observed, and what is not observed because certain barriers to health care may be invisible, camouflaged as another issue, or understated (e.g., social bias, cultural prejudices, or geographical constraints). During the family diagnosis process, the public health nurse recognizes patterns, behaviors, and/or seen/unseen routines from the collected information during the assessment. This step involves identifying issues, risks concerns, and problems

that can negatively alter the health of the family. During the family planning of care step, targeted outcomes and goals are identified based on the patterns of unhealthy behavior and relationships. A plan of care is created and includes interventions, strategies, and interactions, which involves family resources and external services to promote the health of the family. Implementation of family care plan goes beyond just completing the plan of care to achieve the desired outcomes. The public health nurse collaborates with the family, community resources, and external services to organize and complete the plan of care. The family is educated about the resources and how to use them to address the health problems and promote the family health. Also, it is important to be aware of ways to include seen and unseen cultural and social issues in completing the interventions and strategies. Finally, the evaluation step is where the entire process from assessment to implementation is reviewed to determine if (1) the targeted outcomes and goals were achieved, (2) the process was a positive experience for the family, (3) new and current relationships with internal and external resources will maintain and strengthen the efforts for the family health, and (4) the family feels comfortable in participating in their care. With this understanding of the nursing process, the novice public health nurse is ready to prepare to work with families in the community.

Working With Families in Community Settings

Family visits are not limited to the home, and by "thinking outside the box," the nurse has a variety of nonhome settings or public places for visits to accommodate the family's schedules and routines. As long as a family member is comfortable with the nonhome setting, a visit may occur at school or work during a lunch break, in a day care or senior center, in a group home, or myriad after-work or after-school and recreational settings (Dennis, 2014). In general, the nurse must make sure that the family as the client, the school principal, employer, or center director is alright with the visit in a public place, which supports the use of community resources for the family health. This opportunity can be used to strengthen the nurse's relationship with the community and educate the family about community resources, both falling within the steps of the nursing process. The nurse must also remember that families appreciate the individualized effort and respond more positively when nurses are willing to work with family member's schedules (see Perspectives: Voices From the Community).

PERSPECTIVES VOICES FROM THE COMMUNITY

I couldn't believe it when she (the community health nurse) said she could visit me during my lunch break. I have been so worried about Ben's hearing and with my new work hours I kept missing her—I got her notes she left in the screen door. She actually drove all the way out to my work to tell me about his hearing test at school and the teacher's classroom changes. I can't afford to lose this job—and she came here!

Mary Anne, 34, Ben's mother

When making visits in public places, such as worksites or schools, it is important to respect and comply with the family member's wishes (Dennis, 2014). The time and place may have been selected because that individual is able to focus on the visit and feels comfortable to give detailed feedback. The visit may occur during lunch break in a business office on the day that the boss is off or after the lunch crowd disperses in a restaurant so that the individual can take a break. Be mindful of maintaining a confidential atmosphere so that the individual feels safe and not distracted by background noise and/or people. Seek out a place for the visit where other employees or customers cannot overhear your conversation or determine the purpose of the visit. Meeting in the waiting area of a restaurant after lunch may seem ideal, but a table in the back of the restaurant decreases the

risk of distractions, people overhearing the conversation, or people guessing the nature of the visit from the individual's and your body language.

Visiting a family member in the places where he or she spends time during the day can enhance the family assessment. The nurse can assess an individual's ability to function within public places and independent of the home setting. It decreases the potential impact of issues in the home on the individual's response(s) to the questions. The assessment of a child in a day care or an elderly family member in an adult day care will include that individual's ability to manage, participate, and interact in a frequently visited public place. This information can provide insight into problems the family is referring to when you make a home visit. Visiting children during the school hours often give insight into health problems and emotional issues that the parents may be concerned about or unaware of their existence. Such visits can offer the nurse an excellent opportunity to consult with the school's principal, teachers, nurse, counselor, and psychologist. As the public health nurse, you can suggest and coordinate a meeting between the school professionals and the parents while acting as an advocate for the family member(s) and liaison for the school resources during the meeting.

Working With Families Where They Live

Depending on the setting for public health nursing practice, the nurse encounters most family members in their homes and neighborhoods. Some see families in transition, who are living on the streets, in homeless shelters, or with relatives or friends. Regardless of the family's location, the family is the client; the family is the unit of service in public health nursing (Kaakinen, Coehlo, Steele, Tabacco, & Hanson, 2015) (Fig. 19–1).

FIGURE 19–1 Home visit with mother and her young children.

The Home Visit

It is a privilege to be able to visit families in their homes or private space and work with their neighbors within their community. In this unique setting, you are permitted into the most intimate of spaces that we, as human beings, have. Our homes are our creations, our private spaces; they hold our personal treasures and our memories. A home refers to a place that is either a permanent or temporary residence where an individual eats meals, interacts with others, rests her or his body, and engages in recreational activities (Smith, 2013a). The key to this privilege is trust. Family members must have a certain amount of trust to let a stranger and representative of a governmental agency into their home. Family members are trusting that the visiting stranger is there to help enhance their ability to function as a healthy family with internal and external resources. In the same manner, the nurse must have a certain amount of trust to enter an individual's family home. Once the door is shut

behind you, the rules change; you are in the client's world where they are the experts, and you are the guest and may feel like a stranger. Nevertheless, you are trusting that the family welcomes your visit and is ready to work with you for healthier outcomes.

Skills Used During Home Visits

Many skills, in addition to expert nursing skills, are needed when assessing, diagnosing, planning, implementing, and evaluating services in the home to families at a variety of functional levels. Expert interviewing skills and effective communication techniques are essential for effective family intervention (see Chapter 10). It is equally important to enhance these established techniques with your relational skills (e.g., intuition, openness, nurturing, and compassion) (Porr, 2015; SmithBattle, Lorenz, & Leander, 2013). The key to a productive home health visit and effective use of nursing skills is the development of a trusting relationship (Aston et al., 2015). The following paragraphs describe special skills required when making home visits.

Acute Observational Skills

You are preparing for a home visit to a new family in a new environment. You will be using your acute observational skills to assess both the family and the environment, which are equally important for a detailed assessment. Acute observational skills refer to the ability to take note of every detail (physical and nonphysical) that is directly and indirectly related to the family, the environment, the visit, and the entire process. Throughout the visit, you will focus on the family members' concerns and the purpose of the visit while being observant about the neighborhood, travel safety, home environmental conditions, number of household members, client demeanor, and body language, as well as other nonverbal cues. All this information will contribute to understanding the family, identifying patterns, and recognizing how to navigate the neighborhood.

Traveling to new neighborhoods and attempting to locate a family can cause distress to even the most experienced nurse, but this can be decreased by relying on your acute observational skills. Often, the home of a family is difficult to locate because of several reasons that can be addressed by noticing the smallest detail. The house or apartment number is missing, the basement apartment is not numbered, or the residence may be situated behind another house. As you walk through the neighborhood or apartment building, it is useful to notice the layout and the sequence of the addresses, which can help identify a missing address or a house located behind another. Many anomalies in the layout of a building or a neighborhood may make it difficult for the nurse to locate a family. Addresses on referrals may have numbers transposed where 123 Hickory is listed as 132 Hickory. Perhaps there is a North Hickory that is miles away from a South Hickory, or there is a Hickory Boulevard, Drive, Road, Street, Court, Lane, or Way. There is also the chance that the family member has given a fictitious address, for whatever reason, so that the family remains anonymous as long as possible. Again, using your acute observational

skills, it may be possible to prepare ahead of the visit by searching for the address or confirming the information with the referral(s) to identify any anomalies. Of course, this search could also provide information about the environmental conditions of the neighborhood.

Observation of Home Environmental Conditions

Conditions in the neighborhood and home environments reveal important information that can guide diagnosing, planning, and intervention with families. While traveling to and arriving at the family home, you have been gathering information about the neighborhood conditions (e.g., cleanliness, street activities, people's interactions/behaviors) and the physical appearance of the apartment or house. This information can provide an assessment of the resources and barriers encountered by the family. It is important to remember that these observations of the external environment may contradict the family's values, resources, and goals. They may have little control over the neighborhood or the building they live in, especially if they are renting. For instance, a young couple with a baby may be able to rent a $775/month apartment, which is only available in a deteriorating low-income neighborhood with dilapidated buildings. You notice that all occupants are renters and that absentee landlords own the building; they may own several buildings, mainly for profit. A manager handles the property and is employed through a management company owned by the landlords. However, the manager does not seem to know any of the landlords. Yet, upon entering the young couple's apartment, you walk into a nicely furnished, uncluttered, and clean home that is opened to you with pride by the family.

In another situation, you have a home visit with an older couple that lives in an upscale suburban neighborhood. They own their own two-story house that has a two-car garage with a well-groomed lawn and several trees. The husband, an older man, who moves very slowly, greets you at the front door. On entering the house, however, you barely can manage to squeeze through a pathway from the front door to the living room, which is made from ceiling-high piles of boxes, newspapers, and furniture. The pathway continues throughout the house and even into a back bedroom with half the bed covered in papers, books, and a few cats. An older woman is reclining in the other half of the bed. After showing you into the bedroom, the husband leaves the bedroom and heads toward the backyard.

There are many environmental conditions in each of these situations that a nurse can observe and use in her or his assessment that will lead to a family diagnosis and a plan of care to assist each family. Most neighborhoods and homes do not present such extremes. However, if you are unprepared for the extremes, they may overwhelm you, and you may become so distracted that you cannot focus wholly on the family and incorporate these important observations into the plan.

Observation of Body Language and Other Nonverbal Cues

You are gathering data as soon as you have knocked on the door or have rung the doorbell, greeted the people in the doorway, and entered the home (see Perspectives: Public Health Nursing Instructor). Your observations are based on how you perceive the sound of the doorbell or doorknocker, the way the door opens, or the manner in which individuals walk toward and open the door. Assessment from these nonverbal cues and body language are observations that will contribute to your initial opinions and perceptions about the family. Being human, you may form opinions or make judgments about the family before the actual beginning of the meeting. Be aware of this possibility so that you can determine the value of these initial opinions and judgments with the information from the family assessment. Also, realize that *all* family members (present or absent) are doing the same with you. Be aware of all household members; acknowledge and greet them. If some are absent, inquire about them. Make this a habit on all visits. Each family member is important and has opinions and health care needs, even if you only see certain members of the family on each visit.

PERSPECTIVES PUBLIC HEALTH NURSING INSTRUCTOR

How You Knock Helps Families Open the Door

This question may seem trite but, "How do you knock on the door when you visit a family?" Do you use the "I don't want to be here and if they don't hear the knock I can quickly and quietly leave" type of knock that even Superman can't hear? Or do you knock like, "I'm a bill collector and *you better* open this door!" During this knock, the entire family may be running out the back door or through a window! We suggest a knock that is loud enough to be heard, yet friendly and nonthreatening. If necessary, practice "your knock" until you can create this beneficial combination.

With some families, it is helpful to call toward the door as you knock or ring the bell with, "Mrs. Smith, this is Jenny from the Health Department—remember I was coming by today" or, "Ms. Jiminez, it's the student public health nurse, Terry De Leon, and I brought some pamphlets for you" or, "Hello, it's James from the neighborhood clinic, we planned to meet today." Using such a greeting allows the family to know who is at the door and choose to open the door if they want. It will get you into more homes than the "quiet-as-a-mouse" or "bill-collector" knocks.

—Alice K. PHN

Be observant of family's nonverbal cues such as body language and demeanor because

they can provide information that must not be overlooked. Opening statements such as, "You seem anxious today," or "Did I come at a bad time? You seem distracted," will encourage family members to express what is on their minds, which otherwise might not be indicated or addressed. Through their facial expressions, hand gestures, subtle glances, eye movement, and body language, detailed information will be generated to address both direct and indirect concerns of the family. If you are not open to body language while making a visit, you may overlook important cues and continue with *your* agenda instead of the family member's agenda, without realizing that the family is distracted by another, more pressing issue.

On a related note, it is important to be aware of your own body language. Your mannerisms can tell the family a great deal about how you feel being in their home, doing the visit, perceive the family members, and more about you as a person. Fidgeting with car keys during the entire visit or appearing to be rushed can be perceived as nervousness, anxious, or not wanting to be in the current situation—the home visit. Rudeness, unprofessionalism, and not being knowledgeable about the family, the purpose of the visit, and their resources may be a conclusion the family makes from you giving minimal eye contact while continuously looking at your paperwork, chewing gum, or appearing distracted. Your level of discomfort and perhaps "fear" can easily be suggested from the refusal to sit on any of the furniture or a shocked expression at seeing a roach or mouse scampering across the floor. Remember, your behavior will contribute to the family trusting you and your capabilities during the visit and subsequent visits, as well as interventions.

PLANNING THE HOME VISITS TO MEET THE FAMILY HEALTH NEEDS

The greatest barrier to a successful family health visit is lack of planning and preparation. A visit is not successful just because the nurse enters a home or another setting where the family is present. A successful family health visit takes much planning and preparation and requires accurate documentation and follow-up. In addition, safety measures must be followed not only while traveling in the neighborhood, but also in the home.

Components of the Family Health Visit

The structure of family health visits can be divided into five components that follow the nursing process (see Display 19–1). Previsit preparation steps (assessment, diagnosing, and planning) are necessary to ensure that the actual family health visit (implementation) is complete. The documentation and planning for the next visit (evaluation) concludes the responsibilities for one visit and prepares the nurse for the next action needed.

DISPLAY 19–1 GUIDELINES FOR MAKING HOME VISITS: 33 STEPS TO SUCCESS

The following guidelines can be followed to evaluate yourself after making a home visit, or it can be an evaluation tool when another nurse (peer or instructor) evaluates you. Rate yourself using the following scale: 0 = does not apply, 1 = unsatisfactory, and 2 = satisfactory.

Rating	Assessment
	Assessment
_____	1. Studies referral, record, or other available data about the family
_____	2. Gathers community resource information potentially appropriate to the family
_____	3. Obtains appropriate supplies or educational material in anticipation of family needs
	Diagnosis
_____	4. Identifies reoccurring problems, issues, and/or concerns in both internal and external settings
_____	5. Detects gaps in the available data and resources
_____	6. Identifies issues, problems, and/or concerns emphasized by primary client
	Planning
_____	7. Contacts family to set up an appropriate time for the home visit
_____	8. Ascertains correct address and directions to the family for the home visit
_____	9. Formulates a written plan for nursing intervention with each family member
_____	10. Organizes a chart with forms and charting tools based on the focus of the visit
_____	11. Plans a route to the family's home that is the most direct, being resource efficient
	Implementation
_____	12. Travels the community with safety, locating the family home with ease
_____	13. Knocks on the door loudly enough to be heard and in a friendly manner

_____ 14. Introduces self to family members in an appropriate manner
_____ 15. Clearly states the reason for the visit
_____ 16. Allows a few moments of socialization before beginning the visit
_____ 17. Smiles; speaks in a pleasant, friendly tone of voice; and maintains eye contact
_____ 18. Uses aseptic technique when providing nursing care
_____ 19 Respects the dignity, privacy, safety, and comfort of family members
_____ 20. Listens attentively to ascertain what family members are saying or implying
_____ 21. Converses with family members during the home visit
_____ 22. Communicates accurate and meaningful information to family members
_____ 23. Responds to family members in a way that encourages them to continue talking
_____ 24. Uses appropriate words of explanation for family member understanding
_____ 25. Utilizes opportunities for incidental teaching
_____ 26. Commends progress made by individual family members
_____ 27. Explains nursing measures before, during, and after each procedure
_____ 28. Shares the results of nursing measures with family members when indicated
_____ 29. Closes the home visit by summarizing the main points of the visit
_____ 30. Makes plans for the next visit, considering family member wishes

Evaluation

_____ 31. Uses information gathered on the home visit to plan care for next visit
_____ 32. Documents home visit in an appropriate and timely manner
_____ 33. Completes a self-evaluation of the home visit

Previsit Preparation

Based on a referral to the agency, public health nurses identify preliminary family diagnoses and design a plan for the initial family health visit. A referral is a request for service from another agency or person. This request is formalized by use of a form or information that the originating agency has transferred to the receiving agency. Referrals may be formal, coming from physicians or complementary agencies, or they may be informal, resulting from verbal or telephone referrals from friends or relatives who believe that someone needs help. Referrals are the source of new cases for the agencies, and they need timely responses. Some examples include:

- Referrals may come from labor and delivery hospital units, requesting service for low-birth-weight babies and teen mothers.
- Social service agencies might request a home assessment for a child being returned to parents after previous removal from the home.
- A homeless shelter might be seeking services for homeless or transient persons showing signs of uncontrolled diabetes.
- A battered woman's shelter might need services to treat emotional issues of a mother and her children who are running from an abusive husband and father.
- A referral could come via a telephone call from a woman in a city 500 miles away, requesting that a nurse check on an elderly relative who lives alone in the community and has recently exhibited slurred speech and/or has been homebound. Follow-up visits are made to these families based on need and agency protocol.

Nurses must have a physical place to work with access to a telephone, the Internet, and any other supportive resources deemed necessary, such as educational material (pamphlets, brochures, computer, and related Web site addresses to access educational information), charting tools, and any other supplies required for home visits. Nurses also need a resource directory, which is a list of resources for the broader community, or a nurse-made directory of resources created over years of working with people in the community. Some agencies issue a nursing bag to their nurses, but if not, many public health nurses become creative and devise their own carryall tote for supplies. The supplies needed depend on the type of visit; some nurses have several totes for different types of visits. Think about what basic supplies you will need to visit a new mother and her infant or an elderly man with hypertension.

Once the nurse is prepared, contact with the family is made. For a home visit, ideally, the referral contains a correct telephone number for the family, a relative, or a neighbor. If the referral or chart does not contain this information, an unannounced visit is scheduled. During this visit, it is important to get a contact number for the family. When calling for the first time, you, the PHN, will:

1. Introduce yourself
2. Explain the reason for the call
3. Give the reason why the family was referred
4. Indicate what the visit consists of
5. Determine when a visit would be convenient for the family and you
6. Get explicit directions to where the family is staying (the referral may have a different address or the family did not mention that they are staying elsewhere)
7. Repeat the date and time of the scheduled visit

It is possible that some people may question the nurse's intention(s) and become defensive or suspicious. For example, a new young mother may think, "Why is this nurse visiting me so close to my time in the hospital? Did I say something or do something wrong with my baby while I was in the hospital?" In this kind of situation, it is very important that the nurse explain that:

- The visit is a follow-up one to see if the move from the hospital to home is okay.
- The visit is an opportunity for her to ask questions because young mothers often have lots of questions about their new babies, especially outside the hospital. It is also a chance for the nurse to show the mother how to handle the baby in the home.
- The visit is a service provided by the agency to all mothers.
- The visit is paid for by taxes, donations, or by the client's health maintenance organization (if applicable). There is no direct cost to the family.

The nurse needs to extract as much as possible from the referral information, allowing him or her to be specific and exact in preparing for the health visit and contacting the family. This will set the stage for a detailed assessment, appropriate family diagnosing and family-oriented care planning. Following logical steps in the previsit preparation will also enhance the nurse's confidence in her or his ability to intuitively recognize patterns and/or trends from the referral information for preliminary diagnoses to guide preliminary care planning.

Making the Visit

Before the day of the scheduled visit, it is useful to call the family you plan to visit and remind them of the meeting and your arrival time. You will want to reiterate why you are visiting and the anticipated length of time needed for the visit. Once you locate the house and meet the family, the following guidelines for initial contact should be used (Aston et al., 2015; SmithBattle et al., 2013; Porr, 2015):

1. Engage the family in a manner to build a supportive and trusting relationship.
    a. Introduce yourself to the family.
    b. Explain the value of the nursing services provided by the agency.
    c. Spend the first few minutes of the visit establishing cordiality and getting

acquainted (a mutual discovery or "feeling out" time).
   d. Become acquainted with all family and household members if you are making a home visit.
   e. Encourage each person to speak for himself.
2. Use acute observational skills.
   a. Use your "sixth sense" or intuition as a guide regarding family responses, questions they ask, and your personal safety (trust your feelings).
   b. Be sensitive to verbal and nonverbal cues.
   c. Be accepting and listen carefully.
   d. Be cognizant of possible internal and external stressors and effect on mental status of family.
   e. Be aware of your own personality—balance talking and listening—and be aware of your nonverbal behaviors.
3. Help the family focus on issues and move toward the desired goals.
   a. Be adaptable and flexible (you may be planning a prenatal visit, but the woman delivered her baby the day after you made the appointment, and now there is a newborn).
   b. Be aware that most clients are not extremely ill and have higher levels of wellness than are generally seen in acute care settings.
   c. Be prepared to develop a sustained continuity of care by actively collaborating with the family in addressing their issues.
4. Near the end of the visit, review the important points and emphasize the family strengths.
5. Plan with the family for the next visit.

The length and primary focus of the visit will vary depending on its purpose. A visit shorter than 20 minutes is generally not enough time for a thorough assessment, unless you are dropping off supplies, relaying information about a referral, or stopping by at the family's request, for instance. On the other hand, a visit over 60 minutes should be avoided and, if lengthy assessments are needed, should be conducted over two visits. Families have routines that are important to them, and long visits can negatively impact future ones. Similarly, if the family feels that nothing of value occurred during a visit, they may not continue to make themselves available for future visits. This becomes a balancing act for the family and the nurse, and you may want to work at picking up on nonverbal cues (SmithBattle et al., 2013; Porr, 2015). Long home visits are not a productive way to provide nursing services. Taking up too much of the family time can reflect the nurse's hesitation in trusting the family to understand and/or follow the instructions and feedback. These visits also limit the family's ability to seek out community resources for community-based health care. Remember, the outcome of better health for family members must be demonstrated in order to support and validate the value, as well as justify the cost of public health nursing services (Monsen, et al. 2014) (see Evidence-Based Practice).

EVIDENCE-BASED PRACTICE

Home Visiting

The Nurse–Family Partnership (NFP) has a long history of providing prenatal and infancy home visits by nurses to first-time at-risk mothers (Eckenrode et al., 2010; U.S. Department of Health & Human Services [USDHHS], 2011). The overall goal of this program is to prevent child abuse and neglect, children's mental health problems, and infant mortality through home visiting during the first 2 years of the child's life. The program has demonstrated positive results in various ethnic and racial groups and in a variety of living contexts through randomized trials (Mejdoubi et al., 2015; USDHHS, 2011). In order to assess other long-term benefits of the program, 19-year-olds (n = 310) were recruited from among the 400 families enrolled in the NFP between 1978 and 1980 in a semirural area of New York (Eckenrode et al., 2010). Of the sample, 29% of the mothers had received public health nurse home visits during pregnancy and the child's first 2 years, 25% received home visits during pregnancy, and 45% did not receive either form of home visiting. These young adults completed a telephone interview that assessed high-school graduation, employment, sexual behavior, childbearing, substance use, and criminal behavior. The girls, whose mothers received both pregnancy and infancy visits by the nurse, were less likely to have been arrested or convicted, had fewer children, and had less Medicaid use. With respect to the factors assessed, there were few programmatic effects demonstrated for the boys. The researchers noted that adult patterns of criminal behavior and educational attainment cannot be effectively assessed for 19-year-olds and propose further study of these individuals at 27 years of age. They further suggest examination of the coherence of intervention effects between the mothers and daughters that was not demonstrated with the sons.

Nursing Implications: The NFP has demonstrated that comprehensive home visiting by nurses can have a positive impact on both the mothers and the children. The cost savings in terms of reduced use of public assistance programs, decreased criminal behavior, reduced pregnancy rates, and delayed pregnancy can offset the operating costs of the program. In addition, the academic achievement of these children may ultimately prove beneficial to the long-term economic prospects of these at-risk children and the communities in which they live. Communities considering reducing or eliminating home visiting programs may want to consider retaining them or possibly implementing the NFP program.

Research in other countries and with other populations has confirmed the

effectiveness of this PHN home visiting program.

Concluding and Documenting the Visit

After planning for the follow-up visit with the family, it is time to say goodbye and end the visit. This is a good time to pack up any paperwork, materials, and supplies used for this visit in your car and get ready for the next home visit on your schedule. By arriving at the next home visit in this manner, you demonstrate your respect for the family's time, ability to be efficient, and professionalism. You are also being "streetwise" when you use the end of the current visit to prepare for the next home visit. It is safer to expose the contents of your car at the end of your time in the current community because the car, with your equipment, is no longer unattended. Getting your supplies, materials, and paperwork together when you arrive at the next home visit gives clues about what is stored in your car's trunk while you are in the family's home and the car is unattended (Jones, 2015; McDonald, Frazer, & Cowley, 2013).

Documentation or charting of each home visit used to be typically completed as soon as the nurse returned to the agency. Today, charting is encouraged at the end of the visit before leaving for the next one on an agency-provided device (laptop, smartphone, or tablet) linked to electronic charting forms and records. You may be able to chart in your own home after the last visit of the day if time is allowed. For the most part, most agencies expect the charting to be completed as soon as practically possible during that workday.

Agencies use a variety of forms that assist the nurse to document fully and succinctly. Some forms use a checklist format that contains code numbers, letters, or checkmarks on developmental or disease-specific care plans. For example, four pages may be used to document a postpartum visit and newborn assessment: two narrative forms to chart the

expectations for the postpartum mother and baby and two forms to chart the head-to-toe assessment of the newborn. These forms contain a place to document parent teaching according to expected parameters and a place for listing other professionals' involvement with the family. The agency may also use similar developmentally focused checklist forms for high-risk infants, high-risk children, adolescents, and older adults. Other forms may focus on chronic illness (e.g., chronic obstructive pulmonary disease, hypertension, diabetes, alcoholism, HIV/AIDS, communicable diseases) that are common in the agency client base.

Focus of Family Health Visits

The focus of family health visits depends on the mission and resources of the agency providing the service and the needs of the families being served. Some agencies provide education, recreational activities such as summer camps, and support groups for families of people with specific health problems such as Alzheimer's disease, asthma, diabetes, or neurologic disorders. Other agencies provide services directed toward those with special social or economic needs, such as immigrant families, people living in poverty, or the homeless (Ballard, Mooney, & Dempsey, 2013; Dennis, 2014; Lynch et al., 2015; Martins et al., 2015; Salem & Ma-Pham, 2015). Home visits may be a part of the service being provided and are best conducted and received in the comfort and privacy of a family's home. In general, family health visits are designed to be educational, to provide anticipatory guidance, and to focus on health promotion or prevention.

Family Education and Anticipatory Guidance

Official agencies, such as county or city health departments, distribute their services based on the broader community's needs. For example, if there is a large population of teen pregnancies and high-risk infants, the health department may contract with hospitals and private health care providers' offices to provide home or clinic visits to all teens and women with high-risk pregnancies and their newborns after delivery (Schaffer, Goodhue, Stennes, & Lanigan, 2012). On these visits, the public health nurse teaches prenatal, postpartum, and newborn care and provides anticipatory guidance (information needed in the future regarding the child and the need for regular infant health care provider visits, immunizations, and safety awareness). Another community may have a significant number of older adults or migrant workers who need to learn how to manage a chronic illness, enhance their nutrition, and practice safety measures to prevent injuries and falls (Ballard et al., 2013; Ramal, Petersen, Ingram, & Champlin, 2012). For a large concentration of active military families at a nearby army base, the PHN needs to collaborate with military personnel in order to gain access to the base and coordinate services that may be requested.

Family Promotion and Illness Prevention

Teaching people how to prevent illness and how to remain healthy is basic to public health nursing (see Chapter 11). Even within the limitations of chronic illnesses, family members can be taught health promotion activities to live as healthfully as possible (Ha, Narendorf, Maria, & Bezette-Flores, 2015; Kulbok et al., 2012; Williford, Fite, Johnson-Motoyama, & Frazer, 2015). Health promotion activities may include screening for hypertension and elevated cholesterol, performing a physical assessment, and teaching about nutrition and safety. Immunizations are another health promotion activity that has been implemented in the United States for years.

Immunizations are *recommended* for all populations, regardless of age, income, culture,

or nation of origin. Immunizations are one major step in promoting the family health and preventing illnesses by protecting the health of the individual and the larger community. Although immunizations are a responsibility of all health departments, usually such services are not brought into the home. But, it is the responsibility of the public health nurse to promote family health and prevent illnesses. The public health nurse can provide information about immunizations, teach the importance of following an immunization schedule, and follow up with the family during home visits.

Public health nurses' role and commitment to health promotion are highlighted with the following statements: "The work of public health nurses with individuals and families is informed by the broader context of the community and/or the population. Improvement of population health is accomplished through individual health promotion strategies to increase knowledge; explore health attitudes, beliefs, and values; and facilitate behavior change to optimize personal health" (ANA, 2013, p. 4). This holistic emphasis can also be found in the Patient Protection and Affordable Care Act (ACA). In particular, social determinants of health have been added with the ultimate goal of creating "social and physical environments that promote good health for all" (USDHHS, 2016, para. 3; see Display 19–2). For more on social determinants of health, see Chapters 15 and 25.

DISPLAY 19–2 *HEALTHY PEOPLE 2020*—SELECT TOPICS AND OBJECTIVES

Topic: Health-Related Quality of Life and Well-Being

Health-related quality of life (HRQoL) is a multidimensional concept that includes domains related to physical, mental, emotional, and social functioning. It goes beyond direct measures of population health, life expectancy, and causes of death. It focuses on the impact health status has on quality of life. A related concept of HRQoL is well-being, which assesses the positive aspects of a person's life, such as positive emotions and life satisfaction.

Source: U.S. Department of Health and Human Services. (2016). Health-related quality of life & wellbeing. Retrieved from http://www.healthypeople.gov/2020/topics-objectives/topic/health-related-quality-of-life-well-being

Objective: Social Determinants of Health

Goal: Create social and physical environments that promote good health for all. Emerging Strategies to Address Social Determinants of Health.

Overview: Health starts in our homes, schools, workplaces, neighborhoods, and

communities. We know that taking care of ourselves by eating well and staying active, not smoking, getting the recommended immunizations and screening tests, and seeing a health care provider when we are sick all influence our health. Our health is also determined in part by (1) access to social and economic opportunities; (2) the resources and supports available in our homes, neighborhoods, and communities; (3) the quality of our schooling; (4) the safety of our workplaces; (5) the cleanliness of our water, food, and air; and (6) the nature of our social interactions and relationships. The conditions in which we live explain in part why some Americans are healthier than others and why Americans more generally are not as healthy as they could be.

Healthy People 2020, Objective: Lesbian, Gay, Bisexual, and Transgender Health

Goal: Improve the health, safety, and well-being of lesbian, gay, bisexual, and transgender (LGBT) individuals.

Overview: LGBT individuals encompass all races and ethnicities, religions, and social classes. Sexual orientation and gender identity questions are not asked on most national or state surveys, making it difficult to estimate the number of LGBT individuals and their health needs. Research suggests that LGBT individuals face health disparities linked to societal stigma, discrimination, and denial of their civil and human rights.

Healthy People 2020, Objective: Genomics

Goal: Improve health and prevent harm through valid and useful genomic tools in clinical and public health practices.

Overview: The new Genomics topic area and objectives for 2020 reflect the increasing scientific evidence supporting the health benefits of using genetic tests and family health history to guide clinical and public health interventions.

Source: U.S. Department of Health and Human Services. (2016). Healthy people 2020: Topics and objectives. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/default.aspx

Health promotion and/or illness prevention activities can occur during a family health visit, at a family member's home away from home (e.g., work, school, or recreational facility), or at self-help group meetings. Public health nurses provide health promotion services to couples during prenatal classes by teaching about the expected changes during pregnancy and providing anticipatory guidance for safe infant care and postpartum care (Chartier et al., 2015). They may screen older adults at senior centers for hypertension or elevated cholesterol, teach family members who attend support groups such as Alcoholics

Anonymous, or provide mental and health assessments for homeless persons.

FIGURE 19–2 The public health nurse utilizes appropriate safety measures when making home visits.

Personal Safety on the Home Visit

As mentioned earlier, being streetwise is essential when interacting and traveling throughout communities (Jones, 2015). Continuation of personal safety must be considered while maintaining respect for the families, a trusting relationship, and professionalism (Fig. 19–2).

Traveling to and in the Neighborhood

When leaving your "base of operation" (e.g., the health department office, neighborhood clinic, homeless shelter, or campus classroom), make sure you have all the necessary supplies, materials, and paperwork for the scheduled home visits. This effort will make your travel to the community and within the neighborhood safe because you know the contents of your car and how to quickly access them. Always keep your "base of operation" (or agency) aware of your plans and how to promptly reach you by leaving an itinerary of your planned travels, the telephone numbers of families you will attempt to visit, and your mobile phone number. Traveling in the community takes a variety of forms and means different things to different people.

If you are traveling in an agency or private car, you need:

- A full gas tank, addresses for families you are visiting, city/county map or GPS, and a mobile phone (helpful to use speed dialing for emergency numbers such as police, fire department, health department, towing and taxi services).

If you are using public transportation, you need:

- Change for each bus trip, a current bus schedule, knowledge of the exit at the bus stop closest to your family's home, knowledge of the bus stop for the return trip to agency or to the next home visit, and a mobile phone (as above).

You still need to travel safely if you are walking or riding a bicycle to a home visit. Like with all home visits, you will still call ahead to the family and give them an approximate time of your arrival. For some neighborhoods, it is best to ask them to watch out for your arrival. Remember, the families know their neighborhood and may see this as a step toward a trusting relationship. When walking in neighborhoods, be streetwise and walk with direction and purpose. Do not look lost; and if you are, be resourceful in getting help. Use neighborhood shopkeepers as resources for direction and information and as refuge if you feel uncomfortable or threatened. If you need to ask for directions, and you are not near any stores, look for another professional (e.g., a public service employee, police, postal, or utility worker; an apartment manager; or a social worker). If a group of people makes you feel uncomfortable, you want to stay calm. As soon as it is practically possible, cross the street while limiting eye contact with the group, and continue to the home you are intending to visit. Streetwise means to avoid showing fear and/or anxiety while confidently

taking measures to remain safe. Always avoid walking through alleys, dark areas, or along buildings that open onto alleys, and stay in the middle of the sidewalk or closer to the street. You may find it helpful to carry a whistle or pepper spray on your key ring.

It is always safest to avoid compromising situations by staying alert and using safe traveling methods whenever you are in public no matter how "safe" the area appears. However, if an individual or group accosts you, immediately try to break free and run to a public place while making loud and lots of noises. Yell "Fire!" This response gets more attention than "Help!" Do not argue or challenge a criminal or thief if he or she wants your nursing bag, purse, or wallet. Freely give them up because the contents are not worth your safety; they can always be replaced. Some nurses feel safer after they have attended self-defense classes, which are offered by police departments or through an employee in-service program in some agencies. Nevertheless, the goal in these situations is for you to safely get out of the compromising situation, "not to beat up a perp."

Before venturing into any community, know the neighborhood and what resources are available to you for a safe visit. In some rough inner-city neighborhoods, travel to home visits only in pairs or with a security guard or police escort. Experienced PHNs have found it wise to refuse to visit families living in an isolated area with only one apartment building or with only one block, regardless if it is an inner-city neighborhood or not. Similar issues are found in rural areas known for drug manufacturing and distribution. PHNs understand that it is important to know the safety measures that are used by expert nurses, follow these measures for personal safety, and do not challenge them (Dennis, 2014; Jones, 2015). Safety issues are unique to each community.

Another focus of concern is the perceived risk to self when making a home visit. Feeling and being safe, when traveling to a home visit, can relate to the nurse's perception of a situation, views on risk taking, the traveling conditions (e.g., the time and/or the setting), and coping process (Jones, 2015). What one person sees as a risk, another sees as a challenge or an opportunity. Yet another may see nothing. We each perceive risks differently based on knowledge, experience, and personality.

Arriving at the Home

Make sure you are at the right house. Do not go into the home until you are assured that the family you are intending to visit does live there and is home. For example, you may be planning to visit 16-year-old Jennifer and her 5-day-old infant, Marcus. A 50-year-old man answers the door when you knock. Give your name and ask if Jennifer can come to door because you are here to see her. Do not enter the house even if he invites you in to wait for Jennifer. Smile and let him know that you are comfortable waiting for Jennifer at the door. Remain outside the home and go inside only after you talk to Jennifer at the door. This precaution ensures that the family members you want to visit are really home and that this is the right address.

Friction Between Family Members

During a home visit, two or more family members may begin to argue or physically fight with one another. You want to immediately terminate the visit and inform the family what will take place regarding the home visit. It is highly recommended that you following these steps:

1. Inform the family that the visit is now terminated.
2. Calmly let the family know that such distraction takes away from the purpose of the visit.
3. Inform the family that you will return at another convenient time.
4. Remove yourself from the home.

When two or more family members are physically fighting, never intervene, try to stop the fight, serve as a referee, or assist an adult family member. You may be the next victim. If necessary, call 911 from your mobile phone once you are out of the house. Once you are safe, rely on your acute observation skills to recall the altercation. This data may provide significant information about the family's structure, process, and health. Depending on your assessment and processing of the information, it may be appropriate to discuss the altercation and the friction in the family at a later visit.

Family Members Under the Influence

If the focus of the visit is on two family members and a third member's behavior suggests or indicates drug or alcohol use, you must use your judgment as to the best action to take. Although the agency you work for or the school you attend has guidelines you should follow, it is important for you to assess the situation and proceed accordingly. If the intoxicated person goes to another room and remains quiet/calm, it might be appropriate to continue the visit. You might want to discuss your observations with the two family members. If the intoxicated person remains in the room and interrupts the visit by being abusive or distractive, it is best to terminate the visit. Let the two family members know that you want to reschedule when that family member is not under the influence or is not present. You do not want to put yourself in the middle of a situation that could deteriorate rapidly and compromise your safety.

The Presence of Strangers

In some families, it is common to have extended family members, neighbors, and friends present in the home. Although this is the norm and not distracting to the family, it may be to the nurse because it is a different setting from her or his experience. For example, what would you do if you arrived at a home and you had to weave your way past five teenage boys sitting on the front stoop or steps to the front door? What if you found three men sleeping on the living room floor in the small apartment of a teenage mother and her infant? How would you react to two neighbor children riding their tricycles inside the

house during a teaching visit to two young parents who do not seem fazed by the commotion? These situations may not be indicative of danger, but they can make you feel vulnerable and uncomfortable and distract you from the purpose of the visit. Relying on your observation skills, inquire about the people you observe in the periphery of the home visit; ask about their relationship to the family and if they should be included in the visit. The family may suggest that you ignore the other people or say they are transient family members. It may be important to learn who they are, if they have unmet health care needs, or if their presence influences the health of the family you are visiting.

USING THE NURSING PROCESS

The focus of each family visit is different. On the first visit, the public health nurse initiates the nursing process by performing an initial assessment for data that will be later processed for family diagnoses to help the family set their desired goals (see Table 19–1). On subsequent visits, the nurse and the family work collectively on actions and activities to reach the goals. To determine the family's health by using the nursing process in a systematic way, three tools are needed: (1) a conceptual framework on which to base the process, (2) a clearly defined set of data collection categories, and (3) a method of measuring a family's functional level.

Conceptual Frameworks

A conceptual framework is a set of concepts integrated into a meaningful explanation that helps the nurse interpret human behavior or situations (Shi & Singh, 2011). Several conceptual frameworks have been used historically to study families (Hill & Hansen, 1960; Reiss, 1981). Three frameworks that are particularly useful in public health nursing are presented here: the interactional, structural–functional, and developmental frameworks (Raingruber, 2014; Shi & Singh, 2011). Although the family remains the core unit of service, steps of the nursing process are centered on the internal interactions, external influences, or a combination of the two.

The interactional framework focuses on internal relationships of the family. With this framework, the family is described as a unit of interacting personalities with emphasis on communication, roles, conflict, coping patterns, and decision-making processes (Marlowe, Hodgson, Lamson, White, & Irons, 2014). The family's interactions with the external environment are not emphasized.

The structural–functional framework focuses on the family's interaction with the external environment. The family is referred to as a social system in an external environment that results in relationships or interactions with other social systems (e.g., church, school, work, and the health care system). This framework examines the interacting functions between the society and the family. The family social system is built around the family structure, which is used in processing, analyzing, and understanding the function of the family social system in the external environment (Peterson & Bush, 2013).

The developmental framework incorporates elements from both interactional and structural–functional frameworks. The family is studied from a life-cycle perspective by examining family members' changing roles and tasks in the members' progression of life-cycle stage within the environment. Internal relationships are studied to understand the development of the family. External environmental influences are examined to recognize how the family structure is created, functions as a social system, and interacts with other social systems. With this framework, the family structure, function, and interaction are viewed in the context of the environment at each stage of family development (Kaakinen et al., 2015).

The concepts of these 3 core frameworks have been combined in various ways to design family assessment, diagnosing process, and intervention models that focus on human–environmental interactions, interactional and structural–functional frameworks, self-care, responses to stressors, and a developmental framework. A combination of the 3 core frameworks is discussed in the Characteristics of Healthy Families section as an initial framework in assessing and diagnosing the family's health by identifying six characteristics. These 3 core frameworks are the basis for various methods of family assessment.

Data Collection Categories

When using a conceptual framework, the public health nurse identifies one or two priority concerns of the family from the previsit preparation for data collection. The conceptual framework gives the nurse a format by which to collect data for specific categories. The amount of data that may be collected about any given family can be voluminous. Considering the nursing process, both the assessment and diagnosing process can be lengthy, time consuming, and ongoing. Often, the most essential data are collected on the first visit. This data may be useful for assessing, diagnosing, care planning, and serving as a guide for subsequent visits in which to obtain additional information.

Certain basic information is needed to determine a family's health status, identify the diagnosis, and design appropriate nursing interventions. Table 19–2 lists the 12 categories, each grouped into one of three data sets: family strengths and self-care capabilities, family stresses and problems, and family resources (Edelman, Kudzma, & Mandle, 2013).

Table 19–2 Categories of Data Collection for Family Health Assessment

Assessment Categories	Family Strengths and Self-Care Abilities	Family Stresses and Problems	Family Resources
1. Family demographics			
2. Physical environment			
3. Psychological and spiritual environment			
4. Family structure/roles			
5. Family functions			
6. Family values and beliefs			
7. Family communication patterns			
8. Family decision-making patterns			
9. Family problem-solving patterns			
10. Family coping patterns			
11. Family health behavior			
12. Family social and cultural patterns			

1. *Family demographics* refer to such descriptive variables as a family's composition, socioeconomic status, and members' ages, education, occupation, ethnicity, and religious affiliations.
2. *Physical environment data* describe the internal and external physical environment that consists of the geography, climate, housing, space, social and political structures, food availability and dietary patterns, and any other elements that influence a family's health status.
3. *Psychological and spiritual environment* refers to affective relationships, mutual respect, support, promotion of members' self-esteem and spiritual development, and life satisfaction and goals.
4. *Family structure and roles* include family organization, socialization processes, division of labor, and allocation and use of authority and power.
5. *Family function* refers to a family's ability to carry out appropriate developmental tasks and provide for members' needs.
6. *Family values and beliefs* deal with raising children, making and spending money, education, religion, work, health, and community involvement. Values and beliefs influence all aspects of family life.
7. *Family communication patterns* include the frequency and quality of communication within a family and between the family and its environment.
8. *Family decision-making patterns* refer to how decisions are made in a family, which includes who makes the decisions and how they are implemented.
9. *Family problem-solving patterns* describe how a family handles problems and involve who deals with the problems, the family's flexible approach to problem solving, and the nature of solutions.
10. *Family coping patterns* encompass how a family handles conflict and life changes; this consists of the nature and quality of family support systems and family perceptions and responses to stressors.

11. *Family health behavior* refers to familial health history, current physical health status of family members, family use of health resources, and family health beliefs.
12. *Family social and cultural patterns* comprise family discipline and limit-setting practices, family initiative/creativity/leadership, family goal setting, family culture, cultural adaptations to present circumstances, and development of meaningful relationships within and outside the family.

FAMILY HEALTH ASSESSMENT

A thorough family health assessment relies on the public health nurse's commitment and determination to learn and understand as possible about the family in order to promote family health. A limited amount of information is given with the referral; however, the assessment allows the nurse to determine the value of that information and any prior opinions and/or information about the family. Certain assessment tools or guidelines can help the PHN conduct a detailed family assessment and organize data (Fig. 19–3).

FIGURE 19–3 Family health assessments are foundational to the PHN's work with families.

Assessment Methods

Assessment methods are used to generate information about selected aspects of family structure and function, and the methods must match the purpose for assessment. The methods may have an informal approach where the nurse relies on her or his acute observational skills for the assessment. In addition, the nurse uses occasional questioning to confirm the observations and determine the next direction to take. A formal approach may include specific questions and assessment tools such as questionnaires, tests, and/or charts/diagrams. The nurse may ask specific questions about each family member, which may include the health data and history of the family. An assessment tool may contain physical data (e.g., height, weight, pulse, temperature, blood pressure) or items related to the family's development. The public health nurse can work with the family in completing tools to gather information on potential health problems that may not be detected by family members. For example, the use of developmental screening tests for young children can assist in determining if the children were high-risk newborns and the degree to which they have overcome any potential issues. A high-risk infant flow sheet (see Fig. 19–4) is useful in connecting the specific problems with the type of high-risk newborn (e.g., fetal alcohol syndrome newborn, drug-exposed newborn, failure to thrive, birth defect) so that appropriate treatment can be implemented.

FIGURE 19–4 High-risk infant flow sheet.

The eco-map and the genogram are two assessment tools that are developed and completed by both the family and the nurse. The eco-map shows the connections between a family and the other systems in the ecologic environment. Originally designed to help child welfare workers study family needs, the eco-map visually depicts dynamic family–environment interactions (de Cássia Tszesnioski, da Nóbrega, de Lima, & Facundes, 2015). The family or family member is represented by a central circle with smaller satellite circles on the periphery representing people and systems (e.g., school or work) that have significant relationships with the family. Strength of relationships is depicted by the lines to and from the central circle to the satellite circle (see Fig. 19–5). The map is used to discuss and analyze these relationships.

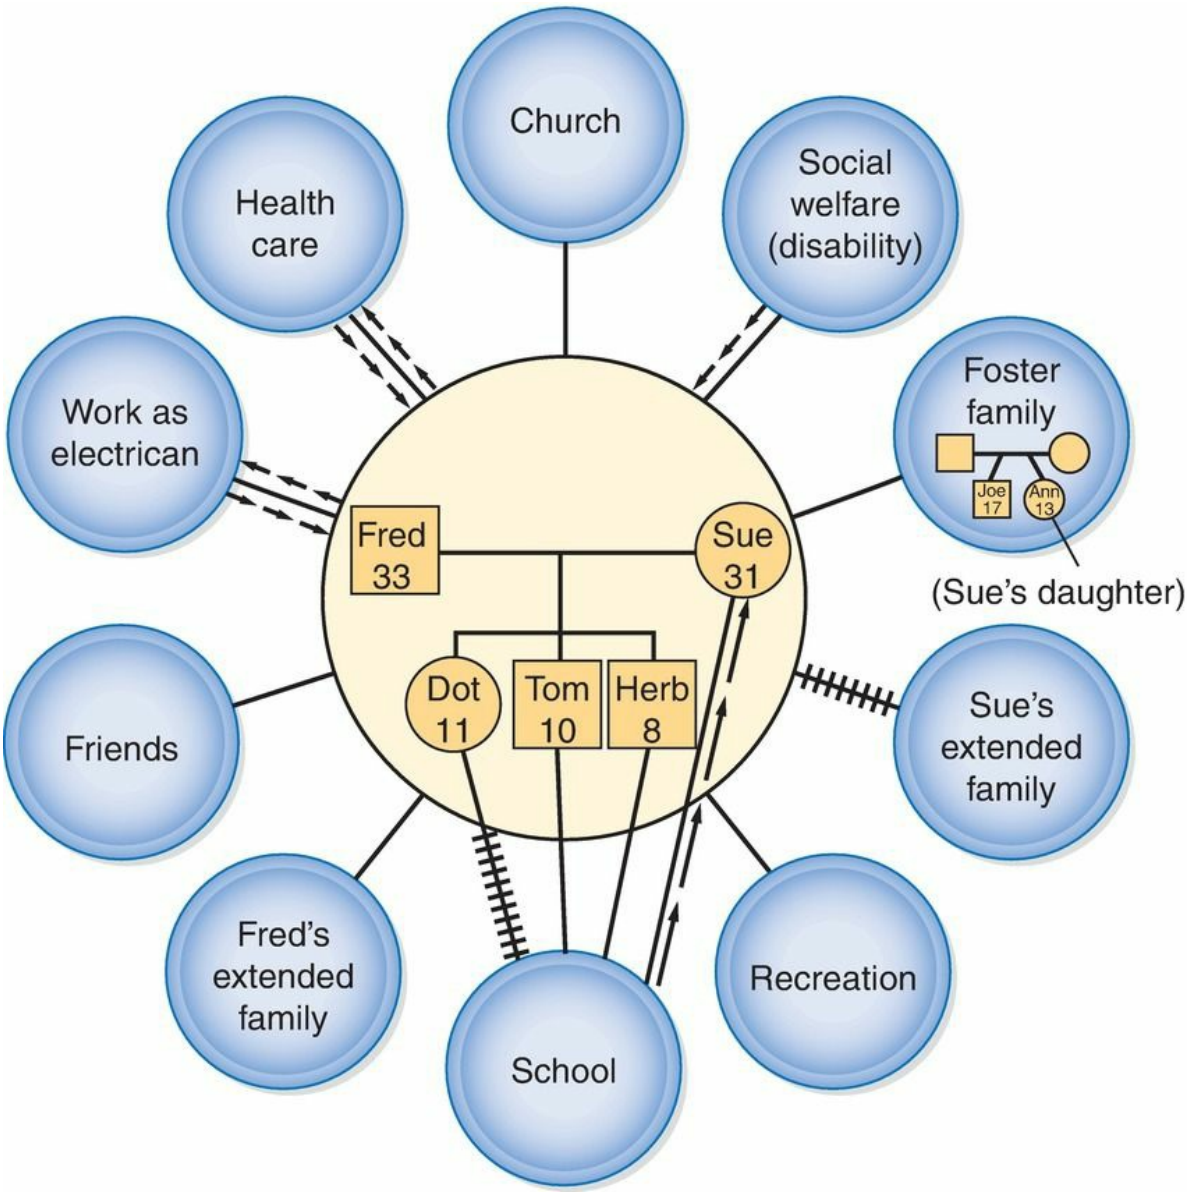

FIGURE 19–5 Eco-map of family's relationship to its environment. Lines indicate types of connections: *solid lines*, strong; *dotted lines*, tenuous; *lines with crossbars*, stressful. *Arrows* signify energy or resource flow, and absence of lines indicates no connection.

The genogram graphically displays family information in a way that provides a quick view of complex family patterns. It is a rich source of hypotheses about a family over a significant period of time, usually three or more generations (Leonidas & Santos, 2015), and is a diagram of the family's genealogy or family relationships. The diagram can visually depict significant life events (e.g., birth, death, marriage, divorce, illness), demographic characteristics (e.g., race, religion, social class), occupations, and places of family residence. Again, this tool is completed with the family. It encourages family expression and sheds light on family behavior and problems (see Fig. 19–6). Recognizing the value of this type of assessment, an initiative was launched in 2005 to bring awareness of the familial links between health outcomes and the need to develop prevention strategies based on potential

health risks (USDHHS, 2012). Using the downloadable materials provided on the Web site www.hhs.gov/familyhistory/, public health nurses can work with families to create their own family health portrait. The genogram has also been stressed as a useful way to guide clinical and public health interventions (Smith, 2013b).

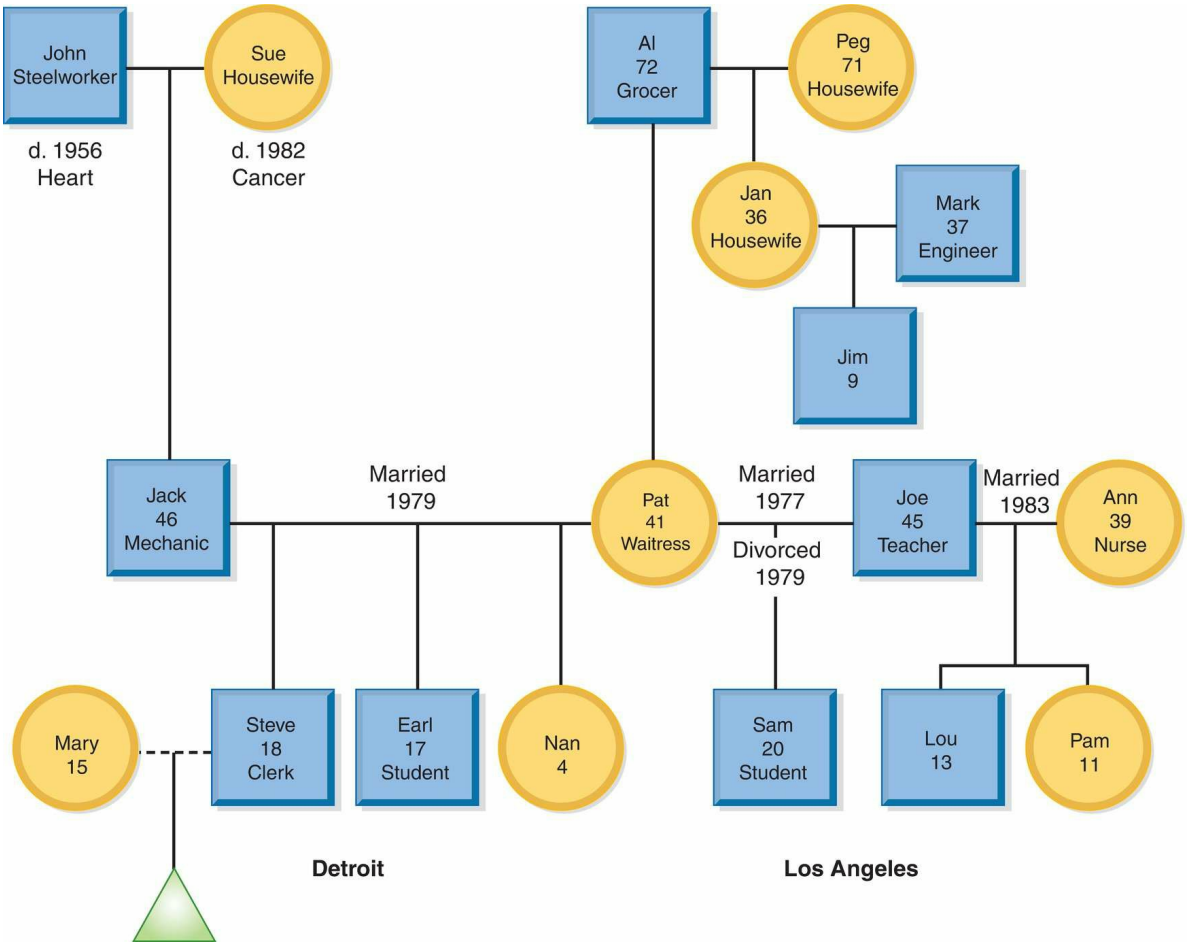

FIGURE 19–6 A genogram depicting three generations of family history. *Square*, male; *circle*, female; *triangle*, infant; *solid line*, married; *broken line*, not married.

A detailed family assessment may involve several different instruments to gather data on family structure, function, and development. For consistency and ease of documentation, public health nursing agencies usually develop their own tools, often in the form of questionnaires, checklists, flow sheets, or interview guides (Monsen et al., 2014). The format varies to fit organizational needs. For example, most agencies have changed to computerized information management systems and have adjusted data collection to be technologically compatible. See Chapter 10 for more on electronic health records. Three sample assessment tools are shown in Figures 19–7 to 19–9. Figure 19–7 shows a checklist format with scores and dates of assessment gathering. It is useful over a span of time for observing family growth or decline, especially for the novice public health nurse, who can document assessment data as rapport with the family is established or as the comfort level with home visits increases.

Family Assessment

Family Name _____

Family Constellation

Member	Birth Date	Sex	Marital Status	Education	Occupation	Community Involvement

Financial Status _____

Using the following scale, score the family based on your professional observations and judgement:

0 = Never 3 = Frequently

FIGURE 19–9 Self-care assessment guide. (Adapted from Cleveland, L., & Allender, J. A. (1999). Environment: Self-care issues. In L. Cleveland, D. S. Aschenbrenner, S. J. Veneable, & J. A. P. Yensen (Eds), Nursing management in drug therapy. Philadelphia, PA: Lippincott Williams & Wilkins, with permission.)

Figure 19–8 offers an open-ended assessment tool. The open-ended format is brief and lends itself to subjectivity. The goal is to create a document that is informative for all who use it while limiting subjective observations—a difficult task with open-ended tools. Such a tool may be useful in a teen perinatal program or a senior support program, in which a primary nurse makes the home visits and an additional nurse visits occasionally.

Figure 19–9, the self-care assessment guide measures a family member's ability to provide self-care. This assessment tool provides a way to compile the data after gathering the family assessment information. With this method, useful information can be gathered about stressors and self-care practices (e.g., prescription medicines, over-the-counter [OTC] medicines, herbal remedies, nutritional supplements, other complementary therapies). Such assessment tools are useful adjuncts, especially for families coming from various cultural groups. Another assessment method is the use of technology such as videotaping family interactions to provide structured observation and analysis of life-changing events. They are often used in combination with other tools to enhance the breadth of data collection and understanding of the family.

Guidelines for Family Health Assessment

A family health assessment can easily result in a lot of data even if the nurse only selects one or two problems to investigate during the home visit. This huge amount of information can challenge even the most experienced of public health nurses. Therefore, here are five guidelines to use when collecting and processing the data for a detailed family health assessment:

1. Focus on the family as a total unit.
2. Ask goal-directed questions.
3. Collect data over time.
4. Combine quantitative and qualitative data.
5. Exercise professional judgment.

You should notice that these guidelines emphasize the family as the core service unit and will strengthen your ability to work collaboratively with the family—promoting a trusting relationship.

Focus on the Family as a Total Unit

Family health is more than the sum of its individual members' health. If you gave a numeric value to the health of each family member and added them up for a total score, the total would not show how healthy that family is. The family is a single entity (a single core unit of service), and it is the family's aggregated behavior that is being assessed (Centers for Disease Control and Prevention, 2012; Rogers, 2012; Wright & Leahey, 2012). Throughout the assessment process, the public health nurse asks, "Is this typical of the family as a whole?" For example, when the nurse is assessing the communication patterns of family members "A" and "B," the nurse is also thinking about the other family members. How do these family members communicate? How do they communicate with "A" and "B"? Further observations show good communication among all but one member. After processing the information, the nurse may decide that the family, as a whole, communicates well and supportively even if one family member does not. The nurse will document that one family member's communication behaviors deviated from the family norm, and this difference needs to be considered in the care planning. Remember, one family member can influence the internal functioning of the entire family.

Ask Goal-Directed Questions

Goal-directed questions are the cornerstone of a detailed assessment (Dennis, 2014; Rodriguez & Margolin, 2015). These types of questions significantly contribute to a detective solving a crime, a teacher discerning a student's learning capabilities, or a mechanic repairing that knocking sound in a car engine. Similarly, the nurse asks goal-directed questions when determining a family's level of health, making family diagnoses,

and crafting a care plan. As a public health nurse, you must ask questions beyond "How is the family today?" Relevant or goal-directed questions yield relevant data (Rodriguez & Margolin, 2015). The family assessment tool shown in Figure 19–7 provides a sample set of questions to use for a family health assessment. Even if you are hesitant about the wording, these questions can guide your thinking and observations because they are built on the characteristics of a healthy family. They direct attention to specific aspects of family behavior to facilitate the goal of discovering a family's level of health.

For example, one of your goals is to determine the steps or behaviors a family uses to cope with change—active coping effort. While visiting this family, you watch everyone closely for signs of the family's response(s) to change and the ability to problem-solve any problems resulting from the change. You, the public health nurse, can ask several goal-directed questions. Does this family recognize when a change needs to be made? How does the family react when a change is forced on the family? If a problem arises from the change, such as the baby having diarrhea or constantly crying, will the family be responsible for dealing with the problem? Is there a family member who knows how to solve the problem, and will this person be willing to accept outside assistance? With these questions, the nurse can determine how the family will respond to the problem. The nurse can continue to see how the family will cope with the problem by asking additional questions. Will someone in the family be responsible to seek out resources, such as reading about causes of infant diarrhea or constant crying, using home remedies, or seeking assistance from a public health nurse, a nurse practitioner, or a doctor? Will this person or another family member be comfortable using the identified resources, or will this person try something new to resolve the problem? As the nurse focuses on these behaviors, she or he is asking goal-directed questions aimed at finding out the family's coping skills—one part of assessing the family's total health picture.

Another more open-ended format or approach is to use the assessment categories listed in Figure 19–8. These categories can be instrumental in stimulating nursing questions such as those exploring family support systems. What internal resources or strengths do this family have? What outside person does the family turn to for help and support? How does the family seek out help from the church, the local community center, or any social organization in the community? The open-ended style of this assessment tool allows questions aimed at determining family health within a specific category.

Collect Data Over Time

Assessing the family's health is a timely process, and most likely, information from the first and/or second visits will provide only a partial picture of the family functioning. You want to take your time to accumulate observations, make notes, identify both major and minor issues, and observe the interactions of all family members (Aston et al., 2015; Parthasarathy et al., 2014; Shepherd, 2011). You also want to take your time so that you can develop a trusting and supportive relationship with the family. To assess the family's communication patterns, for instance, the nurse needs to observe the family as a group at mealtime or

during some family activity. The family needs to feel comfortable with you, the observing nurse, in the room so that they will respond freely and naturally. Time and patience are needed for such rapport to develop.

We can see the importance of a timely assessment in one nurse's experience. Nurse Jolene Burns was working with the Olson family. They were receiving nursing services for health promotion and discussing ways to discipline their young children. Although Jolene had met with the Olson family twice (first in the clinic and then at home), Mr. Olson had not been present at either visit. A third visit was arranged in the early evening so that Mr. Olson could be present and Jolene could observe the family together. The third visit ended with the Olson family contracting with Jolene for six weekly visits to be held in the late afternoon, when Mr. Olson came home from work. After the fourth visit, she filled out an assessment form to keep as a part of the family record. Jolene's assessment of the Olson family began with the first visit where she made notes on their chart and, guided by questions similar to those in Figure 19–8, kept a brief log. However, it was not until the fourth visit that Jolene felt she had collected enough data to make valid judgments about this family's level of health.

Combine Quantitative With Qualitative Data

Any appraisal of family health relies on both qualitative and quantitative information that is used to create a database for planning care. Qualitative data occurs when the nurse is determining the presence or absence of essential family characteristics. Determining the degree or quantifying if the various signs of health are present or not reflects a quantitative measure. Asking if family members engage in some type of behaviors is qualitative; and, asking how often the family engages in the behaviors is quantitative. What about questions like, "Is this behavior fairly typical of the family" or "Does this behavior occur infrequently?" The first one is qualitative and the second is quantitative.

Figures 19–7 and 19–8 demonstrate ways to measure family health quantitatively. When using the tool in Figure 19–7, the nurse can assess the Beck family's ability to enhance individuality by rating the family's behavior on a scale of 0 (never) to 4 (most of the time). After several observations, the nurse concludes that the family responds appropriately to the members' developmental needs most of the time. So, under the section Enhancement of Individual Development (Fig. 19-7), the nurse scores "a" as 4 and notes the date of the assessment.

A quantitative measure provides a way for the nurse to compare the family's development over several home visits. The nurse can determine if the family's health is progressing or regressing by comparing the present score with previous ones. For instance, you have been working with the Kovacs for 6 months, a total of 12 home visits. After comparing the Kovacs' scores for all assessed areas, you discover a drop in their scores in several areas, suggesting a possible regression in their overall health. Many of their communication patterns, role relationships, and coping skills, in particular, show signs of

deterioration. The scored assessment gave a vivid picture of exactly where to target your intervention(s). For this reason, it is useful to conduct periodic assessments when a case is reopened, or every 3 to 6 months if it is kept open for an extended period. The nurse can monitor the progress of high-risk families through early introduction of preventive measures when a trend or regressive behavior is observed. Periodic quantitative assessments also provide a means of evaluating the effectiveness of the planned care and can point to documented signs of growth.

Quantitative data serve another useful purpose. The nurse can compare one family's health status with that of another family as a basis for priority setting and nursing care planning. The difference in the level of health between the Becks and the Kovacs, for example, shows that the Kovacs need considerably more attention right now.

Exercise Professional Judgment

Although nurses seek to validate all their collected data with the use of quantitative measures, a family assessment is still subjective and relies on the nurse's professional judgment or decisions. Assessment tools can guide observations and even quantify the nurse's decisions; but, ultimately, the content of the assessment is driven by the nurse's experiences and intuition (Shepherd, 2011). The nurse may observe that a family makes good use of a community agency, but the decision that using this external resource contributes to the family's health is a subjective one. This determination indicates that effective health care practices depend on sound professional judgment. An assessment tool is only a tool and should be used to guide the care planning. Its value or infallibility should never be overemphasized or interpreted as an absolute and irrevocable statement about a family's health status. These are assessment tools to assist in collecting and organizing the nurse's observations and decisions.

A family health assessment occurs unobtrusively, and any assessment tool is ordinarily not filled out in the family's presence. This documentation occurs at the end of the home visit(s) and is a way to guide the nurse's observations and judgments. Before going into a family's home, the public health nurse may review the questions. She or he may find it helpful to keep the assessment tool in a folder for easy reference during the visit. Depending on the nurse's relationship with the family, notes may be made during or immediately after the encounter. However, the assessment tool is not completed in the presence of the family. Like Jolene, the nurse may choose to keep a short log—an accumulation of notes—until enough data have been collected to complete the assessment form. Occasionally, a family with high self-care capability may be involved in the assessment, such as assisting in developing an eco-map or genogram. This idea should be introduced carefully with the nurse using professional judgment to determine when the family is ready to engage in this kind of self-examination.

THE FAMILY DIAGNOSIS PROCESS

Although the family diagnosing process is critical in moving the data from the family health assessment into care planning, the process is often understated or even omitted when talking about public health nursing. However, it is important to understand how a large amount of information is processed so that the nurse can have objective and realistic family diagnoses. And, this process is an expected standard of practice for public health nurses (ANA, 2013). The family diagnosing process involves the public health nurse using observational skills and clinical reasoning to recognize and understand the patterns in the data from the assessment. This process is key because family diagnosis is the basis for goal setting to reduce family health risks and identify factors that may lead to ongoing risks. In other words, this process is indispensable in planning, implementing, and evaluating the treatment(s) used to address the concerns of the family health.

The diagnosing process involves determining the family's health status based on identified patterns of behavior, barriers preventing the family from being healthy (e.g., potential risks, actual risks, attitudes, beliefs/values, unhealthy routines), and internal and relationships with the external environment (ANA, 2013; Thompson & Adderley, 2015). This process allows the nurse to see what problems take precedence over others and the best action(s) to consider for the desired outcome or goal (McDonald et al., 2013). As indicated earlier, the diagnosing process is lengthy, time consuming, and ongoing. Every interaction with the family provides the nurse with more information that has to be processed and weighed against the known family diagnoses. Using the data from the assessment, the diagnosing process occurs as follows (Odell, 2015; Thompson & Adderley, 2015):

1. Identify the family health problems
    a. Determine what family members are directly and indirectly related to the problem.
    b. Determine what factors from the external environment are related to the problem.
    c. Describe the problem as it impacts the identified family members and external environment.
    d. Indicate the risks that are associated with the description of the problem(s) given in "c."
    e. Prioritize the problems along with their risks with an emphasis on the problems that are overlapping and/or have overlapping risks.
2. Indicate the factors from the family (family unit and family members) and the external environment that are associated with the health problems.
3. Determine the measurements (quantitative and qualitative data) that confirm or verify the health problems.

Sometimes, you, the nurse, will complete this process more than once, especially when there is a lot of data from the assessment, and there may be new information and/or a new understanding of the data. Each review of the data will give a deeper understanding of the

problems, their risks, and how to approach them for treatment, as this is an ongoing process with two major goals—improving the health of the family and giving them the tools for health promotion. After prioritizing the problems and measurements, the nurse can begin to craft a plan of care or intervention to move the family toward a state of health. At this point, you have a more detailed understanding of the family, their relationships (internal and external), and a succinct and logical way to promote family health and prevent future illnesses.

PLANNING AND IMPLEMENTING EDUCATION AND HEALTH PROMOTION

Once the public health nurse has recognized the family's patterns of behavior from the assessment, the nurse has also probably identified and/or confirmed the main concerns, problems, and risks (actual and potential). With that information, the PHN is ready to create the care plan with family input and collaboration. At a certain level, care planning has been informally occurring during the assessment and family diagnosing; but at this stage, it becomes formal. The nurse works with the family to determine if the family agrees with the identified problems and the suggested interventions, and each family member is open to discussing the plan of action (de Cássia Tszesnioski et al., 2015; Porr, 2015; SmithBattle et al., 2013). If the family does not agree with the nurse's family assessment and family diagnosing, it is difficult to move forward with a plan of care. The nurse wants to work *with* the family, so the data should be reviewed and family members should be engaged in dialog in order to further understand their concerns and come to an agreement. The goal is to ensure that both the family and the nurse reach a mutual understanding with the best interventions for the family's health being identified and ready to be put into action. This level of communication is important in contributing to a trusting and collaborative relationship, and the family needs to believe in the plan of action or the nurse will be limited in her or his efforts to prevent identified problems and/or risks while promoting the family's health (Aston et al., 2015; Deutsch, Frese, & Sandholzer, 2014).

If the family is not at a level of functioning that enables members to use anticipatory guidance and teaching, the nurse can provide more basic services such as gathering resources and acting as a counselor. Remember, devising a plan of care with certain treatments/interventions and teaching health promotion activities should begin only after family members express an interest and recognize a need. If family members are ready to learn ways to improve their health status, then the nurse determines the best teaching approach to use and tailors interventions to the specific family needs and functional capability (Pereira et al., 2015; Salem & Ma-Pham, 2015; Schaffer et al., 2012). The family's language barriers, previous knowledge and experience, internal and external resources, and availability are important considerations (see Chapter 11).

EVALUATING IMPLEMENTED FAMILY HEALTH PLANS

The final step in the nursing process is evaluation. The evaluation process relates to the appraisal of your work with the family and a determination of what is needed in preparation for the next visit. The evaluation helps you to further individualize services to the family. It is helpful to use a reflective manner in order to informally evaluate the structure–process of the visit. The self-evaluation is often done while completing the other steps of the nursing process, and it becomes a formal evaluation once the outcomes are documented in the client record. A thorough evaluation also assists you in making the most appropriate referrals and contacting key resources to meet family needs.

Types of Evaluation

The evaluation of the family home visit deals with three components—the structure–process, the outcome, and your self-evaluation. Each one provides a different piece of information that can be helpful in determining what made the visit a success and what made it less than successful. Importantly, each can indicate if the outcomes were achieved and how to advance the outcomes to the next level of family health. A question a public health nurse always asks, "Is there something about the structure– process, my level of preparedness, or my behavior that needs to be changed?" Why? The answer to this question, and those like it, can determine the nurse's ability to promote health in the family, the community, and eventually the population.

Structure–Process

Structure–process refers to the organization of the visit and how it proceeded (see Chapter 12, Fig. 12–1). The structure–process of a visit should be analyzed first. Were there aspects of the organization (resources, number of persons present, timing, environment, or presented materials) or the flow of the assessment (use of observational skills, people's attitudes, reliance on standards) that needed to be changed or modified? How could you have arranged these factors differently? Were you organized and prepared for the visit? Were there distractions in the home that influenced the organization of the visit? Ask yourself these questions so that you can plan to adjust your structure–process for the next visit and reduce or avoid disorganizing distractions. For example, if the first visit was made based on limited information from a referral, you now have additional family data and can be better prepared for the next visit. Perhaps other transportation can be arranged if transportation caused the family to be late for the visit. A visit earlier in the day can prevent the distraction of children returning home from school. If the television was playing loudly during the next visit, you know now to ask the family if they would not mind turning down the volume in the next visit, or turning off the television. You may also ask about choosing a time to visit when they are not watching television. The point is to use the evaluation to modify subsequent visits.

Outcome Evaluation

Evaluating the outcomes of the visit is the second and most important evaluation component because the nurse will want to know if the anticipated outcomes were achieved and what made them possible. This outcome evaluation is a formal process that happens with documentation of the home visits. If the outcome is a change in the family's health status based on mutually agreed activities, the agency may determine the effectiveness of this outcome with the Nursing Outcomes Classification (NOC) System and the Nursing Intervention Classification (NIC) System, as well as the Omaha System (see Chapters 12 and 14). Alternatively, there may be agency-driven criteria to rate success and indicate expectations for each client category or visit type. Progression toward an expected outcome

may be demonstrated by small changes over time in the family dynamics, which are noted on a visit-by-visit basis. These small changes are viewed cumulatively to determine the success or failure of the family to achieve certain outcomes at the conclusion of agency services. Depending on the conclusions, the decision to terminate services may need to be reevaluated. Possibly, the continuance of service is required, and the terms must be renegotiated. Whatever the decision, the family must be included in the decision-making process.

Self-Evaluation

The third component of evaluation is self-evaluation. What aspect of your performance as a public health nurse facilitated the desired outcome during the home visit? Were you prepared? Did you gather enough data so that you can be prepared to assist the family on the next visit? What would you do differently if you could do the visit over? What went right? What went wrong? What are you going to do on the next visit to make it better? This self-evaluation or reflection can be a useful tool for the public health nurse to recognize her or his strengths and failings with internal measures to improve practice (Edelman et al., 2013).

In some agencies, routine peer evaluations are conducted because sometimes we cannot see our own strengths or weaknesses. An agency staff nurse makes a family visit with the public health nurse and provides feedback based on her or his observations. This is a useful technique to employ outside of planned evaluations of all staff members in the agency. Another perspective might be helpful when working with a family that has not made progress toward the desired outcomes or to a family you have not been able to reach (Porr, 2015). Consultation with peers can assist you in becoming better prepared or more focused, and it can also improve your interaction with families from different cultures or in difficult situations (Spector, 2013).

FIGURE 19–10 Referrals are often made to health department clinics or physicians.

Planning for the Next Visit

Planning for the next visit is part of evaluating the family visit. The data collected from the previous visit will guide you to the activities for subsequent visits. You may need to modify goals if the family's situations have changed, making specific outcomes irrelevant. For example, you plan to visit a prenatal family one last time before the second baby is born. Given the information from the last visit, you intend to assess the pregnant mom's rising blood pressure and complaints of backache, as well as go over the babysitting arrangements for the 2-year-old child. You arrive for the visit only to discover that the husband and the 2-year-old child are home alone and the husband is about to leave to bring the mother and new baby home from the hospital. The husband asks you about a diaper rash that just appeared on the 2-year-old and how to secure the new car seat into the car. Outcomes for a problem-free pregnancy and healthy birth are no longer relevant; the situation has changed, and now, there are new outcomes to be formulated and addressed with this family.

More frequently, planning for subsequent visits is relatively predictable and is done to ensure that steps toward outcome accomplishment are achieved on the visit. Being totally prepared each time helps assure a successful family visit. Once you have met and gotten to know a family during a visit, the planning can be individualized and tailored to meet the family's needs. This information is not available from a paper referral, which makes planning for that first home visit important. The tone set during the first visit can affect your continued success with the family (see From the Case Files).

Referrals

A written or verbal referral (by agency-created form, telephone call, fax, or e-mail) initiates contact with a family. The nurse makes referrals on behalf of the family in addition to responding to a referral to begin the relationship with a family (Fig. 19–10). Families often need access to services beyond the agency's scope, and the nurse's knowledge of other resources can mean the difference between the family having and not having access to additional services. Therefore, nurses must have information available to them about the eligibility requirements and availability of services provided by a multitude of official, voluntary, religious, and neighborhood organizations (Allen, Feinberg, & Mitchell, 2014). Public health nurses need to know how to readily access this information to avoid any delay of the services to the family. This is challenging because there are many organizations that frequently change staff, telephone numbers, Web sites, services, and the populations served. Networking with colleagues on a regular basis helps keep nurses up to date with community services for family referrals (Parthasarathy et al., 2014).

Contacting Resources

At times, public health nurses implement their roles as advocates for families by facilitating easier access to services for the family. Public health nurses know how to access key personnel in agencies and can eliminate some of the red tape involved in obtaining services, as well as provide pointers that may help a family procure needed services. For example, a family may receive faster services by going to an agency early in the morning or in the middle of the week. An agency may process a family faster if all forms are completely filled out and the family member has receipts for the last 3 months' rent and utilities. Also, the nurse can suggest that the family member ask to speak with a certain worker—an informal referral.

When nurses seek informal services for families, a relationship with the director of the agency can help nurses gain services for the family. For example, a family with a personal crisis needs a donation of food and a volunteer to stay with a handicapped child for 3 days while the spouse undergoes surgery. The nurse telephones the religious leader of a neighborhood church, shares the family's requests, clarifies the situation, and gets a donation of food from the church's food pantry. The religious leader also offers the name of a church member who can stay with the child. The family may not have been aware of these services, so the connections provided by the nurse are as important as other public health nursing functions.

From the Case Files I

A Family Assessment: Meeting Hector's Needs

You are a public health nurse working in Smithville. You have been given a referral for a new client, Hector. Hector is being released from the rehabilitation unit of Metropolis Hospital. Although he lives in Smithville, Metropolis Hospital, 50 miles away, was the only facility willing to accept a Medicaid client with a severe spinal cord injury.

Hector is a 19-year-old Hispanic male who sustained major injury to his spinal cord (T4 injury) in a motorcycle accident. The injury occurred approximately 6 weeks ago. Hector has been diagnosed as paraplegic with some residual limitation of upper body strength and mobility.

Your job is to facilitate Hector's transition from Metropolis Hospital to his home environment. You will be teaching Hector and his family about the following:

1. Nutrition and fluid intake
2. Signs and symptoms warranting follow-up
3. Medication administration
4. Bowel and bladder care
5. Skin care
6. Activities of daily living (ADLs) and self-care with sensory–motor deficits
7. Safety/injury prevention
8. Community resources
9. Rehabilitative services
10. Anticipatory guidance about mood issues (grief, anger, and suicidal ideations), sexual function, fear of abandonment, role change, and social isolation
11. Altered family processes

Following is a synopsis of information obtained during your initial visit with Hector and his family in their home.

Visit One. Hector lives in a migrant labor camp located on the outskirts of Smithville. His family has resided in the camp for 18 years. Those living in the two-bedroom cabin-like home are:

- Hector, your assigned client.
- Hector's uncle Manuel (32 years old). Manuel's job is seasonal; he has been offered a temporary job for a much higher salary, working out of state.
- Hector's brother Efran (16 years old). Efran is considering dropping out of high school in order to assist with the care of his family. His goal is to become an auto mechanic. He is fluent in both Spanish and English.
- Manuel's wife Marisol (29 years old). Marisol was a teacher in Mexico. She is

extremely supportive of her family. She is concerned about getting pregnant, but does not believe in the use of birth control.

- Manuel and Marisol's children, Arturo (5 years old) and Anna (6 months old). Arturo begins a Head Start program soon and will be gone for 5 hours each day. Anna is a healthy baby who is being breastfed and is thriving at home.
- Hector's paternal grandmother, Lourdes (74 years old). She has recently arrived from Mexico and plans on assisting in Hector's care. Lourdes has congestive heart failure and arthritis. She is not a legal resident of the United States and is not eligible for medical assistance.

The whereabouts of Hector's mother are unknown. Shortly after Efran was born, she moved from their village in Mexico, remarried, and started another family. She has had no contact with Hector or Efran. Hector's father lives in their home village in Mexico. Although he lived in the migrant camp in Smithville for many years, he recently returned to Mexico, remarried, and From the Case FilesI (Continued)has two young daughters. He is aware of Hector's injury, but the father has no plans to return to the United States.

Your ability to speak fluent Spanish has enabled you to collect the above information from Hector and Manuel. Manuel has been very involved in Hector's recovery through daily visits to the rehabilitation unit and frequent discussions with Hector's health care providers. Manuel tells you "Hector is like a son to me … I have a responsibility to my older brother to watch over his son. My brother watched out for me when I was young … he even left school to work to help support our family." Manuel adds, "We don't have much but we will take care of Hector … we'll all work together."

You began the visit by explaining your role as home health nurse. You informed the family about the type of services, education, and interventions you are able to provide. You ask Hector and the family to tell you what they have learned from the health care team at the rehabilitation unit and what plans the family have developed to address Hector's medical and psychosocial needs. As you began the visit, you noticed that Hector's grandmother was sitting quietly in the corner of the room rocking Anna. You learned that Efran was working in the fields. Arturo was in school. Manuel, Marisol, and Lourdes were participating in the home visit this morning. The conversation was as follows.

Nurse: Hector, can you tell me how you feel about being home?

Hector (looks at Marisol): Okay, I guess.

Marisol: He's a little scared, I think. He feels like it's going to be too much for us to deal with.

Nurse (looking at Hector): There's so much happening right now, so much to think about …

Hector: Uh-huh.

(Hector is maintaining eye contact with Manuel and Marisol only; because this is your initial visit to the home, you feel that Hector may be more comfortable in the role of observer.)

Nurse (looking at Manuel and Marisol): Do you have any questions before we begin?

Marisol: They gave us a lot of information at the hospital… I'm most afraid about if the phone doesn't work and Hector needs help. What if something happens to Hector and I can't call anyone? That's the only thing I worry about.

Lourdes: If anything happens to him, I'll be right here with you, "mija." We can do this; we can take care of Hector if we work together.

Manuel: There is a store with a phone only two blocks away; if you needed to, you can call from there. What I want to know is how we can get Hector into school or something that will help him to be around kids his own age. His English is good enough; he even finished high school. He needs to be ready to make a future for himself.

Hector (grins and looks at Manuel): Right, uncle that is what I want, too.

You continued the conversation by revisiting Marisol's concerns about access to a telephone in case of an emergency. You asked specific questions about her concerns and used this as an opportunity to educate the family about circumstances warranting immediate follow-up. Together with the family, you decide that Marisol will develop a list of specific concerns that you will review together at a subsequent visit planned 2 days from today.

Visit One consisted of the following:

I. Assessment
  A. Home environment
    1. Safety
    2. ADLs
  B. Knowledge of disease processes
  C. Fluid volume balance
  D. Nutritional resources of family
    1. Food availability
    2. Food preparation
  E. Insurance and financial status
II. Education
  A. Medications
  B. Warning signs and symptoms and appropriate follow-up procedures
  C. Bowel and bladder care
  D. Hygiene prior to and following patient care

The plan for your visit in 2 days includes the following:

III. Referrals
  A. Community resources
  B. Educational opportunities
  C. Support groups (Spanish speaking)
  D. Peer group opportunities for Hector

IV. Assessment
  A. Continuation of above

V. Education
  A. Continuation of above

Questions

1. What is the social structure of this family (traditional vs. nontraditional)? Be specific about the type of traditional or nontraditional family system that exists in this scenario.
2. Discuss an example of triangulation in this scenario.
3. What essential functions are present within this family system?
4. What developmental stages appear to have been achieved?
5. What steps will you take in order to empower the family to make their own decisions?
6. List the strengths of the family.
7. Prioritize Hector's issues—medical and psychosocial.
8. Prioritize issues facing the other family members.
9. Identify mutual goals for this family:
10. Immediate
11. Midrange
12. Long term
13. What community health nursing interventions will you utilize to achieve these mutual goals?

EFFECTS OF FAMILY HEALTH ON FAMILY MEMBERS

If a family entails the interrelationships of a group of individuals, then the health of each family member affects the health of others. It is this concerted interlacing of individual health that contributes to the level of the family's health. For example, a woman may be able to successfully cope with the physical and emotional demands of caring for a husband who recently had a stroke. However, caring for a husband can deplete her energies, which leaves her with inadequate reserves to effectively meet her children's needs. The mother's level of health significantly affects the level at which her family functions—how well it is able to solve problems and help all members reach their potential. A healthy family promotes each family member's growth and resistance to illnesses so that the family's health can sustain members during times of crisis such as serious illness, emotional dilemmas, divorce, or death of a family member (Deutsch et al., 2014; Miller, Brody, Yu, & Chen, 2014). On the other hand, a family with underdeveloped coping skills or a limited capacity for problem solving, self-management, or self-care is often unable to promote the potential of its members or assist them in times of need.

Standards and practices for family health influence each member's health. For instance, many adults and children adhere to cultural and family patterns of eating, exercise, and communication. Cultural (see Chapter 5) and family values influence decisions about utilizing preventative health care and adhering to recommendations related to immunizations, regular health assessments, or family planning (Spector, 2013). Family patterns also dictate if family members will participate in their health care as well as follow through and comply with professional advice. A family member influences the family health, and the family, as a unit, can either obstruct or facilitate the health of a family member. Remember, the family is the core unit of service, making it the focus of public health nursing throughout the nursing process.

CHARACTERISTICS OF HEALTHY FAMILIES

How does the community/public health nurse determine family health status? Analysis of how basic functions are met does not give a satisfactory picture of a family's health status. More definitive criteria are needed. Although it is difficult to define a "normal" family, studies have provided some standards that characterize a healthy family (Barker & Chang, 2013; Deutsch et al., 2014; Miller et al., 2014). Over the years, research on families and on family health behavior has produced a growing body of data with which to assess family health.

In looking at families over the years, many similar characteristics have been identified. Some characteristics are family unity, loyalty and interfamily cooperation, support and security, role flexibility, and constructive relationships with community (Smith, 2013a). Seven major family strengths have been described as important factors for family functioning and coping with crisis— family pride, family support, cohesion, adaptability, communication, religious orientation, and social support (Smith, 2013a). Specific topics have been used to characterize a healthy family (Becvar & Becvar, 2012):

- A legitimate source of authority that is supported and consistent over time
- A stable and consistent system of rules
- Consistent and regular nurturing behaviors
- Effective child-rearing practices
- Stable and well-maintained marriages
- A set of agreed-upon goals toward which the family and individuals work
- Sufficient flexibility to change in the face of both expected and unexpected stressors

The six signs of a healthy family (Parachin, 1997)) have been used to guide and understand family-oriented interventions (Fort et al., 2015). The six signs are maintaining a spiritual foundation, making the family a top priority, asking for and giving respect, communicating and listening, valuing service to others, and expecting and offering acceptance. From this plethora of information about a healthy family, six important characteristics have consistently emerged (Becvar & Becvar, 2012; Kaakinen et al., 2015):

1. A facilitative process of interaction exists among family members.
2. Individual member development is enhanced.
3. Role relationships are structured effectively.
4. Active attempts are made to cope with problems.
5. There is a healthy home environment and lifestyle.
6. Regular links with the broader community are established.

Healthy Communication Among Family Members

Healthy families communicate. Their patterns of communicating are regular, varied, and supportive. Adults talk with and engage adults, children with children, and adults with children (Deutsch et al., 2014; Fort et al., 2015; Miller et al., 2014). These interactions are frequent and assume many forms. Healthy families discuss problems, confront each other when angry, share ideas and concerns, and write or call each other when separated. They communicate through nonverbal means, particularly families from cultural or subcultural groups that are less verbal. There are innumerable ways to convey feelings and thoughts without words (e.g., smiling encouragingly, embracing warmly, frowning disapprovingly, being available, withdrawing for privacy, doing an unsolicited favor, serving refreshments, giving a gift). The family that communicates effectively has family members who are sensitive to one another. They watch for cues and verify messages to ensure understanding. This kind of family recognizes and deals with conflicts as they arise. This family has learned to share and to work collaboratively with each other (Fig. 19–11).

FIGURE 19–11 Good communication promotes healthy families.

Communication is necessary for the functioning of a healthy family. Family members use communication to demonstrate affection and acceptance, to promote identity and fellowship, and to guide behavior through socialization and social ethics. Importantly, effective communication patterns are associated with a family that promotes the health and development of each family member. Healthy families are more likely than unhealthy

families to negotiate topics for discussion, use humor, show respect for differences of opinion, and clarify the meaning of one another's communications.

Enhancing Family Members' Development

Healthy families are responsive to the needs of family members and provide the freedom and support necessary to promote each member's growth. If a father in a healthy family loses his job, the family works to support his family role by helping him to use his energy constructively to adjust and find a new job. A healthy family recognizes that a growing child needs a certain level of independence so that the family will increase opportunities for the child to try new things alone. This kind of family can tolerate differences of opinion or lifestyle; each member has the right to be an individual and the family respects this right. A healthy family encourages freedom and autonomy for each of its members because it contributes to the family's stability (Kaakinen et al., 2015).

Patterns of promoting a family member's development vary from family to family, depending on cultural orientation. An Italian American family expresses autonomy differently from a Native American family, but each family promotes freedom and autonomy. This level of family promotion of autonomy leads to increased competence, self-reliance, social skills, intellectual growth, and overall capacity for self-management among family members (Deutsch et al., 2014; Pereira et al., 2015; Whittaker & Cowley, 2012; Wright & Leahey, 2012). See From the Case Files.

Effective Structuring of Family Role Relationships

In healthy families, role relationships are structured to meet the family's changing needs over time (Kaakinen et al., 2014). In the context of a stable society, families establish members' roles and tasks (e.g., breadwinner, primary decision maker, homemaker) to maintain workable patterns throughout the life of the family. Families in rural areas, isolated communities, or religious and subcultural groups are more likely than others to retain role consistency because they face little to no external pressure or need to change. For example, the Amish community in Pennsylvania has maintained marked differentiation in family roles for more than 100 years.

In a technologically advanced society such as the United States, most families establish roles for the changing family needs that are created by external forces. Women entering the workforce create a situation where family roles, relationships, and tasks must change to meet the demands of the family. Husbands assume more homemaking responsibilities such as overseeing child rearing. In some families, children, along with adults, share in the decision making. This equal distribution of power in family decisions may be essential for the survival of a single-parent family. Children may need to assume adult responsibilities in the home so that the parent can work to support the family.

Changing life-cycle stages require alterations in the structure of relationships. The healthy family recognizes the changing developmental needs of family members and adapts parenting roles, family tasks, and controls to fit each stage (Deutsch et al., 2014; Fort et al., 2015; Miller et al., 2014). For example, household chores of increasing complexity and responsibility are assigned as children become capable of handling more responsibility. Rules of conduct are relaxed as members learn to govern their own behavior.

Active Coping Effort

Healthy families actively attempt to overcome life's problems and issues. When faced with change, they assume responsibility for coping and seek to meet the demands of the situation (Becvar & Becvar, 2012; Smith, 2013a). Coping skills are needed to deal with emotional problems stemming from tragedies such as substance abuse/addictions, serious illness, or death. If a family member has a substance abuse problem, all family members may participate in the counseling and treatment opportunities. If a family member is seriously ill, the family may ask for and accept assistance from the extended family and/or public health care workers. In the event of a death in the family, an important step in the healing process is accepting consolation and support from one another, the extended family, and friends or clergy. The healthy family recognizes the need for assistance, accepts help, and pursues opportunities to eliminate or decrease the stressors that affect it (Deutsch et al., 2014; Miller et al., 2014).

More frequently, healthy families cope with less dramatic, day-to-day changes. For instance, one family may cope with the increased cost of food by consuming less meat, eating more vegetables and legumes high in protein, and going out to restaurants less frequently. Healthy families are open to innovation, support new ideas, and find creative and energetic ways to solve problems. One family may try to solve the problem of spending too much on transportation by cutting down on daily travel. The family may even support this change although some family members' jobs are in different areas of town or the family is active in school functions and meetings that occur in the evenings. Responding to a personal need for a healthier lifestyle, another family may solve the same transportation problem by walking, bicycling, or carpooling to school, work, and/or other activities. Active coping may go beyond finding a simple, obvious solution. For example, family members may try to rearrange schedules to avoid frequent trips to regular destinations and plan ahead to avoid last-minute trips to stores. Healthy families actively seek and use a variety of resources to solve problems. These resources may be within the family such as self-care or externally by using community resources. A professional couple faced with the unaffordable expense of daytime babysitting, for instance, arranged their work schedules to share childcare by trading off responsibilities during the first 2 years. Later, they joined a cooperative preschool that provided daily age-appropriate childcare and required the parents to work at the preschool only 1 day a week. In another example, a single parent of five children, who was also a full-time nursing student, was able to finance annually two or three weekend family outings by having everyone in the family participate in collecting and recycling cans and bottles.

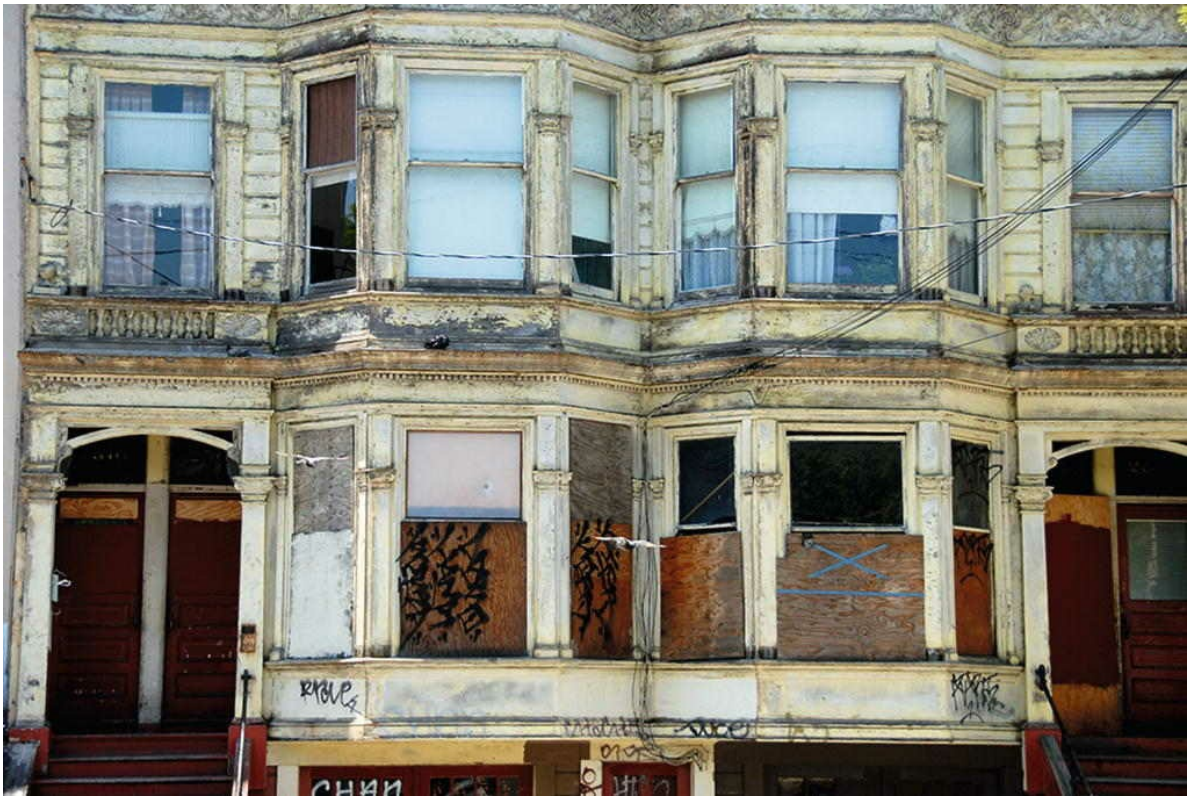

FIGURE 19–12 Families need healthy environments.

Healthy Environment and Lifestyle

Another sign of a healthy family is a healthy home environment and lifestyle (Fig. 19–12). Healthy families create safe and hygienic living conditions for their members. For instance, a healthy family with young children "childproofs" the home by removing potential hazards such as exposed electric outlets and cleaning solvents from the children's reach. A healthy family with an older adult, who is prone to falls, installs night lighting and handrails. A healthy home environment is clean and reduces the spread of disease-causing organisms.

A healthy family lifestyle encourages family members to find balance or harmony in their lives. There is balance between activity and rest so that the family can have sufficient energies for daily living. There is variety in the family diet so that it is both nutritionally sound and appealing. Adequate physical activity helps to maintain a healthy weight while promoting cardiac health. Preventative hygiene habits are taught and followed by family members. Emotional and mental health is encouraged through a support network of caring family members and others. Finally, family members seek out and use health care services and demonstrate adherence to recommended regimens.

The emotional climate of a healthy family is positive and supportive of growth. Contributing to this healthful emotional climate is a strong sense of shared values, often combined with a strong moral ethical orientation (Smith, 2013a). A healthy family demonstrates caring, encourages and accepts expression of feelings, and respects divergent ideas. The home environment makes family members feel welcomed and accepted so that they can express their individuality in simply ways such as their dress or decoration of their room in the home.

Regular Links With the Broader Community

Healthy families maintain dynamic ties with the broader community. They participate regularly in external groups and activities. They may join in local politics, participate in a church bazaar, or promote the school's paper drive to raise money for science equipment. They use external resources suited to family needs. For example, a farming family with teenagers becomes very active in the local 4-H club as a way to promote peer interactions for the adolescents. Another family where the father is out of work joins a job transition support group. A family may be active in a nursing home where a family member resides in order to ensure optimal delivery of nursing home services and maintain that family member's role in the family. Healthy families also know what is going on in the world around them. They show an interest in current events and attempt to understand significant social, economic, and political issues. The families are exposed to a wider range of alternatives and a variety of contacts, which can increase options for finding resources and strengthen coping skills.

Public health nurses need to assess and encourage family's involvement with the broader community as it facilitates a relationship between the family and the community (Davis & Gustafson, 2014; de Cássia Tszesnioski et al., 2015). Importantly, the nurse can promote structural and developmental variations, interaction, coping strategies, and lifestyle for health promotion within the family.

PUBLIC HEALTH NURSING PRACTICE GUIDELINES

The family is often the unit of service in public health nursing (Kaakinen et al., 2015). It is not merely a family-oriented approach in which family concerns that affect the health of an individual are taken into account. A public health nurse asks how the family provides health care to a collection of people. Five principles guide and enhance public health nursing practice:

1. Work with the family collectively.
2. Start at the family's present level of functioning.
3. Adapt nursing interventions to the family's stage of development.
4. Recognize the validity of family structural variations.
5. Emphasize family strengths.

Work With the Family Collectively

Public health nurses focus on the family. They remind themselves that a family is a group of several persons living together and this group or family has a collective personality, collective interests, and a collective set of needs. Viewing a group of people as a unit is similar to the way business organizations are perceived—as a single entity. Many persons may make up the entity, but they function collectively as a single entity with common attributes and activities. For example, you think of a particular corporation as conservative or liberal, not the individual employees. You read and perhaps support the women's group that has taken a stand on family life education, not a specific woman in the group. You believe that it is a government agency that needs to be better organized instead of thinking that it is just one staff member. In each case, the group is viewed collectively. So it is with families. A family has its own personality, interests, and needs.

As much as possible, public health nurses strive to involve all family members during nurse–client interactions (Wright & Leahey, 2012). This approach reinforces the importance of each family member's contributions to the collective functioning of the family. Nurses recognize the importance of encouraging all family members to participate in the work that the nurse and the family jointly agree to do. Like a coach, the nurse rallies family members to work together as a team for their collective benefit. Look at how a nurse works collectively with the Beck family (see Display 19–3).

DISPLAY 19–3 THE BECK FAMILY

A public health nurse had an initial contact with Mr. and Mrs. Beck and their youngest child at the well-baby clinic. The 9-month-old child was over the 95th percentile for weight and at the 40th percentile for height. The nurse also noted that both parents were obese. The nurse asked about the family's eating patterns, the baby in particular, and suggested a home visit to determine whether the Becks were interested in family nursing. The nurse explained the purpose of home visits (to assess all family members, coping patterns, eating patterns, and food purchasing choices) and the importance of including all family members and asked for a time that would be good for the family as a whole. The nurse explained that each person should be involved and committed to the agreed-upon goals; that, like a team of oarsmen, the family has to pull together to accomplish the purpose of the visits. To help the Beck family improve its nutritional status, the nurse might suggest a session

of brainstorming to uncover many causes of poor nutrition. More brainstorming might also lead to more solutions and plans for action. On each visit, the nurse views the Becks as a group so that group responses and actions would be expected. Evaluation of outcomes will be based on what the family did collectively. The Becks were interested, and a home visit date was made.

Start at the Family's Present Level of Functioning

When working with families, public health nurses begin at the present level of functioning and not some arbitrary ideal level. The nurse determines this level of functioning by first conducting a detailed family assessment. As discussed earlier, a family assessment allows the nurse to ascertain the needs and health level of each family member. This assessment will then strengthen the nurse's ability to recognize patterns of behaviors so that she or he can determine collective interests, concerns, problems, risks, and priorities. The accompanying description of the Kovac family illustrates this principle (see Display 19–4).

DISPLAY 19–4 THE KOVAC FAMILY

Marcia Kovac brought her baby, Tiffany, to the well-child clinic once but failed to keep further appointments. Concerned that the family might be having other difficulties, Sara Villa, a public health nurse, made a home visit. The mobile home was cluttered and dirty, and the baby was crying in her playpen. Marcia seemed uninterested in the nurse's visit. She listened politely but had little to say. She repeated that everything was okay and that the baby was doing fine, explaining that Tiffany was just fussy because she was teething. As they talked, Marcia's husband Henry, a delivery van driver, stopped by to pick up a sports magazine to read on his lunch hour. The three of them discussed the problems of inflation and how expensive it was to raise a child. Sara reminded the Kovacs that the clinic was free and that they could at least get good health care without extra cost. They agreed without enthusiasm. After Henry left, the nurse spent the remainder of the visit discussing infant care with Marcia, particularly emphasizing regular checkups and immunizations.

The next visit also focused on the baby, but Sara had an uncomfortable feeling that the Kovacs were not really interested in her help. After consulting her supervisor, Sara did what she wished she had done in the first place. She asked to talk with Marcia and Henry together, explained frankly why she had come to their home, and informed them what she could offer in the way of counseling, teaching, support, and referral to other community resources. She then asked them what problems or concerns they had. The Kovacs were more than responsive. They described their financial difficulties and feelings of isolation from family and friends. They were new in the city, and both their families lived some distance away on farms. The neighbors

were friendly but not close enough to confide in. They believed they would eventually overcome their problems if they just had "someone to lean on," as they put it.

Now Sara could address the Kovacs' primary needs and concerns for friends and emotional support. The nurse began to address the Kovacs' social needs first by introducing them to a young couples' group that met at the community center. Sara continued to make periodic home visits and shared additional information about community services that the Kovacs might find helpful. She praised Marcia and Henry for following up on immunizations for Tiffany. Over time, Sara saw differences in the family's interest in their relationship with the community and their connection to its services. Sara realized that before she could address the issue of Tiffany's health, she needed to address the emotional health of the parents.

Adapt Nursing Intervention to the Family's Stage of Development

Every family engages in the same basic functioning. However, every family does not use the same approaches and/or tasks to accomplish these functions. Furthermore, this variation in achieving these functions can and often do vary with each stage of the family's development. A young family, for instance, can meet the family members' affiliation needs by establishing mutually satisfying relationships and meaningful communication patterns. As the family enters later stages of development, bonds change due to some family members becoming part of another family unit (e.g., through marriage or living together) or because of death. Awareness of the family's developmental stage enables the nurse to assess the appropriateness of the family's level of functioning and to tailor interventions accordingly. Nurses are often adept at family assessment, but they must remember that the assessment is used to determine the problems/risks and implement the interventions needed to move the family to a state of health (Kaakinen et al., 2015; Wright & Leahey, 2012). A nurse's work with the Ravina family illustrates this need (see Display 19–5).

DISPLAY 19–5 THE RAVINA FAMILY

The Ravinas, a couple in their early 70s, recently moved to a retirement complex. They had received nursing visits after Mrs. Ravina's stroke 3 years earlier, but requested service now because Mr. Ravina was feeling "poorly" all the time. He thought that perhaps his diet and lack of activity might be the cause and hoped the nurse might have some helpful suggestions. The couple had eagerly awaited Mr. Ravina's retirement from teaching, with plans to be lazy, travel, visit all their children, and do all those things they never had time to do when they were young. Now, neither of them seemed to have enough energy or the capacity to enjoy their new life. The move from their home of 28 years had been difficult: They were still trying to find space in the tiny apartment for their cherished books and mementos, although they had given many items away.

Ronald Bell, a public health nurse, recognized that the Ravinas were experiencing a situational crisis (leaving their home of 28 years) and a developmental crisis (aging and entering retirement) and may perhaps have some underlying health problems. Many of the Ravinas' expectations for this new life stage were unrealistic; they had not adequately prepared themselves for the adjustments that the loss of their

home and retirement would demand. Through discussion, Ronald was able to help the Ravina family understand their situation and express their feelings. He completed physical assessments on the Ravinas and encouraged regular follow-up with their health care provider. He also helped them join a support group of retired persons who were experiencing some of the same difficulties. Because this nurse was able to help the Ravina family through their crisis in a supportive and nonjudgmental manner, he found them receptive later to discussing preparation for the inevitable loss and bereavement that would occur when one of them died. He was adapting his nursing intervention to this family's stage of development.

Recognize the Validity of Family Structure Variations

Public health nurses work with families from communities that are rich with diverse cultures and subcultures. For a public health nurse, there is no such thing as a traditional or nontraditional family. Why? The nurse works in communities with varying family structures that reflect these communities. Families can be structured and organized around a single parent, a married couple, an unmarried couple, an older sibling, or a single elderly grandparent. For example, the parents may have full-time careers, a husband may provide childcare as an at-home father, a wife may financially support her family, or the parents may telecommute and work at home. Such variations in structure and organizational patterns lead to individualized patterns of family functioning. Family member roles and tasks may differ from what the nurse is used to or may expect. Public health nurses must learn to understand and accept these variations in family structure and organization in order to address the needs of the families. Therefore, there are two important principles to guide this acceptance and understanding (Miller et al., 2014; Ramal et al., 2012; Salem & Ma-Pham, 2015):

1. *Principle One*—Each family is unique in its combination of structures, composition, roles, and behaviors. As long as a family carries out its functions effectively and demonstrates the characteristics of a healthy family, one must agree that its form, no matter how variant, is valid.
2. *Principle Two*—Families are constantly changing. Throughout the life cycle, a family seldom stays the same for very long. Each of these changes forces a family to adapt to its circumstances.

Let's look at some common ways a family changes in today's society. Marriage or cohabiting (living together) transforms two people into a couple without children. This family structure and the family members' roles may change by adding children, the couple separating, or becoming part of another family that already has children. Consider the young mother with a baby and a husband who has deserted her: the young mother is now forced to assume a single-parent role in order to survive. This change creates varying degrees of stress and demands because she adapts her energies to be a mother and the family's provider.

Although change is a part of the expected life-cycle growth, some changes can be unexpected and have a large effect on the family's structure. As a public health nurse, your responsibility is to help families cope with these changes while you remain nonjudgmental and accepting of the family structure. For example, a nurse personally may find it difficult to work with same sex couples or respect their same sex marriage because this lifestyle conflicts with the nurse's personal set of values. However, the nurse is a professional, and it is her or his responsibility to help promote the collective health of that family. See Chapter 18. All families are unique groups, each with its own set of needs, and they are best served through unbiased care. Consider the nurse's work with James Cutler and Brian Hoag (see

Display 19–6).

DISPLAY 19–6 JAMES CUTLER AND BRIAN HOAG

James Cutler and Brian Hoag have a 6-year monogamous relationship. A same sex couple, they worked with an attorney to privately adopt a child. The arrangements were completed and their 2-week-old son, Adrian, arrived in their home last week. Helen Jeffers, a public health nurse, receives a referral from the county hospital where Adrian was born. The request is for an assessment of the home situation and parenting skills. At the hospital, the baby tested positive for cocaine with APGAR scores of 6 and 8 and had some initial difficulty sucking. Birth weight was 2,900 g. Discharge weight, at 3 days, was 2,850 g. At her first home visit, Helen finds a neat and orderly two-bedroom condominium that is well equipped with baby supplies. The infant has gained 200 g and is being well cared for by two fatigued parents whose previous contact with infants was limited. James and Brian have many questions and are anxious learners. Helen plans with the couple to make weekly home visits to assess infant growth and development, provide support, and answer questions. She suggests a neighborhood parenting class and finding a reliable babysitter. She also helps James and Brian develop an infant care work schedule. After 6 weeks of intervention, Adrian is thriving. Helen closes the case to home visits, feeling confident that the parents' goal of becoming knowledgeable and confident has been achieved.

Empowering Families

Throughout the family visit, the public health nurse realizes that the ultimate goal is to assist the family in becoming independent of services (Deutsch et al., 2014; Miller et al., 2014). This is accomplished through the approach used in conducting the visit and the nurse–client relationship. Your working relationship with the family can be guided by four suggestions:

- The current functioning of the family has worked for the family before meeting you.
- Before doing "something" for a family, consider who did this "something" before you.
- Find family strengths even in the most challenging and compromised family situation.
- Think about your ability to manage, cope, or function as well as the family members if you were in a similar situation.

Too often, public health nurses focus on a family's weaknesses, looking for and referring to them as *needs* or *problems*. This negative emphasis can be devastating to a family and can undermine any hope of a therapeutic relationship between nurse and family. Many families have strengths that may be overlooked or interpreted as weaknesses by PHNs. It is the nurse's job to recognize the strengths in families and to help families recognize them and understand their potential for self-efficacy (Whittaker & Cowley, 2012). For example, some families create a supportive neighborhood by borrowing needed items (diapers, food, and clothes) from each other, whereas others may pursue more self-reliance by not seeking assistance from outside or infringing on their neighbors' space. Children from large families often learn to physically care for one another, which strengthens their internal relationships. On the other hand, a child from a small family learns to access community resources for care. A large family provides family members with an accepting internal sociomicrocosm, whereas a small family with one or two children learns to interact more with families in the community, enhancing the environment's impact on the family's health. Although family members without a car have to take public transportation or walk to accomplish errands, they are promoting their health by walking while reducing the family expenses. Families need to have their strengths reinforced. Emphasizing a family's strengths fosters a positive self-image, promotes self-confidence and self-efficacy, and often helps a family feel better able to address other problems as they arise.

At times, public health nurses will want to do a simple task for the family such as driving a family member to the clinic or buying a supply of formula or diapers. It might seem like a simple task because "it is on your way" or "there are extra cans of formula or diapers at the agency." But, the nurse should ask, "Will this type of help promote the family's independence and self-efficacy?" A better gift promotes the family's skill of planning ahead to meet the family's transportation needs (make travel arrangements with neighbors or family members, save loose change for the bus, or even walk) or to find ways

to use the formula wisely (only fill the bottles with the amount the baby consumes, refrigerate unused formula for later use, or avoid overfeeding the baby). The nurse's gift can be to help the family determine the amount of formula consumed in 24 hours so that the correct quantity is always available. Another gift may be the suggestion to keep a can of powdered formula for emergencies or to completely switch to the powdered formula. These gifts will help the family learn skills to deal with daily situations and crises more effectively.

Finally, you should always look for ways to genuinely praise families for managing in difficult situations. On a home visit, you can empower families by pointing out the positive aspects of their self-care and caregiving, rather than pointing out what they do not do or have (Aston et al., 2015; Pereira et al., 2015).

One helpful communication technique is strengthening. This involves verbally listing the positive aspects of an otherwise negative situation in a natural and conversational manner (Aston et al., 2015). For example, a young woman greets you at the door while holding her baby boy. They live in a sparsely furnished one-room apartment, and you notice that the dresser drawer where the baby sleeps is on the floor next to the woman's mattress. She has two baby bottles and a limited assortment of baby clothes. Later during the first visit, you say, "Carlo looks so happy when you cuddle him in your arms, and you are thinking of his safety by letting him sleep in the dresser drawer next to your mattress. I noticed you wash each bottle before making the formula, and you keep him warm in the sleeper and blanket. I think you are managing Carlo's care very well." In this brief scenario, you have positively mentioned bonding, infant health and safety, and proper infant clothing. You have not mentioned the absence of furniture, a full set of bottles, or a variety of clothing. During the rest of the visit, you discuss the services your agency can provide and assess if any of them would be of interest to the young mother. This strengthening technique helps the nurse use a positive approach instead of a negative one that may be viewed by the family as condescending or punitive. The nurse also empowered the young mother to make decisions for her family and to use the nurse as a resource and guide (Wright & Leahey, 2012).

At the least, the public health nurse should be able to say that the family seems to be managing as best as possible if there is nothing else positive to say. This approach does not mean that the nurse should ignore problems. It creates an atmosphere where the assessment can explore all aspects of family functioning, both strengths and weaknesses. Remember, the nurse needs a total picture of the family to know when the family is ready to begin work on problems and to determine adequate nursing care plans. Even as the nurse becomes more aware of a family's unhealthy behaviors, the emphasis should remain on the positive ones. Emphasizing strengths indicates to the family that they are important to the nurse—creating a collaborative relationship.

Family strengths facilitate the ability of the family to meet the needs of the family members and the demands made by systems outside the family unit. Not all behaviors that seem positive are necessarily strengths. Before the nurse emphasizes a behavior, it should be examined closely to determine if it is actually facilitating family functioning. For instance, a

strong work ethic may be viewed a strength when balanced with play and relaxation, but this behavior is a weakness in a family obsessed with working. A public health nurse knows that the amount of free choice, as opposed to compulsive drive, determines if a behavior is either a strength or weakness.

Some behaviors that a nurse may consider as strengths are related to basic family functions, family developmental tasks, and characteristics of family health. For instance, a nurse may wish to note when a family meets family members' needs (physical, emotional, and spiritual needs), shows respect for members' various points of view, or fosters self-discipline in its children. An illustration of this action is in the family nursing care of the Stevensons (see Display 19–7).

DISPLAY 19–7 THE STEVENSON FAMILY

The public health nurse, Keith Dow, made an initial home visit after referral by an outpatient physician who was concerned about possible child abuse. Alice Stevenson had brought her baby boy to the emergency room for treatment of a laceration on the forehead. He had fallen off the table while she was changing him, she claimed. A bruise on his arm made the physician suspicious, but Alice explained it was caused by his older brother's rough play. The nurse opened the visit by stating that he was simply following up on the emergency room treatment and wanted to see how the baby was progressing. Keith made no mention of child abuse. He observed the mother and children closely, looking for small things on which to compliment Alice (strengthening) while learning all he could about the family's background. Because the nurse appeared approving rather than suspicious or judgmental, Alice agreed to further visits. During a later visit, Alice admitted to the nurse that she had slapped the baby and her ring cut his forehead. She could not get him to stop crying, no matter what she did; she just could not endure it any longer, she said. There had been other times when she grabbed him roughly to pull him away from things he wasn't allowed to touch, causing bruises on his arms. Alice told the nurse that she had not planned this baby. When her husband found out she was pregnant, he had left her shortly before the baby was born. Like many abusive parents, Alice had unrealistic expectations of her children's behavior as well as very inadequate self-esteem. Realizing that Alice would be particularly vulnerable to any criticism, the nurse concentrated on her strengths. Keith complimented her on how well she managed her home, dressed the children, maintained her job, and read to her 3-year-

old son. It took many visits before Alice trusted the nurse, but in time, they were able to discuss her feelings frankly and work toward improving this family's health. Keith got her to attend a support group for single parents and she began counseling. Emphasizing strengths had provided a bridge for Alice and assisted in bringing her into a helping relationship.

SUMMARY

The family unit remains the focus of service in public health nursing. Family health and the health of each family member strongly influence each other, and family health affects community health. While assessing, diagnosing, planning, implementing, and evaluating are steps used to deliver care to clients in acute care settings and the extensive clinic system, these steps can be used in delivering care to a family as long as the focus is the family. It is family assessment, family diagnosing, family care planning, family health promotion, and family health evaluation.

It is important for the public health nurse to understand healthy family characteristics and to use a variety of tools so that family assessments are thorough.

Healthy families demonstrate six important characteristics: a facilitative process of interaction exists among family members; individual member development is enhanced; role relationships are structured effectively; active attempts are made to cope with problems; there is a healthy home environment and lifestyle; and regular links with the broader community are established.

To systematically assess a family's health, the nurse needs a conceptual framework as a basis for the steps of the nursing process, a clearly defined set of categories for data collection, and a method for measuring the family's level of functioning. The six characteristics of a healthy family provide one assessment framework that public health nurses can use. Assessment tools to aid the nurse in appraising the health of families include the eco-map and the genogram.

There are 12 main categories of family dynamics for which the nurse must collect data: family demographics, physical environment, psychological/spiritual environment, family structure and roles, family functions, family values and beliefs, family communication patterns, family decision-making patterns, family problem-solving patterns, family coping patterns, family health behaviors, and family social and cultural patterns.

Public health nurses enhance their practices with families by observing five principles: work with the family collectively, start at the family's present level of functioning, adapt nursing interventions to the family's stage of development, recognize the validity of family structural variation, and emphasize family strengths.

During assessment, the nurse should focus on the family as a total unit, ask goal-directed questions, collect data over time, combine quantitative with qualitative data, and exercise professional judgment.

Making family health visits is a unique role for nurses and is one of the activities common to most public health nurses. In some agencies, family health visits is the method of choice for most care. In other agencies, a visit is conducted for only the most high-risk families.

When nurses visit families, they must use acute observational skills, good verbal and nonverbal communication, assessment skills, and their intuition to guide them safely in the community and with the families they visit. Some visits are conducted with families in settings other than their homes. Neighborhood clinics, schools, workplaces, or recreational settings may be the preferred or the only locations in which you can gather most of the family members for the visit. Other families may be in transition and living in homeless shelters or with relatives or neighbors. These settings are familiar to the family and provide a unique environment for the nurse in which to visit the family.

Previsit preparation, conduct of the visit, and postvisit documentation are the main components of a family health visit. Each step is important and has value for the success of the next step. Being well prepared for a visit is the first concern (e.g., know the location, have family health status information and needed materials), and the visit should be conducted in an orderly and organized fashion. Time should be allowed for getting acquainted, for the assessment and the nursing diagnosing process, including teaching and anticipatory guidance, and for any other nursing care that may be a part of the visit. The home health visit concludes with a summary of the important parts of the visit and planning for the next visit.

Being safe in a neighborhood is important for all people. Public health nurses spend a great part of the day in the community, and safe travel is important. Use of a personal or agency car, public transportation, or walking to visit families each has its own set of precautions for personal safety. Even in a family's home, personal safety must be a consideration. If family members are arguing or under the influence of drugs or alcohol, the situation may deteriorate rapidly and become unsafe; at this point, it is best to terminate the visit.

During the implementation phase of the family health visit, the nurse may establish a verbal or written contract with the family that permits understanding of the personal roles and responsibilities in the relationship. Empowerment of family members is significant. People who are empowered can help themselves for a lifetime and can make independent decisions about their own health.

Evaluation and preparation for the next visit complete the family health visit cycle. Three types of evaluation can be conducted at the end of a visit: (a) recall of the structure–process assists the nurse in reflecting on the physical aspects of the visit that were positive or negative; (b) discovering these factors can help enhance the positive and eliminate the negative; and (c) evaluating if the outcomes of the visit were achieved through completion of agency documentation. Because the purpose of conducting family health visits is to bring about positive changes in family behaviors, it is necessary to evaluate if both the family and the nurse have achieved the mutual goals. The hardest part of evaluation is self-evaluation where you reflect on your behavior(s) as the PHN and how you conduct home visits. Often, peer evaluation is a helpful way to obtain feedback, because people tend to minimize their own strengths and overlook their weaknesses.

Conducting family health visits involves making referrals to other agencies and services on behalf of the family. One agency cannot provide all the services that a family needs, and PHNs may contact available resources within a community through either written or verbal forms of referral. Public health nurses have unique skills in knowing and locating both official and voluntary services within their community. Such skills come with experience.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Construct an eco-map of your family or one in your clinical rotation. Ask a peer to do the same, and compare the eco-maps. Assess the balance between your family and the resources in its environment. How does your eco-map compare with that of your peer? What changes are needed in each family system? Are you able to influence the changes that are needed?
2. Draw a genogram of your own family, and ask a peer to discuss it with you. Get input from older family members about illnesses or problems your grandparents or other relatives may have. Make your drawing of the genogram as complete as possible, and then analyze your thoughts and feelings. How did you feel while tracing your family history? Did you learn anything new about your family? Did any family trends or behaviors appear? Did any uncomfortable or suppressed information come to the surface? Do you have any new insights about your family?
3. Assess a family (other than your own) that you know well by completing a family assessment guide. You may use one of the forms in this chapter or an available form from another source. Based on your assessment, recognition of any patterns, or identification of risks (actual or potential), determine as many nursing interventions as you can think of that could be used to promote this family's health as practically as possible.
4. Invite a peer to go on a family health visit with you, and be open to feedback regarding your strengths and weaknesses. How does it make you feel to have someone else on a family health visit with you, knowing they are observing your skills? Offer to do the same for a peer and provide him with feedback. Discuss your experience.
5. Go on several family health visits with an experienced public health nurse and observe the nurse's visiting techniques. Observe how she or he contacts the family; knocks on the door; greets the family; conducts, summarizes, and concludes the visit; and makes plans for the next visit. Discuss the various techniques used and ask questions about your observations to get a better idea of why things are done as they are. Use some of this information on your next home visit.
6. Initiate a small group discussion among your peers about safety on your school campus and in your community. Encourage each person to share the safety habits used. How are these techniques different from safety techniques used when making home visits in the community? If they are different, think about why this is so. Should they be different?

20 CHAPTER

Violence Affecting Families

"The right things to do are those that keep our violence in abeyance; the wrong things are those that bring it to the fore."

—*Robert J. Sawyer* (1960), Calculating God

KEY TERMS

Adolescent dating violence (ADV)
Battered child syndrome
Child abuse
Child maltreatment
Crisis theory
Cycle of violence
Developmental crisis
Elder abuse
Emotional abuse
Infanticide
Intimate partner violence (IPV)
Mandated reporters
Neglect
Neonaticide
Physical abuse
Sexual abuse
Shaken baby syndrome
Situational crisis
Spectrum of prevention

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Explain the difference between developmental crises and situational crises, and give examples of each within families.
- Discuss strategies to prevent the impact of a situational crisis and a developmental crisis at a primary, secondary, and tertiary level of prevention.
- Discuss the global incidence and prevalence of family violence.
- Describe how the United States has responded to family violence.
- Identify characteristics of abuse against infants, children, and adolescents.
- Describe the "cycle of violence" seen in intimate partner/spousal abuse.
- Explain common types of elder abuse.
- Describe the community health nurse role with families in crises at each level of prevention.
- Use the nursing process to outline nursing actions in developmental and situational crises.

A *family crisis* is a stressful and disruptive event (or series of events) that comes with or without warning and disturbs the equilibrium of the family. A family crisis can also result when usual problem-solving methods fail. All families experience periods of crisis: a toddler is diagnosed with a serious illness; a teenager discovers she is pregnant; a father and sole breadwinner in a family loses his job; a mother's social drinking becomes habitual after her children go off to college; or a family's home is destroyed in a hurricane, earthquake, flood, or fire. If you think back on your family's history, you can probably identify one or more periods of crisis that you and your family members experienced. If so, how directly were you affected? How did the crisis resolve? As a result of the crisis, did any permanent changes occur in your family's dynamics or individual behaviors?

People respond to crises differently. Some people approach crisis as a challenge, an event to be reckoned with, whereas others may feel overwhelmed and defeated or give up. Some individuals seek help if needed and come through the experience unscathed or as survivors, perhaps even stronger than before. Other individuals who are unable to cope with the crisis, or who do not cope well, may suffer severe psychological damage or may inflict their feelings of rage, frustration, or powerlessness onto their children, partners, or elders. This chapter focuses on families that have responded to stressors with violence, neglect, or abuse and those that have experienced stress and loss as a result of violence initiated by others.

Regardless of their responses, families in crisis need help, and community health nurses have a unique opportunity and responsibility to provide that help in a broad variety of situations. For example, in one family, an 8-year-old boy begins doing poorly in school; he wets his pants during class twice in 1 week and starts a small fire in the schoolyard. The school nurse is astute enough to begin an investigation into the family dynamics that may be contributing to these symptoms. In another family, a pregnant woman reschedules her appointment at a community clinic twice and then arrives at the appointment with multiple faded bruises on her face and arms. The clinic nurse uses sensitivity and caring while screening her for intimate partner violence (IPV).

Primary and secondary prevention measures used by community health nurses that help prevent crises include teaching families parenting skills and coping strategies and informing them about community resources. In addition to assessment and education, community health nurses provide tertiary responses with direct assistance during times of crisis. This chapter discusses the knowledge and skills that community health nurses use in their practice of crisis prevention and intervention aimed at promoting improved health for families in the community.

DYNAMICS AND CHARACTERISTICS OF A CRISIS

Researchers have studied the nature of crises and have developed a body of knowledge called stress or crisis theory. Initially limited to the field of mental health, crisis theory now influences every field of health care. The theory helps to explain why people respond in certain ways during a crisis and can be predictive of the phases people go through during and after a crisis. These responses and phases are important ideas for the community health nurse to understand before working in prevention or management of crises (Weber, 2011).

How does a crisis occur? Each of us is a dynamic system living within a given environment under circumstances unique to us alone. Our behavior—both consciously and subconsciously—is gauged to maintain a balance within ourselves and in our relations with others. When some internal or external force disrupts our system's balance and alters functioning, a loss of equilibrium occurs. The individual then attempts to restore equilibrium by using whatever resources are available to him or her, in an effort to cope with the situation. Coping refers to those actions and ways of thinking that assist people in dealing with and surviving difficult situations. If individuals cannot readily cope with a stressful event—for example, if one's home is destroyed by fire, or one fails a final examination—the person experiences a crisis (Weber, 2011).

Crises are precipitated by a specific identifiable event that becomes too much for the usual problem-solving skills of those involved. Often, a single distressing event follows a host of previous difficulties and becomes the "straw that breaks the camel's back." For example, a wife who suffers years of spousal abuse finally becomes unable to cope and shoots her husband during a violent attack. Occasionally, tragic events occur suddenly without previous stressors, as when a father is killed in a plane crash or a child drowns in the family swimming pool.

Crises are normal in that all people occasionally feel overwhelmed. A person intervening in a crisis today may well be tomorrow's crisis victim. No individual is immune from sudden overwhelming difficulties. For example, Barbara, a hospice nurse, assists families through crises as part of her job, when suddenly her own spouse is diagnosed with cancer. Her coping skills are strained, as she feels overwhelmed with increased personal demands that require her support and attention.

Often, a crisis is not an event per se, but rather a person's perception of the event. Each person reacts in his own way. A situation that throws one person off course may merely create an interesting detour for another (see Display 20–1). It is usually the individual's interpretation of the event, rather than the event itself, that is crucial. At other times, a community crisis occurs on a large scale or is so unexpected that the crisis directly involves people who are known by others hundreds of miles away, causing distant friends and relatives shock and sorrow. Examples of such crises are Hurricane Katrina, or an apartment

building fire that kills a dozen people, or the terrorist attack in San Bernardino in 2015. Even strangers, knowing no one involved directly, are affected and experience signs and symptoms of stress (Devakumar, Birch, Osrin, Sondorp, & Wells, 2014).

DISPLAY 20.1 TWO FAMILIES' RESPONSE TO CRISIS

The Redondos and the Fosters will be moving to a town in another state, 900 miles away, because of a job change. The Redondos are in crisis over the move. They have never lived in any other town. They will have to leave relatives and lifelong friends who live nearby and a community in which they have been very involved. Mrs. Redondo is the secretary at her family's house of worship. Their teenage daughter, a cheerleader, just started high school. Their son is in kindergarten; Grandma happily watches him in the mornings before school. Everyone is upset because of how the move will affect them. The family is stressed and argues each evening. They don't want to put their house up for sale or even to visit the new community to which they will be moving. Mr. Redondo is second-guessing his decision to move, but his choices were limited as his company is relocating. The Redondos, in crisis, are not exploring alternatives that may allow them to stay in their present community. One possible alternative might be for Mrs. Redondo to work while Mr. Redondo looks for another job. When people perceive that they are in crisis, decision-making and problem-solving become more difficult.

The Fosters, however, are excitedly looking forward to their move. They have two young children who are not yet in school. The move will bring them only 50 miles from old college friends. They hope to realize a significant profit on their house, which they recently remodeled. They can't wait to go "house hunting" in the new town. Everyone is enjoying planning the anticipated move; their two children, aged 3 and 4, have been playing "moving day" with their favorite toys.

Both families are experiencing the same event. The difference is each person's situation and perception of the event. The Redondos' equilibrium is being disrupted. They have not developed previous coping skills and do not see the move as a positive experience. They are at a different time in their family life cycle than are the Fosters. Although the move upsets their equilibrium, too, the Fosters experience it as an exciting event that conjures positive feelings; they are passing these feelings on to their children. They see this move as an opportunity.

Crises are resolved, either positively or negatively, within a brief period, usually 4 to 8 weeks (Kanel, 2012). People's strong need to regain homeostasis and the intense nature of crises contribute toward making the crisis a temporary condition that will not continue indefinitely. In the family in which the wife shot her abusive husband, as shocking as the event might seem, life returns to a recognizable pattern within a few weeks. Even though family members will feel the change for years, the crisis soon subsides. The husband is hospitalized and recovers from his wound; the wife's case goes to trial, and she is sentenced to 2 years in prison; the children stay with relatives and attend school.

Crisis resolution can be an adaptive process in which growth and improved health occur, or it can be maladaptive, resulting in illness or even death (Weber, 2011). The battered wife reevaluates her life, gets divorced, learns employment skills in jail, and becomes more assertive, with stronger self-esteem; after she is paroled, she returns to her children, now able to support them financially and emotionally. She finds personal growth and health while successfully resolving the crisis. The children settle into their aunt's home with minimal difficulty, start a new school, and visit their mother and father regularly. After release, the mother finds an apartment near her sister's home, so that the children can continue in the same school district. The husband recovers from his wounds, gets counseling, relocates to another town, and sees his children frequently. The crisis situation is resolved at a higher level of wellness for all members than existed before the crisis. In this example, the members are determined to improve their situation by working with skilled health care professionals. By using the resources within the community, this family is healthier after the crisis.

Developmental Crises

Developmental crises are periods of disruption that occur at transition points during normal growth and development (see Display 20–2). When developmental crises occur, people feel threatened by the demands placed on them and have difficulty making the changes necessary to fit the new stage of development (Weber, 2011).

DISPLAY 20.2 MAJOR DIFFERENCES BETWEEN TYPES OF CRISES

Developmental Crisis

- Part of normal growth and development that can upset normalcy
- Precipitated by a life transition point
- Gradual onset
- Response to developmental demands and society's expectations

Situational Crisis

- Unexpected period of upset in normalcy
- Precipitated by a hazardous event
- Sudden onset
- Externally imposed "accident"

During the process of normal biopsychosocial growth, people go through a succession of life cycle stages, from birth through old age. Each stage differs from the previous one, and transitions from one stage to the next require changes in roles and behavior. Popular and classic authors such as Bridges (1980, 2001), Sheehy (1976, 1992, 1999), and Sheehy and Delbourgo (1996) have called these periods "passages" and "transitions." These transitions are times when developmental or maturational crises occur.

Most family developmental crises have a gradual onset. The change is evolutionary rather than revolutionary. People usually anticipate and even prepare to start school, enter adolescence, leave home, marry, have a baby, retire, or die. Individuals move into and through each transitional period knowing in advance that some kind of change will be

required. In many instances, people have already seen others experience these transitions. As a result, developmental crises have a degree of predictability. These developmental crises offer a time for anticipation and adjustment.

Developmental crises arise from both physical and social changes. Each new life stage confronts people with changed relationships, responsibilities, and roles. The transition to parenthood, for example, demands a change in role from caring for oneself and one's mate to include nurturing, caring for, and protecting a completely helpless infant. Relationships with adults, children, and even one's parents also change. Parenthood is an entrance into a previously inexperienced part of the adult world. New parents may fear the unknown. Will this infant develop normally? Can I give adequate care? Parents often feel anxiety about the responsibility of shaping this new person's life, satisfying society's expectations for their child's proper education and training, or bringing children into a world that is in crisis and already overpopulated. Parents may worry about the increased financial burden while struggling with mixed feelings about giving up a large measure of freedom. These transitions put people under considerable stress, which contributes to tension, feelings of helplessness, and resultant crisis. Some people adapt quickly; others cannot cope, probably because earlier developmental crises went unresolved. If people lack a repertoire of adaptive skills, even positive and planned changes can develop into crises (Display 20–3) (Fig. 20–1).

FIGURE 20–1 Young couple with a new baby.

DISPLAY 20.3 A DEVELOPMENTAL CRISIS

Marcia Sand is 39 years old. Married for 22 years, she has been a capable homemaker and mother of four children. Her husband, Lou, a construction worker for the past 20 years, thinks Marcia does a "super job at home." In the past, Marcia's time was filled with cooking, laundry, cleaning, shopping, and meeting the endless demands of the family. Their limited income prompted her to adopt many money-saving strategies. She made most of her own and the children's clothes, did all her own baking, and raised vegetables in her backyard garden. Now, the youngest of the children, Tommy, has just left home to join the Navy. Her husband spends much of his spare time at the local bar with his friends, leaving Marcia alone. With a nearly empty house and little need for cooking, baking, and sewing, Marcia has lost her sense of usefulness. She thinks of taking a job but knows her choices are limited because she has only a high school education. Marcia has not slept well in weeks; she wakes up tired and drags through the day barely able to manage the simplest task. She cries frequently but does not know why. Her hair, always neat and attractive in the past, looks bedraggled, and her shoulders slump. "I just can't seem to get on top of things any more," she complains.

Marcia has entered a developmental crisis that is sometimes called the "empty nest syndrome." She faces a turning point in her life, a time when parenting has seemingly ended. Leaving her satisfying homemaker role, she faces a new life stage filled with unknowns, changes, and a seeming lack of purpose. The transition came about gradually, almost imperceptibly, but now she must deal with it. Yet she feels unable to cope and wishes to turn to someone who would understand and lend her strength. She can be helped, but her crisis could also have been prevented at the precrisis phase. Anticipatory planning could have prevented the dilemma Marcia finds herself in now.

Situational Crises

A situational crisis is a stressful, disruptive event arising from external circumstances that occur suddenly, often without warning, to a person, group, aggregate, or community. Typically, the external event requires behavioral changes and coping mechanisms beyond the abilities of the people involved (Weber, 2011).

Such events are not predicted, expected, or planned. The crisis occurs to people because of where they are in time and space. For instance, a baby grabs her mother's hot cup of tea and burns her chest; a college student is raped in the library parking lot; an older adult falls and fractures a hip; a mother with a van full of Little League baseball players is involved in a traffic collision at a busy intersection; or a hurricane devastates a state. These events, which involve loss or the threat of loss, represent life hazards to those affected. Some crisis-precipitating events can be positive, such as a significant job promotion or sudden acquisition of great wealth; however, the change still makes increased demands on individuals who must make major life adjustments. Even positive events involve a modified grieving process, because the individuals involved may be losing or giving up old, familiar, and comfortable situations and facing stressful changes.

Community health nurses see an almost infinite variety of situational crises, including debilitating disease, economic misfortune, unemployment, physical abuse, divorce, unwanted pregnancy, drug and alcohol abuse, sudden death of a loved one, tragic accidents such as a drowning or plane crash, and many others. In each situation, people feel overwhelmed and need help to cope. Skilled intervention can make the difference between a healthy and an unhealthy.

Multiple Crises

Different kinds of crises can overlap in actual experience, compounding the stress felt by the persons involved. For example, a couple may experience a developmental crisis (birth) and a situational crisis (birth defect) simultaneously, thus compounding the resulting stress. The developmental crisis of midlife may be complicated by situational crises such as a divorce or job change. With older adults, the developmental crisis of retirement may be compounded by the situational crisis of a fire that destroys the family home. The transition a child faces entering school may occur at the same time the family moves to a new neighborhood and a new infant joins the family. The child must share the parent's attention and affection with a new sibling at a time when all the child's resources are needed to cope with starting school and adjusting to the new neighborhood. Classic research shows that accumulated stresses can lead to ill health (Holmes & Rahe, 1967; Salleh, 2008), and research continues to examine the link between chronic stress and various illnesses (Epel & Lithgow, 2014; Heidt et al., 2014). Those who normally work through one crisis in a healthy way may find that compounding events overwhelm them, causing more stress than they can handle.

HISTORY OF FAMILY VIOLENCE

Family crisis is not limited to the developmental crises people experience or the situational crises that come upon us suddenly, usually from forces—such as nature—that are external to the family. Many women and children in the world also experience the crisis of domestic violence. The terms domestic violence, family violence, and interpersonal violence refer to morbidity and mortality attributable to violence within the home setting, involving action by a family member or intimate partner. Domestic violence involves "a systematic pattern of assaultive and coercive behaviors, including physical, sexual, and psychological attacks and economic coercion, that adults or adolescents use against their intimate partner" (WHO, 2013b, para.1). This type of violence occurs worldwide and is a global public health burden (WHO, 2016a).

Global History

Family violence is not new. For centuries, children were thought of as the property of their parents, and any treatment doled out by the parents was their prerogative. In fact, most countries had animal welfare laws long before child welfare laws were adopted. In addition, the ideology of childhood that emerged in the Western world in the late 1800s assumed that only "abnormal" children needed protection. These children were casualties of an urban–industrial society and were abandoned, dependent, or delinquent—the products of social dislocation such as orphans or refugee children.

In the early 1900s, sensitive leaders concerned with child welfare issues emerged. Several international agencies were created designed to positively affect the health of children. The British Children's Act was passed in 1908, and the first White House Conference on Children was held in 1909. These were early attempts to define a role for the state in the welfare of children. The U.S. conference was the forerunner of the United States Children's Bureau (USCB), and a national voluntary organization, later known as the Child Welfare League of America, was established to complement federal agency efforts (Cheung, 2012). The USCB became a model for other countries, with well-developed programs targeting infant mortality. In one innovative program of the early 1900s, a heated, mobile, child welfare center was used in rural communities and was staffed by a female physician and a public health nurse to improve health care to children.

Other international organizations emerged in the early 1900s, including the International Association for the Promotion of Child Welfare (IAPCW), the League of Red Cross Societies (LRCS), the Save the Children Fund (SCF), and the Save the Children International Union (SCIU). The latter two agencies were immensely successful in raising funds for children in Germany, Austria, France, Hungary, and Serbia. As these organizations began serving the needs of children internationally, they moved from a sentimental depiction of victims to a medical– social–scientific view of children at risk, expanding and uncovering the concepts of child victimization, exploitation, and abuse (Cheung, 2012).

By the mid-1920s, the work of these agencies began to focus on children from non-European countries. The first conference on children from non-European countries focused on African children in 1931 and included such issues as infant mortality, child labor, education, and child slavery. In 1924, the League of Nations adopted the Declaration of the Rights of the Child, which would influence the League of Nations' successor, the United Nations (UN), in the years to come in the form of the Declaration of the Rights of the Child 1959 and the Convention on the Rights of the Child 1989. The UN continues to hold annual hearings on the Rights of the Child and has addressed global concerns, such as children without parental care, indigenous children, violence against children, children with disabilities, and economic exploitation of children (Office of the United Nations High Commissioner for Human Rights, 2014).

Children are not the only victims of family morbidity and mortality from violence. Historically, women were also treated as property and often suffered physical and psychological damage. Gender-based violence, or violence against women (VAW), has global public health and human rights ramifications (World Health Organization [WHO], 2014). Worldwide, more than 1.3 million people die each year from violence (WHO, 2014). Abuse toward women is often perpetrated by an intimate partner and is not reported. Areas of war and conflict have been known to use sexual violence toward women as a war tactic. Recent global prevalence figures indicate 35% of women worldwide have experienced IPV or nonpartner sexual violence in their lifetime (WHO, 2016c). In 2010, the United Nations Entity for Gender Equality and the Empowerment of Women was established and prioritized the prevention of and response to VAW. The first global and regional estimates of VAW was published in 2013, which resulted in clinical and policy guidelines that have been widely disseminated, and 35 countries have participated in programs to build capacity (WHO, 2014). As with children, the rights of women are socially, culturally, and religiously influenced, with change coming slowly.

United States History

The history of treatment of children, women, and elders in the United States began with early immigration to this continent and has been influenced by the cultural and religious practices of early settlers. In addition, necessity, attitudes of the time, and the stress and hardship of life in the colonies and on the frontier influenced how people were treated. Children were born into families to help with the chores of an agricultural society. Families had many children, infant mortality rates were high, and it was not uncommon for half of the children in a family to die before their second birthday. Older people did not retire; they contributed to family survival until they died. There were no special considerations for children, women, or elders. The best a woman could hope for was that the man she married would not abuse her emotionally, physically, sexually, or fiducially (taking advantage of a person's financial resources). Women had limited or no education, resources, or rights, and children had even less. If a woman married "poorly," she would have to live with the consequences. Separation and divorce were either unheard of or were a "death sentence" for the woman and her children, because there was nowhere they could go and no way for the woman to support her family (Cherlin, 2014).

Public Laws and Protection

It took many years for the United States to establish laws that benefited women and children. Nonetheless, the United States began earlier than did many other countries to protect children, women, and elders. The Children's Bureau began to focus on child abuse in the 1960s, supporting development of a child abuse mandatory reporting law in 1962 to be used as a model by the states. The law required health professionals and child care workers to report suspected child abuse to appropriate officials. In 1974, the Child Abuse Prevention and Treatment Act (CAPTA) was passed, becoming Public Law 93-247 (PL 93-247). This law served to reinforce the earlier mandatory reporting law model and was aimed at solving the growing problem of child abuse in the country. PL 93-247 has been amended several times since 1974. The Child Abuse Prevention and Treatment and Adoption Reform Act of 1978 preceded the Family Violence Prevention and Services Act of 1984. Later, all three acts were consolidated into the Child Abuse Prevention, Adoption, and Family Services Act of 1988 (PL 100-294), and most recently, the Act (PL 108-36) was amended and reauthorized as the Keeping Children and Families Safe Act of 2003 (Child Welfare Information Gateway, 2011).

This act supports funding to states in their efforts to prevent violence in families and to identify and treat victims. The funding comes in the form of the CAPTA and state grants that meet eligibility requirements. One aspect of the funding supports the National Child Abuse and Neglect Data System (NCANDS) that tracks reports of child abuse and neglect and all fatalities from child abuse or neglect in the United States. In 2015, NCANDS reported an estimate of 1,520 child deaths caused by injury or neglect (Administration for Children and Families [ACF], 2013b). Information on adoption, out-of-home care for

children, preventing and responding to child abuse and neglect, supporting and preserving families, and resources are available via the Child Welfare Information Gateway, a program under the U.S. Department of Health and Human Services (USDHHS), Administration of Children and Families. The Administration on Aging, also under the USDHHS, supports similar programs including the National Center on Elder Abuse (n.d.b) that works to educate and assist families, seniors, and health care and legal providers regarding elder abuse. The Centers for Disease Control and Prevention (CDC, 2013) provide videos and resources on violence prevention.

Healthy People 2020 Goals

The goal for *Healthy People 2020* regarding injury and violence prevention is to "prevent unintentional injuries and violence and reduce their consequences" (USDHHS, 2016a, para. 1). Determinants that affect violence include (1) individual behavior, (2) physical environment, (3) access to services, (4) social environment, and (5) societal-level factors. Through previous tracking and program strategies, new focus areas in violence prevention have been identified. Current *Healthy People 2020* trends identified for youth involve "bullying, dating violence, and sexual violence," whereas the rates and causes of elder abuse were also cited as areas needing more research and strategies for prevention (USDHHS, 2016a, para. 15).

The problem of violence is pervasive, affecting the victim directly and family members and society indirectly. Selected violence and abuse objectives for *Healthy People 2020* include the following:

- Reduce homicides from a baseline of 6.1 deaths per 100,000 population that occurred in 2007 to a target of 5.5 homicides per 100,000 population
- Reduce child maltreatment deaths from 2.3 per 100,000 children under age 18 years for 2008 to a target of 2.1 deaths per 100,000 children in 2020
- Reduce the number of adolescents carrying weapons on school property during the past 30 days from a 2009 baseline of 5.6% of students in grade 9 through 12, to a target of 4.6% (data from Youth Risk Behavior Surveillance System [YRBS], CDC, 2012).

The *Healthy People 2010* final review (CDC, 2011a) demonstrated reductions in several areas and identification of new or modified objectives for 2020. Declines were seen in the following:

- Physical assaults by intimate partners dropped from 3.6 to 2.3 per 1,000 population.
- Rape or attempted rape declined by 66.7% from 1998 to 2009.
- Physical assaults dropped by 47.6% between 1998 and 2009 in the 12 years and older population, whereas physical fighting for 9th to 12th grade students dropped by 13.9%.

The *Healthy People 2020 Leading Health Indicator [LHI] Progress Report for Violence* indicates that the homicide rate has declined 15% from 6.1 deaths per 100,000 people in 2007 to 5.3 per 100,000 population people in 2010, exceeding the HP target of 5.5 per 100,000 (USDHHS, 2014). As of March 2014, progress generally has been positive toward achieving the *Healthy People 2020* targets for the 26 LHIs, with 14 indicators (53.9%) having either met their target or shown improvement (CDC, 2014g).

Social environment and societal-level determinants are expanding in the *Healthy People 2020* tracking to investigate what works in violence prevention. This tracking is

multifocused through research, program development, and policy making. Education programs on conflict resolution coping and bullying provide data and strategies to reduce violence among students. Policies and legislation that affect social attitudes and regulations to deter violence, promote community involvement, and create safer communities are also being studied. Investigating individual behaviors, such as risk-taking, drug and alcohol use, or factors influencing individual development, guides further learning of risk, as well as prevention measures.

Myths and Truths About Family Violence

Many myths about family violence need to be dispelled. Strongly held myths by members of society, including community health nurses and other health care providers, may interfere with their ability to help families in crisis get the help they need. Table 20–1 displays some common myths and truths about family violence.

Table 20–1 Common Myths and Truths About Abuse in Families

Myth	Truth
Violence in families is rare.	Family violence is common and increasing.
Violence occurs most frequently among low-income families.	Family violence occurs across all incomes.
Violence occurs more frequently in some racial and cultural groups.	Family violence occurs across all racial and cultural groups.
Violence in families does not coexist with love.	Love may exist but is unable to be displayed appropriately because of conflicting emotions.
Men who batter women are mentally ill.	The percentage of batterers who are mentally ill is the same as in the general population.
Women who accept battering are mentally ill.	The percentage of battered women who are mentally ill is the same as in the general population; however, they have low self-esteem and a damaged spirit.
Violence occurs only in heterosexual relationships.	Domestic violence has no gender or sexual boundaries; it can occur among all people.
Abused women instigate the battering.	Quite the contrary, they go out of their way not to agitate or confront the abuser.
Abuse occurs when the abuser is under the influence of drugs or alcohol.	It can, but many abusers do not drink or use drugs.
Children should not be taken from their parents.	In some violent families, the safest place for the child is with another family member or a foster home (temporarily or permanently).
Even abusive parents are better for a child than a child living elsewhere.	Children must be protected, and living away from abusive parents may save their lives.
Abused children become abusive adults.	Some may but most can learn how to channel their emotions positively if the cycle of violence is broken.

FAMILY VIOLENCE AGAINST CHILDREN

Communicable disease is no longer the leading cause of morbidity and mortality among children. Globally, child maltreatment is a huge problem with a serious impact on victims' physical and mental health, well-being, and development throughout their lives and by extension on the health of societies in general as noted by the WHO and International Society for Prevention of Child Abuse and Neglect in a 2006 press release, yet violence directed at children is preventable. Therefore, ending violence against children would shift resources to aid in prevention of illnesses that affect children worldwide. This continuing morbidity is psychosocial in nature and is associated with behavioral problems that are more difficult to prevent than the diseases known for centuries. The effects of maltreatment of children lead to long-term conditions that include depression, suicide behavior, cardiovascular disease, sexually transmitted disease, and cancers (WHO, 2014).

Child abuse is defined by the federal CAPTA (42 USCA, 5106g) and was amended by the CAPTA Reauthorization Act of 2010 as "at minimum: any recent act or failure to act on the part of a parent or caretaker which results in death, serious physical or emotional harm, sexual abuse or exploitation; or an act or failure to act which presents an imminent risk of serious harm" (Child Welfare Information Gateway, 2012, para. 1). Child maltreatment is identified as maltreatment toward a child under age 18 that may include physical, emotional, general neglect, medical or educational neglect, physical punishment or battering, emotional or sexual maltreatment and exploitation, or other exploitation that results in actual or potential harm to the child's health, survival, or dignity in the context of a relationship of responsibility, trust, or power (WHO, 2014).

Child abuse and the associated psychosocial developmental problems are taking a toll globally in human costs and economically in health care services. Worldwide, almost 23% of adults reported physical abuse during their childhood, over 36% reported emotional abuse, and 16.3% reported neglect. Childhood sexual abuse lifetime prevalence rates are 7.6% for boys, but 18% for girls. High rates of all abuse were found in the African region. Victims of child abuse and IPV have a greater health burden, with higher numbers of health care provider visits, hospitalizations, and generally poorer health (WHO, 2014). Identifying and gathering worldwide data about child abuse is difficult because many cases are not investigated and death reports may not be classified as the result of abuse or homicide.

Another concern for children is their role in families that may require very young children to aid the family financially. A child's "chores" may include spending the whole day scrounging around city dumps gathering bits of food, clothing, or other useful or saleable items. Some children are sold for sexual favors, whereas others spend all day working in fields, home businesses, or "sweatshops" for the equivalent of pennies a day. In some societies, female children are not valued and are killed at birth, given away, or sold into slavery for a pittance.

Child abuse in the United States is most often recognized in the categories of neglect, physical abuse, sexual abuse, and emotional abuse. Often, there is an overlap of maltreatment when a report is made to Child Protective Services (CPS) or the police. The NCANDS reported 3.5 million referrals to CPS departments in 2013, and professionals (e.g., teachers, law enforcement officers, and social services) made 62% of the CPS reports. Infants (birth to 1 year) had the highest victimization rate at 23.1 per 1,000 children in the same age group (ACF, 2013a). Boys were victimized at a higher rate than were girls (2.36 vs. 1.77 per 100,000), whereas 44% of the victims were White, 22% were African American, and 22.4% were Hispanic (ACF, 2013a). Neglect continued as the category of highest occurrence at 79.3%, whereas 18% of children were found to have suffered physical abuse, and sexual abuse was determined as the primary cause in 9.2% of the investigations. Of all child fatalities in the United States, 73.9% were among children 3 years of age or younger (ACF, 2013a). NCANDS estimated 1,560 child fatalities in the United States in 2010 and 1,520 in 2013. The dependence of small children makes them vulnerable to abuse and neglect as shown in both the United States and worldwide child abuse data. Either one or both parents were responsible for almost 80% of all child fatalities (ACF, 2013a).

Nationally, measures have been taken to improve data gathering and information about violence toward children, as well as outcomes for these children. The *National Survey of Child and Adolescent Well-Being* (NSCAW) is a longitudinal study on the well-being of children who have encountered the child welfare system (Office of Planning, Research & Evaluation, 2012). Other important sources of tracking child maltreatment occur in conjunction with *Healthy People 2020*, such as *Youth Risk Behavior Surveillance—United States 2013* (CDC, 2014a; CDC, 2014g; USDHHS, 2016b). The outcomes report describes state-level data and trends, as well as the demographic data of race, age, and ethnicity. Foster care children are also covered in the outcomes report and data. One of the largest investigations ever conducted to assess associations between childhood maltreatment and later-life health and well-being is the Adverse Childhood Experiences Study [ACE]. Study findings suggest certain life experiences are major risk factors leading to illness and death (CDC, 2014b).

Child Neglect

Neglect occurs when the physical, emotional, medical, or educational resources necessary for healthy growth and development are withheld or unavailable. Neglect is obvious to an observer if a very young child is playing unattended outside, is not dressed appropriately for the weather, or has an unkempt appearance. However, neglect is not always so obvious. Parents may refuse to buy eyeglasses for a child who needs them or to access dental care for severely decayed teeth (medical neglect). An 8-year-old may get to school only 3 days a week, possibly without breakfast and no lunch money or packed lunch (educational neglect). A family with three children may live in a sparsely furnished apartment with very little food available and only intermittent heat and multiple people coming and going in the residence, while the children may appear at school unwashed and without coats in winter weather (general neglect). Emotional neglect may be seen when demands placed on a child are excessive or inappropriate for his or her development, or the caretaker berates or verbally humiliates a child frequently and without reason. Thousands of children in the United States experience neglect each day. They are frequently "invisible" victims. At times, sensational stories of severe child neglect are reported in the media and cause public outrage. Examples include 12 children found among piles of garbage in an abandoned apartment building during a drug raid; parents vacationing in Florida while their two daughters, aged 6 and 4, were left unattended at home; or three young children found barely alive, kept in a basement closet. However, most children suffering from neglect do not make newspaper headlines or television reports. They go to school like others, but if a child is fortunate, a school nurse or PHN (or a teacher, neighbor, or counselor) may discover their plight. Because of the invisibility of neglect, its prevalence is hard to estimate. Often, cases of neglect are brought to the attention of the proper authority only during the investigation of other forms of abuse or family issues (Display 20–4) (Fig. 20–2).

FIGURE 20–2 Young boy with signs of physical abuse.

DISPLAY 20.4 SIGNS AND SYMPTOMS OF NEGLECT

Neglect may be suspected if one or more of the following conditions exist:

- The child lacks adequate medical or dental care.
- The child is often sleepy or hungry.
- The child is often dirty, demonstrates poor personal hygiene, or is inadequately dressed for weather conditions.
- There is evidence of poor or inadequate supervision for the child's age.
- The conditions in the home are unsafe or unsanitary.
- The child appears to be malnourished.
- The child is depressed, withdrawn, or apathetic; exhibits antisocial or destructive behavior; shows fearfulness; or suffers from substance abuse or speech, eating, or habit disorders (e.g., biting, rocking, whining).

Physical Abuse

Physical abuse is intentional harm to a child by another person that results in pain, physical injury, or death. The abuse may include striking, biting, poking, burning, shaking, or throwing the child. Corporal punishment, which involves violence against a child as a form of discipline, was an acceptable form of discipline earlier in our country's history and is still condoned in some subgroups (ACF, 2014). Many parents today were raised in families in which physical punishment was used as a form of discipline. Even today, it is not unusual to see a parent slap the hand of a toddler to get his attention after he has been told not to do something several times or to prevent him from touching something that would hurt him more than a slap on the hand. Most families know where to draw the line. Others—especially if they were raised with "the belt" or "the switch"—see no harm in using the same physical disciplinary practices with their children.

Some parents cannot control the degree of physical punishment they give their child. In one case, a mother repeatedly physically assaulted her young daughter while getting her into the car. The mother's behavior was recorded by the store's parking lot surveillance camera. Intervention and follow-up occurred, including incarceration and counseling for the mother and foster home placement for the child. If physical punishment is administered in anger, while the parent is under the influence of mind-altering substances or out of a sense of frustration, the punishment may cross over to become battering of the child.

C. Henry Kempe identified the battered child syndrome in the 1960s as "serious physical abuse" of the child by parents or foster parents (Wolff, 2013, para 4.). This declaration led to a different viewpoint on child abuse as being something that could happen in "average families" and not just those with known psychopathic disorders. Battered child investigations require thorough follow-up and interviews with caretakers, medical personnel, family members, and school personnel. Investigators should be aware that parents often are not able to give credible or even complete explanations for the child's injuries. Severe injuries, like fracture, can be seen on x-rays. Display 20–5 lists behavioral indicators of physical abuse.

DISPLAY 20.5 SIGNS AND SYMPTOMS OF PHYSICAL ABUSE

Types of Injuries

Types of physical abuse injuries include bruises, burns, bite marks, abrasions, lacerations, head injuries, internal injuries, and fractures.

Behavioral Indicators of Physical Abuse

These behaviors are often exhibited by physically abused children:

- The child is frightened of parents/caretakers or, at the other extreme, is overprotective of parent or caretakers.
- The child is excessively passive, overly compliant, apathetic, withdrawn or fearful, or, at the other extreme, excessively aggressive, destructive, or physically violent.
- The child and/or parent or caretaker attempts to hide injuries; child wears excessive layers of clothing, especially in hot weather; child is frequently absent from school or misses physical education classes if changing into gym clothes is required; child has difficulty sitting or walking.
- The child is frightened of going home.
- The child is clingy and forms indiscriminate attachments.
- The child is apprehensive when other children cry.
- The child is wary of physical contact with adults.
- The child exhibits drastic behavioral changes in and out of parental/caretaker presence.
- The child is hypervigilant.
- The child suffers from seizures or vomiting.
- The adolescent exhibits depression, self-mutilation, suicide attempts, substance abuse, or sleeping and eating disorders.

Other indicators of physical abuse may include the following:

- A statement by the child that the injury was caused by abuse (chronically abused children may deny abuse)
- Knowledge that the child's injury is unusual for the child's specific age group (e.g., any fracture in an infant)
- Knowledge of the child's history of previous or recurrent injuries
- Unexplained injuries (e.g., parent is unable to explain reason for injury; there are discrepancies in explanations; blame is placed on a third party; explanations are inconsistent with medical diagnosis)
- A parent or caretaker who delays seeking or fails to seek medical care for the child's injury

Sexual Abuse

Sexual abuse of children includes acts of sexual assault or sexual exploitation of a minor and may consist of a single incident (sexual assault) or many acts over a long period. Sexual abuse is considered to be "exposure of a child to sexual experiences that are inappropriate for his or her level of physical and emotional development, are coercive in nature, and are usually initiated for the purpose of sexual gratification" (Trotman, Young-Anderson, & Deye, in press, p. 1). The abuse usually takes place over some extended time period, and in most cases, the child does not readily disclose the abuse. Sexual assault occurs when there is sexual contact "without consent of the recipient" (Trotman et al., in press, p. 1). It includes rape, gang rape, incest, sodomy, lewd or lascivious acts with a child younger than 14 years of age (in most states), oral copulation, fondling of the child's genitals, penetration of the genital or anal opening by a foreign object, and child molestation. Serious injuries to the child may require trauma care (Abraham, Kondis, & Merritt, 2016). Sexual exploitation of children includes conduct or activities related to pornography that depict minors in sexually explicit situations and promotion of prostitution by minors (U.S. Department of Justice [USDOJ], 2011a). Incest is sexual abuse among family members who are related by blood (e.g., parents, grandparents, older siblings, aunts, and uncles); it constitutes the most hidden form of child abuse. Intrafamilial sexual abuse refers to sexual activity involving family members who are not related by blood (e.g., stepparents, boyfriends). Of the perpetrators who sexually abused their victims, 87.8% were men. The largest relationship category was the parent (91.4%), which reflects the perpetrator could have been a parent to multiple victims. Of the parental relationships, 88.6% were the biological parent, 3.7% the stepparents, and 0.6% were adoptive parents. The age range of the perpetrator was between 6 and 75, with 63.3% being between the ages of 25 and 44, 19.2% between ages of 18 and 24, and 13.1% between ages 45 and 75. Only 2.3% were between ages 6 and 17 (ACF, 2013a). Initial sexual abuse may occur at any age, from infancy through adolescence. However, the largest number of cases involves girls younger than 11 years of age. Regardless of how gentle, trivial, or coincidental the first approach may have seemed, sexual coercion tends to be repeated and to escalate over a period of years. The child may blame himself or herself for tempting or provoking the abuser. Often, the abuser threatens the child or the child's parents in order to assure silence (Trotman et al., in press).

The mother, who is expected to protect the child, may purposely isolate herself from a problem of sexual abuse. Sometimes, the mother is distant, uncommunicative, or so disapproving of sexual matters that the child is afraid to speak up. Sometimes, she is extremely insecure and feels confrontation may cause anger or the loss of her husband or boyfriend, or the mother's economic security may depend on her partner/spouse. The mother may feel threatened or feel that she cannot allow herself to believe or even to suspect that her child is at risk. She may have been a victim herself of child abuse and may not trust her judgment or her right to challenge the man's authority in the home. Some mothers consciously acknowledge that their children are being sexually abused but, for

whatever reason, choose to "look the other way." In some cases, families may not permit the child to admit the assault and cooperate with authorities (Trotman et al., in press). Until the victim is old enough to realize that incest or intrafamilial sexual abuse is not a common occurrence, or is strong enough to obtain help outside the family, there is little chance of escape unless the abuse is reported (Townsend & Rheingold, 2013).

Indicators of sexual abuse are seen in various ways, and attention should be given to a history of sexual abuse, sexual behavior indicators, behavioral indicators in younger children and behavioral indicators of sexual abuse in older children and adolescents, and physical symptoms of sexual abuse (see Display 20–6). As mandated reporters, community health nurses should be aware that sexual abuse of a child may surface through a broad range of physical, behavioral, and social symptoms. Some of these indicators, taken separately, may not be symptomatic of sexual abuse and should be examined in the context of other behaviors or situational factors. See Perspectives.

DISPLAY 20.6 INDICATORS OF SEXUAL ABUSE

I.History of Sexual Abuse

- A child confides to a friend, a classmate, a teacher, a friend's mother, or other trusted adult that she/he has experienced sexual abuse.
- A child may disclose information indirectly by such statements as: "I know someone …""What would you do if … ?""I heard something about somebody…"
- The child has torn, stained, or bloody underclothing (among her/his clothing or is wearing it).
- Knowledge that a child's injury/disease (vaginal trauma, sexually transmitted disease) is unusual for the specific age group.
- Unexplained injuries/diseases (parent/caretaker unable to explain reason for injury/disease); there are discrepancies in explanation; blame is placed on a third party; explanations are inconsistent with medical diagnosis.
- A very young girl is pregnant or has a sexually transmitted disease. Pregnancy alone does not constitute sexual abuse, but if there are indications of coercion or significant age disparity between the minor and her partner, this may lead to reasonable suspicion of sexual abuse that must be reported.

II.Sexual Behavioral Indicators of Sexually Abused Children

- Detailed and age-inappropriate understanding of sexual behavior (especially among very young children)
- Sexually explicit language
- Inappropriate, unusual, or aggressive sexual behavior with peers or toys
- Compulsive indiscreet masturbation
- Excessive curiosity about sexual matters or genitalia (self or others)
- Unusually seductive or flirtatious behavior with classmates, teachers, and other adults
- Excessive concern about homosexuality, especially by boys

III.Behavioral Indicators of Sexual Abuse in Younger Children

- Enuresis (wetting pants or bedwetting)
- Fecal soiling
- Eating disturbances such as overeating or undereating
- Fears or phobias
- Overly compulsive behavior
- School problems or significant change in school performance (attitude and grades)
- Age-inappropriate behavior that includes pseudomaturity or regressive behavior such as bedwetting or thumb sucking
- Inability to concentrate
- Sleeping disturbances (nightmares, fear of falling asleep, fretful sleep pattern, sleeping long hours)
- Drastic behavior changes
- Speech disorders
- Frightened of parents/caretaker or of going home or being at home

IV.Behavioral Indicators of Sexual Abuse in Older Children and Adolescents

- Withdrawal
- Chronic fatigue
- Clinical depression, apathy
- Overly compliant behavior
- Over- or underreaction (hysteria or cavalier attitude) to a genital exam
- Poor hygiene or excessive bathing

- Poor peer relations and social skills; inability to make friends
- Acting out; running away; aggressive, antisocial, or delinquent behavior
- Alcohol or drug abuse
- Prostitution or excessive promiscuity
- School problems, frequent absences, sudden drop in school performance
- Refusal to change clothes for physical education class
- Nonparticipation in sports and social activities
- Fearful of showers or restrooms
- Fearful of home life as demonstrated by arriving at school early and leaving late
- Suddenly fearful of other things (going outside or participating in familiar activities)
- Extraordinary fear of males (in cases of male perpetrator and female victim)
- Self-consciousness of body beyond that expected for age
- Sudden acquisition of money, new clothes, or gifts with no reasonable explanation
- Suicide attempt or other self-destructive behavior
- Crying without provocation
- Setting fires

V.Physical Symptoms of Sexual Abuse

- Sexually transmitted diseases, especially in prepubescent girls
- Genital discharge or infection
- Physical trauma or irritation to the anal/genital area (pain, itching, swelling, bruising, bleeding, lacerations, abrasions), especially if injuries are unexplained or there is an inconsistent explanation
- Pain during urination or defecation
- Difficulty in walking or sitting due to genital or anal pain
- Psychosomatic symptoms (stomach aches, headaches, chronic pain)

Perspectives Emily's Secret

I am a school nurse in a small town. I am assigned to a large school with 1,000 children; this includes every child in town who is in grades K-3, and this is not my only assigned school. I have a busy school nurse office, but I try to be observant to subtle cues. Sadly, sometimes it is so busy that I miss things. Emily, a third grader, had been coming into my office with stomachaches and vague complaints off and on for several months. Thinking back, this usually happened within the last hour of school. After school, she walked to her aunt's house (her mother's sister) and stayed there for a few hours until her mother came to pick her up when she finished working. Emily was a petite child, very quiet, and well behaved, and she usually only responded with a few words in reply to my questions about her ailments. She came in one day with another stomachache and wanted to lie down. I had several children in my office, and when I was free, I asked her what was going on. She shrugged her shoulders and didn't really respond. The final bell rung, and I told her that if she didn't feel well enough to walk home I could call her aunt. She just seemed to really be avoiding having to go to her aunt's house; she wanted me to call her mom at work. The aunt was the emergency contact, so the procedure was to start there. I had a feeling that something was wrong. I had recently attended a workshop on child sexual abuse and remembered that sometimes the hardest thing was to break through the guilt and shame in order for the child to open up to you. I told her that she "could tell me anything, and I wouldn't think that she was bad". She knew I was there to help her, and she began talking. In fact, it was like "verbal vomiting"—the words just came spilling out of her mouth. Her uncle had been "touching her" and she "didn't want to go back there." She began crying and I told her we would call her mom and someone from CPS to help her. I sent someone to get her teacher, a woman with whom she felt comfortable and safe. I stayed with Emily through the lengthy process.

Later, as I thought about the constant stream of children coming into my office everyday, I wondered how many of those kids with subtle, vague complaints might have something they need help with that is as serious as Emily's secret. I try to be even more vigilant and open to their concerns—whatever they may be.

Josie, School Nurse

Community health nurses may be part of the Sexual Assault Response Team (SART). This group's responsibilities include obtaining the evidence and providing support to the victim and family after an episode of sexual abuse has been reported. SART members include nurses, physicians, social workers, police, laboratory personnel, lawyers, and district attorney staff (Moylan, Lindhorst, & Tajima, 2015). Care for children who have been

sexually abused varies, as the duration of the molestation, the age, and symptoms of the child will influence their care measures. Besides the physical trauma, children suffer mentally and emotionally. They have an increased risk for posttraumatic stress disorder (PTSD), major depressive disorder, anxiety, loss of self-esteem, thoughts of suicide, and substance abuse or eating disorders. Some victims of child sexual assault and abuse have early sexual intercourse and pregnancy, as well as a higher risk of later sexual victimization (Trotman et al., in press). Parents may also need counseling and support following the investigation and proceedings involving their child's victimization. Family therapy is often beneficial.

The sexual assault nurse examiner's (SANE) role is more explicit in assisting the victim and appropriate family members immediately after the victim presents to the police or to an emergency department setting. The nurse has very specific actions to take to promote trust, obtain needed specimen evidence, and treat the sexual abuse victim. The victim has already been significantly traumatized, and the nurse can be effective in this role only if trust can be established during this critical time after the sexual assault. The SANE is trained to work with victims of all ages, both genders, and under all sexual abuse situations; some specialize in pediatric populations (Trotman et al., in press).

The majority of those committing ongoing sexual abuse and assault against children are relatives, in fact, about 80% of child sexual assaults are committed by someone known to the child (Rape, Abuse, & Incest National Network, 2013). Pedophiles present a danger. A pedophile is an adult whose main sexual interest is a child and tends to be well liked by children. Pedophiles, who most often are men, frequently choose to work in professions or volunteer organizations that allow them easy access to children, where they can develop the trust and respect of children and their parents. The pedophile believes that sex with children is appropriate and often lures children into sexual relationships with love, rewards, promises, and gifts. He may be among a child's family members (e.g., grandfather, father, uncle, cousin) or a trusted community leader the child knows (e.g., next-door neighbor, teacher, coach, or religious leader). Reports of pedophiles among clergy in the Roman Catholic Church have affected the church, its clergy, and its members. The National Sex Offender Public Registry, sponsored through the Department of Justice, is used in all 50 states thereby improving efforts to safeguard all children. This resource provides information regarding the more than 500,000 registered sex offenders throughout the United States (USDOJ, n.d.).

Human trafficking of children on a national and international scale is recognized by the United States in the Trafficking Victims Protection Act (TVPA) of 2000. This federal law defined human trafficking as the recruitment, harboring, transportation, provision, or obtaining of a person for compelled labor or commercial sex or for labor or services through the use of force, fraud, or coercion (ACF, 2015). The law specifically identified any child <18 years who engaged in commercial sex as a victim of trafficking (ACF, 2015). The USDHHS established a National Human Trafficking Resource Center (2015), which operates a 24-hour crisis line in over 200 languages at 1.888.373.8888.

Emotional Abuse

Emotional abuse of children involves psychological mistreatment or neglect, such as when parents do not provide the normal experiences that produce feelings of being loved, wanted, secure, and worthy (Rodner, 2015), and can be exhibited by insults, belittling, constant humiliation, intimidation, or threats of harm (WHO, 2014). This type of abuse is commonly associated with other types of abuse and may involve verbal abuse, such as name calling, or threatening. A mother may shout at the child, "You're just like your father, a good-for-nothing, lazy bum." A father may say, "You're ugly. You look just like your mother." If the child spills some juice, a parent may scream, "Everything you do is wrong. Can't you do anything right?"

Emotional abuse may also take the form of emotional abandonment. Some parents "shun" their children as a form of punishment. They will not speak to them and do not look at them; they behave as if their child does not exist. This behavior may continue for a day or more, whenever a child displeases the parent. In some cases, the shunning lasts for days.

Verbal threats, although a common discipline practice, are also a form of emotional abuse. Examples of verbal threats include "Take your feet off the furniture or I'll chop your feet off" and "Do that again, and you'll really know what my belt feels like." In the first instance, the child might realize that the parent wouldn't really chop her feet off, but hearing the parent say such a violent thing can be emotionally upsetting. In the second instance, the parent may have beaten the child with a belt in the past, so merely threatening to use the belt again causes emotional trauma. Parental acceptance and rejection have been studied by researchers in the United States and internationally with evidence of empirical cross-cultural generalizations, antecedents, and consequences of undifferentiated rejection. Indifference is an internal psychological feeling or the physical and psychological nonavailability of the parent that is one indicator of emotional abuse (Rodner, 2015).

Emotional abuse alone is rarely reported because it is another "hidden" form of abuse. However, mandated reporters, people who have a responsibility for the welfare of children and include public and private school employees; administrators and employees of youth centers and recreation programs; child welfare employees; foster parents; group home and residential facility personnel; social workers; probation workers; health care workers including nurses, doctors, and chiropractors; animal control workers; and personnel working in film development laboratories are required by law to report *suspected* cases of severe emotional neglect or abuse or deprivation in addition to *suspected* neglect and physical or sexual abuse (Child Welfare Information Gateway, 2014). See Display 20–7.

DISPLAY 20.7 SIGNS AND SYMPTOMS OF EMOTIONAL ABUSE OR DEPRIVATION

Emotional abuse should be suspected if the child displays the following behavioral indicators:

- Is withdrawn, depressed, or apathetic
- Is clingy and forms indiscriminate attachments
- "Acts out" and is considered a behavior problem
- Exhibits exaggerated fearfulness
- Is overly rigid in conforming to instructions of teachers, doctors, and other adults
- Suffers from sleep, speech, or eating disorders
- Displays signs of emotional turmoil that include repetitive, rhythmic movements (rocking, whining, picking at scabs)
- Pays inordinate attention to details or exhibits little or no verbal or physical communication with others
- Suffers from enuresis and fecal soiling
- Unwittingly makes comments such as "Mommy always tells me I'm bad"
- Experiences substance abuse problems

Emotional deprivation should be suspected if the child:

- Refuses to eat adequate amounts of food and therefore is very frail
- Is unable to perform normal learned functions for a given age (e.g., walking, talking)
- Displays antisocial behavior (aggression, disruption) or obvious delinquent behavior (drug abuse, vandalism); conversely, the child may be abnormally unresponsive, sad, or withdrawn
- Constantly "seeks out" and "pesters" other adults such as teachers or neighbors for attention and affection
- Displays exaggerated fears

Specific Abusive Situations

The previous information addressed the major types of child abuse in families, yet other patterns of abuse against children need to be discussed. Shaken baby syndrome, Munchausen syndrome by proxy, and maternal filicide defined as a child murdered by the mother are fairly rare, but by the time the symptoms are recognized, it is often too late, with the diagnosis made during subsequent visits to the emergency department or at autopsy.

In addition, Internet crimes against children, child abduction, and crimes against children by babysitters are an increasingly common fear of parents. These types of abuse are occurring more often as children and adolescents have increased time and access to computers and because both parents (or a single parent) must work, while children are spending more time alone or with babysitters. Community concern regarding child abductions by family members or strangers has resulted in the institution of *Amber Alert* systems in many states. School violence is also an area of increasing concern for families and will be addressed.

Shaken Baby Syndrome

Abusive head trauma (AHT) sometimes called shaken baby syndrome is the intentional abusive action of violently shaking an infant or toddler, usually a child of 2 years or younger (American Academy of Pediatrics [AAP], 2015). The type of damage that occurs to these infants very seldom occurs through play, as in minor falls or as a result of tossing a baby in the air. The classic medical symptoms associated with infant shaking are bilateral retinal hemorrhage, subdural or subarachnoid hematomas, absence of other external signs of abuse, and symptoms that may include breathing difficulties, seizures, dilated pupils, lethargy, and unconsciousness (Parks, Kegler, Annest, & Mercy, 2012; Parks, Sugerman, Xu, & Coronado, 2012). These injuries occur from a violent, sustained action in which the infant's head, which lacks muscular control, is violently whipped forward and backward, hitting the chest and shoulders. According to experts, an observer would describe the shaking as being "as hard as the shaker was humanly capable of shaking the baby" or "hard enough that it appeared the baby's head would come off." AHT includes violent shaking, but also blunt trauma to the head (Allen, 2014). Within minutes to hours after the injury, the baby begins to show symptoms such as irritability, lethargy, vomiting, breathing problems, seizures, or unconsciousness. A typical explanation given by the parents or caretakers is that the baby was "fine" and then suddenly went into respiratory arrest or began having seizures—both common symptoms of shaken baby syndrome. Children who survive shaken baby syndrome may require lifelong care if they endure the AHT. Approximately 30 per 100,000 children younger than 1 year of age are injured from AHT, resulting in at least 1,200 seriously injured infants and approximately 80 deaths each year (AAP, 2015).

Munchausen Syndrome by Proxy

The term *Munchausen syndrome* was first used to describe illnesses or symptoms that were provided or simulated by patients themselves and "is a diagnosis applied to parents and other caregivers who intentionally feign, exaggerate, and/or induce illness or injury in a child to get attention from health professionals and others" (Frye & Feldman, 2012, p. 47). Clients with this disorder may intentionally injure him/herself or induce illness in him/herself. *Munchausen syndrome by proxy* is a form of child abuse played out in the medical setting (Gilbert, 2014). In such cases, a parent or caretaker attempts to bring medical attention to self by injuring or inducing illness in his or her child. About 85% to 98% of those perpetrating this are biological mothers of the child, who often form close bonds with health care providers. A majority of these abusers have some type of mental health illness (e.g., borderline personality disorders) or history of abuse in their own childhood (e.g., sexual abuse, child maltreatment, witness to IPV, family mental illness). Although less common than mothers, fathers can also be perpetrators, and often fathers are characterized as emotionally uninvolved or distant from their families and may appear overbearing and demanding to health care providers (Gilbert, 2014). The following scenarios can be typical of these cases:

- The child's parent or caretaker brings the child to the emergency department or calls paramedics repeatedly for alleged problems that have no medical basis.
- The child experiences "seizures" or "respiratory arrest" only when the parent or caretaker is present—never in the presence of a neutral third party or when hospitalized, unless the parent or caretaker reports that the incident occurred in his or her presence alone.
- While the child is hospitalized, the parent or caretaker shuts off intravenous tubes or life-support equipment, causing the child distress, and then turns everything back on and summons help.
- The parent or caretaker induces illness by introducing a mild irritant or poison into the child's body; chronic ingestion of such substances may cause the child's death.
- The child may have many school absences and a complicated medical history according to the child's mother or father who may seem overinvolved or demanding.

Health providers, mental health professionals, and attorneys may be involved in working with such cases, requiring careful attention to the history of the illness/injury, the treatment, documentation, and communication with the parent/caretaker. Allegations of *Munchausen syndrome by proxy* should be investigated by interprofessional teams that may include nurses working with children in community settings such as schools and home health care (Cabral, 2014; Gilbert, 2014; Grace & Jagannathan, 2015). Although the parent may remove the child from care or take the child to another facility or school district if the caregiver's suspicions are aroused, attention to the child's safety is paramount, and a protective order may be considered.

Child Murder by Mother or Father

A rare, yet concerning type of child death is known as *filicide*, defined as child murder by the parent (Debowska, Boduszek, & Dhingra, 2015). The parent or stepparent is frequently the perpetrator when a young child is murdered; maternal filicide is known to occur in all areas of the world. A parent was the perpetrator in the majority of homicides of children under the age of 5, with 33% being killed by their fathers and 30% being killed by their mothers (USDOJ, 2011b). In the United States, the child homicide rate is 7.2 deaths per 100,000 infants under the age of 5. Infants are most likely to be killed by their mother during the first week of life, but thereafter are more likely to be killed by a male (Child Trends Data Bank, 2015). Research indicates five common motives when a parent murders their child. An *altruistic filicide* is defined as a situation when the parent kills a child out of love, in the belief that the child's life or fate is worse than death; the parent may then commit suicide. A second motive that may occur is an *acute psychotic filicide* wherein the mother or father may suffer from delirium or psychosis and murder her or his child as a result of an unstable mental disorder. A third, and the most common, motive is *fatal maltreatment or accidental filicide* is a situation in which the child's death is an unintentional result from repeated abuse or Munchausen syndrome by proxy. *Unwanted child filicide* occurs when the child is unwanted and the parent feels the child is a hindrance. The fifth and most rare motive is a *spouse revenge filicide* when one parent murders the child as revenge toward the other parent, sometimes as a result of adultery (Debowska et al., 2015).

Infanticide is defined as the murder of a child during the first year of life, whereas neonaticide is the murder of an infant within the first 24 hours of life. Mothers exhibiting specific risk factors most often commit neonaticides— they are frequently adolescent, unmarried woman with an unwanted pregnancy, and who have received no prenatal care. One consistent feature is often denial about the pregnancy, even as labor begins. The newborn is frequently "disposed of" by "flushing down the toilet, drowning in the toilet or a tub, smashing the head with an object, stabbing….or suffocating" (Malmquist, 2013, p. 402). In the United States, these cases are often handled as homicides, but in other countries, there are specific legal provisions recognizing the physiological changes during birth and the postpartum period that can affect mental capacity and distinguish infanticides from homicides. The United States has provided "safe haven" statutes to encourage desperate mothers to leave their unwanted babies in a safe place, but has not followed suit with other countries regarding alternatives to homicide charges (Malmquist, 2013).

In a recent study, infanticide in the United States was found to be associated with economic stress. Other risk characteristics for maternal filicide include a mother who was (a) socially isolated, (b) poor, (c) acted as a full-time caregiver, and (d) often had a history of domestic violence or relationship problems. Neglectful or abusive mothers were often substance abusers, while the majority of perpetrators exhibited psychosis, depression, or suicidality (Debowska et al., 2015). The rate for infanticide in this country is estimated at

6.0 homicides per 100,000 and is similar to the adult homicide rate (Malmquist, 2013). Measures for prevention and support to mothers include parenting classes, emotional support, providing emergency numbers for support, as well as treating maternal substance abuse. See From the Case Files I for two examples of neonaticide.

From the Case Files I

Neonaticide

Case #1: A 17-year-old honor student recognized that she was pregnant, but chose not to tell her parents, friends, or her boyfriend. She kept her pregnancy quiet by wearing loose clothing and complaining that she had "gained weight" over Christmas holidays. Home alone, after school, she went into labor while sitting on the toilet. She stretched out on the bathroom floor and labored for several hours with significant blood loss. She delivered her newborn and used scissors to cut the umbilical cord. She was afraid because she had not stopped bleeding. Blood was everywhere, and she got the keys to the car and drove herself to the local hospital. On the way, she felt dizzy and seemed to pass out. Coming to, she continued to drive to the ER. Upon admission, she was treated to control the hemorrhaging. Later, an ER nurse asked about the newborn baby, and the girl said "I left it; it's on the bathroom floor." Police located the dead newborn as described, but no formal charges were ever filed.

Case #2: A 16-year-old girl, having sex with her boyfriend, became pregnant. But, she thought she was just having stomach and GI problems, so she went with her mother to see her pediatrician. He prescribed medication for her symptoms, but she got no relief. Using an over-the-counter pregnancy test, she got a negative result. Her friend encouraged her to go to the walk-in clinic and get another test, but this one was inconclusive and she was now spotting, so she continued to take her birth control pills, thinking she was not pregnant. A few months later, at a family backyard barbeque, she felt like she is getting the "stomach flu" and told her mother she was going to rest in bed. She tried to have a bowel movement, but couldn't. Eventually, she thought she might be in labor and lay down on the floor of the bathroom. To her shock and horror, she gave birth and quickly stabbed the infant and hid it in a trash bin. When the body was discovered, and a court psychiatrist later examined her, she described "watching the birth and the stabbing from a vantage point above her body." Her defense was limited to testimony about whether or not she noticed the baby's fingers moving and trying to counter the pathologist's findings that the lungs had inflated. Her attorney couldn't bring up issues surrounding her pregnancy and *neonaticidal syndrome*. The jury found her guilty of murder, and she was

sentenced to prison for a life term.

What are your thoughts about the two cases? Have you seen examples like these in your local or regional newspapers or Web news sources? What preventive programs and policies might be helpful in addressing this issue? Are there EBP population-focused interventions available to address this problem?

Adapted from Malmquist, C. (2013). Infanticide/neonaticide: The outlier situation in the United States. Aggression and Violent Behavior, *18*, 399–408.

Internet Crimes Against Children

Communication technologies provide novel opportunities to pursue, monitor or harass other people (Drebing, Bailer, Anders, Wagner, & Gallas, 2014). Internet crimes are insidious because they come right into the home. Children either unintentionally or intentionally may access an Internet chat room or Web site developed or used by pedophiles. The perpetrator establishes contact, usually passing himself off as a teen or young man who has similar interests, and states affection for and understanding of the youth's "problems." Eventually, the pedophile either sets up a meeting time and place or engages in sexually explicit dialogue with the minor. Many minors find the attention from this stranger inviting or exciting and make plans to meet the person. When this happens, the minor falls victim to this individual, putting the child/adolescent at great risk. This computer-based child abuse risk has led the U.S. Attorney General to authorize a federal awareness and justice program focusing solely on technology-facilitated sexual exploitation and abuse against children, named *Project Safe Childhood* (USDOJ, 2014) (Fig. 20–3).

FIGURE 20–3 Children and youth can be victims of Internet crimes.

Community health nurses can assist families to prevent such Internet crimes in various ways by:

- Urging parents to openly discuss with their children the dangers of online "friendships" that seek face-to-face meetings; downloading photos or uploading/posting photos to people they do not really know; giving information that identifies them (name, phone number, school they attend, home address); and responding to e-mails, messages, or tweets that are suggestive or harassing, being aware of phishing and other forms of attempted identity theft
- Establishing parent–child contracts for Internet and smartphone use
- Blocking or only permitting specific phone numbers for smartphone calls and regularly checking for deleted phone calls and texts
- Monitoring the time and Internet sites a child uses (check log of every site accessed on the computer); also the apps on their smartphones
- Keeping the computer in a high-traffic area in the home, affording easy observation of the computer monitor
- Using available parental controls or blocking software
- Installing a firewall, antivirus, and antiadware/spyware programs that increase privacy
- Discouraging downloading of apps, games, and other media that might contain Trojan or worm programs that enable remote access by unauthorized users
- Having access to their child's e-mail and other accounts; randomly checking e-mails and text messages

- Being aware of safeguards in place at their child's school, public areas your child frequents, and homes of their friends (Federal Bureau of Investigation [FBI], n.d.).

There is a constant stream of news around cyberbullying and cyberstalking incidents. Cyberstalking has been defined "as the repeated pursuit of an individual using electronic or Internet-capable devices" (Drebing et al., 2014, p. 61). Thirty-three percent of teenagers report that they have been victims of cyberbullying, and 20.8% of kids between the ages of eight and ten report that they have been cyberbullied at least once in their life (Woda, 2015). Effects of cyberbullying can be more far-reaching than those of traditional schoolyard bullying but is often easier to deal with because there is an electronic trail that provides proof to show parents, teachers, and/or even police. As a nurse, make sure families are prepared to identify and appropriately handle cyberbullying, sexting, and threats from online predators. The rule of three is to ignore, save, and report (Woda, 2015).

Furthermore, parents can contact the Cyber Tip Line at (800) 843-5678 or access the Web site (www.cybertipline.com) if they suspect that an online predator has contacted their child (National Center for Missing and Exploited Children, 2015).

Child Abduction

Child abduction is a crime that every parent fears, and although stranger abduction happens infrequently, it remains the greatest fear for parents. However, intense media coverage gives the impression that such crimes occur frequently, and this causes great stress among parents and community members. Nationally, the Amber Alert program and the Child Abduction Response Teams (CART) were established to provide a prompt and professional response to child abduction. Amber Alerts are now being sent through the Wireless Emergency Alerts (WEA) program to millions of cell phone users. The goal of the Amber Alert is to provide instant collaboration and partnership in the community to assist in the search and safe recovery of the child (USDOJ, 2013a).

Child abduction by family members or intimate partners, such as a divorced mother, father, stepparent, boyfriend, or grandparents, is more common. Nonetheless, the parent from whom the child was taken may be unaware that the abduction was by a relative or known person and may experience the same type of stress and loss as parents who lose a child by stranger abduction. In some cases, knowing the relative or person who abducted the child causes just as much fear because the abductor may have a history of violence or sexual abuse crimes.

Prevention of child abduction is difficult, and at times, parents who think they have taught their children well may have a false sense of security. Some studies assessed the effects on children of taking a "stranger awareness" class. The class included lessons on avoiding strangers, not talking to strangers, identifying who is a stranger, saying "no" to strangers, and running away and screaming if addressed by a stranger. Yet, researchers found that when the children left the classroom, if an unknown person (a stranger sent in by the researcher) asked the child to help him find a lost puppy or go help them get candy,

many of the children responded readily without using any of the actions learned in the stranger awareness class. Parents who watched their children on tapes of these studies could not believe what they saw. Children are trusting and curious, and they may not consider people who look like their parents as *strangers*.

More encompassing skills programs have been evaluated and found to be effective. *Kidpower Everyday Safety Skills Program* was tested with 128 third-graders using school-based workshops and weekly follow-up exercises, as well as homework assignments and parental involvement (Brenick, Shattuck, Donlan, Duh, & Zurbriggen, 2014). Researchers found that those third-grade students that participated, when compared to students in a control group, had increased safety knowledge at posttest and 3 months after the intervention ended. The children learned about stranger safety, but also boundary setting, help seeking, and maintaining confidence and calmness.

Community health nurses can help parents improve their child's safety by promoting close supervision of young children and practicing behaviors that promote anonymity. Ideas that help improve the child's safety include the following:

- Keeping the child in the seat of a shopping cart and holding the child's hand while in malls or stores
- Keeping a young child in sight at all times when playing outside
- Sharing parental supervision with another mother when children play, so that an adult is always supervising the children
- Not putting the child's name or initials on clothing or backpacks
- Teaching the child a "password" that only the parents and child know to use when a different person is picking them up from a neighborhood activity
- Teaching children to recognize when they feel unsafe and get help
- Making safety plans with children and having them practice getting help
- Helping children understand the different circumstances when it is OK to give out personal information (at school, MD office, lost in a store), and when it is not (stranger they don't know)
- Practicing with children about when to "think first" before they talk to a stranger and to keep walking (Kidpower, 2016, para. 8)

Older children and teens who go outside the home unattended by parents should be encouraged to use the following behaviors that promote safety: staying with groups of other children or teens, having a cell phone, leaving an itinerary with the parents, and not changing their plans without contacting parents. Other measures that can benefit older children and adolescents are attending a self-defense class and carrying a whistle and/or pepper spray.

Crimes Against Children by Babysitters

Crimes against infants and young children by babysitters have been reported in the media

(Johnston, 2013). Some parents who have suspected mistreatment of their children by caretakers have used hidden cameras to reveal the problem. Abuse by caretakers is a fear of parents who work and leave their children with others.

The community health nurse can help parents assess day care settings by providing them descriptors for finding good day care providers. Parents who use neighbors as babysitters should get references and should drop by the home or day care setting at various times during the day. They should assess their infants and follow up on any bruises, rashes, burns, conditions, or behaviors they observe that are not normal for their child. With older children, parents need to listen to them and ask about their day and activities. Parents must not ignore signs, such as a child's fear of going to the babysitter or reports of spankings, being shouted at, or other inappropriate treatment. Day care centers and many home day care programs are licensed by the state. Programs for which parent complaints have been filed with licensing agencies are monitored more closely, and the state is mandated to make changes or close the facility if necessary. Parents need to know that their child is safe and cared for when they leave them to pursue their employment or educational activities.

School Violence

An area of growing concern regarding violence against children has been in school settings. Violence in schools may range from bullying, slapping, or punching to weapon use (CDC, 2015g). Random shootings and hostage situations in schools over the past decades have fueled fears about the safety of students and promoted research into how to prevent this type of community violence affecting children. Bullying is defined as "any unwanted aggressive behavior (s) by another youth or group of youths, who are not siblings or current dating partners, involving an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated" (CDC, 2015a, p. 1). Bullying can be verbal, social, or physical or happening via Internet, text, or e-mail (cyberbullying). The child that is at high risk to get bullied may have delayed puberty, be gender nonconforming, have unique physical appearance, or be socially rejected and isolated (Simms, Bushman, & Pederson, 2016). Gay, lesbian, bisexual, and transgender youth were more likely than were heterosexual youth to report high levels of bullying (CDC, 2014c). There is evidence that bullying and violence are linked (Simms et al., 2016).

The Youth Risk Behavior Survey collects information about health and prevention issues of adolescents. Included in the survey are questions about violence risks such as fighting, use of illegal drugs, carrying a weapon, and being threatened or injured with a weapon on school property. In 2013, of a national representative sample of youth in grades 9 to 12, 8.1% of the children reported being in a physical fight on school property in the 12 months before the survey, 19.6% reported being bullied on school property and 14.8% reported being bullied electronically, 7.1% reported feeling unsafe at school or on their way to and from school, 5.2% reported carrying a weapon on school property in the 30 days before the survey, and 6.9% reported being threatened or injured with a weapon on school property (CDC, 2015h). School violence has immediate and long-term effects on students

demonstrated by an increase in depression, anxiety, psychological problems, and fear (CDC, 2015g). See Chapter 22 for more on school-aged children and adolescents.

The U.S. Department of Education, Department of Health and Human Services, and Department of Justice have collaborated to provide funding, programs, and trainings that improve school safety through the *Safe Schools Healthy Students* initiative. Six areas identified for attention in building safe school climates are

- Creating a safe school environment
- Providing alcohol, drug, and violence prevention and early intervention programs
- Supporting school and community mental health prevention and treatment intervention services
- Providing early childhood psychosocial and emotional development programs
- Addressing education reform
- Designing safe school policies (Safe Schools Healthy Students Initiative, 2016)

Risk factors surrounding youth violence can be categorized as individual risks, relationship risks, and/or community/societal risks. Individual risks for perpetrating youth violence may include a history of violent victimization; a history of early aggressive behaviors, attention deficit, hyperactivity, or learning disorders; an association with delinquent peers; gang involvement; high emotional distress; social rejection; family violence and conflict; or poor behavioral control (CDC, 2012). Low parental involvement, parental substance abuse or criminality, poor supervision, low emotional attachment to the parent, and harsh, lax, or inconsistent forms of discipline increase a child/adolescent's risk for violence (CDC, 2015h). Community and societal risk factors for youth violence are associated with diminished economic opportunities, a high concentration of poverty, transiency, and family disruption, with low levels of community participation (CDC, 2012). Youth development programs address these risk factors in schools and communities, as well as promoting activities that help students in meeting their individual needs. Mentoring has been identified as a beneficial program for at-risk teens when effectively trained and supported mentors are utilized. Social skills, conflict resolution, and programs that support student sports, arts, and extracurricular interests decrease an individual's risk in being involved in violence. School and societal strategies include surveillance, maintenance of facilities, and consistent classroom management techniques, along with adequate student supervision (CDC, 2015e). Parent involvement and education are expanding through programs such as with *Healthy Start* and parent-participation preschools, *Loving Solutions* for elementary age students, and the *Parent Project* for parents of difficult adolescents.

PARTNER/SPOUSAL ABUSE

Adult violence is rooted in childhood violence (Fig. 20–4). A father hits a mother. The mother hits her son. The son hits his sister. The sister hits her little brother. The little brother sets fire to the cat, pulls wings off butterflies, and grows up to be a spouse batterer. Although abused girls may grow up to be abusing mothers, more often they grow up to be abused wives. Researchers may refer to the term domestic violence as punching, grabbing, shoving, slapping, choking, kicking, biting, hitting with a fist or some other object, being beaten, or being threatened with a knife or gun by a spouse or cohabiting partner. The USDOJ (2015, para. 1) defines domestic violence as "a pattern of abusive behavior in any relationship that is used by one partner to gain or maintain power and control over another intimate partner"; it may be emotional, economic, physical, psychological, or sexual in nature. See Perspectives: Voices From the Community.

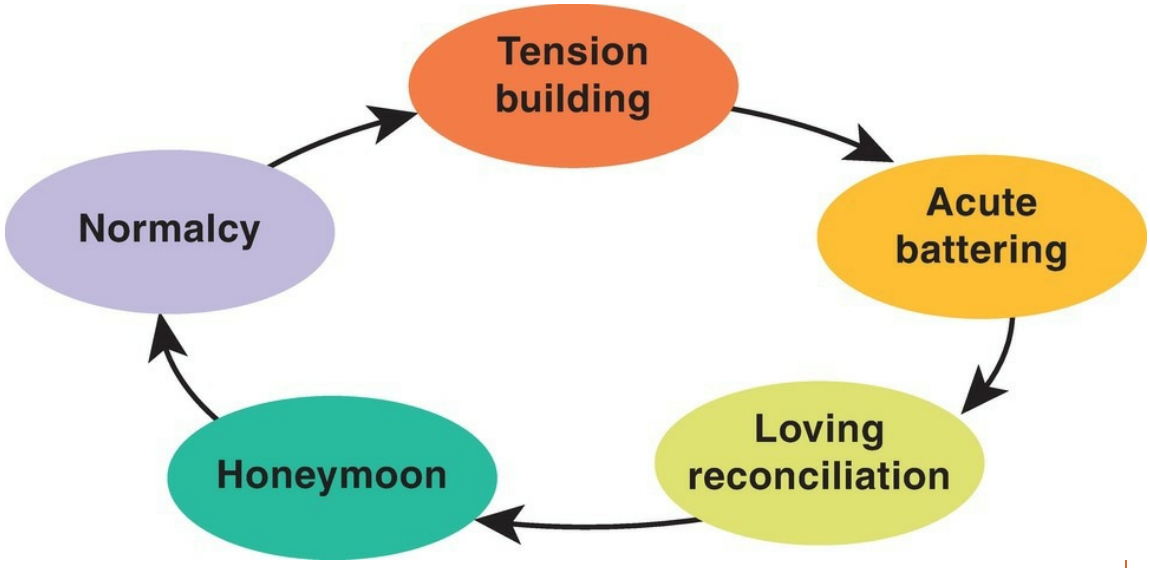
FIGURE 20–4 Domestic violence affects families and not just the immediate victims.

PERSPECTIVES VOICES FROM

THE COMMUNITY

My family was always shouting at each other—it was just the way it was. The hitting—well, that happened, but it wasn't nearly as bad as all that yelling. Now here I am in the same boat all over again—the yelling, the hitting, and I've got this new baby to take care of. I'm just so tired. When the nurse showed up today to check on the baby and me, I swore to myself I wouldn't tell her about the fight we had last night (anyway, it wasn't nearly as bad as the other times). Then she looked at me and asked if I felt safe and that was it … I said NO before I realized my mouth was even open. I told her that he punched me in the side while I was changing the baby's diaper. She was so kind—she didn't tell me how stupid I was for staying with him, but she did help me look at my options. Because I was holding the baby when he hit me, she said she was required to make a report of child abuse. That was awful news, and I started to cry; but like she said, I could have dropped her or he could have missed me and hit her. I knew he'd be furious when he found out—then I was really in a panic. Well, she told me about a place in town I can stay for a time with the baby, and she helped me make arrangements. I'm so tired and scared, but I know now that I need to keep my baby safe. I still don't know what made me tell the nurse—I guess it was because she asked. I know I'm doing the right thing for my baby and me.

Angie



Violence during adolescent relationships sets the stage for problems in future adult relationships (CDC, 2015b). As these minor episodes of violence continue, the victim typically feels that she is doing something wrong and attempts to modify her behavior. She also assumes wrongly that once she and her boyfriend are married, these physical assaults will stop automatically or that in time she will be able to "change" him, yet the cycle has already begun.

Cycle of Violence

The cycle of violence is a repetitive, cyclic pattern of abuse seen in domestic violence situations. This theory of family violence was first described as a three-phase cycle by Walker (1984), after she studied more than 1,000 battered women and a smaller group of battering men. The cycle includes the tension-building phase, the acute battering incident, and the loving reconciliation (Carrington, 2014). The psychological dynamics of these three phases help explain why women feel so guilty and ashamed of their partner's violence toward them, and why they find it so difficult to leave, even when their lives are in danger (see Display 20–8). Later adaptations of the model included additional phases: tension, buildup, standover, explosion, remorse, buyback, honeymoon, and normality (Carrington, 2014). Some like to begin with the honeymoon phase of the cycle, as this most often reflects the beginning of a relationship and the difficulty many women have in perceiving the explosive, battering phase (Carrington, 2014). Carrington (2014) also sees this cycle as more of a "vortex of violence" that sucks the woman deeper into the violence and giving her the feeling that her former self has been "spun off" the longer she remains in the relationship (p. 456). At first, her choices and security are lost, then her comfort and confidence, until finally hope, trust, and energy vanish. Often, as the cycle of violence continues, the frequency of the cycle increases, with the tension-building phase and the acute battering incident occurring more often and diminishment or elimination of the loving reconciliation phase. Without intervention, this shorter, more violent cycle becomes increasingly risk filled for outcomes that may lead to injury or maiming of a partner, incarceration, or death of a partner.

DISPLAY 20.8 THE CYCLE OF VIOLENCE

Normalcy/Calm

This is the normal, everyday interaction for the couple. The usual routines are followed and the woman feels she is in a zone of safety. There is no behavior extreme (e.g., anger/violence or honeymoon phase), but this is the time when expectations are advanced and the woman attempts to adapt to them in order to prevent another violent episode.

The Increasing Spiral of Violence

One aspect of the cycle of violence of particular concern is its progressive and spiraling nature. Once violence has begun, every study indicates that it not only continues but, over time, increases in both frequency and severity. As the violence continues, the cycle begins to change. The tension-building phase becomes shorter and more intense, the acute battering incidents become more frequent and severe, and the loving reconciliation phase becomes shorter and less intense. After many years of battering, the man may not apologize at all.

Tension-Building Phase

The woman senses her partner's increasing tension. She may or may not know what is wrong. The partner is "edgy" and lashes out in anger. He challenges her, calls her names, and tells her she is stupid, incompetent, and unconcerned about him. She "tries hard" not to make any "mistakes" that may upset him. She takes the responsibility for making him feel better and begins to set herself up to feel guilt when he eventually explodes in spite of her best efforts to calm and please him. During the increasing tension, the woman is rarely angry even at the most outrageous demands or blame. Rather, she internalizes her appropriate anger at the partner's unfairness and, instead, experiences depression, anxiety, and a sense of helplessness. As the tension in the relationship increases, minor episodes of violence

increase, such as pinching, tripping, or slapping. The batterer knows his behavior is inappropriate, and he fears the woman will leave him. This fear of rejection and loss increases his rage at the woman and his need to control her.

Acute Battering Incident: The Explosion

The tension-building phase ends in an explosion of violence. The incident that sets off the man's violence is often trivial or unknown, leaving the woman confused and feeling helpless. The woman may or may not fight back. She may try to escape the violence or call for help. If she cannot escape the beating, she may have a sense of unreality—as if it is a dream. Following the battering, the woman is in a state of physical and psychological shock. She may be passive and withdrawn or hysterical and incoherent. She may not be aware of the seriousness of her injuries and may resist help. The man discounts the episode and also underestimates the woman's injuries. He may not summon medical help even when her injuries are life threatening.

Remorse and Loving Reconciliation

The loving reconciliation phase may begin a few hours to several days following the acute battering incident. Both partners have a profound sense of relief that "it's over." Although the woman is initially angry with her partner, he begins an intense campaign to "win her back." Just as his tension and violence were overdone, his apologies, gifts, and gestures of love may also be excessive. He often promises to "never do this again." Showering her with love and praise helps her repair her shattered self-esteem. It is nearly impossible for her to leave him during this phase as he is meeting her desperate need to see herself as a competent and lovable woman. The woman's feelings of power and romantic ideals are nurtured. She believes this gentle and loving person is her "real" lover. She believes that if only she can find the key, she can stop him from further violent episodes. She believes that no matter how often it has happened before, somehow this episode seems different and it will never happen again.

Honeymoon Phase

This is a continuation of the reconciliation phase after an incident, but it is also commonly the first phase in a new relationship. When we are attracted to someone, we develop feelings and emotions that bond us to the person. The man in this phase wants the woman's trust and devotion and is "kind and loving." Some researchers feel that he is "grooming" her, much like a sexual predator does, to trust him and overlook any subtle signs that might indicate later abuse.

Walker, L. E. (1979). The battered woman. New York, NY: Harper and Row.

The Domestic Abuse Intervention Project in Duluth, Minnesota, developed a wheel of violence, identifying power and control at the center and citing eight categories of perpetrator behaviors. This model is a useful tool for visualizing the multidimensional nature of abuse in which threats, coercion, isolation, blaming, intimidation, and use of children, male privilege, and economics convene to control the victim (Fig. 20–5).

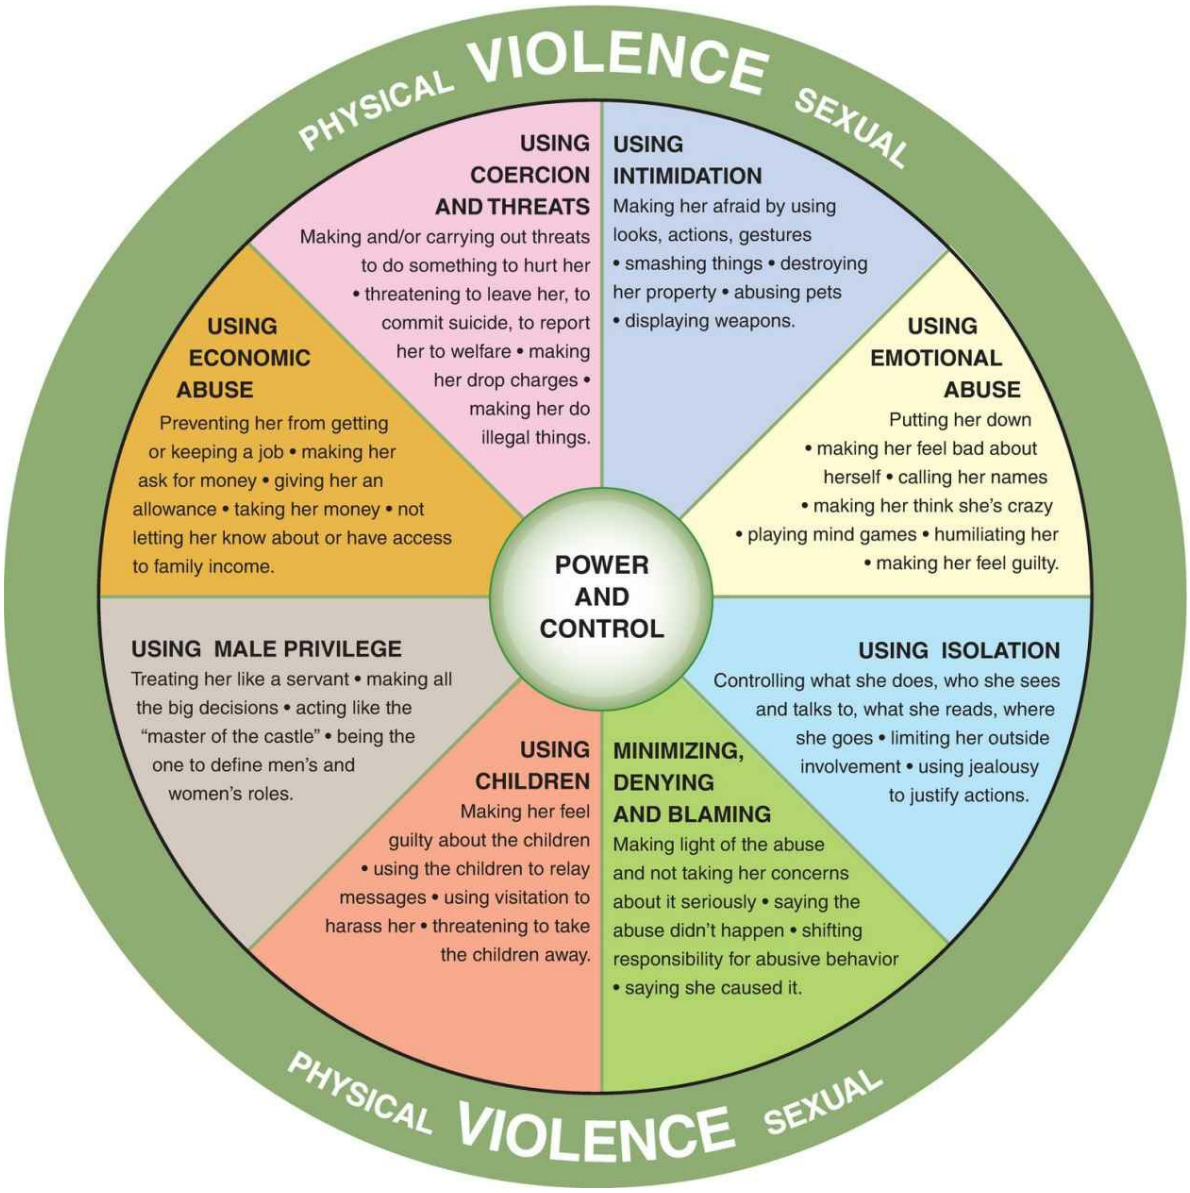

FIGURE 20–5 Wheel of violence.

Reducing violence and its effects happens strategically at all three levels of prevention. Primary prevention efforts attempt to identify risk factors, reduce risks, and increase social support to prevent violence from occurring. Secondary prevention effort involves developing immediate response to violence that addresses the short-term consequences through emergency response and medical care. Tertiary prevention interventions work to address the long-term effect of trauma through counseling and rehabilitation (CDC, 2013).

Dating Violence

Adolescent dating violence (ADV) includes physical, sexual, emotional, and verbal abuse between teenagers who are or have been in a casual or serious dating relationship. It can be electronic or in person and might occur between a current or former partner (CDC, 2015b). In the United States, ADV was reported by nearly 10% of students in the past 12 months; furthermore, victims of dating violence are at higher risk for dating violence in college (CDC, 2015b). Documented risk factors include poverty, limited education, substance abuse, poor family functioning, child maltreatment, and childhood exposure to IPV (Maas, Fleming, Herrenkohl, & Catalano, 2010; Stewart, Vigod, & Riazantseva, 2016). Research on male aggressors found that those who exhibited physical and psychological dating aggression often had a history of suicide attempts, reports of past physical aggression, and low relationship satisfaction/instability and jealousy (Collibee & Furman, 2016; Kerr & Capaldi, 2011). Teens, male or female, who experience dating violence in adolescence, are more at risk for binge drinking, suicide attempts, doing poorly in school, physical fighting, and sexual activity (CDC, 2015b). Programs through schools and communities, such as *Dating Matters*, are part of a national effort to address harmful beliefs about dating violence and promote healthy and respectful dating relationships (CDC, 2015c). Dating violence in adolescent relationships is a serious and prevalent problem (CDC, 2016). Because of its prevalence, community health nurses should include screening for dating violence in all encounters with teens.

Intimate Partner Violence

"Intimate partner violence is a pattern of assaultive behavior and coercive behavior that may include physical injury, psychological abuse, sexual assault, progressive isolation, stalking, deprivation, intimidation and reproductive coercion by someone who is, was, or wishes to be involved in an intimate or dating relationship with an adult or adolescent, and is aimed at establishing control of one partner over the other" (American Congress of Obstetricians and Gynecologists, 2012, para. 2). The WHO reported that 30% of women reported being physically abused by an intimate partner at some point in their lives, and 38% of all women who were murdered were murdered by their intimate partner. Approximately, 18.3% of women had experienced sexual violence by an intimate partner (CDC, 2011b; WHO, 2013b). Global prevalence figures indicate that 35% of women worldwide have experienced either IPV or nonpartner sexual violence in their lifetime (WHO, 2013b). The World Health Organization found that approximately 20% of women and 5% to 10% of men had experienced sexual abuse as a child (WHO, 2013a). Because of the nature of intimate partner violence (IPV), the problems are difficult to study and believed to be underreported. Much remains unknown about factors that increase or decrease the likelihood that men will behave violently toward women. Researchers have examined the physical and emotional consequences of partner violence upon women and their children, as well as the impact on their health (Grip, Almqvist, Axberg, & Broberg, 2014; Karakurt, Smith, & Whiting, 2014). There is evidence to support the importance of screening for partner violence and to support plans for interventions for a quicker and healthy recover for women and their children (Garrido, Culhane, Petrenko, & Taussig, 2011; Symes, Maddoux, McFarlane, Nava, & Gilroy, 2014). See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

Generational Transmission of Intimate Partner Violence

About one quarter of women will experience domestic violence or IPV during their lifetime, and research has linked child exposure to IPV and later adult domestic violence behavior. Some posit that children adopt behaviors that have been role modeled by parents; however, most children who have witnessed IPV do not abuse their partners in adulthood. Others found that abused children, compared to IPV-exposed children, have a similar or even higher risk of becoming perpetrators of IPV as adults. Research has also indicated that there may be an even greater effect for those children who are both abused and who witness interparental violence. Eriksson and Mazerolle (2015) wanted to know if examining gender role–specific behavior

would give a clearer indication of generational transmission. They inspected effects of experiencing domestic violence and child abuse among a group of 303 males who had been arrested on drug-related charges. Further, they examined the differences between childhood observations of mothers abusing fathers and fathers abusing mothers or bidirectional abuse on later IPV behavior in adulthood. Tools and interviews helped determine if participants had themselves been a perpetrator of IPV, if they had experienced physical abuse in their childhood, and if they had observed parental violence (and if father and/or mother was the perpetrator). The Beliefs About Wife Beating scale, along with demographic information, also provided data. Ethnicity was fairly evenly split (46.5% White, 53.5% non-White), and the majority had completed high school (63.4%). Over 44.2% had initiated alcohol use early, and almost half had tried hard drugs (49.8%) or been involved in IPV (43.6%). Almost one in five had experienced child abuse and over 40% had observed IPV, most commonly father-only violence (24.4%). Almost one third had attitudes that indicated justification for wife beating.

Using bivariate analysis, they found that having attitudes that justified wife beating and childhood observation of parental IPV were significantly associated (p = 0.043), but child abuse was not. Having attitudes justifying wife beating was not a mediating variable between childhood observation of IPV and adult perpetration of IPV, but attitudes did have a "direct effect on IPV perpetration" (p. 956). With logistic regression, they determined that those who witnessed parental IPV in childhood were significantly more likely to perpetrate IPV as adults (B = 1.76, p = 0.001 for bidirectional IPV; B = 1.02, p = 0.001 for father-only IPV) and those who both witnessed IPV and were abused as children were even more likely to be adult domestic abusers (B = 1.53, p = 0.001). No significant association was found for observation of mother-only IPV and later adult IPV perpetration. Thus, the researchers concluded that there could be a gender-specific connection to male IPV perpetration (e.g., male children who observe their fathers beating their mothers are more likely to do the same as adults).

Given this evidence and after examining other research on this topic, what interventions might you consider when working with families dealing with domestic violence?

From Eriksson, L., & Mazerolle, P. (2015). A cycle of violence? Examining family-of-origin violence, attitudes, and intimate partner violence perpetration. Journal of Interpersonal Violence, *30*(6), 945–964.

Although domestic violence is categorized as physical abuse, sexual abuse, emotional abuse, economic abuse, or psychological abuse, the victim commonly experiences a combination of these abuses or threats of abuse in these areas. Intimidation and threats create an atmosphere of fear for the victim and may include humiliation, isolation, terrorizing, coercing, blaming, manipulating, stalking, and/or destruction of property or pets valued by the partner. *Stalking* may occur by either partner in a relationship,

demonstrated as a "pattern of repeated and unwanted attention, harassment, contact, or any other course of conduct directed at a specific person that would cause a reasonable person to feel fear" (USDOJ, 2016, para. 2). During 1 year, approximately 1.5% of people age 18 or older will be victims of stalking. Divorced or separated women are at greater risk as victims of stalking, whereas harassment occurs equally between men and women (Catalano, 2012). Breiding et al. (2014) note that over 15% of women report a lifetime prevalence of being a victim of stalking behavior, and 9.3% of men. Cyberstalking, a technology-based attack, can also take many forms that can involve harassment, embarrassment, and humiliation of the victim. Approximately 1 million women and 370,000 men have been stalked through technology annually in the United States (Moore, 2014).

IPV is a leading cause of morbidity and mortality in women worldwide, as well as a public health and human rights issue (WHO, 2012b). In the United States, IPV affects more than 34.2 million women each year with 23 million being raped during their lifetime. Almost 80% of victims experienced the first rape or IPV before age 25, and 40% before the age of 18. Approximately 19.3% of women and 1.7% of men have been raped during their lifetime (Breiding et al., 2014; CDC, 2011b). Health care providers have a responsibility and opportunity to assess and initiate a safety plan when these patients are seen in the emergency room. A compendium of assessment tools for IPV can be found on the CDC Web site.

Violence During Pregnancy

IPV during pregnancy increases a woman's vulnerability to her and her fetus. A form of physical violence during pregnancy is when abusive partners target a woman's abdomen, not only hurting the women but also potentially jeopardizing the pregnancy (WHO, 2011). Abuse during pregnancy results in higher rates of intrauterine growth retardation and preterm labor that can lead to low birth weight and neonatal risks. One international study of domestic violence during pregnancy found a prevalence rate of 43.4% (Coutinho et al., 2015). Approximately 4% of women with a recent live birth in a 30-state area reported some form of IPV in the 12 months prior to becoming pregnant (Child Health USA, 2013). Abuse during pregnancy has been linked with maternal health problems such as smoking, alcohol and substance abuse, delay in prenatal care, stress, physical injuries, headaches, and lack of attachment to the infant (WHO, 2011). Among pregnant women in the United States, homicide is the second most prevalent cause of traumatic death (McMahon & Armstrong, 2012). One finding in a U.S. 11-city review found pregnancy significantly increased a woman's risk of IPV homicide, as men who abused their partner during pregnancy were particularly more dangerous and, therefore, more likely to commit homicide (WHO, 2011). *Femicide,* the killing of women because they are women, happens globally with 35% of all murders of women reportedly committed by an intimate partner (WHO, 2012a). See Chapter 21 for more on maternal child health issues.

Abuse is more likely to be reported by pregnant adolescents than pregnant adults and by women with unplanned pregnancies compared with other pregnant women (WHO, 2011). Unemployment, low levels of education, and an immigrant partner were noted as predictive factors in one study (Coutinho et al., 2015). The pregnant women in that study reported the pregnancies as planned, but not monitored closely. Teen pregnancy is linked to various types of violence, and several studies found that teens are at increased risk of abuse during pregnancy (National Campaign to Prevent Teen Pregnancy, 2014). IPV rates for adolescents seeking prenatal care range from 16% to 37% (Kulkarni, Lewis, & Rhodes, 2011). Pregnant teens that have been abused also associate with other adverse health behaviors such as smoking and alcohol and substance abuse. Once born, the infant of an abused teen or adult is at risk for child abuse.

Studies indicate that the prenatal care visit is one of the few times when women are seen by the helping professions. This visit is an important opportunity to identify women who are abused and therefore at risk for homicide. It is imperative that nurses conduct an assessment for danger and lethality, so that the women can be aware of their own level of risk and take safety precautions as needed. A series of questions requiring a "yes" or "no" response and inquiries about occurrences of abuse, escalation of abuse, frequency, severity, weapons, drugs or alcohol use by the perpetrator, and safety of other children should be incorporated into prenatal home visit assessments. This is especially important with women who have not followed through with prenatal care, thereby allowing health care professionals to monitor the progress of their pregnancies (Display 20–9).

DISPLAY 20.9 DOMESTIC VIOLENCE SCREENING TOOL

Although some research notes that screening and educational interventions/providing resources on domestic or IPV do not lead to increased knowledge and behavior change (Klevens, Sadowski, Kee, & Garcia, 2015), this type of screening remains part of the Women's Preventive Services Guidelines (Health Resources & Services Administration, n.d.).

Frame the Questions by Stating:

"Because abuse and violence are common in the lives of women, I have begun to ask about it with all women (or all pregnant women). I don't know if this is a problem for you, but I would like to ask you some questions, talk about ways to reduce your risk of being hurt, and give you some information and phone numbers that might be helpful to you."

Universal Questions

	Yes	No
1. Do you feel safe in your current relationships? Comments: _____	____	____
2. Have you ever been physically abused (pushed, shoved, hit, punched, bitten, burned, etc.)? Comments: _____	____	____
3. Have you ever been emotionally abused (neglected, called names, controlled, threatened, had your activities or decisions hindered, been	____	____

denied resources to meet your physical or financial needs)?
Comments: _____

4. Have you ever been sexually abused (forced to have an unwanted sexual act)? _____ _____
Comments: _____

5. Have your children ever been threatened or abused?
Comments: _____

6. Do you want to talk to someone about receiving help? _____ _____
Comments: _____

Batterer Characteristics

Although men who batter come from all walks of life educationally, culturally, and socioeconomically, perpetrators have some common characteristics. The following attributes represent personal characteristics often seen in batterers:

- Low income
- Low self-esteem
- Low academic achievement
- Involvement in aggressive or delinquent behavior as youth
- Heavy alcohol and drug use
- Depression
- Anger and hostility
- Personality disorders
- Prior history of being physically abusive
- Having few friends and being isolated from other people
- Unemployment
- Emotional dependence and insecurity
- Belief in strict gender roles (e.g., male dominance and aggression in relationships)
- Desire for power and control in relationships
- Being a victim of physical or psychological abuse—this is consistently one of the strongest predictors of perpetration (CDC, 2015f, para. 4).

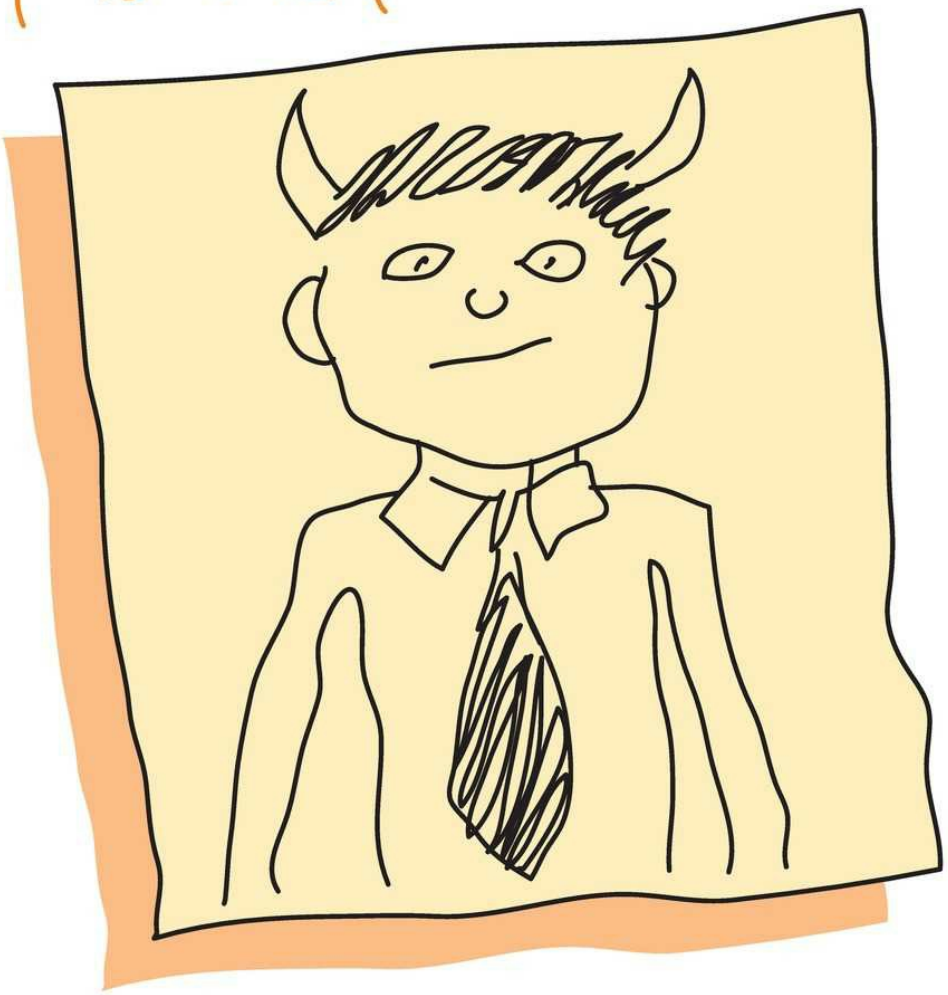
Relationship, community, and societal factors have also been identified that affect a perpetrator's risk for battering. Identified relationship factors include marital fights and tension, divorce and separations, money problems, and problematic and difficult family relationships, as well as the male's need for dominance and control in the relationship. Societal factors associated with increased risk are strict role stereotyping about the roles the husband and wife should follow in a relationship. Aspects identified within a community that lead to increased risks for IPV may be a lack of resources in the community, a failure or unwillingness of others to intervene or contact authorities when they are aware of the abuse, and factors associated with poverty, such as overcrowding and unemployment (CDC, 2015f).

Victim Characteristics

Studies have also revealed risk factors associated with victims. Increasing the victim's abilities to manage and improve their behaviors and understanding of relationship patterns and abuse allows victims to change their risk of being a victim. Individual risk factors for IPV victims include:

- A prior history of IPV
- Being female
- Young age, especially if pregnant
- From low-income household
- Witnessing or experiencing violence as a child
- Lower education level
- Unemployment
- Single parent with children or separated/divorced/previously widowed
- For men, having a different ethnicity from their partner
- For women, having a greater education level than their partner
- For women, being American Indian/Alaska Native or African American
- For women, being disabled
- For women, having a verbally abusive, jealous, or possessive partner
- Veterans and active-duty military
- Some research indicates higher levels of IPV (especially emotional victimization) in same-sex couples (Hart & Klein, 2013)

Marked differences between partner's incomes, levels of education, or job status place a victim more at risk for IPV. Community characteristics are similar to those of the perpetrator, revealing that those communities with fewer available resources, in areas of poverty, and having a lack of sanctions against violent behaviors increase one's risk; there is some indication that rates of IPV are higher in rural versus urban areas. Traditional gender roles, such as a belief that men work and women are submissive and should stay home, are societal risk factors associated with higher IPV risk (Hart & Klein, 2013).



Effects of Violence on Children

Twenty to fifty percent of children around the world suffer from abuse (Finkelhor, 2013). The consequences of exposure to violence and abuse hinder children's health and development and can have lifelong impact, negatively affecting health and increasing the risks of further victimization and becoming a perpetrator of violence (WHO, 2013a). Sexual assault in children can result in PTSD, suicidal thoughts, depression, and later risk of substance abuse and nonviolent or violent criminal behavior (Trotman et al., in press). Children who are exposed to family violence are more at risk for abuse and for violence later in their life as either a perpetrator or a victim. Although domestic violence may not be directed at a child, that child may become a victim as a bystander or when trying to protect a parent. Effects of family violence are often seen in emotional, cognitive, physical, and/or behavioral manifestations of the child. Children who have been exposed to violence are more likely to use drugs and alcohol, experience depression anxiety and/or posttraumatic stress syndrome, do poorly in school, or exhibit delinquency/participate in criminal activity. More immediate child reactions include high levels of activity, anxiety, and aggression, as well as problems with sleep/nightmares, concentration, and separation anxiety (National Child Traumatic Stress Network, n.d.).

Most often, wife abuse and child abuse occur together. Literature reviews consistently suggest that a positive correlation exists between children's witnessing IPV and some aspects of impaired child development. Young children are particularly vulnerable to the effects of violence, as they lack the ability to understand the trauma and are likely to exhibit somatic complaints (e.g., headaches, eating or sleep problems) and/or behavior regression, such as clinging, whining, or becoming nonverbal (National Child Traumatic Stress Network, n.d.). Meanwhile, school-age children and adolescents are more likely to either act out with delinquent behaviors or withdraw. It is more common for girls to become withdrawn and an important reason for health care providers to include an assessment for family violence concerns. Children in families with domestic violence are at risk for depression, negative mental health effects, and consequences that last far into their adult lives. These maladjustments may be behavioral (aggression and conduct problems), emotional (withdrawal, anxiousness, fearfulness), social, cognitive (learning disabilities), and/or physical. Researchers have linked physical alterations in the child's brain (e.g., cerebral cortex, limbic system, corpus callosum, hypothalamus) with PTSD following child exposure to domestic violence (Tsavoussis, Stawicki, Stoicea, & Papadimos, 2014). For some children, high cortisol and other hormonal responses may lead to chronic levels of arousal, aggression, anxiety, depression, eating disorders, and other problems (e.g., self-harm, general irritability). In others, during adulthood, attempts to adjust to new stressors may lead to down-regulation of receptors and the ability to only respond minimally to stress hormones. Providers who work with children need to listen in a sincere, nonjudgmental manner and provide ongoing support when assisting the child and family with resources, such as counseling, education, or community violence prevention programs

(Fig. 20–6).

My Daddy is a Monster

He hurts my mommy
He hurts me too
Sometimes he hits
Sometimes he says things
that scare me and
make my mommy cry
after he leaves
Sometimes I wish he
won't come back ...ever.
I love my daddy.

FIGURE 20–6 Poster of “My Daddy Is a Monster.”

MISTREATMENT OF ELDERS

"Elder mistreatment (i.e., abuse and neglect) is defined as intentional actions that cause harm or create a serious risk of harm (whether or not harm is intended) to a vulnerable elder by a caregiver or other person who stands in a trust relationship to the elder. This includes failure by a caregiver to satisfy the elder's basic needs or to protect the elder from harm" (National Center on Elder Abuse, Elder Abuse [NCEA], 2013b, para 3). The mistreatment or exploitation of older adults may involve physical, sexual, or emotional or psychological abuse; neglect; abandonment; financial or material exploitation; or self-neglect or any combination of these mistreatments (NCEA, n.d.a; Falk et al., 2012). Of the population ages 60 or older, 1 out of every 10 who live at home suffers abuse, neglect, or exploitation. Abuse against elders is not new, but research on elder abuse is new. Until recently, the reasons for elder abuse were extrapolated from the literature on abuse in younger populations. The Elder Justice Roadmap (USDOJ, 2013b) provides specific recommendations for five top priorities and delineates action items for direct service, education, policy, and research.

As longevity increases, and the number of elderly individuals in the population increase, so does the incidence of elder abuse (Administration on Aging, 2015). Forms of physical abuse were found to include rough handling during caregiving, pinching, hitting, and slapping. Emotional abuse, which can take many forms, included being shouted at or threatened and having needed care withheld. More rarely, elders are sexually abused, which may include rape. Some elders are neglected by those they depend on to meet their caregiving needs. Elders with dementia and those requiring assistance for all activities of daily living (ADLs) are more at risk because of caregiver stress or burnout, which increases an elder's risk for abuse and neglect. With neglect, the elder may appear unwashed and unkempt or may suffer from malnutrition and dehydration or even pressure sores. Elders who are dependent on others for their care often do not report abuse for fear of being abandoned. They feel powerless and at a loss about how to change a bad situation. They often fear reprisal from the perpetrator if they tell others about the abuse.

Older adults are frequently exploited in a variety of ways. Family members may take their Social Security retirement money, savings, or investments and use these funds on themselves. Criminals often approach elders with get-rich-quick schemes, sham investment opportunities, or overpriced home repairs or as collectors for illegitimate charities, thereby preying on the trusting nature of older adults. See Chapter 24 for more on older adults.

Perpetrator and Victim Characteristics

The incidence and prevalence of elder abuse is very difficult to estimate as every 1 in 24 cases are not reported, but estimates are often about 1 in 10 elderly experiencing some type of abuse (National Center on Elder Abuse [NCEA], n.d.b). Adult protective services show an increased trend in reporting, and information is becoming more available.

Approximately two thirds of elder abuse victims are women, often about half of individuals suffering from dementia (USDOJ, 2013b). Ninety percent of abusers are family members, most often the elder's adult children, spouses, and partners. Family members who feel burdened by their caregiver responsibilities and who abuse drugs or alcohol or have a mental or emotional illness abuse at higher rates than those who do not (NCEA, 2013b).

The dominant underlying factors that contribute to abuse of an elder by a family member are social isolation and pathology on the part of the perpetrator. Research has identified emotional or financial dependence on the victim, alcohol use, and isolation or few external contacts as major contributing factors. Abuse happens more frequently to elderly individuals with dementia, and individuals with mental illness are often perpetrators (Rosen, 2014).

Some characteristics of older people appear to increase their risk of abuse. These risks include dementia and poor health, increased age, disability, and lesbian, gay, bisexual, and transgender (LGBT) lifestyle and being a resident of an assisted living facility (NCEA, 2013a). Newly diagnosed cognitive impairment correlates with occurrences of abuse. If violence or threats of violence by the elder toward the caregiver accompany dementia, this contributes to the elder's risk for abuse. The failing health of an elder may also contribute to self-neglect or diminished ability for self-defense or escape from maltreatment. Finally, if the abuser and victim live together, the close proximity can bring up unresolved family conflicts or create new conflicts and tension (NCEA, 2013b). Abuse in an elder often leads to a downward spiral in their life with a loss of independence, increased health complications, and greater risk of mortality especially in most vulnerable populations (Dong & Simon, 2014).

Risk Factors

Regardless of the type of abuse an elder suffers or the motivation of the abuser, two factors are common to all elder abuse situations. The first factor is the *invisibility* of elders in general and abused elders specifically. Reasons for invisibility among the elderly are multifaceted. Older people usually have less contact with the community. They are no longer in the workforce or in public on a regular basis, which keeps their problems hidden longer. In addition, older adults are reticent to admit to being abused or neglected. Because the abuser is most often a family member, the elder desires to protect the abuser; without this abusing family member, the elder may be entirely alone. On the other hand, the elder may fear reprisal from the abuser for coming forward with a self-report of abuse or telling someone about the home situation. Cultural and societal values also contribute to keeping "family matters" private, while shame and embarrassment make it difficult for many elders to tell others of the abuse (New York City Elder Abuse Center, 2013).

The second risk factor is the *vulnerability* of older adults. Vulnerability refers to a cluster of risk factors that include age, sex, race and ethnicity, socioeconomic status, cognitive impairment, depression, functional ability, social network, and social participation (Dong & Simon, 2014). Many elders who are frail are dependent on others for some aspect of their day-to-day survival. At first, they may need to rely on others for transportation, shopping, and housekeeping. Later, they may need help with financial affairs, cooking, and laundry. In time, the elder may need help managing medications, bathing, and eating. The degree to which an elder needs assistance is often kept hidden from others because the elder fears being removed from his present living situation and being placed in a more restrictive environment. Additionally, vulnerability in elders is increased when any of the following characteristics are present: (1) impairment and isolation, (2) poverty and pathologic caregivers, (3) learned helplessness and living in a violent subculture, and (4) living in deteriorating housing and crime-ridden neighborhoods.

Prevention of Elder Abuse

Awareness of elder abuse and education about the types of abuse via media campaigns has improved community recognition of the problem. Increasing attention is now directed at the unique care needs of elders, including resources for the elderly, and the need for caregiver respite has also received increased attention and services. Training for caregivers as well as health care and social service providers that focus on recognizing stress and initiating measures for intervening has developed new understanding of effective interventions (e.g., use of physical therapists, occupational therapists, and geropsychiatrists). Statutory requirements for reporting abuse and providing crisis hotlines for reporting elder abuse are also integral aspects of a community's response to the problem of elder abuse (Falk et al., 2012). World Elder Abuse Awareness Day has been designated as an annual observance on June 15th to promote public awareness and prevention education regarding elder abuse (NCEA, 2015).

OTHER FORMS OF FAMILY VIOLENCE

Three other forms of violence that directly affect families are suicide, homicide, and rape. These three forms of violence demonstrate the ultimate extreme of violence to the victim and are the most traumatic to the surviving family members.

Suicide

Suicide is taking action that causes one's own death. In the United States, suicide is the 10th leading cause of death. Not all suicide attempts are successful, approximately 1.3 million adults (aged 18 or older) attempted suicide in 2013 (CDC, 2015d). These attempts to cause or actually cause self-harm are known as *parasuicidal acts*. In 2013, 494,169 individuals were treated in emergency departments for self-inflicted injuries (CDC, 2015d). Gender has an influence on suicide rates and fatalities—men are four times more likely than women to die and represent 77.9% of all suicides (CDC, 2015d). The *Healthy People 2010* goal was to reduce suicides to not more than 6 per 100,000 people, yet in 2013, there were 41,149 suicides, a rate of 12.6 per 100,000. Suicide is the leading cause of death among persons aged 10 to 14.

Worldwide, 75% of suicides occur in low- and middle-income countries with a global mortality rate of 11.4 per 100,000 people. The estimate for suicide attempts is up to 20 times more frequent than the fatality rate. Older men have traditionally had the highest suicide rate, 57% higher in men than in women, although there is a noted increase in younger and older people in higher-income countries (WHO, 2016b). The association between mental health disorders and suicide is well established in high-income countries, particularly depression and alcohol use disorders; many suicides happen impulsively in moments of crisis. Rates are high in vulnerable groups such as refugees, migrants, prisoners, and LGBT populations (WHO, 2014).

It is important to be aware of warning signs of potential suicide when working with people in crisis. The strongest risk for suicide is a previous suicide attempt (WHO, 2014). Warning signs fall into three categories: what the person talks about, types of behaviors, and mood. The more warning signs the greater the risk (American Foundation for Suicide Prevention [AFSP], 2016). An individual may talk about not having a reason to live, feeling trapped, or suicide. Threats or comments that indicate a plan or giving personal items away are potential indicators of a person contemplating suicide. Isolation, sleeping too much, acting recklessly, and increased use of alcohol or drugs are high-risk behaviors for suicide. Moods that may reflect increased risk are depression, irritability, rage, humiliation, and anxiety. Access to guns increases one's risk regardless of age, gender, or ethnicity because firearms are the most utilized method of suicide. Health providers and others may find *IS PATH WARM*, a mnemonic from the American Association of Suicidology helpful when looking at possible warning signs for suicide (AAS, 2014). These signs are:

I—ideation
S—substance abuse
P—purposelessness
A—anxiety
T—trapped
H—hopelessness

W—withdrawal

A—anger

R—recklessness

M—mood change

Completed suicides are carried out in a variety of ways, some more violent than others. Women usually choose less violent methods, such as overdosing on medications. Men choose more violent forms of suicide, such as hanging, use of firearms, or vehicle crashes. Deaths from suicide are underreported because of a tendency to group them as accidental deaths or deaths from undetermined causes. See Chapter 27 for more on behavioral health in the community.

Community awareness campaigns and education programs are needed to help a person recognize the risks and the importance of initiating prevention for someone who is suicidal. Crisis hotlines with 24-hour access are a vital resource for a distraught individual, friend, or loved one to contact and find help during a crisis and to learn about local resources to contact. Appropriate and consistent treatment, most often a combination of antidepressants and psychotherapy approach, is needed for those suffering from depression because individuals with a major depressive disorder have approximately a 20 times higher risk for suicide than the general population (AAS, 2014). The surviving loved ones require attention to their grief and bereavement. Support groups often provide benefits, allowing the bereaved to share their intense feelings of guilt and learn how to deal with any sense of a stigma, embarrassment, or shame felt by the survivors.

Homicide

Homicide is any non–war-related action taken to cause the death of another person. Violence has historically been associated with crime and is generally categorized by the method or age group affected. In 2012 globally, intentional homicide took the lives of half a million people (United Nations Office on Drugs & Crime, 2016). In 2013, 12,253 murders were committed and 89.3% involved males. In incidents of murder in which the victim relationship was known, 55.9% were killed by someone they knew, 24.9 % of victims were killed by family members, and the relationship was unknown in 45.5 % of murder and manslaughter incidents in 2013 (FBI, 2014). Young adults ages 18 to 24 had the highest homicide rate of any age group from 2002 to 2011 with a rate of 11.9 per 100,000 in 2011 (Bureau of Justice Statistics [BJS], 2013).

The homicide rate in the United States has declined by nearly half, from 9.3 to 4.7 per 100,000 in 1992 and 2011, respectively (BJS, 2013), which is below the *Healthy People 2020* objective of 5.5 per 100,000 (USDHHS, 2016a). Many homicide casualties are victims of domestic abuse as the cycle of violence escalates; a partner may be killed during a violent episode or by a recruited third party. Homicide in young infants and children is most often perpetrated by a parent, a stepparent, or a caregiver. Conflict between adolescent males may escalate if weapons or guns are available, resulting in homicide.

Evidence suggests that violence can be prevented by measures aimed at individuals, families, relationship, community, and society. The Community Guide provides evidence-based recommendations for each level of prevention (CDC, 2015e). Although biologic and personal factors may influence one's predisposition to violence, an interaction between one's family, community, cultural, and other factors combine to create violence (WHO, 2014). The WHO cites four key steps in developing a public health approach to violence. These steps include

- Uncovering as much knowledge as possible about all aspects of violence
- Investigating why it occurs
- Exploring means of violence prevention
- Taking action, which includes disseminating information and evaluating programs' effectiveness (WHO, 2014)

Prevention methods include education programs for preschool, school-aged children, and adolescents to decrease bullying and improve social skills; parent education courses and parent resources such as advice lines, support groups, or a crisis nursery; and community measures that improve firearm safety and reduce firearm injuries.

Rape

Rape is an act of aggression in which the perpetrator is motivated by a desire to dominate, control, and degrade the victim. Once considered an act of sexuality, it is now believed to be a combination of domination and sexuality or defined as a "sexual expression of aggression." The National Violence Against Women Survey (NVAWS) working with the CDC and National Institute of Justice reports that 302,091 women and 92,748 men are raped each year in the United States. Furthermore, the survey estimates that one in five women and one in 71 men have been a rape victim at some time during their life, with 42.2% of all rapes occurring before the age of 18 and 12.3% of the rapes occurring before age 12 of female rape victims (CDC, 2014f). Female rape victims reported intimate partners (51.1%), family members (12.5%), and acquaintances (40.8%) as perpetrators (CDC, 2014e).

The violence of rape creates physical and psychological harm for the victim and those close to them. Health problems for the victim may include head, pelvic, back, or facial pain; depression; suicidal ideation; eating disorders; gastrointestinal disorders; or substance abuse (Breiding et al., 2014). Fear, anxiety, or shame may become debilitating for the victim. Counseling and professional care are necessary for the rape victim from the time the rape is reported through any legal process that may result.

Community measures useful in preventing rape include Rape Prevention and Education (RPE) program for adolescents and college students, date rape education, hotlines staffed to provide help for victims of rape or VAW, and having trained professionals, such as SART members, on hand (CDC, 2014d). SART members are trained to understand the psychological and physical assessment needs of the victim, as well as the legal requirements for an investigation and court proceeding (Moylan et al., 2015). Rape crisis centers and state sexual assault coalitions work together with law enforcement, health care providers, and community-based organizations (CBOs) to provide community education and care and support to victims.

LEVELS OF PREVENTION: CRISIS INTERVENTION AND FAMILY VIOLENCE

Family violence is a family crisis and needs intervention. Community health nurses are in a unique position to prevent, identify, and intervene during crisis situations. Because community health nurses encounter people in their own settings, a more accurate assessment with direct observation, discussion, and intervention can occur. The community health nurse's assessment skills, familiarity with the community, and access to resources enhance his ability to help families in crisis. By using the three levels of prevention, the nurse can begin to assist families in a variety of ways to counter problems arising from domestic violence.

Primary Prevention

The cycle of violence within the family can be interrupted. Even when partners, spouses, or parents have been brought up in violent homes by abusive parents, they can learn to rechannel and control their emotions and behaviors and use more appropriate coping strategies. Primary prevention is the most effective level of intervention in terms of promoting clients' health and containing costs. Primary prevention reflects a fundamental human concern for well-being and includes planned activities undertaken by the nurse to prevent an unwanted event from occurring, to protect current health and healthy functioning, and to promote improved states of health for all members of a community. For the community health nurse, any activity that fosters healthful practices will counteract unhealthful influences, thereby empowering an individual or family help prevent a crisis. Health promotion must take into account the physical, psychological, sociocultural, and spiritual needs of the individual and family.

Opportunities for families to improve relationships with their partner or spouse and children may begin with learning social problem-solving skills. Both partners benefit by participating in these learning sessions/opportunities. Assertiveness skills for women provide a foundation on which additional empowerment can build. Many people have not learned positive problem-solving skills that are socially acceptable, while women may have learned passivity and submissiveness in response to their own childhood parenting or from an abusive upbringing.

Healthy self-esteem improves education and occupational success. If poverty is a factor related to the violence, adequate educational preparation and having a successful employee role may eliminate this stressor. Violence occurs across all socioeconomic levels; however, if a family is so impoverished that its basic needs cannot be met, stress can lead vulnerable family members to seek illegal ways to solve their financial problems. Living in neighborhoods where criminal activity is common often leads to increased violence and risk of abuse.

Parenting, one of life's most difficult roles, influences children in their coping strategies, decision-making, and sense of self-confidence. Parenting classes are an important resource to assist parents, particularly parents who are at high risk, such as teens, people with no exposure to children in their upbringing, and people raised in violent and abusive families. Parenting classes offer an opportunity for parents to share information and the stresses of parenting, while learning new strategies for managing their children's behaviors and appropriate physical, emotional, and developmental expectations for their children's ages.

Community health nurses often make home visits to families based on referrals from hospital perinatal departments. During the mother's postpartum stay, a nurse may have noted some inappropriate parenting behaviors or that the parents may meet high-risk parameters set by the hospital, such as being age 17 or younger, being a single parent, or

having a history of substance abuse. On the first few visits to the family, the nurse can assess parenting skills and need for further teaching. If a parenting class is recommended, the course should cover age-appropriate content, such as safety, breast-feeding, formula preparation, food progression, anticipatory guidance for growth and development, discipline techniques including behavior modification and time-out, well-baby care, and immunizations. Additional benefits for the parents are the social support they receive from participating with other parents and having the opportunity to share needs and concerns about child rearing.

Home visiting has been formalized into public health nursing model programs around the country, based on two decades of work by David Olds and others. This evidenced-based program has shown that nurse follow-up and interventions during the pregnancy and for the first 2 years of the child's life was effective in preventing child abuse, decreasing the mother's reliance on government assistance, having mothers with longer spacing between their children and fewer subsequent pregnancies, and improving health habits, such as less smoking by mothers (Eckenrode et al., 2010; USDHHS, 2011). In these programs, a nurse visits the mother and child on a regular basis over 1 to 3 years, teaching and role modeling parenting techniques, providing needed support, and initiating necessary referrals. Home visitation by nurses is a means of reducing all-cause mortality among mothers and in first-born children preventable-cause mortality (Olds et al., 2014; Miller, 2015).

The interrelatedness between families and communities cannot be overlooked or underestimated. Neighborhoods need to be enfranchised, developed, and attentive to the needs for health and safety for all community members. Empowered families and communities can take back their neighborhoods from criminals, and their empowerment acts as a source of growth for other families.

Secondary Prevention

Early diagnosis and prompt treatment of the effects of family crisis or violence is the focus at a secondary level of prevention. Secondary prevention seeks to reduce the intensity and duration of a crisis and to promote adaptive behavior. By creating a positive relationship with family members and seeing them in their homes, the community health nurse can often uncover and intervene in a crisis or stop abusive situations.

FIGURE 20–7 PHN client in a homeless shelter.

People in crisis need help. Often, they desperately want help. The crisis, or violence, and its associated disequilibrium, has a twofold effect on the individuals involved: it renders them temporarily helpless and unable to cope on their own, and it makes them especially receptive to outside influence. Community health nurses can implement crisis resolution models to assist clients at the secondary level. The following process has been used successfully in the mental health field by those working on crisis hot lines, in mental health centers, or in emergency departments (James & Gilliland, 2013). These steps are as follows:

1. Establish rapport.
2. Assess the individual and the problem for lethality.
3. Identify major problems and intervene.
4. Deal with feelings.
5. Explore alternatives and coping mechanisms.

6. Develop an action plan.
7. Follow up, including anticipatory planning for coping with future crises.

People in crisis will seek and generally receive some kind of help, but the nature of that help may act in favor of or against a healthy outcome from which the participants can grow and evolve. A client's desire for assistance gives the helping professional a prime opportunity to intervene; this opportunity also presents a challenge to make the intervention as effective as possible (Fig. 20–7). Behaviors found to be helpful in these interventions include the following:

- *Respect confidentiality*. Discussions must occur in private, without other family members present or in within the proximity for hearing. Confidentiality is essential to build trust and ensure the client's safety.
- *Believe and validate the client's experiences*. Listen to and believe the client. Acknowledge the client's feelings, and validate that many others have had similar experiences.
- *Acknowledge any injustice*. In the case of violence, acknowledge that no one deserves to be abused.
- *Respect clients' autonomy*. Respect their right to make life decisions, particularly regarding whether to involve the police. Validate and respect clients' choices. They are the experts in their lives.
- *Help the client plan for future safety*. What past strategies have been successful for self-protection? Does the client have a safe place to escape to if necessary? If children are involved, what plans are available to protect them? Help clients to recognize danger in their lives.
- *Promote access to community services*. Know the resources in your community. Is there a shelter for battered or homeless clients? A domestic violence hotline? A rape crisis center? Give clients the appropriate phone numbers (James & Gilliland, 2013).

The Quality and Safety Education for Nurses Project [QSEN] provides a guide for preparing future nurses to improve the quality and safety of the health care system in which they work (QSEN Institute, 2014). Knowledge, skills, and attitudes are delineated for the domain of safety. Although framed specifically for acute care settings the domain of safety identifies factors that create a culture of safety such as communication and reporting systems (i.e., mandatory reporting). Effective use of strategies to assess and reduce harm is important when working with families in crisis. Valuing safety, vigilance, monitoring, and reporting are skills necessary for community health nursing practice.

One goal of crisis intervention should be to help clients reestablish a sense of safety and security while allowing them to ventilate their feelings and have those feelings validated. This process helps reestablish equilibrium at as healthy a level as possible and can result in client change and growth. Minimally, the goal is to resolve the immediate crisis and restore clients to their precrisis level of functioning. Ultimately, however, intervention seeks to

improve their functioning to a healthier, more mature level that will enable them to cope with and prevent future crises. As discussed earlier, crises tend to be self-limited; intervention time generally lasts from 4 to 8 weeks, with resolution (one way or another) within 2 or 3 months (James & Gilliland, 2013). The urgency of the situation represents a window of opportunity that invites prompt, focused attention by the client and nurse in working together to achieve intervention goals.

Special programs for children who live in homes where crises and violence are chronic include Head Start programs for prekindergarten children who meet certain socioeconomic characteristics. These programs are designed to give children social and academic stimulation, thereby increasing their skills for when they enter kindergarten. Other programs for social skills development may include a Special Friends program designed explicitly for children who have survived abusive situations, or primary intervention programs (PIP), in which the child works with a trained, supportive, and caring adult.

Abuse survivors and those living in homes with domestic violence experience multiple developmental and psychological problems. Children who are experiencing academic and social failure should receive ongoing services as needed through their elementary, middle, and high school grades. Early identification and intervention with conduct-disordered youth ensure that appropriate resources are obtained and, hopefully, that behavior outbursts and violence will be eliminated. School nurses are important interprofessional team members in providing assessments and programs for these youth.

Intervention at the secondary level for adults who experience abuse focuses on women and their children. Shelters for women and children are available in most communities and offer a variety of services, including counseling, classes in self-esteem building and assertiveness training, referrals to or programs for job training, and even money/budgeting and time management classes. Some shelters offer programs that last up to 2 years with progressive independence and employment skill development while the women and their children live in a protected home environment with their addresses kept confidential from abusers.

Depending on the situation that brings the woman to a shelter, the perpetrator may or may not be incarcerated or on probation. If arrested during the most recent violent episode, the abuser may be released, on parole, or incarcerated. Even while incarcerated, the abuser may be able to take part in an anger management class, psychological counseling, substance abuse treatment, Alcoholics Anonymous (AA) meetings, or Narcotics Anonymous (NA) meetings. Visits between the abuser and the children are supervised, if that is part of a court order.

At times, the nurse may be responding to a referral regarding suspected abuse; at other times, an abusive or neglectful situation may be uncovered on a home visit made for another reason. In any case, the community health nurse has an important role in reporting suspected abuse and encouraging the child, partner/spouse, or elder to go to the appropriate facility to seek care and to file required documentation about the abuse (see From the Case

Files II).

From the Case Files II

Community Health Nursing and a Potential Family in Crisis

You are a community health nurse working for Smithville Health Department. You are following up on a referral from a community clinic's family planning clinic. The referral was made for a 19-year-old woman, Sandy, who presented in clinic and exhibited inappropriate behaviors with her 6-month-old daughter. In their referral, staff stated that they observed the mother shouting at the child, accusing her of "being spoiled rotten." They added that the mother appeared quite anxious and seemed to have difficulty waiting the 15 minutes for her examination. Although the behaviors described in this referral were insufficient to warrant a report to social services, the staff felt that this young mother would benefit from intervention on the part of the nurse.

You prepare for this home visit by reviewing the medical records of both Sandy and her child to determine whether the family has had previous involvement with social service agencies such as CPS. You find that the maternal grandparents made a referral to Child Welfare on behalf of Sandy when she was 15. They were concerned about the relationship between Sandy and her stepfather. The report cited suspected sexual involvement between the two. An investigation occurred but was inconclusive, and the charges were never pursued.

You also discuss the case with family planning and immunization clinic staff, because the family receives services at both clinics. The staff advises you that they are familiar with Sandy and her husband Nick. They state that their only interaction with Nick was during a family planning clinic 2 months ago. They report that Sandy appeared anxious and in a hurry on that day, stating, "I really need to hurry, Nick is waiting in the car and he gets impatient." Shortly after that, the staff tells you, Nick came running into the clinic shouting, "What the hell is taking you people so long?" He reportedly glared at Sandy, and the two quickly exited the clinic.

You phone the client and advise her that you are a nurse with the local health department. You inform her that nurses often visit new mothers to assist them in finding resources. You add that as a community health nurse, you will be available to talk with her about her child's growth and development.

The client expresses interest in the visit and states, "I want you to show me some things about feeding her and stuff. I need help figuring out what to do at night, she still isn't sleeping much and it's driving me crazy." You advise the client that you will be happy to discuss those issues with her and that you will bring information that you will review with her. You add that you noted in her medical record that the father of the baby is living in the home and assure her that she may involve other family members, including the father of the baby, in the home visit. You jointly decide that the visit will occur the following day at 10:30 AM and that the father of the baby will be present if his work schedule allows.

On the day of the visit, as you walk up the stairs toward the apartment, you notice someone looking at you through the curtains. As you near the apartment door, the curtains close. Your repeated knocking on the door is met with no response. You call the client's name but there is no answer.

1. Would this scenario provoke anxiety for you? How would you deal with your reaction?
2. How is this different from a scenario in the acute care setting in which a supervisor would be readily available?
3. Given this scenario, what actions will you take?
4. If you had been working in the family planning clinic on the day that Nick came in, what, if anything, would you have done differently?
5. As young parents, Nick and Sandy are part of an aggregate that has unique risk factors for parenting. List as many of these risk factors as you can think of and brainstorm about possible community health nursing interventions for each.
6. What methods would you suggest the clinic staff utilize to detect signs and symptoms of physical, sexual, or emotional abuse among this aggregate?

Reporting Abuse

All states have reporting laws for suspected abuse, although states differ on aspects of the timeline for reporting, who to notify, and the sequence of events. The following steps represent one state's guidelines for reporting suspected child abuse (Child Welfare Information Gateway, 2014):

1. All mandated reporters must report known or suspected abuse.
2. Immediately, or as soon as reasonably possible, a local child protective agency (police department after normal working hours) must be contacted and given a verbal report. During this verbal report, mandated reporters must give their name—which is kept confidential and may be revealed only in court or if the reporter waives confidentiality (others can give information anonymously)—the name and age of the child, the present location of the child, the nature and characteristics of the injury, and any

other facts that led the reporter to suspect abuse or that would be helpful to the investigator.

3. Within 2 working days, a written report must be completed by the mandated reporter and filed. If a mandated reporter fails to report known or suspected instances of child abuse, they may be subject to criminal liability, punishable by up to 6 months in jail or a fine of $1,000.

Similar steps are required for nurses when reporting elder abuse. Cases of maltreatment and neglect among elders are reported to a local area agency on aging, Adult Protective Services, or to the police, and a screening/documentation form is used to gather and record pertinent information. Guidelines for filing the report and agency notification are specific within each state.

In cases of partner/spousal abuse, adults who are mentally competent cannot be removed involuntarily from the abusive situation. The community health nurse can encourage the victim to leave the perpetrator for the victim's safety until the perpetrator gets professional help and can give information regarding community resources, such as a shelter for women and children. If the adult has a life-threatening injury or illness, medical follow-up must be encouraged; however, the victim may still be reluctant to seek help. At times, another family member or neighbor who witnesses the abusive event calls 911; when the police and paramedics arrive, the victim may have support to seek care and needed protection. A PHN completes a domestic violence screening/documentation form as a part of the official health records for the client.

Tools

Assessment of suspected abuse cannot be overemphasized. The community health nurse may be the only person entering the home of a family in crisis where abuse is occurring. Asking the right questions, being a careful observer, and following the correct reporting process and recording procedures may mean the difference between life and death for a victim of violence.

Displays 20–10, 20–11, and 20–12 consist of three sample tools that the community health nurse and other advocates can use in their role as a mandated reporter. These forms include a Suspected Child Abuse Report, a two-page Medical Report of Suspected Child Abuse, and a Domestic Violence Screening/Documentation Form.

Tertiary Prevention

Tertiary prevention focuses on the rehabilitation of the family from the violence and crisis they have sustained. The family may never again have the same connections because partners may separate—by choice, motivated by fear or hatred; by court order, if the perpetrator is incarcerated; or by death. If the family chooses to stay together, long-term intervention for all family members is needed to establish a climate more conducive to family normalcy. Many of the services discussed as part of the secondary level of prevention are continued into the tertiary prevention phase to promote healing and to restore and promote family growth.

If incarceration is a part of tertiary prevention, the effects of having one family member living in this environment must be factored into the services and support provided by the community health nurse to the family as a whole (see Chapter 30 for information on working in correctional facilities). Even if the partner/spouse has separated from the perpetrator emotionally and/or legally, the perpetrator usually has legal rights to see the children. This may mean that other family members, usually from the abuser's side of the family, can bring the children to the prison to visit their parent. Just making arrangements for these visits can cause stress to the visitors. The community health nurse needs to be aware of the complicated dynamics and emotional stress such difficult situations can produce for all family members. The victim– perpetrator relationship is as complex as the forces that created the violence and abuse.

FAMILIES FACING VIOLENCE FROM OUTSIDE THE FAMILY

The concern of violence coming into the family from outside the home, often beyond the family's control, is a relatively new phenomenon in the United States. There has always been some degree of violence that affects families in their homes, such as burglaries, or at times murder, or abduction. Increasingly, however, home invasion, a form of forced entry to terrorize family members, is a violent crime perpetrated most frequently by strangers. Other forms of violence of which families are more aware include the potential for terrorist activities through planned community violence (such as the 9/11 attacks or the Sandy Hook school shooting) and biologic, chemical, or radioactive actions (see Chapter 17). Communities have developed resources such as the National Organization for Victim Assistance (NOVA) and crisis response teams (CRT), to assist individuals and groups experiencing a disaster or violent event (e.g., child murder or school shootings).

Home invasion is an increasing new form of terror. It occurs mainly in large cities, although rural areas are not immune. *Home invasion* is the purposeful and sudden entry into a home by force while the family is home and awake. The effectiveness of this form of terror relies on surprise. Motivation may be material or thrill; household belongings are frequently stolen while family members are incapacitated by being bound, blindfolded, and/or gagged. In some cases, family members are killed. Often, the perpetrators are under the influence of drugs or alcohol, and at times, the violence may be gang related. Violence, terrorism, and war profoundly affect individuals, families, and society (Devakumar et al., 2014). Lethal violence can create a climate of fear and uncertainty. Intentional homicide victimizes the family and the community of the victim (United Nations Office on Drugs and Crime, 2016). Fear of violence can create psychological and physiologic stress reactions similar to the sensations that occur when one actually experiences the violence. These fears should not be ignored. It is important to understand the impact of violence on the health of individuals, families, and the community (Joyce, Najera-Aguiree, Brown, & Sievers, 2014).

So many forces in the social, cultural, and physical environment conspire against an individual's desire to change behavior. Poverty, associated with overcrowding, lack of institutional relationships and low levels of community participation, and sanctions provide a catalyst for community violence. Historically, society has depended on the criminal justice system to respond to community violence with emphasis on deterrence and incarceration, which has limited prevention capacity. Community correctional facilities provide a form of rehabilitation in some states, to facilitate transitioning of prisoners back to community after incarceration.

To put primary prevention into practice an integrated multifaceted approach is required. The Spectrum of Prevention offers a systematic framework for developing

effective and sustainable primary prevention programs (Cohen, Chavez, & Chehimi, 2010). The *Spectrum* identifies multiple levels for community intervention: (1) strengthening individual knowledge and skills, (2) promoting community education, (3) educating providers, (4) fostering coalitions and networks, (5) changing organizational practices, and (6) influencing policy and legislation. When used together, these levels are complementary and create synergy that results in greater effectiveness (Cohen et al., 2010).

Nurses may work at each level of the *Spectrum,* by educating individuals and high-risk target populations, working on coalitions to foster increased awareness and use of screening tools by health care providers, and working with multisector partnerships to foster change in workplace, organizational, and community policy. Nurses may work with extended family members of the victims or families who have reported such a happening in their neighborhood and are now fearful of a reoccurrence. See Chapters 11 and 12. The role of the nurse includes four steps discussed in the generic approach to crisis intervention (see discussion in "Generic Approach").

METHODS OF CRISIS INTERVENTION

Crisis intervention in community health nursing uses either a generic or individual approach, or both (Fig. 20–8). For the majority of crisis encounters, the generic approach is more appropriate. Family violence is a major situational crisis in which community health nurses intervene. However, many other situational and developmental crises affect families, and these families are benefited by the skills of the community health nurse. Newly recognized crises include community violence coming into the home and the potential of terrorism at home.

FIGURE 20–8 Crime is a type of community violence that can affect families.

Generic Approach

The generic approach creates interventions to fit a particular type of crisis, focusing on the nature and course of the crisis rather than on the psychodynamic of each client (James & Gilliland, 2013). Crisis intervention using the generic approach is tailored to a specific kind of crisis, situational or developmental, and comprises four important elements: (1) use of adaptive behavior and coping strategies, (2) support of the individual/family, (3) preparation for the practical and emotional future, and (4) anticipatory guidance.

As an example, the generic approach is used with families experiencing child abuse. The child may be in foster care while the family receives needed services and rebuilds itself. The nurse encourages the parents to discuss and analyze their feelings, teaches stress reduction techniques and positive coping skills, and creates a supportive, caring atmosphere, especially through self-help groups such as Parents Anonymous. The nurse can help individual family members strengthen their self-esteem by encouraging positive interpersonal relationships. The community health nurse also teaches needed parenting skills, providing anticipatory guidance, so that parents are prepared to raise their children with consistent and age-appropriate discipline techniques.

The generic approach does not require advanced professional psychotherapy skills. More importantly, this approach works well with families, groups, and even communities in crisis. The community health nurse may work with a group of cancer clients, abused elders, adolescents struggling with developmental crisis, or an entire community recovering from a natural or man-made disaster. The generic approach allows the nurse to intervene with any group of people who have a crisis in common. This approach also offers a broad base of support because the crisis group members can provide resources for one another beyond those brought by the nurse.

Individual Approach

The individual approach is used for clients who do not respond to the generic approach or who need special therapy. Individual crisis intervention should not be confused with individual psychotherapy, which tends to focus on a client's developmental past. In contrast, crisis intervention directs treatment toward the immediate state of disequilibrium, identifying its causes and developing coping mechanisms. Family members or significant others are included during the process of crisis resolution. An entire group may need this type of intervention. If this approach is needed, clients should be referred to a professional with specialized training.

ROLE OF THE COMMUNITY HEALTH NURSE IN CARING FOR FAMILIES IN CRISIS

Crisis intervention in community health assumes that clients have resources. If their potential for managing stressful events can be tapped, people in crisis will need minimal direct assistance. In accordance with the self-care concept, crisis intervention seeks to identify and build on client strengths. James and Gilliland (2013) outlined a series of four steps for intervention during crisis: assessment, planning, intervention, and resolution. Interventions to promote crisis resolution are presented using the three levels of prevention in Table 20–2.

Table 20–2 Levels of Prevention to Promote Crisis Resolution

Phase	Goals	Interventions
Primary prevention		
Precrisis	Health promotion Disease prevention Education	Anticipatory guidance Reduce factors that increase vulnerability Reduce hazards in some events (safety and multiplicity of stressors) Reinforce positive coping strategies Mobilize social support and other resources
Secondary prevention		
Crisis	Reduction of stress load Cure or restoration of function	Assist with reaction to the event and functioning Allow behavior: dependence, grief Set goals with client Refer to resources
Tertiary prevention		
Postcrisis	Rehabilitation and maintenance	Promote adaptation to a changed level of wellness Promote interdependence Reinforce newly learned behaviors, lifestyle changes, coping strategies Explore application of learned behaviors to new situations Identification and use of additional resources

Assessment and Nursing Diagnosis

Initially, the nurse must assess the nature of the crisis and the client's response to it. How severe is the problem, and what risks are the clients facing? Are other people also at risk? Assessment must be rapid but thorough and focused on specific areas.

First, the nurse concentrates on the immediate problem during the assessment. Why have clients asked for help right now? How do they define the problem? What precipitated the crisis? When did it occur? Was it a sudden accidental or situational event, or a slower developmental one?

Next, the nurse focuses on the clients' perceptions of the event. What does the crisis mean to them, and how do they think it will affect their future? Are they viewing the situation realistically? When a crisis occurs to a family or group, some members see the situation differently from others. During intervention, all family members should be encouraged to express themselves, to talk about the crisis, and to share their feelings about its meaning. Acceptance of the wide range of feelings is important.

Determine who is available to offer support to the individual or family. Consider family, friends, clergy, other professionals, community members, and agencies. Who are the clients close to, and whom do they trust? One advantage of group intervention is that the members provide some of this support for one another. In subsequent sessions, the quality of support should be evaluated. Sometimes, a well-meaning individual can worsen the situation or deter clients from facing and coping with reality.

Finally, the nurse assesses the clients' coping abilities. Have they had similar kinds of experiences in the past? What techniques have they tried in this situation, and if they did not work, why not? Clients should be encouraged to think of other stress-relieving techniques, perhaps ones they have used in the past, and to try them.

The nurse gathers all of these data and mentally begins to form nursing diagnoses. As a plan of care is developed for the client, these nursing diagnoses are formalized in writing. Standardized nursing diagnoses are available for reference, or the agency where the nurse works may have a preferred format for nursing diagnoses. These nursing diagnoses are effective tools for the nurse to begin planning interventions. When the violence problem is more community centered the Omaha System of documentation and information management may be useful as a nomenclature as it comprehensively includes the family and community as clients or modifiers. The system consists of three relational, reliable, and valid components used together: the Problem Classification Scheme, Intervention Scheme, and the Problem Rating Scale for Outcomes (Martin & Monsen, 2015). The Problem Classification Scheme includes neighborhood/workplace safety in the environmental domain. The benefits of using the Omaha system enables interdisciplinary problem identification and functioning with intervention targets that reflect communication with health team members across multiple settings, using electronic health records (Bowles, 2011; Bowles et al., 2013; Martin & Monsen, 2015).

Planning Therapeutic Interventions

Several factors influence clients' reaction to crises. Nurses should try to determine what factors are affecting clients before making intervention plans. The major balancing factors —clients' perceptions of the event, situational supports, human resources, and clients' coping skills—have been assessed in the first step (James & Gilliland, 2013). While continuing to explore these, the nurse now also considers the clients' age, past experiences with similar types of situations, sociocultural and religious influences, general health status, and the actual assets and liabilities of the situation. This assessment helps clarify the situation and gives the nurse an opportunity to further encourage the clients' participation in the resolution process. If clients are defensive, resistant, and rigid, they are not processing clearly and can complete only simple tasks. It will take time before these clients can begin to solve problems related to the effects of the crisis on themselves and the loss they are experiencing, but the nurse will want to encourage them to reach this level.

A therapeutic plan is based on multiple factors:

- The kind of crisis (situational or developmental, acute or chronically recurring)
- The effect the crisis is having on clients' lives (can they still work, go to school, and keep house, or are they secured within their home for an indefinite period, not knowing whether other family members have survived a major natural or man-made crisis?)
- Where they are in coming to resolution of the crisis
- The ways in which significant others are affected and respond
- Their level of preparation for such a crisis
- The clients' strengths and available resources

Using this problem-solving process, the nurse and clients develop a plan. They review the event that precipitated the crisis, obvious symptoms, and the disruption in the clients' lives. The plan may focus on several areas. For instance, clients may need to grasp intellectually the meaning of the crisis, to engage in greater expression of feelings, or work both on the intellectual and emotional aspects. Part of the plan may be directed toward finding appropriate and safe shelter, counseling, or physical care. Another part may focus on helping clients identify and use more effective coping techniques or locate supportive agencies and resources. The plan may also include development of realistic goals for the future.

Implementation

During implementation, communication between the nurse and clients is important. Discussions about what is happening, reviewing the family's plan and rationale for this approach, and making appropriate changes are necessary parts of this communication. Assigning definite activities at the end of each session will help clients try out different solutions and evaluate various coping behaviors (Gambrill, 2013). Using the following guidelines is helpful during implementation:

1. *Demonstrate acceptance of clients*. A crisis often shatters the ego. Clients need to feel the support of a positive, caring person who does not judge their feelings or behavior. Some negative expressions, such as anger, withdrawal, and denial, are normal aspects of the crisis phase. Accept them as normal.
2. *Help clients confront crisis*. Clients need to face and discuss the situation. Expressing their feelings reduces tension and improves reality perception. Recounting what has actually occurred may be painful, but it helps clients confront the crisis. Do not assume that once clients have told about the event, no further recounting is necessary. Each time the story is told, the client comes closer to dealing realistically with the crisis.
3. *Help clients find facts*. Distorted ideas and unknown factors of the situation create additional tension and may lead to maladaptive responses. For instance, it would help inexperienced parents to know that children younger than 2 years of age cannot deliberately misbehave. Facts about childhood development and parenting training may be important for preventing crisis.
4. *Help clients express feelings openly*. Suppressed feelings can be harmful. For instance, a widow may feel guilty that she is glad her husband is gone. Expression of such feelings helps reduce tension and gives clients an opportunity to deal with them.
5. *Do not offer false reassurance*. Clients need to face reality, not avoid it. A statement such as "Don't worry, it will all work out" is demeaning and meaningless. Instead, make positive statements about faith in the clients' ability to cope: "It is a very difficult situation, but I believe you will be able to deal with it."
6. *Discourage clients from blaming others*. Clients often blame others as a way to avoid reality and the responsibility for problem-solving. Withhold judgment when clients blame others, but point out other causal factors and avenues for dealing with the situation.
7. *Help clients seek out coping mechanisms*. Explore and test old and new techniques to reduce stress and anxiety. Ask questions. What are the things that need to be done? What do clients think they can do? This assistance gives clients more adaptive energy to work toward resolution.
8. *Encourage clients to accept help*. Denial in the early phases of crisis cuts off help. Encouraging clients to acknowledge the problem is a first step toward acceptance of help. Often, clients fear the loss of their independence and the invasion of their

privacy. A client may say, "We ought to be able to handle this problem." At this point, the community health nurse can reassure clients that people in a crisis of this sort almost always need help. Preparing people to accept help enables them to make the best use of what others have to offer.

9. *Promote development of new positive relationships*. Clients who have lost significant others through unintentional or intentional death, divorce, incarceration, or an act of perpetrated violence should be encouraged to find new connections, purpose, and people to fill the void and provide needed supports and satisfactions.

Evaluation of Crisis Resolution and Anticipatory Planning

In the final step, clients and the nurse evaluate, stabilize, and plan for the future. Evaluating the outcome of the intervention might address the following:

- Are the clients using effective coping skills and exhibiting appropriate behavior?
- Are adequate resources and support persons available?
- Is the diagnosed problem solved?
- Have the desired results been accomplished?

Analysis of these outcomes will provide a greater understanding for coping with future crises.

To stabilize the change that has occurred, identify and reinforce all of the positive coping mechanisms and behaviors. Discuss why they are effective, and explore ways to use them in future stressful situations. Summarize the crisis experience, emphasizing the clients' successes with coping, reconfirm their progress, and reinforce their self-confidence. It is especially important to point to the evidence that the client has reached their pre crisis level, or an even higher level of functioning.

Clients' plans for the future should include setting realistic goals and means to implement them. Review with clients how their handling of the present crisis can help them cope with, minimize, or preferably prevent future crises.

SUMMARY

Crisis is a temporary state of severe disequilibrium for persons who face a threatening situation. A crisis is a state that individuals can neither avoid nor solve with their usual coping abilities and occurs when some force disrupts normal functioning, thereby causing a loss of balance or normalcy in life. Crises create tension; subsequently, efforts are made to solve the problem and reduce the tension. If such efforts meet with failure, people feel upset, redefine the situation, and try other solutions, and if failure continues, the person eventually reaches the breaking point.

Two main types of crisis are developmental and situational. Developmental crises are disruptions that occur during transitional periods in normal growth and development. These transitions usually have a gradual onset and are often predictable. Situational crises are precipitated by an unexpected external event and occur suddenly, sometimes without warning.

Family violence constitutes a unique crisis for the victim and the entire family and is becoming disturbingly prevalent in the world. Historically, family violence is not new. Only in the last half century of our nation's history have laws and societal concerns been raised about the treatment of spouse/partners, children, and seniors. Although advances in human rights have been made, abuses against women and children remain socially and culturally accepted in some countries, and attitudes have been slow to change.

Child abuse occurs among children of all ages, from infancy through the teen years, and may be physical, emotional, and/or sexual. Neglect and sexual exploitation are additional forms of child abuse. Neglect may be described as general neglect or specific, such as medical or educational neglect. Child abuse, such as shaken baby syndrome or Munchausen syndrome by proxy, is sometimes identified only on autopsy. Teen dating violence, violence during pregnancy, and VAW in general constitutes partner/spousal abuse. Finally, a most unsettling form of violence—elder abuse, neglect, and exploitation—is occurring more frequently than previously suspected.

New and unexpected forms of violence are becoming a reality in our unsettled world. Within communities, violence comes into the home in the form of Internet crimes against children, child abductions, and home invasions. Globally, terrorist groups threaten attacks on civilians in the United States and abroad. For people in the Unites States, this form of terror is a new reality. Preparation against and survival of such attacks is a new concern for most Americans, and the community health nurse has an important role to play (see Chapter 17). Community violence creates fear and uncertainty and impacts individuals and families that may live, work, play, and pray in close proximity.

Community health nurses use three levels of prevention when working with families. Primary prevention focuses on providing people with the skills and resources to prevent violent situations. Secondary prevention involves immediate intervention at the time of the

violent episode. This secondary level includes providing different services for each family member, such as medical attention, emotional support, and police involvement. Tertiary prevention offers family rebuilding services and helps the family establish equilibrium with a structure that may be different, but healthier. The *Spectrum of Prevention* offers a multidimensional approach to building community capacity to address issues of violence.

People in crisis need and often seek help. Crisis intervention builds on these two phenomena to achieve its primary goal—reestablishment of equilibrium. The two major methods of crisis intervention are the generic and the individual approaches. The generic approach is used with groups of people involved in the same type of crisis, such as rape victims, mothers who have lost children because of drunken driving, or a family experiencing child abuse. The individual approach is used if clients do not respond to the generic approach or need additional therapy. Crisis intervention begins with assessment of the situation, followed by planning a therapeutic intervention. The nurse then implements and carries out the intervention, building on the strengths and self-care ability of clients. Crisis intervention concludes with resolution and anticipatory planning to avert possible future crises.

Regardless of the method of intervention the community health nurse uses, the steps of the nursing process provide a framework within which to intervene. Assessing the family's assets and liabilities, their willingness to change, and the nature of the violence helps the nurse form a nursing diagnosis. With this diagnosis, the nurse can begin to plan appropriate interventions and implement plans in concert with the family. Evaluation of the intervention techniques provides the nurse with new data to assist with ongoing assessment of the family's progress and additional anticipatory guidance needs.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. What are the major differences between a developmental and a situational crisis? Give examples of each from personal experiences.
2. Describe a developmental crisis experienced by a family. What was this family's response? Describe some actions a PHN might have taken (alone or within an interdisciplinary team) to help the family cope with the crisis.
3. Search news sources (e.g., news programs, Internet news) for examples of developmental or situational crises occurring to families. Analyze the situations and anticipate what the role of a community health nurse would be during the crises selected.
4. Family violence is a significant public health problem. Assume that a battered wife becomes a community health nurse's client, and the nurse suspects there may be more women with this problem in the community. Describe how the nurse might provide assistance using the crisis intervention steps. Then discuss how a three-level preventive program might be instituted in the community.
5. Talk with a PHN or social worker that has experience in child abuse cases. What are the most frustrating aspects of their job and why? Do they feel that the system can protect children from their abusers and why or why not? If possible, discuss cases (no names) dealing with physical, emotional, and sexual abuse, as well as neglect. How can nurses be more attuned to signs and symptoms of abuse?
6. With a group of fellow students, explore the child abuse and domestic violence statistics for your city, county, and state. Compare these with national statistics. Research available programs at each level to address these problems. If possible, volunteer at a battered women's shelter to learn more about this problem.
7. Research statistics and evidence-based practice related to Veteran's health and domestic violence. Does this population (e.g., active military, returning veterans) have higher rates of spousal abuse than the general population? Does the Veterans Administration offer any special programs to address this issue (e.g., for the serviceman, spouse)?

6 UNIT

PROMOTING AND PROTECTING THE HEALTH OF AGGREGATES WITH DEVELOPMENTAL NEEDS

21 CHAPTER

Maternal–Child Health: Working with Perinatal, Infant, Toddler, and Preschool Clients

"Be gentle with the young."

—*Juvenal* (55–127 AD)

KEY TERMS

Alcohol-related birth defects
Alcohol-related neurodevelopmental disorder
Child abuse
Environmental tobacco smoke (ETS)
Fetal alcohol effects
Fetal alcohol spectrum disorders
Fetal alcohol syndrome
Gestational diabetes mellitus (GDM)
Head Start
High-risk families
Infant
Low birth weight (LBW)
Population health
Preconception care
Preschooler
Shaken baby syndrome
Smokeless tobacco products
Sudden infant death syndrome (SIDS)
Toddler
Very low birth weight (VLBW)

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify major health problems and concerns for childbearing women, infant, toddler, and preschool populations globally and in the United States.
- Identify the *Healthy People 2020* goals established for the maternal–child population.
- Discuss major risk factors and special complications for childbearing families.
- Describe the important considerations in developing effective health promotion programs to fit the needs of diverse maternal–child populations.

- Describe various roles of a public and community health nurse in serving the maternal–child population.
- Describe a variety of programs that promote and protect health and prevent illness and injury of infant, toddler, and preschool populations.
- State the recommended immunization schedule for infants and children and give the rationale for the timing of each immunization.
- Give examples of methods and interventions the public and community health nurse might use in working with infants, toddlers, and preschool populations to help promote their health.

Maternal and child populations have always been priorities for public health and public and community health nursing (P/CHN). These populations consist of childbearing women, including pregnant adolescents, and infants and children through adolescence. In this chapter, the focus is on childbearing women, including adolescents and infants through age 4. Often, more than half of P/CHN practice in official public health agencies involves primary prevention work with mothers, such as family planning, preconception care, provision of prenatal care, and monitoring infant health. Why should maternal–infant populations require this amount of attention from P/CHN? Despite advanced technology and availability of excellent perinatal services in the United States, we often have less than optimal birth outcomes —for instance, 318,847 low-birth-weight (LBW) and 381,321 preterm infants were born in 2014 (Centers for Disease Control and Prevention [CDC], 2016j). Also, certain segments of the maternal and infant populations, such as adolescent mothers and those who are economically disadvantaged or women and children of color, remain at high risk for disparities in regard to maternal deaths and complications and child risk and illness. Although some women receive excellent prenatal care and benefit from diagnostic and technological resources, many others are without access to prenatal care.

Child Health USA (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2014) reports that adequate prenatal care is associated with adequate health insurance. In 2012, 88% of privately insured women and 83% of Medicaid insured women received adequate prenatal care (four or more provider visits during pregnancy). Seventy-two percent of those who

were uninsured were least likely to receive adequate prenatal care. This correlates to health inequity characteristics such as race and ethnicity, poverty, and low maternal education levels (less than high school education).

Historically, the health of U.S. women and children has largely fallen under the umbrella of Title V, of the Social Security Act, enacted in 1935. (For more on the Social Security Act, see Chapter 6.) Funding for state Maternal and Child Health and Crippled Children programs was part of this original legislation, as was some provision for child welfare services. Title V is "the longest-standing public health legislation in American history" and came to fruition after other legislation established a National Birth Registry; provided *Infant Care*, the first educational pamphlet; established the Children's Bureau; and enacted the first Child Labor Law of 1916 (Maternal Child Health Bureau [MCHB], n.d.b, para. 4). For an illustration of MCHB functions and programs, see Display 21–1.

DISPLAY 21.1 TYPES OF SERVICES OFFERED THROUGH FEDERAL MATERNAL–CHILD HEALTH FUNDING

Direct Health Care Services (Gap Filling)

Examples: Basic Health Services and Health Services for Children with Special Health Care Needs (CSHCN)

Enabling Services

Examples: Transportation, Translation, Outreach, Respite Care, Health Education, Family Support Services, Purchase of Health Insurance, Case Management, Coordination with Medicaid, WIC, and Education

Population-Based Services

Examples: Newborn Screening, Lead Screening, Immunization, Sudden Infant Death Syndrome Counseling, Oral Health, and Injury Prevention

Infrastructure Building Services

Examples: Needs Assessment, Evaluation, Planning, Policy Development, Coordination, Quality Assurance, Standards Development, Monitoring, Training, Applied Research, Systems of Care, and Information Systems

U.S. Department of Health and Human Services. (2008). State MCH-Medicaid Coordination: A Review of

Title V and Title XIX Interagency Agreements (2nd ed.). Retrieved from http://mchb.hrsa.gov/pdfs/statemchmedicaid.pdf

In 1909, formal prenatal care was first provided in Boston by the Instructive District Nursing Association and spread across the country to outpatient clinics (MCHB, n.d.b). Since the inception of Title V, many programs have been developed with the goal of improving the health of women of childbearing age, as well as infants and children. Research areas have included prenatal and pregnancy, child development and parenting, improving health care systems and delivery of care, as well as obesity, nutrition, medical homes, school services and outcomes, and behavioral health (MCHB, n.d.c). Healthy Start grants were first awarded in 1991 to 15 agencies, with the goal of reducing rates of infant mortality, LBWs, premature births, and maternal deaths (MCHB, n.d.a). Evaluation of Healthy Start programs reveals that almost all programs provide home visitation to prenatal clients, and most continued these visits to infants and toddlers. Health education, smoking cessation counseling, services for perinatal depression, and involvement of male partners are hallmarks of most programs.

In 2016, $345 million in grants were awarded to expand the Maternal, Infant, and Early Childhood Home Visiting Program (Federal Home Visiting Program). This program provides PHN visits, assistance from social workers, early childhood educators, and other professionals to expectant families, much like the program designed by David Olds (Health Resources & Services Administration [HRSA], 2016). Early improvements in six benchmark areas were noted:

- Maternal and newborn health
- Child injuries, child maltreatment, and ED visits
- School readiness and achievement
- Crime or domestic violence
- Family economic self-sufficiency
- Service coordination/referrals for other community resources/support (MCHB, 2016, p. 4).

This chapter addresses major areas of concern regarding population health for maternal–infant clients. It also explores the global needs of and related services available to the youngest and thus most vulnerable of society's members. Health services that are commonly available in the United States for pregnant and postpartum women, infants, toddlers, and the preschool population are examined, and the role of the public and community health nurse in providing those services is explored.

HEALTH STATUS AND NEEDS OF PREGNANT WOMEN AND INFANTS

Public and community health nurses constitute a key group of health professionals involved in both program planning and the actual delivery of services to mothers and babies in the community. In the public health sector, these nurses are the largest group of professionals practicing public health. A solid understanding of vital statistics and other data regarding mothers and infants is important to determine the appropriateness and the effectiveness of programs and services. A review of some global and national vital statistics provides insight into the major problems facing maternal and child populations.

Global Overview

One of the major indicators of population health is maternal health, which is often measured by the maternal mortality rate (MMR). The MMR is a measure of obstetric risk and is determined by dividing the number of maternal deaths by the number of live births per 100,000. Most maternal deaths are the result of direct causes (complications of pregnancy, labor, and delivery), hypertensive disorders, intervention omissions or incorrect treatment, the chain of events resulting from any one of these, and unsafe abortions. In 2015, more than 50% of maternal deaths occurred in sub-Saharan Africa and about 33% in South Asia. In these developing countries, the MMR is 239 per 100,000 live births. This compares to developed countries, such as Canada, Australia, New Zealand, Japan, and most European countries where the MMR is around 12 per 100,000 live births—a very wide disparity (World Health Organization [WHO], 2016b). The U.S. MMR was 17.8 per 100,000 women in 2011 and 15.9 in 2012 (CDC, 2016k). Ireland and Greece's MMR is <4, making them very good places for expectant mothers. Although the MMR has decreased since 1990 by 44%, the worldwide goal is to eliminate maternal mortality by 2030 (WHO, 2015c). This goal is achievable because most maternal mortality can be prevented. For an example of a country that has implemented successful policies to eliminate maternal–child inequities, see Evidence-Based Practice: Reducing Child Mortality in Bangladesh.

EVIDENCE-BASED PRACTICE

Reducing Child Mortality in Bangladesh

Child mortality rates have declined significantly in Bangladesh over the last decade. In 2000, Bangladesh experienced a 53% reduction in the under-five mortality rate (88 per 1,000) compared to 41 per 1,000 in 2012. Additionally, the neonatal mortality rate was decreased by 40% from 40.7 per 1,000 in 2000 to 24.4 per 1,000 in 2012. Routine childhood immunizations, oral rehydration therapy, and supplementation of vitamin A are interventions that have significantly influenced this reduction in child mortality rates. It is estimated that 98% of the children aged 12 to 23 months have access to routine immunizations. Completed immunization rates are at 93% among these children. Furthermore, the government of Bangladesh implemented a nutrition plan in its National Health Strategy. This included utilizing community health workers to improve access to health care, improvements in the quality of health care, and increases in the number of health facilities that have

demonstrated improved rates. Although these improvements are dramatic, additional improvements in sustainable trends and equity are essential (Baruah et al., 2013).

Baruah, S., Haines, S., Hewitt, S., Holly, L., Jensen, P., Johnson, R., … Olayemi, D. (2013). Lives on the line: An agenda for ending preventable child deaths. London, UK: Save the Children.

Infant Mortality

Another critical population health indicator is the infant mortality rate (IMR). Globally, 6.3 million children under 5 years died in 2013; 44% of these deaths took place in the neonatal period and are primarily caused by preterm birth, birth asphyxia, and infection. More than half of the deaths for children under 5 years are preventable and the interventions are affordable (WHO, 2015c). In the United States, the IMR was 6.14 infant deaths under age one per 1,000 live births in 2010, a decrease from 6.86 in 2005 (MacDorman, Mathews, Mohangoo & Zeitlin, 2014). For non-Hispanic Blacks, the rate is 2.3 times higher than for the non-Hispanic White population at 12.67 versus 5.52 (HRSA, 2013). Among American Indian and Alaska Natives, the IMR is also higher at 8.42 and 7.29, whereas Asian/Pacific Islanders have a much lower overall rate of 4.51, but some variability exists with Native Hawaiians having higher rates. See Figure 21–1 for U.S. infant mortality rate ethnic comparison data. WHO estimated in 2015 that 800,000 million infants worldwide would be saved if there were more infants exclusively breast-fed for the first 6 months of life. Currently, breast-feeding practice worldwide is at 35% (WHO, 2015b).

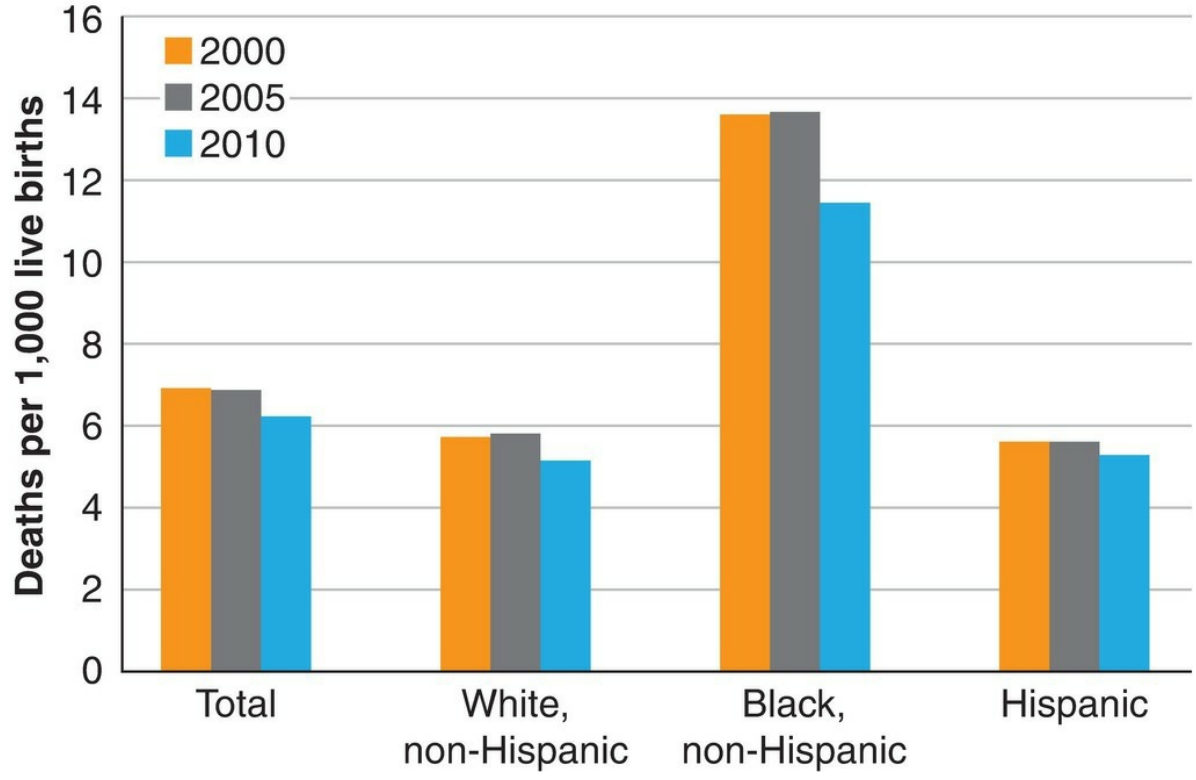

FIGURE 21–1 U.S. infant mortality rates, by race and Hispanic ethnicity of mother:

comparisons for 2000, 2005, and 2010. (From MacDorman, M. F., & Mathews, T. J. (2014). QuickStats: Infant mortality rates, by race and Hispanic ethnicity of mother—United States, 2000, 2005, and 2010. Morbidity & Mortality Weekly Report (MMWR), 63(1), 25. Retrieved from http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6301a9.htm)

HIV/AIDS

There are 36.9 million individuals living with human immunodeficiency virus (HIV). Almost 70% of all cases are found in sub-Saharan Africa (WHO, 2016a). Most children with acquired immunodeficiency syndrome (AIDS) are children of HIV-positive mothers (WHO, 2015a). Mother-to-child transmission (MTCT) of HIV can be almost fully prevented with antiretroviral treatment for mother and infant (WHO, 2015a). To reduce MTCT, women must seek prenatal care early enough in their pregnancies for the antiretroviral drug to be effective. Antiretroviral therapy was provided to an estimated 14.9 million persons in 2014, and approximately 823,000 of them were children (WHO, 2015a).

National Overview

In the United States, 3.9 million women gave birth in 2013, 1% more for the first time since 2007 (Martin, Hamilton, Osterman, Curtin, & Matthews, 2015). The general fertility rate declined to a total of 62.5 births per 1,000 women ages 15 to 44 years. Birth rates declined for non-Hispanic White and Hispanic populations and remained unchanged for African American women. Just over 40% of births were to unmarried women (Martin et al., 2015). When unmarried women rely on a single income, financial resources are more limited, and many of these women raise their children at poverty or near poverty income levels, which impacts their health and their children's health over the life course of both.

Support for mothers and children helps ensure healthier families. (Author's private photo with permission from Christian and Samantha Nelson.)

Birth Weight and Preterm Birth

Birth weight is one of the most important predictors of infant mortality. Low-birth-weight (LBW) babies are those weighing <2,500 g (or <5.5 pounds) at birth; very-low-birth-weight (VLBW) babies weigh <1,500 g (or <3 pounds 4 ounces) at birth. In the last 25 years, the rate of preterm births has increased by 33% with the majority of these births occurring late preterm (34 to 36 weeks' gestation) (Shapiro-Mendoza & Lackritz, 2012).

Presently, preterm birth rates have been slowly declining. Preterm birth rates for 2013 were 11.39% and declined for non-Hispanic White, African Americans, and Hispanics; overall LBW rates were unchanged at 8.02% down from the 2006 high of 8.32% (Martin et al., 2015). Statistics for VLBW are 1.5% overall but 3.0% for African Americans (Martin et al., 2011). These numbers represent a significant disparity for African Americans.

Infant in NICU. (Author's private photo with permission from Danielle Rector.)

Infant complications of preterm birth include hearing and vision problems; acute respiratory, gastrointestinal, and immunologic problems; and central nervous system (CNS), motor, cognitive, behavioral, and socioemotional disorders. A variety of growth concerns as well as acute and chronic health and developmental problems often occur, and the families of these infants are burdened with additional economic and emotional costs. In a study of preterm infants from birth to age two, those with feeding difficulties and at risk for feeding difficulties had significant neurodevelopmental problems such as impaired cognition, language, motor, and socioemotional skills that led to increased parental stress, poorer maternal mental health, or family stressors than those preterm infants that did not have feeding difficulties. Maternal mortality, LBW, and VLBW births are three areas requiring attention by health care providers and the public health system. Public and community health nurses can contribute to reducing these rates and societal costs by outreach, surveillance, health teaching, counseling, and referral (Save the Children, 2015).

In addition to infant deaths and LBW, the effects of pregnancy and childbirth on women are other important indicators of health and reflect discrepancies in access to reproductive health care. The United States is not ranked among the top 10 countries in maternal–child health in the *2015 Mother's Index*. It is ranked 33rd out of the more developed countries. The U.S. ranking is largely due to poorer scores on the indices of maternal and child health. Eastern European countries, such as Slovakia, the Czech Republic, Belarus, Croatia, and the developing countries such as Peru and Ethiopia, rank higher than the United States (Save the Children, 2015).

In the United States, the MMR is higher than in other developed countries, mostly because of the disparities found among women of color. The MMR for Blacks (42.8 per 100,000 live births) is four times greater than that for Whites (12.5), and the gap has continued to widen since 1986 when the MMR surveillance was initiated (CDC, 2016k). Pregnancy-related death risk increases with age and with lack of prenatal care for women of every race, but the risk of pregnancy-related death for U.S. Black women is three to four times greater than for White women. Even though maternal deaths are low, most maternal deaths are preventable.

One of the maternal–child objectives for *Healthy People 2020* is to improve the proportion of infants who are breast-fed. Breast-feeding is beneficial to both mother and infant, and currently, 79.2% of mothers reported ever breast-feeding. Only 49.4% of U.S. infants were breast-fed for the recommended 6-month period, and 18.8% were breast-fed exclusively for this 6-month period. These proportions do not reach the *Healthy People 2020* targets of 81.9% for "ever breast-feeding," and 60.6% for "breast-feeding for the first 6 months" (CDC, 2014a). An evidence-based quality improvement project that promoted mother-to-infant skin-to-skin contact in the delivery room showed significant improvement in exclusive breast-feeding (Brown, Kaiser, & Nailon, 2014). It is estimated that if 90% of U.S. families would comply with the recommended American Academy of Pediatrics guidelines regarding exclusive breast-feeding, $3.7 billion in direct and indirect pediatric health costs and $10.1 billion in premature death related to pediatric disease would be saved (Bartick, 2011). See Table 21–1 for *Healthy People 2020* maternal, infant, and child health objectives.

Table 21–1 *Healthy People 2020:* Summary of Objectives for Maternal, Infant, and Child Health

Goal: Improve the health and well-being of women, infants, children, and families

Number	Objective
Morbidity and Mortality	
MICH-1	Reduce the rate of fetal and infant deaths
MICH-2	Reduce the 1-year mortality rate for infants with Down's syndrome
MICH-3	Reduce the rate of child deaths
MICH-4	Reduce the rate of adolescent and young adult deaths
MICH-5	Reduce the rate of maternal mortality
MICH-6	Reduce maternal illness and complications because of pregnancy (complications during hospitalized labor and delivery)
MICH-7	Reduce cesarean births among low-risk (full-term, singleton, vertex presentation) women
MICH-8	Reduce low birth weight (LBW) and very low birth weight (VLBW)
MICH-9	Reduce preterm births
Pregnancy Health and Behaviors	
MICH-10	Increase the proportion of pregnant women who receive early and adequate prenatal care
MICH-11	Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women
MICH-12	Increase the proportion of pregnant women who attend a series of prepared childbirth classes (Archived)
MICH-13	Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies (Developmental)
Preconception Health and Behaviors	
MICH-14	Increase the proportion of women of childbearing potential with intake of at least 400 mcg of folic acid from fortified foods or dietary supplements
MICH-15	Reduce the proportion of women of childbearing potential who have low red blood cell folate concentrations
MICH-16	Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors
MICH-17	Reduce the proportion of persons aged 18–44 years who have impaired fecundity (physical barrier preventing pregnancy or carrying pregnancy to term)
Postpartum Health and Behavior	
MICH-18	Reduce postpartum relapse of smoking among women who quit smoking during pregnancy
MICH-19	Increase the proportion of women giving birth who attend a postpartum care visit with a health worker (Developmental)
Infant Care	
MICH-20	Increase the proportion of infants who are put to sleep on their backs
MICH-21	Increase the proportion of infants who are breast-fed
MICH-22	Increase the proportion of employers that have worksite lactation support programs
MICH-23	Reduce the proportion of breast-fed newborns who receive formula supplementation within the first 2 days of life
MICH-24	Increase the proportion of live births that occur in facilities that provide recommended care for lactating mothers and their babies
Disability and Other Impairments	
MICH-25	Reduce the occurrence of fetal alcohol syndrome (FAS)
MICH-26	Reduce the proportion of children diagnosed with a disorder through newborn blood spot screening who experience developmental delay requiring special education services
MICH-27	Reduce the proportion of children with cerebral palsy born as LBW infants (<2,500 g)
MICH-28	Reduce occurrence of neural tube defects
MICH-29	Increase the proportion of young children with autism spectrum disorder (ASD) and other developmental delays who are screened, evaluated, and enrolled in special services in a timely manner
Health Services	
MICH-30	Increase the proportion of children, including those with special health care needs, who have access to a medical home
MICH-31	Increase the proportion of children with special health care needs who receive their care in family-centered, comprehensive, and coordinated systems
MICH-32	Increase appropriate newborn blood spot screening and follow-up testing
MICH-33	Increase the proportion of VLBW infants born at level III hospitals or subspecialty perinatal centers

Adolescent Mothers

In 1991, after a steady 5-year upward trend, the United States reached a 20-year high in the number of children born to teen mothers (aged 15 to 19 years). That trend then declined with 2013 marking a 57% decline in teen birth rates (Ventura, Hamilton, & Matthews, 2014). In 2013, there were 26.5 births per 1,000 women age 15 to 19 years (Martin et al., 2015). The drop in teen birth rates translates into an estimated 4 million fewer births to teenagers from 1992 through 2012. The decrease in teen birth rate can be attributed to several behavioral changes, such as decreased sexual activity, increase use of contraception at first sex and at most recent sex, and the increased use of contraception methods (Ventura et al., 2014). Although the United States has seen a decrease in teen births, the country continues to have much higher teen birth rates compared to other developed countries, including Canada and the United Kingdom (United Nations Statistics Division, 2015). See Chapter 22 for more on adolescent pregnancy.

The *Healthy People 2020* (USDHHS, 2016) document encompasses specific goals and objectives for the maternal–child population, based on the previous achievements in the same or similar areas. After years of working toward improving maternal–child health, the United States has made limited progress. One objective, however, has been met; 70% of infants are now sleeping on their backs, up from a 35% baseline. The rate for sudden infant death syndrome (SIDS) had dropped by over 50% since 1994. This can be attributed to the national public health education campaign known as "Back to Sleep" (Eunice Kennedy Shriver National Institute of Child Development and Health, 2016).

Risk Factors for Pregnant Women and Infants

Most pregnant women in the United States are healthy; they have normal pregnancies and produce healthy babies. Many factors contribute to the health problems of those mothers and babies who figure in the statistics on infant mortality and LBW. The factors associated with LBW and infant mortality can be grouped into three categories (CDC, 2014e):

1. Lifestyle: Smoking, secondhand smoke exposure, inadequate nutrition, alcohol consumption, substance abuse, late prenatal care, environmental toxins, stress, violence, and lack of social support
2. Sociodemographic: Maternal age below 15 and above 35, low educational level, poverty, domestic violence, and unmarried status
3. Medical and gestational history: Primiparity, multiple gestation, short interpregnancy intervals, premature rupture of the membranes, uterine abnormality, febrile illness during pregnancy, spontaneous abortion, genetic factors, gestation-induced hypertension, less than ideal weight gain during pregnancy, and diabetes

It is in the area of lifestyle choices that nurses can have the most significant impact on pregnancy outcomes such as LBW, preterm birth, and infant mortality. Programs that provide access and funding to PHNs are available through federal, state, and local funding.

Substance Use and Abuse

Another area of concern is substance use and abuse among the childbearing population. The range of adverse consequences associated with the use of tobacco, alcohol, and illicit drugs during pregnancy is wide and includes preterm birth, LBW, and fetal alcohol syndrome (FAS) (described later in this chapter). This puts these women and their unborn children in double jeopardy; not only are they at risk from the consequences of alcohol or drug use, but also they do not receive the preventive prenatal care that can eliminate or reduce other obstetric complications. This is most often related to the pregnant woman's concerns about legal ramifications of substance use while pregnant if they do seek care. In a study conducted in the Netherlands, nurse home visitor intervention had significant effects on the cessation and reduction of smoking in pregnant women compared to regular care (Mejdoubi et al., 2014).

Substance abuse during pregnancy is a problem with staggering social and medical implications, such as preterm births, LBW, miscarriage, placental abruption, developmental delays, and child behavior and learning problems later in life (American Pregnancy Association, 2016). The precise rate of substance abuse among pregnant women is difficult to determine. In a large study (n = 27,874) of substance abuse and pregnancy, 26.3% of the women reported previous use and 2.6% current use. Adverse outcomes of these pregnancies included LBW, preterm birth, babies born small for gestational age (SGA), and admissions to neonatal intensive care units (NICUs). The investigators also noted that many

substance-using women also used tobacco and alcohol while pregnant (Hayatbakhsh et al., 2012). In a large Danish population study, it was found that among opiate-exposed newborns compared to nonexposed newborns there was greater prevalence of preterm birth, LBW at term, and being SGA. In addition, there were twice the number of congenital birth defects (Nørgaard, Nielsson, & Heide-Jørgensen, 2015).

In the United States, almost 90% of substance-abusing women are of reproductive age and are most commonly reported to abuse cocaine, methamphetamines, heroin and opioids, alcohol, marijuana, and tobacco. Also, the use of several substances—or polysubstance abuse—is fairly common in this population (Hayatbakhsh et al., 2012). The use of stimulants such as cocaine and methamphetamines during pregnancy is associated with impaired fetal growth, neonatal seizures, and congenital anomalies. Neonatal withdrawal is characterized by abnormal functions of the gastrointestinal tract, the CNS, and the respiratory system. Poor feeding, abnormal sleep patterns, long-term learning disabilities, and delayed language development may be observable results of maternal drug use.

The United States has seen an increased incidence of neonatal abstinence syndrome (NAS) as a result of heroin or opioid use in pregnancy. It is estimated that from 2009 to 2012, the incidence increased from 3.4 to 5.8 per 1,000 births. Geographically, this increase has been seen in the Southeast states of Kentucky, Tennessee, Mississippi, and Alabama and the South Central states of Texas, Oklahoma, Arkansas, and Louisiana (Patrick, Davis, Lehmann, & Cooper, 2015). NAS occurs as a result of the sudden discontinuation of fetal exposure to substances such as heroin or other opioids during pregnancy. Withdrawal symptoms experienced by these infants include irritability, excessive/high-pitched crying, tremors, and gastrointestinal problems such as diarrhea. In the event nonpharmacologic care does not alleviate these symptoms, morphine is the most commonly used pharmacologic treatment for NAS. The long-term effects of NAS are not known and are currently being studied (Kocherlakota, 2014).

A lifestyle choice that includes the use of drugs during pregnancy, and subsequent maternal addiction, has placed millions of children at risk. These children are seen in NICUs, foster care, special education programs in the public schools, and later in the juvenile court system. Family structure patterns are altered because grandparents may find themselves primary caregivers for their grandchildren. A woman who is an illicit intravenous drug user may lose her inhibitions and engage in high-risk sexual behaviors introducing other public health problems; these include acquisition of sexually transmitted infections (STIs), including HIV, and possible spread of the infection to the fetus or others (CDC, 2015h). The primary, secondary, and tertiary prevention interventions of the PHN cannot be underestimated when drug use takes such a high toll on every aspect of society.

Alcohol Use

Alcohol use during pregnancy can cause serious problems for the fetus.

Another societal problem is the use and addiction to alcohol. It is difficult to establish accurate statistics on the number of women who drink during pregnancy, but results from the 2011 to 2013 Behavioral Risk Factor Surveillance System (BRFSS) indicate that roughly 1 in 10 pregnant women drank alcohol within the past 30 days, compared to 53.6% of nonpregnant women. Prevalence of binge drinking was 18.2% for nonpregnant women, and 3.1% for pregnant women, with a 4.6 times greater rate for unmarried pregnant women (Tan, Denny, Cheal, Sniezek, & Kanny, 2015).

Alcohol use can cause devastating effects in the fetus, even when limited to early pregnancy and in the absence of addiction, and can lead to an array of neurocognitive and behavioral disorders, sometimes with structural anomalies, now described as fetal alcohol spectrum disorders (FASD). For example, regular intake of alcohol during pregnancy, especially in the first trimester, can cause the most recognizable form of the disorder: fetal alcohol syndrome, which is characterized by structural abnormalities of the head and face (e.g., microcephaly and flattening of the maxillary area), intrauterine growth retardation, decreased birth weight and length, developmental delays related to CNS abnormalities that can cause intellectual impairment, hyperactivity, altered sleep patterns, feeding problems, perceptual difficulties, impaired concentration, mood problems, and language dysfunction (NCBDDD, 2015b). FASD is estimated to occur at a rate of 0.2 to 1.5 per 1,000 live births in selected areas of the United States (NCBDDD, 2015a). Among the Native American population, alcohol abuse is a major public health problem, and FASD rates are as high as 8.97 per 1,000. PHNs working collaboratively with FASD specialists among this population have been effective in preventing FASD and in helping children born with FAS (Beckett, 2011). This completely preventable leading cause of birth defects imposes major costs for educational and health care systems.

What was once termed fetal alcohol effects (FAEs) syndrome, characterized as causing some but not all of the symptoms of FASD, is now separated into the more descriptive categories of alcohol-related birth defects (ARBDs), indicating problems with hearing, bones, heart, and kidneys, and alcohol-related neurodevelopmental disorder (ARND), represented by mental or functional problems, including cognitive and/or behavioral abnormalities (NCBDDD, 2015b). Recent research has helped to better classify the fetal effects of alcohol and may continue to lead to more specific classifications. These conditions occur in children whose mothers have used varying amounts of alcohol while pregnant, and physical signs are often much more subtle than in cases of FAS. However, those with FASD may have one or more of the following behaviors or characteristics (NCBDDD, 2015b):

- Small size for gestational age or small stature in relation to peers
- Facial abnormalities (e.g., smooth philtrum)
- Poor coordination
- Hyperactivity, attention problems, and learning disabilities
- Difficulties in school, especially with math

- Developmental disabilities (e.g., speech and language delays)
- Intellectual disability or low IQ
- Vision and hearing problems; problems with heart, kidneys, and bones
- Poor reasoning and judgment skills
- Sleep and sucking disturbances in infancy (para. 5)

It is important to provide evidence-based primary prevention before pregnancy and to reach women before a lifestyle of drinking becomes such a part of their lives that they are unable or unwilling to abstain during pregnancy. For example, the Pregnancy Risk Assessment Monitoring System (PRAMS) is a surveillance system developed by the CDC and state health departments to collect population-based information on maternal preconception, prenatal, pregnancy, and postpartum behaviors and experiences. Recent data collection revealed that prior to conception, 23% of women used tobacco and 12.8% continued to smoke while pregnant (CDC, 2013b). Children are also at risk based on maternal alcohol use during child-rearing, especially for adolescent mothers age 15 to 19 years.

Working with women of childbearing age to improve their general health behaviors and promote better preparation for pregnancy is essential. For those pregnant women and mothers already using substances, maternal drug and alcohol treatment programs that focus on supportive parent–child attachment, enhancement of parenting and child-rearing capabilities, and encouragement of the use of support systems that can improve child health and cognitive development are needed. In-home family skills training and parenting education programs that are evidence based and promote PHN and client rapport can be effective methods of working with substance-abusing mothers and their at-risk children; however, more studies are recommended. In a systematic review of home visitation with alcohol- and drug-using mothers, there was no significance in reduction of substance abuse among mothers entering drug and alcohol rehabilitation programs for those receiving home visitation. However, individual studies showed significance of home visitation in reducing these mothers' involvement with Child Protective Services indicating a positive effect on parenting and childcare practices even if it did not effectively diminish the addictive behavior (Turnbull & Osborn, 2012).

Tobacco Use

Tobacco use has increased dramatically among women, especially since the women's movement of the 1970s, inevitably affecting maternal and newborn health. The nicotine in tobacco is a major addictive substance, and smoking is an addiction that many people find difficult to stop. Although the risk factors of smoking are well documented, many pregnant women continue to smoke. Smoking during pregnancy is one of the most studied risk factors in obstetric assessment. Women, who may have started smoking as adolescents, often continue to smoke in response to life stressors. From a population and community health nurse perspective, one study found that a higher level of smoking in one's

neighborhood environment increased smoking during pregnancy for Latina women (Chesnokova, French, Weibe, Camenga, & Yun, 2015). The use of e-cigarettes, or vaping, is considered to be a health danger for pregnant women and developing fetuses. This nicotine delivery system poses threats to the baby. Also, the exhaled aerosol that is advertised to be "water vapor" actually contains nicotine and other chemicals such as metals, nitrosamines, and volatile organic compounds (CDC, 2016h).

Passive smoking or environmental tobacco smoke (ETS)—exposure to tobacco smoke from other people smoking in one's environment—also puts a person at risk for smoking-related disease. The Surgeon General has outlined major conclusions related to ETS based on years of research findings. One conclusion is that there is no risk-free level of secondhand smoke. Related to children and ETS, there is an increased risk of SIDS, more acute respiratory infection, ear disease, worse asthma, and risk for poor lung growth (CDC, 2013b). If a pregnant woman lives with a smoker, she and her fetus can be negatively affected by the other person's addiction. The use of smokeless tobacco products, such as snuff and chewing tobacco, has led to an increase in oral cancers related to tobacco exposure. Maternal smokeless tobacco use among some women has been associated with lower birth weight by an average of 78 g, controlling for other factors, and a mean of 331 g for pregnant women who smoke (England et al., 2012). An initial health history of a pregnant woman should always include the assessment of tobacco use, smoking status, and exposure to smoke in the personal environment.

Public and community health nurses and other health care professionals must be involved in the control of tobacco products on many levels, especially in health policy development, community outreach, education, and advocacy. It is very common to see smoking incentives and advertisements in poorer neighborhoods and communities of color. It is also important to have skills in smoking risk assessment, cessation options, and symptom management interventions for smoking withdrawal. Nurses should serve as positive nonsmoking role models and to be active in research implementation using clinical guidelines and evidenced-based practices. In the case of tobacco control, health policy development has made important strides at the grassroots level (see Chapter 13). A top priority of health care policy development is to reduce access of youth to tobacco products by restricting tobacco product advertising and promotion. Some significant policy steps that have been taken to discourage young people from smoking include imposing substantial cigarette excise taxes; requiring that public places, such as malls, restaurants, and even bars, be smoke-free; monitoring tobacco retailers for illegal sales to minors; and keeping cigarettes in locked cases. Most smokers become addicted to tobacco use in their early teens. If fewer adolescents begin smoking (primary prevention), there will be fewer women of childbearing age who smoke in the future (CDC, 2015e).

The community health nurse must not only advise clients to quit smoking but also offer supportive and empathetic approaches to stress reduction during smoking cessation, including methods or interventions that can help other symptom management that is associated with smoking cessation. For example, the PHN may counsel clients individually,

refer for behavioral therapy, provide self-help manuals, or recommend nicotine replacement therapy or medication. Other approaches, such as support groups, can be helpful. Any permanent reduction in the number of cigarettes smoked, amount of secondhand smoke inhaled, or amount of smokeless tobacco products used is helpful in improving the health of the mother and her fetus. Particular attention should be paid to adolescent mothers (15 to 19 years), as their rates of smoking are much higher than for adolescents of similar age who are not mothers (Substance Abuse & Mental Health Services Administration, 2014).

Nurses can be positive role models for health and demonstrate health promotion strategies to clients by their own behavior—if a nurse has struggled with smoking cessation, her admission of failures or explanation of successful strategies offers an opportunity to enhance credibility with clients as they recognize that the nurse struggles with some of the same health issues.

Intimate Partner Violence

Intimate partner violence (IPV) is any coercive action taken by someone against an intimate partner (New York City Department of Health and Mental Hygiene, 2012). Pregnancy is a vulnerable period for women and can increase their risk for IPV. IPV can range from physical abuse to woman and fetus (e.g., blows to the belly) to psychological coerciveness. It is estimated that between 4% and 8% of pregnant women from all walks of life experience IPV per year (New York City Department of Health and Mental Hygiene, 2012). Reasons for increased IPV during pregnancy can be an unintended pregnancy, increased stress related to supporting a child, and jealousy. Victims of IPV have high levels of stress that may lead to or prevent cessation of smoking and substance use such as alcohol and drugs. These women may also avoid prenatal care services for a variety of reasons such as injuries, control by their partners, and a lack of resources such as transportation or money for mass transit. Pregnant women who experience psychological IPV have a 1.5- to 2-fold increase in the risk of postpartum depression (Beydoun, Beydoun, Kaufman, & Zonderman, 2012). IPV can also have effects on the newborn and infant. In a study of low-income women who had experienced IPV, posttraumatic effects were found to influence the infant as indicated by regulatory issues and socioemotional problems (Ahifs-Dunn & Huth-Bock, 2014).

Sexually Transmitted Infections

The Centers for Disease Control and Prevention (CDC) estimates the prevalence of all STI cases in the general population to be 110 million, with an annual incidence of 20 million, and health care costs of $16 billion. The CDC (2013a) has recommended STI screening of all pregnant women at the initial prenatal visit for *Chlamydia*, hepatitis, HIV, and syphilis. Further, they recommend screening high-risk pregnant women for gonorrhea.

STIs can pass from mother to baby. Syphilis can cross the placenta and infect the fetus, as can HIV—which can also be passed to the infant through breast-feeding (CDC, 2016l).

Between 2012 and 2014, the rate of congenital syphilis rose 38% to 11.6 cases per 100,000 live births (Bowen, Su, Torrone, Kidd, & Weinstock, 2015). Other STIs (e.g., gonorrhea, hepatitis B, *Chlamydia*, genital herpes) can infect the baby as it passes through the birth canal during delivery. LBW, stillbirth, conjunctivitis, blindness, deafness, neurologic damage, chronic liver disease, and cirrhosis, along with neonatal sepsis and pneumonia, are possible infant complications of maternal STIs. Mothers may have premature rupture of membranes and resultant infection or may have a premature onset of labor. Some STIs can lead to cervical and other cancers, pelvic inflammatory disease, infertility, chronic hepatitis, and many other health problems (CDC, 2016m). Vaginosis during pregnancy has been linked to premature labor. However, a Cochrane systematic review determined that giving antibiotics to all pregnant women to "eradicate all vaginosis" did not significantly reduce the overall incidence of preterm births and that more evidence is needed (Brocklehurst, Gordon, Heatley, & Milan, 2013, para. 3).

A pregnant woman who discovers she has an STI often feels ashamed, betrayed, embarrassed, and angry. Those who are asymptomatic may not realize they are infected or deny the existence of the disease and fail to carry out the treatment plan after diagnosis. Although educating the pregnant client about the effects of STIs is critical, providing information alone is not enough. The community health nurse has a pivotal role in enhancing the empowerment of women so they can act on the information they receive. The PHN engages with the pregnant clients and helps them understand that they have control over their bodies. Usually, STIs are first discovered in pregnancy during routine prenatal screening, which places the clinic nurse and the nurse who may make home visits in the position to take an affirmative approach to treatment and follow-up.

HIV and AIDS

The HIV epidemic is the great tragedy of the final two decades of the 20th century, but great strides are being made in the 21st century. As a result of early detection and antiviral therapy, there has been a substantial decline in the number of infants born with HIV since the height of the epidemic. A large-scale study conducted from 2005 to 2008 examining the association between mother and child HIV transmission in 15 jurisdictions of the United States found that of the 8,054 births of HIV-infected mothers, 179 infants (2.2%) were diagnosed with HIV. It was concluded that there was an increased risk of having an HIV-infected infant among those mothers that received late testing/prenatal care or no prenatal antiretroviral therapy (Whitmore et al., 2012). An HIV-positive woman who is pregnant or who has delivered a baby requires special nursing management of the pregnancy and of the family after the birth of the newborn. There are many teaching opportunities for the PHN during a high-risk pregnancy, such as helping the client identify, change, or curtail high-risk behaviors and promoting adherence to prenatal and HIV care. Success in changing behaviors often requires an interdisciplinary approach of health care, social, emotional, and financial resources (Bungay, Massaro, & Gilbert, 2014 CDC, 2015f).

In the United States and other developed nations, HIV-infected women are advised not to breast-feed their infants because there is a chance that the infants will become infected with HIV from breast milk (Mofenson et al., 2013). The community health nurse focuses teaching on providing a safe, available, and low-cost form of infant formula. In developing countries, the lack of clean water still makes formula feeding dangerous, and breast-feeding is usually recommended. The infection rate for HIV from breast-feeding and the mortality rate from formula made with impure water are about the same, resulting in a dilemma for women and health care providers in developing countries.

Poor Nutrition, Weight Gain, and Oral Health

Nutrition is very important to the unborn child, and mothers' choices, even before conception, can affect the baby's health and development. It is at about 3 weeks' gestation —often before the woman recognizes that she is pregnant—the infant's neural tube is forming. Hormones and nutrients set gene switches that affect later life.

Research has demonstrated a positive correlation between weight gain during pregnancy and normal birth weight in the babies. In 2009, the Institute of Medicine (IOM) released new guidelines for weight gain during pregnancy based on body mass indices (BMIs). Weight gain between 25 and 35 pounds during pregnancy is recommended for women with BMIs ranging from 18.5 to 24.9, and the recommendation is 28 to 40 pounds for underweight women with a BMI under 18.5, whereas overweight women with a BMI between 25 and 29 should gain 15 to 25 pounds, and obese women with a BMI over 30.0 should hold their weight gain to between 11 and 20 pounds (IOM, 2009). The American College of Obstetricians and Gynecologists (ACOG) reaffirmed in 2015 that the 2009 IOM gestational weight gain guidelines are important for clinicians to use. It is recommended that clinicians determine a woman's BMI at the initial prenatal visit and discuss weight gain, diet, and exercise goals initially and throughout the pregnancy (ACOG, 2013b).

Weight gain during pregnancy should be monitored regularly.

Obesity currently affects about 36% of all American women (National Institute of Diabetes and Digestive and Kidney Diseases, 2012). Approximately 20% of UK women weighed at their first prenatal visit were determined to be obese (Midwives Information & Resource Service, 2016). Studies have shown that about 48% of pregnant women in the United States gain more than the recommended amount of weight (CDC, 2016n). Gestational diabetes poses the greatest risk to obese pregnant women and increases the risk for preterm birth (CDC, 2014e). Obese women often have nutritional deficiencies, such as anemia, and low levels of B12 and folic acid and need to be guided toward eating less processed foods, more lean meats, and more fruits and vegetables (University of Rochester Medical Center, 2011). PHNs who work with morbidly obese pregnant women can help them most by emphasizing good nutrition and by encouraging them to maintain their prepregnant weight without drastically reducing caloric intake. This can be accomplished primarily by a marked decrease in consumption of "empty calories" from junk food and replacing with increased intake of fruits, vegetables, and low-fat sources of calcium. Pregnancy is never a time for dieting. Following nutritional guidelines ensures the proper number of servings and portion sizes. Nutritional counseling can have an additional benefit in that it may ultimately decrease the risk of obesity or eating disorders in the client's children. For women who are prone to gaining too much weight, nutrition-rich, low-calorie foods are recommended.

Exercise during pregnancy is essential and can moderate maternal weight gain and improve overall fitness that is desirable for the labor and delivery process. After assessment, the PHN can determine whether the unwanted weight gain is related to the consumption of additional calories, to limited activity, or to fluid retention. Each cause must be managed differently. Underweight women have twice as many LBW babies as women whose weight is within normal range. Low maternal weight gain is associated with LBW infants who have higher incidences of growth problems, developmental delays, CNS disorders, and mental retardation (Han, et al., 2011). Nutritional teaching is part of the PHN's role when working with a pregnant woman who has difficulty gaining the recommended weight during pregnancy. Finding ways to add calories to foods and increasing the woman's desire to eat are effective methods to improve maternal weight gain. Insufficient caloric intake in pregnant adolescents (who themselves are still growing) is an additional concern for their future health and health of the infant over the life course.

Oral health during pregnancy is also very important to assess (Oral Health Care During Pregnancy Expert Workgroup, 2012). Periodontal infection may affect around 40% of women of childbearing age and is especially common among disadvantaged and ethnic or racial minorities who may not have adequate access to dental health care. Maternal periodontal disease has been linked to preterm birth, LBW, preeclampsia, and early fetal loss; however, recent studies have not shown the reduction of preterm birth or LBW among those infants whose mothers received periodontal therapy in pregnancy. Therefore, additional research in this area is needed. Although the research is conflicting, it is evident that dental health procedures have generally been found to be effective and safe

for pregnant women, especially during the second trimester (ACOG, 2013a). Sugar-free gums that contain xylitol and chlorhexidine may be helpful in reducing the maternal–child transmission of caries-causing bacteria (Nayak, Nayak, & Khandelwal, 2014). Not only dental health is important during pregnancy but poor dental hygiene and disease have been linked to health conditions, such as cardiovascular disease and diabetes. High maternal levels of the bacteria that cause cavities have been associated with a greater chance of subsequent dental caries in the infant (ACOG, 2013a).

Public and community health nurses should teach women of childbearing age the importance of regular dental health checkups and proper dental hygiene, along with making referrals for dental treatment when needed. Because there is frequently a shortage of dental providers to see vulnerable or low-income women, the nurse sometimes has to advocate for pregnant women who have major oral health treatment problems, such as gingivitis or dental caries or infections. Dental health should be a part of general primary preventive education for all childbearing-age women and a major teaching and screening element of prenatal care.

Socioeconomic Status and Social Inequality

Socioeconomic disparities can affect outcomes of pregnancy and the health of the mother as

well as the infant.

As noted earlier, poverty plays a role in pregnancy and birth outcomes. Social and economic disparities are factors in preterm birth in both developed and developing nations and reflect some of the social determinants of health. These relationships may be more indirect, as poorer women often lack health insurance, have less access to quality prenatal care services, have poorer nutrition, and are exposed to more situational and psychological stressors. In the United Kingdom, a retrospective study with a very large sample (n = 59,487) was done that focused on the poorly understood factors that delay seeking antenatal care and engagement in that care. Findings indicated that higher parity, pregnancy during the teenage years, higher parity, non-White ethnic background, unemployment, unmarried, poor social support, and smoking were significantly associated with late access to antenatal services and poor fetal outcomes (Kapaya et al., 2015). Prenatal stress is difficult to research because of the multiple variables that can affect prenatal stress. In vitro fertilization (IVF) is a relatively new area to consider for pregnancy stress. Differences in stress based on method of pregnancy (IVF and spontaneous pregnancy) indicate that the sources of prenatal stress differ based on pregnancy method and that nurses should be aware of the pregnancy method in their assessment interview when discussing stress (Shih et al., 2015). Other stressors should also be assessed (e.g., unintended pregnancy; nutrition; chronic stress and daily hassles; levels of social support; mental health issues, such as depression or anxiety, work stressors, racism, or discrimination; and any significant life events, such as death or other significant losses).

Prenatal care is crucial to ensure good outcomes of pregnancy. Studies continue to reiterate the need for regular care visits, showing an association between regular and early care and fewer preterm deliveries and higher infant birth weights. Significant disparities in prenatal care are present among Black, Hispanic, and American Indian/Native American women (HRSA, n.d.). Access to obstetrical and gynecological health care is difficult in many areas of the country. It is at crisis levels in some rural areas. Lack of adequate access to prenatal care leaves many pregnant women in danger (see Perspectives: Student Voices). Other factors, outlined in more detail in Chapter 25, may also affect the health of both mothers and babies.

PERSPECTIVES STUDENT VOICE

I began working as a nurse's aide at our local hospital when I

started nursing school. I learned firsthand the dangers of childbirth and the long-term consequences that can result. One night, a single young female reported to the emergency room in labor and was admitted to the labor and delivery department and seen by the nurse midwife who had provided prenatal care for the mother in the clinic. The young mother-to-be was very excited. Her contractions continued, and she did not progress with the labor process, so she was to be started on oxytocin (Pitocin) to increase the effectiveness of her labor. The nurse midwife checked on her patient frequently, but problems began after the first 8 hours of labor. As the dosage was increased, the fetus reacted with bradycardia, and the nurse midwife did not notify the physician. The Pitocin dosage was decreased and then the heart rate stabilized; this process continued for three cycles. The nurse midwife signed off her 12-hour shift and handed care of the patient over to the nurse midwife coming on shift. Again, whenever the Pitocin dosage was increased to the point of becoming effective, the fetus would respond with bradycardia. Report was given, and the physician in charge was still not notified. The first two times, the fetus recovered. The third time, the fetus did not recover; instead, the bradycardia increased. By this time, the mother had been in labor for over 24 hours, and the fetus was in irreversible distress. The physician was notified of an emergency and reported to the bedside within 5 minutes. An emergency cesarean section was performed, and the Apgar scores at delivery were 0 at 1 minute, 0 at 5 minutes, 0 at 10 minutes, and 3 at 15 minutes. The infant was severely neurologically damaged. I found out later that the infant was diagnosed with severe cerebral palsy and will never walk, talk, or feed normally. She cannot swallow and will require suctioning, gastrostomy tube feeding, and total care throughout her lifetime. She is also cortically blind. The hospital and physician were sued. The nurses and the nurse midwives in the labor and delivery room were found negligent in not reporting to the physician when the patient's labor failed to progress. The nurse midwives from both shifts were found negligent for failure to recognize fetal distress and summon the physician. A multimillion-dollar award was given, and the nurses and nurse midwives employed by the hospital were fired. It is sad to think that this tragedy could have been avoided with prudent nurse–patient advocacy, reporting, and appropriate documentation—the things our nursing instructors are always drumming into our heads. I know that as a new graduate, I am now in a position of responsibility to make decisions to notify the physician or not. I have decided that the choice should always be to notify the physician. Even though it may seem inconvenient, it really should be done. I will never forget this case and its long-reaching consequences for the child and family, as well as for the nursing staff and nurse midwives.

Lyndsay, Student Nurse

Adolescent Pregnancy

Adolescent pregnancy poses risks for both mother and baby.

Pregnancy during the adolescent years (13 to 19) is considered a health risk because of the ongoing physical growth and the demands of psychosocial development during these years. The United States leads most developed nations in the rates of teenage pregnancy, abortion, and childbearing. Young maternal age at time of pregnancy and birth creates several medical risks for the mother and baby because of the immature physiology of the mother-to-be such as preterm labor, LBW, and pregnancy complications. There are also many social risks such as high school dropout rates, lifetime poverty for mother and children, high rates of incarceration of the teen's child in later years, and poor school performance. Infants born to Black adolescents are more likely to be LBW babies than are infants of White teens. Infants born to very young adolescents (aged 10 to 14 years) are at very high risk for neonatal mortality. Adolescent mothers have increased psychological risks, such as isolation, powerlessness, depressive disorders, and increased somatic complaints. Developmental and maturational processes are disrupted or compromised. There is also a high prevalence of psychological distress that impacts the mental health of the teen parent and their offspring, with not enough community mental health resources in many communities (Smithbattle & Freed, 2015). It is important for PHNs to assess each pregnant adolescent's situation in order to promote the best outcomes based on available evidence and community resources including family support and living situation, relationship with the father of the baby and other supportive friends, school plans, and the ability to care for her own health and that of her infant, as well as her hopes, goals, strengths, and weaknesses, in order to effectively plan interventions (Nurse-Family

Partnership, 2011).

The markers for successful pregnancy outcomes and future life events are complex and dependent on the expectant mother's health behavior, social determinants, and living environment. The mother's educational attainment, marital experiences, subsequent fertility behavior, labor force experience, occupational attainment, and experiences with poverty and public assistance are all directly related to the adolescent pregnancy and are often negatively affected (Pinzon, Jones, Committee on Adolescence, & Committee on Early Childhood, 2012). The issues of adolescent parenting are complex. They encompass many areas, including emotional, physical, and social issues, and the life experiences of adolescent mothers are often characterized as unequal to those of their peers who delayed childbirth (Ruedinger & Cox, 2012). Pregnant adolescents are less likely to receive early and continuous prenatal care, and they are more likely to use alcohol and to smoke during their pregnancies. Moreover, their diets are often lacking in essential vitamins and minerals.

The P/CHN has a unique challenge when developing plans of care and implementing them with pregnant teens. Part of the challenge is the developmental needs of the adolescent mother herself and preparation for becoming a mother. Teaching and counseling related to pregnancy-related changes and prenatal self-management, preparation for labor and delivery, breast-feeding, and infant care and development are some of the most immediate learning needs Development of a trusting relationship helped teens to continue breast-feeding. Emotional support is provided by relationships that engender love and appreciation, and instrumental support is more concrete (e.g., a ride to the clinic, help with homework, or money to buy food). Informational support is the provision of information or advice. Another issue with pregnant adolescents is the problem of repeated pregnancies. Public and community health nurses can provide interventions that may help postpone subsequent pregnancies such as counseling, referral, and intensive case management (Nurse-Family Partnership, 2011).

Emotional Needs

Teenagers who become pregnant deal with this change in their life in a variety of ways. Some have such a strong denial system that they deny the pregnancy, even to themselves. They may be 3 or 4 months into the pregnancy before they can admit it and seek a pregnancy confirmation. Often, their parents are the last to know. What is difficult about this scenario is that prenatal care is delayed into the second or third trimester of pregnancy. If the teen chooses to continue with the pregnancy, the delayed prenatal care could compromise the well-being of both the young mother and the fetus. Teenagers also take longer to develop their competence and identity as mothers in many cases. The major life transition of "becoming a mother" can take longer or create more developmental and situational risk. Early interventions for both prenatal and parenting support are needed to build resilience and strong mental health (Smithbattle & Freed, 2015).

Caring and supportive parents, community health nurses, and school nurses can be

instrumental in guiding an adolescent through this difficult time. Adolescent parents have difficult choices to make, including decisions about continuing with the pregnancy, keeping the baby, or finding adoptive parents. Some may choose abortion. These choices are difficult, may be strongly influenced by peer opinions and social pressure, and are fraught with emotion. Adolescents and supportive parents, in consultation with professionals, can explore all options. This may be the time that the nurse first begins to work with the teen, perhaps at school or in a school-based clinic. First contact may also occur in a clinic or physician's office or on a home visit resulting from a referral from a health care provider. Home visiting programs for adolescent mothers have been effective in improving prenatal care, parenting scores, and school continuation rates (Peacock, Konrad, Watson, Nickel, & Muhajarine, 2013). The nurse can offer educational services, emotional support, and referrals for services as needed. Because postpartum depression is not uncommon, and adolescents are at increased risk, it may be important for P/CHN contact to continue periodically for 1 to 2 years postpartum. The goal of any pregnancy is positive maternal–infant outcomes, including a positive relationship. For some adolescent mothers, positive relationships are more difficult to achieve than for older mothers. Positive relationships and self-esteem have an impact on the quality of mothering and positive responses to infant distress. In classic home visitation studies conducted by Olds et al. (2007), by Nurse–Family Partnership (2011), and by Koniack-Griffin, Anderson, Verzemnieks, and Brecht (2000) and Koniack-Griffin et al. (2002) and (2003), intensive intervention programs improved parenting outcomes, including self-esteem and self-confidence. A recent systematic review confirmed that home visiting programs were effective in improving child development, reducing child abuse, and overall improving the lives of at-risk children and their families (Peacock et al., 2013).

Public health nurses who have special training in the evidenced-based home visitation models for high-risk maternal–child populations can provide each participant with services that promote the overall health of the mother and maternal–infant bonding. Results of studies, like those for the Nurse–Family Partnership, can further guide nurses in their work with pregnant adolescents and their children (Olds et al., 2013).

Physical Needs

Pregnant teens have myriad physical needs that can be addressed by routine prenatal care and education, but there is a need for continuity if such endeavors are to be successful. Routine prenatal care is one of the most important needs, and adolescents may require assistance in recognizing the value of health professionals monitoring the pregnancy. Some may feel embarrassed and uncomfortable with male health care providers and refuse to keep appointments or may want to be accompanied by the baby's father or a girlfriend. Whatever it takes to get the teen to prenatal appointments should be encouraged, including making arrangements for transportation (e.g., procuring bus tokens, calling a taxi, or arranging for a friend or social worker to drive the teen to her appointments). Where

feasible, specialty-focused clinics for pregnant and parenting teens may be most effective. School-based clinics have shown promise in providing easily accessible prenatal care. One study found a 14.2% increase in school attendance with a program targeted to pregnant teens, the Prenatal at School Program (Griswold et al., 2012). The pregnant adolescent needs education regarding changes in her emotional state and her body, the growth and development of the fetus, dietary requirements, and rest and relaxation needs. She also needs anticipatory guidance for caregiving and parenting. Teaching can take place as part of each prenatal appointment, in specific classes at school for pregnant teens, in the health department clinic, or during home visits. In each setting, the PHN can modify the teaching methods to the setting and the individual needs of the adolescent. Studies show that home visits and motherhood classes are effective in promoting better outcomes for adolescents and their infants (Schaffer, Goodhue, Stennes, & Lanigan, 2012). Changing adolescent behavior during pregnancy can be challenging, and P/CHNs must keep in mind the developmental differences between early, middle, and late adolescents with regard to intentions and health habits. The P/CHN may focus on one important and seemingly less complex issue of nutrition during pregnancy. However, it is a more difficult task to change the eating habits of teens than it is to change those of adults. In their stage of development, adolescents usually are more concerned with body image than with fetal growth and development. Fad diets, peer pressure, and personal control are all issues with which the pregnant adolescent is struggling. If a teen has been raised in poverty, a multiplicity of other issues can affect her motivation to make dietary changes during pregnancy. Adolescents are more often concerned with present needs and respond better to relaxed, informal group approaches to education that involve topics of their choosing and do not resemble the school setting. Pregnancy diaries, creative activities (crafts, drawing, making snacks), small group activities and games, videos with discussions, social media and computer-assisted interventions, and visits to local community resources (hospital delivery rooms, social services, lactation counselors) are more appealing than classroom lectures. Programs that offer empowerment and group prenatal care are helpful. Also, teaching and support groups may be helpful in promoting healthy prenatal behaviors and preparing for motherhood (National Clearinghouse on Families & Youth, n.d.).

Social Needs

Peer support and acceptance is an expected part of adolescent development but can also influence the stress level of the teen. There may be changes in acceptance by social groups or in types of activities (e.g., surfboarding, mountain climbing) based on the pregnancy. The group may participate in behaviors that the pregnant adolescent should not participate in, such as smoking, drinking, or taking illicit drugs. This causes conflict for a pregnant teen who has a strong need to be accepted by her peer group and who also knows that she has a responsibility to her unborn child. Peer support almost universally changes once an adolescent girl finds herself pregnant. This can lead to conflict and isolation. The PHN can facilitate help for the adolescent client to problem solve her dilemma by providing a social

support system among the attendees at prenatal classes. The nurse can also convince the teen's parents or other adults in her life to offer her more support. Often, a developmental crisis such as an adolescent pregnancy can help cement the mother–daughter relationship. It takes time and work on the part of the parents and the teen. The adolescent will need the support of her parents after the baby is born, and strengthening the relationship during pregnancy is an important start. Another social outlet and an important resource is school. The teen should be encouraged to continue her studies, with the goal of graduation. This helps her chances for self-sufficiency, employment, and stable housing, as well as a sense of self-worth (Family and Youth Services Bureau, n.d.). Teen pregnancy and education are discussed more thoroughly in Chapter 22.

Maternal Developmental Disability

For couples that are developmentally disabled, having a child puts increased stress on a system that is already burdened. Parenting requires attending to not just the child's physical care but socialization and developmental stimulation, well-child and illness health care, emotional nurturing, and age-appropriate supervision. Depending on the social support, and coping skills of the developmentally delayed parent, the stress and need for emotional control and positive decision making can be monumental. Evidence from a large cohort study in Britain found that, for 4- to 6-year-olds, there was "no association of parental IQ with conduct or emotional problems" in the children; however, for children age 7 into adolescence, "strong evidence was observed" between lower parental IQ and child "conduct, emotional, and attention problems" (Whitley, Gale, Deary, Kivimaki, & Batty, 2011, p. 1032). Confounding variables included the environment of the home, parental affect, and child IQ. Even though there may not be strong evidence for these problems, children are still at risk for understimulation and environmental insecurity. Parent training/childcare skills programs, peer-to-peer support groups, community agencies, and careful home monitoring can reduce the risk of child abuse and neglect and promote more effective parenting (Promising Practices Network, 2012).

Much of the pediatric literature discusses the needs of developmentally disabled infants and children and the roles of nurses and health care professionals in assisting the families of these children. Developmentally disabled adults, however, are not often represented in studies of parenting, so there is limited information about their experiences and success as parents. Sometimes bizarre behaviors can occur because the parent does not understand basic concepts regarding normal child development. As with nondevelopmentally delayed parents, more responsive and involved developmentally disabled parents have better parenting outcomes. Periodic developmental screening, infant stimulation and home visitation programs, and special health care instruction have demonstrated some evidence-based results (Promising Practices Network, 2012), but there is a great need for more research. How does the PHN work with developmentally disabled parents effectively? Most importantly, nursing support must enhance the natural resilience of the family. Extended family support systems, along with community agencies and religious organizations that

provide services for mentally disabled adults and children, can improve the outcomes for these families. The success of family support depends on immediate and continuing health promotion visits by multidisciplinary providers. The goal is to establish safe parenting routines that will serve as a foundation for parenting skills needed when the infant begins to walk and explore—a time when the infant's safety is more in jeopardy. A list of helpful resources is available from Connecticut Department of Developmental Services (2014).

The establishment of a trusting relationship between the nurse and the family is of foremost importance. Teaching by demonstration with many visual aids and prompts, along with games and creative approaches to engage and sustain attention, can challenge the nurse's creativity. Modeling of appropriate parenting behavior needs to occur on each visit. Supervision and monitoring of family functioning must continue until the child reaches adulthood. As part of the transition to other systems of care, PHNs often advocate for families with maternal developmental disability regarding the plan of care, interpreting it for other professionals and multiple disciplines. Many agencies employing nurses cannot provide the intensive follow-up that such a family requires. It is then necessary to make referrals to organizations that can provide support, such as the American Association of Retarded Citizens (AARC) or Exceptional Parents Unlimited. The nurse may stay involved as a consultant to the paraprofessionals or make periodic home visits at times of developmental or situational crisis.

Complications of Childbearing

Some maternal deaths are not preventable (e.g., amniotic fluid embolism). Morbidity is also a factor, and although some major risk factors among pregnant women and infants have been discussed, several common medical complications of childbearing bear mentioning. The effects of hypertensive disease in pregnancy, gestational diabetes, postpartum depression, and grief in families who have lost a child are important areas in which the P/CHN can intervene effectively.

Hypertensive Disease in Pregnancy

Blood pressure measurements in all people show daily variation, regardless of physical and mental activities. Hypertension in pregnancy may be chronic or related specifically to pregnancy. In a 13-year study (1995–2008) reviewing primary and secondary chronic hypertension in pregnancy, the prevalence almost doubled during the study period (0.90% to 1.52%), and this was shown to contribute to adverse maternal outcomes of renal failure, pulmonary edema, preeclampsia, and in-hospital mortality (Bateman et al., 2012).

Preeclampsia results in new-onset high blood pressure and protein in the urine, along with nondependent edema, and can result in eclampsia (characterized by convulsions and/or coma), pulmonary edema, liver rupture, renal failure, disseminated intravascular coagulopathy (DIC), and cortical blindness, as well as maternal death. The effects from pregnancy-induced hypertension on infants are often serious because placental health is associated with fetal growth (Skjaerven, Klungsoyr, Morken, Rich-Edwards, & Wilcox, 2015). Although protein in the urine has been a consistent marker, it may take a while to show up in lab tests and is no longer required in order for a health care provider to diagnose preeclampsia (ACOG, 2013c). Various biomarkers are helpful in predicting preeclampsia early in pregnancy (e.g., placental protein-13, PAP-A), and others (homocysteine, asymmetric dimethylarginine [ADMA], leptin) found during the first trimester can be indicative of third trimester onset (Masoura et al., 2012). A prospective study of 252 women found that in the 49 who developed preeclampsia, ADMA and homocysteine levels began to rise 1 month prior to onset, indicating that careful monitoring of these biomarkers may help identify pregnant women at risk of developing this condition (Lopez-Alarcón et al., 2015). It occurs in about 6% to 8% of pregnancies and the goal is to prevent maternal cardiac or cerebrovascular complications and preserving the fetal circulation until the baby can safely be delivered; some risk to mother is still present in the immediate postpartum period (Kattah & Garovic, 2013). Various methods are employed to attempt to prevent and control hypertension during pregnancy, namely, careful and constant monitoring of blood pressure, use of blood pressure medications if needed, frequent prenatal visits with monitoring of lab tests, a diet rich in fresh fruits and vegetables, lower sodium food choices, adequate fluid intake, weight gain limitations, rest, and regular exercise. Intermittent fetal monitoring may be required. These remain the most common preventive suggestions that PHNs, in collaboration with the clients' primary health care providers, can give to their

pregnant clients. A calm environment, periods of rest, and the pregnant woman either elevating her feet or reclining in a left sidelying position are also recommended. Additional assessment data may guide the nurse to focus teaching on stress reduction techniques and modification or elimination of smoking. Public and community health nurses can provide frequent monitoring of blood pressure and other symptoms and encourage the client to be vigilant in keeping prenatal appointments. However, medication or even hospitalization may be necessary. The PHN can offer support and understanding while continuing to be a resource for the client as the pregnancy progresses and the infant is born.

Gestational Diabetes

Gestational diabetes mellitus (GDM) occurs in pregnant women who have never had a problem with high blood glucose but do during pregnancy. The average onset for GDM is around the 24th week of pregnancy (American Diabetes Association, 2016). GDM is estimated to occur in about 2% to 10% of pregnancies and is estimated to cost $1.3 billion (Dall et al., 2014). For the mother with GDM, there is a higher risk of hypertension, preeclampsia, urinary tract infections, cesarean section, and future risk of type 2 diabetes. As far as pathophysiology, GDM is similar to type 2 diabetes, and more than one third of women with GDM eventually develop type 2 diabetes during their lifetimes. Although type 2 diabetes prevalence is higher in some racial and ethnic groups, for GDM, the effects of poorer pregnancy outcomes are spread out across ethnic and racial groups with similar rates of complications of pregnancy-induced hypertension and preterm birth (Mocarski & Savitz, 2012). Because growth and maturation of the fetus are closely associated with the delivery of maternal nutrients, particularly glucose, maintenance of appropriate glucose levels is essential to the health of the fetus. Daily self-monitoring of blood glucose levels is recommended. Women should be encouraged to monitor blood glucose levels regularly 6 weeks postpartum and periodically throughout their life (CDC, 2012a).

The infant is at increased risk for fetal death because GDM has been associated with macrosomia, or large-for-gestational-age (LGA) babies, birth injuries such as broken shoulders, breathing problems, and abnormally high blood sugars at birth (Rosenstein et al., 2012). The public and community health nurse can help in the control of GDM by encouraging early prenatal care, adequate nutrition, rest and exercise, and adherence to the particular dietary, activity, and blood glucose monitoring regimen suggested by the woman's health care provider. Those P/CHNs working with pregnant women should provide education on early warning signs for GDM and the importance of regular prenatal care, reminder about getting the glucose tolerance test around the 24th week of pregnancy, and follow-up.

Postpartum Depression

PHNs need to watch for signs of postpartum depression among their clients and offer assistance.

Although most people recognize the common fleeting mood swings immediately after childbirth known as "baby blues," high-profile cases like Andrea Yates, who suffered from postpartum psychosis and drowned her five small children, are rare (1 or 2 per 1,000 births) but nonetheless tragic (Criminal Justice, n.d.). Actresses Brooke Shields and Hayden Panettiere, among others, have discussed their postpartum depression and treatment with antidepressant medications, making this condition more visible and less stigmatizing (Davis, 2016).

According to a national survey, approximately 11% of nonpregnant and 8% of postpartum women experienced depression from 2005 to 2009 (Ko, Farr, Dietz, & Robbins, 2012). Also, depression and posttraumatic stress disorder (PTSD) have been found in both mothers and fathers subsequent to a healthy birth following a prior perinatal loss (Christiansen, Elklit, & Olff, 2013). Meta-analyses have indicated that risks for postpartum depression include a family history of psychiatric illness, poor social support, stressful life events, anxiety during pregnancy, the personality traits of neuroticism, and

more recently perfectionism (Gelabert et al., 2012). Depression can affect anyone, even women without a history of prior depression. Perinatal depressive symptoms may not indicate major clinical depression. Nevertheless, symptoms may cause considerable psychological distress, such as irritability and restlessness; feeling hopeless, sad, and overwhelmed; having little energy or motivation and crying unexpectedly; sleeping and eating too little or too much; problems with cognition (memory, decision making, focus); loss of pleasure or interest in usually pleasant activities; and withdrawal from family and friends.

The value of confidantes to new mothers is evident, and mothers should be encouraged to ask for help from family and friends or to talk with other new mothers or join support groups. Group and individual therapy are helpful, as is medication. PHNs can encourage new mothers with depressive symptoms to sleep while baby is sleeping, be realistic and not try to be the perfect homemaker, ask for help from her partner with feedings during the night and with household chores, get out of the house periodically, and spend quality time with her partner. They can also refer them for a mental health evaluation.

There are several nonpharmacological interventions the nurse can initiate in addition to the ones mentioned above. First, caffeine can lead to sleep disturbance, and alcohol is a depressant that has been implicated in depression. A simple yet helpful suggestion is the elimination of both. Getting adequate sleep is important because sleep deprivation exacerbates psychiatric symptoms. Napping when the baby naps, resting when possible throughout the day, and going to bed early (albeit with the knowledge that sleep may be interrupted two or more times to feed the infant) will provide more hours of rest and sleep. Exercise is helpful and raises levels of endorphins. Anxiety symptoms often coexist with depression. Relaxation techniques that reduce anxiety can be helpful, including listening to relaxing music, doing yoga, or performing a simple exercise routine. Having a daily routine and setting realistic goals are also helpful (Griffin, 2016). Participation in a support group allows women to identify with others who may be experiencing similar difficulties. Through discussion, women provide each other with both emotional and practical support.

A final area of assistance is client education. A woman with postpartum depression is more likely to manage her depression successfully if she is aware of the symptoms of depression; the need for a support system; the importance of adequate rest, sleep, and nutrition; and the possibility of supportive psychological or pharmacologic therapy. The critical nature of postpartum depressive symptoms and the potential negative ramifications for mothers and their children are evident. Depression during pregnancy can result in lower birth weight or premature infants. Moreover, postpartum depression can affect parenting and infant stimulation that can lead to delays in infant language development and emotional bonding, lower activity levels, and behavior and sleep problems. Untreated depression can lead to substance abuse, inadequate prenatal care and nutrition, poor pregnancy outcomes, family disruption, and inadequate mother–infant bonding. However, the safety of antidepressants in pregnant and breast-feeding women is not clear. Even though psychotropic medications have been shown to cross the placental barrier and have

been found both in amniotic fluid and breast milk, the ACOG encourages routine depression screenings and recommends that the use of antidepressants be individualized (ACOG, 2015). Further research supports the importance of prenatal health care providers collaborating with psychiatric health care providers to determine the best treatment for pregnant and lactating women (Chaudron, 2013). Women on any medications should be educated and advised to discuss with their providers if they become pregnant.

Community health nurses can intervene by initiating primary preventive mental health and coping measures that promote mental health throughout pregnancy and the postpartum period. Helping pregnant women to appreciate themselves and their strengths, embrace their new body changes, and positively anticipate their new role is primary preventive intervention for good mental health and promotion of attachment to their infant. If women are assessed to be at risk, mental health resources can be identified, and then, positive mental health outcomes may be fostered by supporting their self-esteem, optimizing the quality of their primary intimate relationships, anticipatory guidance on issues that may arise during pregnancy and the postpartum period, and reducing day-to-day stressors. At times, the nurse's efforts alone are not sufficient, and a referral to community mental health services for early detection and treatment is essential for the women and their children.

Fetal or Infant Death

An infrequent role for nurses in maternal–child health is that of grief counselor, but this may be a role for the advanced practice nurse in certain settings or communities. A couple may experience a miscarriage or ectopic pregnancy, stillbirth, or the death of an infant from sudden infant death syndrome (SIDS), which is "the unexpected, sudden death of a child under age 1, with onset of the fatal episode apparently occurring during sleep, that remains unexplained after a thorough investigation, including performance of a complete autopsy and review of the circumstances of death and the clinical history" (Trachtenberg, Haas, Kinney, Stanley, & Krous, 2012, p. 630). The exact cause of SIDS is not certain, but it may be associated with brainstem control of heart and lung functions (Illinois Department of Public Health, n.d.). It is more common in boys and most often occurs in infants between 1 and 4 months of age (Safe to Sleep, 2015). Increased rates of SIDS are associated with side/stomach sleeping position, exposure to cigarette smoke, premature birth, cosleeping, having a sibling that died of SIDS, and soft bedding in the crib. SIDS is the leading cause of death for infants from 1 to 12 months of age; about 2,500 infants die annually from SIDS. Since 1990, the SIDS rate has dropped, but the rates for Black and American Indian/Alaska Native infants are disproportionately higher (Illinois Department of Public Health, n.d.). A study by Trachtenberg et al. (2012) examined changed in San Diego after the Back to Sleep campaign was initiated. Infant deaths while in prone position dropped from 84% in 1991–1993 to 48.5% in 1996–2008. However, bed sharing increased from 19.2% to 37.9% overall, and for infants ≤2 months, it is more than doubled (29% to 63.8%). Researchers noted that 99% of SIDS infants had a minimum of one risk

factor and only 5% had no extrinsic risk factors.

In each situation of loss, the PHN has an important supportive role. People respond to grief in a variety of ways: some express deep sadness, shock, or disbelief; some weep and are unable to talk; and others talk incessantly about regrets or guilt. Even if a miscarriage occurs early in a pregnancy, the bonding between the mother and fetus has begun, and expressions of grief may be as intense as with the loss of an infant or child. Women often have feelings of abandonment, bereavement, and guilt, thinking that they did something wrong. When parents are unable to identify the exact cause of their fetal loss, they have a more difficult time letting go of grief and anxiety. Increased anxiety levels are also found, sometimes more frequently than depression. Psychological counseling has been associated with greater decreases over time in levels of worry, grief, and self-blame (Bhat & Byatt, 2016). For couples that have delivered a stillborn baby, the shock is compounded by the experience of carrying the pregnancy to full term, along with the anticipation of an imminent delivery and the expectation of an addition to the family. This is especially true if all signs before the birthing event itself were positive. They may say such things as, "We felt him move just yesterday and now he's dead—what did I do wrong?" or "I did everything right during this pregnancy. Why did this happen?" These are questions for which there may be no answers. Frequently, a stillbirth is related to birth defects (15% to 20%), fetal entanglement in the umbilical cord (15%), placental problems (10% to 20%), reduced fetal growth (20%), or an infection (10% to 20%). Trauma and *Rh* disease can also lead to stillbirths (March of Dimes, 2015).

Mothers who experience stillbirths recognize the need for spiritual and psychosocial support from professional caregivers. Families must acknowledge the death of the child and integrate the loss into their family lives. Home visitation and simply being there for the family and listening well are invaluable nursing interventions. Referral to mental health counseling or support groups specific to parents of stillborn children where they can share their feelings may be very helpful (March of Dimes, 2015). Providing continuity and support to the family for months after the death of an infant gives the P/CHN an opportunity to assess the family for signs of unresolved grief. Grieving families may find comfort, support, and helpful information from support groups and resources such as Compassionate Friends or First Candle. When a family experiences loss of an infant after the baby has been brought home from the hospital, grief and guilt are compounded by the loss of an anticipated future and the disrupted continuity in family life. An infant may die of SIDS, a congenital anomaly, an infection, or an accident. There are constant reminders of the infant's presence in the home from memories, photos, videos, and accumulated possessions. This death disrupts family homeostasis and the psychological and physiologic equilibrium of the family. In many cases, the police are involved and an autopsy is required, contributing to the anguish of the grieving family. This promotes both guilt and loss of self-esteem and can even threaten the marriage.

INFANTS, TODDLERS, AND PRESCHOOLERS

Healthy children are a vital resource to ensure the future well-being of nations. They are the parents, workers, citizens, leaders, and decision makers of tomorrow, and their health and safety depend on today's decisions and actions. Their futures lie in the hands of those people responsible for their well-being, including the PHN, whose dominant responsibility is to the community and populations, such as dependent children.

The well-being of children has been a subject of great public health concern globally and in the United States. Its importance has been emphasized through development of numerous laws and services, yet the needs of many children continue to go unmet. Young children (up to age 4) are totally dependent on their caregivers. This contributes to their vulnerability during these years. Many young children often go to bed hungry; some infants and toddlers do not receive even the most basic immunizations before they reach school age. Accidents and injuries are a leading cause of death; preventable communicable diseases increase mortality among the very young.

Whereas the United States provides leadership in many arenas, its failure to protect and promote the health of its youngest citizens represents a significant population health breakdown. However, in many other nations—mostly less-developed countries—child health and well-being are in even greater jeopardy.

Global History of Children's Health Care

Only recently in the history of the world have children been considered valuable assets, even in countries where there are now well-developed programs of infant health promotion and protection, infant and child day care services, and strict educational expectations for all children. In some countries today, however, female infants and children or those born with congenital anomalies are not valued. Countries, such as India and China, provide inequitable care for male and female children. Gender-selective abortions or infanticide also occur. Some birth, growth, and developmental rituals are harsh and would be considered illegal if judged by Western standards. Cultural practices that are fostered by political forces prevent many countries from improving the health of infants and young children (Save the Children, 2015). For these reasons, there are great differences globally in child health care systems. The health of children in one country can affect that of children in other countries, including the United States. Major natural disasters place whole populations at risk, especially the very young and the very old.

National Perspective on Infants, Toddlers, and Preschoolers

Author's private photo with permission from Deanna Rector.

The infant (birth to 1 year), toddler (ages 1 and 2 years), and preschooler populations (ages 3 and 4 years) are generally healthy years. Most U.S. children have a usual source of health care (96.9%), and their parents report them to be in excellent or very good health (Bloom, Cohen, & Freeman, 2011; CDC, 2016f). Growth and development of infants and young children should be monitored regularly. Pediatricians and P/CHNs often provide anticipatory guidance for parents so that they better understand what to expect as their child grows and can plan for safety issues that may arise. See "Internet Resources" posted on thePoint (http://thepoint.lww.com/Rector) for growth charts and educational resources.

The IMR in 2013 was 5.96 per 1,000 live births. The mortality rate for children ages 1 to 4 years is 25.5 per 100,000. Major causes of death include congenital malformations or deformities, as well as chromosomal abnormalities. The mortality rate for children ages 5 to 14 years is 13.0 per 100,000. Major causes are unintentional injuries (motor vehicle crashes, falls, drowning, fires, and burns), cancer, and suicide (CDC, 2016g; Xu, Murphy, Kochanek, & Bastian, 2016). Some variation in mortality rates continues among racial/ethnic groups.

Accidents and Injuries

Toddlers and preschoolers are at risk for many types of accidents and unintentional injuries, such as those caused by unsafe toys, falls, burns or scalding, drowning, motor vehicle crashes, and poisonings. These unintentional injuries are the leading cause of mortality and morbidity for children from age birth to 19 years (CDC, 2015a). Male children have higher rates of death from injuries than females; it is almost twice the rate. Causes of injury deaths vary across age groups. For those children under age one, about 66% are caused by suffocation. Between ages 1 and 4, drowning is the leading cause. In 15- to 19-year-olds, being a passenger in a motor vehicle crash was the most frequent cause of injury death. American Indian/Alaska Native children had the highest death rates from injury, and Asian/Pacific Islander children had the lowest. The loss of children's lives resulting from all injuries combined represents a staggering number of productive life years lost to society. Childhood unintentional injuries lead to almost 12,175 deaths annually (CDC, 2015a).

The *National Action Plan for Child Injury Prevention* addresses child safety and provides an agenda for injury prevention (CDC, 2012b). It brings together 60 partners in implementing injury prevention activities and providing a blueprint for collecting/interpreting data and surveillance and plans to promote research and enhance communication/education/training on injury prevention. Improving the outcomes of childhood injuries by working with health care and health systems and supporting strong policies to prevent injuries are further goals. Risks for childhood injuries that increase child vulnerability include "poverty, crowding, young maternal age, single parent households, and low maternal educational status" (USDHHS, CDC, & National Center for Injury Prevention & Control, 2012, p. 9). Using a public health model, the three levels of prevention are utilized to prevent injuries from occurring (e.g., safety latches on cabinets containing cleaning supplies or medications), minimize injuries (e.g., child safety seats), and improve emergency response and care after injury occurs (e.g., paramedica, trauma care). For instance, to prevent infant suffocation and SIDS, infants should go to sleep on their backs, in a crib or child-friendly bed without soft bedding or pillows, and parents should be cautioned about risk factors for SIDS and the potential dangers of sleeping with their babies. Information about the SIDS prevention campaign *Back to Sleep* should be provided to all parents of infants, and education should begin with hospital nurses and continue with PHNs in the community.

Burn injuries can affect children of all ages. Bath water that is too hot can also cause serious scalding injuries. Cigarette lighters and matches are fascinating to young children. Toddlers or preschoolers may be able to start a flame, injuring or killing themselves or others. The sound of a smoke alarm may frighten young children, and it is important for P/CHNs to instruct parents not only to teach their young children about fire prevention but also to be aware of the sound of the alarm and know what actions to take when they hear it, such as the *Stop Drop and Roll* program taught in Head Start and other preschool

programs (National Fire Protection Association, n.d.). The PHN should also take every opportunity on home visits and in other health education settings to ask or observe if parents have a functional smoke detector in their home. Most community fire departments will install and test smoke detectors for free. Preventing the sources of injury or death from burns may be accomplished by eliminating opportunity and source. Through child supervision, safe storage of matches and lighters, and keeping children away from stoves and electrical outlets, burns and fires can be prevented.

Drowning is another category of unintentional injury in children. Brief lapses in supervision can have disastrous consequences. Young children are at risk for drowning wherever water occurs in depths exceeding a few inches—such as in toilet bowls, bathtubs, mop buckets or cans filled with rainwater, puddles, ponds, spas, and swimming pools. Lakes, rivers, streams, and irrigation ditches or canals are other water hazards. Infants, toddlers, and preschool-aged children are especially vulnerable because they are not aware of water dangers and they explore without fear. Poor children, especially children of color, are at higher risk for drowning because of lack of access to swimming lessons. The PHN can work with community groups and recreation centers to promote swimming for children. Parents need to provide a drown-free environment. Guidelines include the following (American Academy of Pediatrics, 2016; Government of Alberta, 2015):

- Bathe young children in shallow water.
- Never leave young children unattended during a bath.
- Keep toilet lids down and bathroom doors closed—preferably secured with childproof safety handles.
- Never leave full mop buckets unattended.
- Eliminate water collection sites around the home by turning over or removing empty buckets, containers, flowerpots, and other items that can collect rainwater.
- Fence swimming pool areas and install childproof locks or alarm devices that sound when the water is disturbed.
- Promote water safety measures, including teaching young children to swim.
- Be aware of the dangers of open pool drains and suction outlets than can lead to drain entrapment and hair entanglement and ensure that drain covers and safety vacuum-release systems are installed.
- Vigilant supervision of young children at play to prevent involvements with neighborhood water sources.

Supervising children in or around bathtubs, spas, pools, or other water receptacles is critical and requires close (arm's length) distances. Parents of young children should be encouraged to get CPR training. The real dangers of accidental drowning are related in From the Case Files I.

From the Case Files I

1952

Mop Bucket Drowning

I am a Head Start nurse, and one of my assigned centers is located within a farm-labor camp. There are many large, hardworking families in the camp. Older siblings often watch over young children and help with household chores. Most families keep their cinder block homes tidy and clean, and floors are constantly being mopped (no one has carpeting—it is a bare-minimum type of accommodation). One day, several children were absent from school, and when I made home visits to determine the cause of the absences, I discovered that one of the Garcia family's children, a toddler named Miguel, had unexpectedly died. Because many of the absent children were cousins, parents had kept them home while attending to the family. I knew the Garcia family well, and when I stopped by to check on them, they told me that Miguel had fallen into a large mop bucket the older sister had been using to clean the kitchen floor. She had gone outside for just a minute to separate the 5-year-old twins who were fighting, and when she returned, she found Miguel head first in the bucket. She tried to revive him but could not. The parents were working, trying to earn extra money for an elderly grandmother who needed surgery, and only learned of the tragedy when they returned home at the end of a long day. It was a very sad situation, and it reminded me of how even an everyday item can become deadly. Safety and prevention of unintentional injuries, especially with curious toddlers and preschoolers, is extremely important to teach all families.

Myra, Head Start Nurse

Injuries and deaths from motor vehicle crashes continue to be a major safety problem in the United States. Although 88.5% of United States families use safety belts (Pickrell & Li, 2016), some families do not use infant safety seats or child booster seats consistently, even though for decades the law has required their use. Many families have them and use them regularly but do not install them properly, placing the child at as much risk as if there were no restraint. Greenwall (2015, para. 3) reports that 59% of child car seats and 20% of child booster seats were "misused" (e.g., not properly installing seat or restraining child). The most current recommendations for safety seat use are categorized by age. For children birth up to age 2 years, a rear-facing seat should be used (placed in car's back seat); the child should continue in rear-facing seat until reaching the height or weight limit of the seat placed in the back seat; age 2 to at least 5 years, child should use forward-facing car seat until reaching upper weight and height limit for the seat; age 5 years and up, keep child in

back seat with a seat belt–buckled booster seat until they reach height limit of 57 inches and can use a car seat belt alone; seat belts are considered to be properly fitting when the lap belt portion lays across the upper thighs (not stomach area) and the seat belt lays across the chest and not the neck (CDC, 2016g). There is much opportunity in this area for the community health nurse to educate the public and ensure that parents have the information and skills to secure their children properly when traveling by car. Safety seat clinics, where installations are checked and corrected, can help to promote the proper use of age-appropriate child restraints. See Evidence-Based Practice: Getting Families to Use Child Booster Seats for an example of effective interventions.

EVIDENCE-BASED PRACTICE

Getting Families to Use Child Booster Seats

Many health departments, law enforcement, and social service agencies educate parents about the laws and benefits related to the use of child safety seats. Still, not every family consistently uses them. Education and awareness are essential to increase the use of child safety seats.

The Strike Out Child Passenger Injury (Strike Out) intervention program provided booster seat education for children ages 4 to 7 years at instructional baseball programs in four states. Twenty communities participated in the nonrandomized, controlled trial. The study tested the effectiveness of the education program before and after baseball season in increasing proper restraint use among participating children.

Findings revealed that the intervention program did increase the use of child restraint use in three of the four participating states (Alabama +15.5%, Arkansas +16.1%, and Illinois +11.0%). The study reinforces the importance that unique interventions can positively influence child safety use. It is essential for PHN/community health nurses to use evidence and a variety of approaches to combat public health problems.

Source: Aitken, M. E., Miller, B. K., Anderson, B. L., Swearingen, C. J., Monroe, K. W., Daniels, D.,… Mullins, S. H. (2013). Promoting use of booster seats in rural areas through community sports programs. The Journal of Rural Health, 29(s1), s70–s78.

Poisoning is a constant safety concern for young children, and toddlers are most often at risk. Sources of poisoning include household plants, prescription medications, over-the-counter drugs, unintentional medication overdoses, household cleaning products, other chemicals stored within a child's reach, and lead. PHNs can provide parents with the number for the Poison Help Hotline (1-800-222-1222) and encourage them to post it next to each telephone and call immediately in the event of a suspected poisoning or overdose (American Association of Poison Control Centers [AAPCC], n.d.b). They can also educate and demonstrate for parents how to childproof the home by eliminating major sources of poisoning. This includes keeping plants out of a child's reach or eliminating them from the home until the child is older, locking up household chemicals (e.g., toilet bowl cleaner, bleach, mouthwash, oven and drain cleaners, pesticides, gasoline, paint thinner, hair products) and storing them out of a child's sight and reach, using childproof medication containers, and storing all medicines in a locked box with a key that is kept out of reach (AAPCC, n.d.a). Alcoholic beverages should also be kept out of reach, as should tobacco products. Outside hazards, such as wild mushrooms and poisonous plants, flowers, and berries, must also be considered (AAPCC, n.d.b). It is also important to eliminate sources

of lead in and around the home.

Lead Poisoning

Lead poisoning historically resulted in encephalopathy and death. Today, morbidity from lead poisoning is subtle and most often affects the child's CNS with long-term changes in behavior and IQ. The CDC estimates that 250,000 children between the ages of 1 and 5 years have elevated blood lead levels, or 10 μg of lead per deciliter of blood (CDC, 2016i). Lead in paint, dust, and soil can be inadvertently consumed, and lead also crosses the placental barrier. It can be transferred in breast milk and is also found in some infant formulas (Schnur & John, 2014). Lead is one cause of childhood poisoning. There is no safe level of lead, and the elimination of elevated blood lead levels in children is a U.S. health goal. The primary sources of lead exposure in preschool-aged children continue to be lead-based paint and lead-contaminated soil and house dust. The critical age of exposure (or peak level) is thought to be between ages 18 and 36 months. Levels generally begin to decline after age 3 years. Children who live in poverty and play in substandard housing areas remain at risk for direct exposure to significant sources of lead. Lead safety and housing code enforcement, along with periodic monitoring to detect new lead hazards, can help prevent future lead exposures. Public and community health nurses, working together with environmental health sanitarians, should promote opportunities for blood lead screening, especially if it is suspected that children in certain homes, apartments, or neighborhoods are at risk for lead poisoning. Children have also been exposed to lead in some toys, candies, cosmetics, traditional medicines, and eating or drinking utensils imported from other countries. Many of these have been tested and revealed to have high levels of lead. Education and public awareness campaigns can help prevent this type of lead poisoning. Cost–benefit analysis has estimated a return of between $17 and $221 for every dollar spent in lead paint hazard control (Schnur & John, 2014). One example is Rochester, NY; the city passed a comprehensive rental housing-based lead law in 2005. Researchers subsequently evaluated its effects by reviewing city inspections of housing and health department data on child blood lead levels and discussed the new law with landlords. They noted reduced lead hazards in housing and decreased blood lead levels in children (Korfmacher, Ayoob, & Morley, 2012). PHNs can alert clients to the dangers of lead and its sources and work as an advocate for policies to reduce this danger for infants and children. See Chapter 9 for more on lead poisoning and water contaminated with lead.

Child Maltreatment

Child maltreatment is a major public health concern for the United States. It is any type of abuse directed at a child under 18 years old. Child maltreatment can be physical, emotional, and sexual abuse and child neglect (e.g., withholding feeding or medical care). Neglect is more an act or acts of omission in which a child's basic needs are not met. Children under age 4 years are at the greatest risk for severe abuse and neglect (CDC, 2014d). In 2012, approximately 686,000 children were found by child protective workers to be abused or neglected, and 1,740 died of neglect or abuse (CDC, 2014d). In 2014, over 702,000 children were documented victims of child abuse and neglect and over 1,500 children died from abuse or neglect (CDC, 2016d). Exposure of infants to drugs in utero is considered by many states as a form of neglect. In recent years, there has been an increase in reported cases of physical and sexual abuse in day care centers, nursery schools, children's organizations, and churches. Evidence suggests there are multiple long-term complications that occur because of child maltreatment. These complications include mental disorders, substance use, suicide attempts, STIs, and risky sexual behavior (Norman et al., 2012). It is believed that many more children also suffer from forms of abuse and neglect, but thousands of cases are not reported and not reflected in the statistics. The problem is often difficult to detect and is underreported (CDC, 2014d). One example of an often-overlooked form of abuse is shaken baby syndrome. Shaken baby syndrome, suspected in infants or toddlers who exhibit traumatic brain injuries caused by violent shaking or impact, is characterized by a triad of symptoms: retinal hemorrhage, subdural hemorrhage, and/or subdural hemorrhage with few signs of external trauma (Ramya, 2014). The soft brain tissues are injured as they move violently against the rough cranial bones as the infant is shaken or thrown against a hard object.

Failure to thrive (FTT) is characterized by slowing growth rate in height and weight, as well as head circumference among infants and toddlers. If an infant's growth rate is consistently below third to fifth percentiles, drops more than two percentiles, or is lower than the 80th percentile of median weight for height, a diagnosis of FTT may be made. Problems with growth may be due to many behavioral or physiological etiologies for infants but can also be related to child neglect or abnormal maternal–infant bonding. Child neglect differs from child abuse in that the action of the parent or guardian is more one of omission with neglect rather than commission as in the case of an injury related to abuse. Risk factors that point to child neglect as the basis for FTT include those most often cited for abuse and neglect, along with specific concerns about parents intentionally withholding food, being resistant to recommended interventions, and having rigid beliefs about nutrition and health regimens that may jeopardize the infant. The exact incidence of FTT is difficult to determine and no accurate estimates are available. The PHN can take a careful nutritional history and determine the mother's knowledge of basic infant needs, as well as checking for developmental milestones. A psychosocial history is also helpful (e.g., income/poverty level, cultural beliefs, social support networks, domestic abuse, substance abuse, mental health

disorders), with careful attention to maternal bonding and feeding practices. Growth problems in the first 2 months of life may result in cognitive, language/speech, and fine motor deficits in childhood, and early intervention programs that involve home visitation have been effective in attenuating the long-term effects of FTT (Sirotnak, Chiesa, Windle, & Pataki, 2015).

Child maltreatment is seldom the result of any single factor but rather a combination of a chaotic environment, stressful situations, and parents who have difficulty coping with problems and stress (USDHHS, Administration for Children & Families, 2016). Risk factors for child maltreatment are found in four general areas (CDC, 2016d):

- Parent or caregiver behaviors
- Family/community characteristics
- Child factors
- Environment

Parental behaviors may include personality characteristics that include an external locus of control and poor self-esteem, along with problems with impulse control and antisocial behavior. Witnessing violence during one's own childhood may influence the use of violence as a form of parental discipline. Depression and anxiety may also play a role, and parents who had a childhood history of abuse or neglect may maltreat their children. Substance abuse is often a factor in child abuse and neglect cases. Alcohol and drug abuse often lead to neglect, as parents use money meant for household expenses on substances. Little knowledge of normal age-appropriate child development can result in unrealistic expectations. Holding negative attitudes toward their children, viewing them as property, exhibiting harsh parenting styles and verbal aggression, not knowing how to handle children's behaviors, and being easily frustrated are parental characteristics that have also been associated with risk of child maltreatment. Young parental age is also a factor, although this may be because it is also associated with poverty, lower levels of social support, and higher levels of stress. Cohabitation or sharing child supervision with a nonbiological parent can also increase the risk of child maltreatment under certain conditions (American Psychological Association, 2016; CDC, 2016d; USDHHS, 2016).

Family characteristics that include disorganization, IPV and marital conflict, financial stress and unemployment, and social isolation may lead to increased risk of child maltreatment. Children living with single parents (most often mothers) are at higher risk of physical and sexual abuse, as well as neglect; they are also more likely to live in poverty. Single parents have the sole caretaker burden and experience more stress than parents who have joint responsibilities. In a national study, children from single parent homes where a cohabiting partner is present have 10 times higher rates of abuse than children living with both biological parents; they also have 8 times higher rates of neglect. Neglect, including emotional neglect, often occurs in children living with single parents. The lowest rates of abuse and neglect were found for children living with both biological parents. Families in which child neglect occurs often are characterized by greater numbers of children or report

a larger number of people living in the household. The household is frequently more chaotic, with constantly changing players—for example, mothers and children living on and off with grandmothers, aunts, boyfriends, or others. Families at high risk for child abuse may be those that are either chronically troubled or temporarily experiencing increased stressed. Disadvantaged communities and neighborhood violence can also increased risk factors for child abuse (American Psychological Association, 2016; CDC, 2016d; National Parents Organization, 2016).

Child characteristics often involve younger age (≤4) in cases of physical abuse and neglect, because of the greater need for continual care by the parent/caregiver. Maltreatment rates vary by gender (there are more girls than boys, mostly because of higher incidence of sexual abuse) and race/ethnicity (Black children have significantly higher rates than White or Hispanic). Children who are premature or LBW may be at greater risk of maltreatment because of the greater parental stress engendered by more demands on the caregiver. Children with difficult temperaments or behavior problems, or whose parents perceive them to have problems, including disabled children, could be at greater risk for abuse or neglect because of the greater caregiving demands and few community respite resources (Sedlak et al., 2010).

The environment can play a part, along with parental, family, and child factors, in determining risk for child abuse and neglect. Parents who maltreat their children have reported more loneliness, greater isolation, and lower levels of social support. Social isolation may indicate a lack of positive role models to help them better understand parenting and the consequences of child maltreatment. Unemployment, poverty, and neighborhood factors such as crime, violence, and substance use play a part in the stress placed on families. Strong, significant relationships have been found between unemployment, poverty, and child maltreatment, especially child neglect. The availability of affordable, quality, licensed day care facilities is recognized as one long-term solution for the prevention of child abuse. When their young children are safely cared for, two parents or a single parent can work and provide more resources for the family, thereby decreasing the stress that may precipitate abuse. Although poverty and lower parental education level are often linked with child abuse and neglect, no socioeconomic level is immune. Parent training programs can help teach parents to cope with fussy infants and difficult toddlers, and child sexual abuse prevention programs may also be helpful. However, P/CHN home visitation programs, like the Nurse–Family Partnership, have been researched and found to be very effective (American Psychological Association, 2016; CDC, 2016e; Krugman, Lane, & Walsh, 2007; National Bureau of Economic Research, 2016). Also, mandated reporters need to take the initiative to report suspected abuse. Only 54% of mandated reporters working in schools, compared to 77% of health agency staff and 87% of law enforcement staff, reported abuse in the last national study of child maltreatment (Sedlak et al., 2010). About 20% of schools forbid staff from making direct Child Protective Services reports. School nurses and other community health nurses can lobby for safer reporting policies and educate school staff on how to report suspected abuse.

A child with high self-esteem and an optimistic and creative nature and who is independent and uses humor is better able to cope with the adversity of child maltreatment. Other protective factors include positive mentors and role models (e.g., teachers, clergy, neighbors, peers), as well as social supports (e.g., safe schools/neighborhoods, regular health care). A parent who listens to the child's concerns, provides consistent monitoring/expectations/rules, and allows for safe ways for the child to exert independence promotes good child health and development. When families can provide for themselves, have a socially supportive network of neighbors/friends/family, and are able to cope with stressors involved in daily life, their children are at decreased risk of abuse (American Psychological Association, 2016; CDC, 2016d; USDHHS, 2016). See Display 21–2. See also Chapters 20, 22, and 30 for more on child abuse and neglect.

DISPLAY 21.2 REPORTS OF AN EMERGENCY FOSTER HOME

The following are examples of the various situations from which abused and neglected children come, as reported by a couple who had an emergency foster home for the county department of social services. The examples represent children placed with them over a 2-year period in which they cared for 256 children.

- Two-week-old Jose was taken to their home because the parents (under the influence of drugs) were found swinging Jose upside down in circles in an infant carrier as they walked along a downtown street at 3 AM. After being returned to his parents, he returned to foster care 1 month later after being found abandoned in an infant carrier at the county fair.
- Andre, Otis, and Selma, ages 8, 5, and 4, went to the foster home when the social services agency discovered they had been living with their father in an abandoned car for 2 years. They stayed for 3 weeks while the social worker found suitable housing for this family and counseling for the father.
- Victoria, 5 years old, a loving and passive child, arrived wearing a diaper and appeared developmentally delayed. She had a history of being physically and sexually abused. Her family was very dysfunctional, and it took the social worker several weeks to sort out relatives and their intentions before placing Victoria in a long-term foster home.
- Ronald and Randall, 6-year-old twin boys who were forced to "sexually please their mother" for several years, came to the emergency foster home before being placed with relatives while their mother underwent psychiatric

treatment. The boys began counseling during their stay in the emergency foster home.

- Antoinette, age 7, had severe asthma and was very withdrawn. She came to the emergency foster home because her mother (and the mother's boyfriend) refused to care for her. The child came with every photograph of herself and personal mementos because the mother wanted no reminders of the child. The social worker located a grandmother who would be the child's guardian.
- Thirteen-year-old Robert came home from school one day and found his mother and all their furniture gone. After a few weeks of Robert living in the basement of the apartment building, someone alerted the social services agency, and he was placed in the emergency foster home for 2 months. His mother finally called social services after 6 weeks, saying Robert was too difficult for her to handle, but she may want to see him again someday. Robert was eventually placed in a group home for boys.
- Quyn, a 17-year-old Laotian girl, came into foster care after being referred by the school nurse because of wounds observed on her wrists and ankles. Quyn reported being strapped to a chair for 12 or more hours at a time by her father because she was not following the old ways and was shaming the family by being seen in public with a boy, and without a chaperone. Several meetings were held between the parents, a Southeast Asian community leader, and the social worker to resolve this situation so that Quyn could go home safely.

Communicable Diseases

Infants, toddlers, and preschoolers are constantly putting things in their mouth and sharing items with others. (Author's photo used with permission from Deanna Rector.)

Infants, toddlers, and preschool-aged children experience a high frequency of acute illnesses, more so than any other age group. Acute conditions commonly seen from birth to

age 5 include fever, respiratory infections (including ear infections, colds, influenza), conjunctivitis (pink eye), and gastrointestinal problems. Communicable diseases are prevalent in these age groups, as very young children are building an immune system and are just beginning to come in contact with a greater number of people outside their families (Benaroch, 2015).

Acute respiratory illnesses (ARIs) are common in children under age five. PHNs need to emphasize that over-the-counter cough and cold medications should not be used for children under age 2. The U.S. Food and Drug Administration (FDA) questioned their safety and effectiveness at a hearing in October 2007, and manufacturers removed medication targeted to infants and toddlers; they also changed labels all cold and cough medications to read that they should not be used in children under age 4 (Hampton, Nguyen, Edwards, & Budnitz, 2013). This was in response to emergency room visits and deaths linked to their toxic effects. In 2011, the FDA formally recommended that the drugs not be used in children under age 2 as they had "serious and potentially life-threatening side effects" (FDA, 2011, para. 1). Evidence has found a reduction in emergency department (ED) visits related to cough and cold medication adverse drug events for infants and toddlers under 2 and children 2 to 3 years of age (Hampton et al., 2013). However, parents may be uninformed about this and may use old bottles or try to give smaller doses of adult medications to their infants and toddlers. Public and community health nurses should inform parents of the dangers and suggest safer interventions (Stockwell et al., 2014).

Bronchiolitis is the most common type of lower respiratory infection among infants and starts with a runny nose, fever, and cough. It is a common cause of hospitalization in this age group; about 2% of children with respiratory syncytial virus (RSV), the most common cause of bronchiolitis, are hospitalized every year. The majority of hospitalizations for bronchiolitis are for infants 6 months and younger. RSV is the cause in 70% of cases and can rise to 100% during winter epidemics. Although wheezing, tachypnea, and chest retractions can be frightening to parents, most healthy infants survive (95%). However, P/CHNs working with at-risk infants need to work with parents and pediatricians to ensure that palivizumab (monoclonal antibody) or RSV immunoglobulin is given to preterm infants or those born closer to term but exposed to environmental pollution or to other children. An effective RSV vaccine has not yet been found, but palivizumab (Synagis) can be used to help prevent the most severe cases of RSV in high-risk infants (e.g., premature, congenital heart problems) and is given monthly by injection during RSV season (Benaroch, 2015; CDC, 2015d; Mersch & Nettleman, 2011).

As with older children and adults, air pollution increases the susceptibility of bronchitis and other respiratory illnesses among infants and children under age 5. Preschool-aged children are a target population for respiratory illness monitoring. A study of gene–environment interactions found an incidence rate of 53 episodes of bronchitis over 1,000 child months, indicating an "air pollution-induced pathogenesis" of inflammatory bronchitis (Ghosh et al., 2016). Public and community health nurses can inform families

who live in areas where air pollution is significant to take the necessary precautions (see Chapter 9).

Vaccine-Preventable Diseases

Vaccines are one of the greatest achievements of public health. The number of childhood vaccines increased from 5 in 1961 to 16 in 2011 (Hinman, Orenstein, & Schuchat, 2011). Since 1980, there has been a 99% or greater decrease in deaths because of the vaccine-preventable diseases of mumps, pertussis, tetanus, and diphtheria and 80% or greater decline in deaths associated with vaccines instituted since 1980: hepatitis A and B, *Haemophilus influenzae* type B (HiB), and varicella. Smallpox has been eradicated worldwide, and the viruses for polio, rubella, and measles are no longer endemic in the United States. The decline in the number of cases of measles, mumps, rubella, pertussis, and tetanus has been dramatic (99.9%, 95.9%, 99.9%, 92.2%, and 92.9%, respectively), and cases of varicella have declined 88%. Intensive immunization campaigns have been successful in preventing infectious diseases and improving public health by reducing death and suffering from several microbial threats (Nabel, 2013). It is estimated that the childhood series of vaccines (DTP, polio, MMR, Hib, hepatitis B, and varicella) saves almost $10 billion in direct costs, $33 billion in indirect costs, 14 million infections, and 33,000 premature deaths for each fully vaccinated U.S. birth cohort (Schuchat, 2011). Newborns immature immune systems and lack of exposure to antigens, along with somewhat porous physical barriers to microbes, put them at high risk of infection. By the age of 4 to 6 months, however, a brisker antibody response to vaccines becomes possible. Successful infant and childhood immunization programs have been responsible for high vaccine coverage and the subsequent decline in morbidity and mortality from these preventable diseases.

The CDC's Advisory Committee on Immunization Practices develops policies and guidelines, based on review of current scientific research. The committee provides suggestions for available immunizations for the 17 vaccine-preventable diseases through the Vaccines for Children Program, a federal program providing uninsured and low-income families with vaccines at no charge through their primary care providers and local health department clinics. The National Immunization Survey provides surveillance for this program, with recent findings revealing that vaccination coverage rates for children aged 19 to 35 months was met or near *Healthy People 2020* objectives (Hill, Elam-Evans, Yankey, Singleton, & Kolasa, 2015).

State-level immunization registries help track vaccine coverage at all age levels. Because day care centers and schools require proof of immunization, vaccination rates have improved over the last two decades. The 2009 HITECH Act proposed adoption of electronic health records (EHRs) and Immunization Information Systems (IIS) are a logical extension of that law. State and federal immunization databases help public health agencies track of immunization levels and provide data for further education, planning, and services (Hedden, Jessop, & Field, 2012). The financing of immunizations for infants and children has significantly improved as a result of two major initiatives. The Vaccines for Children Program and the Child Health Insurance Program (CHIP) cover children on Medicaid, uninsured children, and American Indian/Alaska Native children. In addition, underinsured children who receive immunizations at federally qualified health centers and rural health clinics are covered. Additional state programs and funds help provide free or

low-cost vaccines for children who are not covered by the other programs. There are several ways for PHNs to help all families obtain free or low-cost immunizations and contribute to maintaining adequate levels of community immunity to communicable disease (see Chapters 8, 10 and 12).

Even if financial barriers are removed, there are other barriers. Transportation is a significant problem for some parents, especially in rural areas and for families in urban areas who have several children and need to take public transportation. All 50 states provide for medical exceptions to mandatory vaccination, and 47 allow religious exemptions; 18 permit philosophical or personal exemptions (National Conference of State Legislatures, 2016). Despite public health announcements in the media, some mothers remain unaware of the disabling consequences of diseases such as polio and do not realize the importance of fully vaccinating their children. Also, as more vaccines become available and the deadly diseases they prevent become a distant memory in the public's mind, more concerns about the safety of vaccines emerge. There has not been any link established between thimerosal, a vaccine preservative, and autism (Colaizzo, 2016). The use of thimerosal has been reduced or completely curtailed; single-dose packaging does not require the ethyl mercury preservative (Hinman et al., 2011). Numerous Web sites have emerged that advise against childhood immunization and provide graphic horror stories about the handful of severe reactions to vaccination. Media coverage and online Web sites about vaccine adverse events also contribute to decreased compliance on the part of parents in getting their children immunized. Public and community health nurses and other health professionals are encouraged to provide parents of very young children with meaningful stories of preventable deaths because of vaccines and to educate parents about scientifically based Web sites and resources rather than relying solely on dispassionate facts and figures.

At the start of the 21st century, some resurgence of pertussis, varicella, and mumps was noted, and changes were made to vaccination recommendations. Pertussis immunity was found to wane with age, and a reformulated vaccine was recommended for adolescents and adults (Tdap) so that pertussis was not inadvertently spread among infants who had not yet received their full vaccine series (Hinman et al., 2011). A two-dose varicella series is now recommended over the single-dose vaccine; measles outbreaks were found in populations where parents had refused MMR vaccination and received personal belief exemptions (Faulkner et al., 2015; Hinman et al., 2011; Kutty et al., 2015; Lopez, Schmid, & Bialek, 2015). Greater education and improved education and policies are needed to overcome this concern (see Chapters 10 and 13).

Worldwide, vaccine coverage has increased because of effects of manufacturers and philanthropists (e.g., Bill & Melinda Gates Foundation). The WHO has specific disease eradication and vaccine promotion programs around the world (see Chapter 16).

Dress up and playtime are important for toddler and preschooler development. (Author's photo used with permission from Samantha Nelson.)

Chronic Diseases

Infants and young children can be afflicted with chronic diseases that affect their quality of life. For instance, the most common chronic disease among the 6 to 11 age group is *dental caries* (CDC, 2014c). Some children begin to show signs and symptoms of cavities by the age of 10 months, and decay can begin to develop as soon as teeth erupt. Enamel defects, and subsequent caries, are more prevalent in children living in poverty and in preterm or LBW infants. One study examining the association of household socioeconomic status (SES) and food security with children's oral health outcomes found that in children aged 5 to 17 those with lower SES and those low to very low food security had significantly higher dental caries (Chi, Masterson, Carle, Mancl, & Coldwell, 2014). Dental sealants are helpful in preventing further cavities (CDC, 2014c, 2015g).

Asthma symptoms may begin in infants and toddlers. Asthma is considered by some to be the most common chronic disease of childhood, with 8.6% (6.3 million) of children younger than age 18 years diagnosed with asthma (CDC, 2016a). Inner-city, low-income, and minority children are disproportionately affected, and asthma hospitalizations are common. Otitis media in infancy and early childhood has been shown to exert an effect on the developing immune system and increases the risk for asthma and eczema (MacIntyre & Heinrich, 2012). Public and community health nurses can assist families in finding appropriate health care providers and encourage proper administration of asthma medications and treatments. They can also teach families to reduce the presence of asthma triggers in their homes (see Chapters 9 and 22 for more information on environmental triggers, asthma, and other chronic diseases of childhood and adolescence).

Autism is a developmental spectrum disorder that is often first noticed in toddlers. Parents become aware that the child's communication and interaction with others are different and that the child may also display obsessive and narrow interests. Autism spectrum disorder (ASD) is a complex developmental disorder and spectrum of ASD indicates that symptoms for each child varies and may range from mild to severe (CDC, 2016b). A child's communication skills and interaction with others are most often affected, along with obsessive behavior and narrowed interests. Behaviors associated with autism include:

- Language problems (no language, delay in language, repetitive use of language)
- Motor mannerisms (often repetitive rocking, hand flapping, object twirling)
- Fixation on objects (restricted interests)
- No spontaneous play or make-believe play; no interest in peers (problems making friends)
- Little or no eye contact (may also resist hugging)

Boys are four times more likely than girls to develop autism. An average of 41% of children with ASD also have intellectual disabilities (NCBDDD, 2012). What causes

autism is unclear—some genetic links have been found, but environment may also be a factor. There is a higher risk of subsequent children having autism in a family with one autistic child or a parent with ASD (CDC, 2016b; National Institute of Neurological Disorders and Stroke [NINDS], 2015). It is often associated with other disorders (e.g., congenital rubella syndrome, Down syndrome, fragile X syndrome, tuberous sclerosis), but the exact causes are not fully understood (CDC, 2014b; NINDS, 2015). The CDC is conducting multistate research, the Study to Explore Early Development (SEED), to get a clearer picture of the number of children with ASD, "discover the risk factors and causes, and raise awareness of the signs and symptoms" (NCBDDD, n.d., para. 6). Families may need to be referred to early educational intervention programs and social service agencies for assistance. Parents need to be vigilant with daycares and preschools about their child's environmental sensitivities. It is important for PHNs to educate parents that parenting practices are *not* a cause of autism and that multiple, large-scale research studies on childhood immunizations have shown that there is no relationship between immunizations and autism (CDC, 2016b; National Vaccine Information Center, 2016; NINDS, 2015).

Sickle cell disease, an inherited blood disorder, affects thousands of children in the United States, most often those of African or Hispanic Caribbean ancestry. The characteristic chronic and severe anemia are common in young children with this condition, and it can affect memory, learning, and behavior. Children can also exhibit jaundice, gallstones, and joint pain. When both parents have the genetic mutation, the newborn will be afflicted with the disease. Those with the sickle cell trait have no symptoms of the disease but can pass it on to their offspring. In many states, routine newborn screening for sickle cell anemia is offered. Because sickle cell anemia can lead to splenic sequestration (or pooling of blood in the spleen), many children either have nonfunctioning spleens or have had them surgically removed. Risk of infection is always a concern when this occurs before age five (University of Chicago Medical Center, 2016). Public and community health nurses working with populations at risk for this disease can educate and refer families for diagnosis and treatment.

The incidence of *food allergies* is increasing in the population. Infants with close family members who have atopic diseases are at risk for development of allergies. Prolonged breast-feeding for 1 year is recommended for these infants or the use of hypoallergenic infant formula. The National Institute of Allergy and Infectious Diseases (2012) does not recommend a delay in the introduction of the most allergic foods (milk, eggs, and peanuts) for infants past the usual 4 to 6 month of age as this will not prevent a child from developing an allergy. Fortunately, once allergies are diagnosed, they can be managed through dietary changes and by avoidance of allergy-producing foods. Parents need to be educated, so that they can consistently read food labels and alert family members to the young child's allergy so that inappropriate foods are avoided.

Other chronic illnesses can have a profound effect on child and family. *Muscular dystrophy* (MD) and *cystic fibrosis* (CF) are two diseases that not only affect quality of life but also severely shorten the child's life. MD is a constellation of genetic disorders

characterized by progressive atrophy and weakening of skeletal muscles. The onset of some forms of MD begins in infancy or early childhood, and MD is more common in boys (1 in than 3,300 male births). Girls are usually carriers, but a few may be "manifesting carriers" that have milder symptoms of muscle weakness (Muscular Dystrophy Association, 2016, para. 16). *Duchenne MD* usually begins before age 6 and progresses rapidly until most boys are wheelchair bound and require a ventilator (NINDS, 2016). Genetic testing can determine who is a carrier of the gene and can aid in confirming the clinical diagnosis.

CF is a genetic disease that usually begins in infancy—about 1,000 new CF cases are diagnosed annually and 75% are diagnosed before a child reaches age two. CF is characterized by a persistent cough or wheeze, shortness of breath, poor weight gain despite a good appetite, and a salty taste to the skin. Sticky, thick mucus builds up in the lungs and digestive tract. Respiratory infections become increasingly more frequent as the child ages. It is the major cause of severe chronic lung disease in children. Chest physiotherapy to help mobilize secretions is performed daily, usually by the parents. Sometimes, a vibrating inflatable vest is used that loosens mucus. Aerosolized antibiotic treatments and mucus-thinning medications help to improve lung function and reduce respiratory infections. Mucus also affects the pancreas and prevents release of digestive enzymes needed to digest food and absorb nutrients. Pancreatic enzyme supplements help with nutrient absorption (Cystic Fibrosis Foundation, n.d.; PubMed Health, 2014). Community health nurses reinforce these techniques and teach the family to avoid exposure to respiratory infections and to initiate prescribed antibiotic prophylaxis promptly. As much as feasible, the young child should be involved in his own care, offered valid choices, and encouraged to participate in decision-making. The family needs genetic counseling and emotional support as members work through feelings of anticipatory grief.

Antecedents for a number of chronic diseases that develop in adolescence and adulthood may be found in infancy and early childhood. Recent research has noted that genetics may account for 30% to 40% of risk, but environment (e.g., diet) may be responsible for 60% to 70% of risk of *diabetes*. Further, there is some evidence that suggests that exclusive, long-term breast-feeding may result in less risk of type 1 diabetes (Patelarou et al., 2012). More epidemiologists are beginning to recognize the importance of a life course approach and the effects of social determinants relative to chronic disease and early death and the societal costs of disadvantaged fetal and child health and development (Roberts & Bell, 2015). Among other variables, diet and nutrition play an important role in later health, and more research about these health connections are being released every year.

Poor Nutrition and Dental Hygiene

Other health problems found in the birth to preschool-aged group include nutritional problems (underfeeding or overfeeding, overeating, and inappropriate food choices) and poor dental health. Nutritional and dental health needs are great during this period of rapid growth. Many factors contribute to early nutritional and dental problems.

Breast-feeding has many benefits for both infant and mother.

A Healthy Start is foundational to well-being later in life. Nutrition is basic in strengthening this foundation. Bonding between mother and infant and overall maternal health are predictors of infant weight gain. Both nutrition and bonding can be accomplished by breast-feeding. Some of the benefits of breast-feeding include (American Academy of Pediatrics, 2012):

- *Convenience*: Milk is always at the perfect temperature, and no preparation is needed; the infant can instantly begin feeding when hungry.
- *Cost*: No formula or bottles to buy; costs are limited to healthful diet for the mother, breast pads, nursing bras, and (possibly) a breast pump.
- *Nutrition*: Breast milk is species specific; the proteins are easily digested, and fats are well absorbed; it is the most complete form of nutrition for human infants.
- *Anti-infective and antiallergic properties*: Breast milk contains immunoglobulins, enzymes, and leukocytes that protect against pathogens, and it decreases the

incidence of allergy by eliminating exposure to potential antigens. Babies exclusively breast-fed for 6 or more months have fewer respiratory illnesses, ear infections, and cases of diarrhea. The chance of hospitalization for respiratory infection is reduced by 72% for infants that are breast-fed for more than 4 months.

- *Infant growth*: Breast-fed babies usually gain weight at a more moderate rate and are leaner than bottle-fed babies; rapid weight gain in infancy has been associated with later chronic diseases.
- *Long-term health effects*: Breast-feeding exclusively for at least 6 months is associated with reduced risk of overweight in later life, and breast-fed infants have slightly higher IQ scores and less change of developing atopic dermatitis, asthma, and inflammatory bowel disease. Incidence of type 1 diabetes is reduced by 30% and type 2 diabetes is reduced 40%, among infants receiving only breast milk for a minimum of 3 months.
- *Benefits for mothers*: Breast-feeding burns extra calories, helps to reduce postpartum bleeding, and delays ovulation and menstruation; it also lowers the risk of later ovarian and breast cancers. Studies show that the longer the period of lactation, the lower chance she has of developing hyperlipidemia, hypertension, cardiovascular disease, and diabetes.

The benefits of breast-feeding are well established and include protection against respiratory infections and diarrhea, long-term increased cognitive development through adolescence, and some improvement in blood pressure and total cholesterol. A systematic review found that breast-feeding had a positive effect on cognition and was associated with improved results on intelligence tests (Horta, Loret de Mola, & Victora, 2015). Several systematic reviews have found that the longer a mother breast-feeds her infant, the greater the protection against later obesity for the child (Yan, Liu, Zhu, Huang, & Wang, 2014). Public and community health nurses can encourage pregnant women to consider the benefits of breast-feeding their infants and provide education and interventions to assist them with the most common barriers: concern about insufficient supply of breast milk, problems with the baby latching onto the breast, painful nipples, and scheduling problems. Women often choose to breast-feed their babies when they fully understand the health effects for their infants and themselves and when they receive positive influence from family and friends. The community health nurse can join with labor and delivery nurses and lactation consultants in promoting breast-feeding among mothers in the community. Nurses can lobby local hospitals to educate new mothers about the benefits of breast-feeding and stop the routine distribution of free samples of infant formula.

Breast-feeding gives infants a healthy head start. (Author's photo used with permission from Deanna Rector.)

Child and adolescent obesity prevalence in 2009 to 2010 was 16.9%, with 9.7% of infants and toddlers characterized as overweight. A significant trend in obesity prevalence

was found for males between the ages of 2 and 19 over the previous 12-year period; this was not the case for females (Ogden, Carroll, Kit, & Flegal, 2012). In 2011 to 2012, there was a higher prevalence of obesity among Hispanic children and adolescents (22.4%) and non-Hispanic Blacks (20.2%) than among non-Hispanic Whites (14.1%) (CDC, 2015c). Another large study of 4-year-olds found prenatal and early childhood risk factors to be more prevalent among Black and Hispanic populations (e.g., maternal depression, rapid infant weight gain, higher sugar-sweetened beverage intake, and higher intake of fast foods). There were also lower rates of breast-feeding among those populations (Perrin et al., 2014).

Childhood obesity can be connected to the rise in type 2 diabetes (Copeland et al., 2013). Although overfeeding can lead to problems, poor infant growth is also problematic. The pattern of growth may also be important, such as growth problems in infancy along with overweight in later childhood. The most common sources of energy and nutrients for infants and toddlers are breast milk, formula, and milk. Fortified foods (e.g., grain-based foods with added vitamin A, folate, and iron) become increasingly more significant in toddler diets. In general, most nutrition recommendations include providing for a wide variety of foods for children. Public and community health nurses can encourage parents to continue to introduce new healthy foods to their toddlers and not give up or give in too soon. Home visiting programs that promote fruit and vegetable consumption in preschoolers have been shown to be effective in increasing the number of servings for both children and parents (Tabak, Tate, Stevens, Siega-Riz, & Ward, 2012).

Young children's diets, often unreasonably high in sugar, increase the incidence of dental caries in this population group. The practice of allowing infants to feed from the bottle beyond 15 to 16 months, or to fall asleep with a bottle, can lead to *baby bottle tooth decay* or *nursing caries*. Baby bottle tooth decay occurs when others persist in giving toddlers and preschool-aged children milk, juice, sodas, or sugared drinks continually throughout the day (Çolak, Dülgergil, Dalli, & Hamidi, 2013). Frequent snacking and sippy cups filled with juice or sugary drinks can lead to cavities. It is recommended that sugary foods be eaten at mealtimes and not as snacks and that regular snack times be established. Also, between ages 6 and 12 months, sippy cups are often used to wean infants from the breast or bottle, but between-meal drinks should consist of water or milk. Nighttime breast-feeding beyond what is needed for nutrition can also lead to increased risk of dental caries (American Dental Association, 2016). Parents of infants older than 6 months who have several erupted teeth should be instructed to rub the infant's gums with a damp, clean cloth and to begin toothbrushing, using a soft pediatric toothbrush with a very small amount of fluoride toothpaste—about the size of a grain of rice. The first dental exam should be made within 6 months of the first tooth eruption. Addressing parental misconceptions about dental health and understanding cultural beliefs and practices related to dental health and hygiene are important (American Dental Association, 2016).

Fluoride supplementation may be needed by 6 months of age if local water supplies are not fluoridated. Generally, breast-feeding infants do not require supplemental fluoride, and liquid or chewable fluoride supplements should not be given with formula or milk because

absorption will be decreased (Çolak et al., 2013). As children reach the toddler years, they are able to brush their own teeth. Toothpaste should be used sparingly, and adults should continue to supervise tooth brushing. Children of this age can get overzealous with the amount of toothpaste they use and it should not be ingested. The American Academy of Pediatric Dentistry (2013) recommends an initial dental visit no later than 12 months of age. Medicaid benefits among states have varying dental benefits. Oral checks by health care providers should be a part of the well-child checks, especially in the younger years.

Dental caries is a preventable condition that can be addressed with proper nutrition and hygiene. The younger the age when dental caries first appear, the greater the risk for future tooth decay that increases the risks of chronic health conditions due the inflammatory response. Untreated dental caries can also lead to serious infections. Pain can interfere with learning at school. Many health departments are using fluoride varnishes as a means of preventing dental caries in young children. Dental hygienists and PHNs may be trained to apply the sealants and varnishes while making home visits, or children and families may visit clinics for treatment (Association of State & Territorial Dental Directors, 2015).

HEALTH SERVICES FOR INFANTS, TODDLERS, AND PRESCHOOLERS

A variety of programs that directly or indirectly serve the health needs of very young children may be found in most communities. Public and community health nurses play a major and vital role in delivering these services especially for the working poor and vulnerable populations. In public and community health, programs fall into three categories, which approximate the three priorities of PHN practice: prevention, protection, and promotion.

Preventive Health Programs

Neighborhood community centers found in urban and rural settings provide families with parenting education, health and safety education, immunizations, various screening programs, and family planning services. In some areas, nurse-run clinics are established at local schools or community centers to assist in outreach services to the community. Public and community health nurses, in collaboration with an interdisciplinary team, are often the primary care providers in these programs. The major goals are to keep communities healthy by focusing on primary and secondary prevention services. Three examples of preventive health programs for infants and young children are immunization programs, parent training programs, and quality day care health services.

Immunization Programs

Health departments, community clinics, and private health care providers continue to offer immunizations against the major childhood infectious diseases—measles, mumps, rubella, varicella, polio, diphtheria, tetanus, pertussis, hepatitis A and B, and Hib—some of which can cause permanent disability and even death. Pneumococcal, meningococcal, and influenza vaccines are also recommended, as is the vaccine for rotavirus (CDC, 2016c). Many of these diseases no longer plague infants and children, and newer vaccines offer an even greater promise of health. The current immunization schedule is available in Chapter 22.

Although the threat of these diseases has been substantially reduced, vigilance is still essential. Low immunization levels in many areas of the United States, particularly among the poor and medically underserved, and increased disease rates signal the need for constant surveillance, outreach programs, and innovative educational efforts. PHNs can help young families find low-cost vaccinations by using the Vaccines.gov Web site (http://www.vaccines.gov/getting/where/). Whenever infants and young children come in contact with public health and other community clinics, it is always important to check immunizations and provide the necessary vaccines. Public and community health nurses are deeply involved in preventive activities that promote immunizations. One important intervention is to provide each parent with immunization record that they can keep so that they have a record of their children's immunizations. This is very important until a national immunization registry is implemented. Health departments and day care centers often work collaboratively to provide vaccinations. A compulsory immunization law, varying in its application from state to state, has enabled public health personnel to carry out these preventive services (Groom et al., 2015).

Parent Training Programs

Parent education and training programs have been useful in providing parents with the tools needed to deal with the stresses and challenges of parenting effectively. A meta-

analysis of 77 program evaluations revealed that effective programs consist of teaching parents to use time-out rather than corporal punishment as a means of discipline, promoting consistency in discipline, encouraging emotional communication skills and positive parent–child interaction, and requiring that parents practice these skills during classroom sessions. An effective training program for parents of preschool children is the Incredible Years Parent Training Program. Parent participants report decreased levels of stress and positive changes in their children after participating in this program (Moreland, Felton, Hanson, Jackson, & Dumas, 2016).

Some health and social service agencies offer this program for high-risk families of young children, and some evaluation studies have found this program to improve behavior and reduce symptoms of attention deficit hyperactivity disorder (ADHD) in preschool-aged children (Trillingsgaard, Trillingsgaard, & Webster-Stratton, 2014).

Quality Day Care and Preschool Programs

In 2011, nonrelative child providers cared for approximately 51% of children (birth to 4 years) of working mothers (Federal Interagency Forum on Child and Family Statistics, 2015). About 24% spent time in center-based child care. A study examining the effects of home environment and childcare facilities impact on the development of children's language, communication, and early literacy found quality childcare centers combined with a stimulating home environment resulted in better cognitive and language development (Pinto, Pessanha, & Aguiar, 2013).

Author's private photo with permission from Danielle Rector.

Although safe, affordable child care is important, the long-term benefits of early childhood education are numerous. These benefits include higher rates of high school completion, college attendance, and full-time employment and lower rates of felony arrests,

convictions, and incarcerations (Goodwin & Miller, 2013). Head Start, a federally funded program that offers early childhood education to low-income children between ages 3 and 5, has consistently demonstrated significant improvements in preschoolers' social, emotional, and cognitive development, and those attending Head Start do better on several developmental and educational measures. Head Start children are also more likely to receive dental and health screenings, to have up-to-date immunization coverage, to have better school attendance, and to be less likely to be held back in school. The benefits of Head Start extend to families because more Head Start parents read more frequently to their children than do parents of children not enrolled in the program. Because parents of preschoolers in Head Start must demonstrate parent involvement in the program, they are more likely to demonstrate upward mobility and positive growth (Cooper & Lanza, 2014; Lee, 2016; Nix et al., 2016). Many states provide preschool programs, and Head Start has been criticized for uneven effectiveness in learning outcomes (Whitehurst, 2013). However, the quality of day care and preschool programs varies considerably; licensing laws can regulate only minimum safety and health standards. In addition, numerous childcare operations are too small to require licensing, leaving quality and compliance unevaluated. Community and public health nurses can influence the quality of day care and preschool programs through active childcare consultation efforts that focus on health educational efforts for staff, monitoring of health and safety standards, and working to improve the state's or community's role in passing stronger licensing laws. They can also work with parents and communities providing referral to regulatory agencies and teaching about what characteristics to look for in a quality childcare center.

Health Protection Programs

1984

1985

A preschooler helps the bride with her bouquet. Author photo used with permission of Tobey Roos.

Health protection programs for infants and young children are designed to protect them from illness and injury. Ultimately, these programs may even protect their lives.

Safety and Injury Protection

Accident and injury control programs serve a critical role in protecting the lives of children. Efforts to prevent motor vehicle crashes, a major cause of death, may include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into the causes of various types of crashes. Injury prevention and reduction have been addressed through strategies such as state laws requiring the use of safety restraints (e.g., seat belts, child safety seats), availability of front and side driver and passenger airbags, substitution of other modes of travel (air, rail, or bus), lower speed limits, stricter enforcement of drunk-driving laws, safer automobile design, and helmets for motorcyclists, bicycle riders, and skaters.

For infants, toddlers, and preschool-aged children to be safe when traveling in vehicles, they must be restrained in an approved infant carrier, child restraint seat, or booster seat. These must be positioned and secured as described by the manufacturer; used at all times, even for the shortest distances; placed in the back seat, never in the front seat; and installed in the appropriate position (facing rear or front) based on the weight or age of the infant or young child. Hospital-based and community programs provide training, education, and child safety seat checks improving child safety and safety seat use (Brown, Finch, Hatfield, & Bilston, 2011; McDonald et al., 2016).

Lead poisoning prevention programs can be found in most state and local health departments. The Lead Contamination Control Act of 1988 provided for CDC funding and programs to eliminate childhood lead poisoning (CDC, 2015b). The CDC provides technical assistance, training, and surveillance at a national level. PHNs can help with targeted screening and case management and provide education to clients and communities about lead poisoning at the local level. They also work with environmental health personnel and epidemiologists to reach out to neighborhoods and communities at risk for testing. See more on this in Chapter 9.

Protection From Child Abuse and Neglect

Services to protect children from abuse are not as well developed or effective as safety and injury prevention programs, an observation accounted for by a variety of factors. Most child abuse occurs in the home, so only the most blatant situations become evident to outsiders. Public and community health nurses and providers who see injured children may find parents' explanations plausible and may not suspect or want to believe that abuse might be responsible. Avoidance of legal involvement keeps others from reporting

suspected cases. In order to protect children, this attitude must change among professionals who work with children and other community members. With reporting and intervening in child abuse, nurses practice a form of professional coercion to protect children from threats to their health.

For many years, states have had mandatory reporting laws. Enacted in 1974, the Child Abuse Prevention and Treatment Act (CAPTA) supplies funding to states to aid in preventing and investigating child abuse and neglect. Over the years, numerous amendments have expanded the definition of child abuse and the persons who are required to report. People mandated to report suspected child abuse include all those who work with children: day care providers, teachers, social workers, nurses, doctors, clergy, coaches, and so forth. In addition, animal humane workers and commercial photograph developers are mandated reporters. Procedures for reporting categories of child abuse have also been clarified, and 1990 updates included services for homeless children and families. Today, professionals and the public are more aware of the problem, and there has been an increase in reporting. In 1974, the National Center for Child Abuse and Neglect was established as a result of the CAPTA. The center collects and analyzes information on child abuse and neglect, serves as an information clearinghouse, publishes educational materials on the subject, offers technical assistance, and conducts research into the problem. The Adoption and Safe Families Act, enacted in 1997, gives further direction in working with families and promotes the safety of children while recognizing the child's need for a permanent home (U.S. Department of Health and Human Services, 2016).

In addition, these acts spurred all of the states to pass mandatory reporting laws and design procedures for investigation of suspected cases of child abuse and neglect. All states have some form of child protective services or family services, whose charge is to protect children and strengthen families. They often work with law enforcement and the judicial system, but health professionals and educators are also important team members. The basic dilemma facing those who work in this area is maintaining the family unit, if possible while at the same time keeping children safe. Most professionals adopt the *levels of prevention* model to describe child abuse and neglect prevention efforts.

Primary Prevention

Primary prevention measures include the use of public service announcements that promote positive parenting, family support groups, and public awareness campaigns about child maltreatment and how to report it, along with establishing community education to enhance the general well-being of children and their families. Educational-type services are designed to enrich the lives of families, to improve the skills of family functioning, and to prevent the stress and problems that might lead to dysfunction and abuse or neglect. The Safe Environment for Every Kid (SEEK) program has been effective in helping to prevent child maltreatment (Dubowitz, Lane, Semiatin, & Magder, 2012; Dubowitz et al., 2011).

Primary prevention also focuses on parent preparation during the prenatal period;

practices that encourage parent–child bonding during labor, delivery, the postpartum period, and early infancy; and provision of information regarding support services for families with newborns. This is often the ultimate outcome sought by home visitation programs carried out or managed by PHNs. It is also helpful to provide parents of children of all ages with information regarding child-rearing strategies, anticipatory guidance for developmental milestones and tasks, and community resources. Child sexual abuse prevention curricula, such as *Good Touch/Bad Touch*, teach children skills to avoid victimization, promote discussion with children, and encourage them to tell an adult.

Secondary Prevention

Services are designed to identify and assist families who may have risk factors for impaired parenting to prevent abuse or neglect. High-risk families are those families that exhibit the symptoms (risk factors) of potentially abusive or neglectful behavior or that are under the types of stress associated with abuse or neglect. These can include families living in poverty, substance abuse or mental health problems, parents who were abused when they were children, and parents or children with developmental disabilities. Early intervention with high-risk families can improve emotional and functional coping and help prevent further problems. High school parent education programs for pregnant adolescents, home visitation programs targeted to at-risk families, and respite care for families with special needs children are all examples of secondary prevention actions. Family resource centers in schools or community centers located in low-income neighborhoods can offer resource and referral services to families who may be dealing with multiple sources of stress. Evidenced-based home visitation programs, such as the Nurse–Family Partnership, Early Head Start, and Healthy Families America, provide parental support and education and promote healthier family functioning and have resulted in decreased rates of child abuse and neglect (Kopko, n.d.).

Tertiary Prevention

Intervention and treatment services are designed to assist a family in which abuse or neglect has already occurred, so that further abuse or neglect may be prevented and the consequences of abuse or neglect may be minimized. Often, families are referred to mental health counselors to improve family communication and functioning. Some families may require crisis respite when they feel they cannot manage the stresses of child care. Role models, through the use of parent mentor programs, provide support and nonjudgmental coaching to parents who have sometimes been the victims of abuse themselves (Child Welfare Information Gateway, n.d.).

The public health nurse and school nurse have major roles in all levels of prevention of child maltreatment. In addition, the nurse is in a unique position to detect early signs of neglect and abuse. The nurse must establish rapport with families and assist with

appropriate interventions and referrals at the secondary and tertiary levels of prevention. The advanced practice nurse may also work with families of abused and neglected children as part of an interdisciplinary approach with teachers, the department of social services, the judicial system, foster families, and other health care providers if needed. The effectiveness of local programs depends, in large measure, on the willingness of health professionals to increase their awareness and work as a team to detect, report, develop, and evaluate interventions for the perpetrators and victims of abuse and neglect. Ongoing education of health care providers is recommended to increase awareness of changing child abuse patterns, new reporting laws, and resources available to families.

Health Promotion Programs

Early childhood development and intervention programs are designed to have positive effects on the outcomes of children's cognitive and social development. Some health promotion programs have considered children's physical health, and fewer have focused on parent–child interaction and child social development. All are considered important health promotion programs from birth through preschool years.

Infant Brain Development Research and Parent–Child Interactions

New research into the normal brain development of infants and toddlers has revealed that brain maturation in the first few years of life is very rapid: the brain grows to 80% of adult size by age 3, and the myelination pattern of an 18- to 24-month-old child is similar to that of an adult (Zero to Three, 2016). The prefrontal cortex of 4-year-olds is already functional and becomes more organized throughout later adolescence. Early environment exerts a lasting influence on brain development, even in the womb. Appropriate early environment and stimulation promotes healthy development.

Because brain development is thought to be "activity dependent," and *pruning* or selection of only the most active neural circuits occurs in early childhood, parents are encouraged to provide appropriate nutrition, avoid potentially harmful substances, and provide appropriate stimulation for their infants, toddlers, and preschoolers (Zero to Three, 2016). During the first 2 years, when rapid myelination is taking place, 50% of total calories should come from fat, but after age 2, 1% or 2% milk should be the norm. Harmful substances, such as tobacco (cigarettes), chemicals, and radiation, should be avoided during pregnancy, as should contact with people who have infectious diseases. Meaningful parent–child interactions should be established early; they include holding, rocking, comforting, touching, talking, and singing. When parents talk to infants and read to young children, children later demonstrate more advanced language and literacy skills. Providing a caring and supportive environment, with opportunities to learn and explore, is supportive of healthy brain development and promotes secure infant attachment (Zero to Three, 2016). Young children who do not have early exposure to this type of environment —for example, those who are in institutional care—exhibit delays in cognitive and social development, as well as attachment disorders (van IJzendoorn et al., 2011). Important parental behaviors that promote social development include gazing into an infant's eyes, paying attention to and interacting with toddlers, and listening to and answering preschoolers' questions. Providing infants and young children with secure, learning-rich environments where they can use their senses to discover new things helps them to maximize their potential. Emotional comfort and a secure environment ensure that young children will better deal with their feelings. Public and community health nurses can provide information to parents on the most current research results about brain

development as well as tangible suggestions such as low-cost brain-stimulating toys and community resources to encourage quality parent–child interactions that promote appropriate physical growth and cognitive and social development.

Developmental Screening

With the emphasis on infant and early childhood development, PHNs often routinely carry out developmental screenings. Tools such as the Ages and Stages Questionnaire (ASQ-3), Ages and Stages Social Emotional Questionnaire (ASQ: SE), Parents' Evaluation of Developmental Status (PEDS), the Child Developmental Inventory, the Denver II, and the Bayley Infant Neurodevelopmental Screening (BINS) are often used by PHNs and other child development professionals as they make routine home and childcare center visits to follow at-risk infants, children, and families. They may also access families during outreach interventions at special events such as community health fairs. Those working with high-risk or medically vulnerable infant programs periodically screen their clients to determine gaps in development and provide suggestions to parents that promote advancement (Oregon Health Plan, 2015).

Developmental screening tools are also helpful in educating parents about normal child development and can provide a means of anticipatory guidance on developmental milestones and future safety issues. *Bright Futures*, an important resource for nurses and parents, provides tools to help families determine appropriate developmental milestones and expected behaviors, along with suggestions about when to seek help from professionals. A variety of screening tools available to nurses and other health professionals, ranging from parent report instruments to those that involve direct assessment of behaviors and skills, can examine overall physical and cognitive development or screen for such things as temperament, behavior, autism, and speech and language problems. It is important for the PHN to use tools that have reported validity and reliability. Early identification of problems can lead to interventions such as enrollment in early intervention programs and help children with school readiness. These early intervention programs are available in most communities or through the public school system. Early identification is essential, but unfortunately, many children with developmental disabilities are not recognized before age 10 (Boyle et al., 2011).

Programs for Children with Special Needs

Many children have special needs. They may have a congenital or acquired developmental disability, birth defect, or a chronic emotional, mental, or physical disease. The CDC conducts a periodic randomized national survey on CSHCN, with the most recent data available for analysis being 2009 to 2010 (CDC, 2015d). About 1 in every 33 U.S. infants are born with a birth defect each year (CDC, 2014b, 2015d). Some children suffer injuries after birth (see From the Case Files II). Autism and other mental or behavioral disorders develop after infancy and may require special services. Educational, health, and social or recreational services should be available for all children.

From the Case Files II

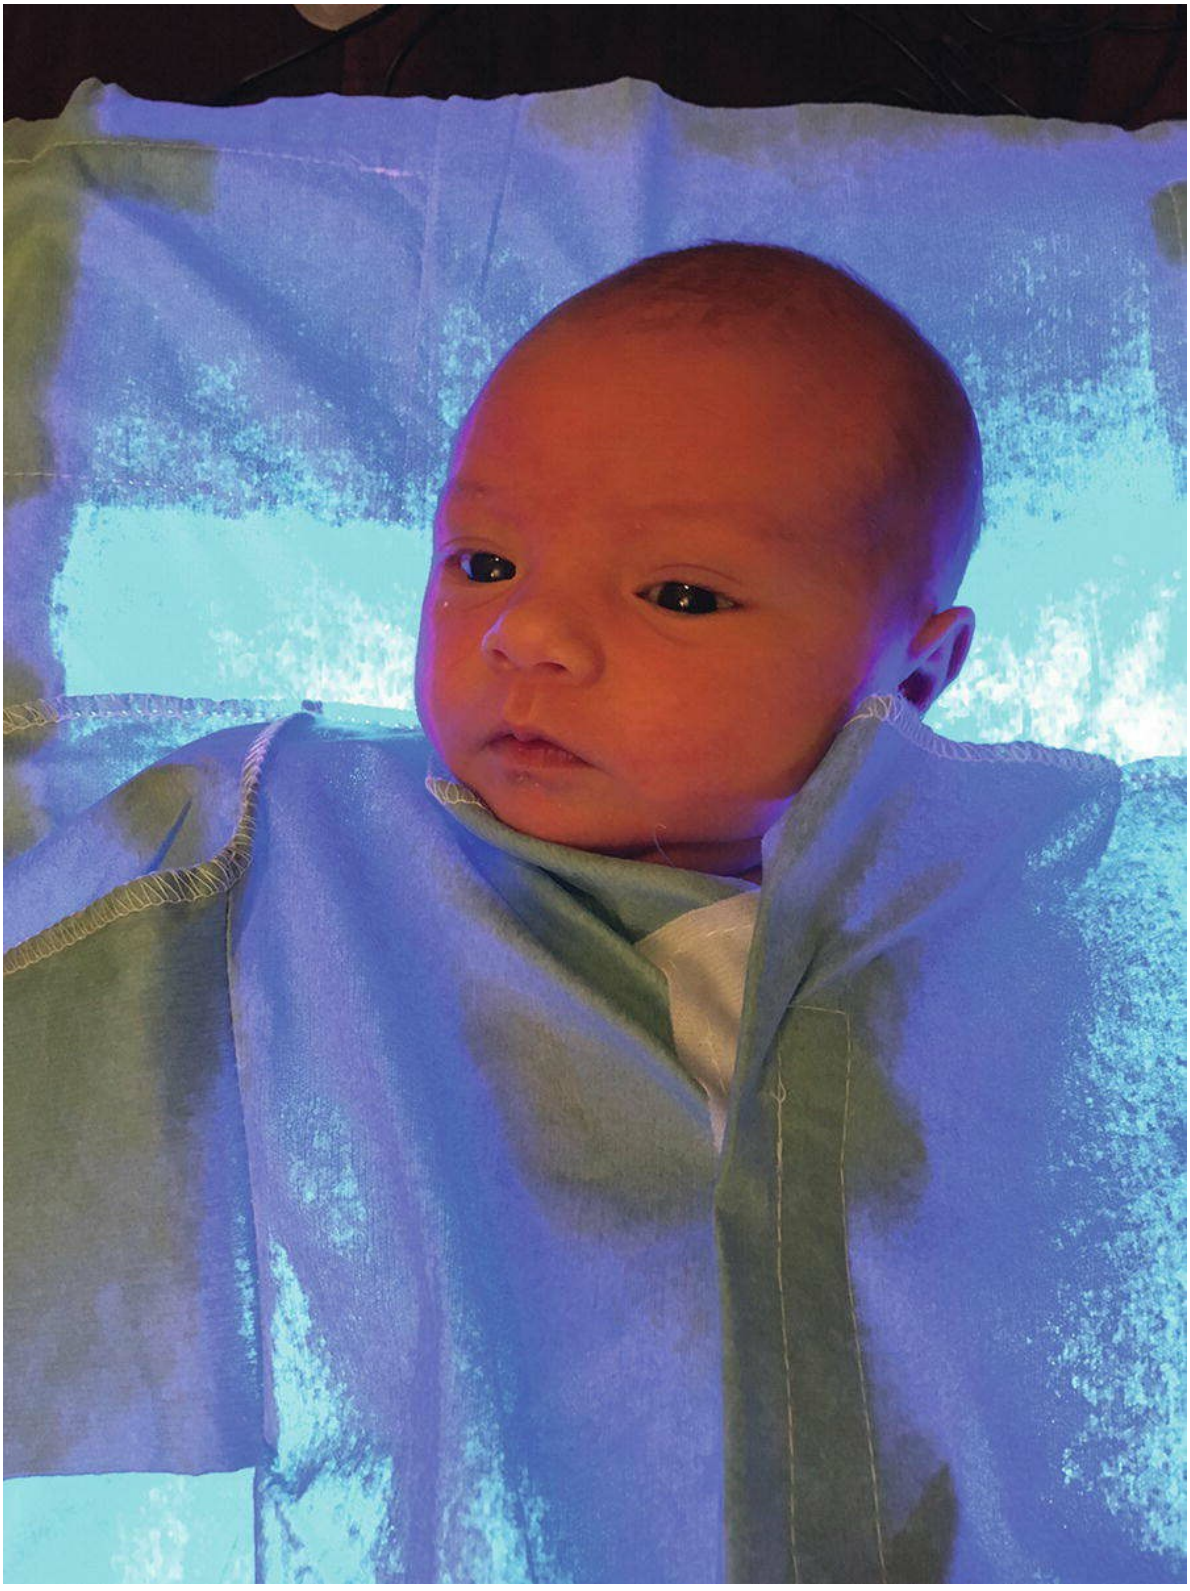
1993

A Case of Kernicterus

A young mother was hospitalized for the birth of her second daughter, a beautiful little girl born without incident. The infant was taken to the mother for feeding and care by the nursing staff, and the mother noticed that her daughter was not very active. The infant had difficulty latching on for breast-feeding. The mother told her obstetrical nurse that the infant seemed very different from her first child. The infant was irritable, but the nurse reassured the mother that the baby was fine and "not all babies are alike." Still, the new mother was concerned.

By the second day, the mother noticed that the baby was not very alert and did not want to feed. She also noticed that the baby's color was "yellowish," and the mother notified the nurse. Again, the nurse reassured the mother that this was "normal" for infants of Asian descent. The baby still was not feeding well, and there was yellowish-orange color stool in the baby's diaper. The mother notified the nurse and asked the nurse to call the doctor. The nurse refused and told the mother that she was "overreacting." The nurse again reassured the mother that the baby was "fine" and no action was taken. The mother felt that the nurse was not listening to her concerns. The baby continued to be irritable, and the nurse said that the baby just needed to breast-feed and was insistent that the new mother was "not breast-feeding properly." The new mother was instructed not to give the baby water or additional fluids, so that the baby would breast-feed. No additional fluids were offered. The young mother was not satisfied with the nursing care and was offended that the nurse would not listen to her. A referral was made to the breast-feeding specialist at the hospital to help the new mother feed her infant. There were no phone calls documented to the physician nor was there documentation of the "yellowish-orange" stool. (The young mother kept the diaper for further proof of her concerns, though.) There was no documentation of irritability, inability to breast-feed, lethargy, or jaundiced appearance of the skin. The physician discharging the infant did not receive any information regarding irritability or yellowish stool. The nursing emphasis postpartum was on breast-feeding, and the nurses documented that the young mother had an "uncooperative attitude."

The young mother and infant were discharged home on the second postpartum day. No blood work was done for the "yellowish" color of the baby's skin, even though the yellowish tone to lower extremities and abdomen was documented in the nurse's notes and on the discharge summary. No referrals were made to Home Health or Public Health for follow-up.



Within 48 hours of discharge, the young mother brought her lethargic baby to the hospital's emergency room. On day 4 of life, the infant's bilirubin was 46. The infant was severely neurologically damaged, and the brain damage that resulted was

irreversible. She was diagnosed with severe cerebral palsy, secondary to kernicterus (excessive bilirubin). The child will never be able to walk or talk. She will be fed through a gastrostomy tube for the rest of her life. She has normal intelligence, but it is locked into a dysfunctional body. The patient and family were devastated.

The physician and hospital (nurses) were sued. The nurses on duty could not defend their actions with their charting or lack thereof. The attorneys for the hospital, representing the physician and nurses, could not defend the actions of their clients. A multimillion-dollar settlement was granted, and the nurses were fired. Unfortunately, this is not an isolated case. The irreversible brain damage that occurs as a result of untreated hyperbilirubinemia should not occur in the 21st century. This was a no-win situation that could have been avoided with proper nursing intervention. Hyperbilirubinemia should always be in the forefront of newborn assessment during the first few days of life.

The nurses involved in this case were not acting as the patient's advocate. The young mother tried to tell the nurses, and the nurses should have listened to their patient. The physician should have been notified immediately when signs and symptoms were first noted. Incorrect assumptions were made because of the nationality of the patient, an indication of lack of cultural competence. Home health nursing or public health nursing care should have been arranged for infant follow-up after discharge, but these interventions did not happen.

Federal law mandates early identification and intervention services for those with a variety of developmental disabilities. Developmental delays are characterized by slower development in one or more areas. The Individuals with Disabilities Education Act (IDEA)

provides early intervention services, usually at home, for those from birth to age 2 who have developmental delays in physical, cognitive, communication, social/emotional, and adaptive development. Intervention services are also available to children with a mental or physical problem that is likely to result in a developmental delay. Newborns can receive infant stimulation services at home or in some schools specially designed to meet the needs of the very young. These programs are offered on a part-time basis for 1 to 2 hours, two to three times a week. Special education preschools are available for young children from ages 3 to 5. By preschool age, children may advance to half-day programs. Additional services can be provided to assist the families in getting children to the programs. Door-to-door bus service in specially equipped small buses or vans safely transports young children who arrive at school in wheelchairs or with other assistive devices (Child Welfare Information Gateway, 2013).

Availability of health services for children with special needs varies with the size of the community. In small rural communities, children and their parents may have to travel long distances to receive specialized services, and in inner-city neighborhoods, lack of money for transportation can make even nearby services equally inaccessible. Accessibility is also influenced by lack of knowledge, attitudes, and prejudices. Another area of concern for special needs children is quality day care for their child. Research has shown that including special needs children in early childcare programs provides a positive experience for those children along with their normal developing peers (Extension, 2015). Public health nurses must recognize the power of these immobilizing factors and be able to deal with them effectively to make positive changes. See Chapter 25 for more on barriers to health care.

Most communities offer additional social and recreational programs for children with special needs. For example, American Lung Association affiliate offices sponsor camping programs for children with asthma or other lung diseases. Often, these are camps for school-aged children that may last up to 1 week and be located in mountain or beach areas, but they may also be day camps, with parents in attendance for preschoolers. Nationwide programs, such as the Special Olympics, offer recreational competition for children with special needs in a variety of sports, such as bowling, track and field, skiing, and swimming. The PHN best serves families as a resource for such programs. Some parents are not aware of the rights or services available for their special needs children. Nurses can advocate for parents and help establish services in communities where needed services are lacking.

Nutritional Programs

Adequate nutrition must begin before birth. One of the most productive health promotion programs is the Special Supplemental Food Program for Women, Infants, and Children (WIC). In addition to supporting women and young children with nutritious foods and achieving the initial goals of decreasing the rates of preterm and LBW babies, increasing the length of pregnancy, and reducing the incidence of infant and child iron deficiency anemia, WIC also improves pregnant women's nutritional status. WIC is not an entitlement program, but rather, Congress sets funding and eligibility requirements yearly (U.S.

Department of Agriculture, 2016).

WIC provides information to parents about eating healthfully and promoting healthy rates of growth. Parents become more aware of the need to reduce consumption of saturated fat, salt, sugar, and overprocessed foods. The P/CHN, through nutrition education, reinforcement of positive practices, and referral, plays a significant role in promoting the health of infants and young children (see Levels of Prevention Pyramid). For more information about WIC, see Chapter 22.

LEVELS OF PREVENTION PYRAMID

SITUATION: Desire for a healthy, full-term infant

GOAL: Using the three levels of prevention, negative health conditions are avoided, promptly diagnosed, and treated, and/or the fullest possible potential is restored.

TERTIARY PREVENTION		
Rehabilitation	**Primary Prevention**	
	Health Promotion and Education	*Health Protection*
• The parents and significant others begin to bond with the newborn. • Parents get to know the newborn and establish a successful breast- or bottle-feeding routine. • The infant returns home in an age-appropriate infant car seat, which is used properly when traveling. • The infant's birth is celebrated according to cultural and religious preferences. • Parents resume sexual intercourse using a family planning method of their choice. • The parents enjoy the new life they have created.	• Educate about benefits of early postpartum care. • Set goals with client to make and keep appointments for postpartum and newborn visits to health care providers.	• Educate to avoid exposure to people with infectious diseases. • Educate and follow up to assure that infant immunization schedule begins on time and continues through childhood.

SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
• The mother starts prenatal care early in the first trimester and continues care at regular intervals throughout the pregnancy.	• The mother does not use alcohol, tobacco, or other mood-altering substances during the pregnancy. • The mother takes a daily prenatal vitamin with folic acid. • Parents avoid exposure to people with infectious disease. • The mother has adequate nutrition, rest, sleep, and exercise. • The mother begins supportive services if eligible (WIC, Temporary Assistance for Needy Families). • Family and significant others continue to be supportive. • The parents attend labor preparation, infant care, and parenting classes. • Name(s) is selected for the infant. • Delivery method and location are selected. • The home is prepared for the infant, e.g., adequate infant furnishings and supplies are acquired within the parents' budget. • Preparations and plans are made regarding breast- or bottle-feeding. • A pediatrician or pediatric nurse practitioner is selected. • An infant car seat is acquired and properly installed. • Plans are made to get to the chosen health care facility when in labor.

PRIMARY PREVENTION	
Health Promotion and Education	**Health Protection**
• The pregnancy is planned. • Pregnancies are spaced 2 years (or more) apart. • Mother has a positive attitude going into the pregnancy. • A health care provider is chosen. • There are financial resources to meet the expanding family's needs. • Family and significant others are supportive. • Mother's weight is as close to ideal as possible before conception.	• Parents do not use alcohol, tobacco, or other mood-altering substances when planning to conceive. • The mother begins a vitamin regimen containing folic acid before the pregnancy.

Public health nurses' role with young families is very important. (Author's photo used with permission of Deanna Rector.)

ROLE OF THE PUBLIC AND COMMUNITY HEALTH NURSE
