Public and community health nurses face the challenge of continually assessing each population's current health problems as well as determining available and needed services. PHN interventions with maternal, infant, toddler, and preschool populations are focused on health promotion, health protection, and early intervention. They may include work in family planning or high-risk clinics, telephone information services and hotlines, outreach interventions, childcare consultation, or home visitation programs. The nurse uses educational and health coaching interventions when teaching family planning, nutrition, safety precautions, and appropriate health seeking or childcare skills. Such interventions involve providing information and encouraging client groups (parents and young children) to participate in their own health care. Other interventions include strategies in which the nurse uses a greater degree of persuasion or positive manipulation, such as conducting voluntary immunization programs, working in a lead screening program, encouraging smoking cessation during pregnancy, preventing communicable diseases, and encouraging appropriate use of child safety devices such as car seats. Finally, the nurse may use interventions that motivate people into adherence with laws that require certain immunizations or mandate reporting of suspected child abuse and environmental health standards violations, such as sanitation issues. PHN home visiting programs are effective in addressing needs of high-risk and hard to reach families (Avellar & Supplee, 2013). See Chapter 6 for new programs available through health care reform.

The PHN acts as an advocate and a resource for childbearing women and couples and families of young children. The PHN may be called upon to provide information to young mothers about infant temperament, sleep schedules, colic, parenting, discipline, toilet training, television or video choices, and nutrition and feeding. The nurse should be aware of federal, state, and local laws that preserve and protect the rights of children and families. Knowledge about educational, medical, social, and recreational services needed by young families is helpful. The nurse works to secure these services in the community. Ensuring that families have the resources to provide a safe and healthy environment for their children can take many forms. The nurse may lobby to change existing laws, initiate the effort needed to establish programs and services in the community, and teach families about infant safety or the importance of immunizations. The PHN also has skills of community and neighborhood assessment. These skills are vital to health departments and community-based organizations and primary care centers for development of programs needed for women and children (Stewart-Brown & Schrader-McMillan, 2011).

SUMMARY

Maternal–child health clients are an important population group to PHNs because their physical and emotional health is vital to the future of society. The United States does not fare well in comparison to other developed nations on maternal–child health indicators. Most developed countries have universal home visiting programs by nurses for new mothers and families, especially for the first-born child and those at high risk.

Problems of substance abuse, sexually transmitted diseases, and teen pregnancy can lead to less than optimal outcomes for newborns. Complications of pregnancy and childbirth, such as hypertension, gestational diabetes, postpartum depression, and fetal or infant death, offer opportunities for community health nurses to provide education, outreach, monitoring, and support.

IMRs in the United States are higher than those in many other countries around the world. Toddler and young child mortality and morbidity are often related to unintentional injuries. Worldwide, toddlers and preschoolers are at risk for accidents (falls, drowning, burns, and poisoning); acute illnesses, particularly respiratory illnesses; and nutritional, dental, and emotional ailments. Violence against children and deaths from homicide elicit valid concerns. These problems create major challenges for the PHN who seeks to prevent illness and injury among children and to promote and protect their health. The public health intervention of outreach is one community intervention that can lead to prevention.

Health services for children span three categories: preventive, health protecting, and health promoting. The PHN plays a vital role in each. Preventive services include immunization programs, along with quality day care and preschool. Health protection services include accident and injury prevention and control, as well as services to protect children from child abuse. Health promotion services include infant development through effective parent–child interaction, developmental screening, and services to children with special needs.

The role of PHNs includes providing interventions to serve young children's health needs (e.g., educational interventions for parents on nutrition and healthy habits). Other interventions involve encouraging age-appropriate immunizations or cessation of smoking during pregnancy, and community health nurses may employ persuasive tactics, coaching, and motivational strategies to move clients toward more positive health behaviors.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. What specific objectives has your local health department developed for mothers and infants to help achieve the goals listed in the *Healthy People 2020* document? How do your county's statistics compare with those of others in your state on (1) infant mortality rates (collectively and by specific ethnic groups), (2) incidence of LBW and VLBW infants, and (3) incidence of birth defects?
2. Locate some national Web sites that give you current information about progress toward meeting some of the *Healthy People 2020* goals with mothers, infants, toddlers, and preschool-aged children. Are we making progress? What can a PHN do locally to promote meeting these goals? What needs to be done on the regional, state, or national level?
3. Describe three different maternal–child populations in your county. What are their most pressing health needs? Do any existing services target these populations? How well, in your judgment, are clients' needs being met? Interview a city or county PHN and other public health professionals to help you find answers.
4. Sonia, an 18-year-old woman, is single and 14 weeks pregnant. Her first prenatal visit was made at the urging of her aunt, who uses the health department women's clinic. Sonia reluctantly admitted to the clinic nurse that the pregnancy was unplanned. She consumes alcohol two to three times a week—frequently as much as six 12-ounce cans of beer and 16 ounces of wine—and she smokes one pack of cigarettes a day. She has tried a variety of street drugs in the last 3 months but does not use any on a regular basis. The clinic nurse believed that Sonia might not return for regular prenatal care and made a referral to the PHN for follow-up home visits to assess Sonia's home environment and educate about prenatal care and preparation for the infant. You have been assigned to the case. How would you approach Sonia and make her feel comfortable with you? Design a plan of care to address Sonia's needs. What specific services and programs might you recommend? What barriers might exist? How would the prenatal and postpartum teaching delivered to Sonia differ from care needed by other single teens?
5. What is the major cause of death among infants, toddlers, and preschool-aged children? What community-wide interventions could be initiated to prevent these deaths? Select one intervention for each age group, and describe how you and a group of community health professionals might develop this preventive measure.
6. Describe one health promotion program that you as a PHN could initiate and carry out to improve the health of children in a day care center or preschool program.
7. Look at the pertussis, MMR, and maternal–child health vital statistics in your county or community. What do these statistics tell you about your community's health? What other related statistics are important to gather to determine if your community

is a positive and healthy place for childbearing women and young children?

8. Go to the *Centers for Disease Control and Prevention* (CDC) Web site (www.cdc.gov) and look up the current childhood immunization schedule for children ages 0 to 4 years. How would you determine how to modify the schedule for a 30-month-old who is missing his last set of immunizations?

22 CHAPTER

School-Age Children and Adolescents

"Youth isn't always all it's touted to be."

—*Lawana Blackwell*, The Dowry of Miss Lydia Clark, 1999

KEY TERMS

Anorexia nervosa
At risk of overweight
Attention deficit hyperactivity disorder (ADHD)
Autism spectrum disorder (ASD)
Binge eating
Bulimia
Eating disorders
Food insufficiency
Learning disability
Overweight
Pediculicide
Pediculosis

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify major health problems and concerns for U.S. school-age children and adolescent populations.
- Explain how health status can influence academic achievement.
- State the recommended immunization schedule for school-age children and adolescents.
- Examine the trends in mortality and injury among school-age children and adolescents and identify the most important areas needing intervention.
- Discuss *Healthy People 2020* objectives affecting adolescents and the barriers that may be involved in attaining these objectives.
- Describe types of programs and services that promote health and prevent illness and injury of school-age children and adolescent populations.

According to Erick Erickson's developmental framework, the school-age and adolescent years are a time of task mastery and development of competence and self-identity. During these years, children grow physically, as well as emotionally and socially. They move from the total control of parents and families during infant and toddler years to deriving more and more influence from outside the home—from school, teachers, peers, and other groups (Adler-Tapia, 2012).

The challenges of childhood and adolescence include developmental issues, school

concerns, behavioral and learning problems, emotional and mental health issues, and the risk behaviors characteristic of teenage years. This chapter explores the health needs of school-age children and adolescents and describes various services that address those needs, along with the community health nurse's role in assisting families with children.

SCHOOL–CHILD'S WORK

In the United States in 2011, about 55 million school-age children and adolescents (5 to 18 years old) attended more than 132,000 public, private, and charter schools (National Center for Education Statistics [NCES], 2014, Table 105.30; National Clearinghouse for Educational Facilities, 2012). In 2014, the U.S. population aged 0 to 17 was composed of 51.9% White/non-Hispanic, 13.8% Black/non-Hispanic, 4.8% Asian/non-Hispanic, 24.4% Hispanic, and 5.2% all other groups (Federal Interagency Forum on Child and Family Statistics [FCFS], 2015a).

Children and adolescents spend most of their waking hours in school. Their academic success can predict future education, employment, and income. The quality of their educational experiences (e.g., teacher–child interactions) can influence learning (Gifford, Evans, Berlin, & Bai, 2011; Quan-McGimpsey, 2011). These children are the parents, workers, leaders, and decision makers of tomorrow, and their future success depends in good measure on achievement of their educational goals today. Child health has been linked to school success—healthy children are found to be more motivated and prepared to learn (Centers for Disease Control and Prevention [CDC], 2014b; London & Castrechini, 2011), and coordinated school health programs are linked to academic achievement (Ickovics et al., 2014). This is well known to school nurses and public health nurses (PHNs) working in schools.

High school is a critical time in an adolescent's life. (Author's private photo with permission from Merysa Schultz.)

HEALTH PROBLEMS OF SCHOOL-AGE CHILDREN

The well-being of children has been a subject of great concern in the United States since the days of Lillian Wald. For many years, international organizations, including the World Health Organization (WHO), the United Nations International Children's Education Fund (UNICEF), and U.S. governmental agencies, nonprofit groups, and charitable foundations, have focused their resources on improving the health and well-being of children (U.S. Department of Health and Human Services [USDHHS], 2015a). Nonetheless, the needs of millions of children in the United States and worldwide remain unmet. The *Healthy People 2020* document has four objectives for early (birth to age 8) and middle childhood (aged 6 to 12):

- Increase the proportion of children who are ready for school in all five domains of healthy development (physical and social–emotional development, approaches to learning, language, and cognitive development).
- Increase the proportion of parents who use positive parenting and communicate with their health care professionals about positive parenting.
- Decrease the proportion of children who have poor quality of sleep.
- Increase the proportion of elementary, middle, and senior high schools that require health education (USDHHS, 2015b).

Even in the wealthiest nations, many children face complex and often chronic health problems that cause them to miss school days or participate only marginally in the classroom. Because childhood is a critical period during which certain behaviors or health conditions are known to lead to more serious adult illnesses, it is vital for community health nurses and school nurses to screen children and identify problems early (Haines et al., 2011; Ruggieri & Bass, 2015). The chronic health problems of children younger than age 18 are often characterized by severity (e.g., persistence of symptoms and impact on social functioning) and duration (usually longer than 3 to 12 months) and often include

- Diabetes
- Asthma
- Autism spectrum disorder (ASD)
- Cystic fibrosis
- Spina bifida
- Neuromuscular disorders
- Juvenile rheumatoid arthritis
- Seizure disorders
- Hemophilia
- Congenital heart disease

- Attention deficit hyperactivity disorder (ADHD)
- Nutritional problems—anemia or obesity/overweight
- Cerebral palsy
- Mental illnesses (Perrin, Andersen, & Van Cleave, 2014)

Other conditions may also be defined as chronic, such as allergies, ear infections, and sinusitis, as well as hearing or speech disorders. Some chronic conditions may affect a child socially and emotionally, as well as physically. School attendance and relationships with family and peers may be affected.

Chronic Diseases

Stomachaches, headaches, colds, and flu are frequent complaints of school-age children, but it is not uncommon for this same age group to be afflicted with some type of chronic disease. Common chronic problems include hay fever, sinusitis, dermatitis, tonsillitis, asthma, and hearing difficulties. Chronic health problems such as these can affect a child's ability to learn and/or his or her physical and social development. Other more serious conditions, such as diabetes, sickle cell anemia, or seizure disorders, have definite effects on academic achievement and educational attainment (Champaloux & Young, 2015).

The growth in the number of chronic health conditions in children and adolescents has been astounding. Since 1960, when <2% reported a condition that interfered with daily activities, the incidence rose by 400% in 2010 when 8% reported severe health conditions. Most of the increase has centered on four broad areas: asthma, mental health conditions, obesity, and neurodevelopmental disorders. Rates of asthma and obesity have begun to slow at the start of the 21st century. Growth, in some cases, has been thought to be because of an interaction of genetic susceptibility and exposures or environmental triggers, along with changes in diet and exercise as well as use of electronic devices (e.g., computers, televisions, video games). Some of the conditions, such as ASD and attention deficit hyperactivity disorder (ADHD), are thought to be increasing because of better public awareness and diagnosis rather than actual increases in prevalence. Gender differences in chronic health conditions have been found, with males having 50% higher rates. Racial/ethnic differences have also been noted, as Black children have higher rates than White children, despite income level. Puerto Rican children's rate of asthma is 140% higher than that of White children. These differences are also found with obesity: Black children and Hispanic children had reported rates of 24% and 21%, respectively, in 2009–2010. For ADHD, White and Black children have the largest share of prevalence compared to Hispanics (Perrin et al., 2014).

A large study of almost 100,000 children and adolescents born to immigrant or U.S.-born parents found lower prevalence of behavioral problems and depression in immigrant children, and autism prevalence for immigrant Asian children of only 0.3%, whereas the rate for native-born White and Hispanic children was between 1.3% and 1.4%. Interestingly, immigrant children had lower rates of asthma, ADHD, learning disabilities, speech/hearing and sleep problems, and total number of chronic health conditions than native-born children. The risk rose as their mother's years in this country increased over time (Singh, Yu, & Kogan, 2013).

The numbers of children with chronic conditions are increasing, and more children with significant health problems are present in schools (National Association of School Nurses, 2012). In the school setting, some children require specialized physical health care procedures, such as catheterization, suctioning, or ventilator care. The U.S. Supreme Court ruled that even complex nursing services (i.e., ventilator care) must be provided by schools,

even though school nurses are not always present in each school building every day (New York State United Teachers, 2012). The Individuals with Disabilities Education Act (IDEA) and Section 504 of the Rehabilitation Act of 1973 mandate that services must be provided for children identified as *disabled*. Many conditions may be characterized as disabling under these two laws, including autism, deafness or hearing impairment, blindness or vision impairment, emotional disturbances, mental retardation, specific learning disabilities (LD), speech or language impairments, or other health impairments (e.g., ADHD, asthma). Once they have been characterized as disabled, children may qualify for special educational services. Children with chronic health conditions that can affect learning (e.g., diabetes, seizure disorders) may receive medications or other related services while in school, to maintain their health and promote their ability to learn.

Chronic diseases of childhood and adolescence affect the entire family and can lead to developmental and social issues for children, as well as missed school days and eventual school failure (CDC, 2014b; Reuben & Pastor, 2013). In a large study of over 22,700 students with chronic health conditions in grades 2 through 11, researchers found that seizure and neurodevelopmental disorders (e.g., autism, ADHD) were associated with poor school performance. Diabetes and cardiovascular disorders were not independently associated with low school performance, and asthma had a weak association before adjustments were made for absenteeism. The adjusted odds ratio for any chronic health condition and below average performance for math was 1.25 when compared to students without chronic health conditions (Crump et al., 2013).

Many children with chronic health conditions take multiple medications at home and at school. One study that examined parents' mediation administration for children with seizure disorders and sickle cell disease included 52 home visits and 280 medications administered at home. Researchers found 61 medication errors, and 31 errors with the potential for harm or injury, as well as 9 causing actual injury (Walsh et al., 2011). Problems in communication with the physician, pharmacy, and spouse led to failure to fill new prescriptions, failure to change dosage, and problems with medication preparation, all leading to inaccurate medication administration. Also, 95% of parents didn't use support tools like reminders or alarms to remind them to give medications on time. Home visits and consultations by PHNs and school nurses could be helpful to parents and children or youth with chronic health conditions. See Chapter 30 for more on school nursing.

Asthma

Asthma is one of the most common chronic diseases of childhood. In 2013, it was estimated that 13% of children younger than age 18 have at some time been diagnosed with asthma. Childhood asthma rates steadily increased between 1997 and 2011; however, during 2012–2013, the prevalence of diagnosed asthma slightly decreased. Black, non-Hispanic children exhibited the highest asthma attack rates at 13%, compared with 8% for White, non-Hispanic children and 7% for children of Mexican heritage. Overall, about 5% of all children reported an episode within the past year (FCFS, 2015b).

Although reasons for increased cases of asthma over the past two decades are somewhat unclear, experts speculate that better recognition and diagnosis of the disease, overcrowded conditions, and exposure to air pollution (indoor or outdoor), allergens, and irritants in the environment are probable culprits and may trigger asthma attacks. Many schools have high levels of allergens and irritants. Children and adolescents with asthma may have attacks triggered by infections, exposure to cigarette smoke, stress, strenuous exercise, or weather changes (e.g., cold, wind, rain; Sleath et al., 2011; Sweet, Polivka, Chaudry, & Bouton, 2014).

Pediatric asthma is among the respiratory system ailments (including pneumonia and acute bronchitis) that were the top cause of hospital stays for children in 2012 (Witt, Weiss, & Elixhauser, 2014). Treatment for chronic asthma usually includes cromolyn sodium, leukotriene modifiers, inhaled and oral corticosteroids or long-acting beta agonists, and anti-IgE therapy, but acute symptoms may involve inhaled $beta_2$ agonists and sometimes anticholinergics (National Heart, Lung, and Blood Institute, 2014). Parent and child education, along with adherence to oral corticosteroid regimens, can help decrease the number of emergency room visits and hospitalizations because of asthma attacks (Sweet et al., 2014).

Teaching families to reduce allergens in their homes by controlling dust mites, vacuuming frequently, preventing animal dander and the entry of pollen into the home, and avoiding mold and mold spores may help minimize asthma symptoms for many children. In addition, families should be educated on the danger of indoor environments with mold and mold spores and the use of household items or products (e.g., furniture, flooring, and paints) made from volatile organic compounds (VOCs) (Asthma and Allergy Foundation of America [AAFA], 2015). School nurses and PHNs often work with students, families, and physicians to develop an asthma action plan to control, prevent, or minimize the untoward effects of acute asthma episodes. The goal is to control asthma symptoms and minimize school absences resulting from asthma (Basch, 2011a). Asthma triggers are noted, and school staff members are taught to assist the child in avoiding these triggers. Peak flow meters can be used to determine early signs of asthma problems and to facilitate early interventions; asthma action plans and holding chambers/spacers are used. Although only one third of schools have a full-time school nurse (viewed as vital to the success of an asthma control program), 80% allowed students to self-administer their inhalable asthma medications (Robert Wood Johnson Foundation, 2013).

Monitoring asthma medications and teaching proper methods of inhaler use are also vital school nursing or PHN functions. Although the link between asthma and academic achievement is not definitive, some evidence exists that school nurse case management of asthmatic children can lead to fewer absences and contribute to better overall asthma control (Healthy Schools Campaign, 2014).

Autism

Autism spectrum disorder (ASD) is a complex developmental disorder often originally noticed within the first few years of life. The spectrum of ASD indicates that symptoms for each child varies and may range from mild to severe (CDC, 2014a). A child's communication skills and interaction with others are most often affected, along with obsessive behavior and narrowed interests. Behaviors associated with autism include

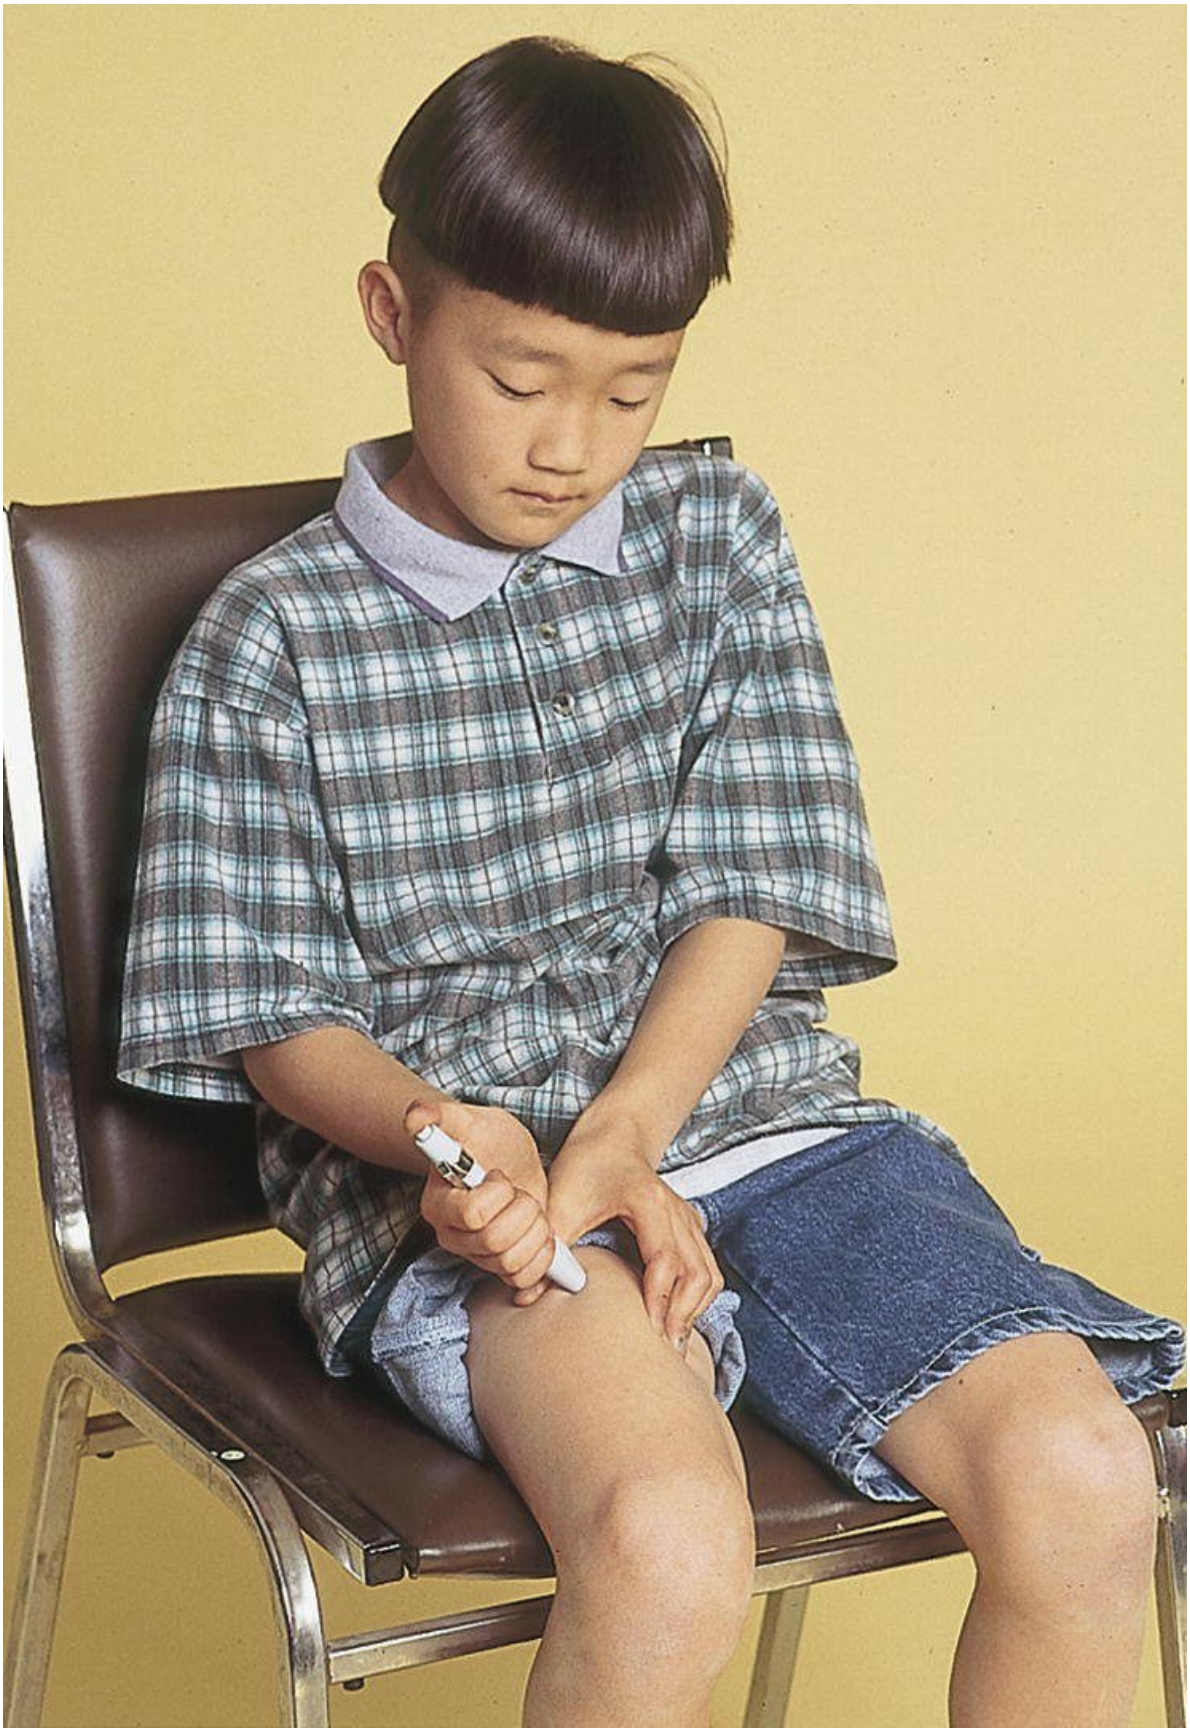
- Language problems (no language, delay in language, repetitive use of language)
- Motor mannerisms (often repetitive rocking, hand flapping, object twirling)
- Fixation on objects (restricted interests)
- No spontaneous play or make-believe play; no interest in peers (problems making friends)
- Little or no eye contact (may also resist hugging)

Autism prevalence has been estimated at approximately 1 out of every 68 children (CDC, 2014a). The yearly expense for care of an autistic child is approximately $17,000 greater than the cost of a child without ASD (CDC, 2014a). When autism involves intellectual disabilities, the lifetime cost may be as high as $2.4 million/individual and $1.4 million if no intellectual disability is involved (Autism Society of America [ASA], 2014). Autism is not a new disorder—descriptions of autistic behavior have been identified in 18th century writings. Currently, early detection and intervention therapies focusing on speech, coordination, and interaction skills can help to improve development. Boys are five times more likely than girls to have the disorder (CDC, 2014a). Because autism is a "spectrum disorder" that presents differently among individuals, behaviors and severity can vary widely (ASA, 2014).

The cause of autism is not clear—some genetic links have been found, but environment may also be a factor. There is a higher risk of subsequent children having autism in a family with one autistic child or a parent with ASD (CDC, 2014a; National Institute of Neurological Disorders and Stroke [NINDS], 2012). It is often associated with other disorders (e.g., congenital rubella syndrome, Down syndrome, fragile X syndrome, tuberous sclerosis), but the exact causes are not fully understood (CDC, 2014a; NINDS, 2012).

PHNs may come in contact with families dealing with autism through work in well-child or immunization clinics. It is important to educate parents that parenting practices are now known *not* to be a cause of autism and that multiple, large-scale research studies on childhood immunizations have shown no relationship between immunization and autism (CDC, 2014a; NINDS, 2012; National Vaccine Information Center, 2012). The CDC is conducting a multiyear study to identify risk factors for autism, the Study to Explore Early Development (SEED), in an effort to better understand the causes of autism. It is also important to assist families in accessing services for their children, as early intervention is most helpful.

Diabetes



Diabetes is another common chronic illness in children, with type 1 being the leading cause of diabetes in all children (National Diabetes Education Program, n.d.). About 50% of children diagnosed with type 1 diabetes mellitus (T1DM) are diagnosed before age 10, but most children with type 2 diabetes (T2DM) are diagnosed after age 10, with a mean of 13.5 years (Jesitus & Kim, 2015). Redondo and colleagues (2014) found that newly diagnosed autoimmune T1DM children who were obese had higher levels of proinflammatory adiposity-induced biomarkers than those who were lean, adding that this may contribute to diabetic complications and cardiovascular disease (CVD). Both type 1 (T1DM) and type 2 diabetes (T2DM) are found in school-age children, with T2DM rising almost exponentially in this age group, leading some scientists to call this a major public health crisis. T2DM in children and adolescents, virtually nonexistent before 1999, now comprises about half of new cases in many communities (Reinehr, 2014) and 8% to 45% of all new T2DM diagnoses in the United States (Caple & March, 2015). This epidemic is thought to stem from increasing rates of childhood obesity, sedentary lifestyle, and the predisposition of certain ethnic groups (e.g., American Indian, Mexican American) to the disease. Some research has shown a connection between a secreted protein, pigment epithelium-derived factor (PEDF), and childhood obesity with insulin resistance in obese children, both with and without type 2 diabetes, leading researchers to put a greater emphasis on obesity as a risk factor (Tryggestad, Wang, Zhang, Thompson, & Short, 2015). A family history of T2DM may also play a role; in over 74% of cases, the child or adolescent has a first- or second-degree relative with T2DM (Reinehr, 2014). A longitudinal study of 699 10- to 17-year-olds with recent-onset T2DM, the Treatment Options for Type 2 Diabetes in Adolescents and Youth (TODAY) study, concluded that the disease progression for children and youth is different than for adults and that it progresses more rapidly than originally expected. Early results revealed that 50% of participants required insulin within only a few years of diagnosis and, by the end of the 4-year study, almost one third had hypertension, 17% had early signs of kidney disease, and 13% demonstrated signs of visual problems. Early and aggressive treatment is recommended, as 50% of participants responded to metformin therapy and were able to maintain glycemic control over the time period of the study (TODAY Study Group, 2012).

Another recent national study with shocking results found an increase in the prevalence of prediabetes/diabetes from a rate of 9% in 1999 to 23% in 2008 (May, Kuklina, & Yoon, 2012). This study included youth aged 12 to 19 years, and researchers found that those who were more overweight or obese had greater increased prevalence of CVD risk factors (e.g., hypertension, higher LDL cholesterol). Approximately 37% of those of normal weight, 49% of those considered overweight, and 61% of obese adolescents had at least one CVD risk factor. Other considerations include "chronic and toxic levels of stress… that lead to a number of chronic physical conditions," and, with the rise in obesity and metabolic disorder among children and adolescents, screening for CVD risk factors (e.g., cholesterol, hypertension) needs to be more routine and widespread (Halfon, Verhoef, & Kuo, 2012, p. 51).

A more recent category of diabetes, double diabetes, is found when a child or adolescent presents features of both T1DM and T2DM. For instance, when a child with T2DM develops antibodies to β cells or when an adolescent with T1DM becomes overweight or obese, they may be characterized as having double diabetes (Cleland, Fisher, Colhoun, Sattar, & Petrie, 2013; Pozzilli, Guglielmi, Caprio, & Buzzetti, 2011; Robinson & Estell, 2012).

Research continues on the pathophysiology of the disease and prevention strategies (e.g., lifestyle changes, causes of autoimmunity), as well as refining methods of diagnosis and treatment (e.g., insulin pumps, continuous glucose monitoring, closed loop systems). Even though carbohydrate counting has not shown definitive results, it is still largely used (Cameron & Wherrett, 2015). Large-scale studies of T1DM youth under age 18 have shown racial/ethnic disparities in both methods of treatment and outcomes (Willi et al., 2015).

Younger children with T1DM, especially those who use insulin pumps, may need careful monitoring, something that is not always possible for the school nurse, who is often assigned to several school sites and may not be present when problems arise. Also, it is important for PHNs and others working with children and youth who have diabetes to consider their psychosocial needs, as well as their physical needs (see Evidence-Based Practice). A multidisciplinary team approach to care is needed, coordinating family, school staff, and physician collaboration. See Chapter 30 for more on the school nurse's role with school-age children with diabetes.

PHNs and school nurses work with diabetic school-age children to assure proper glucose monitoring and insulin administration.

EVIDENCE-BASED PRACTICE

Children and adolescents with diabetes (both T1DM and T2DM) are faced with additional challenges. They are required to pay stricter attention to their health and management of their chronic condition. In addition, there are emotional costs. Nurses Sparapani, Jacob, and Nascimento (2015) wanted to better understand the emotional impact of children with diabetes. They conducted a small qualitative study with nineteen 7- to 12-year-olds with T1DM to determine feelings, thoughts, and self-management of diabetes. In an effort to better engage the children, they used puppets that the children created to help them convey their thoughts and feelings. When asked, "What is it like to be a child with T1DM?" their responses were grouped into four main themes: (a) conflicting desires, (b) insecurity, (c) fear, and (d) pain.

They expressed worry about control of their diabetes, dietary restrictions, and hypoglycemic reactions. They expressed frustration about not being able to eat sweets. One girl said, "I think if there were no sugar in the world, the world would be a better place" (p. 18). When having to monitor blood sugar and administer insulin, most children noted fear of needles and skin pricks, and some asked their parents to do this for them. Children noted the need for control of their diabetes, with one girl stating, "if you have a lot of sugar, you can amputate a leg, an arm, and even, you can die" (p. 18). Other children could not fully explain their disease and were ashamed of talking about it with others. Some mentioned problems in relationships with other children, because of their diet restrictions and need for self-care. One girl, testing her blood sugar in class, relayed "I am ashamed of the others who keep looking at me" (p. 19).

In addition to the usual developmental stressors of childhood, these children had additional conflicts: on the one hand, they want to be children like their peers and do what they wanted, but, on the other hand, they must adhere to the restrictions imposed upon them by having T1DM. Children in this study reported problems relating to peers, and some assistance may be needed with that. One child participant noted that a hypoglycemic episode was used to gain access to "sweets" (p. 20); because this propensity for sweet things is a common childhood occurrence, this should be kept in mind. Adults (e.g., parents, caretakers, nurses) need to be aware of children's physical needs and offer assistance, but they also must consider their emotional and psychosocial needs.Sparapani, V. D., Jacob, E., & Nacimento, L. C. (2015). What is it like to be a child with type 1 diabetes mellitus? Pediatric Nursing, 41(1), 17–22.

Children and adolescents with diabetes may be reluctant to comply with their medical regimen, but strict adherence has proved to reduce later microvascular complications. Intensive treatment control in a study of adolescent diabetics reduced clinical neuropathy by 60%, retinopathy by 53%, and microalbuminuria by 54%, as well as HbA1c levels; at a 17-year follow-up, cardiovascular events were 50% lower and clinical neuropathy 60% lower in those adhering to stricter control. Although vascular complications in childhood and adolescence are rarely clinically evident, intensive treatment is beneficial for long-term outcomes (Donaghue et al., 2014). Testing blood glucose levels and taking insulin at school can be frustrating and cause children to feel singled out or different from their peers. Adolescents with T1DM or T2DM have higher rates of depression than those without diabetes (Hood et al., 2014). Also, other researchers noted that, among adolescents with diabetic duration of 2 to 5 years, early microvascular complications are not uncommon (Cho et al., 2011), and puberty is noted to accelerate diabetes complications in a recent review of research (Cho, Craig, & Donaghue, 2014). It is important for school nurses and PHNs to understand each child's unique concerns and to alert teachers and school personnel to the signs and symptoms (as well as treatment) of hypoglycemia.

In addition to the obvious emergency health-related concerns for diabetic children, other studies have demonstrated mild cognitive impairments and somewhat reduced intellectual functions in children with T1DM that may affect school achievement (Cato et al., 2014; Schwartz, Axelrad, & Anderson, 2014). A comparative study of children between ages 4 and 10, with and without diabetes, found slower growth of white and gray brain matter and differences in white and gray matter regions of the brain in those children with diabetes. Researchers concluded that chronically higher levels of glucose could be harmful to brain development (Mauras et al., 2015). Moreover, the youth's own perception of obesity and overweight has been found to correlate with lower academic performance (Florin, Shults, & Stettler, 2011). Boogerd and colleagues (2015) found more psychosocial problems among children with T1DM than among a group of healthy children, although in 40% of their sample, neither parents nor children (ages 4 to 16) reported any psychosocial problems. Alerting teachers to these concerns may help them better understand the academic complications of this disease and ensure their support.

It is imperative to teach children and families that proper diet, oral antidiabetic medications or insulin administration, physical activity, and blood glucose testing are vital strategies to keep blood glucose levels as close to normal as possible. The prevention of T2DM through education and improvement in exercise, nutrition, and lifestyle can be one of the most important areas of focus for health professionals who work with the school-age population—including PHNs who may come into contact with them during immunization or child health clinics. Health education and health promotion to decrease childhood obesity and sedentary lifestyles may help stem the tide of T2DM in children and adolescents (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

SITUATION: The public health nurse and children with type 2 diabetes (T2DM)

GOAL: By using the three levels of prevention, negative health conditions are avoided, promptly diagnosed and treated, and/or the fullest possible potential is restored.

	Health Promotion and Education	*Health Protection*
• Monitor the child's health • Work closely with the child, family, physician, and teacher to ensure proper follow-up • Be alert to monitor for any possible complications (e.g., medication side effects)	• Continue to promote a healthy lifestyle that includes appropriate food choices and daily physical activity within the limitations of T2DM	• Educate the teachers on safety precautions for children in their classroom diagnosed with T2DM • Monitor children taking medications for T2DM (e.g., over- or underdosage and adverse reactions)

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Teach older children to calculate their body mass index (BMI) • Monitor BMI scores • Yearly screenings for height and weight (calipers are useful) • Complete health histories on at-risk children	• Initiate referrals for health care provider follow-up in collaboration with parents of students at risk for T2DM • Initiate referrals to health care providers in collaboration with parents of students with signs and symptoms of T2DM

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Educate to promote good nutrition and a physically active lifestyle • Provide classroom contact in the early primary grades to encourage children to make good food choices • Limit passive activities and increase sports and physical activity • Teach older children how to make better food choices at fast-food restaurants	• Advocate for policies that limit access to sugary beverages and snacks at school, and programs that raise awareness and family involvement in better nutrition and promote physical activity for families.

Juvenile Rheumatoid Arthritis

Juvenile rheumatoid arthritis is a painful autoimmune disorder characterized by persistent joint swelling and stiffness with periods of remission and flare-up. It is often diagnosed between the ages of 6 months and 16 years. It is treated with nonsteroidal anti-inflammatory drugs (NSAIDs), disease-modifying antirheumatic drugs (DMARDs), such as methotrexate, and sometimes corticosteroids or newer biologic response modifiers (Pub Med Health, 2011). Exercise is often an important component of therapy, and an adapted physical education program may be developed for these children. Long-term sequelae may

result, such as slow rate of growth or uneven growth of arm or leg, as well as pericarditis and joint destruction. Many adolescents with this disorder require additional support and counseling (Pub Med Health, 2011). Once again, the school nurse or PHN can serve as a liaison between the health care and education communities and advocate for any necessary accommodations.

Seizure Disorders

Seizure disorders are not uncommon in the school-age population. Epilepsy is a disorder of the brain in which neurons sometimes transmit abnormal signals. Epilepsy is considered to be one of the most common disabling neurologic conditions, and it is most common in the very young and in elderly populations. Over 300,000 children under age 15 and more than 570,000 older adults have epilepsy; more than 90,000 children may have treatment-resistant seizures (Epilepsy Foundation, n.d.). Lifetime prevalence of seizure disorders/epilepsy is estimated at 10.2 per 1,000, and prevalence is higher in low-income families, as well as for male, older children. Those with seizure disorders have an increased risk for developmental (ASD, delays), mental health (e.g., anxiety, depression, ADHD, conduct disorders), and physical comorbidities (e.g., headaches) and were over 2.5 times more likely to repeat a grade (Russ, Larson, & Halfon, 2012). Although sudden unexplained death can occur in children with epilepsy, it is considered quite rare and is much more common among adults with epilepsy (Arts, 2012). More commonly, childhood deaths are due to the underlying conditions causing the seizures, and some are due to accidents that happen while the child is seizing (e.g., drowning, falls).

Although there are some instances of intractable or drug-resistant epilepsy, many children diagnosed with seizure disorders/epilepsy can have their seizures controlled with medications such as Tegretol, Dilantin, Depakote, Neurontin, Topamax, and Lamictal (WebMD, 2012). Vagus nerve stimulators are used in some cases after other treatments have failed (Elliott et al., 2011; Wilfong, 2015). Rectal diazepam is commonly prescribed for younger children and those with developmental disabilities, yet nurses are not always available to make an appropriate nursing assessment of the child before the drug is given to stop a seizure (Wong-Kisiel, 2013). Often, school secretaries or health aides are trained to give the emergency medication—highlighting the conflict between education laws and nurse practice acts (see more on this in Chapter 30). Treatment of epilepsy has been greatly enhanced by the use of newer antiepilepsy drugs (AEDs) specific to the pediatric population and, in some cases, by a diet rich in proteins and fats and low in carbohydrates —a *ketogenic diet* (Epilepsy Foundation, n.d.).

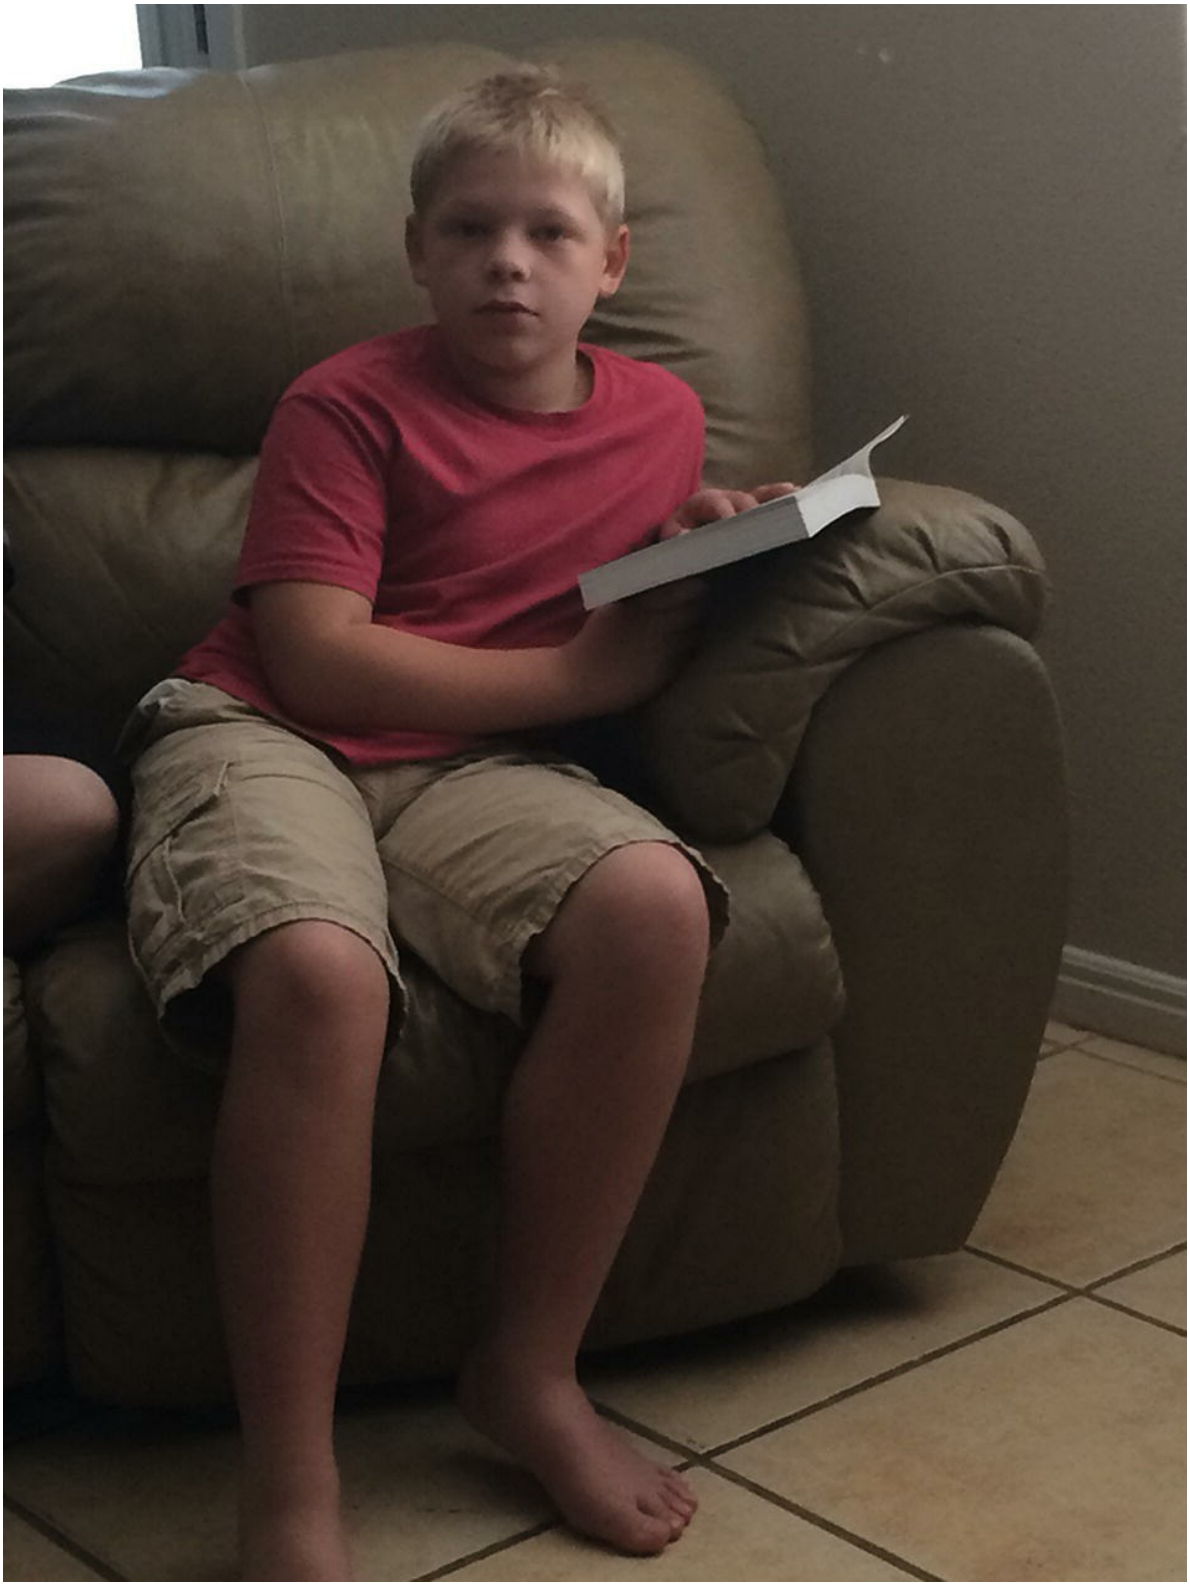
It is important to monitor medication compliance and teach school staff about first-aid measures for seizure victims. When teachers are anxious about having a child with epilepsy in the classroom, educational programs for them and other school staff members can be provided. Community health nurses or school nurses can help allay fears and promote appropriate and timely care.

Family dynamics are also a consideration, as behavior problems can arise (Rodenburg, Wagner, Austin, Kerr, & Dunn, 2011; Sprague-McRae & Rosenblum, 2013). Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying. They may exhibit signs of school avoidance, or they may have problems learning. Seizure activity, along with the side effects of antiepileptic medications, may lead to problems with memory and learning, as well as changes in behavior (Epilepsy Foundation, n.d.). Moreover, seizures can affect short-term memory or language functions (Epilepsy Foundation, n.d.). It is important for school nurses to work with children with epilepsy and to teach all students about the disease process and the need for empathy and understanding.

Childhood Cancers

In 2013, cancer was the leading cause of death from disease among U.S. children between infancy and age 14 years. Leukemias and brain, central nervous system, and neuroblastoma cancers are the most common types of childhood cancers (National Cancer Institute [NCI], 2015). Childhood cancers, especially leukemias, now have better outcomes than ever before. Five-year survival rates for childhood cancers increased from 60% in the 1970s to 86% in recent years, generally as a result of treatment advances and participation in clinical trials (NCI, 2015). More children are surviving childhood cancers, and concern has shifted to later complications of treatment rather than about cancer recurrence. Survivors are at greater risk of gastrointestinal, auditory, and cardiovascular complications (Goldsby et al., 2011; Whelan et al., 2011). Also, children who have been treated with chemotherapy and/or radiation may develop a second primary cancer, and the risk of leukemia may be increased (NCI, 2014). White children, more than children from any other racial/ethnic group, are more likely to develop a childhood cancer (NCI, 2014).

The cause of most childhood cancers remains unknown; however, acquired immune deficiency syndrome (AIDS), high levels of ionizing radiation, Down syndrome, and other genetic syndromes (e.g., Gorlin syndrome) have been linked to a higher risk for some childhood cancers. Pesticide exposure may be a factor, but research findings have not been decisive. Parental smoking may be linked to an increased cancer risk, but evidence for this is also inconclusive (NCI, 2014).



Because many children return to school after initial hospitalization and treatment for cancer, school nurses or PHNs can help make this transition easier by educating classmates about cancer (e.g., it is not contagious), helping the children make necessary adjustments, and vigilantly protecting any immunocompromised students from communicable diseases (American Cancer Society, n.d.; Hakim, 2015).

Behavioral and Learning Problems

Other childhood health problems, less easy to detect and measure but often just as debilitating, are those of emotional, behavioral, and intellectual development. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished. Emotional or behavior problems and LD are prevalent in childhood. Of the 5.7 million school-age children with disabilities in the United States, 42% have LDs (National Center for Learning Disabilities [NCLD], 2014). One classic study of national data found a lifetime prevalence of LD at 9.7% (Altarac & Saroha, 2007). In a national survey, 6.4 million of 4- to 17-year-olds reported being diagnosed with ADHD. Parent report of ADHD was 22%, with rates increasing 3% annually from 1997 to 2006 and approximately 5% from 2003 to 2011. Approximately 5.6% of girls and 13.2% of boys reported having a diagnosis of ADHD. LDs, along with ADHD, were reported in 4% of children; and this was more commonly found in the older age group of 12 to 17 years (NCLD, 2014)

Learning Disabilities

Children and adults who have average or above-average intelligence and who demonstrate significant difficulties in one or more areas of learning (e.g., reading, writing, mathematics, attention, coordination) may have a learning disability. Thinking and organization skills can also be affected. LD may occur in one area or be overlapping—they are often lifelong conditions (NINDS, 2015). LDs, or learning disorders, are often recognized as the child progresses in school, and special education services may be needed. Causes of LD and emotional behavioral problems appear to have genetic, environmental, and cultural influences. Approximately 8% to 10% of students have an LD, formally defined as a "neurologically based processing disorder" (Silver, 2011, para 5). About two thirds of learning disabled students receiving special education services are male (NCLD, 2014). The number of children with LD in the lowest economic group is greater than that in the highest economic group (NCLD, 2014). Additionally, children and adolescents with LD are more likely to have health and safety concerns than those without LD (American Academy of Pediatrics, 2015).

Reading is an important to education and may be problematic for children with learning disabilities. (Author's private photo with permission of Danielle Rector.)

Children with LDs can be helped through special education services. In fact, about 41% of children receiving special education services have an LD (NCLD, 2014). Students

must first be carefully diagnosed through psychoeducational testing (IQ testing, achievement tests, and measures of processing abilities); then, special education or resource teachers can build on the child or adolescent's strengths while working to compensate for weaknesses (NINDS, 2015). Some LDs are apparent in early school years, whereas others do not present problems until early adolescence. Battles over homework, poor grades, acting out in school, or frequent child complaints about school, teachers, or schoolwork are often harbingers of LDs. Common signs of LDs are (LD Online, 2014; Silver, 2011):

- Reading problems
- Writing problems (fine-motor control and handwriting; problems with spelling, grammar, punctuation, capitalization; difficulty controlling flow of thoughts)
- Math problems (problems learning and understanding concepts, missing steps or sequencing of problems, and placement of numbers in columns)
- Language problems (cannot quickly process what is heard, problems with multiple instructions, difficulty organizing thoughts and speaking in classroom situations)
- Motor problems (problems with fine-motor planning activities, such as tying, cutting, coloring, and gross motor planning, such as jumping and running; trouble with visual–motor activities, such as hitting or catching a ball)
- Sequencing (getting letters or numbers out of order); organization (messy binders)
- Memory (difficulty retaining what was learned); abstraction (confused, or not understanding what was said)

If LDs are not dealt with in childhood and adolescence, they can lead to later, more serious, problems related to employment, relationships, and quality of life in adulthood. Approximately 55% of adults (18 to 64 years) with LD, compared with 76% of those without LD, reported that they were employed. Children can receive services in schools, based on IDEA and Section 504; provisions of the Americans with Disabilities Act (ADA) provide protections for adults with LD (NCLD, 2014). The PHN and school nurse can assist individuals and families in recognizing LDs and locating necessary resources. Some students with significant LDs may qualify for special education services, and school nurses can be helpful in facilitating this process along with teachers and learning specialists.

Attention Deficit Hyperactivity Disorder

ADHD, a common childhood disorder, is a cluster of problems related to hyperactivity, impulsivity, and inattention. Its estimated prevalence has ranged from 3% to 5%, representing about 2 million children (National Institute of Mental Health (NIMH), n.d.a). As mentioned earlier, there is an overall 9.5% lifetime prevalence of ADHD, with one study indicating 9% lifetime prevalence for 13- to 18-year-olds, and 1.8% for severe ADHD (Merikangas et al., 2010). Another study found the rate of ADHD diagnosis increased from 7% to 9% from 1998 to 2009, with the largest increase among low-income and poor children, and higher prevalence among non-Hispanic White children (Akinbami, Liu, Pastor, & Reuben, 2011). The National Resource Center on ADHD (CHADD) states

that the rate of ADHD diagnosis increased to 10.2% between the years 2012 and 2014 (CHADD, 2015a). Along with the increase in ADHD diagnosis, there has been a rise in prescriptions to treat this disorder; there has also been a rise in ADHD stimulant medication abuse by adolescents. It is estimated that 5% to 10% of high school students misuse the stimulants and poison control centers calls rose over a 7-year period by 76%—a rate much higher than for overall substance abuse calls. ADHD prescription estimates over the same time period showed increases of 133% for amphetamines, 52% for methylphenidates, and 80% for combined medications (Clemow & Walker, 2014). Clemow and Walker (2014) indicate that 5% to 35% of college students use ADHD medications to enhance studying and improve attention problems, although they had no medical justification for use. Although research has shown medications to be effective in controlling behavioral issues, and with less success improve academic achievement, medication titration is a trial-and-error proposition (Hale et al., 2011). Boys are often recognized as having ADHD in early elementary grades, because they most often exhibit hyperactivity symptoms. Girls, on the other hand, are at increased risk for not receiving appropriate services because they often do not exhibit the hyperactivity component and may not be appropriately diagnosed and treated for ADHD.

Although a number of parents believe that sugar, food-coloring agents, or other food additives may worsen ADHD symptoms in their children, research shows no behavioral or learning differences in double-blind studies using sugar and sugar substitutes. And additive-free or non-Western diets are difficult to achieve (Millichap & Yee, 2012). Some research shows that prenatal exposure to nicotine and psychosocial adversity are associated with ADHD (CDC, 2015a). Symptoms of ADHD may be related to such diverse causes as lead poisoning and traumatic brain injuries, but new research focuses on evidence of decreased blood flow in the prefrontal regions of the brain, and the inherited tendencies for problems with dopamine receptors and transporter genes, and research noting that some of the same genes found in childhood ADHD may also be found in adult ADHD (Franke et al., 2012; Thapar, Cooper, Jefferies, & Stergiakouli, 2012). Some researchers are developing functional and structural imaging techniques to identify adolescent ADHD (Iannaccone et al., 2015). These findings support a neurobiological basis for the condition. Some evidence indicates that children with ADHD who are medicated properly later show peak cortical thickness in the frontal areas of the brain consistent with control subjects without ADHD, indicating that medication can restore brain development to a more normal rate, rather than the 3-year delay seen in previous studies (NIMH, n.d.a). Some classic family and twin studies reveal a higher heritability factor for ADHD and its symptoms of inattention and hyperactivity than for other psychiatric disorders, and researchers consider ADHD a heritable, familial disorder (Bezdjian, Baker, & Tuvblad, 2011) In families that have children with ADHD, about 25% of close relatives also had ADHD (NIMH, n.d.a).

Not all behaviors related to ADHD, such as hyperactivity, may truly be ADHD. Health and psychological professionals must take a careful history and note if sudden family changes may have recently occurred (e.g., divorce, death, family crises) that may

cause children to behave erratically. Untreated chronic middle ear infections, undetected temporal lobe seizures, and anxiety or depression can also be the source of some behavior problems that mimic ADHD, as can other brain disorders (NIMH, n.d.a). Although some health professionals believe that many of the symptoms found in people with ADHD are part of the normal spectrum of human behavior, others note that people with ADHD have functional impairment in academic, social, or occupational areas resulting from their problem behaviors. Noted differences have even been reported in the results of electroencephalograms between children with and without ADHD, possibly because of cortical hypoarousal in children with ADHD (Nazari, Wallois, Aarabi, & Berquin, 2011). Over time, nursing researchers have documented data from children and adolescents who described their difficulties, as well as mother's parenting experiences (Paidipati & Deatrick, 2015). This disorder can be very disruptive for children and families, and additional support and counseling are often needed.

At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school are often involved in conflicts with peers and have problems organizing tasks. They may be more prone to accidents and may have more school-related problems, such as grade retention and suspension or expulsion. They often have problems with grooming and handwriting, and they exhibit difficulty sleeping and making friends. As adolescents, 80% still exhibit symptoms of inattentiveness, hyperactivity, and impulsiveness. Compared with non-ADHD teens, they may have more conflict with their parents, poorer social skills, and ongoing problems at school. They may face more difficulty driving and are more prone to injury while driving, biking, or walking than their peers. They are also more likely to use tobacco and alcohol, spend less time with their families, and more often experience negative moods. As young adults, they are less likely to be enrolled in college, more likely to have begun sexual activity at an earlier age and to have been treated for a sexually transmitted infection (STI), and more likely to experience lower job performance ratings than their peers. In adulthood, they tend to have more marital and occupational problems. They often have less formal education and lower levels of savings. Poor social skills may also continue to be an issue (NIMH, n.d.a). About 60% of adults with ADHD were first diagnosed as children. Adult ADHD is thought to affect 4.4% of U.S. adults, and it often goes undiagnosed and untreated; only 10% to 25% of those having adult ADHD have been diagnosed and are receiving treatment. Almost 95% of them continue to have attention deficit problems, but about one third report symptoms of hyperactivity (Anxiety and Depression Association of America (ADAA), n.d.).

ADHD is sometimes found with associated disorders, such as communication or language disorders and LDs. About half of ADHD children and adolescents have learning or other mental disorders. Common comorbid conditions are bipolar, depressive, and anxiety disorders, Tourette's syndrome, as well as conduct disorders and oppositional defiant disorder (NIMH, n.d.). Childress and Berry (2012) note that ADHD is associated with higher risk of psychiatric disorders (e.g., conduct, mood, substance abuse disorders). Differentiating between ADHD and bipolar condition can be difficult in early childhood,

as bipolar disorder in children can present as a chronic mood problem, with some symptoms related to depression, irritability, and elation (CHADD, 2015b). There is a growing body of evidence showing the use of stimulant medications to treat ADHD may reduce the risk of developing later psychiatric comorbidities (including substance abuse disorder). A meta-analysis of studies on adults with ADHD found that those who took stimulant medication had normalization of ADHD structural abnormalities (e.g., reduced gray matter volume), as did those with increasing age, indicating some preliminary evidence of benefits to use of stimulant medications and the improvement in brain structure over time (Nakao, Radua, Rubia, & Mataix-Cols, 2011). However, a longitudinal study over an 8-year period found that adolescents with ADHD are at higher risk of using cigarettes and abusing substances; the authors concluded that ADHD, not treatment medications, was the major influence (Stovell, 2013). Although the medications are helpful, they can also be abused.

Collaboration among the child's family, school, and physician is needed to diagnose ADHD and to plan appropriate interventions and educational accommodations. Although parents have a wealth of knowledge about the child, teacher confirmation of ADHD-related behaviors is very important. School nurses and PHNs can assist parents in recognizing the symptoms of ADHD and in obtaining appropriate treatment and follow-up.

A multimodal treatment approach is recognized as most effective. This includes medication, usually methylphenidate (Ritalin, Metadate, or Concerta), dextroamphetamine (Dexedrine or Dextrostat), or combined dextroamphetamine and amphetamine (Adderall), school accommodations for learning problems, and social skills training for the child with ADHD (NIMH, n.d.a). Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this treatment method. Not all children and adolescents respond to medication and a good number do not fully comply with their medication regimen; medication dosage must be carefully monitored and adjusted (Charach & Fernandez, 2013). The main goal of medical treatment for school-age children is academic improvement. If this does not occur, medication may need to be changed or discontinued. Parental response, severity of ADHD symptoms in children, and types of treatment plans are all important factors in the success of interventions for ADHD children and families. School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens.

Parents often voice concern about giving their children a stimulant medication to treat ADHD, and some families pursue alternative treatments (Charach, Yeung, Volpe, Goodale, & Dosreis, 2014). Families may use some type of complementary and alternative medicine (e.g., acupuncture, nutritional supplements, diet), and they may not discuss this fact with health care providers. Neurofeedback has produced some promising results, and newer equipment and techniques are even more efficient (Koberda et al., 2014). Nonstimulant medications, such as clonidine, atomoxetine (Strattera), and guanfacine hydrochloride

(Intuniv), have been used in children and adolescents (DeSousa & Kalra, 2012).

Parental resistance to treatment may result from side effects (e.g., problems with sleep, appetite, greater anxiety) or stem from fears about later abuse of substances. However, Cormier (2012) indicates that most parents eventually reach a point where medication administration is felt to be both beneficial to the child's function and a less disruptive family life. As adolescents, those with ADHD may experiment with alcohol and other substances earlier than non-ADHD teens do, whereas concurrent hyperactivity has been shown to predict low self-esteem, leading to social withdrawal and abuse of substances (CHADD, 2015c). One large-scale Finnish study found that symptoms of inattentiveness and hyperactivity in childhood were more predictive of alcohol use disorders and illicit drug use in later adolescence than an ADHD diagnosis (Sihvola et al., 2011). Some pediatricians are recommending supplementation with omega-3 fish oils when parents refuse medication, as there has been some evidence that this may be beneficial in reducing symptoms (Millichap & Yee, 2012).

Behavioral and Emotional Problems

The lifetime prevalence of any mental disorder among 13- to 18-year-olds is 46.3% (Merikangas et al., 2010; NIMH, n.d.b). It is estimated that 5.4% of children between the ages of 6 and 17 have ever been diagnosed with a behavioral or conduct problem (Ghandour, Kogan, Blumberg, Jones, & Perrin, 2012). About 10% of children and adolescents have been diagnosed at some point with anxiety or depression. Around 20% of school-age children display behaviors consistent with oppositional defiant disorder (e.g., hostile, stubborn, disobedient, belligerent, defiant), and 2.1% of children have been diagnosed with conduct disorder characterized by a persistent violation of norms/rules and others' rights (American Academy of Child & Adolescent Psychiatry [AACAP], 2011a). Early symptoms of conduct disorder (CD) in 3-year-old preschool children (e.g., fighting, stealing, property destruction) have been shown to be predictive of later conduct disorder at age 6, with an effect stronger for boys than girls (Rolon-Arroyo, Arnold, & Harvey, 2014). Symptoms of conduct disorder, sometimes thought to be a more severe form of antisocial behavior than oppositional defiant disorder, is often characterized by behaviors that may include destruction of property, fire setting, cruelty to animals or people, and/or bullying and threatening behavior. Schizophrenia in childhood affects 1 in 40,000 children under age 12, and adult schizophrenia, which affects 1 in 100 people, usually begins in young adulthood (age 18 for males, age 25 for females). Bipolar disorder, most often found in adults, is also found in children and adolescents. Early identification of children and adolescents at risk for developing bipolar disorder may be accomplished through the use of behavior checklists and other psychometric tools that reveal higher scores related to aggression, delinquent behavior, and attention problems or withdrawal and anxiety/depression (Axelson et al., 2015). It is important to find referral sources for these children and their families, and this may be difficult in more rural or outlying areas.

School-age problem behaviors stem from many causes, some of them genetic and

others environmental. Corporal punishment may be a risk factor for antisocial behavior, and several studies have noted a link between corporal punishment and restricted development of cognitive ability, as well as increased externalizing behaviors and receptive vocabulary scores (Gershoff, Lansford, Sexton, Davis-Kean, & Sameroff, 2012; MacKenzie, Nicklas, Waldfogel, & Brooks-Gunn, 2013). For children who already live in difficult situations, repeated spanking and harsh parenting measures only amplify the cumulative risk (MacKenzie, Nicklas, Brooks-Gunn, & Waldfogel, 2014). Physical punishment (e.g., slapping, spanking, pinching, pulling ears) is thought to both trigger and maintain child behavior problems, and decreasing this parental behavior could be associated with better child mental health and lower levels of behavior problems (Scott, 2012). Despite decades of research highlighting its deleterious effects, 55.2% of mothers and 43.2% of fathers of children age 3 were found to use spanking as a disciplinary measure in an urban birth cohort study (MacKenzie, Nicklas, Waldfogel, & Brooks-Gunn, 2012). Researchers found that 5-year-old children whose mothers spanked them frequently at age 3 were more likely to have externalizing behavior and decreased verbal expression at age 5. The effects of corporal punishment and the use of parental psychological aggression were shown to continue to affect children into adulthood, even after positive parenting was incorporated. These adults had higher levels of anxiety and poorer self-esteem (Taillieu & Brownridge, 2013).

Children are barometers of their environment. The current rate of divorce in the United States is double what it was in the 1950s. Over the last 30 years, the percentage of children living with two married parents decreased from close to 80% to 64% in 2014; about 4% of children lived with two unmarried parents. Four percent of children did not live with either parent, and 56% of those children lived with grandparents. The majority of children living with one parent live with their mother. Children of divorce are more likely to exhibit behavior problems, with children who are products of highly contentious divorces most at risk (FCFS, 2015d). School nurses can be alert to early symptoms and refer parents to marital counseling or suggest family therapists. Some schools also offer support groups for children of divorce.

Fewer children now live in two-parent homes. (Author's private photo with permissions of Merysa Schultz, Deanna Rector, Jon Rector.)

School refusal, where a child develops a pattern of refusing to go to school or remain in school for the entire school day, is found in 2% to 5% of school-age children and differs from truancy. Unlike truancy, school refusal is commonly associated with symptoms of emotional distress—usually anxiety or depression—but may also be associated with oppositional defiant disorder, ADHD, or other disruptive behavior disorders. Often, the children complain of headaches, stomachaches, or other physical ailments, but some are motivated to miss school to gain parental attention (ADAA, n.d.). School refusal (formerly called school phobia) is most commonly found in children between ages 5 and 6 or ages 10 and 11. Transitional periods, such as school entry or moving to middle school or high school, are often the most difficult. Rates are generally reported by parents to be higher for girls and younger children (ADAA, n.d.). Children usually present to the school nurse or PHN with headaches and/or abdominal pains. They may throw tantrums, cry, or exhibit panic and fear to their parents in an attempt to stay home from school. Sometimes, children are afraid of something in the school environment (e.g., bullies, teachers, test taking), or they may have a type of separation anxiety. Family enmeshment or detachment, or high levels of family conflict, may contribute to school refusal problems, as well as parental anxiety disorders like agoraphobia and panic disorder (Maynard et al., 2015). The best interventions include early return to school, with parental involvement in school, systematic desensitization (graded exposure to the classroom), relaxation training, and counseling being the most effective (ADAA, n.d.). Family therapy and cognitive–behavioral therapy is often used (Maynard et al., 2015). Occasionally, antidepressant medications are used as well. PHNs and school nurses can serve as a liaison with the child, family, school,

and health care/mental health care providers to promote a positive outcome.

Disabled Children

Children with disabilities accounted for almost 6% of the total school-age population in 2010. Cognitive and self-care difficulties were the two most common disabilities reported, followed by vision, ambulatory, and hearing problems (Brault, 2011). Between 2012 and 2013, almost 6.4 million students were classified as disabled, or 13% of school-age students; this was down slightly from 2003 to 2004 (13.7%). The most commonly cited disabilities are specific LD, speech or language disability, intellectual disability, emotional disturbance, and other health impairments (NCES, 2015). The prevalence of developmental disabilities in children aged 3 to 17 increased from 12.84% to 15.04% between 1997 and 2008. Hispanic children had the lowest prevalence, and boys had higher overall prevalence than girls. Rates for autism and ADHD, along with other developmental delays, increased; hearing loss declined (Boyle, Boulet, Schieve, & Cohen, 2011; CDC, 2015e).

Many children with perceived disabilities or problems are referred for assessment and possible placement in special education programs each year. School nurses often serve as a liaison between parents, physicians, and educators and are part of the team developing an individualized education plan (IEP) for children who qualify for special education services. Most children receive special services in a regular classroom because *full inclusion* or *mainstreaming* legislation mandates that fewer children be segregated into special classes or separate schools. See Chapter 26 for more on clients with disabilities and Chapter 30 for more on school nursing.

Problems Associated with Economic Status

After reaching a low point (16.2%) in 2000, childhood poverty in the United States rose to 22 % in 2013 (FCFS, 2015d). This increase in poverty did not vary by parents' place of birth, employment status, or educational level, leading many to speculate that this jump in the poverty rate reflects overall economic conditions. According to the Children's Defense Fund (CDF, 2014), 1 in 5 Black and 1 in 7 Hispanic children live in extreme poverty, as does 1 in 18 White children. About 1 in 3 children of color lives in poverty, along with 1 in 10 White children. Overall, children make up 24% of the U.S. population, but they represent 34% of all those in poverty (Addy & Wight, 2012; CDF, 2014). Although the United States ranked number one among industrialized nations in gross domestic product (GDP), health expenditures, defense expenditures, and military technology, it ranked 17th in reading scores and 30th in infant mortality. It ranked last because of high rates of relative child poverty and adolescent birth mothers (aged 15 to 19) and was also last in protecting children against gun violence (CDF, 2014). It is in society's best economic interest to care for its children, because they will become the taxpayers of tomorrow. Historically, experts posited that single-parent families (usually without an adult man present), welfare reform, and economic trends that kept less well-educated populations from entering all but the most menial jobs combined to produce a powerful synergistic effect on children and adolescents.

Poverty has profound and lasting effects on children, as research has consistently shown over many years. A classic study found that more than 20% of low-income children between the ages of 6 and 17 have some type of mental health problem (Chau & Douglas-Hall, 2007). A large, often cited, birth cohort study found that family poverty predicted increased rates of depression and anxiety in adolescents and young adults and that an increased frequency of child poverty exposure, or repeated exposures, was associated with poorer mental health and reduced levels of cognitive development (Najman et al., 2010). Childhood poverty, leading to high levels of chronic stress and allostatic load, is inversely associated with adult working memory levels (Evans & Fuller-Rowell, 2013). Evans and Fuller-Rowell (2013) indicate, however, that a child with enhanced self-regulatory skills may be somewhat protected from the adverse effects of poverty. Children living in poverty have poorer health and are more likely to suffer from a chronic health condition (e.g., asthma, anemia), as well as injuries and accidents (CDF, 2014). As adolescents, they more often experience depression and mental health problems and engage in more health risk behaviors (e.g., smoking, early sexual activity), and more externalizing/adolescent delinquent behaviors (Child Trends Databank, 2015a).

As adults, these children will be more likely to have lower occupational status and lower wages. Poor children and adolescents are at higher risk for negative cognitive outcomes and learning problems, resulting in fewer school days, lower math and reading scores, more grade failures, and earlier high school dropout (Child Trends Databank, 2015a). Parental education level and employment status play large roles in childhood poverty. For children

with parents having less than a high school diploma, 85% live in low-income families; and 73% of children with one parent who works less than full time annually live in poverty (Addy & Wight, 2012).

The social, emotional, and behavioral problems of some poor children may be the end result of disproportionate exposure to environmental toxins, parental substance abuse, maternal depression, trauma and abuse, divorce, violent crime, low-quality child care, inadequate nutrition, and decreased cognitive stimulation and exposure to vocabulary in early childhood and infancy (Child Trends Databank, 2015a).

The relationship between lower socioeconomic status (SES) and poor health persists throughout childhood and adolescence into adulthood (Doubeni et al., 2012), and childhood SES is strongly associated with morbidity and mortality during adulthood (Cheng, Goodman, & Committee on Pediatric Research, 2015). A population-based cohort study found that lower childhood SES was significantly related to obesity and higher systolic blood pressure in women, and some association was found for men and smoking. These outcomes are cardiovascular risk factors, and even when social inequalities level off with age, early poverty may affect cardiovascular health through these risk factors (Schumann et al., 2011). A study by Levine, Cole, Weir, and Crimmins (2015) examined childhood SES, traumas, and health, as well as adult traumas and SES, and found that childhood traumas were associated with an increase in "inflammatory transcription" in later adulthood (p. 16). Childhood traumas also potentiated the effect of low SES in adulthood on elevated "inflammatory gene expression" (p. 16); researchers thought that early childhood traumas may affect the stress response throughout life and affect health outcomes in later adult life, especially for those who have lower SES. Another study, looking at childhood SES and affect on adult health over time, found racial/ethnic differences among men in their study with White men most affected by adult low SES (Hargrove & Brown, 2015).

Some specific physical health problems are related to poverty (e.g., lead poisoning, iron deficiency anemia, increased susceptibility to illness). Children living in poorer neighborhoods are exposed to higher levels of community violence and may be more prone to seeing the world as a hostile and dangerous place; they are often also exposed to higher levels of family violence and are more at risk of subsequent mental health issues (Child Trends DataBank, 2015b). Longitudinal research, along with a series of preliminary studies, on the many stresses of childhood poverty (e.g., crowded homes/classrooms, inadequate child care, low SES, family/peer problems) found that levels of the stress hormone cortisol influenced results on school readiness testing and affected cognitive functioning (e.g., impulse/emotional control, planning, attention): that, in turn, affects school success (Blair, 2012). For more affluent children, other stressors (e.g., divorce, learning disabilities, harsh parenting) can affect stress levels and outcomes. Continuing periods of high stress can lead to either high levels of cortisol or immediately high dropping to very low levels that blunt children's responses to new challenges. Those with blunted responses or very high cortisol responses were found to have lower executive function and

more problems with writing, math, and reading, as well as poor self-control in class. The reverse was found for those with more characteristic patterns of cortisol response (elevated with stressful event and then normalized afterward). Children were tested in Head Start and again in kindergarten. Parenting style was also examined, and lower SES parents were more prone to harsher forms of discipline that demanded obedience. Their children had lower executive functioning and either high or blunted cortisol levels. Parents using a more sensitive approach, who interacted with children during play and allowed more exploration, had children with better executive function and normal cortisol response. Researchers saw this as evidence that parenting style was an important part of child stress response. They noted that psychological stress in childhood "can substantially shape the course of their cognitive, social, and emotional development … and impair specific learning abilities in children, potentially setting them back in many domains of life" (p. 67).

The negative impact of childhood poverty on learning and later income along with health continues to be well documented. Schickedanz, Dreyer, and Halfon (2015) state "poverty is the most pervasive of risks for America's children" (p. 1111). It is important to put in place programs and safeguards to reduce child poverty and its long-term negative effects (Anthony, King, & Austin, 2011; Schickedanz et al., 2015). Many school-age children suffer from the effects of poverty-related hunger. It is difficult to concentrate and learn properly if meals are often skipped or if food consistently does not provide enough nourishment (American Psychological Association, [APA] n.d.). Food insufficiency is defined as not having enough food to eat, whereas food insecurity is characterized by "reduced quality, variety, or desirability" of one's diet, but there may be no real indication of a reduction of food intake (U.S. Department of Agriculture [USDA], 2011, para. 5). About 15.4% of U.S. households reported some degree of food insecurity in 2014, representing 48.1 million people. Variation among states occurs, with North Dakota reporting 8.4% and Mississippi 22%. In December 2014, more than 46.2 million Americans participated in the Supplemental Nutrition Assistance Program (SNAP, or food stamps); this represents a decrease of approximately 0.5 million over the previous year (Food Research & Action Center [FRAC], 2015). About 30% of those who are eligible use any of the largest federal food assistance programs, such as food stamps, free or reduced school lunches, and women, infants, and children (WIC). Thus, children go hungry because many eligible families do not use these services. In 2013, about 14.6% of Americans surveyed reported a hardship providing food for their families (FRAC, 2015). Those children who participate in school lunch and breakfast programs suffer fewer of the side effects of hunger that affect learning; however, not all schools participate in these programs. For more on poverty, see Chapter 25.

Welfare Reform

Welfare reforms enacted in 1996 (i.e., the Personal Responsibility and Work Opportunity Reconciliation Act [PRWORA]) have been successful in moving many families from welfare to work. With a combination of welfare time limits, increasing work

requirements/sanctions, and reducing financial disincentives for work, welfare reform and work success programs were projected to lead to greater employment. Although the number of families receiving cash assistance (Temporary Assistance for Needy Families [TANF]) decreased between 2001 and 2008, the number increased between 2008 and 2010 as the recession spread nationally. The majority of TANF adult recipients are single mothers with young children and Hispanic children represented the greatest number of recipient children in 2011 (Folk, 2014).

A study of Wisconsin welfare leavers found that those who left before the recession had less difficulty finding jobs and child care, whereas those exiting the welfare system during the recession had lower employment rates and more difficulty with child care because of sporadic employment (Kwon & Meyer, 2011). More than 1 million single mothers are now thought to be in the "no work, no welfare" group—with no jobs and no government support. Although welfare reform was found to reduce the probability of high school dropout by 15% for adolescents from disadvantaged families, it also decreased the probability of college enrollment for adult women eligible for welfare by 20% (Dhaval, Corman, & Reichman, 2012). As part of welfare reform, the mission of case workers changed from eligibility verification/payments to service delivery/promoting client self-sufficiency; the decline in social worker caseloads by over half has been linked to a drop in service to qualifying families, rather than a reduction in the numbers of poor families (Godfrey & Yoshikawa, 2011). Also, employment and earnings success are often tied to client–caseworker interaction and personalized client attention, with great variation among states and counties (Godfrey & Yoshikawa, 2011).

The SNAP, formerly the Food Stamp Program, is one of the largest programs offered by federal Food and Nutrition Services. In 2013, the number of children receiving SNAP benefits rose to 20.5 million. This increase in SNAP recipients coincided with the U.S. Great Recession of 2007–2009. Positive health benefits for children are linked with SNAP. These positive outcomes include improved birth outcomes and improved adult health and self-sufficiency (Child Trends Databank, 2015c). Although children living in immigrant families are more likely to live in poverty than their counterparts with native-born parents, immigrant families are less likely to receive SNAP benefits. This disparity is thought to be the result of additional challenges faced by foreign-born parents such as language and cultural barriers (Hanson, Koball, Fortuny, & Chaudry, 2014). Some affected by welfare reform decreased their food stamp participation while turning more to the special supplemental food program for WIC, or the National School Lunch/Breakfast Program, as a source of essential food items for their children. Safety-net programs—specifically, WIC and the Food Stamp Program—have been shown to reduce the risk of nutrition-related problems (e.g., anemia, nutritional deficiency, failure to thrive). They have also been associated with a reduction in the risk of child abuse and neglect (Slack et al., 2011). Some studies indicate that about half of the families who leave welfare for work actually have fewer economic resources than they had while on welfare. Research regarding PRWORA and the ensuing SNAP and TANF programs suggests that increased evaluation is needed

regarding the effectiveness at reducing poverty and the overall effect for children's health (Pimpare, 2013).

Although almost 22% of children live below the federal poverty level ($23,624 or less for family of four in 2013), economists note that families need about twice the income of the federal poverty level to survive (Child Trends DataBank, 2015a; Coverage for All, 2012). These families are characterized as low income, and more than 16 million children live in these circumstances. Millions more children live in moderate-income families that have inadequate child care, limited health insurance, limited access to higher education, and poor housing. Almost 20% of children live in distressing situations and are at risk of being homeless. In 2013, about 10% of children living in low-income families did not have health insurance and approximately 9% of children living below the poverty line had no health insurance (Miller, 2011). Public insurance now covers the majority of poor (81%) and low-income (68%) children. Abdus, Hudson, Hill, and Seldon (2014) indicate, however, that although Medicaid and Children's Health Insurance Program (CHIP) offer insurance coverage for low-income children, insurance premiums are associated with increased numbers of uninsured children. See Chapters 6 and 25 for more on insurance and vulnerable populations.

Injuries

The loss of children's lives that results from all injuries combined suggests a staggering loss to society in the number of years of productive life lost. An injury is damage to the body, either unintentional or intentional, but use of the word accident is considered incorrect, as injuries may be prevented through environmental, individual behavioral, legislative, and institutional policy changes. In the United States, unintentional injuries are the leading cause of death and disability for children between the ages of 1 and 19 years. Approximately 36% of all childhood and adolescent deaths result from unintended injuries. One out of nine children under the age of 19 years in the United States will be seen in the emergency room for unintentional injuries, with the resulting annual cost of medical treatment estimated at $11.5 billion (CDC, 2012a; Child Trends Databank, 2015e). The total lifetime cost for injured children between the ages 0 and 14 years is approximately $80 billion. The causes of death vary between age groups. Motor vehicle–related injuries remain the leading cause of death for children age 5 to 19 years and ranks second for children 0 to 4 years of age. Other common causes of death include suffocation, drowning, and poisoning (Child Trends Databank, 2015e).

Injuries are responsible for approximately 75% of deaths during adolescence. The death rate for adolescents (15 to 19 years) dropped to 45 per 100,000 in 2013 from 49 per 100,000 in 2011. During 2013, approximately 60% of adolescent deaths were a result of motor vehicle accidents or were firearms related (FCFS, 2015a, 2015c). For children aged 5 to 14, the death rate in 2012 and 2013 was 13 per 100,000, with the death rate dropping by 58% since 1980 (FCFS, 2015c). Black, non-Hispanic children had the highest death rates at 40/100,000 (ages 1 to 4) and 18/100,000 (ages 5 to 14). As the leading cause of childhood death, unintentional injury and injury death rates were 8 (1 to 4 years) and 4 (5 to 14 years) per 100,000 overall. For the 5- to 14-year-olds, this was followed by cancer (2), homicide (1), and birth defects (1). Injury death rates have dropped over the past two decades (FCFS, 2015c).

For all racial and ethnic groups, death rates were higher for infants and late adolescents and dropped during the middle years. Homicide rates were highest for black children in all age groups (Sumner et al., 2015). Injuries not resulting in death often cause permanent disabilities or emotional and physical consequences for children and their families.

Each year, about 4 million children and adolescents are injured at school, and over 1 million sports- or recreation-related injuries occur in 0- to 19-year-olds (CDC, 2013c). Nonfatal injuries among adolescents most often involve being struck by or against an object or person, but for younger children, the cause is most often a fall (FCFS, 2015c).

A large-scale study examining the risk factors for passenger deaths in fatal motor vehicle crashes found that in more than 21% of cases of child passenger fatalities, alcohol was a factor. Quinlan, Shults, and Rudd (2014) indicate that alcohol-impaired driving continues to be a safety threat to child passengers. Although the overall fatality rate associated with

young drivers (age 15 to 20 years) has steadily decreased since 2004, 9% of all drivers involved in a fatal accident are within this age group (National Center for Statistics and Analysis, 2015b). Suicide was the second leading cause of death of 15- to 19-year-olds during 2011 and homicide ranked third. Firearms were involved in 42% of teen suicides and 87% of teen homicides (Child Trends Databank, 2015d).

Another, more recent danger for adolescents is use of cell phones while driving. Although not only a concern among adolescents, among the general population, cell phone usage while driving leads to distractions and has been estimated to lead to a three times greater risk of crashing (Fitch et al., 2013). In 2014, it was estimated that cell phone use was involved in 26% of all car accidents. Approximately 10% of drivers under the age of 20 involved in a motor vehicle accident report being distracted at the time of the crash (National Highway Traffic Safety Administration, n.d.). The use of cell phones can lead to injury in younger populations, as many school-age children now have them. It is estimated that approximately 78% of teens (age 12 to 17 years) now have cell phones (Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013). An interesting pair of longitudinal studies (first with 13,000 and later with 28,745 children) examined exposure to cell phones prenatally and postnatally; researchers found that behavior problems at age 7 were associated with cell phone exposure before birth and cell phone use in early childhood (Divan, Kheifets, Obel, & Olsen, 2012). In comparing American drivers to those in European countries, the prevalence of talking on a cell phone while driving was found to be 68% in the United States, much higher than 21% in the United Kingdom. Texting or emailing while driving was 31% in the United States and only 15% in Spain (Naumann & Dellinger, 2013). Legislation in many states has banned the use of cell phones (talking and/or texting) while driving. A study by Ferdinand, Menachemi, Sen, Blackburn, and Morissey (2014) found 31 states passed texting-while-driving laws, with 7 of the states banning only young drivers. Researchers found that where laws were primarily enforced (officer can stop driver for any reason), rather than secondarily enforced (officer must have another reason to stop driver in order to cite for texting), mortality reduction was improved. Also, broader texting bans were helpful in reaching the younger, more at-risk populations and that handheld bans were the most effective method of targeting the adult population. The research regarding cell phone use and distracted driving legislation continues and Qiao and Bell (2015) also indicate that legislation specific to texting while driving is effective at decreasing high school student text use.

Cell phone use while driving is dangerous, especially for inexperienced adolescent drivers.

For children and adolescents, aged 6 to 19, unintentional strangulation deaths from the "choking game" are often misreported (Mechling, Ahern, & McGuiness, 2013). This behavior involves self-strangulation or strangulation by a friend through the use of hands or a noose, causing a brief euphoric high because of cerebral hypoxia. Most of the victims are male (estimated at almost 87%), and the average age is estimated at 13.3 years. Survivors may have serious neurological impairments, concussions/broken bones, or eye hemorrhages (Mechling et al., 2013). Most parents were unaware of this potentially fatal activity until a child's death occurred, but warning signs, such as bloodshot eyes; disorientation after being alone; belts, scarves, and ropes tied to doorknobs or bedroom furniture; and marks on the neck, should lead parents to suspect this dangerous activity (Mechling et al., 2013). Although difficult to track because of misreporting, the game continues to be of concern among the adolescent population and has recently shown resurgence on social media (Ruryk, 2015)).

PHNs can promote injury prevention and control through education, promotion of safety engineering and environmental protection strategies, and legislative advocacy. PHNs can advance the prevention of unintentional injuries and deaths by working with families to initiate consistent use of seat belts and child safety seats in vehicles and the use of helmets and other protective gear for children riding bikes and skateboarding (see From the Case Files I). Where water is a natural hazard, wearing life jackets while boating and swimming can help decrease accidental drowning. Promotion of smoke and carbon monoxide detectors, poison prevention, and sudden infant death syndrome (SIDS) education can help to further decrease injury death rates. Teaching parents about presetting hot water heaters to lower than 130°F, recognizing the hazards of infant walkers, storing matches and lighters safely, and using pool fencing can help to prevent common unintentional injuries (Safe Kids Worldwide, 2015). Advocacy for stricter seat belt and child safety seat enforcement, as well as programs to provide child safety seats and bicycle helmets, has been shown to positively affect mortality and injury rates (National Center for Statistics and Analysis, 2015a).

From the Case Files I

The use of restraints (seatbelts, infant car seats, child booster seats) has been shown to be an effective population-level intervention that reduces fatalities and serious injuries (National Center for Statistics and Analysis, 2015a,b). I was part of a group of pediatric nurses, epidemiologists, health educators, and physicians from a large mid-Western medical center who worked with 20 elementary schools to evaluate the most effective way to provide information on booster seat use in kindergarten children. Because we understood that most children use a seat belt and not a car or

booster seat, increasing their chances of injury, we wanted to address this issue even though our state did not have any specific regulation about booster seats at that time. Our group designed three interventions: (1) a group receiving information only, (2) a group receiving a 1-hour class for parents offered at the school, or (3) a classroom presentation for children about proper booster seat use with a follow-up letter to parents about the presentation. Three to six months later, telephone follow-up was made. Parents in all three groups did not report the 70% goal of knowledge that booster seat use could protect their children in an automobile crash. The group with the greatest improvement in booster seat use was the one receiving a parent presentation and a booster seat. It was difficult to determine the best educational approach, because the demographics of the three groups were too different (language spoken, immigrant status, reading level), but we believed that the gift of a booster seat, along with personal contact and interaction, was most effective. Involving both parents and children was thought to be a better way to go in future research. The use of written educational material alone did not increase use of booster seats. Written information alone is often not effective—a good thing to keep in mind when you drop off pamphlets to clients and don't spend time going over them and answering questions.

—Julie, RN

Adapted from Philbrook, J., Kiragu, A., Geppert, J., Graham, P., Richardson, L., & Kriel, R. (2009). Pediatric injury prevention: Methods of booster seat education. Pediatric Nursing, 35(4), 215–220.

Community health nurses can work with their local health departments and community action groups to provide seats and helmets to families who cannot afford them, organize clinics to educate about proper installation and use, and encourage local police to enforce seat belt and safety seat laws.

Communicable Diseases

The mortality rates of school-age children 5 to 14 years old are comparatively low and have decreased substantially over the last century, a reduction that can be attributed to the effective prevention and control of the acute infectious diseases of childhood, a significant achievement in the last century. Although mortality rates are low in this country, worldwide mortality because of communicable diseases is 6 million deaths annually; morbidity because of communicable diseases among school children worldwide is also high. Tuberculosis (TB), HIV, and malaria are common, as is pneumonia because of upper respiratory infections and parasitic infections (World Bank, 2011). Among school children, the incidence rates of measles, rubella (German measles), pertussis (whooping cough), infectious parotitis (mumps), and varicella (chickenpox) have dropped considerably because of widespread immunization efforts (see Fig. 22–1 for childhood immunization schedule).

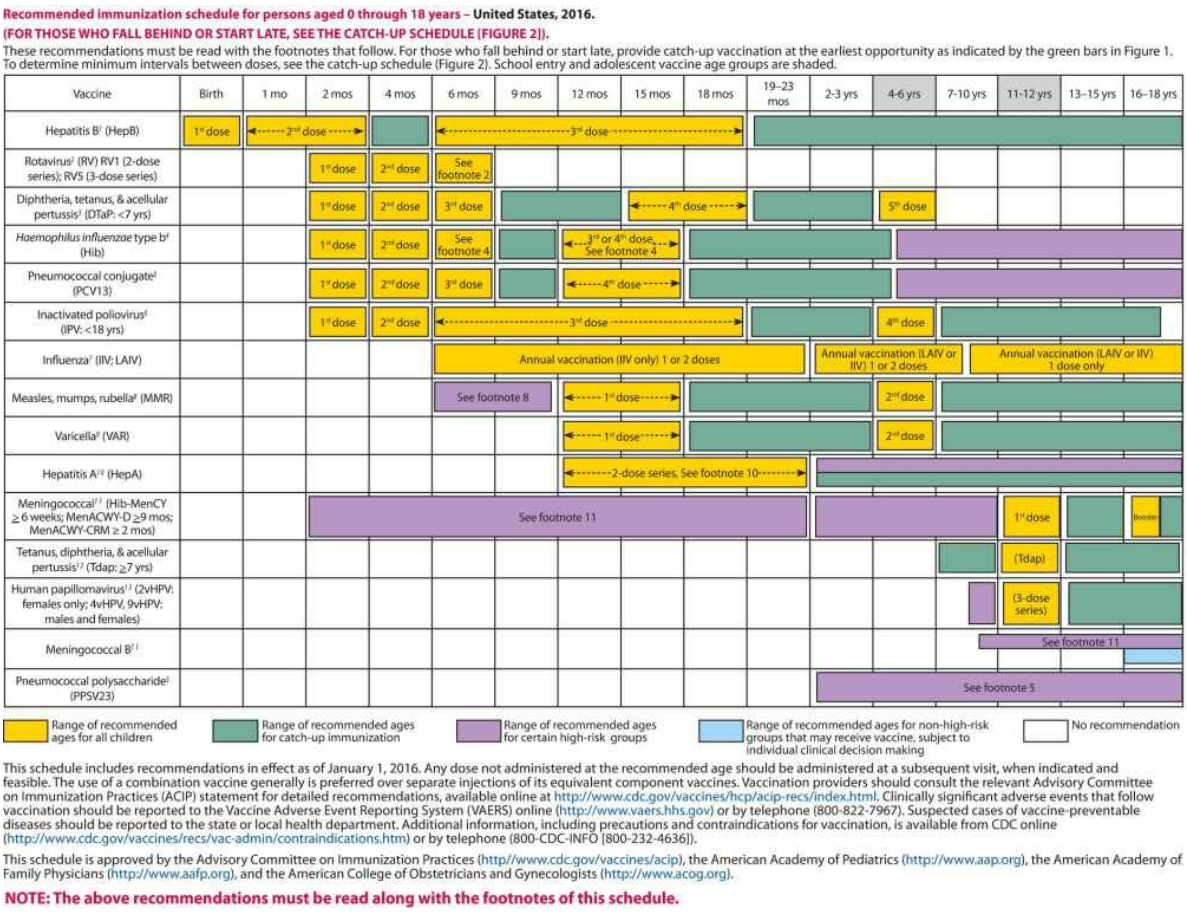


FIGURE 22–1 Childhood immunization schedule, 2015. (Retrieved from http://www.cdc.gov/vaccines/schedules/downloads/child/0-18yrs-child-combined-schedule.pdf.)

Over the past several decades, the incidence of vaccine-preventable diseases has generally decreased, although in recent years, multiple measles outbreaks were reported. In

2014, the largest number of measles cases was reported since 2000. The 667 cases involved persons from 27 different states (CDC, 2015g). A total of 159 cases of measles were reported to the CDC between January and April 2015 in the United States. Of these cases, 96% were import associated and 80% were either unvaccinated or persons with unknown vaccination status. The reported cases of mumps, hepatitis A, and meningococcal disease decreased in the under age 5 population between 2007 and 2009 (Maternal and Child Health Bureau, 2011). Some of these communicable illnesses carry potentially serious complications, such as birth defects from rubella and nerve deafness from mumps. Cases of pertussis increased by 15% between 2013 and 2014. This increase included children from all ages, with infants exceeding all other groups. The majority of pertussis-related deaths occurred in infants (CDC, 2015i).

Vigorous campaigns have been undertaken by health departments to get children immunized. Along with the standard diphtheria, tetanus, and pertussis vaccine, an immunization for mumps, measles, and rubella (MMR) has been available for more than 25 years, and newer vaccines for *Haemophilus influenzae* type b (Hib), hepatitis A and B, and varicella have been developed and are now included in the childhood immunization schedule. Meningococcal, pneumococcal, and rotavirus vaccines have also been added, along with yearly influenza vaccines for all children younger than age 5 (Barclay, 2012). Human papillomavirus (HPV) for girls aged 11 and above was recommended in 2009, and in 2011, the Advisory Committee on Immunization Practices recommended routine use for 11- and 12-year-old males. It recommended that previously unvaccinated 13- to 26-year-olds also receive the vaccine, noting that males up to age 21 may be safely vaccinated (Petrosky et al., 2015).

As increasing numbers of school-age children must show proof of required vaccinations before they are allowed to enroll in school, the percentages of children in this age group who are immunized against specific diseases may continue to rise. But more parents of young children are choosing not to immunize their children, invoking religious or personal belief exceptions. This practice has led to outbreaks of vaccine-preventable diseases including the 2014–2015 measles outbreak in a recreational theme park (CDC, 2015g; Reinberg, 2011). However, immunization compliance for adolescents has often been problematic because of lack of sufficient insurance coverage and poor systems for tracking and recall, as well as fewer well-child visits to health care providers among this age group. This has improved in recent years, though. Results from a 2013 national immunization survey revealed that 70.4% of children between ages 19 and 35 months have received the full vaccine series. Results, however, also indicate continuing disparities between vulnerable populations; for example, non-Hispanic black children were less likely to receive the full immunization series than non-Hispanic white children. Strategies shown to improve vaccination rates include the Vaccine for Children (VFC) Program, cost reduction, home visits, and linking vaccination opportunities with WIC visits. Among adolescents, vaccination rates increased for the Tdap and meningococcal conjugate vaccine. Lower rates were documented for the HPV vaccine and recommendations made for clinicians to

administer all of the age-appropriate vaccines in a single visit (USDHHS, 2015b). Diekema (2012) suggests that efforts to improve immunization rates should focus on eliminating socioeconomic barriers, strengthening school-entry requirements, addressing vaccine misinformation, and using effective communication to influence the vaccine-hesitant. See Figure 22–2, adolescent immunization schedule.

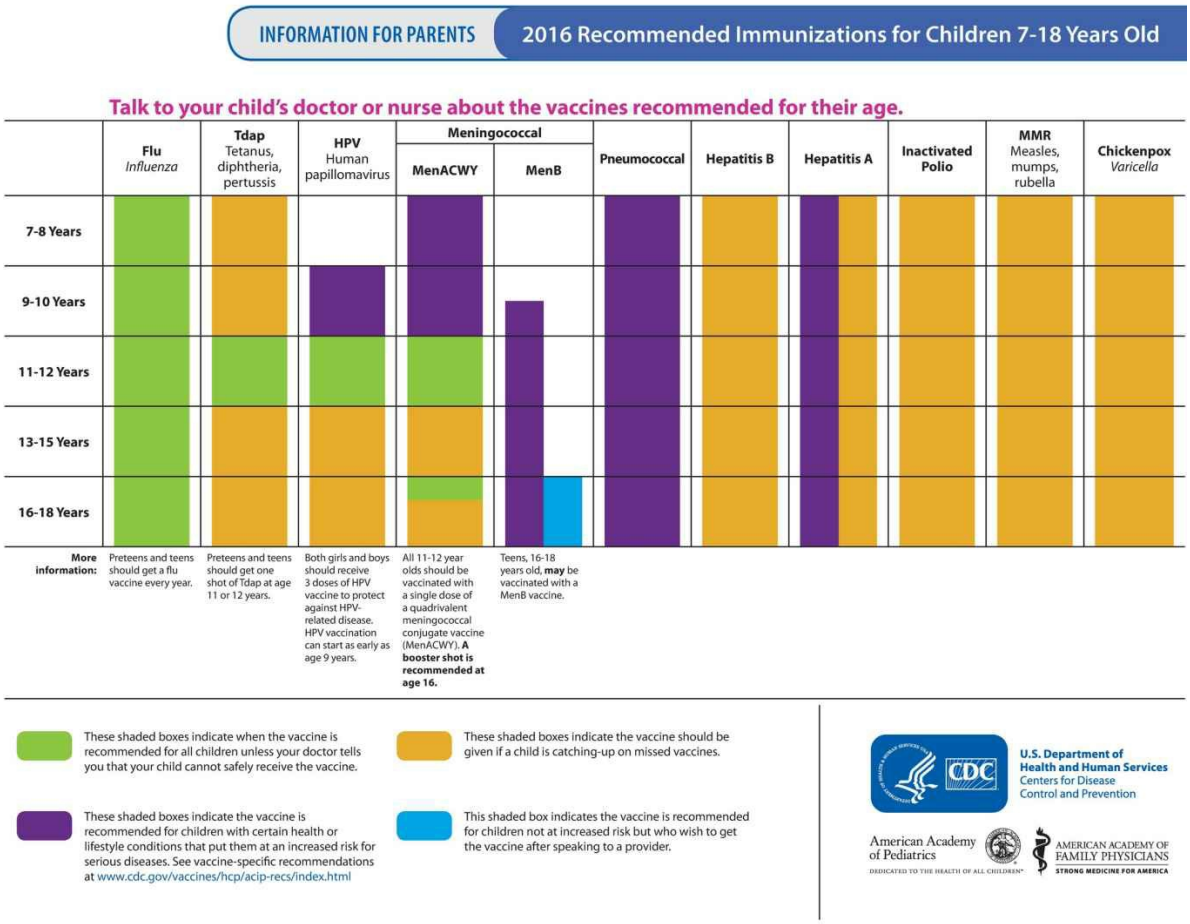

FIGURE 22–2 Adolescent immunization schedule, 2015. (Retrieved from http://www.cdc.gov/vaccines/who/teens/downloads/parent-version-schedule-7-18yrs.pdf.)

With the marked rise in community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA), PHNs and school nurses must be alert when skin infections or other conditions do not resolve quickly in children and adolescents (CDC, 2013b). Sports teams, for instance, may spread this infection, along with others like molluscum contagiosum, as participants come into close contact. Referral to an infectious disease specialist may need to be considered (Fritz et al., 2012).

Head Lice

Pediculosis (head lice) is a frustrating and common problem for many preschool and school-age children, and the incidence has been increasing with approximately 6 to 12 million 3- to 11-year-olds infected annually (CDC, 2013a). Preschoolers and elementary-age children and their caretakers and family members are at highest risk for head lice. Close crowded conditions can also be a risk factor (CDC, 2013a). An infestation of *Pediculus humanus* var. *capitis*, the parasite that lives and feeds on the human scalp, can be an embarrassing nuisance to families of any socioeconomic level. These very tiny, wingless

insects need blood to survive and can cause itching and skin irritation. They do not transmit disease, but secondary bacterial infections can occur from children scratching their scalps (CDC, 2013a; Pontius, 2014). They are most often found behind the ears, toward the nape of the neck, where hair is usually thickest, but their pearly white eggs (nits) are distributed all over the head. They are attached to the hair shaft with a glue-like substance and can be detected by careful examination of the scalp. Nits typically hatch within 8 to 9 days, and the immature louse passes through three developmental stages before reaching adulthood during the next 9 to 12 days. Viable nits are closer than one-quarter inch from the scalp, and those further away are not viable. Adult head lice, similar in size to a sesame seed, may be whitish, gray, or brown colored and may live for about 30 days. Without treatment, the cycle repeats every 3 weeks. Complete eradication generally requires that all viable nits be removed along with lice; family and close contacts should be checked for head lice and, if found, treated at the same time (Devore, Schutze, & Council on School Health & Committee on Infectious Diseases, 2015; Pontius, 2014).

Head lice are most often transmitted by direct contact (head-to-head) or may occasionally be passed from infected to uninfected children through shared items such as combs and brushes, hats, scarves, sheets, and towels (items called *fomites*). However, this is thought to rarely be the case. Most infestations begin in the community, not in schools. Children who play closely together and share beds give head lice the opportunity to crawl from one person's head to another's. Contrary to some popular myths, lice do not fly or jump, and they cannot be contracted from animals—they live only on humans. They do not survive long off the human head, generally 1 or 2 days (CDC, 2015a; Devore et al., 2015; Pontius, 2014). Schools may have recurring outbreaks of head lice that can be traced back to particular families who have failed to completely eradicate an infestation. Because of perceived social stigma, some families may be defensive and unresponsive to attempts at education and intervention. Some schools resort to "no-nit" policies and establish routine head lice examinations, with a goal of early detection and treatment. However, the American Academy of Pediatrics, the Centers for Disease Control and Prevention, and the National Association of School Nurses call for abandonment of such policies because they have not been effective in curbing head lice infestations, they often result in significant lost school days and negative social impact, and they may lead to misdiagnosis and unnecessary treatment (Devore et al., 2015; Pontius, 2014).

Treatment of head lice has been estimated to cost over $1 billion annually in direct and indirect costs (Devore et al., 2015). Treatment commonly includes over-the-counter insecticide shampoos (or pediculicides), such as pyrethrin-based *RID*, *R&C*, *Pronto*, or *A-200*. Malathion (*Ovide*), from chrysanthemum extract, and benzyl alcohol lotion (*Ulesfia* lotion) are also recommended treatments. Lindane (*Kwell*) is no longer a recommended treatment for head lice (CDC, 2013a; Devore et al., 2015). Oral antibiotic and anthelmintic agents, such as Septra and Ivermectin, and natural products (*HairClean 1-2-3)*, as well as occlusive agents, such as petroleum jelly or essential oils, may also be used, although they are not controlled by the FDA and have not been evaluated for safety by

research and are not recommended (Devore et al., 2015; Pontius, 2014). Solvents that aid in dissolving the "cement" that holds the nit in place have been shown to be helpful when using fine-tooth combs (e.g., LiceMeister)—these include white vinegar and formic acid (Guenther, 2012). In some cases, resistance to topical pediculicides may necessitate the use of other measures. A custom machine, blasting hot air for 30 minutes (*AirAllé*), has shown some promising results but is expensive and requires training for operators. Frustrated families, having repeated problems with head lice infestations, have tried such unusual remedies as kerosene, acetone, bleach, vodka, and other extreme measures to try to kill lice and nits without success. Such flammable agents are not appropriate treatment for head lice (Devore et al., 2015; Pontius, 2014).

School nurses and PHNs also need to educate families about reducing reinfestations by careful application of pediculicides, retreating in 2 weeks if necessary, and cleaning of any fomites (e.g., combs, hats, towels, sheets, clothing, upholstered furniture) and removal of any viable nits. Drying sheets, blankets, and towels on high heat and washing all hats and clothing are effective measures. It is not necessary to use fumigant sprays, as they can be toxic (CDC, 2013a). It is difficult, however, to prevent children—who are social creatures—from coming into close contact with one another and becoming reinfected. In some larger cities, entrepreneurs have started nit removal businesses (e.g., Nit Pickers, Hair Fairies) to assist parents with this tedious task, but most experts in the field feel that this is an unnecessary expense (Pontius, 2014). Some resistance to pediculicides has been found, but most treatment failures have been found to be because of initial misdiagnosis, noncompliance or inappropriate application of treatments, new lice infestation after treatment, and using products that do not kill eggs (no ovicidal ingredients). When checked by an entomologist, head lice samples sent for identification were found to be only 11% accurate for physicians and 47% correct for families (Pontius, 2014).

Other Health Problems

Other health problems found in this age group are nutritional problems (primarily overeating and inappropriate food choices) and poor dental health. Obesity often begins in childhood and becomes a risk factor for CVD, diabetes, cancer, stroke, and osteoarthritis later in life (CDC, 2015b; Dixon, Pena, & Taveras, 2012; Nadeau, Maahs, Daniels, & Eckel, 2011). The percentage of children and adolescents who are obese has risen over 50% in the past 30 years, with 18% of children aged 6 to 11 considered obese in 2012 and 21% of adolescents age 12 to 19 years considered obese despite the fact that 21% of American children lived in households characterized by food insecurity at some time during the year with rates steadily rising since the recent recession (CDC, 2015b; Child Trends Databank. 2014c, 2014d)

(Fig. 22–3).

Catch-up immunization schedule for persons aged 4 months through 18 years who start late or who are more than 1 month behind —United States, 2016.

The figure below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age. Always use this table in conjunction with Figure 1 and the footnotes that follow.

Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Children age 4 months through 6 years					
Hepatitis B[1]	Birth	4 weeks	8 weeks *and* at least 16 weeks after first dose. Minimum age for the final dose is 24 weeks.		
Rotavirus[2]	6 weeks	4 weeks	4 weeks[2]		
Diphtheria, tetanus, and acellular pertussis[3]	6 weeks	4 weeks	4 weeks	6 months	6 months[3]
Haemophilus influenzae type b[4]	6 weeks	4 weeks if first dose was administered before the 1st birthday. 8 weeks (as final dose) if first dose was administered at age 12 through 14 months. No further doses needed if first dose was administered at age 15 months or older.	4 weeks[4] if current age is younger than 12 months **and** first dose was administered at younger than age 7 months, **and** at least 1 previous dose was PRP-T (ActHib, Pentacel) or unknown. 8 weeks *and* age 12 through 59 months (as final dose)[4] • if current age is younger than 12 months **and** first dose was administered at age 7 through 11 months (wait until at least 12 months old); OR • if current age is 12 through 59 months **and** first dose was administered before the 1st birthday, **and** second dose administered at younger than 15 months; OR • if both doses were PRP-OMP (PedvaxHIB; Comvax) **and** were administered before the 1st birthday (wait until at least 12 months old). No further doses needed if previous dose was administered at age 15 months or older.	8 weeks (as final dose) This dose only necessary for children age 12 through 59 months who received 3 doses before the 1st birthday.	
Pneumococcal[5]	6 weeks	4 weeks if first dose administered before the 1st birthday. 8 weeks (as final dose for healthy children) if first dose was administered at the 1st birthday or after. No further doses needed for healthy children if first dose administered at age 24 months or older.	4 weeks if current age is younger than 12 months and previous dose given at <7months old. 8 weeks (as final dose for healthy children) if previous dose given between 7-11 months (wait until at least 12 months old); OR if current age is 12 months or older and at least 1 dose was given before age 12 months. No further doses needed for healthy children if previous dose administered at age 24 months or older.	8 weeks (as final dose) This dose only necessary for children aged 12 through 59 months who received 3 doses before age 12 months or for children at high risk who received 3 doses at any age.	
Inactivated poliovirus[6]	6 weeks	4 weeks[6]	4 weeks[6]	6 months[6] (minimum age 4 years for final dose).	
Measles, mumps, rubella[7]	12 months	4 weeks			
Varicella[8]	12 months	3 months			
Hepatitis A[9]	12 months	6 months			
Meningococcal[10] (Hib-MenCY ≥ 6 weeks; MenACWY-D ≥9 mos; MenACWY-CRM ≥ 2 mos)	6 weeks	8 weeks[11]	See footnote 11	See footnote 11	
Children and adolescents age 7 through 18 years					
Meningococcal[10] (Hib-MenCY ≥ 6 weeks; MenACWY-D ≥9 mos; MenACWY-CRM ≥ 2 mos)	Not Applicable (N/A)	8 weeks[11]			
Tetanus, diphtheria; tetanus, diphtheria, and acellular pertussis[12]	7 years[12]	4 weeks	4 weeks if first dose of DTaP/DT was administered before the 1st birthday. 6 months (as final dose) if first dose of DTaP/DT or Tdap/Td was administered at or after the 1st birthday.	6 months if first dose of DTaP/DT was administered before the 1st birthday.	
Human papillomavirus[13]	9 years	Routine dosing intervals are recommended.[13]			
Hepatitis A[9]	N/A	6 months			
Hepatitis B[1]	N/A	4 weeks	8 weeks **and** at least 16 weeks after first dose.		
Inactivated poliovirus[6]	N/A	4 weeks	4 weeks[6]	6 months[6]	
Measles, mumps, rubella[7]	N/A	4 weeks			
Varicella[8]	N/A	3 months if younger than age 13 years. 4 weeks if age 13 years or older.			

For further guidance on the use of the vaccines mentioned below, see: http://www.cdc.gov/vaccines/hcp/acip-recs/index.html. For vaccine recommendations for persons 19 years of age and older, see the Adult Immunization Schedule.

Additional information

- For contraindications and precautions to use of a vaccine and for additional information regarding that vaccine, vaccination providers should consult the relevant ACIP statement available online at http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.
- For purposes of calculating intervals between doses, 4 weeks = 28 days. Intervals of 4 months or greater are determined by calendar months.
- Vaccine doses administered 4 days or less before the minimum interval are considered valid. Doses of any vaccine administered ≥5 days earlier than the minimum interval or minimum age should not be counted as valid doses and should be repeated as age-appropriate. The repeat dose should be spaced after the invalid dose by the recommended minimum interval. For further details, see *MMWR. General Recommendations on Immunization and Reports* / Vol. 60 / No. 2; Table 1. *Recommended and minimum ages and intervals between vaccine doses* available online at http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf.
- Information on travel vaccine requirements and recommendations is available at http://wwwnc.cdc.gov/travel/destinations/list.
- For vaccination of persons with primary and secondary immunodeficiencies, see Table 13, "*Vaccination of persons with primary and secondary immunodeficiencies*," in *General Recommendations on Immunization* (ACIP), available at http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf.; and American Academy of Pediatrics. "Immunization in Special Clinical Circumstances," in Kimberlin DW, Brady MT, Jackson MA, Long SS eds. *Red Book: 2015 report of the Committee on Infectious Diseases*. 30th ed. Elk Grove Village, IL: American Academy of Pediatrics.

1. Hepatitis B (HepB) vaccine. (Minimum age: birth)

Routine vaccination:

At birth:

- Administer monovalent HepB vaccine to all newborns before hospital discharge.
- For infants born to hepatitis B surface antigen (HBsAg)-positive mothers, administer HepB vaccine and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. These infants should be tested for HBsAg and antibody to HBsAg (anti-HBs) at age 9 through 18 months (preferably at the next well-child visit) or 1 to 2 months after completion of the HepB series if the series was delayed; CDC recently recommended testing occur at age 9 through 12 months; see http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6439a6.htm.
- If mother's HBsAg status is unknown, within 12 hours of birth administer HepB vaccine regardless of birth weight. For infants weighing less than 2,000 grams, administer HBIG in addition to HepB vaccine within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if mother is HBsAg-positive, also administer HBIG for infants weighing 2,000 grams or more as soon as possible, but no later than age 7 days.

Doses following the birth dose:

- The second dose should be administered at age 1 or 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks.
- Infants who did not receive a birth dose should receive 3 doses of a HepB-containing vaccine on a schedule of 0, 1 to 2 months, and 6 months; starting as soon as feasible. See Figure 2.
- Administer the second dose 1 to 2 months after the **first** dose (minimum interval of 4 weeks), administer the third dose at least 8 weeks after the second dose AND at least 16 weeks after the first dose. The final (third or fourth) dose in the HepB vaccine series should be administered **no earlier than age 24 weeks**.
- Administration of a total of 4 doses of HepB vaccine is permitted when a combination vaccine containing HepB is administered after the birth dose.

Catch-up vaccination:

- Unvaccinated persons should complete a 3-dose series.
- A 2-dose series (doses separated by at least 4 months) of adult formulation Recombivax HB is licensed for use in children aged 11 through 15 years.
- For other catch-up guidance, see Figure 2.

2. Rotavirus (RV) vaccines. (Minimum age: 6 weeks for both RV1 [Rotarix] and RV5 [RotaTeq])

Routine vaccination:

Administer a series of RV vaccine to all infants as follows:

1. If Rotarix is used, administer a 2-dose series at 2 and 4 months of age.
2. If RotaTeq is used, administer a 3-dose series at ages 2, 4, and 6 months.
3. If any dose in the series was RotaTeq or vaccine product is unknown for any dose in the series, a total of 3 doses of RV vaccine should be administered.

Catch-up vaccination:

- The maximum age for the first dose in the series is 14 weeks, 6 days; vaccination should not be initiated for infants aged 15 weeks, 0 days or older.
- The maximum age for the final dose in the series is 8 months, 0 days.
- For other catch-up guidance, see Figure 2.

3. Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine. (Minimum age: 6 weeks. Exception: DTaP-IPV [Kinrix]: 4 years)

Routine vaccination:

- Administer a 5-dose series of DTaP vaccine at ages 2, 4, 6, 15 through 18 months, and 4 through 6 years. The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.
- Inadvertent administration of 4th DTaP dose early: If the fourth dose of DTaP was administered at least 4 months, but less than 6 months, after the third dose of DTaP, it need not be repeated.

Catch-up vaccination:

- The fifth dose of DTaP vaccine is not necessary if the fourth dose was administered at age 4 years or older.
- For other catch-up guidance, see Figure 2.

4. *Haemophilus influenzae* type b (Hib) conjugate vaccine. (Minimum age: 6 weeks for PRP-T [ACTHIB, DTaP-IPV/Hib (Pentacel) and Hib-MenCY (MenHibrix)], PRP-OMP [PedvaxHIB or COMVAX], 12 months for PRP-T [Hiberix])

Routine vaccination:

- Administer a 2- or 3-dose Hib vaccine primary series and a booster dose (dose 3 or 4 depending on vaccine used in primary series) at age 12 through 15 months to complete a full Hib vaccine series.
- The primary series with ActHIB, MenHibrix, or Pentacel consists of 3 doses and should be administered at 2, 4, and 6 months of age.
- The primary series with PedvaxHib or COMVAX consists of 2 doses and should be administered at 2 and 4 months of age; a dose at age 6 months is not indicated.
- One booster dose (dose 3 or 4 depending on vaccine used in primary series) of any Hib vaccine should be administered at age 12 through 15 months. An exception is Hiberix vaccine. Hiberix should only be used for the booster (final) dose in children aged 12 months through 4 years who have received at least 1 prior dose of Hib-containing vaccine.
- For recommendations on the use of MenHibrix in patients at increased risk for meningococcal disease, please refer to the meningococcal vaccine footnotes and also to *MMWR* February 28, 2014 / 63(RR01);1-13, available at http://www.cdc.gov/mmwr/PDF/rr/rr6301.pdf.

Catch-up vaccination:

- If dose 1 was administered at ages 12 through 14 months, administer a second (final) dose at least 8 weeks after dose 1, regardless of Hib vaccine used in the primary series.
- If both doses were PRP-OMP (PedvaxHIB or COMVAX), and were administered before the first birthday, the third (and final) dose should be administered at age 12 through 59 months and at least 8 weeks after the second dose.
- If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a third (and final) dose at age 12 through 15 months or 8 weeks after second dose, whichever is later.
- If first dose is administered before the first birthday and second dose administered at younger than 15 months, a third (and final) dose should be administered 8 weeks later.
- For unvaccinated children aged 15 months or older, administer only 1 dose.
- For other catch-up guidance, see Figure 2. For catch-up guidance related to MenHibrix, please see the meningococcal vaccine footnotes and also *MMWR* February 28, 2014 / 63(RR01);1-13, available at http://www.cdc.gov/mmwr/PDF/rr/rr6301.pdf.

4. *Haemophilus influenzae* type b (Hib) conjugate vaccine (cont'd)
Vaccination of persons with high-risk conditions:
- Children aged 12 through 59 months who are at increased risk for Hib disease, including chemotherapy recipients and those with anatomic or functional asplenia (including sickle cell disease), human immunodeficiency virus (HIV) infection, immunoglobulin deficiency, or early component complement deficiency, who have received either no doses or only 1 dose of Hib vaccine before 12 months of age, should receive 2 additional doses of Hib vaccine 8 weeks apart; children who received 2 or more doses of Hib vaccine before 12 months of age should receive 1 additional dose.
- For patients younger than 5 years of age undergoing chemotherapy or radiation treatment who received a Hib vaccine dose(s) within 14 days of starting therapy or during therapy, repeat the dose(s) at least 3 months following therapy completion.
- Recipients of hematopoietic stem cell transplant (HSCT) should be revaccinated with a 3-dose regimen of Hib vaccine starting 6 to 12 months after successful transplant, regardless of vaccination history; doses should be administered at least 4 weeks apart.
- A single dose of any Hib-containing vaccine should be administered to unimmunized* children and adolescents 15 months of age and older undergoing an elective splenectomy. If possible, vaccine should be administered at least 14 days before procedure.
- Hib vaccine is not routinely recommended for patients 5 years or older. However, 1 dose of Hib vaccine should be administered to unimmunized* persons aged 5 years or older who have anatomic or functional asplenia (including sickle cell disease) and unvaccinated persons 5 through 18 years of age with HIV infection.
* *Patients who have not received a primary series and booster dose or at least 1 dose of Hib vaccine after 14 months of age are considered unimmunized.*

5. Pneumococcal vaccines. (Minimum age: 6 weeks for PCV13, 2 years for PPSV23)
Routine vaccination with PCV13:
- Administer a 4-dose series of PCV13 vaccine at ages 2, 4, and 6 months and at age 12 through 15 months.
- For children aged 14 through 59 months who have received an age-appropriate series of 7-valent PCV (PCV7), administer a single supplemental dose of 13-valent PCV (PCV13).
Catch-up vaccination with PCV13:
- Administer 1 dose of PCV13 to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
- For other catch-up guidance, see Figure 2.
Vaccination of persons with high-risk conditions with PCV13 and PPSV23:
- All recommended PCV13 doses should be administered prior to PPSV23 vaccination if possible.
- For children 2 through 5 years of age with any of the following conditions: chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure); chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy); diabetes mellitus; cerebrospinal fluid leak; cochlear implant; sickle cell disease and other hemoglobinopathies; anatomic or functional asplenia; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; solid organ transplantation; or congenital immunodeficiency:
  1. If neither PCV13 nor PPSV23 has been received previously, administer 1 dose of PCV13 now and 1 dose of PPSV23 at least 8 weeks later.
  2. If PCV13 has been received previously but PPSV23 has not, administer 1 dose of PPSV23 at least 8 weeks after the most recent dose of PCV13.
  3. If PPSV23 has been received but PCV13 has not, administer 1 dose of PCV13 at least 8 weeks after the most recent dose of PPSV23.
- For children aged 6 through 18 years with chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure), chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy), diabetes mellitus, alcoholism, or chronic liver disease, who have not received PPSV23, administer 1 dose of PPSV23. If PCV13 has been received previously, then PPSV23 should be administered at least 8 weeks after any prior PCV13 dose.
- A single revaccination with PPSV23 should be administered 5 years after the first dose to children with sickle cell disease or other hemoglobinopathies; anatomic or functional asplenia; congenital or acquired immunodeficiencies; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; generalized malignancy; solid organ transplantation; or multiple myeloma.

6. Inactivated poliovirus vaccine (IPV). (Minimum age: 6 weeks)
Routine vaccination:
- Administer a 4-dose series of IPV at ages 2, 4, 6 through 18 months, and 4 through 6 years. The final dose in the series should be administered on or after the fourth birthday and at least 6 months after the previous dose.
Catch-up vaccination:
- In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk of imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
- If 4 or more doses are administered before age 4 years, an additional dose should be administered at age 4 through 6 years and at least 6 months after the previous dose.
- A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months after the previous dose. If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age. If only OPV were administered, and all doses were given prior to 4 years of age, one dose of IPV should be given at 4 years or older, at least 4 weeks after the last OPV dose.
- IPV is not routinely recommended for U.S. residents aged 18 years or older.
- For other catch-up guidance, see Figure 2.

7. Influenza vaccines. (Minimum age: 6 months for inactivated influenza vaccine [IIV], 2 years for live, attenuated influenza vaccine [LAIV])
Routine vaccination:
- Administer influenza vaccine annually to all children beginning at age 6 months. For most healthy, nonpregnant persons aged 2 through 49 years, either LAIV or IIV may be used. However, LAIV should NOT be administered to some persons, including 1) persons who have experienced severe allergic reactions to LAIV, any of its components, or to a previous dose of any other influenza vaccine; 2) children 2 through 17 years receiving aspirin or aspirin-containing products; 3) persons who are allergic to eggs; 4) pregnant women; 5) immunosuppressed persons; 6) children 2 through 4 years of age with asthma or who had wheezing in the past 12 months; or 7) persons who have taken influenza antiviral medications in the previous 48 hours. For all other contraindications and precautions to use of LAIV, see *MMWR* August 7, 2015 / 64(30);818-25 available at http://www.cdc.gov/mmwr/pdf/wk/mm6430.pdf.
For children aged 6 months through 8 years:
- For the 2015-16 season, administer 2 doses (separated by at least 4 weeks) to children who are receiving influenza vaccine for the first time. Some children in this age group who have been vaccinated previously will also need 2 doses. For additional guidance, follow dosing guidelines in the 2015-16 ACIP influenza vaccine recommendations, *MMWR* August 7, 2015 / 64(30);818-25, available at http://www.cdc.gov/mmwr/pdf/wk/mm6430.pdf.
- For the 2016-17 season, follow dosing guidelines in the 2016 ACIP influenza vaccine recommendations.
For persons aged 9 years and older:
- Administer 1 dose.

8. Measles, mumps, and rubella (MMR) vaccine. (Minimum age: 12 months for routine vaccination)
Routine vaccination:
- Administer a 2-dose series of MMR vaccine at ages 12 through 13 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 4 weeks have elapsed since the first dose.
- Administer 1 dose of MMR vaccine to infants aged 6 through 11 months before departure from the United States for international travel. These children should be revaccinated with 2 doses of MMR vaccine, the first at age 12 through 15 months (12 months if the child remains in an area where disease risk is high), and the second dose at least 4 weeks later.
- Administer 2 doses of MMR vaccine to children aged 12 months and older before departure from the United States for international travel. The first dose should be administered on or after age 12 months and the second dose at least 4 weeks later.
Catch-up vaccination:
- Ensure that all school-aged children and adolescents have had 2 doses of MMR vaccine; the minimum interval between the 2 doses is 4 weeks.

9. Varicella (VAR) vaccine. (Minimum age: 12 months)
Routine vaccination:
- Administer a 2-dose series of VAR vaccine at ages 12 through 15 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 3 months have elapsed since the first dose. If the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
Catch-up vaccination:
- Ensure that all persons aged 7 through 18 years without evidence of immunity (see *MMWR* 2007 / 56 [No. RR-4], available at http://www.cdc.gov/mmwr/pdf/rr/rr5604.pdf) have 2 doses of varicella vaccine. For children aged 7 through 12 years, the recommended minimum interval between doses is 3 months (if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid); for persons aged 13 years and older, the minimum interval between doses is 4 weeks.

10. Hepatitis A (HepA) vaccine. (Minimum age: 12 months)
Routine vaccination:
- Initiate the 2-dose HepA vaccine series at 12 through 23 months, separate the 2 doses by 6 to 18 months.
Children who have received 1 dose of HepA vaccine before age 24 months should receive a second dose 6 to 18 months after the first dose.
- For any person aged 2 years and older who has not already received the HepA vaccine series, 2 doses of HepA vaccine separated by 6 to 18 months may be administered if immunity against hepatitis A virus infection is desired.
Catch-up vaccination:
- The minimum interval between the 2 doses is 6 months.
Special populations:

10. Hepatitis A (HepA) vaccine. (cont'd)
- Administer 2 doses of HepA vaccine at least 6 months apart to previously unvaccinated persons who live in areas where vaccination programs target older children, or who are at increased risk for infection. This includes persons traveling to or working in countries that have high or intermediate endemicity of infection; men having sex with men; users of injection and non-injection illicit drugs; persons who work with HAV-infected primates or with HAV in a research laboratory; persons with clotting factor disorders; persons with chronic liver disease; and persons who anticipate close personal contact (e.g., household or regular babysitting) with an international adoptee during the first 60 days after arrival in the United States from a country with high or intermediate endemicity. The first dose should be administered as soon as the adoption is planned, ideally 2 or more weeks before the arrival of the adoptee.

11. Meningococcal vaccines. (Minimum age: 6 weeks for Hib-MenCY [MenHibrix], 9 months for MenACWY-D [Menactra], 2 months for MenACWY-CRM [Menveo], 10 years for serogroup B meningococcal [MenB] vaccines: MenB-4C [Bexsero] and MenB-FHbp [Trumenba])
Routine vaccination:
- Administer a single dose of Menactra or Menveo vaccine at age 11 through 12 years, with a booster dose at age 16 years.
Adolescents aged 11 through 18 years with human immunodeficiency virus (HIV) infection should receive a 2-dose primary series of Menactra or Menveo with at least 8 weeks between doses.
For children aged 2 months through 18 years with high-risk conditions, see below.
Catch-up vaccination:
- Administer Menactra or Menveo vaccine at age 13 through 18 years if not previously vaccinated.
- If the first dose is administered at age 13 through 15 years, a booster dose should be administered at age 16 through 18 years with a minimum interval of at least 8 weeks between doses.
- If the first dose is administered at age 16 years or older, a booster dose is not needed.
- For other catch-up guidance, see Figure 2.
Clinical discretion:
- Young adults aged 16 through 23 years (preferred age range is 16 through 18 years) may be vaccinated with either a 2-dose series of Bexsero or a 3-dose series of Trumenba vaccine to provide short-term protection against most strains of serogroup B meningococcal disease. The two MenB vaccines are not interchangeable; the same vaccine product must be used for all doses.
Vaccination of persons with high-risk conditions and other persons at increased risk of disease:
Children with anatomic or functional asplenia (including sickle cell disease):
Meningococcal conjugate ACWY vaccines:
1. Menveo
   - *Children who initiate vaccination at 8 weeks:* Administer doses at 2, 4, 6, and 12 months of age.
   - *Unvaccinated children who initiate vaccination at 7 through 23 months:* Administer 2 doses, with the second dose at least 12 weeks after the first dose AND after the first birthday.
   - *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
2. MenHibrix
   - *Children who initiate vaccination at 6 weeks:* Administer doses at 2, 4, 6, and 12 through 15 months of age.
   - If the first dose of MenHibrix is given at or after 12 months of age, a total of 2 doses should be given at least 8 weeks apart to ensure protection against serogroups C and Y meningococcal disease.
3. Menactra
   - *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart. If Menactra is administered to a child with asplenia (including sickle cell disease), do not administer Menactra until 2 years of age and at least 8 weeks after the completion of all PCV13 doses.
Meningococcal B vaccines:
1. Bexsero or Trumenba
   - *Persons 10 years or older who have not received a complete series:* Administer a 2-dose series of Bexsero, at least 1 month apart. Or a 3-dose series of Trumenba, with the second dose at least 2 months after the first and the third dose at least 6 months after the first. The two MenB vaccines are not interchangeable; the same vaccine product must be used for all doses.
Children with persistent complement component deficiency (includes persons with inherited or chronic deficiencies in C3, C5-9, properdin, factor D, factor H, or taking eculizumab (Soliris®):
Meningococcal conjugate ACWY vaccines:
1. Menveo
   - *Children who initiate vaccination at 8 weeks:* Administer doses at 2, 4, 6, and 12 months of age.
   - *Unvaccinated children who initiate vaccination at 7 through 23 months:* Administer 2 doses, with the second dose at least 12 weeks after the first dose AND after the first birthday.
   - *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
2. MenHibrix
   - *Children who initiate vaccination 6 weeks:* Administer doses at 2, 4, 6, and 12 through 15 months of age.
   - If the first dose of MenHibrix is given at or after 12 months of age, a total of 2 doses should be given at least 8 weeks apart to ensure protection against serogroups C and Y meningococcal disease.
3. Menactra
   - *Children 9 through 23 months:* Administer 2 primary doses at least 12 weeks apart.
   - *Children 24 months and older who have not received a complete series:* Administer 2 primary doses at least 8 weeks apart.
Meningococcal B vaccines:
1. Bexsero or Trumenba
   - *Persons 10 years or older who have not received a complete series:* Administer a 2-dose series of Bexsero, at least 1 month apart. Or a 3-dose series of Trumenba, with the second dose at least 2 months after the first and the third dose at least 6 months after the first. The two MenB vaccines are not interchangeable; the same vaccine product must be used for all doses.
For children who travel to or reside in countries in which meningococcal disease is hyperendemic or epidemic, including countries in the African meningitis belt or the Hajj:
- administer an age-appropriate formulation and series of Menactra or Menveo for protection against serogroups A and W meningococcal disease. Prior receipt of MenHibrix is not sufficient for children traveling to the meningitis belt or the Hajj because it does not contain serogroups A or W.
For children at risk during a community outbreak attributable to a vaccine serogroup:
- administer or complete an age- and formulation-appropriate series of MenHibrix, Menactra, or Menveo. Bexsero or Trumenba. For booster doses among persons with high-risk conditions, refer to *MMWR* 2013 / 62(RR02);1-22, available at http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6202a1.htm.
For other catch-up recommendations for these persons, and complete information on use of meningococcal vaccines, including guidance related to vaccination of persons at increased risk of infection, see *MMWR* March 22, 2013 / 62(RR02);1-22, and *MMWR* October 23, 2015 / 64(41); 1171-1176 available at http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf, and http://www.cdc.gov/mmwr/pdf/wk/mm6441.pdf.

12. Tetanus and diphtheria toxoids and acellular pertussis (Tdap) vaccine. (Minimum age: 10 years for both Boostrix and Adacel)
Routine vaccination:
- Administer 1 dose of Tdap vaccine to all adolescents aged 11 through 12 years.
- Tdap may be administered regardless of the interval since the last tetanus and diphtheria toxoid-containing vaccine.
- Administer 1 dose of Tdap vaccine to pregnant adolescents during each pregnancy (preferred during 27 through 36 weeks' gestation) regardless of time since prior Td or Tdap vaccination.
Catch-up vaccination:
- Persons aged 7 years and older who are not fully immunized with DTaP vaccine should receive Tdap vaccine as 1 (preferably the first) dose in the catch-up series. If additional doses are needed, use Td vaccine. For children 7 through 10 years who receive a dose of Tdap as part of the catch-up series, an adolescent Tdap vaccine dose at age 11 through 12 years should NOT be administered. Td should be administered instead 10 years after the Tdap dose.
- Persons aged 11 through 18 years who have not received Tdap vaccine should receive a dose followed by tetanus and diphtheria toxoids (Td) booster doses every 10 years thereafter.
- Inadvertent doses of DTaP vaccine:
  - If administered inadvertently to a child aged 7 through 10 years may count as part of the catch-up series. This dose may count as the adolescent Tdap dose, or the child can later receive a Tdap booster dose at age 11 through 12 years.
  - If administered inadvertently to an adolescent aged 11 through 18 years, the dose should be counted as the adolescent Tdap booster.
- For other catch-up guidance, see Figure 2.

13. Human papillomavirus (HPV) vaccines. (Minimum age: 9 years for 2vHPV [Cervarix], 4vHPV [Gardasil] and 9vHPV [Gardasil 9])
Routine vaccination:
- Administer a 3-dose series of HPV vaccine on a schedule of 0, 1-2, and 6 months to all adolescents aged 11 through 12 years. 9vHPV, 4vHPV or 2vHPV may be used for females, and only 9vHPV or 4vHPV may be used for males.
- The vaccine series may be started at age 9 years.
- Administer the second dose 1 to 2 months after the first dose (minimum interval of 4 weeks); administer the third dose 16 weeks after the second dose (minimum interval of 12 weeks) and 24 weeks after the first dose.
- Administer HPV vaccine beginning at age 9 years to children and youth with any history of sexual abuse or assault who have not initiated or completed the 3-dose series.
Catch-up vaccination:
- Administer the vaccine series to females (2vHPV or 4vHPV or 9vHPV) and males (4vHPV or 9vHPV) at age 13 through 18 years if not previously vaccinated.
- Use recommended routine dosing intervals (see Routine vaccination above) for vaccine series catch-up.

FIGURE 22–3 Catch-up schedule for immunizations, 2016. (Retrieved from http://www.cdc.gov/vaccines/schedules/downloads/child/0-18yrs-child-combined-schedule.pdf.)

Food allergies can also play a role in poor nutritional status, especially with school-age children and adolescents. Between the years 2009 and 2011, the prevalence of reported food allergies in children and youth increased from 3.4% to 5.1% (Jackson, Howie, & Akinbami, 2013). Researchers estimate that about 6 million children have food allergies, with teens and young adults being at greatest risk of anaphylactic reactions (Food, Allergy, Research, and Education [FARE], n.d.). Food allergies can be especially problematic in the

school setting (see Chapter 30), and although new food labeling initiated in 2006 makes identification of the eight most common food allergens (i.e., milk, eggs, fish, shellfish, tree nuts, peanuts, wheat, soybeans) a much easier process, it is recommended that parents and adolescents carefully read labels at the time of each use as ingredients can change without warning (FARE, n.d.).

Dental caries is another common problem among school-age children. Approximately 17% of U.S. schoolchildren (5 to 19 years) have untreated cavities. In 2013, 83% of children age 2 to 17 visited a dentist during the year (CDC, 2015d).

Childhood Obesity

About one third of U.S. children are classified as overweight or at risk of becoming overweight (CDC, 2015b; Gurnani, Birken, & Hamilton, 2015). The CDC uses the term overweight, rather than obese, in defining children who have a BMI at or above the 95th percentile. Children with a BMI between the 85th and 94th percentile are defined as at risk of overweight (National Heart, Lung, and Blood Institute, 2013). (See Display 22–1 for an explanation and examples.) The obesity rate has tripled for children and adolescents, and about 17% of children aged 2 to 19 are obese. Although there has been a decrease in obesity in 2- to 5-year-old children, the rate has remained constant for adolescents through 2012 (Ogden, Carroll, Kit, & Flegal, 2014). In New York, the drop in early childhood obesity was thought to be related to home food consumption changes at the prompting of media messages and school/child care policy changes that also reinforced behavioral change (Farley & Dowell, 2014). Obese children are more likely to become obese adults. A classic Surgeon General's report states that there is a 70% chance of adult overweight or obesity if an adolescent is overweight; if at least one parent is overweight, the risk jumps to 80% (2007). Results of a recent Youth Risk Behavior Survey (YRBS) indicated that almost 78% of high school students surveyed ate fewer than five servings of fruits and vegetables the day before, and almost 30% drank soda at least once a day (CDC, 2013c).

DISPLAY 22.1 EXPLANATION AND EXAMPLES OF OVERWEIGHT CLASSIFICATION FOR CHILDREN AND TEENS

BMI is used as a screening tool to identify weight problems in children and teens. The criteria are different from those used for adults, as body fat differs between boys

and girls and the amount of body fat changes with age. BMI-for-age growth charts for boys and girls are available at http://www.cdc.gov/growthcharts.

Weight Status Category	Percentile Range
Underweight	Less than the 5th percentile
Healthy weight	5th percentile to less than the 85th percentile
At risk of overweight	85th to less than the 95th percentile
Overweight	Equal to or greater than the 95th percentile

Source: Centers for Disease Control and Prevention. (2015). About child & teen BMI. Retrieved from http://www.cdc.gov/healthyweight/assessing/bmi/childrens_bmi/about_childrens_bmi.html

The poor eating habits that develop during childhood are generally thought to persist into adulthood, contributing to the leading causes of death and disability—CVD, cancer, and diabetes. Treating hypertension and high cholesterol, stopping tobacco use, controlling diabetes, reducing obesity, and improving physical activity are all helpful in reducing CVD. Evidence of early atherosclerosis and fatty streaks has been found in autopsy studies of children as young as 6 years, and many now acknowledge the need to prevent cumulative cardiac risk factors, per a classic study by Masia et al. (2009). Childhood cancer survivors were examined and found to have evidence of stiffness in carotid arteries and increased risk for CVD and early arteriosclerosis (Dengel et al., 2014). Another study found that obese 7- to 14-year-olds had "early subclinical arthrosclerosis when compared to their normal weight peers" (Alpsoy et al., 2014, p. 141). Childhood obesity is also associated with metabolic syndrome, insulin resistance, as well as CVD and hypertension (Saha, Sarkar, & Chatterjee, 2011). Preventive measures and early management of cardiovascular risk factors are now considered more effective forms of treatment than just clinical treatment of the disease complications after the fact. Aside from its relationship with inactivity, television viewing and other sedentary behaviors have been associated with higher intake of fats, sweet and salty snacks, and carbonated drinks, as well as lower intakes of fruits and vegetables in a systematic review of studies with children, adolescents, and adults (Pearson & Biddle, 2011). Watching television while eating meals has been shown to lead to increased frequency of poor food choices, and food is the most heavily advertised product on children's television. Highly sweetened products (e.g., sweetened beverages and sugar-rich cereals), as well as fast food, are the most frequently advertised foods. American children and adolescents watch more than 3 to 4 hours of television daily, and increased television watching has been associated with less exercise, increased overweight, lower grades, and less

time spent reading (AACAP, 2011b). A review of international research on food marketing to children through the use of television and the Internet found prevalent food advertising promoting "energy dense, nutrient poor foods" and that "even short-term exposure results in children increasing their food consumption" (Boyland & Whalen, 2015, p. 331). In a study examining causes of weight loss failures, bulletin board, chat room, and pool responses over a 10-year period on an interactive weight loss Web site for preteens and teens were analyzed. Researchers found that many of the participants showed symptoms of substance abuse addiction (per DSM-IV criteria) when they discussed their "relationship with highly pleasurable foods" (Pretlow, 2011, p. 295).

As children move from elementary to middle school, their food choices change dramatically. Fad diets and peer pressure become more of an issue. Media fast-food promotion, targeted to middle and high school students, is common. Diets most often include fast-food French fries and hamburgers, pizza, and sweetened carbonated beverages. The average adolescent diet consists of excess fat and added sugars and often is lacking in micronutrients, such as calcium, iron, and zinc, as well as many vitamins and folic acid. Deficits in micronutrients can compromise development; some people advocate multiple food fortification to improve nutritional status and reduce anemia, but unequivocal evidence is lacking (Best et al., 2011). A study by Bruening et al. (2014) suggests an association between adolescent friends, sugar-sweetened drinks, and fast-food restaurant visits, noting that nutrition education efforts could be improved by taking into consideration the influence of friends. They recommend that parents, schools, and communities work with youth to find other venues for friend groups that will not expose adolescents to unhealthy foods. This is also a time when school-based nutrition education programs can have an influence. During the 2014–2015 school year, under the direction of the Healthy, Hunger-Free Kids Act of 2010, new school meal standards were outlined. In addition, all schools are now required to sell "Smart Snacks" in vending machines, a la carte, and in school stores (CDC, 2015c; Food & Nutrition Service, 2014; USDA, 2015). Some school-based programs also include physical activity, but one longitudinal study of over 200 children concluded that physical activity was not the cause of obesity, but rather, it was the result; they questioned if this might be the reason why most efforts to reduce childhood obesity through increased physical activity have not been very successful (Metcalf et al., 2011) (see Using the Nursing Process).

USING THE NURSING PROCESS

James Lopez is entering third grade. His teacher comes to you, the school nurse,

because she is concerned about his poor performance in school. He frequently comes to school late and often puts his head on his desk and appears to be falling asleep. You notice that James has gained a significant amount of weight over the summer. His face is much fuller now than in his second grade picture.

Assessment (Initial Visits)

You call James' mother and make an appointment for a home visit.

You do a health history, noting family history of diabetes, current eating, activity, and sleeping patterns for James and the family, and determine whether he has a regular physician and insurance or Medicaid.

You assess his vital signs, height and weight, hearing, and vision.

You talk more with his teacher about his activity on the playground and any signs of excessive thirst, hunger, or general fatigue.

Nursing Diagnoses

After a home visit, a meeting with James' teacher, and two observations and interviews with James, you decide on the following nursing diagnoses:

1. Nutrition: More than Body Requirements related to James' eating as a way of coping and his sedentary lifestyle.
2. Altered Family Process related to mother's recent change from being a stay-at-home single mom to attending truck driving school (necessitating absences of several days at a time, with James cared for by a married teenage sister and her husband).

Findings, Plan, and Implementation

James has been eating large quantities of snack food and fast-food meals for the last 3 months, since his mother started her training. He has also quit participating in soccer and baseball, because his mother can no longer provide transportation. His bicycle was recently stolen, and he spends a lot of time playing video and computer games. James misses his mother when she is away and says that he "stays up late watching television" and has "trouble getting up for school" when he is at his sister's house.

You plan to work with the family to refer James to his physician to rule out diabetes. A family meeting is scheduled so that you can provide some health education on childhood obesity and inactivity. You discuss some possible interventions that the family can put into place:

- Decrease reliance on fast-food meals.
- Have a regular evening mealtime and encourage less snacking.
- Provide fresh fruit and vegetable snacks and decrease purchases of high-calorie,

high-fat snack foods.
- Decrease sedentary activity (e.g., video and computer games, television viewing) and increase physical activity (e.g., team sports, walking, bicycling, active outdoor games).
- Establish a reasonable bedtime and consistently enforce it.
- Offer referral for family counseling so that James can discuss his feelings in a safe environment.
- With the family's input, seek ways for James and his mother to keep in better contact and for his sister to gain a greater understanding of good parenting practices.
- Meet with the teacher, the family, and James to discuss ways to help with his school performance.
- Continue to monitor James' progress with monthly height and weight checks, personal interviews, home visits, and teacher conferences.

Evaluation

The physician reported that James does not have diabetes; however, if he continues to gain weight and remains inactive, he is at a higher risk for type 2 diabetes. Evaluation of nursing diagnoses 1 and 2 includes the following goals:

- The family will report less reliance on fast food and more meals cooked at home.
- The family will report more purchases of fresh fruits and vegetables and fewer purchases of high-calorie, high-fat snacks.
- James will report more physical exercise (by the use of a calendar) and fewer hours spent in sedentary activity (corroborated by family).
- James will exhibit less tardiness and fewer signs of sleep deprivation at school, and his school performance will improve.
- James and his family will complete sessions with a family counselor.
- James' weight will remain stable or will decrease as his height increases over time.

For many years, research studies have examined childhood obesity and its causes. A link between weight gain in early infancy and later risk of obesity may exist (Young, Johnson, & Krebs, 2012). In a retrospective cohort study, 18-month-olds who were obese or overweight were two times more likely to be obese between the ages of 4 and 6. Those that were obese at 18 months of age were over three times more likely to be obese when they were between age 4 and 6 (Wheeler, 2013). In another long-term study following children from age 5 to age 15, intake of sweetened beverages (not fruit juice or milk) was associated with greater adiposity and higher body fat percentages and waist circumference at age 15

(Brown, Halverson, Cohen, Lazorick, & Skelton, 2015). Some studies show that children who are lacking in sleep duration may have higher BMIs (odds ratio 2.15), and other studies have shown that having an obese mother is significantly associated with childhood overweight or obesity (Fatima, Doi, & Mamun, 2015; Rosas et al., 2011; Young et al., 2012). A longitudinal study of 13,170 UK children between the ages of 7 and 11 found that both sugar-sweetened and artificially sweetened beverages were associated with increases in body fat percentages and BMI (Laverty, Magee, Monteiro, Saxena, & Millett, 2015). Parents can help their younger children develop better habits by implementing suggestions recommended by the American Heart Association (2014), for example:

- Serve a variety of fruits and vegetables. Limit juice to 4 to 6 oz. per day.
- Keep fat intake between 25% and 35% of total daily calories (aged 4 to 18).
- Provide foods low in saturated fat, trans fat, cholesterol, added sugar, and salt.
- Encourage kids to eat only enough calories to maintain healthy weight.
- Help kids be physically active at least 60 minutes each day.
- Serve whole-grain/high-fiber cereals and breads.
- Serve low-fat and fat-free dairy products (two to three cups of milk daily).
- Serve fish more often, but avoid fried fish.
- Keep introducing a variety of healthy foods, but don't overfeed your child.

One European study found that children and adolescents who had higher consumption of dairy products (e.g., yogurt, milk) had lower levels of body fat and were at less risk of CVD and showed evidence of better cardiorespiratory fitness (Moreno, Bel-Serrat, Santaliestra-Pasias, & Bueno, 2015).

Physical activity is important for health and in childhood obesity prevention. Author's private photo with permission of Holly Raphael.

Inadequate Nutrition

Poor nutritional status of schoolchildren is a global issue but also a problem in this country. Undernutrition can also have serious consequences, including effects on the cognitive development and academic performance of children and chronic health (Weitzman & Zhou, 2012). Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition. Infection and illness that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics. Food insecurity has been associated with child development problems, psychological and social issues, and poor

general health (Weitzman & Zhou, 2012).

About 14.0% of U.S. households reported some degree of food insecurity in 2014, representing 48.1 million people. Approximately 19.2% of households with children were food insecure, and of those headed by single women with children, 35.3% reported food insecurity (Coleman-Jensen, Rabbitt, Gregory, & Singh, 2015). Reviews of research studies done over the past 15 years have shown mixed results with the association of food insecurity and childhood obesity (Eisenmann, Gundersen, Lohman, Garasky, & Stewart, 2011; Larson, & Story, 2011). A national study by Kaur, Lamb, and Ogden (2015) suggests that there is an association between food insecurity and obesity in school-age children (6 to 11 years) but not between preschoolers, age 2 to 5 years. These results provide additional validation for healthy school meal programs. There is some indication that there is a significant relationship between food insecurity and increased BMI in young adult females, and a growing consensus that both problems warrant further research (Gooding, Walls, & Richmond, 2011).

Longitudinal research has found that long-term childhood exposure to poverty is related to young adult overweight and obesity for White, Black, and Hispanic young women (Hernandez & Pressler, 2014). A Canadian study found that parents and caregivers viewed their low-income status as a contributing factor for poor nutrition in their children and cited dependence on nutrient-poor, energy-dense food because it was longer lasting than more nutritious fresh foods and easier to obtain (Bhawra, Cooke, Hanning, Wilk, & Gonneville, 2015). Research findings of Holben and Taylor (2015) confirm the relationship between food insecurity and central obesity.

Undernutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful undernutrition. Because prepubertal children often exhibit a period of adiposity before a growth spurt, they are at risk for developing eating disorders. Along with childhood obesity, prevention of eating disorders is also a high priority in this age group. Some sources find pediatric eating disorders to be more prevalent than T2DM, and minority groups, boys, and younger children have higher rates. The lifetime prevalence for anorexia nervosa is 0.5% to 2%, and for bulimia, it is 0.9% to 3%, with mortality rates of 5% to 6% and around 2%, respectively (Campbell & Peebles, 2014). A landmark 5-year study of the frequency of reading magazine articles about dieting and weight loss found that girls who frequently read these magazines were two times more likely to engage in unhealthful weight-control measures (e.g., skipping meals, smoking more cigarettes, fasting) than those who did not read magazine articles about dieting and weight loss. Extreme weight-control measures (e.g., laxative use, vomiting) were found three times more often in high-frequency readers versus nonreaders (van den Berg, Neumark-Sztainer, Hannan, & Haines, 2007). The Youth Risk Behavior Survey (SYRBS) found that almost 14% of high school students reported not eating for 24 hours or more in order to keep from gaining or lose weight; vomiting and laxatives were used by 4% (CDC, 2013c). A study by Holm-Denoma, Hankin, and Young (2014) suggests that for boys, the association between depression and eating disorders was greater between third and sixth

grades and then stabilized. However, eating disorder symptoms and depressive symptoms became more manifest in females between sixth and ninth grade. They recommend that eating disorder prevention programs begin before age 12 and depressive symptom interventions target males by third grade and females by sixth grade.

Although there has been some concern about the possibility that obesity prevention measures may lead to eating disorders, no real evidence of that has surfaced, and experts feel that both problems can be effectively addressed through evidence-based interventions. Suggestions include stressing family meals and physical activities, promoting a positive body image, avoiding weight talk, and decreasing media focus. More specific suggestions include:

- Foods to *encourage* (fruits, vegetables) versus foods to *limit* (high-fat/high-sugar/low nutritional value) rather than *good* or *bad* foods
- A focus on dietary restraint/portion size rather than dieting or deprivation
- More research on the continuum of mindless eating to obsessive preoccupation with food intake and on helping individuals more effectively use internal cues for hunger or satiety
- Simultaneous promotion of healthy eating behaviors while protecting positive body images in children (Campbell & Peebles, 2014)

It is important to talk with overweight children and adolescents about their experiences of being mistreated because of their problems with weight and to encourage families to not just talk about weight but to do more together to promote healthy eating and increased physical activity. Also, early detection of eating disorder is important, as this problem can irreversibly affect growth and development and early intervention and treatment show better outcomes (Campbell & Peebles, 2014). School nurses and PHNs should be aware of signs and symptoms of this disorder, noting that T1DM children may be at higher risk, and watch for unexplained weight loss, stunting of normal growth patterns, concerns about body image, delayed puberty, and abnormal or restrictive eating (e.g., newly committed vegetarians, food rituals, swallowing disorders, textural aversions). They can provide families with necessary information to promote healthful eating and exercise, as well as provide guidance for parental and child support (Hertz, Jones, Barrios, David-Ferdon, & Holt, 2015). Some school districts include BMI screening programs as part of healthy lifestyle promotion (Ruggieri & Bass, 2015), and school nurses are encouraged to provide educational programs that promote healthy eating and help students see through advertising efforts that promote an unrealistic body image (Funari, 2013).

Inactivity

An association between poor eating habits and physical inactivity has been found in numerous research studies (Nesbit, Kolobe, Sisson, & Ghement, 2014). More television watching, fewer family meals eaten together at home, and living in an unsafe neighborhood were shown to be associated with overweight (Nesbit et al., 2014). The YRBS revealed that

66.7% of children surveyed who were enrolled in physical education classes did not attend class on a daily basis. In addition, fewer than 19% of respondents stated that they were physically active for 60 minutes daily. Almost 33% watched three or more hours of television daily and just below 25% used a computer (other than for schoolwork) or played a video game on a daily basis (CDC, 2013c).

In a study of adolescent girls and their families, researchers found that parents' modeling of physical activity, television viewing, fruit and vegetable consumption, and use of soft drinks were significantly associated with the teens' behaviors, indicating that improvements in parent behaviors can affect adolescents (Bauer, Neumark-Sztainer, Fulkerson, Hannan, & Story, 2011). School nurses and PHNs can work with families to increase their levels of physical activity and to encourage limited television viewing for school-age children. They can also advocate for increased physical education in the school setting and for increased safe recreational opportunities in all neighborhoods.

Dental Health

Dental caries is thought to be the most prevalent childhood infectious disease, and mother-to-infant transmission of the bacteria most commonly involved in tooth decay occurs before primary teeth are visible (Caple & Schub, 2015). Caries affect 37% of children between the ages of 2 and 8, with 14% having untreated cavities in primary (baby) teeth. About 21% of children (6 to 11 years of age) have dental caries in their permanent teeth and 6% have untreated caries. Hispanic children have the highest rates of decay in both primary and permanent teeth (CDC, 2015d). In a classic study, comparing African refugee children with U.S. children, the rate of dental caries for refugee children was half that of U.S. children (Cote et al., 2004). Poor children report twice the rate of untreated dental caries than do children from higher-income families (CDC, 2012b). Those children with high or very high food insecurity were found to have significantly higher prevalence of dental caries than those children living in food-secure households (two times the rate) (Chi, Masterson, Carle, Mancl, & Coldwell, 2014).

The prevalence of dental caries in school-age children has decreased significantly since the early 1970s because of community fluoridation projects and the use of fluoride toothpaste (FCFS, n.d., Table HC4.C). Fluoridated drinking water, the availability of school-provided fluoride rinse or gel, and dental sealant programs are cost-effective, proven methods of reducing dental caries in school-age children (National Institute of Dental & Craniofacial Research, 2015).

The peak incidence of dental caries is found among school-age children and adolescents, although the effects of decay are observed in adulthood as caries activity recurs or various restorations fracture or wear out and must be replaced. In 2013, 88% of children age 2 to 17 years visited a dentist in the past year, but for children living in poverty, only about 82.3% did, and approximately 56% of uninsured children saw a dentist. Over time, these rates have improved with coverage through the State Children's Health Insurance

Program (SCHIP) and preventive programs such as community water fluoridation and the expansion of sealant programs. The number of children between 5 and 19 years with untreated dental caries has decreased from 24% in 1994 to 17% in 2011–2012 (FCFS, 2015e). Yet, access to dental care is still problematic. Barriers to dental care are more prevalent among the poor (Caple & Schub, 2015).

Financial barriers and lack of education lead to poor dental health values and adversely affect the appropriate use of early dental services and conscientious personal oral health care. School-based dental sealant program research was reviewed and found to be effective in managing cavities in this age group (CDC, 2015j). Prescription fluoride supplements should be used when drinking water is deficient in fluoride and children are at high risk of developing cavities. Some interventions have shown promise in reducing caries transmission and improving tooth-brushing habits. Motivational interviewing with parent post–dental examination of their children, along with a brief instructional DVD were employed in a large-scale study, and at 6-month follow-up, researchers found that participating caregivers were more apt to check children's teeth and ensure nightly brushing. This continued at the 2-year follow-up (Ismail, Ondersma, Jedele, Little, & Lepkowski, 2011). Second through fifth grade students' motivations for brushing teeth were examined in focus group research. Cues to motivate brushing included wanting to have good teeth, relatives with dentures, social media that instructed them on the link between oral health and CVD or smoking, and cancer (Walker, Steinfort, & Keyler, 2015). Albert, Barracks, Bruzelius, and Ward (2014) found that a Web-based educational program significantly increased knowledge of caries transmission and plans to prevent maternal caries transmission between pre- and posttest in a largely college-educated group of participants. PHNs and other community health nurses working with school-age children and families can promote good dental health through education and advocacy, as well as through collaboration to provide adequate dental services to uninsured children and promotion of fluoridation and sealant programs.

ADOLESCENT HEALTH

Adolescence is a time of self-discovery, movement toward self-reliance, increasing opportunities, and pivotal choices that can affect the remainder of an individual's life. Adolescence generally begins with puberty and encompasses the ages between 10 and 24; it consists of early adolescence (aged 10 to 14), middle adolescence (15 to 17), and late adolescence (18 to mid-20s). Adult society largely segregates adolescents and often has ambiguous expectations for them (Park, Scott, Adams, Brindis, & Irwin, 2014). Adolescents are part of a subculture, one with its own language, dress, social mores, and values. The tasks of adolescence remain fairly constant: adolescents must become autonomous, come to grips with their emerging sexuality and the skills necessary to attract a mate, and acquire skills and education that can prepare them for adult roles, all while resolving identity issues and developing values and beliefs (Park et al., 2014). The search for and expression of developing identity, along with the strong drive for social acceptance, are evident in the personal home pages and blogs of adolescents on social networking Internet sites such as Twitter and Facebook (Spies-Shapiro & Margolin, 2014).

Common first jobs for adolescents include babysitting and yard work. (Author's private photo with permissions of Merysa Schultz and Deanna Rector.)

Adolescents are generally healthy, but parents and teens may differ in their perceptions of the adolescent's health. Adolescents from lower-income brackets frequently report poorer health than those from higher-income groups. As with other population groups, socioeconomic level and health are inversely related for adolescents. Adolescents also exhibit inverse relationships between income level and school achievement, most likely because of a lack of successful strategies for academic success (Office of Disease Prevention and Health Promotion, 2014a; Oyserman, Johnson, & James, 2011). Parental long-term unemployment is also negatively associated with adolescent self-reported health status and depressive symptoms and psychosomatic complaints. These, along with poor health behaviors related to lack of physical activity and drug use or smoking, contribute to self-perceived poor or fair health (Nichols, Mitchell, & Lindner, 2013). Social stressors and strained relations with peers and parents are also related to health complaints, including psychosomatic complaints (Child Trends Databank, 2014e; van Geelan, Rydelius, & Haagquist, 2015). Common complaints of adolescents include sleep deprivation, fatigue, chronic insomnia, acne, and concerns about weight and body image (van Geelan et al., 2015). As children become adolescents, their sleep patterns change—they move from early risers/sleepers to staying up later and sleeping in later or catching up on sleep over weekends. This transition becomes more apparent through high school. Scientists believe that these changes in circadian and homeostatic sleep regulation support this delayed sleep phase, and there are concerns about consistent lack of sleep (Orzech, Acebo, Seifer, Barker, & Carskadon, 2014). A national survey of adolescents revealed that 68.9% reported getting insufficient sleep and this was associated with higher odds of several risk behaviors such as use of cigarettes, alcohol, and tobacco, as well as current sexual activity, physical fighting, and physical inactivity (McKnight-Eily et al., 2011). Another U.S. survey of over 14,000 adolescents corroborated the association of short sleep duration and high cholesterol, with "each additional hour of sleep … associated with … significantly decreased odds of being diagnosed with high cholesterol in young adulthood" for females (Gangwisch, Malaspina, Babiss & Opler, 2010, p. 956; IglayReger et al., 2014). Lytle, Pasch, and Farbakhsh (2011) found a relationship between sleep duration and BMI in middle school students but did not find the same results among high school students. They noted that waking up later on weekends was related to lower body fat and healthier weight for girls, but not for boys, and warned "inadequate sleep is a risk factor for early adolescent obesity" (p. 324). Sleep deprivation, along with television viewing time, has been related to increased BMI and blood pressure, and a poor body weight perception (being overweight or underweight) has predicted problem behaviors in both male and female adolescents (Nesbit et al., 2014). Many schools have instituted later start times in order to correlate with youth circadian rhythms. Recent studies confirm the support for delaying adolescent school start times and indicate benefits of improved duration of sleep, decreased daytime sleepiness, and reductions in depression and caffeine use (Minges & Redecker, 2016). One study suggests that the benefit of delayed start times past 8:01 AM is not significant. Based on research findings, Paksarian, Rudolph, He, and Merikangas (2015) recommend that modest delays in start times may be beneficial but other factors, such as travel time to school, should be

considered. Further research in this area is suggested.

In the past, routine health care visits by adolescents were not commonplace. However, newer recommended vaccines and better awareness of the health needs of adolescents have led to improvement, but concerns remain. In 2012, 88.1% of 10- to 17-year-olds had a physician visit within the past year, and 73.8% had a well-child checkup (Park et al., 2014). This shows an increase in visits compared to data from an earlier national survey when 38% of adolescents had a visit for preventive care within the last year, but only 40% spent time alone with their health care provider (Irwin, Adams, Park, & Newacheck, 2009). Sadly, only 10% had all areas of recommended anticipatory guidance addressed (e.g., healthy diet, seat belt/helmet use, smoking/secondhand smoke), and teens from low-income or uninsured families were at greater risk of not having any preventive health care visits. Most health care visits for adolescents were for female reproductive health care, and birth control was a common prescription written at outpatient visits. An update to the 2009 review indicates that the majority of health indicators have changed very little for adolescents over the past decade (Park et al., 2014). However, encouraging trends among adolescents and youth include a decrease in unintentional injury, tobacco use, and assault rates. Increases were also noted in exercise trends. Additionally, the number of adolescents having health care insurance has increased with the advent of the Affordable Care Act, Medicaid Expansions, and CHIP (Park et al., 2014).

Although hospitalization rates for adolescents are low, the leading cause of hospitalization in 15- to 24-year-olds is pregnancy related. Trauma and mental disorders were the next two causes of hospitalization, and trauma-related disorders are the leading reason for emergency room visits. Almost 17% of adolescents have some special health care need; this prevalence has changed little (Park et al., 2014).

Health literacy during adolescence is an important consideration. Teens are frequent users of mass media (Internet, television, radio, text messaging), and specific health-related educational interventions can be targeted to them by using these media. One study found that 56% of high school students in an online sample had heard of MedlinePlus, and 52% had "adequate levels of health literacy" as measured by an online test (Ghaddar, Valerio, Garcia, & Hansen, 2012, p. 28). PHNs can help young people find reliable sources of information, as well as work with families to ensure proper monitoring of Internet use. Sexual predators, pornography, and cyberbullying are among the Internet dangers encountered by adolescents (Spies-Shapiro & Margolin, 2014).

During the period that roughly encompasses the teen years, adolescents encounter many complex changes, physically, emotionally, cognitively, and socially (Park et al., 2014). Rapid and major developmental adjustments create a variety of stresses with concomitant problems that have an impact on health. Recent advanced neuroimaging techniques have demonstrated marked changes in the adolescent brain, especially related to white and gray matter and the prefrontal cortex (Krongold, Cooper, & Bray, 2015). The uneven changes in brain development may help explain the risk-taking behaviors and higher incidence of unintentional injuries found in this population (Steinberg, 2015).

Unintentional injuries were the leading cause of death in the 10- to 19-year-old age group. Most deaths in this adolescent/young adult age group are due to preventable causes. The overall injury death rate in 2009 for adolescents 10 to 14 years of age was 17.9 per 100,000 and for 15- to 19-year-olds, it was 69.7, indicating a dramatic rise as teens gain more freedom and begin to drive (Kochanek, Kirmeyer, Martin, Strobino, & Guyer, 2012). In 2013, nearly 75% of adolescent deaths were related to injury with unintentional injuries responsible for approximately 50% of these adolescent deaths. Motor vehicle and firearm-related deaths accounted for approximately 60% of adolescent injury deaths (FCFS, 2015a). The death rate from motor vehicle–related injuries for this age group peaked during the 1970s and 1980s and then declined throughout the next two decades, although motor vehicle–related injuries remain the number one cause of injury mortality for this age group (Park et al., 2014). Gender differences are also apparent: girls are much less likely than boys to engage in behaviors that put them at risk for injuries, resulting in twice the rate of unintentional injury death rate for male than female adolescents. This gender difference has persisted over three decades and is greater than age or ethnic differences in both unintentional and violence-related injury deaths (FCFS, 2015a; Sorenson, 2011) (see Fig. 22–4).

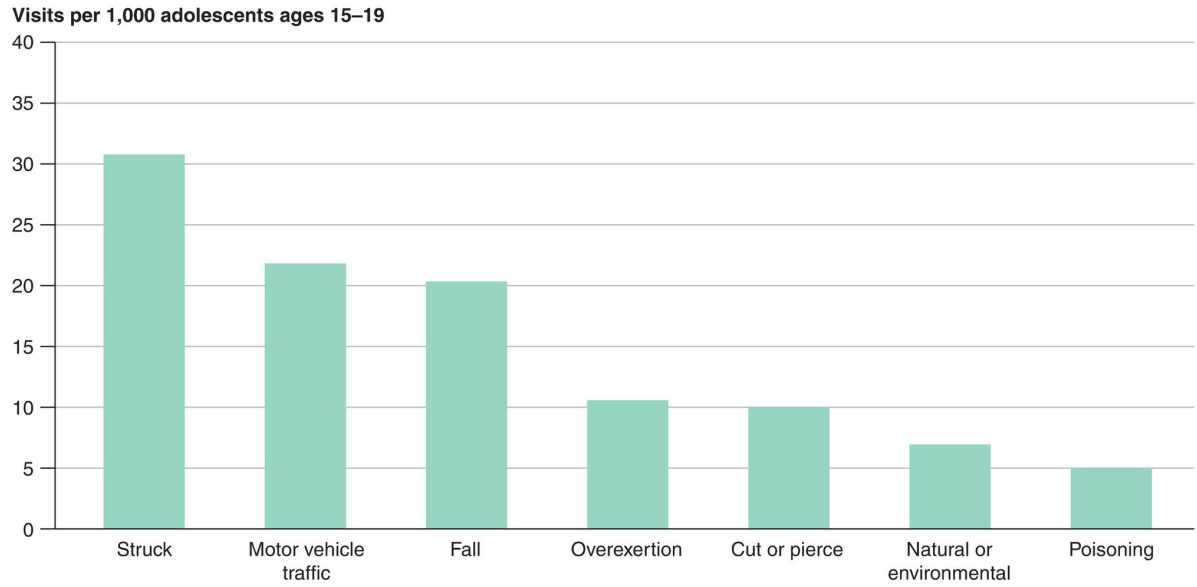

FIGURE 22–4 Death rates among adolescents aged 15 to 19 by all causes and all injury causes and selected mechanisms of injury, 1980–2009. (From http://www.childstats.gov/americaschildren/phenviro8.asp.)

Unintentional injuries also cause the greatest level of morbidity, and the largest cause is transportation (drivers and passengers, bicyclists, pedestrians). Other causes include crime, drowning, poisoning, fires, sports, and recreation, reckless driving, and work-related injuries (Steinberg, 2015). Almost 2.6 million sports- and recreation-related injuries (aged 0 to 19) are treated annually in EDs. The causes of most injuries requiring treatment include bicycling, playground activities, football, basketball, and soccer. Football and girl's soccer have the highest injury rates among youth sports (0.47 and 0.36 per 1,000 exposures), and the incidence of traumatic brain injury (TBI)/concussion ED visits has risen 60% over the last decade (CDC, 2015f).

Health Objectives for Adolescents

Healthy People 2020 objectives are focused on improving the health of all Americans. Goals and objectives for adolescent health have been developed. Because much of the mortality and morbidity in this age group stems from risk-taking behaviors, many objectives addressing alcohol-related unintentional injuries, violent behaviors, and suicide and mental health issues, as well as more responsible reproductive health behaviors, are included throughout the document under Substance Abuse, Mental Health, etc. (Jiang, Kolbe, Seo, Kay, & Brindis, 2011; see Table 22–1). The 2014 review of these critical objectives found overall mortality trends varied, with decreases for 15- to 19-year teens since 2007. Trends in injury mortality for ages 10 to 24 years decreased with the exception of motor vehicle accidents associated with alcohol-impaired young drivers. Adolescent use of seat belts improved. The objectives related to violence and mental health objectives have shown mixed results. Overall, homicide rates show little change for the adolescent age group. Black, non-Hispanic and Hispanic male homicide rates have decreased, although the current rate for this population is six to seven times greater than the general rate. Suicide rates and reported attempted suicides are not significantly improved, and only modest increases are found in other objectives related to mood and treatment. Binge drinking and marijuana use remain the same, and physical activity reports are improving. Tobacco use has gone down considerably; unfortunately, this rate increases fourfold between the teen years and young adulthood. Obesity and overweight rates remain at about 17%. The adolescent pregnancy rate has decreased and related objectives are on pace to reach targets (e.g., never having sex, used a condom with last sexual contact). *Chlamydia* infection rates have increased but may be an artifact of more sensitive testing and improved reporting (Park et al., 2014). Analysis of the *21 Critical National Health Objectives* for *Healthy People 2010* relating to adolescents and young adults revealed that only 2 targets had been met (i.e., rode with a driver who had drunk alcohol, physical fighting), but progress had been made toward 12 of the objectives. Jiang and colleagues (2011) reported that no progress was made on four objectives and two objectives actually showed worse results (i.e., rates of *Chlamydia* infection and overweight). But significant progress was made in decreasing adolescents' use of alcohol or illicit drugs (Office of Disease Prevention and Health Promotion, 2014b).

Table 22–1 *Healthy People 2020:* 21 Critical Health Objectives for Adolescents and Young Adults

Goal: Improve the healthy development, health, safety, and well-being of adolescents and young adults.

Number	Objective
AH-1	Increase the proportion of adolescents who have had a wellness checkup in the past 12 mo.
AH-2	Increase the proportion of adolescents who participate in extracurricular and out-of-school activities.
AH-3	Increase the proportion of adolescents who are connected to a parent or other positive adult caregiver.
AH-4	Increase the proportion of adolescents and young adults who transition to self-sufficiency from foster care.
AH-5	Increase the proportion of schools with a school breakfast program.
AH-7	Reduce the proportion of adolescents who have been offered, sold, or given an illegal drug on school property.
AH-8	Increase the proportion of adolescents whose parents consider them to be safe at school.
AH-9	Increase the proportion of middle and high schools that prohibit harassment based on student's sexual orientation or gender identity.
AH-10	Decrease the proportion of public schools with a serious violent incident.
AH-11	Reduce adolescent and young adult perpetration of, as well as victimization by, crimes.

From U.S. Department of Health and Human Services (USDHHS). (2014). Adolescent health. Retrieved from http://healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicId=2

Because adolescents have less contact with the health care system than children, many conditions may go undetected. Also, a shift occurs from a childhood preponderance of physical conditions to more social behavioral problems in adolescence. Risk behaviors become much more evident, along with their attendant outcomes: unsafe sexual activity, substance use, violence, and motor vehicle–related issues. Also, the transition from high school into early adulthood is often difficult and those individuals with mental health issues often have worse outcomes than those with physical conditions (Park, Adams, & Irwin, 2011).

Emotional Problems and Suicide

The adolescent years are a time of rapid growth and change. Hormonal influences may cause a teen to be emotional and unpredictable at times (Chulani & Gordon, 2014). The influence of peers increases, and peer pressure may influence behavior. Teens test family rules and generally search for their own identity and individuality apart from the family. Most parents and teens ride out this period with love and understanding and no long-term negative effects. For some children, however, a real or perceived lack of emotional support can lead to temporary or permanent emotional problems. Additionally, increased risk behaviors such as suicide, risky sexual behavior, and mental health disorders are associated with child and adolescent maltreatment (Chulani & Gordon, 2014; National Institute of Justice, 2011; Norman, et al., 2012). Gender differences in types and trajectories of emotional and behavioral problems have also been noted, with more females developing adolescent-onset depression and males demonstrating more conduct problems at an earlier age of onset (Zimmer-Gembeck & Skinner, 2015).

Depression, schizophrenia, and eating disorders may first appear during adolescence. About 50% of mental health conditions begin before age 14, and 75% by age 21. It is estimated that approximately 20% of adolescents have mental health disorders with depression being the most commonly reported diagnosis. Prevalence rates of depression vary (Fig. 22–5). About 29% of high school students report feelings of sadness or hopelessness every day for longer than 2 weeks. Of those reporting symptoms, 36% are female and 22% are male. Anxiety disorders such as OCD, posttraumatic stress disorder, social anxiety disorders, and phobias are reported by approximately 10% of students between ages 12 and 17 years (Murphey, Barry, Vaughn, Guzman, & Terzian, 2013). Researchers have concluded that 26% to 30% of adolescents display symptoms of emotional distress, and about 9% have moderate to severe symptoms (Child Trends Databank, 2014a). Adolescent brain maturation may explain susceptibility to depression during this period of development (Ahmed, Bittencourt-Hewitt, & Sebastian, 2015).

FIGURE 22–5 Percentage of youth ages 12 to 17 who had at least one major depressive episode (MDE) in the past year by race and Hispanic origin, 2004–2014. (Retrieved from http://www.childstats.gov/americaschildren/health_fig.asp.)

Many adolescents are reluctant to seek help for emotional problems, or help may not be readily available to them. Most mental health disorders are treatable; however, it is estimated that approximately 60% to 90% do not receive treatment. Barriers to treatment may include social stigma and missed opportunities for identification and prevention (Murphey et al., 2013). Survey results have found that 12.7% of youth aged 12 to 17 have been given some type of mental health services, but the usual disparities apply (e.g., ethnicity, income level, rural vs. urban locale). Treatment for serious mental health problems may include hospitalization or placement in a group home. The most common reasons for youths to receive mental health treatment during 2012 include depression (50.7%), home-based problems (29.1%), rule breaking (24.2%), suicidal ideation or suicide attempts (23.8%), and fear/anxiety (22.7%) (Substance Abuse and Mental Health Services Administration [SAMHSA], 2013). Mental health disorders experienced during adolescence may persist into adulthood. It is critical to identify negative adolescent mental health behaviors, provide access to services, and educate teens about healthy physical and mental health skills. School-based programs to educate adolescents about depression and suicide prevention have been useful (Melnyk et al., 2015; Murphey et al., 2013). For some, more universal approaches are viewed as more effective in preventing a wider range of social and emotional problems (Durlak, Weissberg, Dymnicki, Taylor, & Schellinger, 2011). PHNs and school nurses often participate in the development or administration of these types of programs.

Suicide is the third leading cause of death in 10- to 14-year-olds and the second leading cause in 15- to 24-year-olds. In 2013, suicide accounted for 11.3% of child and adolescent deaths. This is an increase from 10.7% in 2012 (Osterman, Kochanek, MacDorman, Strobino, & Guyer, 2015). Overall, male suicide rates are four times higher than female rates and comprise 77.9% of all suicides (CDC, 2016). A classic study found that a psychiatric diagnosis is noted in 90% of suicide victims, with depression reported in over 50% of all cases (National Alliance for Mental Illness [NAMI], 2011). Untreated depression is often a factor in adolescent suicide and should be screened for and evaluated (Pelkonen, Karlsson, & Marttunen, 2011). Although questions have been raised and the FDA issued a black box warning that adolescents beginning treatment may be at increased for suicidal ideation, selective serotonin reuptake inhibitors (SSRIs) are among the more commonly prescribed antidepressant medications and are not considered to increase suicide risk (Cousins & Goodyer, 2015). In 2013, almost 17% of high school students reported that they seriously considered suicide in the previous 12 months (up from 13.8% in 2009), and 8% made at least one suicide attempt. Almost 2.7% made an attempt that required medical attention. Suicide rates for adolescent female versus male students are higher (10.6% vs. 5.4%; Child Trends Databank, 2015d). As adolescents grow older, they are more at risk for suicide: the rate increases from 1.5 per 100,000 for ages 10 to 14 to 8.2 for ages 15 to 19. It is 12.8 for older adolescents (20 to 24), and about 2 million adolescents attempt suicide each year (NAMI, 2011).

Male adolescents are more likely to die as a result of suicide; females are more likely to report suicide attempts. It is important to question a teen about a history of depression or feelings of hopelessness, as well as the quality and quantity of her social support systems and the availability of means to follow through on suicide threats; it is also helpful to have intensive therapy visits early on and discussions about safety planning (Pelkonen et al., 2011). School and discipline problems, family discord, and depression, as well as drug and alcohol abuse, can increase the risk of suicide (Adrian, Miller, McCauley, & Stoep, 2015). Recent stressful events and preoccupation with suicide, as well as substance use, are also important to note. Being bullied, a history of sexual or physical abuse, aggressive conduct disorders, and personality disorders are risk factors for adolescent suicide attempts (Murphey et al., 2013). Major depressive disorder is most commonly associated with lifetime prevalence of adolescent suicidal ideation, plans, and attempts. This is followed by "specific phobia, oppositional defiant disorder, IED, substance abuse, and conduct disorder" (Nock, et al., 2013, p. 303). *Suicide contagion* refers to copycat suicides, especially among high school students, after a highly publicized suicide. This can lead to suicide clusters—deaths of three to seven adolescents over a 3- to 9-month period (Sullivan, Annest, Simon, Luo, & Dahlberg, 2015).

Suicide prevention programs and direct intervention by counselors or school nurses to determine an adolescent's suicide intentions may be effective school-based interventions. It is important for counselors to identify markers for attempted suicide, such as a precipitating event, intense affective state, suicide ideation or actions, deterioration in social or academic

functioning, or increased substance abuse. PHNs and community mental health counselors may serve as consultants to schools in the development of sound prevention programs. Hallmarks of good prevention programs include student education on suicide awareness and intervention; coping and problem-solving skills training; skill building by reinforcement of strengths and protective factors while dealing with risk-taking behaviors; and teaching about the association between suicide and mental health (especially depression). Suicide screening is often thought to be effective in reducing suicidal ideation (Gray & Dihigo, 2015). Youth suicide has been of great concern over the past several decades. Communities across the nation have been urged to implement effective school-based suicide prevention programs. Although many programs have been implemented, many have not been based on evidence or have not shown a positive impact. The "Surviving the Teens" program is designed to help all adolescents and specifically identify teens exhibiting help-seeking behaviors. This evidence-based program teaches adolescents to communicate emotional health issues and seek help when experiencing suicidal ideation. It also teaches teens how to help friends experiencing depression or suicidal ideation. The program demonstrated a decrease in suicidal ideation reports and increased help seeking by youth over a 3-month period (Strunk, Sorter, Ossege, & King, 2014). Another study examined the effect of the 12-month "COPE Healthy Lifestyles TEEN Program" on adolescent obesity and depressive symptoms. Study results demonstrated improved outcomes for both long-term physical and mental health among participating teens (Melnyk et al., 2015). Skills training programs that target a broader range of problems (e.g., depression, anxiety, negative self-perceptions) have been effective in teaching adolescents how to monitor feelings, identify triggers, and avoid and reframe negative thoughts. Relaxation skills training, learning how to seek out help from others, and promoting healthier responses to stress have also been successful in impacting internalizing behaviors (Terzian, Hamilton, & Ericson, 2011). Brown and Green (2014) indicate that research gaps in the literature continue; however, follow-up screening and the expansion of services and research within new populations and settings are needed (Fig. 22–6).

FIGURE 22–6 A young woman with evidence of "cutting" self-injury.

A behavior that can sometimes accidentally result in suicide is *self-injury* or *cutting*. Adolescents with this abnormal behavior who overdose, head bang, cut, burn, brand, mark, or otherwise dangerously harm themselves are attempting to find relief from profound psychological pain. The physical injury distracts them from these painful emotions, possibly giving them a feeling of control or providing a means of feeling emotions when they are cut off from them. Scars often remain long after the behavior has stopped (AACAP, 2013). A large study of almost 2,000 adolescents found an 8% rate of self-harm and a reduction in frequency of self-injury with age (7% no longer self-harmed as young adults). Adolescent self-harming behaviors were associated with use of marijuana, alcohol, and cigarettes, as well as higher rates of depression and anxiety symptoms and antisocial

behavior (Moran et al., 2012). One smaller longitudinal study found that over the 2.5 years, data were collected, 18% of 11- to 14-year-olds engaged in nonsuicidal self-injury, with 14% reported as new cases (Hankin & Abela, 2011). This behavior most often begins in early adolescence or late childhood. It can continue into adulthood. It is more common in girls and in those with a family history of suicide, self-injury, or maternal depression. Isolation, neglect, or abuse may predispose an adolescent to this behavior. Depression, poor quality of relationships, excessive seeking of reassurance, and eating disorders are commonly associated with self-injury. PHNs and school nurses can provide education to adolescents and families about this condition and can work with schools to promote prevention strategies, such as early detection and referral to mental health providers.

Violence

The total costs of youth violence (e.g., quality of life, medical costs, lost productivity) are more than $158 billion each year (Hammond & Arias, 2011). The Youth Risk Behavior Surveillance, United States, 2013, indicated that 17.9% of 9th through 12th grade students carried a weapon at least one day within 30 days of the survey and 5.2% of students had carried a weapon such as a gun, knife, or club one day prior to the survey. In 2013, 7.1% of students did not go to school on at least one day prior to the survey because of safety concerns (Kann et al., 2014).

Homicide is the third leading cause of death for adolescents and youth (aged 15 to 24), it is more common in males than females, and in 87% of adolescent cases, it involved the use of a firearm. In 2013, the homicide rate was the lowest it has been since before 1970 at 6.7 deaths per 100,000 (Child Trends Databank, 2015d). The homicide rate among African American male adolescents is 45.0 per 100,000, and for Hispanic males, it is 11.7; it is only 2.2 among White males, indicating a wide disparity (Child Trends Databank, 2015d). Almost 1,580 homicides of school-age youth occurred in the 2008–2009 school year, but only 17 of these occurred on school grounds (Robers, Zhang, & Truman, 2012). In 2011, there were 11 homicides of school-age youth at school (National Center for Injury Prevention and Control, 2015).

Delinquency is thought to peak during middle adolescence—around age 16. The National Institute of Justice (2014) indicates that 40% to 60 % of juvenile offenders no longer participate in or offend by early adulthood. Children assault and kill other children at school and on the streets. Eight percent of high school students reported being injured or threatened with a weapon, such as a gun, knife, or club, on school grounds. Four percent of students (aged 12 to 18) reported victimization during the 6 months prior to the survey, and public school students had twice the rate of those in private schools (Robers et al., 2012).

Gangs are often associated with teen violence. U.S. gangs are now found in communities across the country, with a rise in gang membership to more than 1 million members. Authorities believe that gangs are responsible for up to 85% of crimes and are the primary distributor of most illegal drugs. In 2011, 18% of adolescents (12 to 18 years) indicated that there were gangs present at school. The 2012 National Youth Gang Survey reported an increase in the number of gangs, gang membership, and gang-related homicides (Egley, Howell, & Harris, 2014). Although youth gangs may not effectively manage drug distribution as well as more established, older gangs, they are involved in various forms of violence that often includes intergang conflict (Egley & Howell, 2011). Public schools reported gang activity at 16% in 2009–2010, down from 20% 2 years earlier; but 20% of students reported gang presence at their schools with more high school students than sixth graders noting gangs being present (Robers et al., 2012). Although gang members may engage in violence and intimidation, other instances of school violence have captured

greater media attention. Incidents of high school shootings, such as the one at Columbine High School, have raised concerns among parents and teachers. These high-profile events are rare, but they bring attention to the need for change. School violence has been linked to bullying and the overall school environment and should be addressed quickly. However, the incidence of homicides on school property has actually decreased over the past 15 years (Virginia Youth Violence Project, n.d.). Multiple successful antigang programs have been implemented in communities including Homeboy Industries, Boys Town and SOS Villages, and Open Door Youth Gang Alternatives in an effort to prevent gang activity (National Crime Prevention Council, 2012).

Bullying can result in depression, social anxiety, internalizing and psychosomatic symptoms, loneliness, and poor school performance (Hertz et al., 2015). Daily or weekly bullying incidents were reported by 23% of public schools during the 2009–2010 school year, and 28% of students reported bullying at school; cyberbullying was reported by 6% of students (Robers et al., 2012). The percentage of young adolescents who do not feel safe at school decreased slightly over the past 5 years. In 2013, 17.9% of adolescents reported carrying a weapon to school during the past month (5.5% carried a gun), and more than 24.7% were involved in physical fights in the last year (8.1% on school property). Males were more likely to be involved in carrying weapons and fighting (Kann et al., 2014). Another form of violence found among adolescents and young adults is dating violence (or date rape), and females can also be the perpetrators of this although it is more common among males (Kann et al., 2014).

Cultural and environmental influences on youth include the violence to which children and adolescents are exposed. Increased aggressive behavior among children and teens has been attributed to violence in the environment, the home (spousal and child abuse), and the community, as well as to what children see on television and in movies. The effects of family violence (domestic violence, child maltreatment) can lead to internalizing and externalizing behaviors among youth (Child Trends Databank, 2015b). Personally experiencing violence and witnessing it as a child are risk factors for adolescent behaviors such as school dropout, running away from home, attempting suicide, and delinquency (Child Welfare Information Gateway, 2013). Violence is an increasing threat as students move from elementary school into middle and high school. Ninth grade students reported the highest rate of physical fights in a study of high school students (Robers et al., 2012). However, adolescents who are better connected to school are less likely to engage in violent behaviors. A longitudinal study of early adolescents found links between poor school engagement and delinquency, as well as depression and substance use (Li & Lerner, 2011). School climate is important in reducing the levels of violence in this age group, as is adequate parental support (Sumner et al., 2015). Family cohesion can also be a mediating factor for delinquency as a consequence of childhood effects of violence (Barr et al., 2012; Child Trends Databank, 2015b).

In 1994, with the implementation of the Gun-Free School Act and the Safe and Drug-Free Schools and Communities Act, juvenile crime rate peaked and then decreased over the

next decade. During this time, zero-tolerance policies were implemented in schools in an effort to decrease weapon bearing at schools (Kang-Brown, Trone, Fratello, & Daftery-Kapur, 2013). In 2009–2010, 39% of public schools took serious disciplinary action against youth accused of specific offenses (Robers et al., 2012). Many schools now have metal detectors and security guards, and some schools conduct random searches of students' lockers in an effort to prevent violence. In 2008, the American Psychological Association Zero Tolerance Task Force examined 20 years of research studies and found little evidence of effectiveness and some indication that these policies actually may be worse than ineffective. They noted that these policies actually lead to increased violent and disruptive behavior and higher dropout rates. The task force found that a disproportionate number of Black and Hispanic students were expelled or suspended from school and that zero-tolerance policies do not consider children's lapses in judgment as a normal aspect of development. They recommended adaptations to zero-tolerance policies to make them more flexible and individualized to students, school sites, and situations. Students with disabilities are also disproportionately affected and this type of school discipline is seen as reactive, rather than proactive, and punitive, rather than corrective (Kang-Brown et al., 2013). Research over the past two decades validated concerns regarding the effectiveness of zero-tolerance policies in schools and a more positive approach to discipline has been recommended (Kang-Brown et al. 2013). In 2014, the Obama Administration recommended that zero-tolerance policies be discontinued in schools (Hefling, 2014).

Community efforts, youth development and violence prevention programs, and parenting education have been used to address youth violence, and a multimodal approach is often most effective (Allison, Edmonds, Wilson, Pope, & Farrell, 2011; Child Trends Databank, 2015b). Because family cohesion has been found to be a moderating influence for adolescents who witness community violence, programs that improve parenting practices and promote family cohesion are needed (Barr et al., 2012). Focusing on high-risk youth to improve parenting, peer relationships, academic achievement, and social cognition may be an effective means of preventing adolescent conduct disorder and delinquency (Child Trends Databank, 2015b).

Substance Abuse

Substance abuse among young people was almost unknown before 1950, and rare before 1960, but exploded in the mid-1960s. By 1981, 66% of high school students had ever tried an illicit drug and this dropped to 47% by 2008 (Johnston, O'Malley, Bachman, & Schulenberg, 2009). With the exception of a decrease in tobacco use, substance abuse among adolescents has changed very little over the past decade (Park et al., 2014). Adolescent drug experimentation and use pose serious physical and psychological threats. A national survey of high school students found that nearly 4 out of 10 teens reported drinking alcohol within 30 days before the survey and approximately 2 of 10 students reported binge drinking within the previous 2 weeks. In 2011, 50% of adolescents reported using an illicit drug by their senior year in high school. Forty-six percent of those students report using marijuana at least once. Prescription drug abuse is reported by 22% of 12th grade students and approximately 8% reported ever using inhalants like glue or aerosols (Murphey et al., 2013).

Why do adolescents turn to alcohol or illicit drugs? Substance abuse is one of the greatest threats to adolescent health. There are many influences associated with adolescent substance use including influence and monitoring by parents and guardians, family structure, history of physical abuse and maltreatment, adult example and parental substance use, and teen peer influence. Some research indicates that friend and peer influence becomes an even stronger predictor of substance abuse as a teen ages (Ewing et al., 2015). Depression has also been linked to alcohol and substance use (Fig. 22–7). Increased emphasis on family values is noted to be a protective factor for alcohol use. This includes not only the parenting style of the adolescent's parents but also the parenting influences of the teen's friend's parents (Ewing, et al., 2015; Shikaya, Christakis, & Fowler, 2012).

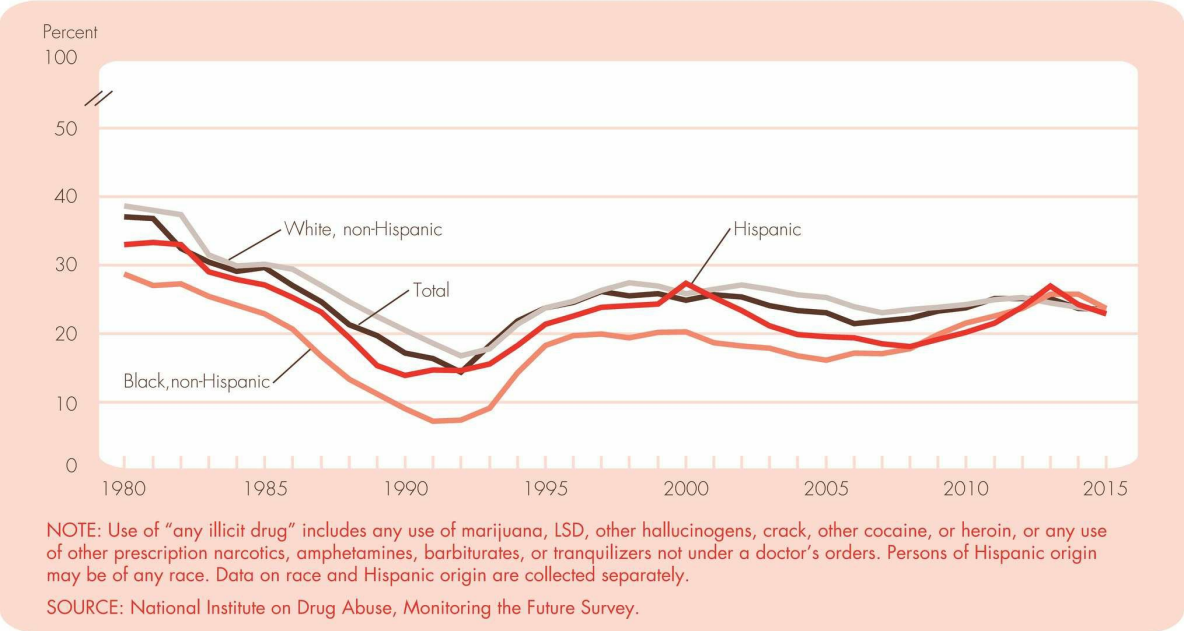

FIGURE 22–7 Percentage of 12th grade students who reported using any illicit drugs in the past 30 days by race and Hispanic origin, 1980–2015. (Retrieved from http://www.childstats.gov/americaschildren/beh_fig.asp.)

Alcohol is the most frequently used substance for U.S. adolescents—it is often their first drug of choice. In one large study, the reasons cited by adolescents for trying alcohol included such things as "to find out what effect it would have," "to have more fun at a party," and "because it was exciting." Teens drinking for the last two reasons were more likely to engage in risky drinking, and those with symptoms of depression were three times more likely to binge drink (Kuntsche & Muller, 2012, p. 34). The teen brain is very susceptible to the damaging effects of alcohol and a number of social, physical, and academic are associated with its use. Early drinkers more often report damaged family relationships, academic problems, problems with concentration and memory, use of other substances, and delinquent behavior in middle and high school. Analysis of national survey data found that adolescents who begin first alcohol use before the age of 13 had significantly more involvement in violent behaviors and suicide attempts than those who delayed the initiation of alcohol (Murphey et al., 2013). Early use of alcohol was found to be a marker for later alcohol and drug dependence (SAMHSA, 2014), and age of alcohol initiation for Whites was earlier than for Blacks and Hispanics and more quickly progressed to alcohol dependence in a recent national survey (Alvanzo et al., 2011). It is important to stress education and prevention in late childhood to delay the initiation of alcohol use.

More than $1.7 billion was spent on alcohol advertising in 2009, and some feel that this influences adolescent drinking (Moreno, 2011; Murphey, Barry, Vaughn, Guzman, & Terzian, 2012). A study regarding brand-specific alcohol advertising and underage alcohol consumption by teens indicates that exposure via advertising was a significant predictor of consumption by the adolescent (Ross et al., 2015). Ross et al. (2015) recommend that

decreased exposure of alcohol brands may be beneficial in decreasing underage consumption of alcohol. Binge drinking is generally defined as having five or more drinks at one time—usually within a couple of hours—and it often increases as adolescents get older (Murphey et al., 2012). Binge drinking has been associated with poor academic achievement and other risk behaviors (e.g., sexual activity, smoking, using illicit drugs, riding with a driver who had been drinking, attempting suicide), and the more adolescents binge drink, the more they engage in risk behaviors (Park et al., 2014). Adolescent binge drinking was associated and parental alcoholism was influential in later adult substance use disorders (Murphey et al., 2012).

Family drinking and perceived family norms related to drinking have been found to affect adolescents' perceptions of the benefits of drinking. This perception, in turn, predicts their drinking behavior (Murphey et al., 2012). Parenting practices (e.g., monitoring, discipline, enforcing rules related to alcohol use) have also been found to have an influence on adolescent drinking behavior (Ewing et al., 2015). Factors prevalent during adolescence, such as divorce, parental trust, social class and relationships, along with depressive symptoms and poor impulse control and self-esteem, were associated with excessive alcohol use in adults (SAMHSA, 2014).

Adolescents who are engaged emotionally and connected to school generally have better outcomes; lower levels of engagement were linked to substance use and delinquency in one longitudinal study (Li & Lerner, 2011). Positive parenting practices such as open communication, monitoring adolescent activities, and teaching methods of self-control have also been associated with a reduction in adolescent alcohol use (Murphey et al., 2012). Family mealtimes have been shown to promote family cohesion and problem- and emotion-focused coping by encouraging parents to help their children feel part of the family and allowing them valuable time to coach them in effective methods for dealing with daily stresses and problems. The benefits of family mealtime include improved self-esteem, improved mental health, decreased alcohol and substance abuse, and decreased depression (Harrison et al., 2015). To promote the health and welfare of adolescent children, it is vital to stress to families with young children the continued importance of family meals throughout adolescence (Fig. 22–8).

FIGURE 22–8 Marijuana use is common among adolescents.

Marijuana is the most commonly used illicit drug among 14- to 17-year-olds—46% of high school seniors reported ever using marijuana. Use of marijuana by early adolescents has remained constant, but middle to late adolescent use has slightly increased since 2009 (Murphey et al., 2013). This is an important finding, because early marijuana use (before age 15) has been associated with a much greater likelihood of adult cocaine and heroin use and drug dependency (Office of National Drug Control Policy, 2012). Marijuana use has negative health effects, including anxiety, panic attacks, increased heart rate, frequent respiratory infections, impaired memory and learning, and tolerance. Regular marijuana smokers often have respiratory complications similar to those of tobacco smokers—cough, phlegm, respiratory infections, and airway obstruction (Office of National Drug Control Policy, 2012).

Inhalant abuse is very common and frequently used by young teens. Inhalant use begins in early adolescence—more 12- and 13-year-olds reported using inhalants than any other illicit drug. The most commonly reported inhalants used were shoe polish, glue or toluene, spray paints, and lighter fluid or gasoline (Johnston, O'Malley, Miech, Bachman, & Schulenberg, 2015). Other inhalants commonly used include amyl nitrite "poppers"; locker room deodorizers or "rush"; cleaning fluid, degreasers, or correction fluid; halothane, ether, or other anesthetics; lacquer thinner or other paint solvents; butane or propane gases; nitrous oxide or "whippets"; and other aerosol sprays (Center for Behavioral Health Statistics and Quality, 2015). Inhalant abuse can result in severe nervous system damage or death. Control of legal products, such as spray paint, lighter fluid, household solvents,

gasoline, and glue, is difficult, making this problem almost impossible to monitor adequately.

Other drugs that are used by adolescents and young adults include "club drugs" such as MDMA (Ecstasy), a synthetic drug with amphetamine and hallucinogenic properties, and its purer form "Molly" often glamorized by singers and musicians; Rohypnol (the date rape drug that is often mixed with alcohol to produce sedative hypnotic effects); ketamine (a rapid-acting anesthetic); lysergic acid diethylamide (LSD), a hallucinogen originally popularized in the 1960s; and gamma-hydroxybutyrate (GHB, a drug that is touted as a synthetic steroid in fitness clubs and that has been associated with sexual assaults). Fentanyl use has been noted in several areas of the country, along with its derivative, acetyl fentanyl, and overdoses have occurred leading to deaths. Rates of use for ketamine, Rohypnol, and GHB have declined over the past few years, but psilocybin or "magic mushrooms" are still widely used. Ecstasy use has generally declined but may become popular again among younger adolescents. Over-the-counter cold and cough medications containing the cough suppressant dextromethorphan are sometimes used to produce a "high," and between 2% and 4.1% of adolescents are reported to have used them (Johnston et al., 2015; Templeton, 2013). Visits to the ED and deaths have occurred from the use of many of these drugs.

Cocaine use has remained steady in recent years, after peaking in the late 1990s. Heroin use fell below peak levels reached in 2001 but continues to remain steady. Smoking or snorting of heroin, which is popular among adolescents and young adults because they mistakenly believe it precludes the strong physical addictiveness of this drug, has been found to lead to injection drug abuse (Johnston et al., 2015). Methamphetamine may be smoked, along with marijuana, or injected. Methamphetamine labs are a public health hazard and can often be found in rural areas. Prolonged exposure to methamphetamine can result in cognitive deficits and psychosis (Chen et al., 2015). PHNs should be aware of this when making home visits in outlying areas.

Another drug used by adolescents is anabolic steroids. The illicit use of anabolic steroids is difficult to monitor; however, 0.6% of 8th graders, 0.8% of 10th graders, and l.5% of 12th graders reported using steroids in a national survey (Johnston et al., 2015). A survey of high school students noted that use was higher in males, especially those participating in sports, and 49% of students believed that athletic performance could be improved with steroid use; 38% thought that use improved appearance (Lorang, Callahan, Cummins, Achar, & Brown, 2011). Some coaches have, at times, turned a blind eye to steroid abuse, but educational campaigns to fight the rising level of abuse in adolescents have led to decreases in use since peak levels were reached in 2000. Adverse effects of illicit steroid use include irritability, increased risk-taking behavior, extreme mood swings, paranoia, jealousy, and euphoria, as well as psychiatric conditions that may be intensified or induced. Because steroids are often readily available through Internet pharmacies, policymakers, health educators, and parents must make adolescents aware of the dangers, such as altered serotonin levels and increased aggression (U.S. Food and Drug Administration [FDA], 2013). A recent study regarding parental communication with

adolescent athletes indicates that discussions should emphasize "protective" health and the social consequences of misusing steroids (Dodge & Clark, 2015).

Adolescents are becoming more involved with prescription drugs, often found in their parents' medicine cabinets, purchased on the Internet, or bought from friends at school (McCabe et al., 2012). Medications are often mixed with alcohol, and adolescents often mistakenly believe prescription medications are safer than street drugs when used to produce a high. Ritalin, prescribed to students with ADHD, may be given or sold to others, but the most commonly used medications are OxyContin, Vicodin, tranquilizers, and sedatives. In 2014, 3.3% of high school seniors tried OxyContin, and 4.8% of high school seniors used Vicodin (Johnston et al., 2015). Although the prevalence rates have decreased, the trend is concerning because of society's nonchalant, casual attitude toward prescription medications and their easy access. Early onset (before age 13) of nonmedical use of prescription medications is a predictor of later prescription drug abuse and drug dependence (Swartz & Bilbo, 2013). A large national survey found the number of adolescents admitting to nonmedical use of prescription drugs remained about the same between 2012 and 2014. Although the most common nonmedical use of a substance was pain medications, sedatives, stimulants, and tranquilizers were also frequently abused. Approximately 655,000 teens between ages 12 and 17 years abused psychotherapeutic drugs during 2014 (Center for Behavioral Health Statistics and Quality, 2015).

POPULATION-FOCUS SUBSTANCE ABUSE PREVENTION FOR ADOLESCENTS

School nursing runs in my family. In the 1980s, when my mother was a school nurse in a small, rural school district located in an agriculturally dependent county, there was only one high school in the small town of about 10,000 people. School personnel were aware of some "keg parties" after football games, and the occasional alcohol-related fight on school property between some of the rougher students, but they were not fully aware of the substance abuse problems. The school psychologist conducted an anonymous survey and found, much to the surprise of teachers and administrators, that most of the teens involved in alcohol and drug abuse were the athletes and cheerleaders. They had assumed that the lower-income, trouble-making kids were much more involved, but this was not necessarily the case. My mother worked with the psychologist to implement health education classes in the high school and eventually the middle school and elementary schools to address this issue

and health promotion in general.

I am a school nurse at a more suburban, larger school district serving over 30,000 students with four high schools, a charter high school and a continuation high school. Each high school has a full-time school nurse, and the middle schools have one most of the week. We utilize evidence-based practice as school nurses, and there are many resources available to us. We are aware of national surveys on substance use among adolescents and have conducted some ourselves (e.g., YRBS) in order to better understand our students' needs. Although alcohol is still a concern, drug use has increased since my mom's school nursing experience. A national survey found that almost 1 in 10 adolescents use some type of illicit drugs (Center for Behavioral Health Statistics and Quality, 2015), and 7.4% are currently using marijuana; this is similar to statistics in 2005. The next concern is illicit use of psychotropic drugs (i.e., prescription-type pain relievers, stimulants, sedatives, and tranquilizers), and 2.6% of 12- to 17-year-olds are currently using these (1.9% use pain relievers, 0.7% use stimulants, 0.2% use sedatives, and 0.4% use tranquilizers). When you consider that 2.5% of the population (over the age 12) use psychotropic prescription drugs either nonmedically or illicitly, you have a clearer picture of the problem.

The district school nurses met with our advisory board, parent groups, school administration, and eventually the school board to discuss the problem and address potential interventions. We discussed our population demographics, our various cultural and ethnic influences, and our community statistics. After examining the best research-based methods, we found that school-based interventions can be effective if they include the following components (Griffin & Botvin, 2010; Lowe, Acevedo, Griffin, & Botvin, et al., 2013):

- Social Resistance Skills—Increasing students' awareness of the social influences around them that encourage substance use and then given them specific skills sets to more effectively withstand media and peer pressures to drink and use drugs or tobacco.
- Normative Education—There is a need to correct teens' misperceptions that "everybody is doing it" and become part of the crowd. Information from national, state, and local surveys are used to demonstrate actual prevalence rates, and data from current research are presented that show substance abuse is not socially acceptable and is a danger.
- Competence Enhancement—Life skills such as problem-solving and decision-making are taught, as well as cognitive skills for resistance of adverse influences (peers, media). Skills are also taught to improve self-esteem and self-control, along with coping strategies to reduce anxiety and relieve stress (e.g., relaxation). Students are also taught assertiveness and social skills. All of these are helpful to the development of adolescents in their everyday experiences, even when not facing pressures to drug experimentation.

Family-focused prevention programs often provide skills to parents (e.g., parenting, helping children develop social resistance skills, monitoring/rule setting). Some programs included children and their families (e.g., improve communication, family functioning, develop family rules on substance abuse/enforcement). These family bonding interventions have been found to be most effective. Community-based prevention programs usually not only include both school-based and family-based intervention components but also encompass mass media campaigns and policy/legislative initiatives, along with other community activities and improvements (e.g., teen-focused recreation). These have also shown promise when they are comprehensive and well coordinated and have broad support of stakeholders (Griffin & Botvin, 2010).

Some programs have shown great promise in addressing nonmedical prescription drug use, along with other substances. *Life Skills Training* was found to be the only school program that, when delivered without family and community interventions or other methods, significantly reduced use of nonmedical prescription drugs in 12th grade comparative to the control group. It was considered the most cost-effective program. When a family-based program, *Strengthening Families*, was added for 6th graders, the results doubled (Crowley, Jones, Coffman, & Greenberg, 2014).

Our school district decided to purchase the Life Skills Training program for elementary, middle, and high school students. They also plan to institute a family-based prevention program for upper elementary students and their parents within the next few years. Population-Focus Substance Abuse Prevention for Adolescents

I hope we can eventually encourage a more community-based approach to population health for our children and adolescents. I feel that with the resources we have today, we can really make a difference in the lives of our students and their families. I know my mother is proud of the work I am doing, and I hope my daughter considers carrying on the family tradition!

Holly, Age 30, School Nurse

relationships between self-management skills and substance use in an urban sample of predominately minority adolescents. Journal of Drug Issues, 43(1), 103–118.

Tobacco products are also easily acquired, often from parents. About $10 billion is spent annually on marketing tobacco products (Koch, 2012). Approximately one in three high school seniors report ever trying a cigarette. In 1997, 25% of 12th graders reported to regular smoking; however, this percentage has been steadily declining, and in 2014, it reached an all-time low of 7% of high school students reporting to daily, regularly smoking (Office of Adolescent Health, 2015). Males almost exclusively use smokeless tobacco products (e.g., snuff, chew), and 8.4% of 12th graders reported using smokeless tobacco during 2014. Electronic cigarettes (e-cigarettes) are becoming increasingly used in the adolescent population. Between the years 2010 and 2014, the number of adolescents reporting that they had used e-cigarettes in the past 30 days increased from 1.5% to 17.2%. Of concern is the unknown long-term effect of e-cigarettes and the possibility that adolescents using e-cigarettes may later use tobacco (Johnston et al., 2015).

Social disapproval and heightened perception of health risks are thought to help contribute to the downward trend of smoking and smokeless tobacco use, along with price increases and advertising bans (Johnston et al., 2015). But tobacco marketing continues to be problematic, as the tobacco industry has joined with convenience stores to more prominently display tobacco products, and even though state and federal taxes comprise about half the cost of a pack of cigarettes, states have not always sufficiently invested these funds in adolescent tobacco prevention (Koch, 2012). One longitudinal study found that adolescents who had low academic aspirations, perceived themselves to be unconventional, and had internalizing behaviors (e.g., depressive symptoms) were less likely to participate in smoking cessation programs. Parental smoking also was a negative influence, and other research demonstrated less effective quit attempts for adolescents with at least one smoking parent (Kong, Carmenga, & Krishnan-Sarin, 2012). Motivational interviewing techniques may be an effective intervention for smoking cessation. This strategy has been shown to be effective when used during in-person counseling and with telephone counseling (Boccio et al., in press; Lindson-Hawley, Thompson, & Begh, 2015). In addition, parental disapproval was related to a greater number of attempts at abstinence for boys but not for girls (Kong et al., 2012).

Primary health care providers do not always question adolescents about smoking, drinking, and use of other substances. Some evidence highlights the effectiveness of brief interventions by health care providers in encouraging smoking cessation and improvement in other risk behaviors. Research recommends that health care professional counseling be provided as a preventive measure to adolescent tobacco users (Schauer, Agaku, King, & Malarcher, 2014). But the long-term effectiveness of this type of intervention was not demonstrated in a Finnish cohort study (Saari, Kentala, & Mattila, 2012). PHNs and community health nurses can provide information to teens about smoking cessation

programs and promote primary prevention by educating children and adolescents to choose not to smoke or engage in other health risk behaviors. They can also encourage physicians and parents to question and monitor adolescents about smoking and the use of tobacco products.

Teen Sexuality and Pregnancy

Teenage pregnancies, sexually transmitted diseases (STDs), and HIV/AIDS are public health concerns associated with the sexual activity of adolescents. In the 2013 YRBS, 46.8% of high school students reported ever having sexual intercourse, and 59.1% used a condom during their last sexual intercourse. Almost 15% reported having had sexual intercourse with four or more persons, and 19.0% used birth control pills to prevent pregnancy (Kann et al., 2014). In 2013, teens (aged 15 to 19) experienced 274,641 pregnancies and those under age 14 had 3,108 pregnancies (Ventura, Hamilton, & Matthews, 2014). Although early sexual debut has been associated with delinquency, as well as with other negative outcomes, a recent study by Butera, Lanza, and Coffman (2014) suggests that more research is needed regarding this effect. Research findings posit that early sex and delinquency may have a common cause (such as family structure and maternal education) and that interventions for early sex prevention "may not be an effective intervention target for reducing rates of adolescent delinquency" (Butera et al., 2014, p. 405). Early puberty has also been related to greater sexual activity and higher rates of delinquency in a large study of 9- to 13-year-olds (Negriff, Susman, & Trickett, 2011).

The United States leads most developed nations in rates of teenage pregnancy, abortion, and childbearing. The teen birth rate in this country declined to its lowest level in 70 years from 1991 to 2009; yet the U.S. rate was six to nine times higher than that of "developed countries with the lowest birth rates" (Pazol et al., 2011, p. 419). Despite a slight increase in 2006–2007, since 1991, pregnancy and birth rates for 15- to 19-year-old girls have declined by 37%. In 2013, the rate was 26.6 births per 1,000 females. The rate for Hispanic adolescent girls was 46.3 per 1,000; for non-Hispanic Blacks, the rate was 43.9 per 1,000. For non-Hispanic Whites, the rate was 20.5 per 1,000. There is a wide discrepancy between states, with rates varying from 13.84 to 47.5, and southern and southwestern states having higher numbers of teen pregnancies and births (Ventura et al., 2014). Some research has indicated that shared social norms about adolescent pregnancy may vary among racial/ethnic groups, and this may account for a larger amount of influence than religious or socioeconomic factors (Mollborn, Domingue, & Boardman, 2011). An examination of state-level characteristics found that those states with higher rates in 1991 and sharper increases through 2007 were more likely to have higher rates of unemployment, unmarried births, violent crime, and a higher proportion of Hispanic and Black residents than lower birth rate states. They were also less likely to have public funding for abortion (Terzian & Moore, 2012). The downward trend for teen birth rates is thought to be associated with a drop in the percentage of students who had sexual intercourse and those having sex without contraception. The use of two forms of birth control (i.e., condoms together with birth control pills or Depo-Provera) increased from 5% to 9% in the decade preceding 2009 (Pazol et al., 2011). The rate of teenage abortion was 17.8 per 1,000 in 2008, the lowest since abortions became legal. This declining trend continued in 2010, when the rate was 14.7 per 1,000. The highest rate was in 1988 at 43.5 (Kost &

Henshaw, 2014). The rate of adolescent fatherhood also declined; between 1991 and 2010, it dropped from 25 to 16 per 1,000 males. Almost half of male teens state they would be very upset if they were responsible for a pregnancy (Guttmacher Institute, 2014).

Teenage pregnancy is associated with increased health risks to both the mother and the child. These risks include increased risk of illness and death, increased risk of mother's death from violence, and increased developmental concerns of the child. In addition, young mothers are more likely to live in poverty and to be delayed in their own education (Medline Plus, 2015). Young mothers are more likely to smoke tobacco and are at high risk of bearing infants with low birth weights. They are also less likely to receive adequate prenatal care or to gain the recommended weight during pregnancy. Adolescent mothers are at a greater risk than mothers over age 20 to experience a complication of pregnancy (e.g., anemia, hypertension, premature labor), and the risk increases for those under age 15 (Wallace & Harville, 2013). Compared with women giving birth at age 30, teen mothers can expect 2 years less education and they are 10% to 12% less likely to finish high school; they are also less likely to attend college (Basch, 2011b). Adolescent girls living with a single parent or not living with either parent have higher teen birth rates than those who live with both parents (Wildsmith, Manlove, Jekielek, Moore, & Mincieli, 2012). The children of adolescent mothers are more likely to exhibit disorganized attachment with the mother, suffer abuse, and show developmental delays. Their mothers also face social, physical, and mental health challenges (Crugnolaa, Ierardia, Gazzottia, & Albizzatib, 2014). Teenage mothers who choose to end their pregnancies by abortion may additionally encounter other physical and psychosocial complications (SmithBattle & Fried, 2016).

By 19 years of age, 71% of males and females have had sexual intercourse. Approximately 16% of teens have had sex by age 15 (Guttmacher Institute, 2014). As such, it would behoove U.S. society to provide effective sexuality education. There is often debate about the virtues of comprehensive versus abstinence-only educational programs. Despite the contentiousness about the subject, in 2006, 87% of private and public schools in the United States required health education, most of it at the high school level. Most adolescents (age 15 to 19) received education about STIs (93%) and abstinence (84%), but about 33% were not instructed about contraception. Many sexually active teens have no instruction on contraception before their first sexual experience (33% girls, 46% boys; Fields, 2012; Guttmacher Institute, 2012). Teaching about contraception has not been shown to increase the risk of adolescent sexual activity or STIs, but it may decrease the risk of pregnancy. Analysis of data from a national survey found that sex education, of any type, when compared to no education was associated with delayed sexual intercourse for both adolescent males and females. When education included instruction in birth control, along with abstinence, adolescents were more likely to use contraception (birth control pills or condom) at first sexual intercourse and less likely to have a much older partner (Lindberg & Maddow-Zimet, 2012). Besides formal education through schools, adolescents note that peers, the media, and parents are also sources of information on sexual health. Between 70% and 79% of teens report talking with a parent about sex, although girls more often

talk with parents about how to say no to sex or use birth control (Guttmacher Institute, 2012, 2014) (Fig. 22–9).

FIGURE 22–9 Pregnancy prevention programs can be helpful in decreasing rates of

adolescent pregnancy.

Pregnancy prevention programs can be effective in reducing teen pregnancy and birth rates, as well as in reducing the number of second births to teenage mothers. A prospective cohort study found that increased levels of sexuality education within schools was associated with decreased teen birth rates, although the reverse was found in some states with higher religiosity and political conservatism (Cavazos-Rehg et al., 2012). Another study comparing the curriculum effectiveness of the comprehensive teen pregnancy prevention (TPP) intervention and the abstinence-only TPP taught in schools indicates that the comprehensive TPP program is slightly more effective than the abstinence intervention. Results were based on adolescent attitudes and perceptions, knowledge-based questions, and behavioral outcomes. Study recommendations include the "need to focus on improving attitudes about sexual activity, especially related to male and female sexuality, peer norms, and refusal skills" (Oman, Merritt, Fluhr, & Williams, 2015, p. 892). Positive youth development (PYD) programs have been found to promote adolescent sexual and reproductive health by focusing on social and cognitive competence, prosocial bonding, future orientation, and self-determination. These programs focus on overall youth development, not just sexuality, and emphasize positive, personal strengths of all adolescents (Geldhof et al., 2014).

Primary care providers often miss opportunities to provide counseling on prevention of pregnancy, HIV, and STDs, as well as other risk factors for unintentional injury (Ozer et al., 2011). Nurses can provide information and counseling on birth control and emergency contraception to adolescent clients and collaborate with schools to promote effective pregnancy prevention programs. It is important for PHNs to provide education and health counseling on these subjects. A recent study by Borawski et al. (2015) demonstrated the importance of nursing collaboration in high school sexual education and counseling, stating "those taught by school nurses reported significant and sustained changes (up to 12 months after intervention) in attitudes, beliefs, and efficacy" (p. 189).

Sexually Transmitted Infections

STI and HIV infections are epidemic among adolescents worldwide (World Health Organization, 2016). More than 20 diseases can be transmitted sexually; only the most common are reportable. Each year, about half of the STI cases occur among the 15- to 24-year-old age group, even though they represent only 25% of the population of sexually active individuals. These diseases include syphilis, gonorrhea, *Chlamydia*, HPV, and herpes simplex virus. Approximately 30 of the 100 known types of HPV strains are sexually transmitted; some of these are related to cervical cancer, and others lead to genital warts. Gardasil, a vaccine effective against some forms of HPV-related disease, can be administered in three doses to 11- to 12-year-old females and now to males as well (Dunne et al., 2011; Guttmacher Institute, 2014).

Chlamydia, gonorrhea, and syphilis are other STDs/STIs found in the adolescent population. Of the 19 million new cases of STIs annually, about half are among adolescents (15 to 24 years old), and 21% of 13- to 24-year-olds in reporting states had a new HIV infection in 2011 (Guttmacher Institute, 2014). In the adolescent population, STIs are more common among those engaging in sexual risk behaviors. In 2013, 46% of high school students reported ever having sexual intercourse and 34% were active within the previous 3 months. Almost 15% had sex with four or more partners, and 59% used a condom with their last sexual contact (Child Trends Databank, 2014b). *Chlamydia* is the most common STI; adolescent girls 15 to 19 years of age had the second highest reported cases of *Chlamydia* and gonorrhea. Adolescent males had a lower prevalence of both *Chlamydia* and gonorrhea (CDC, 2015k).

About one in four adolescent females (aged 15 to 19) have an STI; and the rate for African American girls is 4.9 times the rate for white females (CDC, 2015k). Compared with adults, adolescents (10 to 19 years) and young adults (20 to 24 years) are at increased risk for acquiring STIs. Reasons for this may include a greater likelihood of multiple sex partners, unprotected intercourse, and selection of higher-risk partners, as well as immature biology making them more vulnerable to infection and earlier sexual initiation. Barriers to improvement include lack of health insurance and transportation, concerns about confidentiality, and lack of quality STI prevention services or clinics targeted to younger age groups (CDC, 2015k). Adolescent girls also have a physiologically amplified susceptibility to *Chlamydia* infection because of increased cervical ectopy (CDC, 2014d). Serious complications from STIs include pelvic inflammatory disease (PID), sterility, increased risk of cancers of the reproductive system, and, with syphilis, blindness, mental illness, and death. There are also complications for the unborn children of those infected with STIs. In one study on follow-up for adolescents with STIs diagnosed in EDs, a large number did not receive appropriate treatment. Of those who did, 25% did not realize they had an STI, which put them at risk of avoiding reinfection and nontreatment of sexual partners (Reed & Huppert, 2011).

Even though death rates from HIV/AIDS have dramatically fallen, new HIV infections reported annually do not reflect the same steep decline. It is estimated that as many as 50% of youth with HIV are not aware of their infection (CDC, 2015m). Adolescents and young adults (aged 13 to 24) comprised 26% of all new cases of HIV infection in 2010 and black youth accounted for 57% of the new cases. New medications are thought to be the cause of the declining death rate, whereas new cases are increasing within adolescent and young adult populations. Females, males having sex with other males, injection drug users, and racial minorities have higher rates of STI/HIV during adolescence Also, those experiencing childhood sexual abuse are more at risk for HIV/AIDS risk behaviors as adolescents (CDC, 2015k, 2015m).

As noted earlier, sex education is effective at both delaying the onset of sexual activity and increasing the use of contraception in adolescents who are already sexually active. It is also effective in increasing safer sex practices, knowledge of birth control method efficacy, and overall sexual knowledge when that content is taught (Borawski et al., 2015). Prevention strategies, identified by systematic review of research, found the best strategies to reduce sexual risk behaviors included targeting behaviors that are most easily amenable to change (e.g., condom use, decreased number of sexual partners, abstinence), tailoring programs to the target population (e.g., subgroups such as African American females, gay/bisexual males), using theory as a guide in development of programs (e.g., modeling discussions with partners about condom use, skill building by role-playing situations, increasing self-efficacy), and addressing a broader content than just STI/HIV prevention education (e.g., problem-solving, social skills, gender pride, capacity building). Evidence-based interventions are the most effective (CDC, 2015m). See Chapter 30 for the school nurse's role with STI/HIV.

Acne

About 80% of individuals between the ages of 11 and 30 have acne. Most of these are adolescents, although pediatric acne (ages 7 to 11) cases are growing (Mancini, Baldwin, Eichenfield, Friedlander, & Yan, 2011). The precise cause of acne is not fully understood. It is generally related to several factors. Genetics plays a part (there is often a family history of acne), and hormonal influences are also at play (especially an increase in male hormones), and greasy cosmetics may plug cells of follicles, producing a plug (National Institute of Arthritis and Musculoskeletal and Skin Diseases [NIAMSD], 2014). Acne generally begins during puberty (10 to 12 years of age) with the increase in circulating male hormones that stimulate sebaceous glands in the skin. The excess sebum (oil) causes irritation in the pores and results in a buildup of cells, leading to whiteheads. Open pores are known as blackheads. A red and inflamed pustule can develop or, in serious cases of acne, cysts or nodules can form. Untreated, this can lead to pitting and scarring.

It is now known that greasy foods and chocolate do not cause acne but may be aggravating factors (along with stress, environmental irritants, and certain cosmetics) in susceptible adolescents. Abrasive scrubbing of the skin; pressure from backpacks, tight collars, or sports helmets; and picking or squeezing blemishes may make acne worse (NIAMSD, 2014). Common treatment regimens include skin cleansers, peelers, and medications to decrease sebaceous gland activity. Topical retinoids are the first-line drugs of choice because of their anti-inflammatory properties. Benzoyl peroxide is used to kill bacteria on the skin and in the pores. It may be sold over the counter (OTC) or by prescription. Other OTC medications include salicylic acid and resorcinol. Retin A (a topical vitamin A ointment), glycolic acid, and alpha hydroxy acids help to peel the impacted cells from the pores. Antibiotics (oral or topical), such as tetracycline (Ala-Tet) or doxycycline (Adoxa), may be prescribed to help control bacteria on the skin. Isotretinoin (Accutane) reduces the size and activity of sebaceous glands but can cause liver or kidney dysfunction. Because of an extremely high risk of birth defects, female adolescents taking Accutane are prescribed oral contraceptives; these may also be prescribed for girls not taking this drug who have hormonally influenced acne (NIAMSD, 2014; Ramanathan & Hebert, 2011). Sun sensitivity is another side effect of this medication. Corticosteroids may be injected directly into the comedones. Dapsone gel (Aczone) can be applied twice daily to the face, and some adolescents choose to try complementary therapies such as tea tree oil, aloe vera, or witch hazel, as well as biofeedback and hypnosis (Ramanathan & Hebert, 2011).

The best preventive measures are keeping the skin clean, eating a balanced diet that includes fresh fruits and vegetables, drinking lots of water, and getting adequate sleep. It is important for male adolescents to shave carefully and for all teens with acne to avoid touching their faces or picking at their blemishes. They may want to use skin and hair products that are noncomedogenic. Adolescents with severe acne may need to be referred to dermatologists who specialize in this skin disorder.

Poor Nutrition and Eating Disorders

Poor nutrition and obesity are not uncommon among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. Increased fast-food consumption has been tied to poor diets and the increase in obesity in the United States (Brown et al., 2015). The eating behavior of adolescents is influenced by many things, among them psychosocial factors, family and peers, availability of fast food, and mass media marketing (Brown et al., 2015). Girls are more at risk for problems with nutrition for several reasons: they tend to diet inappropriately, to have more finicky eating habits, and to be less physically active than teenage boys. Boys typically eat large quantities of food, which increases the likelihood of obtaining adequate nutrients, and they also tend to be more physically active than girls. The quality of an adolescent's diet has implications for later health, as evidenced by a study of fruit and vegetable consumption among 13- to 17-year-olds. The beneficial effects of vegetable and fruit intake on inflammatory and oxidative stress markers were already evident in these adolescents, indicating a good basis for future health (Kann et al., 2014). Habitual unhealthy snacking is of concern among the adolescent population. A study by De Vet, Stok, De Wit, and De Ridder (2015) shows promising results for adolescent snacking and suggests that self-regulation strategies may be helpful in curbing an adolescent's habitual unhealthy eating.

Issues with body image and control are at the heart of anorexia nervosa and bulimia nervosa, common problems for adolescent girls. Eating disorders are considered psychiatric conditions, but there is a continuum of altered eating that does not fall within the diagnostic guidelines of an eating disorder (American Dietetic Association, 2011). Anorexia nervosa is an eating disorder with an emotional etiology that is characterized by body image disturbance (i.e., girls see themselves as fat although they may be extremely thin), an intense fear of becoming fat or gaining weight, and refusal to maintain adequate body weight (i.e., BMI of 18 or greater). Bulimia is an eating disorder characterized by recurrent episodes of binge eating with repeated compensatory mechanisms to prevent weight gain, such as vomiting (purging type) and fasting or exercise (nonpurging type). Lifetime prevalence of anorexia nervosa is 0.3%, and bulimia is 0.9% (Swanson, Crow, LeGrange, Swendsen, & Merikangas, 2011).

Binge eating, also a recognized eating disorder, involves recurrent episodes of binge eating without fasting, self-induced vomiting, or other compensatory measures, and lifetime prevalence of this disorder is 1.6% (Swanson et al., 2011). Self-esteem, depressive symptoms, and emotional eating are very sensitive predictors of binge eating, and 34% of adolescents have reported secretive eating (Knatz, Maginot, Story, Neumark-Sztainer, & Boutelle, 2011). Low levels of support from peers can also be linked to binge eating, and binge eating is associated with an increased risk of becoming overweight or obese (Knatz et al., 2011). There is evidence of later onset of eating disorders in males versus females, with a peak in prevalence before age 25 (Michison & Mond, 2015).

These diseases have emotional causes that are often associated with role impairment and other psychiatric conditions, along with suicidality, and pose complex challenges to treatment (Swanson et al., 2011). A review of current research on eating disorders notes how environmental factors (e.g., nutrition, stress) may lead to epigenetic changes that affect the risk of developing an eating disorder (Campbell, Mill, Uher, & Schmidt, 2011). There is some evidence of mother and peer attitudes and behaviors increasing the risk of later escalations of symptoms among adolescents. The transition from adolescence into young adulthood is an important one as "eating disorder risk factors and symptoms increase over time" (Linville, Stice, Gau, & O'Neill, 2011, p. 749). Nutrition education, psychological counseling, and cognitive–behavioral techniques that teach clients how to control stimuli, substitute alternative behaviors, and use positive visualization are all part of treatment; development of a support network is also important. Family and individually based treatments are most often used for severe cases of adolescent eating disorders and have been studied most often. Self-concept is often distorted and self-esteem is low; therefore, activities are initiated to improve the adolescents' feelings about themselves and to bolster their coping mechanisms. Medications (e.g., antidepressants) have been used to treat some adolescents with eating disorders, but there is little evidence of their effectiveness (Lock, 2010).

The key to prevention with girls may be tied to perceptions of their appearance and education about the risks of dieting. One classic study indicated that adolescent girls who were severe dieters were 18 times more likely to develop an eating disorder than those who did not diet. Even moderate dieters were at risk; they were five times more likely to develop an eating disorder. Psychiatric morbidity was also a factor; it increased risk sevenfold. Exercise is seen as a more viable alternative than extreme dieting for adolescents who want to control their weight. Adolescents who use unhealthy and extreme weight-control behaviors (e.g., binge eating, fasting, skipped meals) continue these behaviors into adulthood. This is more common for females, but one third of males reported these behaviors in a recent study (National Association of Anorexia Nervosa and Eating Disorders, 2015; Pedersen, 2011).

HEALTH SERVICES FOR SCHOOL-AGE CHILDREN AND ADOLESCENTS

A number of programs serve the health needs of school-age children and adolescents. Community health nurses play a major and vital role in delivering these services. Such programs fall into three categories that approximate the three practice priorities of community health nursing practice: illness prevention, health protection, and health promotion.

Preventive Health Programs

Among programs to prevent physical illness and other health problems among adolescents are immunizations and TB testing, as well as school- and community-based education and support programs. Private and public counseling programs and other social services are also geared to promote health and prevent illness.

Immunizations and Tuberculosis Testing

PHNs are deeply involved in each of the preventive activities of immunizations and tuberculosis testing. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws are helpful in carrying out these preventive services, but recent survey results reveal that not all adolescents are fully covered. A national immunization survey revealed mixed results for achievement of *Healthy People 2020* goals for adolescent vaccination (80% coverage). Whereas there were significant increases in vaccination rates for hepatitis B, varicella, tetanus/diphtheria/acellular pertussis (Tdap), and meningococcal conjugate vaccine, HPV lagged behind at 57% for females and 35% for males (Schneyer, Yang, & Bocchini, 2015). It is important for adolescents, as well as adults, to get a single dose of Tdap to protect themselves and infants who may be around them from whooping cough. Although pertussis in adolescents or adults often manifests as an upper respiratory infection with a chronic cough, for infants who have not yet been fully immunized, it can lead to serious complications. It is now recommended that all pregnant women receive a Tdap dose with each pregnancy, including adolescents who may have more recently received an update (Schneyer et al., 2015).

In the recent past, adolescents were only given "catch-up" vaccinations (those missed in childhood), except for a tetanus/diphtheria booster. Now, recommended immunizations include Tdap, meningococcal vaccine (MCV4), pneumococcal polysaccharide vaccine (PPV), both hepatitis A and B, influenza vaccine, and HPV vaccine for both boys and girls —along with any missed vaccines, for example, polio and varicella (see Figs. 22–2 and 22–3). Often, school nurses and community health nurses work with nurse volunteers to provide immunization clinics at elementary and middle schools; these are convenient for adolescents and their parents. School-based clinics are also great places to catch adolescents who need updated immunizations. There is some evidence that adolescent vaccinations are becoming more available at retail pharmacies—much like flu shots for older adults (Goad, Taitel, Fensterheim, & Cannon, 2013; Skiles, Cai, English, & Ford, 2011). Researchers note, however, that higher levels of medical and dental health needs are met when children and adolescents have a *medical home* (or regular source of primary care). But only 56.9% of 1- to 17-year-olds did in 2007, and adolescents were less likely than younger children to have a medical home (Strickland, Jones, Ghandour, Kogan, & Newacheck, 2011). Another study, using national data from 2007 to 2008 survey and telephone follow-up, noted 58% of children overall had a medical home, but only 53.4% of those ages 12 to 17 (Aysola, Bitton, Zaslavsky, & Ayanian, 2013).

Although immunization clinics may improve rates of compliance, it is recommended that 11- and 12-year-olds be scheduled for routine health care visits to their physicians, so that immunizations can be administered, checked, and updated. Adolescents who have not had chickenpox and have not received prior vaccination should be given the varicella virus vaccine. Routine visits give the health care provider an opportunity to discuss risk behaviors and health concerns with adolescents and to intervene early as problems arise.

In addition to immunizations required for school entry, many states or local school districts now require TB skin tests for school-age children and adolescents. Children have a much higher risk of disease progression than do adults. Annual testing is often recommended for children and adolescents from high-risk populations (CDC, 2014d). Annual testing is often recommended for children and adolescents from high-risk populations. Targeted TB skin testing identifies adolescents and children at risk for latent TB who could benefit from treatment to prevent progression of the disease. See Chapter 8 for more on TB skin testing. The following questions should be asked to determine risk:

- Was the child born outside the United States? If so, where? (Children born in Asia, Africa, Latin America, and Eastern Europe require TB skin testing.)
- Has the child traveled outside the United States? If so, where and with whom? (If child stayed with friends/family in Latin America, Asia, Africa, or Eastern Europe for 1 week or more, TB skin testing should be done.)
- Has the child been exposed to anyone with TB? Who? Did contact person have active or latent TB? When was child exposed and what was the nature of contact? (Notify the local health department if the child had contact with a person having TB.)
- Does the child have close contact with a person who had a positive TB skin test? (Other questions may relate to contact with persons who have HIV, have been in jail or shelters, or are injection drug users; or if the child ingested raw milk/products? Does the child live in a household with members who were born or traveled outside the United States?)
- Positive skin tests for children and adolescents have three cutoff points (CDC, 2014c):
    - Induration ≥5 mm (if child has close contact with known or suspected TB, if child or adolescent is suspected of having TB disease, if child or adolescent's immune system is suppressed).
    - Induration ≥10 mm (if child or adolescent is at an increased risk of disseminated disease or if child or adolescent has been exposed to cases of TB disease).
    - Induration ≥15 mm (if child is 4 years old or older and has no known risk factors).

Education and Social Services

The health education of school-age children and adolescents includes a wide variety of approaches and can range from the basics of handwashing for elementary school students (Lecky et al., 2011) to hearing conservation for students who like to listen to loud music (Blood & Blood, 2011).

Parental support services are commonly available through many public and private agencies, including churches. These services can have long-range effects on the health of school-age children, because emotionally healthy parents and stable families offer a healthful environment and support system for children and can facilitate their progress in school. In most states, community health nurses provide teaching and counseling services to parents in their homes and in groups. School nurses, school mental health counselors, and school psychologists also organize parent support groups in local schools. This is particularly important during periods of transition (e.g., from elementary to middle school, from middle to high school). Discussing parenting concerns and increasing parents' understanding of normal child growth and development help to allay fears and prevent problems. Through such efforts, family violence and abuse can be averted. Reduction in rates of divorce and the attendant consequences may also be a benefit of strengthening family resilience.

Family planning programs, often stationed strategically in inner cities, near schools, or in school-based clinics, provide birth control information and counseling to young people. In some communities, the school-based clinic dispenses condoms. In many states, adolescents have the right to consent for sexual and reproductive health care without parental permission. It is important that health care providers be aware of local and regional options for counseling (Society for Adolescent Health and Medicine, 2014). PHNs, in collaboration with an interdisciplinary team, are usually the primary care providers in these programs. Their major goals are to prevent teenage pregnancy, educate teens about reproduction and contraception, and encourage responsible sexual behavior. Teaching parents about adolescent sexuality is important, as parents can influence their child's sexual behavior (Dittus et al., 2015). A review of studies examining caregiver-targeted interventions that address adolescent risk/protective behaviors noted that personal contact targeting parents and other caregivers leads to effective improvements in adolescent health (Burrus et al., 2012; Dittus et al., 2015). Other forms of contact were not as effective (e.g., Internet), but person-to- person interventions were the most effective.

Providing STI services and HIV/AIDS education can be a daunting task. Many young people with STIs are often afraid or embarrassed to seek help, and others who have been exposed to the HIV virus may not know that they are infected. Gay and bisexual young men are particularly at risk, as are youth who have been sexually abused. Furthermore, community health professionals receive very little training in these areas and may be uncomfortable and judgmental in their approaches. Quality services that are easily accessible, provide anonymity for clients, are age appropriate or targeted to adolescents, and are staffed with health care providers who exhibit nonjudgmental attitudes are better able to attract young people who need help (Borawski et al., 2015). Some argue that drastic

changes in the provision of services to young people are needed to effect change, as adolescents often feel more comfortable when services are targeted to them rather than the general population.

Vulnerable groups, particularly minority youth, inner-city residents, incarcerated youth, and LGBT adolescents, may be best reached at targeted sites (e.g., STD clinics, HIV testing sites in clinics and health departments, family planning clinics, private health care providers, schools, juvenile rehabilitation facilities, employers). PHNs are available in most of these settings; they are usually the professionals who deal most directly with these clients. An open, matter-of-fact, yet respectful, demeanor is helpful in reaching adolescents and establishing rapport and trust with them. This is especially helpful when dealing with sexual issues. Youth asset development programs, mentioned in Chapter 11, have been shown to reduce health risk behaviors, including sexual risk-taking (CDC, 2015k). Improved public awareness and education, screening of high-risk groups, appropriate treatment of infected people, and identification and treatment of sexual partners can reduce the threat of STIs (Fig. 22–10).

FIGURE 22–10 Children and adolescents can be influenced by adults' smoking in the home.

PHNs should educate parents about the effects of smoking in the home and its relationship to adolescent smoking. A national survey on tobacco use among youth found

that smoking at home was associated with current smoking across all of adolescence, whereas smoking decreased as adolescents moved from early to middle stages in relationship to peer smoking influences (Villanti, Boulay, & Juon, 2011). Media campaigns for tobacco use prevention have been successful, as have some school-based education programs. In 2014, the U.S. Federal Drug Administration (FDA) launched the first national antitobacco campaign targeting youth (U. S. Food and Drug Administration, FDA, 2014). Targeted smoking cessation messages from peers that emphasized benefits of quitting were the most effective for adolescents in one evaluative study (Latimer et al., 2012). Social marketing campaigns to decrease alcohol, drug, and tobacco use have also shown some effectiveness among adolescents (Jones, 2014). It is essential that PHNs work with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay the use of tobacco products. Information on smoking cessation and resources to help prevent tobacco use by children and adolescents is available through the Foundation for a Smokefree America.

Health Protection Programs

Safety and Injury Prevention

Accident- and injury-control programs serve a critical role in protecting the lives of school-age children and adolescents. They are cost-effective: seat belt laws, child safety seats, and helmet laws have saved millions of dollars in medical care. Efforts to prevent motor vehicle accidents, a major cause of death, include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into what causes various types of crashes. Injury prevention and reduction have been addressed through strategies such as state laws requiring the use of safety restraints, installation of driver and front passenger airbags, substitution of other modes of travel (air, rail, or bus), lower speed limits, stricter enforcement of drunk driving laws, graduated drivers licenses (GDLs) for teenagers, safer automobile design, and helmets for motorcyclists, bicycle riders, and skaters. Although adolescents may have negative attitudes toward GDLs and learner supervision requirements, these have been effective in reducing deaths and injuries (Brookland & Begg, 2011).

In developing interventions, community health nurses need to recognize that adolescents are prone to risk-taking/novelty-seeking behaviors as a result of their cognitive, physical, and psychosocial developmental stage (Johnson & Jones, 2011). Students Against Drunk Driving (SADD) and Friday Night Live activities can promote more responsible driving habits among teens. Communities can also work with law enforcement officials to ensure compliance with mandatory seat belt laws and to promote safe speeds and appropriate driving behaviors near schools.

Safety programs also seek to protect school-age children and adolescents from the hazards of poisonings, ingestion of prescription or OTC drugs, product-related accidents (unsafe toys, bicycles, skateboards, skates, playground equipment, and furniture), and recreational accidents, including drowning and sports-related injuries. Safety services assume various forms. Poison control centers in many localities offer information and emergency assistance. Whereas the federal Consumer Product Safety Commission monitors the safety of products, education programs in schools or through local fire or police departments teach school-age children about bicycle and water safety, fire dangers, and hazards related to poisoning. Generally, the community health nurse can educate families to recognize potentially hazardous situations and encourage efforts to eliminate them. Working with school nurses and school district officials to reduce playground hazards can contribute to the reduction of school-related injuries.

Environmental hazards and other dangers await school-age children and adolescents in the workforce. There were approximately 18.1 million workers under age 24 in 2013, and 357 workers under age 24 died from a work-related injury in 2012. Hospitals treated almost 800,000 work-related injuries that occurred to adolescent workers between 1998 and 2007, almost twice the rate for workers over age 25. One *Healthy People 2020* objective

seeks to reduce the number of ED-treated occupational injuries among 15- to 19-year-olds (CDC, 2015l). Because teens often work in restaurants where floors can be slippery and kitchen equipment can be hazardous, they have a higher frequency of workplace injuries. The federal government notes that fatal occupational injuries among adolescents are most often in the service sector (32%), construction (28%), wholesale/retail trade (10%), and agriculture (10%). The highest death rates in mining, agriculture, and construction were among younger workers (Estes, Jackson, & Castillo, 2010). Public health nurses can join with occupational health nurses and school nurses to teach parents and children about the dangers and risks inherent in the workplace, and they can work with local employers to ensure safe working conditions and reasonable hours of employment that do not interfere with school. One study noted that 17- and 18-year-old students working an average of 14.7 hours weekly who experienced lack of adequate sleep, psychological distress, and higher physical work had greater levels of fatigue (Laberge et al., 2011).

Infectious Diseases

Programs that protect school-age children and adolescents against infectious diseases encompass such efforts as closing swimming pools that have unsafe bacteria counts, conducting immunization campaigns in conjunction with influenza or measles outbreaks, and working with hospital pediatric units to reduce the incidence and threat of iatrogenic disease. Prevention of community-acquired MRSA is a new challenge for public schools, and PHNs may work with school nurses or others to provide educational programs covering a variety of infectious diseases. Epidemiologic investigations, especially with school sports teams, may be necessary to determine the cause of outbreaks (Fritz et al., 2012).

Child Protective Services

In 1974, the National Center for Child Abuse and Neglect was established as a result of the Child Abuse Prevention and Treatment Act. The center collects and analyzes information on child abuse and neglect, serves as an information clearinghouse, publishes educational materials on the subject, offers technical assistance, and conducts research into the problem (Administration on Children and Families [ACF], 2015a).

In 2013, an estimated 3.5 million referrals were made alleging child abuse and/or neglect of approximately 6.4 million children. Over 60% of these referrals were screened and almost 3.2 million cases had Child Protective Services (CPS) responses. Over 679,000 cases of child abuse or neglect were substantiated (ACF, 2015b). Most victims suffered from neglect (79.5%), approximately 18% were physically abused, and 9% were sexually abused. There were 2.04 deaths per 100,000 children, and 73.9% of children were under age 3. More than 70% of deaths were attributed to neglect or a combination of neglect and another form of maltreatment. Nearly 50% of deaths were attributed to physical abuse or a combination of physical abuse and another form of maltreatment. Most perpetrators of child abuse and maltreatment—more than 80%—were biological parents. Fathers or male caretakers are most often perceived to be perpetrators for physical abuse fatalities; mothers

are more often thought to be associated with deaths stemming from neglect (Child Welfare Information Gateway, 2015). Consequences for affected children include lower self-esteem, depression, suicide, self-abuse, substance abuse, eating disorders, less empathy for others, antisocial behavior, delinquency, aggression, violence, low academic achievement, and sexual maladjustment. Long-term emotional, social, cognitive, and physical consequences are well documented and often follow abused children into adolescence and adulthood—posttraumatic stress disorder, poor attachment and problems with trust, difficulties with language development and abstract reasoning, high-risk health behaviors, and abusive or violent behavior (Child Welfare Information Gateway, 2013). These findings were first noted in a large-scale, landmark research study, the Adverse Childhood Experiences study (Felitti et al., 1998).

Neglectful families are generally profiled as having high levels of problems among adults, reports of stressful life events, and a higher incidence of maternal depression, and these families often live at or below the poverty level. Children and adolescents who are raised in blended homes (where one parent is not their biologic parent) are at greater risk of physical or sexual abuse (Friedman & Billick, 2015). Adolescents who run away, act out at school, commit illegal acts, or engage in high-risk behaviors (e.g., drug abuse, sexual promiscuity) may be exhibiting externalizing behaviors in response to years of abuse and neglect (Child Welfare Information Gateway, 2013; Felitti et al., 1998). Young adults who have been arrested for general or violent offenses and those who use illicit drugs are more likely to have been abused or neglected in adolescence (Sumner et al., 2015).

The average lifetime cost per child nonfatal victim of maltreatment is estimated in 2010 at $210,012, and for each child death, it is $1,272,900 including the loss of productivity (Fang, Brown, Florence, & Mercy, 2012). Services to protect children from abuse are not as well-developed or as effective as safety and injury protection programs, for a variety of reasons. Most child abuse occurs in the home, so only the most blatant situations become evident to outsiders. Child social workers are also often unable to assess recurrent risk of child maltreatment. A wish to avoid legal involvement keeps others from reporting suspected cases, although this attitude is changing among professionals who work with children and other community members (Sumner et al., 2015). Teachers (17.5%), legal and law enforcement personnel (17.5%), social services staff (11.5%), and medical personnel (9%) were the highest reporters of child abuse in 2013; others reporting maltreatment include friends, neighbors, relatives (18.6%), and anonymous reporters (19.8%; Child Welfare Information Gateway, 2015).

In some areas, PHNs are working together with social workers, mental health workers, and substance abuse counselors as part of a team that provides services to families. Improved training of mandated reporters, such as teachers and physicians, has led to better reporting of abuse; as professionals and the public become more aware of the problem, an increase in reporting has occurred. Child abuse prevention education programs can be found in many public health departments and through some school districts as a primary preventive intervention. Primary prevention of child maltreatment can also occur through

home visiting programs utilizing PHNs. These visits can also help to connect high-risk families to the community and promote better child outcomes (Miller, 2015).

Families often have many time constraints that can lead to difficulties in providing adequate social support and sufficient opportunities for teaching children socialization skills and appropriate methods of coping with stress. Family stressors can cause parental conflict and lead to disruptions in parent–child relationships. Outcomes for children are worse when these situations occur early in childhood and continue for longer periods of time. Programs that target at-risk families, especially adolescent mothers and young couples prone to partner violence or harsh parenting practices, may help to prevent later child abuse. PHNs, school nurses, and other nurses working in the community setting must be vigilant for signs of family stress, harsh parenting practices, family violence, and other risk factors for child abuse and neglect and provide resources and respite as needed (Miller, 2015; Sumner et al., 2015). Home visiting programs such as the Nurse Family Partnership Program are showing promising and far-reaching effects for families at risk for child maltreatment. Projected outcomes include decreases in infant deaths, child maltreatment, violent crimes, and youth substance abuse (Miller, 2015).

Child death review teams are found at state and local levels and, through their work, improvements in interagency collaboration, procurement of more comprehensive data sets, and identification of gaps in CPS have led to better services for families and prosecution of abusers, along with improvements in child protective and other community supportive services (Keleher & Arledge, 2011).

Oral Hygiene and Dental Care

School-based programs that provide fluoride rinses and dental sealants and promote toothbrushing and nutrition education for dental health can be found in most areas of the country. Fluoridation of community water supplies is considered the most effective, safe, and low-cost means of protecting the dental health of children and adolescents. Fluoridation of drinking water, school-provided fluoride rinse or gel, and dental sealant programs are cost-effective and can reduce dental caries (CDC, 2015j; FCFS, 2015e).

Fluoride makes teeth less susceptible to decay by increasing the resistance of tooth enamel to the bacterially produced acid in the mouth. Since 1945, public water supplies have been fluoridated at relatively low cost to communities. Water fluoridation has been ranked as one of the 10 greatest public health achievements of the 20th century (Division of Oral Health, 2012).

Some individuals and groups oppose fluoridation because of possible adverse effects (including fluorosis, which can cause mottling of tooth enamel). Research results have been mixed, although most studies have supported the low risk of water fluoridation and the benefits of decreased caries. In the United States, because of children's potential for multiple exposures to fluoride through drinking water, processed foods and beverages, toothpaste, gels, and rinses, physicians may prescribe lower doses of fluoride supplements or

deem that they are not needed (American Academy of Pediatrics, n.d.). Although most dental care is focused on children, adolescents remain in need of dental health services. In addition to regular dental care, good nutrition, and proper oral hygiene, PHNs can promote public water fluoridation as an important program for protecting children's dental health. Nurses can also recommend that parents talk with their primary health care provider and dentist about fluoride varnish or supplements (CDC, 2015h).

Health Promotion Programs: Nutrition and Exercise

Nutrition and weight-control programs form another important set of health promotion services. Children need to learn sound dietary habits early in life to establish healthy lifelong patterns. Being overweight during childhood or adolescence may persist into adulthood and may increase the risk for some chronic diseases later in life (Dixon et al., 2012; Nadeau et al., 2011). Some school programs teach and provide good nutrition and encourage eating patterns that prevent obesity (USDA, 2015). A number of weight-control programs for overweight children and adolescents are available through schools, health departments, community health centers, health maintenance organizations, and private groups.

Children and adolescents are particularly vulnerable to media and peer pressures with regard to their food choices. Because of increased rates of childhood obesity and a greater awareness of the need for better nutrition in adolescence, legislative support to limit soft drink sales at public schools is growing. Parents and children are becoming more aware of the need to cut consumption of saturated fat, salt, sugar, and overprocessed foods and increase fruit and vegetable consumption in order to feel and look better. The community health nurse, through nutrition education and reinforcement of positive practices, plays a significant role in promoting the health of children.

SUMMARY

Physical health and illness, developmental issues, schooling, behaviors, and emotional and mental problems are major concerns for all Americans and especially for U.S. school-age and adolescent populations. Children and adolescents are important population groups to community health nurses, because their physical and emotional health can affect not only their academic achievement but also the future of society. This population particularly needs the guidance and direction that can be provided by community health nurses. Among the health problems that affect learning and achievement in school-age children are chronic diseases, such as asthma, autism, and diabetes; behavioral and learning problems, such as ADHD and learning and other disabilities; poverty; injuries; communicable diseases, such as measles and mumps; and dietary problems involving inadequate nutrition, obesity, inactivity, and poor dental health.

One nationwide measure to prevent communicable diseases is the federally and state-mandated immunization program for school-age children and adolescents. Among vaccines given on schedule throughout childhood are those that prevent polio, smallpox, diphtheria, tetanus, typhoid, and many other diseases, so that these diseases will not be passed from one person to another in epidemic proportion.

Mortality rates for children and adolescents have decreased dramatically since the early 1900s, but morbidity rates remain high. Children and adolescents are vulnerable to many illnesses, injuries, and emotional problems, often as a result of a complex and stressful environment. Violence against children and deaths because of homicide occur in the United States at alarming rates. Unintentional injuries, suicide, and homicide are the leading threats to life and health for adolescents. Other health problems include alcohol and drug abuse, unplanned pregnancies, STIs and HIV/AIDS, and poor nutrition. All of these problems create major challenges for the community health nurse who seeks to prevent illness and injury among children and adolescents and to promote their health.

Among the objectives for children and adolescents proposed by *Healthy People 2020*, some key goals are reduction of alcohol-related unintentional injuries; declines in violent behaviors, suicide, and mental health issues; and more responsible reproductive health behaviors. Barriers to achieving these goals vary. Some include economic inequities; lack of sufficient immunization, educational, and community-supported health programs; and the presence of risk behaviors typical among developing youth. Community health nurses play a large role in promoting the health of young people, their families, and communities through education programs and by developing strategies to support healthy growth and development and prevent risky behaviors that lead to injury, teen pregnancy, and sometimes death.

Health services for children and adolescents span three categories: prevention, health protection, and health promotion. The community health nurse plays a vital role in each. Preventive services may include immunization programs, parental support services, family

planning programs, services for those with STIs, and alcohol and drug abuse prevention programs. Health protection services often include accident and injury control, programs to reduce environmental hazards and control infectious diseases, and services to protect children and adolescents from child abuse and neglect. Health promotion services may include programs in nutrition and weight control, along with HIV/AIDS prevention, and smoking, alcohol, and drug abuse education. PHNs are integral to the health and well-being of children and adolescents, through their work with families, schools, and other community agencies.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. You are a community health nurse assigned to work at a school. You learn that more than 20% of the students in this school district are receiving Ritalin, Adderall, or some other medication for treating ADHD. What issues should you consider in determining whether these medications are being appropriately prescribed?
2. What is the major cause of death among younger school-age children? Adolescents? What community-wide interventions could be initiated to prevent these deaths? Select one intervention for children and one for adolescents and describe how you and a group of community health professionals might develop effective preventive measures.
3. A 14-year-old girl from a middle-class family and a 14-year-old girl from a poor family both come to the health department clinic where you work. The girls have similar symptoms that suggest gonorrhea. Would your assessment and intervention be the same for the two girls? What are your values and attitudes toward people with infections that are sexually transmitted? Does social class, race, age, or sex make any difference in how you feel about them? What is one action the community health nurse can take to prevent such infections in this population group?
4. Discuss possible methods of doing nutritional assessments in school-age children and adolescents. What programs could be instituted to encourage healthier diets and increased exercise? What other factors might need to be considered? How could you, as a community health nurse, work with schools and parents to increase physical activity and improve nutrition for school-age children and adolescents?
5. A new elementary school to which you have been assigned has repeated outbreaks of head lice and very limited access to health care. Search the Web for research into the causes for recurrent head lice infestations and effective over-the-counter treatment products. Are "no-nit" policies effective? Why or why not? Discuss possible education programs you might implement or other innovative methods of treatment and control you might be able to institute.
6. Your school district allows personal exemptions for vaccination (i.e., parents can refuse to get mandatory vaccinations for their children based upon personal, not solely religious, beliefs). You have been informed by the public health department that there is a measles epidemic in your county. What actions will you need to take in regard to these unvaccinated children and their families? What are your feelings and attitudes about personal exemptions?

23 CHAPTER

Adult Women and Men

"Male and female represent the two sides of the great radical dualism. But in fact, they are perpetually passing into one another. Fluid hardens to solid, and solid rushes to fluid. There is no wholly masculine man, no purely feminine woman."

—*Margaret Fuller* (1810–1850), Woman in the Nineteenth Century, 1845

KEY TERMS

Adult
Anorexia nervosa
Binge eating
Bioidentical hormone therapy
Bisexual
Bulimia nervosa
Cancer
Cardiovascular disease
Chronic fatigue and immune dysfunction syndrome/myalgic encephalomyelitis
Chronic lower respiratory disease
Diabetes mellitus
Erectile dysfunction
Genitourinary syndrome of menopause (GSM)
Health disparities
Health literacy
Hormone replacement therapy (HRT)
Life expectancy
Menopause
Obesity
Osteoporosis
Prostate
Substance use
Transgender
Unintentional injuries

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify key demographic characteristics of women and men throughout the adult life span.
- Provide a health profile of adult women and men living in the United States.
- Discuss the major chronic illnesses found in adult women and men in the United States.
- Compare and contrast the manifestations of chronic illnesses in adult women and men.

- Identify primary, secondary, and tertiary health promotion activities designed to improve the health of women and men.
- Describe the role of the community health nurse in promoting the health of adult women and men across the life span.

The term *adult* has many different meanings in society. To children, an adult is anyone in authority, including a 14-year-old babysitter. As people age, they tend to redefine the term upward. It is not unusual, for example, to hear an elderly person describe a couple in their mid-30s as "kids." The U.S. Criminal Justice System distinguishes between adults and juveniles for purposes of delimiting types of crimes and possibilities for punishment, and labor legislation provides different protections for children than for adult workers. Even hospitals and health care systems vary somewhat as to the ages at which they distinguish pediatric and geriatric clients from middle-aged adults.

How would you characterize an adult? Does your definition rest solely on age or is it influenced by other factors, such as marital status, employment status, financial independence, amount of responsibility for self and others, and so on? For the purposes of this chapter, an adult is defined as anyone 18 years of age or older. Obviously, there are tremendous differences in health profiles and health care needs as people age. As adults enter their middle years (35 to 65), they experience many normal physiologic changes. However, some changes are the result of disease, environment, or lifestyle and can be modified through behavior change (Fig. 23–1).

FIGURE 23–1Health care needs for men and women of varying ages are often different.

Throughout history, the health care needs of women and men have differed more often than shown similarities. Many health promotion and health protection programs are designed specifically for women or for men. Mammography screening programs and prenatal clinics are designed with women's health in mind. Teaching testicular self-examination (TSE) and prostate cancer screening are health promotion programs for men. Programs in many areas, such as cardiac rehabilitation, stress management, and dating violence prevention, may have had one gender in mind at one time but are now established as programs for both genders. Nevertheless, morbidity and mortality statistics, historical development of research foci, and workforce changes require that health care needs of women and men be examined separately. This chapter focuses on the health of women and

men across the adult life span. A physical profile of middle-aged adults is organized by body systems and can be found in Display 23–1.

DISPLAY 23.1 PHYSICAL PROFILE OF MIDDLE-AGED ADULTS BY BODY SYSTEM

Body System	Physical Characteristic
Skeletal system	Intervertebral disks flatten over time.
Integumentary system	Decreased secretions by sebaceous glands lead to drier skin. Sweat glands diminish in size and number. Skin loses elasticity and is more prone to wrinkles. Hair bulbs lose melanin usually resulting in gray hair by age 50.
Muscular system	Muscle fibers decrease by approximately 10%. Lean body mass is replaced by adipose tissue. Decreased grip strength occurs at this age.
Endocrine and reproductive system	Menses stops. Synthesis of estrogen decreases. Tissues of the reproductive system (e.g., cervix and uterus) gradually atrophy. Uterine changes make pregnancy less likely. Intercourse may be more painful because of diminishing natural lubrications. Less frequent erections Testosterone levels decline gradually.
Neurologic system	Nerve impulses are conducted 5% slower. Cognition is unaffected, although there is a gradual loss of neurons. Eyesight is poorer because of loss of elasticity in the lens. Auditory discrimination of certain tones and consonants gradually decreases.
Cardiovascular system	By age 50, the heart's efficiency may be only 80%. Elasticity of heart and blood vessels decreases. Cardiac output decreases.
Respiratory system	Elasticity of lungs decreases. Breathing capacity decreases to 75% because of diminished strength of chest wall muscles.
Urinary system	Decreased glomerular filtration rate appears in women. Loss of bladder tone and tissue atrophy may lead to incontinence or possibly prolapse. In men, an enlarged prostate may result in nocturia or dribbling.

Demographics of Adult Women and Men

Examining mortality statistics provides key information to understanding changes in the health and well-being of a population. In 2012, a total of 2,543,279 people died in the United States. The age-adjusted death rate was 732.8 per 100,000 for all ages (Murphy, Kochanek, Xu, & Heron, 2015). Causes of death varied by age, gender, and ethnicity, but the 10 leading causes of death for all people in rank order included the following:

1. Diseases of the heart (heart disease)	599,711
2. Malignant neoplasms (cancer)	582,623
3. Chronic lower respiratory diseases (CLRDs)	143,489
4. Cerebrovascular diseases (stroke)	128,546
5. Accidents (unintentional injuries)	127,729
6. Alzheimer's disease	83,637
7. Diabetes mellitus (diabetes)	73,932
8. Influenza and pneumonia	50,636
9. Nephritis, nephritic syndrome, and nephrosis (kidney disease)	45,622
10. Intentional self-harm (suicide)	40,600

Diseases of the heart and malignant neoplasms accounted for 46.5% of deaths in 2012, and these diseases are the top two causes of death for both women and men. Differences include the following:

- Cerebrovascular diseases (stroke) were the third leading cause of death for women.
- Unintentional injuries (accidents) were the third leading cause of death in men (Murphy et al., 2015).

In 2012, deaths because of four causes increased significantly: intentional self-harm (suicide) by 2.7%, unintentional harm (accidents) by 1.1%, malignant neoplasms (cancer) by 1.0%, and diseases of the heart (heart disease) by 0.5%. Deaths from influenza and pneumonia and Alzheimer's disease decreased significantly, 5.9% and 1.6%, respectively (Heron, 2015).

Since the beginning of the 21st century, the major causes of death have remained fairly consistent. This was a major shift from the turn of the 20th century, when communicable

diseases, such as tuberculosis and pneumonia, were leading causes of death. The shift from communicable to chronic illness can be attributed to the significant advances in public health, prevention, technology, pharmacotherapy, and biomedical research. See Chapters 1 and 7.

Life Expectancy

Life expectancy is the average number of years that an individual member of a specific cohort (usually a single birth year) is projected to live. It is another standard measurement used to compare the health status of various populations, typically calculated from age-specific death rates. Health statistics often report life expectancy figures at birth, at 65 and 75 years of age (see Table 23–1).

Table 23–1 Life Expectancy at Birth and 65 Years of Age According to Sex: United States, Selected Years, 1900–2013

	At Birth			At 65 Years		
Year	Both Sexes	Male	Female	Both Sexes	Male	Female
1900	47.3	46.3	48.3	—	—	—
1950	68.2	65.6	71.1	13.9	12.8	15.0
1960	69.7	66.6	73.1	14.4	12.9	15.9
1970	70.8	67.1	74.7	15.2	13.1	17.1
1980	73.7	70.0	77.4	16.5	14.2	18.4
1990	75.4	71.8	78.8	17.3	15.2	19.1
2000	76.8	74.1	79.3	17.7	16.1	19.1
2010	78.7	76.2	81.0	91.1	17.7	20.3
2013	78.8	76.4	81.2	19.3	17.9	20.5

—, data not available.

Extracted from National Center for Health Statistics (NCHS). (2015). Health, United States 2014. Retrieved from http://www.cdc.gov/nchs/data/hus/hus14.pdf

In the United States, life expectancy has increased consistently over time. Between 1990 and 2013, life expectancy at birth increased 4.6 years for men and 2.4 years for women. The gap between men and women narrowed from 6.8 years in 1990 to 4.8 years in 2013. There are, however, differences in the life expectancy between Whites and Blacks for both genders. In 2013, life expectancy at birth for White males was 4.4 years greater than Black males, and White females' life expectancy was 2.8 years greater than Black females (National Center for Health Statistics [NCHS], 2015a).

Globally, life expectancy in the United States trails that of many countries (Table 23–2). Japan reports the highest life expectancy for males and females. In all countries, disparities exist between male and female life expectancy, some as much as 6.7 years. The smallest disparity can be found between women and men living in Iceland, at 2.7 years (NCHS, 2015a).

Table 23–2 Life Expectancy at Birth for Selected Countries by Sex, 2012

	Female	Male	Disparity
Japan	86.4	79.9	6.5
France	85.4	78.7	6.7
Switzerland	84.9	80.6	4.3
Spain	85.5	79.5	6.0
Australia	84.3	79.9	4.4
Iceland	84.3	81.6	2.7
Germany	83.3	78.6	4.7
Greece	83.4	78.0	5.4
Korea	84.6	77.9	6.7
United States	80.4	75.4	5.0

Health Disparities

One of the goals of *Healthy People 2020* is to eliminate health disparities. A health disparity is defined as a difference in health status that occurs by gender, race/ethnicity, education or income, disability, geographic location, or sexual orientation (U.S. Department of Health and Human Services [USDHHS], 2015). Disparities in health occur when one segment of the population has a higher incidence of disease or mortality rate than another or when survival rates are less for one group than another (Meyer, Yoon, & Kaufmann, 2013). Often, persons with the greatest health burden have the least access to health care services, adequate health care providers, information, communication technologies, and supporting social services. Interdisciplinary, collaborative, public, and private approaches as well as public–private partnerships are needed to develop strategies to address the health disparity goal of *Healthy People 2020*. Chapter 25 discusses health disparities in more detail.

Health Literacy

Health literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health-related decisions. The ability to read and understand health information is key to managing health problems. Low health literacy contributes to health disparities and has been documented as an increasing problem among certain racial and ethnic groups, non–English-speaking populations, and persons over 65 years of age in the United States (American Medical Association, 1999; Beauchamp et al., 2015; Weiss, 2014). See Chapters 1 and 11 for additional information on health literacy.

Major Health Problems of Adults

Morbidity and mortality among adults vary substantially by age, gender, and race/ethnicity. Several leading causes of death are presented in this section. Heart disease is the first leading cause of death in adults and is presented along with stroke. Malignant neoplasms, chronic lower respiratory diseases (CLRDs), unintentional injuries, and diabetes mellitus are among the top 10 leading causes of death and are discussed separately. Other selected major causes of death are covered in detail in other chapters: suicide (Chapter 27), Alzheimer's disease (Chapter 24), and homicide (Chapters 17 and 20).

Coronary Heart Disease and Stroke

Over the last three decades, cardiovascular mortality in the United States has declined by about 50%. These gains are attributed to increased use of evidence-based medical therapies for secondary prevention and reduction in risk factors associated with lifestyle and environment. Despite these gains, 31.3% of all deaths in the United States are still due to cardiovascular disease (CVD). Currently, an estimated 85.6 million adults (>1 in 3) are living with one or more types of CVD and over half of these individuals are 60 years of age or older. It is estimated that every 34 seconds, an American will have a coronary event and every 60 seconds, someone dies from a heart-related disease. By 2030, researchers predict that 43.9% of the population will have some form of CVD (Centers for Disease Control and Prevention [CDC], 2015a; Mozaffarian et al., 2015; Patel, Winkel, Ali, Narayan, & Mehta, 2015) (Fig. 23–2).

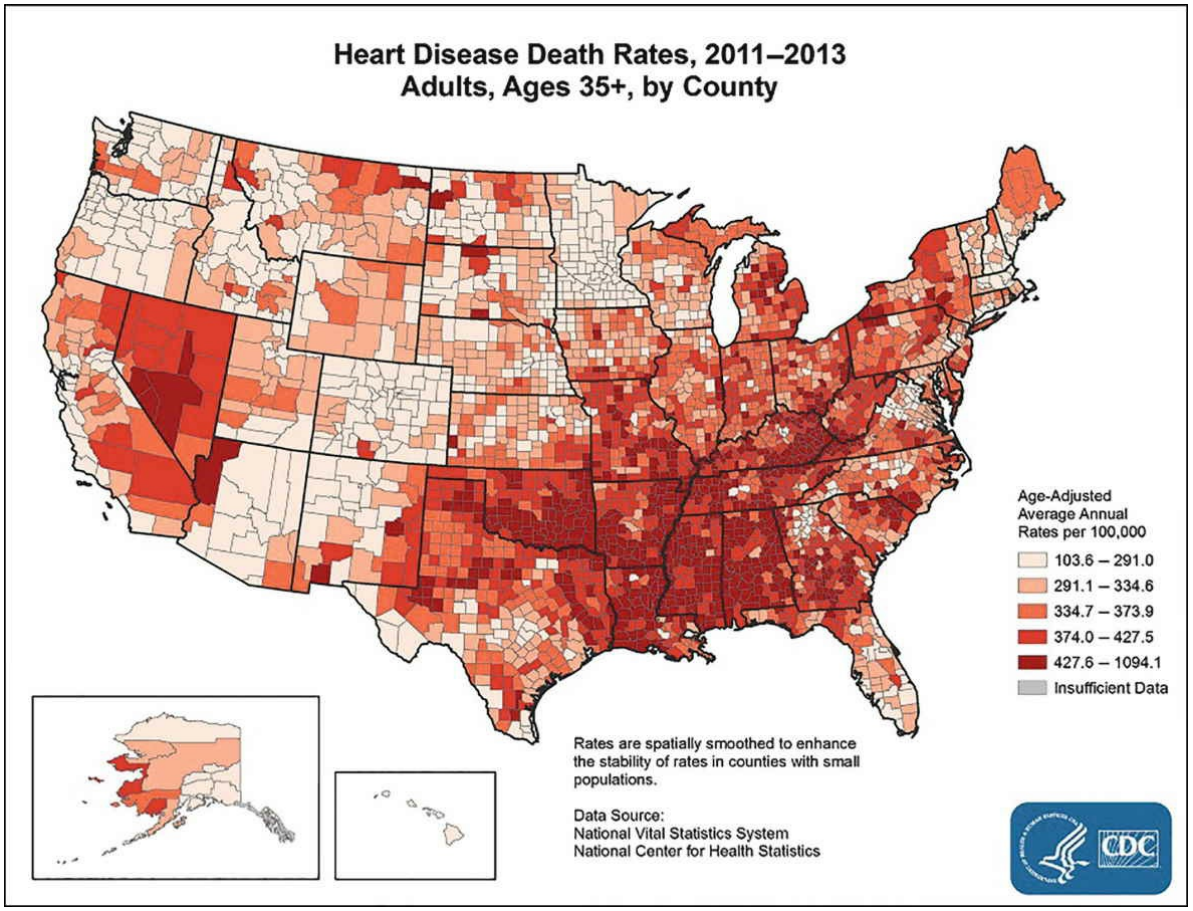

FIGURE 23–2 Heart disease death rates, 2011 to 2013 adults ages 35+ by county. (Retrieved from http://www.cdc.gov/dhdsp/maps/national_maps/hd_all.htm)

CVD and stroke are responsible for 15% of total national health expenditures. Annually, this represents $320.1 billion for direct and indirect costs. The direct costs ($195.6 billion) include expenditures for physicians and other health care professionals,

hospital services, prescribed medications, and home health care, but not the cost of nursing home care. The indirect costs ($124.5 billion) include lost productivity attributed to premature CVD and stroke morality (CDC, 2015a; Mozaffarian et al., 2015).

Through ongoing research, we now know that CVD affects more women than men, but there are also race/ethnicity disparities in heart disease that we are still discovering. For example, Black and Hispanic/Latino women are at a higher risk of death from heart disease, yet they are less likely to recognize their risks. The overall death rate in 2009 from CVD was 236.1 per 100,000 persons, but death rates among Black females and males in the same year were higher than the general population, (267.9 and 387.0, respectively). In addition, Blacks are twice as likely to have a first stroke and much more likely to die from one compared to Whites (Graham, 2014; Singh, Hu, Wheeler, & Hall, 2015).

Just like the general population, CVD is the leading cause of death among Hispanics/Latinos living in the United States. However, most studies on prevalence and incidence of CVD in Hispanics/Latinos have primarily included Mexicans. Recent estimates indicate that the prevalence of CVD is 33.4% for Mexican males and 30.7% for Mexican females. This is lower than the overall prevalence among Whites (36.6% males and 32.4% females) and Blacks (44.4% males and 48.9% females), but the lack of data from other Hispanic/Latino groups (Puerto Ricans, Central and South Americans) does not allow for an accurate prevalence rate of CVD among this population (Graham, 2014; Rodriguez et al., 2014).

Asian Americans are a rapidly growing racial/ ethnic group in the United States, but understanding CVD among this population is distorted by the aggregation of subgroups (Asian Indians, Chinese, Filipinos, Japanese, Koreans, and Vietnamese) in epidemiological reports. Limited data suggest that some subgroups may be at higher risk for CVD compared to others (de Souza & Anand, 2014). Based on available data, it appears that CVD causes more deaths for Asian Americans than all forms of cancer combined. The estimated prevalence of coronary heart disease (CHD) in Asian and Pacific Islanders is 4.3% compared to 6.4% of the total U.S. population (American Heart Association [AHA], 2013a; Graham, 2014; Jose et al., 2014).

Unfortunately, in the United States, racial/ethnic minority populations encounter more barriers to CVD diagnosis and care, receive lower-quality treatment, and experience worse health outcomes. Such disparities are linked to complex factors such as income and education, genetic and physiological factors, access to care, and communication barriers. To tackle inequalities in CVD morbidity and mortality, actions that focus on the social determinants of health are needed. This includes development and implementation of health and social policy interventions that improve access to and quality of health care services and a reduction in poverty and unemployment (Graham, 2014; Singh, Siapush, Azuline, & Williams, 2015).

Risk factors contributing to CVD can be separated into two categories: personal and hereditary. Personal risk factors include gender, age, race/ethnicity, cholesterol levels,

diabetes, obesity, physical inactivity, high blood pressure (BP), and cigarette smoking. The most modifiable of these factors are cholesterol, high BP, cigarette smoking, obesity, and physical inactivity. Heredity obviously cannot be changed. About half of all Americans (47%) have at least one of the three key risk factors for heart disease: high BP, high cholesterol, and cigarette smoking. The likelihood of heart disease or stroke multiplies with the increasing number of risk factors present (CDC, 2015b; Patel et al., 2015) (Table 23–3).

Table 23–3 Primary Risk Factors for Coronary Heart Disease and Symptoms of Heart Attack in Adults

Risks	Symptoms
• Age	• Pain: chest, neck, jaw, arm, shoulders, upper part of abdomen, or back
• Gender	• Chest: pressure, squeezing, or fullness
• Heredity (includes race/ethnicity)	• Shortness of breath
• Cigarette smoking	• Cold sweat
• Sedentary lifestyle	• Nausea and vomiting
• Excess body weight	• Light-headedness or sudden dizziness
• Hypertension	• Feeling unusually tired without cause
• Diabetes mellitus, HbA1C	
• Hyperlipidemia	
• Stress

Stroke ranks fourth among all causes of death in the United States and is a leading cause of serious physical and cognitive long-term disability in adults. Approximately

795,000 Americans experience a new or recurrent stroke each year—610,000 of these are first attacks and 185,000 are recurrent attacks. On average, someone in the United States has a stroke every 40 seconds. Disparities exist among people who are at risk for having a stroke. For example, women have a higher lifetime risk of having stroke as compared to men, with approximately 55,000 more women than men experiencing a stroke each year. Risk of having a first stroke is nearly twice as high for Blacks than Whites, and Blacks are more likely to die following a stroke as compared to their White counterparts. The risk for stroke among Hispanics/Latinos falls between that of Whites and Blacks. In the southeastern United States (the "Stroke Belt"), stroke death rates are higher than in any other part of the country (see Fig. 23–3). Strokes cost the United States about $34 billion each year. This total includes the cost of health care services, medications, and missed days of work (CDC, 2015c; Mozaffarian et al., 2015).

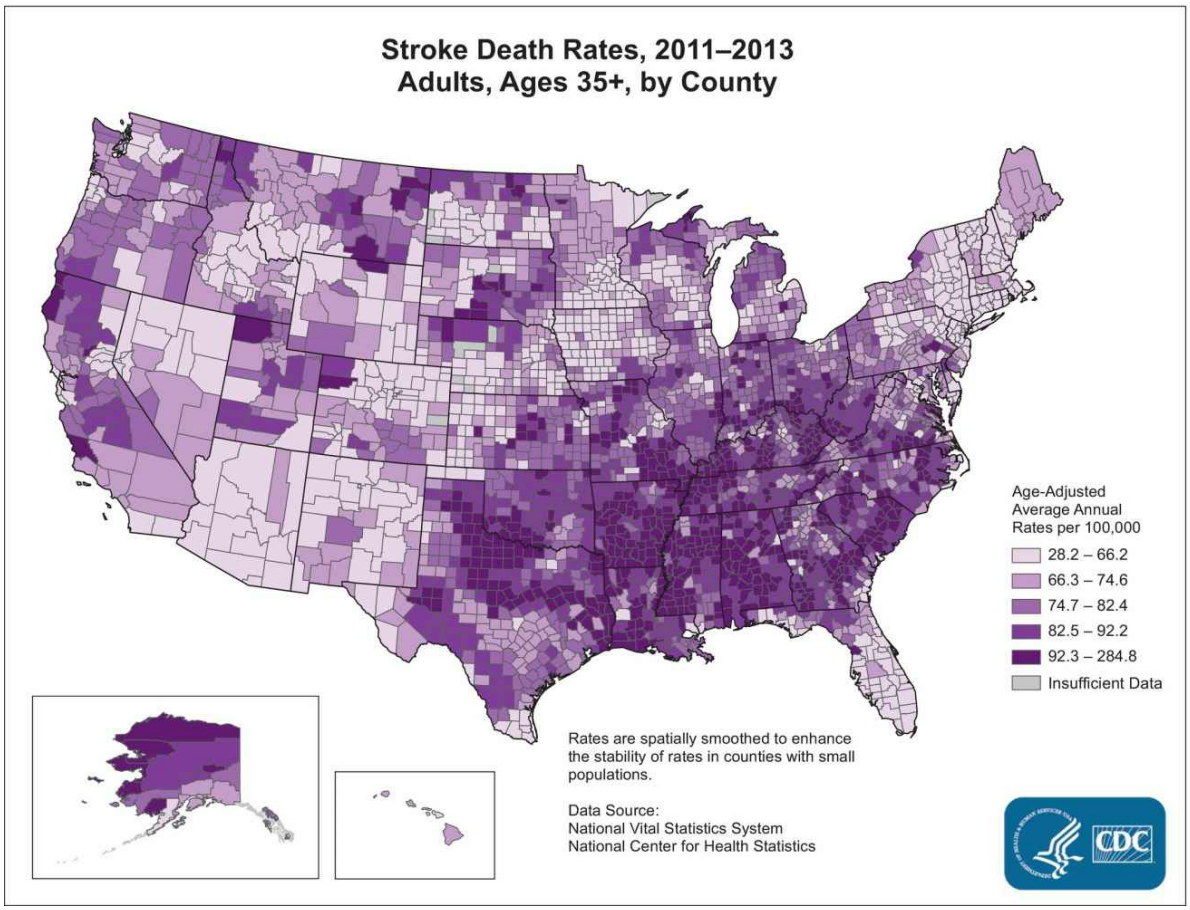

FIGURE 23–3 Stroke death rates, 2011 to 2013 adults ages 35+ by county. (Retrieved from http://www.cdc.gov/dhdsp/maps/national_maps/stroke_all.htm)

EVIDENCE-BASED PRACTICE

Landmark Research on Cardiovascular Disease

The hallmark Framingham Heart Study identified major risk characteristics associated with the development of CVD and the effects of related factors such as blood triglycerides, gender, and psychosocial issues. The study began in 1948 under the direction of National Heart Institute, now known as the National Heart, Lung, and Blood Institute (NHLBI). At that time, the death rates from CVD were rising, but little was known about the general causes of heart disease and stroke. The Framingham Heart Study researchers recruited 2,336 men and 2,873 women between the ages of 30 and 62 in an effort to identify common factors or characteristics that contribute to CVD. All participants lived in the town of Framingham, Massachusetts. Every 2 years, these individuals were scheduled for an extensive medical history, physical examination, and laboratory tests. In 1971, the study enrolled 5,124 of the original participants' adult children and their spouses (offspring cohort) (NHLBI, 2015).

In an effort to reflect the changing demographics that occurred in the town of Framingham since the original cohort was enrolled, researchers implemented a new study in 1994. This study included individuals of Black, Hispanic/Latino, Asian, Indian, Pacific Islander, and Native American origin (Omni cohort). In 2002, a third generation (the children of the offspring cohort) was recruited and a second group of Omni participants was enrolled in 2003. Over the last several years, investigators expanded their research into the role of genetics and CVD. Between 1950 and 2015, a total of 3,093 research articles have been published in peer-reviewed medical journals. Fortunately, findings from the Framingham Heart Study will continue to make important scientific contributions about the causes and treatment of CVD and related health issues (NHLBI, 2015).

Cancer

Cancer is a major chronic illness and the second leading cause of death in the United States (Murphy, Xu, & Kochanek, 2013). The National Cancer Institute's (NCI) Surveillance, Epidemiology, and End Stage Program (SEER) estimated that in 2012, there were approximately 13.7 million Americans living with cancer. It is estimated that in 2015, 1,658,370 new cancer cases will be diagnosed and, of these cases, 589,430 persons are expected to die. Approximately 78% of all cancers are diagnosed in persons 55 years of age and older, and as individuals age, they are more likely to develop cancer. Among ethnic groups, Blacks are more likely to develop and die from cancer. Over their lifetime, men living in the United States are more likely to develop cancer than women. The Agency for Healthcare Research and Quality (AHRQ) estimated the total expenditures for cancer in 2011 at $88.7 billion (American Cancer Society [ACS], 2015a; SEER, 2015).

Cancer is caused by internal and external factors. External factors include tobacco and alcohol use, chemicals, radiation, infectious organisms, and poor lifestyle choices. Internal factors are inherited gene mutations, hormones, immune conditions, and gene mutations that occur from metabolism. These factors can occur in isolation or together to initiate illness. However, only a small percentage of cancers are hereditary. The ACS estimates that in 2015, cancer deaths caused by tobacco use will reach 171,000 and one third of cancer cases will be related to overweight or obesity, physical inactivity, and/or poor nutrition. Screenings can reduce the cancer mortality rate, especially malignancies associated with the breast, colon, rectum, cervix, and lung (ACS, 2015a).

Lung cancer is the number one cause of cancer deaths among adults. An estimated 158,040 or 27% of all cancer deaths in 2015 will be attributed to lung cancer (ACS, 2015a). Overall, death rates have been declining for both men (since 1991) and women (since 2003). Cigarette smoking is the predominant risk factor for lung cancer. Quantity of cigarettes smoked and the number of years a person smoked both increase an individual's risk of developing lung cancer. Other risk factors include occupational or environmental exposure to secondhand smoke, radon, asbestos, genetic susceptibility (disease at an early age), and a history of tuberculosis. Current efforts to reduce mortality by early detection have been unsuccessful. Early detection of lung cancer by chest x-ray, analysis of cells in sputum, and fiberoptic examination of the bronchial passages has shown limited effectiveness in reducing lung cancer deaths. However, low-dose spiral computed tomography (CT) scans and molecular markers in sputum have produced more promising results in detecting lung cancers at an earlier stage of the disease (ACS, 2015a; U.S. Preventive Services Task Force, 2014a).

Colon and rectal cancers are the third most common cancers in adults. Among adults, an estimated 93,090 cases of colon and 39,610 cases of rectal cancers are expected to occur in 2015 and result in 49,700 deaths. The risk of developing colorectal cancer increases with age, and 90% of all cases are diagnosed in individuals 50 years of age or older. There are

several modifiable factors associated with the increased risk of colorectal cancer. These factors include obesity, physical inactivity, a diet high in red or processed meat, alcohol consumption, long-term smoking, and low intake of whole grains, fruits, and vegetables. Other risk factors include certain inherited genetic mutations, personal or family history of polyps or colorectal cancer, and personal history of chronic inflammatory bowel disease. Screening for colon and rectal cancer should begin at age 50 for men and women who are at average risk (ACS, 2015a; see Display 23–2).

DISPLAY 23.2 SCREENINGS AND CHECKUP SCHEDULE FOR WOMEN AND MEN

	When?	Ages 20–39	Ages 40–49	Age 50+
Physical Exam: Performed to review overall health status. Have a thorough physical examination and discuss health-related concerns and topics.	Every 3 years	X		
	Every 2 years		X	
	Every year			X
Blood Pressure: High blood pressure can have no symptoms but can cause permanent damage to body organs and systems.	Every year	X	X	X
Blood Tests and Urinalysis: Screens for various illnesses and diseases, such as cholesterol, kidney, or thyroid disorders, before problems or symptoms occur.	Every 3 years	X		
	Every 2 years		X	
	Every year			X
Electrocardiogram (EKG): EKG screens for heart abnormalities.	Baseline–age 30	X		
	Every 2 years		X	
	Every year			X
Immunizations				
Tetanus and diphtheria booster (plus 1-time booster of pertussis—Tdap)	Every 10 years	X	X	X
Flu vaccine	Every year	X	X	X

Pneumonia vaccine: Administered earlier if there is a history of diabetes, sickle cell, HIV/AIDS, pulmonary, cardiovascular, or liver disease	Age 65			X
Zoster vaccine	Age 60			X
HPV: Discuss with your health care provider.		X		
Rectal Exam: Screens for hemorrhoids, lower rectal problems, colon, and prostate cancer	Every year	X	X	X
Prostate-Specific Antigen (PSA) Blood Test: PSA is produced by the prostate. Levels increase when there is an infection, enlargement, or cancer. Testing should be done in collaboration with your health care provider.	Every year			X
Clinical Breast Exam (Women): Breast exam by health care provider	As recommended by health care provider			
Mammography (Women): Screening should begin at age 50 unless recommended sooner by health care provider.	Every 2 years			X
Pelvic Exam: A pelvic exam is performed to evaluate the size and position of the vagina, cervix, uterus, fallopian tubes, and ovaries.	Every year beginning at age 21 (unless sexually active at an earlier age)	X	X	X
Pap Test: A Pap test is performed to look for changes in the cells of the cervix, such as dysplasia or cancer.	Every 3 years	X	X	X
Self-Exams: *Testicles* are examined to find lumps. *Skin* is checked to look for signs of changing moles, freckles, or early skin cancer.	Monthly	X	X	X
Oral to look for cancerous lesions in the mouth.				
Fecal Occult Blood Test: Screens the stool for microscopic amounts of blood that can be the first indication of polyps or colon cancer	Every year			X
Colon Rectal Health: A flexible endoscope is used to examine the rectum, sigmoid, and descending colon for cancer at its earliest stages. The exam also detects polyps that can progress to cancer if not found early. Or, colonoscopy every 10 years starting at age 50	Every 5 years			X
Lung: Current or former smokers ages 55–74 in good health with at least 30 pack-year history should consider having a low-dose helical CT scan.	Discuss with health care provider			X
Hepatitis C: Get screened once if born between 1945 and 1965, ever injected drugs, or received a blood transfusion before 1992.	Discuss with health care provider			
TB Test: Should be done on occasion of exposure or suggestive symptoms at the direction of the health care provider. Some occupations may require more frequent testing for public health indications.	Every 5 years	X	X	X

Chronic Lower Respiratory Diseases

Chronic lower respiratory disease (CLRD) comprises three major conditions: chronic bronchitis, emphysema, and asthma. CLRD is the third leading cause of death in the United States. The term chronic obstructive pulmonary disease (COPD) includes emphysema and chronic bronchitis. COPD is a major cause of disability, and over 11 million adults in the United States (aged 18 and over) are estimated to have the disease. However, approximately 24 million adults in the United States demonstrate evidence of impaired lung function, which could indicate an underdiagnosis of COPD (American Lung Association [ALA], 2015a; Guarascio, Ray, Finch, & Self, 2013). By 2020, the annual cost of medical care for adults living with COPD will be more than $49 billion. Medicare and Medicaid pay for the majority of national health care costs related to this disease, 51% and 25%, respectively. On average, total costs incurred by COPD patients are approximately $6,000 higher than non-COPD patients (CDC, 2014a; Ford et al., 2015).

Cigarette smoking is the major risk factor for developing COPD, accounting for 85% to 90% of cases. Pipe, cigar, and other types of tobacco smoke also can cause COPD, especially if the smoke is inhaled. The remaining COPD cases are attributable to environmental exposures and genetic factors (ALA, 2015b). Since 2000, the number of women dying from COPD has surpassed the number of men. This rise is probably related to the increase in smoking among women after World War II and the difference in how cigarette smoke is metabolized by women as compared to men. Women are also more vulnerable to lung damage from cigarette smoke and other pollutants because their lungs are smaller, and research has found that estrogen plays a role in worsening the disease (ALA, 2013a).

People of all ages can develop chronic bronchitis, but it occurs more frequently in people who are 45 years of age or older. Many adults who develop chronic bronchitis are smokers and women are more than twice as likely as men to be diagnosed with the disease. Contact with dust, chemical fumes, and vapors from certain jobs also increase the risk for developing chronic bronchitis. Examples include jobs in coal mining, textile manufacturing, grain handling, and livestock farming; work in nail salons has also been associated with respiratory and neurological effects (ALA, 2013b; CDC, 2014e; Halldin, Doney, & Hnizdo, 2015).

The exact cause of asthma is unknown, but research indicates that both genetic and environmental factors contribute to its cause. In the United States, approximately 18.9 million adults have been diagnosed with asthma. Among adults, the prevalence rate is highest among 18- to 24-year-olds (10.3%) and lowest among adults 65 years of age or older (8.1%). The prevalence of asthma is higher in women (10.7%) than men (6.5%), respectively. When compared with White adults (8.7%), higher rates of asthma occur in multiracial (15.1%) and Black (10.8%) adults. Approximately one in three adults miss at least 1 day of work because of asthma (ALA, 2015c; CDC, 2013a).

Unintentional Injuries

Unintentional injuries refer to any injury that results from unintended exposure to physical agents, including heat, mechanical energy, chemicals, or electricity. They are the fifth leading cause of death overall and the leading cause of death for persons 44 years of age and younger. The top three causes of unintentional injuries include motor vehicle crashes, poisoning, and falls. Approximately 193,000 Americans die from injury each year —one person every 3 minutes. However, millions of other people are injured every year and survive. These individuals are often left to face lifelong mental, physical, and financial problems (CDC, 2015d, 2015e) (Fig. 23–4).

FIGURE 23–4Unintentional injuries are the leading cause of death for those aged 44 years and younger.

In 2013, 3 million people were hospitalized due to injuries and 27 million were treated in emergency departments. The costs associated with fatal injuries were $214 billion, whereas nonfatal injury costs were over $457 billion. Males account for the majority of fatal injury costs (78%, $166.7 billion), as well as nonfatal injury costs (63%, $287.5 billion; CDC, 2015d, 2015e; Florence, Simon, Haegerich, Luo, & Zhou, 2015).

Mortality from unintentional injuries in the United States based on age includes the

following:

- Unintentional poisoning is the leading cause of death among persons 25 to 64 years of age and younger.
- Motor vehicle accident is the leading cause of death among persons 15 to 24 years of age and second among persons 25 years of age and older.
- Firearm suicide is the third leading cause of death among persons 35 years of age and older.
- Firearm homicide is the third leading cause among persons 25 to 34 years of age.
- Unintentional falls are the leading cause of death among persons 65 years of age and older (CDC, 2015f).

Drugs, both pharmaceutical and illicit, cause the vast majority of poisoning deaths in the United States. From 2000 to 2013, the age-adjusted drug-poisoning death rate more than doubled, from 6.2 to 13.8 per 100,000. Of the 43,982 deaths because of drug poisoning in 2013, 81% were unintentional, 12% were suicides, and 6% were of undetermined intent. Opioid analgesic pain relievers are involved in a substantial number of drug-poisoning deaths. These include natural and semisynthetic opioid analgesics such hydrocodone, morphine, and oxycodone. Synthetic opioid analgesics that contribute to drug-poisoning mortality are fentanyl and methadone (NCHS, 2015b). See Chapter 27 for more on substance use.

In 2012, there were 22,912 motor vehicle–related fatalities and over 2.5 million emergency department visits for motor vehicle crash–related injuries. Approximately 7.5% of the persons who came to the emergency department were admitted to the hospital because of their injuries. The average lifetime medical cost per treated and released patient was $3,362, whereas a hospitalized patient's average lifetime cost was $56,674. The lifetime cost of work loss because of motor vehicle crash injuries was $9.4 billion for treated and released patients and $23.5 billion for hospitalized patients (Bergen et al., 2014).

Despite increasing traffic on highways, motor vehicle crash injuries have declined almost 25% between 2004 and 2013. This decline is due to improvement in vehicle and road designs, seat belt laws, ignition interlocks to prevent alcohol-impaired driving, publicized sobriety checkpoints, and graduated driver licensing systems for teens (Dischinger, Ryb, Kufera, & Ho, 2013; National Highway Traffic Safety Association, 2014).

A *disabling injury* is one that results in restriction of normal activities of daily living (ADLs) beyond the day on which the injury occurred. Disabling injuries occur disproportionately among the young and the elderly. Seat belts, helmets, smoke detectors, and poison control centers save billions of dollars in direct and indirect medical costs. These primary and secondary prevention strategies save lives and money. See Chapter 26 for more on those living with disabilities and chronic illness.

An *unsafe condition* is any environmental factor, either social or physical, that increases

the likelihood of an unintentional injury. An icy walkway is an example of an unsafe condition; although it poses a hazard, it does not cause an injury but makes it more likely that an injury will occur. *Injury prevention* and *injury control* refer to any effort to prevent injuries or lessen their severity. These efforts often focus on assessment of the environment for unsafe conditions, such as loaded guns in the home or asbestos in school buildings and workplaces (Li & Baker, 2014).

Diabetes Mellitus

Diabetes mellitus is the seventh leading cause of death in the United States. According to the CDC, over 29 million Americans have type 1 or type 2 diabetes (CDC, 2015g; see Fig. 23–3). Diabetes affects 12.3% of Americans 20 years of age and older and 25.9% of Americans 65 years of age and older. Among individuals 20 years of age and older with diabetes (diagnosed and undiagnosed), 13.4 million (11.2%) are women and 15.5 million (13.6%) are men (see Table 23–4). After adjusting for population age differences, minorities continue to have higher rates of diabetes. Among individuals 20 years of age or older, 7.1% of Whites, 8.4% of Asian Americans, 12.8% of Hispanics, 13.2% of Blacks, and 15.9% of Native Americans were diagnosed with diabetes between 2010 and 2012. In 2012, there were 1.7 million new cases of diabetes diagnosed in people 20 years of age and older (CDC, 2015g; CDC, 2015h) (Fig. 23–5).

Table 23–4 Diagnosed and Undiagnosed Diabetes Among People Ages 20 Years or Older, United States, 2012

Group	Number or Percentage Who Have Diabetes
Ages 20 y or older	28.9 million, or 12.3%, of all people in this age group
Ages 65 y or older	11.2 million, or 25.9%, of all people in this age group
Men	15.5 million, or 13.6%, of all men ages 20 y or older
Women	13.4 million, or 11.2%, of all women ages 20 y or older

Extracted from Centers for Disease Control and Prevention (CDC). (2015). National diabetes statistics report: Estimates of diabetes and its burden in the United States, 2014. Atlanta, GA: U.S. Department of Health and Human Services; 2014. Retrieved from http://www.cdc.gov/diabetes/pubs/statsreport14/national-diabetes-report-web.pdf

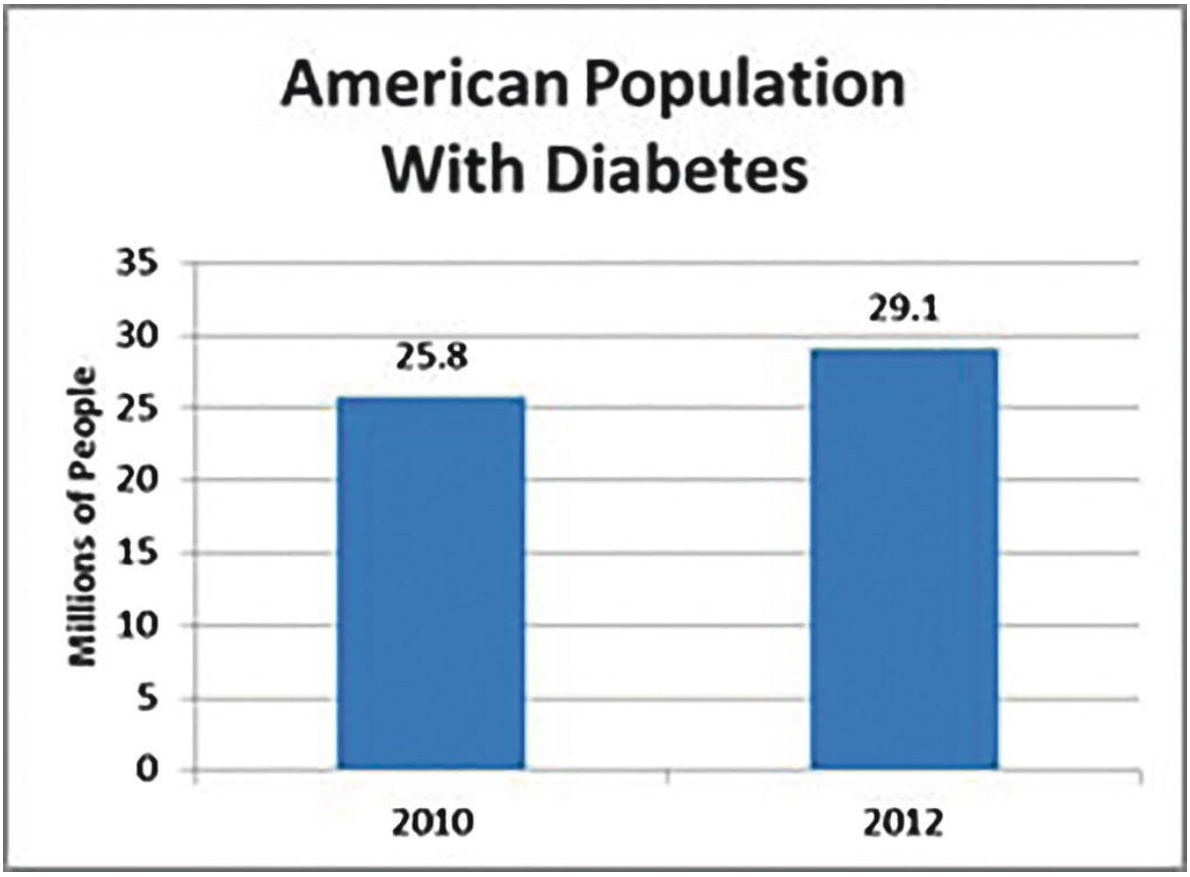

FIGURE 23–5 Rising prevalence of diabetes in the United States. (Adapted from American Diabetes Association. (2014). National diabetes statistics report, 2014. Retrieved from http://www.diabetes.org/diabetes-basics/statistics/?loc=db-slabnav)

Diabetes is a major chronic health condition that puts individuals at risk for other serious health conditions including heart disease, stroke, hypertension (HTN), blindness, kidney disease, and nervous system disease (i.e., neuropathy, which is a loss of sensation or pain in the feet or hands). Because diabetes can affect any part of the body, damage to other body systems can be minimized by good blood glucose control (assessed by hemoglobin A1c [HbA1c]). In 2012, the estimated direct and indirect costs for individuals diagnosed with diabetes totaled $245 billion. Direct costs represented medical care, and indirect costs were for disability, work loss, and premature mortality. After adjusting for population age and gender differences, people diagnosed with diabetes had expenditures that were 2.3 times greater than individuals who did not have diabetes (CDC, 2015g).

Obesity

Obesity is defined as having a body mass index (BMI) of 30 or greater and is recognized as a national health threat and a major public health challenge. Individuals who have a BMI of 40 or greater or are more than 100 pounds overweight are considered to have extreme or severe obesity. In 2011 to 2012, based on data from the *National Health and Nutrition Examination Survey*, the age-adjusted prevalence of obesity in the United States indicated that among adults 34.9% were obese and 6.4% extremely obese (National Institute of Diabetes and Digestive & Kidney Diseases [NIDDKD], 2012). Based on the National Health Survey from 2012, more men than women were overweight, obesity was greatest among Native Americans (41%), Blacks (36%), and 32% of Hispanics/Latinos (Blackwell, Lucas, & Clarke, 2014; Ogden, Carroll, Kit, & Flegal, 2014). Obesity is a major risk factor for CVD, along with certain types of cancer, type 2 diabetes, obstructive sleep apnea, and premature death (CDC, 2015k). One of the *Healthy People 2020* objectives is to decrease the proportion of adults who are obese by 10% (USDHHS, 2015).

Over the past 20 years, there has been a dramatic increase in obesity in the United States. Currently, every state in the country has a prevalence of obesity >20%, 45 states have a prevalence ≥25%, and 3 states exceed 35% (i.e., Arkansas, West Virginia, and Mississippi). Arkansas has the highest prevalence of obesity at 39.5%, and Colorado the lowest at 21.3% (Robert Wood Johnson Foundation, 2015). Recent medical care costs related to obesity in the United States are estimated to be $147 billion (CDC, 2015l). This high prevalence and cost of this disease underscore the need for additional measures to educate persons regarding healthier lifestyle choices, increasing physical activity, and decreasing caloric intake.

Bariatric surgery is a clinically and cost-effective intervention for moderately to severely obese individuals; however, this is a very serious decision. There are four types of bariatric produces: adjustable gastric band, Roux-en-Y gastric bypass, biliopancreatic diversion with a double-duodenal switch, and vertical sleeve gastrectomy. Careful consideration must be given; for example, the individual has been unsuccessful in losing weight, the person is knowledgeable regarding risks and benefits of the surgery, the person is aware of how life may change following surgery, and a commitment by the person of engaging in healthy eating following the surgery to maintain weight loss, to name a few. The average cost of a bariatric procedure is $20,000 to $25,000, and about $1.5 billion is spent annually (NIDDKD, 2011). However, research supports the notion that bariatric surgery is a cost-effective procedure when obesity is viewed as a chronic disease (Wang & Furnback, 2013).

Substance Use

According to the Substance Abuse and Mental Health Services Administration (SAMHSA), a substance use disorder occurs when the recurrent use of alcohol and/or drugs causes clinically and functionally significant impairment such as health problems, disability, and failure to meet major responsibilities at work, school, or home. It is a serious and continuing problem among adult women and men living in the United States (Center for Behavioral Health Statistics and Quality, 2015).

In 2014, 139.7 million Americans aged 12 or older reported current use of alcohol, 60.9 million reported binge alcohol use in the past month, and 16.3 million reported heavy alcohol use in the past month. In the United States, a standard drink contains 0.6 ounces of alcohol: 12 ounces of beer, 8 ounces of malt liquor, 5 ounces of wine, or 1.5 ounces of 80-proof distilled spirits. Definitions for the different levels of drinking include the following:

- Moderate drinking—According to the *Dietary Guidelines for Americans*, moderate drinking is up to one drink per day for women and up to two drinks per day for men.
- Binge drinking—SAMHSA defines binge drinking as drinking five or more alcoholic drinks on the same occasion on at least 1 day in the past 30 days. The National Institute on Alcohol Abuse and Alcoholism defines binge drinking as a pattern of drinking that produces blood alcohol concentrations of >0.08 g/dL. This usually occurs after four drinks for women and five drinks for men over a 2-hour period.
- Heavy drinking—SAMHSA defines heavy drinking as drinking five or more drinks on the same occasion for each of five or more days in the past 30 days (CDC, 2014b; Center for Behavioral Health Statistics and Quality, 2015).

In 2014, males 18 years of age and older were more likely than women to have had at least 1 day of heavy drinking in the past year. From 2004 to 2013, the percentage of women who had at least one heavy drinking day in the past year increased from 11.2% to 14.5%. Among men, the percentage that had at least one heavy day of drinking decreased from 31.6% in 1997 to 27.8% in 2006 but then increased to 32.4% in 2009. Since 2009, there has been no change in the drinking rate among men. Based on race/ethnicity, White adults (30.6%) were more likely to have had at least one heavy day of drinking in the past year followed by Hispanic/Latinos (21.7%) and Black adults (16.4%) (USDHHS, CDC, & NCHS, 2015).

Alcohol consumption is very common in our society, but excessive use can harm an individual's health. Between 2006 and 2010, excessive alcohol use accounted for 1 in 10 deaths among adults 20 to 64 years of age, and it is currently the third leading lifestyle-related cause of death in the United States (CDC, 2014c; Kanny et al., 2015). In 2013, alcohol-impaired driving fatalities accounted for 10,076 deaths. This represents 30.8% of overall driving fatalities during that year (National Institute on Alcohol Abuse and

Alcoholism, 2015). In 2010, excessive use of alcohol cost the United States over $249 million or about $2.05 per drink ($807 per person). Government-sponsored health programs paid for $100.7 billion (40.4%) of these costs (Sacks, Gonzales, Bouchery, Tomedi, & Brewer, 2015).

Tobacco use is a major public health problem and the leading cause of preventable diseases and deaths in the United States. More than 10 times as many U.S. citizens have died prematurely from cigarette smoking than have died in all the wars fought by the United States during its history (USDHHS, 2014a). Because of the significance of the problem, 18 of the *Healthy People 2020* objectives are related to tobacco use.

Among adults 18 years of age or older, 18 out of every 100 adults (42.1 million or 17.8%) currently smoke cigarettes and young adults 18 to 24 years of age are more likely to smoke than people 65 years of age or older. When examining cigarette smoking based on gender, men are more likely to smoke cigarettes (20.5%) than women (15.3%). The prevalence of smoking based on race/ethnicity indicates that American Indians and Alaska Natives (26.1%) smoke more cigarettes than Whites (19.4%), Blacks (18.3%), and Hispanics/Latinos (12.1%). In the United States, the rate of cigarette smoking is lowest among Asians, at 9.5% (CDC, 2015i).

Despite significant declines in cigarette smoking among adults in the United States over the past five decades, the use of other tobacco products such as cigars and smokeless tobacco has been unchanged. Additionally, the prevalence and use of emerging products such as electronic cigarettes (e-cigarettes) and water pipes/hookahs have rapidly increased. During 2012–2013, an estimated 21.3% of adults in the United States used any tobacco product every day or some days. The prevalence of every day or some day use was cigarettes (18%), cigars/cigarillos/filtered cigars (2%), regular pipes (0.3%), water pipes/hookah (0.5%), and e-cigarettes (1.9%), and 2.5% used smokeless tobacco (Agaku et al., 2014).

In the United States, smoking is responsible for 87% of lung cancer deaths, 32% of CHD deaths, and 79% of COPD cases. Changes in the design and composition of cigarettes have increased the risk of developing adenocarcinoma of the lung, the most common type of lung cancer. Between 1959 and 2010, lung cancer risks for smokers rose dramatically. Among female smokers, the risk increased 10-fold, and it doubled for male smokers (USDHHS, 2014a). Smoking-related illness in the United States costs more than $300 billion each year. This includes approximately $170 billion for direct medical care for adults and more than $156 billion in lost productivity (CDC, 2015j). To reduce tobacco-related disease and deaths in the United States, population-level interventions such as mass antitobacco campaigns, comprehensive smoke-free laws, regulation of tobacco products, and increased access to smoking cessation programs are critical (CDC, 2014d).

The health and well-being of millions of Americans is impacted by *illicit drug use*. Illicit drug use refers to use and misuse of illegal and controlled drugs. In 2014, an estimated 27 million persons (ages 12 and older) used an illicit drug in the past 30 days. This represents about 1 in 10 Americans or 10.2% of the population. The most common illicit drugs used

in the United States are marijuana (22.2 million people) and nonmedical use of prescription pain relievers (4.3 million). The percentage of persons 12 years of age and older in the United States who were current illicit drug users in 2014 was higher that than the percentages from 2002 to 2013. This increase may be reflective of a rise in illicit drug use among adults aged 26 and older (Center for Behavioral Health Statistics and Quality, 2015).

Prescription drug misuse or abuse is the intentional or unintentional use of medication without a prescription, in a way other than prescribed, or for the experience or feeling the drug elicits. The illegal use of prescription drugs is one of the fastest-growing forms of drug abuse and is a major public health concern. Although many medications can be abused, the following three classes are most common:

- Opioids—usually prescribed to treat pain
- Central nervous system (CNS) depressants—used to treat anxiety and sleep disorders
- Stimulants—most often prescribed to treat attention deficit hyperactivity disorder (ADHD; National Institute on Drug Abuse [NIDA], 2014)

Overall, males are more likely than females to abuse prescription drugs in all age groups, except the youngest (12 to 17 years of age). Prescription drug abuse is highest (11.8%) among young adults 15 to 18 years of age. However, it is important to note that illicit drug use is increasing among the baby boomers (persons between the ages of 50 and 69). This is because illicit drug use was historically higher in this generation as compared to those of previous generations (NIDA, 2015; SAMHSA, 2015a).

Nonmedical use of prescription pain relievers varies by race/ethnicity: Asians (1.8%), Blacks (3.6%), Whites (4.3%), Hispanics/Latinos (4.5%), and American Indians/Alaska Natives (6.9%). The highest rates of nonmedical use of prescription pain relievers were found to be among individuals of two or more races (8.1%) (SAMHSA, 2015b). A recent study estimated the number of emergency department visits for nonmedical use of prescription drugs, over-the-counter drugs, or other pharmaceuticals to be over 1.2 million. Overall, medical emergencies related to nonmedical use of pharmaceuticals increased 132% between the years 2004 and 2011 (USDHHS, SAMHSA, & Center for Behavioral Health Statistics and Quality, 2013). This health issue is covered in greater detail in Chapter 27.

Women's Health

Women have not been the focus of medical attention throughout the centuries. Health benefits achieved by women were incidental compared to men. Advances in women's health are very recent and primarily an advantage for women living in Western countries, where the women's or feminist movement has made major inroads (Fig. 23–6).

FIGURE 23–6Women's health has not historically been the focus of health care research.

Overview of Factors Influencing Women's Health

Women's rights in the United States started in the second half of the 19th century and over time addressed issues directly or indirectly impacting the health of women: voting rights, labor laws, reproductive rights, and violence against women (Fried, 2013; International Women's Day, 2015). This section of the chapter examines women's health concerns over the adult life span and the major causes of acute and chronic illness and death and the issues, trends, and policies that have and currently affect women.

Women's health is still overlooked in much of the world. Only in the past few decades has the health of women been a formidable issue in the United States, coming not so coincidently with the modern women's feminist movement that began in the 1960s. The landmark 1963 publication *The Feminine Mystique* helped launch the modern women's movement by critically examining the role of women in American society (Foster, 2015; Friedan, 2013). The Boston Women's Health Book Collective's *Our Bodies, Ourselves* (initial release 1973) represented the first book to explore women's health issues, exclusively written by and for women. In addition, this publication served as a model for women who wanted to learn about themselves, communicate their findings with doctors, and challenge the medical establishment to change and improve the care that women received (Our Bodies Ourselves, 2015). To further expand the dialogue regarding women's health, consumer activists created the National Women's Health Network in 1975, primarily to shape health policy and support consumer health decisions (National Women's Health Network, 2015). These historical occurrences likely contributed to more female researchers and women as participants in research. Feminists paved the way for women to have their voices heard on many health, social, and political issues. Women sought out higher-education opportunities in greater numbers and entered workplaces once solely occupied by men, especially during and after World War II. These positive changes escalated women toward greater equality, and with equality came the freedom—and pressure—for women to compete with men in their social and work settings. Issues related to women's health were discovered as a result of research that now more regularly includes women. The importance of women's research was reaffirmed in the National Institute of Health's (NIH) Revitalization Act of 1993, Subtitle B—clinical research equity regarding women and minorities to "identify projects for research on women's health that should be conducted or supported by the national research institutes; identify multidisciplinary research relating to research on women that should be so conducted or supported …" (NIH, 1993, section 486).

Women's Health Research

In response to changing priorities, researchers have designed and implemented major studies that focus exclusively on women. Five significant studies have and continue to provide important health information about women:

- The *Women's Health Initiative* (WHI), a major 15-year research program addressing the most common causes of death, disability, and poor quality of life in postmenopausal women—CVD, cancer, and osteoporosis
- The *Women's Health Study* (WHS) that evaluated the effects of vitamin E and low-dose aspirin therapy in primary prevention of CVD and cancer in apparently healthy women
- The *Nurses' Health Study I* involved with investigating risk factors for cancer and CVD, and the *Nurses' Health Study II* that researched diet and lifestyle risk factors in a population younger than the original Nurses' Health Study cohort
- The *Nurses' Health Study III* that is investigating women's health issues related to lifestyle fertility/pregnancy, environment, and nursing exposures

The *WHI* addressed CVD, cancer, and osteoporosis and was one of the largest prevention studies of its kind in the United States, starting in 1991 and spanning 15 years. The three major components of the WHI were a randomized controlled clinical trial of promising but unproven approaches to prevention, an observational study to identify predictors of disease, and a study of community approaches to developing healthful behaviors. This study was sponsored by the NIH and the NHLBI involving 161,808 women ages 50 to 79 and was considered to be one of the most far-reaching clinical trials for women's health ever undertaken. Enrolled women participated in a follow-up phase of this study until 2010. To date, more than 616 publications have been associated with findings from this study, which address coronary artery calcium, breast cancer risk, colorectal cancer, venous thrombosis, peripheral arterial disease risk, risk of CHD, dementia and cognitive function, and the effects of estrogen alone in reducing the risk of CHD (Database of Genotypes and Phenotypes, n.d.).

The *WHS* was a randomized, double-blind, placebo- controlled clinical trial sponsored by the NHBLI and the NCI. It was the first large clinical trial to study the use of low-dose aspirin to prevent heart attack and stroke in women 45 years of age and older. This study began in 1991 and continued through March 2009 for additional observation and follow-up of the original 28,345 participants. Current findings indicate that low-dose aspirin does not prevent first heart attacks or death from cardiovascular causes in women; however, stroke was found to be 17% lower in the aspirin group. More than 110 professional articles are associated with this investigation. Recent publications address the association of dietary fat intake with risk of atrial fibrillation in women and the novel protein glycan biomarker and future CVD events (WHS, 2015).

The *Nurses' Health Studies* (three separate phases) represent the longest running study related to women's health in the world, investigating factors that influence the health of women. The *Nurses' Health Study I*, a prospective study that began in 1976, enrolled 122,000 registered nurses ages 30 to 55 from 11 states that responded to 170,000 mailed questionnaires. Every 2 years, participants received a follow-up questionnaire with questions about diseases and health-related topics including smoking, hormone use, and menopausal status. Later in the study, questions regarding diet and nutrition and quality of life were added. The *Nurses' Health Study II* represented women who started using oral contraceptives in adolescence, a population with long-term exposure during early reproductive years. Participants were between 25 and 42 years of age, and 116,686 women were enrolled and followed forward in time. Every 2 years, participants received a follow-up questionnaire and were surveyed about diseases and health-related topics including smoking, hormone use, pregnancy history, and menopausal status. Women also received nutrition and quality-of-life assessments later in the study. The *Nurses' Health Study III* began recruitment in 2010 and will continue until 100,000 nurses (registered and licensed practical, 22 to 45 years of age) are enrolled. Also, nurses from Canada are participants and the study aims to be more representative of the diverse backgrounds of nurses. This investigation is supported by major nursing organizations. Overall, as of 2015, outcomes from phases I and II have spawned 1,200 professional publications (Harvard School of Public Health & Brigham and Women's Hospital, 2013; Nurses' Health Study, n.d.)

What do *you* think?

A woman's dressing style that included a tightly laced corset was popular from the late 1700s throughout the late 1800s in Germany, England, and the United States. In 1793, this practice was brought into question by S. T. von Soemmerring, an anatomist. He identified compression of rib cages and internal organs as contributing to digestive problems, fainting, and shortness of breath. For the next century, dress reformers advocated looser lacing and clothes that allowed for a more natural movement. However, these reformers belonged to the "radical fringe" of the feminist movement, and the tiniest waists, regardless of their impact on health, continued to be in vogue as both middle-class and upper-class women sought the "hourglass" figure. More recently, hiatal hernias caused by overly tight girdles and corsets have been termed "Soemmerring's syndrome" in tribute to the first physician to warn of the dangers, more than 200 years ago.

In 2015, thanks to social media and our fascination with celebrities and social media personalities, waist trainers (a newer version of the traditional corset) have become popular. Even though some women have fainted from having worn them for extended periods, and despite the fact that there is no evidence to show that they truly reduce fat at the waistline, there is still the allure of a tiny waist even over a century after Soemmerring's findings.

Do you know someone who has tried a waist trainer? What was their reason for using it? What was their experience like? As a PHN, how would you approach this subject with them?

Women's Health Promotion Across the Life Span

What health care needs do women have that are different from those of men? Is there a need to look at health promotion throughout the life cycle of adult women? How is the health of an 18-year-old different from that of a 50-year-old woman? Most of us would have no trouble agreeing that women have different health care needs that must be considered and that these concerns vary with age. Knowing what the needs are is essential to knowing how to help women promote their health.

Healthy People 2020 Goals for Women

As a nation, we have been focusing on improving the health of all citizens through the *Healthy People* initiatives, commencing with the 1979 Surgeon General's report, *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention*, providing measurable population objectives. *Healthy People 2000* set a standard for change and improvement in objectives that were met or exceeded in some areas and were far from being reached in others. In that initiative, objectives in 14 areas focused specifically on women's health. *Healthy People 2010* focused on two overarching goals: increasing the quality of life and eliminating health disparities, containing 25 objectives relating to women. *Healthy People 2020* reaffirmed the goals of *2010* and added two additional goals: quality of life, healthy development, along with healthy behaviors across the life span and creating social and physical environments that promote good health (USDHHS, 2015). In the nation's fourth generation of health planning, 27 objectives pertain to the health of women (Display 23–3). As the community health nurse works with women at various stages in the life cycle, the objectives in *Healthy People 2020* can give structure to program planning and services offered to women in the community at the primary, secondary, and tertiary levels of prevention.

DISPLAY 23.3 *HEALTHY PEOPLE 2020* OBJECTIVES FOR WOMEN

1. Reduce the breast cancer death rate, from 22.9 deaths per 100,000 women to 20.6 deaths per 100,000.
2. Reduce the death rate from cancer of the uterine cervix, from 2.4 deaths per 100,000 to 2.2 deaths per 100,000 women.
3. Reduce invasive uterine cervical cancer from 7.9 new cases per 100,000 females

to 7.1 new cases per 100,000 females.

4. Reduce late-stage female breast cancer from 43.2 new cases per 100, 000 females to 41.0 new cases per 100,000 females.
5. Increase the proportion of women who receive a cervical cancer screening based on the most recent guidelines from 84.5% of women aged 21 to 65 years to 93% of women aged 21 to 65 years.
6. Increase the proportion of women who receive a breast cancer screening based on the most recent guidelines from 73.7% of females aged 50 to 74 years to 81.1% of females aged 50 to 74 years.
7. Increase the proportion of pregnancies that are intended, from 51% to 56%.
8. Reduce the proportion of females experiencing pregnancy despite use of a reversible contraceptive method from 12.4% to 9.9%.
9. Reduce the proportion of pregnancies conceived within 18 months of a previous birth from 35.3% to 31.7%.
10. Increase the proportion of females or their partners at risk of unintended pregnancy who used contraception at most recent sexual intercourse from 83% to 91.3%.
11. Reduce pregnancy rates among adolescent females aged 15 to 17 years from 40.2 pregnancies per 1,000 to 36.2 pregnancies per 1,000.
12. Increase the proportion of females in need of publically supported contraceptive services and supplies who receive those services and supplies from 53.8% to 64.5%.
13. Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling from 23.3% to 25.6%.
14. Reduce the rate of maternal mortality from 12.7% to 11.4%.
15. Reduce maternal illness and complications because of pregnancy (complications during hospitalized labor and delivery) from 31.1% to 28%.
16. Reduce cesarean births among low-risk (full-term, singleton, vertex presentation) women from 26.5% to 23.9%.
17. Increase the proportion of pregnant women who receive early and adequate prenatal care form 70.8% to 77.9%.
18. Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women from 89.4% to 98.3%.
19. (Developmental) Increase the proportion of pregnant women who attend a series of prepared childbirth classes.
20. (Developmental) Increase the proportion of mothers who achieve a recommended weight gain during their pregnancies.
21. Increase the proportion of women of childbearing potential with intake of at least 400 μg of folic acid from fortified foods or dietary supplements from 23.8% to 26.2%.
22. Reduce the proportion of women of childbearing potential who have low red blood cell folate concentrations from 24.5% to 22.1%.

23. Increase the proportion of women delivering a live birth who received preconception care services and practiced key recommended preconception health behaviors (took multivitamins/folic acid every day in the month prior to pregnancy) from 30.1% to 33.1%.
24. (Developmental) Reduce postpartum relapse of smoking among women who quit smoking during pregnancy.
25. (Developmental) Increase the proportion of women giving birth who attended a postpartum care visit with a health worker.
26. Reduce iron deficiency among young children and females of childbearing age (12 to 49 years) from 10.4% to 9.4%.
27. Reduce iron deficiency among pregnant females from 16.1% to 14.5%.

Young Adult Women (18 to 35 Years)

Women in the earlier years of adulthood have different tasks to accomplish and issues to address than do women in later adulthood, and the transition from adolescence to adulthood can be stressful. There are major developmental tasks that young women need to accomplish such as forming an identity and the development of intimacy. Behaviors associated with young adulthood include attracting and choosing a significant other for the long term and establishing a home. Young women during this stage also prepare and choose a life's work that is personally satisfying, plan for children by using a variety of parenting models (childbirth, adoption, foster parenting), and develop a personal philosophy that encompasses meaningful and comforting spiritual beliefs that are consistent with day-to-day living (Hutteman, Hennecke, Orth, Reitz, & Specht, 2014; Lane, 2015) (Fig. 23–7).

FIGURE 23–7 Choosing a significant other is a developmental task of young adulthood.

Women in this age group tend to be healthy. Unfortunately, during this period, many women engage in health risk behaviors such as physical inactivity, eating poorly, participating in unprotected sexual intercourse, and smoking. Some, if not all, of these behaviors may have been established in adolescence and represent modifiable behaviors. If not addressed, these behaviors can contribute significantly to the leading causes of morbidity and mortality: diseases of the heart and vascular systems, cancers, chronic respiratory diseases, and diabetes (USDHHS, Health Resources and Services Administration, Maternal and Child Health Bureau, 2013); the majority of health concerns for many of these women are related to eating disorders, reproductive health and sexually transmitted infections (STIs), physical activity, mental health and mood disorders, and substance use.

Eating Disorders

Eating disorders are complex, chronic illnesses primarily affecting young women. There is no single cause of these disorders; however, several things may contribute: culture, personal characteristics, emotional disorders, stressful events, biology, and families. The three most common are anorexia nervosa, bulimia nervosa, and binge eating. Anorexia nervosa is an eating disorder that is marked by weight loss, emaciation, a disturbance in body image, and a fear of weight gain. Persons affected lose weight either by excessive dieting or by purging

themselves of ingested calories. This illness is typically found in industrialized nations and usually begins in the teen years. Young women are 10 to 20 times more likely than young men to suffer from this disorder. The young woman claims to feel fat even when she is emaciated. Refusal to maintain body weight can be life threatening because of electrolyte disturbances, anemia, and secondary cardiac arrhythmias. Affected women need to understand that low body weight can cause the body to stop producing estrogen, which leads to amenorrhea (absent menstrual periods). Low estrogen levels contribute to losses in bone density. If anorexia nervosa is suspected, the client must be referred to a health care provider for follow-up as soon as possible (Bulik, 2014; Chelvanayagam & Newell, 2015; National Institute of Mental Health, n.d.; Office on Women's Health, 2012a).

A related disorder, bulimia nervosa, is marked by recurrent episodes of binge eating, self-induced vomiting and diarrhea, misuse of laxatives or diuretics, excessive exercise, strict dieting or fasting, and an exaggerated concern about body shape or weight in self-evaluation. Females in cultures where emphasis is placed on a certain ideal of beauty, individuals who have been sexually abused or come from families with a history of eating disorders, and individuals with low self-esteem and a history of not being "in control" or with communication and emotional difficulties are at greater risk. The community health nurse should refer a woman suspected of practicing bulimic behaviors to an appropriate health care provider (National Eating Disorders Collaboration, 2015a; Office on Women's Health, 2012b).

Binge eating is an eating disorder characterized by repeated episodes of uncontrolled eating. It is the newest clinically recognized eating disorder. The onset is usually in late adolescence and the early 20s and starts following significant weight loss from dieting. However, many binge eaters are obese because they usually do not induce vomiting and diarrhea or engage in excessive exercise. Typically, individuals with this disorder eat quickly, eat until they are uncomfortably full, eat when they are not hungry, eat large amounts of food alone, have difficulty expressing their feelings, have difficulty controlling impulses and stress, and feel depressed about overeating. This disorder also puts these women at increased risk for type 2 diabetes, high cholesterol, osteoarthritis, kidney disease or renal failure, heart disease, and high BP (National Eating Disorders Collaboration, 2015b; Office on Women's Health, 2012c).

Overall, eating disorders are not gender specific; females are commonly affected; however, millions of men and boys battle all forms of this illness. Because of the complexities of these disorders, there are differences of opinion in the literature among the experts regarding this topic (National Eating Disorders Association, n.d.). The community health nurse can play a vital role in identifying affected persons and refer these individuals to appropriate health care providers, mental health counselors, and self-help groups. A screening tool that may be helpful in this effort is the Malnutrition Universal Screening Tool, a five-step instrument to identify adults who are malnourished, at risk of malnutrition (undernutrition), or obesity (British Association for Parental and Enteral Nutrition, 2015).

By age 25, at least 50% of childbearing women have given birth once. Women (also men) need to be as healthy as possible to have positive pregnancy outcomes. Based on published research and input of experts from the CDC/ATSDR Preconception Care Work Group and the Select Panel on Preconception Care, the CDC (2015m) has made 10 recommendations for preconception care and health care. Four goals of preconception care are to improve knowledge and attitudes, assure that all women of childbearing age in the United States receive preconception care services, reduce risks through interventions, and reduce disparities in adverse pregnancy outcomes. The recommendations for preconception care address (Fig. 23–8):

FIGURE 23–8A group of pregnant women at a support group class.

- Consumer awareness
- Individual responsibility
- Preventive visits
- Interventions for identified risks
- Interconception care
- Prepregnancy checkups
- Health insurance coverage for women with low incomes
- Public health programs and strategies
- Monitoring improvements

- Research (CDC, 2015m)

Although preconception care is addressed in *Healthy People 2020*, many of the preconception objectives are related to family planning and maternal health (see Display 23–3). Community health nurses have been at the forefront of maternal and child health care for decades, and they must continue to strive to incorporate components of preconception care into their practices. Nurses must advocate for clients to influence public policy, which has the potential to improve access to care for many women and improve pregnancy outcomes (CDC, 2015m).

Sexual health and STIs are important health concerns for young women. Sexual activity typically commences in adolescence and continues throughout the life span. STIs are epidemic in the United States, especially among young adults (see Chapter 8). Many of the common infections are asymptomatic, but not always. The two most common STIs affecting women are Chlamydia and gonorrhea. Approximately 1.4 million cases of Chlamydia occurred in the United States in 2014, and this STI is the most reported nationally notifiable disease. Females 20 to 24 years of age have the second highest rate, preceded by 15- to 19-year-old adolescents. The rate of gonorrhea is lower than Chlamydia, but in 2014, there were 350,062 cases reported, making it the second most nationally reported notifiable disease in the United States. The current prevalence is 110.7 cases per 100,000 persons. Historically, gonorrhea rates for men were higher than women, and in 2014, this continued, with 120.1 cases per 100,000 for men and 101.3 per 100,000 for women. Both Chlamydia and gonorrhea are underdiagnosed, which can have deleterious consequences for women. If treatment is delayed, women can develop pelvic inflammatory disease, chronic pelvic pain, ectopic pregnancy, and infertility (CDC, 2015n, 2015o). See Chapter 8 for more information on communicable diseases.

Community health nurses working with adult women need to provide factual information to increase women's knowledge of STI risk. This information should be a part of frank discussions regarding condom use, sexual partners (male and female), type of sexual activity (oral, anal, vaginal), life-threatening consequences of an undiagnosed STI, and undesirable pregnancy outcomes. Outside of abstinence, condom use is the first line of prevention against STIs. See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

Bridging Financial Gaps

A survey was conducted using a 15-item instrument (multiple choice and completion questions; English and Spanish versions) at 21 metropolitan sexually transmitted

disease (STD) clinics in the United States from August to December in 2013. The aim was to assess the characteristics of STD clinic patients, their reasons for seeking care at the clinics, and the patients' ability to access health care at other providers. The survey was distributed to 100 males and 100 females at each clinic while they were waiting for service. Time to complete the survey was 5 minutes. The overall response rate was 86.6%, and 4,364 individuals completed the survey. Of the patients who declined to complete the survey, 86 cited language barrier as the reason. Researchers noted the most frequently reported reasons for persons using the clinics were a perceived health problem or STD symptoms (18.9%), STD screening (33.8%), and HIV testing (13.6%). However, the main reasons why patients selected the STD clinic included walk-in or same-day appointments (49.5%), low cost of care (23.9%), or availability of expert STD care (8.3%). Of note, if the STD clinics were not available, 20.9% of patients would have delayed seeking care (waiting to see what would happen) and 50.2% would have sought care at an emergency room or urgent care provider.

STI are a major burden on the already overtaxed public health system. More than 19 million new STI cases are diagnosed annually and over $15.6 billion are spent to diagnose and treat STIs and their complications in the United States. When interacting with clients who are sexually active, nurses need to consider incorporating brief educational interventions about STIs into client care; nurses cannot assume that persons are knowledgeable. The more informed individuals are about STI transmission and prevention, the more likely they are to protect themselves. By increasing knowledge and prevention strategies, the costs related to STI treatment can be reduced.

Hoover, K. W., Parsell, B. W., Leichliter, J. S., Habel, M. A., Tao, G., Pearson, W. S., & Gift, T. L. (2015). Continuing need for sexually transmitted disease clinics after the Affordable Care Act. American Journal of Public Health, 105(Suppl 5), S690–S695. doi: 10.2105/AJPH.2015.302839.

Adult Women (35 to 65 Years)

Women in the adult age group of 35 to 65 years have established themselves into patterns of living that have served them well or ill. During this period, the results of years of choices may present themselves in the form of chronic illnesses. Nevertheless, many women in this age group have time to change health habits to possibly reverse encroaching chronic illnesses. For other women, lifestyle choices and undetected diseases have shortened their life spans, and large numbers of women in this age group are dying prematurely.

Menopause and Hormone Replacement Therapy

Menopause is a time that marks the permanent cessation of menstrual activity (last

menstrual period). The average age is 51 years (range = 45 to 55); however, it can occur as early as age 40. Perimenopause, or the time period that leads up to the last menstrual cycle, is characterized by cycle changes and irregularity. Menstrual flow may be light or heavy, and spotting may occur, depending on varying estrogen and progesterone levels. This perimenopausal period may last 10 years, and women may see their health care providers more frequently because of irregular bleeding that could be due to more serious causes (American College of Obstetricians and Gynecologists [ACOG], 2011). Natural menopause is defined as cessation of menstrual periods for 12 consecutive months, with no other apparent cause. Because of the sudden loss of estrogen with surgical removal of the ovaries, some women have an early, *surgical menopause*. Because estrogen levels do not simply decline evenly over time, but rather have peaks and valleys, blood tests are not effective in the diagnosis (Bostock-Cox, 2015). Menopause symptoms differ among women and may last from months to years. They range from hardly noticeable in some women to very severe in others. Symptoms include nervousness or anxiety, hot flashes (flushes), chills, excessive sweating (often at night), excitability, fatigue, mood disorders (apathy, mental depression, crying episodes), insomnia, palpitations, vertigo, headache, numbness, tingling, myalgia, urinary disturbances, and vaginal dryness (National Institute on Aging, 2015; Shaheen, Mahmood, & Kadri, 2015). Some women experience problems with sexual functions (e.g., infrequent sexual relations, decreased libido), and one study of almost 500 women who had wither a natural menopause or a surgical menopause found an association between problems with sexual functioning and the intensity of menopausal symptoms like hot flashes and sweating, especially for those experiencing surgical menopause (Topatan & Yildiz, 2012). The *Study of Women's Health Across the Nation* (SWAN) revealed that hot flashes and some of the other menopausal symptoms may last longer than the 7 years previously thought; in fact, they may last up to 14 years and Australian researchers noted that a small percentage of women (about 7%) may experience them well into their 60s (Freeman, Sammel, & Sanders, 2014; Harvard Health, 2015) (Fig. 23–9).

FIGURE 23–9Menopause is another transitional period in a woman's life, and healthy diet and exercise are important.

Genitourinary syndrome of menopause (GSM) describes a group of symptoms related to decreased estrogen and other steroids involved in changes to the female genitourinary system. These symptoms include genital dryness, irritation, or burning, sexual symptoms that include inadequate lubrication and painful or impaired sexual functioning, and symptoms of urinary frequency, urgency, painful urination, and frequent urinary tract infections (Portman & Gass, 2014). Sleep problems are common among menopausal women, and researchers noted more restless sleep, decreased quality of sleep, and more instances of waking during the night among postmenopausal women, compared to premenopausal women (Lampio et al., 2014). Many women complain of weight gain, especially in the abdominal area, during perimenopause. Davis et al. (2012) found that all weight gain can't be blamed on the menopausal transition period, but there are indications that the hormonal changes accompanying menopause are correlated with both an increased level of body fat and increased levels abdominal fat. Those women who received hormone replacement therapy (HRT) generally had an overall fat mass reduction and increased insulin sensitivity, along with lower rates of type 2 diabetes. Lifestyle interventions (e.g., healthy diet, exercise programs) have also shown promise in addressing changes in body weight during menopause (Jull et al., 2014).

Other research on menopausal symptoms and outcomes includes topics such as hot flashes and dizziness during menopause, iron changes during menopause and associated insulin resistance, and earlier age of menopause being associated with cumulative lead

exposures, as well as the effects of premature menopause and later life cognitive functioning and later age of natural menopause and increased cardiovascular death rates (Eum, Weisskopf, Nie, Hu, & Korrick, 2014; Kim, Nan, Kong, & Harlow, 2012; Owada & Suzuki, 2014; Ryan et al., 2014; Tom, Cooper, Wallace, & Guralnik, 2012).

How do women really feel about menopause? Anthropologists at the University of Hawaii conducted a qualitative study of a multiethnic sample of 185 women who were pre-, peri-, and postmenopausal. The most common theme among premenopausal women was anxiety over the expected changes that would occur during menopause. They feared the stories that they had heard from others about this stage of life, such as the "hormonal rages, personality changes," depression, osteoporosis, divorce, and sexual or physical dysfunctions (Morrison et al., 2014, p. 535). For perimenopausal women, they were transitioning from negative to more positive thoughts about the experience. The benefits of no longer having periods or worrying about getting pregnant, and liberation from an intense focus on family concerns to being more able to take care of themselves, seemed less frightening than the stories they had heard from other women of the "raging menopausal maniacs." For postmenopausal women, there was more of a focus on developing a "postmenstrual identity" as a wiser, more optimistic woman who has gone through a natural body change.

A quantitative study of over 1,000 baby boomer females from a national sample examined adaptation to menopause and resulted in a two-factor model. Women who had positive responses to menopausal effects about the end of menstruation/loss of fertility were generally less educated, but more financially secure, and older than those who had more positive viewpoints toward physical attractiveness and health concerns related to menopause (Strauss, 2011).

The Endocrine Society recommendations include menopause diagnosis; discussions about menopausal symptoms, osteoporosis, cancer screening, and assessment for CVD; along with a determination of the need for hormonal therapy (usually estrogen for those having had a hysterectomy and estrogen/progesterone for those who have not). In some cases, SSRIs or other medications are indicated, and vaginal lubricants or hormone creams are used (Stuenkel et al., 2014). Bethany Hays (2011), an OB/GYN physician and contributor to a functional medicine textbook, considers that menopause is not a hormone deficit disorder, as many believe, but a period of necessary normal hormonal adjustment. She describes the hormonal balancing act between adrenaline, insulin, and cortisol, along with estrogen, progesterone, and testosterone, and notes that dysregulation of the hyopothalamus because of estrogen changes leads to hot flashes. Estrogen and testosterone are involved in decreased libido and atrophic vaginitis, and she cautions health care providers to use hormone therapy carefully. She prefers delivery of hormones by transdermal patches or vaginal creams and urges physicians to pay careful attention to a woman's signs and symptoms and to regularly utilize lab tests in order to "normalize hormone levels across the board" (p. 43).

Based on the severity of symptoms and to address long-term body changes such as bone loss and the risk for CVD, HRT may be recommended. Treatment typically involves the

use of estrogen alone, estrogen plus progesterone, or estrogen plus progestin (a synthetic hormone with effects similar to progesterone). However, there still remains controversy regarding use of HRT as evidenced by the following: in 2002, researchers found an increased rate of breast cancer, ovarian cancer, heart disease, and stroke among healthy women in the *WHI* study who were taking combined estrogen and progestin HRT. The initial reaction to this information was a dramatic decline in prescribing by physicians, which included both combined HRT and estrogen alone. The debate over the risk versus benefit of long-term HRT is ongoing; however, there is strong agreement that HRT should not be used for the primary or secondary prevention of CVD. However, it is clear that menopausal women should discuss the risks of HRT with their primary care provider (deVilliers et al., 2013; LaCroix et al., 2011; Mosca et al., 2011; NCI, 2011; Stuenkel et al., 2014). Some providers voice concern about the changes in treatment options for menopausal women, and the lack of physician training on this issue, as well as not providing hormone therapy for the "20% to 30% of those who experience distressing symptoms without adequate relief" (Manson & Kaunitz, 2016; Rubenstein, 2014, p. 218). In place of HRT, some women choose to use bioidentical hormone therapy—chemically similar hormones derived from plants—that may (e.g., micronized estradiol and progesterone) or may not be approved (e.g., Triest, Biest, pregnenolone) by the Food and Drug Administration (FDA). Both the FDA and the Endocrine Society have determined that the term bioidentical hormone therapy is not scientifically based and is used mainly for marketing purposes (ACOG, 2012). Researchers examined the differences in menopausal symptom relief between those women taking bioidentical hormones that have been prepared by a compounding pharmacist (BCH) and other women using conventional HRT (Iftikhar, Shuster, Johnson, Jenkins, & Wahner-Roedler, 2014). About 59% of BCH preparations also included androgens, and both groups of women reported similar menopausal symptoms at baseline. Both groups reported relief of symptoms, but those using BCH therapy had better relief of sexual symptoms of menopause; researchers thought this might have been related to the inclusion of androgens like testosterone. The greatest concern involved lack of knowledge in the BCH group. Women in the study thought BCH compounds were safer than HRT; however, BCH risk is similar to that of HRT (Iftikhar et al., 2014). A systematic review of the use of soy isoflavones for relieving the vaginal dryness of menopause was inconclusive, although some relief was indicated (Ghazanfarpour, Sadeghi, & Roudsari, 2016). Jacob (2016) reports a 79% drop in HRT use from 2002 to 2010, after the *WHI* study results were publicized and notes that between 50% and 80% of women now use some type of nonhormonal therapy to deal with menopausal symptoms. Cognitive behavioral therapy, hypnosis, and the SSRI paroxetine have been shown to decrease both the frequency and irritation of night sweats and hot flashes. Short-term HRT can relieve the vasomotor symptoms (e.g., hot flashes) and presents a low risk to women who do not have breast cancer and CVD risks. A smartphone/tablet app, *MenoPro*, helps women and health care providers evaluate all available recommended options. Risk calculators for osteoporosis/fracture, breast cancer, and CVD, as well as information of various medications, are also available on the app.

Osteoporosis

A gradual loss in bone density is known as osteoporosis. Typically, bone density peaks about age 25, and over time, bones become fragile and easily facture. It is estimated that one out of five women in the United States has *osteoporosis*. Therefore, it is important for women to build strong bone early. Bone density is influenced by many factors such as heredity, race/ethnicity, physical activity, and nutrition. It is important for women of all ages to maintain a healthy diet and engage in physical activity. There are several classes of medications that can be used to treat osteoporosis: bisphosphonates (helps build bone mass), selective estrogen receptor modulators (slows rate of bone loss), calcitonin (slows rate of bone loss), and teriparatide (helps build up new bone). Every woman 65 years of age or older should be screened for osteoporosis (Office on Women's Health, 2012d). See Chapter 24 for more on osteoporosis in older women.

Heart Disease

Heart disease, or CVD, is the number one killer of women, causing the death of 292,188 females in 2009 (CDC, 2013b). Racial disparity exists, with CVD-related death rates for Black women at 204.5 per 100,000 compared to 150.5 per 100,000 for White women. The most common heart problem, CHD, is underdiagnosed, undertreated, and underresearched in women. In addition, women have a higher mortality rate after heart attack and poorer outcomes than do men, and this may be related to delayed diagnosis and treatment. Risk factors for heart disease in women are age, family history, race/ethnicity, physical inactivity, obesity, diabetes mellitus, high BP, high cholesterol, and cigarette smoking (Boudi, 2015; CDC, 2013b; Kochanek, Xu, Murphy, Miniño, & Kung, 2011; Mosca et al., 2011).

Family history, race/ethnicity, and advancing age cannot be changed, but women can make lifestyle changes to alter other risk factors. The remaining risk factors are issues that the community health nurse can discuss with female clients in this age group. Community health nurses can help raise awareness regarding heart disease when working with women at the individual, family, or aggregate levels. Some important facts that can be shared are as follows:

- More than 1 million Americans have a heart attack yearly, and about half of them are women (Rajan, 2015).
- According to a recent survey, 36% of women were not aware that heart disease was the leading cause of death in women (CDC, 2013b).
- Almost two thirds of women who suddenly die from heart disease have had no previous symptoms (CDC, 2013b).
- Heart disease is sometimes thought of as a "man's disease," but about the same number of women and men die each year of heart disease (CDC, 2013b).
- Women have atypical heart symptoms or less acute chest pain, which may delay them

from seeking care (CDC, 2013b).

- Hormone therapy does not reduce coronary events (deVilliers et al., 2013).
- Nine out of 10 women have at least one risk factor for heart disease (Heart Foundation, 2015).
- One in 3 female deaths are from CVD, compared with 1 in 31 from breast cancer (Heart Foundation, 2015).

An excellent lay resource is "*Go Red for Women*," a public awareness program of the American Heart Association to help improve knowledge (AHA, 2015). Also, *Well-Integrated Screening and Evaluation for Women across the Nation* (WISEWOMAN), a CDC program that helps women with little or no health insurance reduce their risk for heart disease, stroke, and other chronic diseases (located in 21 sites across 19 states), can be helpful. The program assists women ages 40 to 64 in improving their diet, physical activity, and other behaviors. This program also provides cholesterol tests and other screening (CDC, 2013b; Mosca et al., 2011) (Fig. 23–10).

FIGURE 23–10Regular exercise is an important part of health promotion.

Regular exercise is an important part of health promotion.

Cancer

Cancer is the second leading cause of death for women, estimated to kill 24,480 females in

the United States in 2015. Genetic mutations play a role in cancer; but only a small percentage of cancers are hereditary. Thus, the vast majority of cancers are random, and most cancers (78%) occur in persons 55 years of age and older. The lifetime risk of a woman getting cancer is a little more than one in three. To help address this disparity, community health nurses can provide more opportunities for education and screening for this population. Screening has reduced the deaths for cancers of the breast, colon, rectum, and cervix (ACS, 2015a).

Breast cancer is the most common cancer among women; however, more women die of lung cancer. In 2015, it is estimated that 40,290 deaths related to breast cancer will occur (ACS, 2015a). Overall, the death rates from breast cancer have declined since 1990, and the biggest decline was among women under 50 years of age. This can be attributed to early detection and improvements in treatment. The sooner breast cancer is discovered, the more successfully it is treated. By obtaining regular clinical breast exams and mammograms, eating a diet low in fat and high in fruits and vegetables, breast-feeding (if possible), and avoiding prolonged use of menopausal HRT, a woman is doing what she can to promote breast health. Although breast self-examination (BSE) continues to be taught in many communities, it is no longer considered to be a routine screening recommendation. However, it is important that women be aware of any overt changes in their breasts, especially changes related to size, shape, symmetry, and nipple discharge. Knowledge of and engaging in BSE can heighten awareness of breast changes for many women. The community health nurse has many resources available to provide information and to teach women in their homes, small groups in clinics, or in various other community settings to enhance knowledge of breast health (ACS, 2015b). See Chapters 11 and 12. See Table 23–5.

Table 23–5 Breast Cancer Death Rates Among All Women: 2008 to 2012

(Age-Adjusted Rates per 100,000)

Women	Rate
All races	21.9
Black	30.2
White	21.3
American Indian/Alaska Native	15.0
Hispanic	14.5
Asian/Pacific Islander	11.4

Extracted from Surveillance, Epidemiology, and End Stage Program (SEER). (n.d.). SEER stat fact sheets: Female breast cancer. Retrieved from http://seer.cancer.gov/statfacts/html/breast.html

Screening for breast cancer is important as it leads to early detection when tumors are likely to be smaller and confined to the breast. Early detection is associated with better prognosis for survival. In April of 2015, the U.S. Preventive Services Task Force released its breast cancer screening draft recommendations for public comment. These recommendations are based on the current scientific evidence so that women can make the best choices regarding their breast health in concert with health care providers. These recommendations are biennial mammography screening for women 50 to 75 years; evidence is insufficient to assess the benefits and harms of screening mammography in women 75 years and older; current evidence is insufficient to assess the additional benefits and harms of clinical breast examination (CBE) beyond screening mammography in women 40 years or older; BSE is not recommended; and biennial mammography screening before the age of 50 years should be an individual decision and the patient's context (risk for disease) should be taken into account. Women who have a first-degree relative with breast cancer (mother, sister), have a breast cancer gene (BRCA 1 or BRCA 2), or have had previous breast cancer are at a higher risk for developing the disease than other women in the general population. Therefore, these individuals need to consult their physicians regarding timelines for screenings (ACS, 2015b; NCI: SEER, n.d.).

Papanicolaou (Pap) smears have improved early detection and prevention of cervical cancer dramatically. Both the incidence and the death rates for cervical cancer have

declined in recent decades because of treatment of preinvasive cervical lesions. The major risk factors for this disease are infection with certain types of the human papillomavirus (HPV), unprotected intercourse at an early age, and multiple sex partners. In 2015, it is estimated that 12,900 new cases of invasive cervical cancer will be diagnosed in the United States, contributing to 4,100 deaths among women from this disease. The 5-year survival rate for this cancer, if prompt treatment is initiated, is 68% for all stages and 91% for local infiltration, making it one of the most successfully treated cancers. Community health nurses can continue to improve screening and early diagnosis through education and advocating for low-cost screening, which will allow many at-risk elderly, low-income, and rural women access to regular Pap screenings. In addition, making women aware of the HPV vaccines Gardasil (given between the ages of 9 to 26 years), Gardasil 9 (works against nine different viruses, given between the ages of 9 and 26 years), and Cervarix (effective against two different viruses, given between the ages of 9 to 25 years) may reduce the incidence of cervical cancer in upcoming decades. Of note, both Gardasil vaccines are approved for use in males (ACS, 2015a; NCI, 2015).

Ovarian cancer contributes to more deaths than any other cancer of the female reproductive system and accounts for 5% of cancer deaths among women. Examining 2007 to 2011 data, death rates have steadily declined by 2% each year since 2007. In 2015, a total of 21,290 cases were anticipated and 14,180 deaths were expected. The primary risk factor for this disease is heredity, or a strong family history of breast or ovarian cancer. The 5-year survival rate is 45% compared to cervical (70%) and breast (89%) cancers. Women at high risk should receive a pelvic exam, a transvaginal ultrasound, and a blood test for the tumor marker CA 125. An ongoing clinical trial in the United Kingdom is examining the efficacy of screening, using the serial values of CA 125 to estimate risk and referring women with high risk for ultrasound examination to improve survival. Therefore, public health nurses need to continue to stress the importance of early detection (ACS, 2015a; Hartge, 2011).

Chronic Fatigue and Immune Dysfunction Syndrome/Myalgic Encephalomyelitis

Chronic fatigue and immune dysfunction syndrome (CFIDS) also known as myalgic encephalomyelitis (ME) is characterized by persistent and debilitating fatigue and additional nonspecific symptoms such as sore throat, headache, painful muscles, joint pain, difficulty thinking, and loss of short-term memory. It is estimated that ME affects between 836,000 and 2.8 million persons in the United States and the majority are women. Rest does not relieve the fatigue. Symptoms may wax and wane and are difficult to validate objectively, but they are subjectively debilitating. Symptoms can last for months or years. Because the cause is unknown, there is no specific treatment and no prevention suggestions. Treatment is focused on supportive care for the associated pain, depression, and insomnia. The ME/CFS Initiative provides support and information for women and is one of seven organizations that contributed to the newly released paper, *Impact of Chronic Overlapping*

Pain Conditions on Public Health and the Urgent Need for Safe and Effective Treatment, a report that raises awareness of chronic pain conditions that disproportionately impact women. The community health nurse can assess activity level and degree of fatigue, emotional response to the illness, and coping ability. Emotionally supportive family members and health care providers are helpful. Referring women to mental health counseling or a local support group is useful for many women and within the role of the community health nurse (CDC, 2015p; Chronic Pain Research Alliance, 2015; Institute of Medicine, 2015; Solve ME/CFS Initiative, 2015).

Men's Health

Gender is among the numerous factors that influence health. More male neonates die at birth, and men are more likely to die earlier from a chronic illness than women. This is evidenced by the difference in life expectancy between men and women in the United States; women survive an average of 5 years longer than men (Mathews, MacDorman, & Thoma, 2015; Xu, Kochanek, Murphy, & Arias, 2014) (Fig. 23–11).

FIGURE 23–11Men have different health care needs at various stages of life.

Overview of Factors Influencing Men's Health

The concept of masculinity is an influencing factor in men's health. Men are socialized to be independent and conceal their vulnerability. Therefore, even when they are aware of personal physical or mental health problems, they are less likely to access the health care system. How the male identity is maintained can include activities that are hazardous to their health, and the result is a high death rate from unintentional injuries among young men. Examples of these activities include working in dangerous jobs, engaging in behaviors that lead to increased risk of homicide or car crashes, excessive alcohol consumption, smoking, substance use, and unsafe sex practices (Gough, 2013; Levant & Wimer, 2014; Lutfiyya, Cannon, & Lipsky, 2014).

Factors that contribute to the deteriorating state of men's health include a lack of quality health education programs for men, health care services that are only accessed half as much by men when compared to women, and a lack of male gender-specific research (Lipsky, Cannon, & Lutfiyya, 2014). Considering all of these factors, the PHN must determine the health care needs of men at various stages and how nurses can best meet these needs throughout the adult life span.

Men's Health Promotion Across the Adult Life Span

In the early years of young adulthood (between 18 and 35 years), men continue to grow and mature. Adult men aged 35 to 65 years have reached maturity, the peak of their physical and intellectual development, and their greatest earning power. What specific needs do men in these age groups have? Are their needs being met through provided services?

Healthy People 2020 Goals for Men

Although *Healthy People 2020* includes 27 health objectives specifically for women and 7 for men, many apply to both women and men of all ages. The 7 men's objectives focus on prostate health, reproductive health, and disease prevention among men, especially men who have sex with men (MSM) (see Display 23–4).

DISPLAY 23.4 *HEALTHY PEOPLE 2020* OBJECTIVES FOR MEN

1. Reduce the number of prostate cancer death rates from 23.5 deaths per 100,000 to 21.2 deaths per 100,000
2. (Developmental) Increase the proportion of men who have discussed with their health care provider whether or not to have a prostate-specific antigen (PSA) test to screen for prostate cancer
3. Increase the proportion of sexually active males aged 15 to 44 years who received reproductive health services by 10%, from 14.9% to 16.4%
4. Reduce the number of new AIDS cases among adolescents and adult MSM by 10%, from 16,749 new cases to 15,074 new cases
5. Increase the proportion of adolescents and adults who have been tested for HIV in the last 12 months among (developmental) MSM
6. (Developmental) Decrease the proportion of MSM who reported unprotected anal sex in the past 12 months
7. Increase the proportion of sexually active unmarried males 15 to 44 years of age who used a condom at last intercourse by 10%, from 60.7% to 55.2%

Adapted from U.S. Department of Health and Human Services (USDHHS). (2015). Healthy people 2020: Topics and objectives. Retrieved from https://www.healthypeople.gov/2020/topics-objectives

Young Adult Men (18 to 35 Years)

The young adult male has many tasks to accomplish. These tasks include the acquisition of training or education that will lead to a personally and financially rewarding career, selecting a compatible lifetime companion and establishing a life together, finding comfort with and meaning to existence through practicing and internalizing a belief and value system that works for him, actively planning for having (or not having) children, and participating in the betterment of the greater community. Young men may choose work that involves physical labor, office work, or a variety of other endeavors, including active duty military. They may also be veterans of military service (Fig. 23–12).

FIGURE 23–12Choosing a career path is one developmental task for young adult males.

Depending on his attitudes and practices before a man enters young adulthood, he may or may not be enticed to experiment or continue with the use of tobacco, alcohol, or illicit drugs. Experimentation or usage of these substances can occur in college, the military, or working at a full-time job. Young men also engage in behaviors or take risks without thinking about the consequences. They respond to challenges such as drag racing, exceeding speed limits, and binge drinking. This is an important age group for the PHN to reach with health information because decisions made in these formative years affect how young men live the rest of their lives. The nurse can meet with young adult men in work settings, college campuses, military bases, health clubs and bars, and at single-adult groups

sponsored by religious communities and other organizations.

Another issue to address during the early years is the young man's attitudes and beliefs toward sex and sexual experimentation. Young men may question their sexuality as they mature, and during this stage, some men come to the realization that they are homosexual. Gay is a commonly accepted term for a homosexual—a person who has sexual interest in or sexual intercourse exclusively with members of his or her own gender. Some men who have sex with men, women, or both often do not consider themselves to be gay or bisexual. They are categorized as MSM. When taking a sexual history, community health nurses must ask men if they have sex with women, men, or both, and they should be aware of issues affecting the lesbian, gay, bisexual, and transgender (LGBT) population.

Transgender, another term associated with sexuality, is used to describe individuals who experience and/or express their gender differently from what people might expect. These individuals express characteristics that do not correspond with the person's apparent or presumed gender. An example is when a presumed male chooses to put on makeup and clothes that a female would traditionally wear. Some transgender individuals define themselves as *female to male* or *male to female* and may take hormones and/or undergo medical procedures to enhance or make permanent their gender selection, including gender reassignment surgery. Others prefer to simply be called *male* or *female*—the gender they present to others, whether or not they have undergone permanent gender reassignment.

Sexual experimentation, whether heterosexual or homosexual, can place young men at risk for diseases that affect long-term health or are life threatening. Men who are sexually active can reduce the possibility of being infected with an STI by limiting the number of sexual partners and using condoms consistently and correctly. Condoms also serve as a form of birth control for men. *Monogamy*, having sex with only one partner and abstinence can further reduce or eliminate the chance of contracting an STI. Public health nurses can serve as a resource for young men and can help them obtain free or low-cost condoms and treatment for STIs.

Human Immunodeficiency Virus and Men

Despite advances in the prevention and treatment of human immunodeficiency virus (HIV), the disease continues to disproportionately impact men in the United States. At the end of 2012, there were 42 jurisdictions in the United States with numerically stable HIV estimates. Within these jurisdictions, the CDC estimated 914,826 persons aged 13 and older were living with HIV. The percentage or persons living with the disease ranged from 110 cases per 100,000 in Iowa to 3,936 cases per 100,000 in Washington, DC. Because the percentage of persons diagnosed with HIV varies by geographic region, it is important that prevention, testing, and treatment interventions be tailored for each area's distinctive milieu (CDC, 2015q; Hall et al., 2015).

In 2012, men accounted for 75% of all diagnoses of HIV infection among adults and adolescents, and 69% of those males were men who had sex with men (MSM). The rate of

HIV infection among men was 540.7 per 100,000 persons compared to 167.0 in women. Most new infections occurred in adult males aged 25 to 34 years, except among Black men for whom 38% of all new infections occurred in the youngest age group, 13 to 24 years. When examining trends in the disease based on race/ethnicity, the burden of the disease is highest among men of color. The rate of new HIV infections among Black men is 6.5 times higher than White men and 2 times higher than Hispanic/Latino men (CDC, 2015r; Singh, Hu, Wheeler, & Hall, 2014).

Alcohol and illicit drug use are known to decrease social inhibitions and increase the risk for HIV transmission through risky sexual behaviors (e.g., lack of condom use) and the sharing of needles or other injection equipment. Community health nurses must be able to talk openly and nonjudgmentally with men about their use of substances and their sexual relationships. These conversations can be challenging, but they have to occur if the number of HIV infections is to be reduced (CDC, 2015s; USDHHS, 2014b).

Testicular Cancer

The risk for testicular cancer is a health problem that young men should be aware of even before early adulthood. The disease occurs most often in men between 20 and 34 years of age. Only a few risk factors have been identified that increase a young man's chance of developing testicular cancer. These include a personal history of an undescended testicle, family history of testicular cancer, race/ethnicity (White), age, and tall stature (ACS, 2015c; Ghazarian, Trabert, Devesas, & McGlynn, 2015). It is a rare form of cancer and is not on the list of objectives for men in *Healthy People 2020*. However, if detected early, this cancer is highly curable. According to the American Cancer Society, it may be beneficial to the overall health of a young man to know how to perform a testicular self-exam (TSE), although clinical guidelines no longer recommend this (ACS, 2015c; U.S. Preventive Services Task Force, 2014b). Teaching men how to do this exam appropriately is a role for nurses working in community settings such as schools and clinics (see Display 23–5).

EVIDENCE-BASED PRACTICE

The Global Community

HTN has become a significant cardiovascular disorder in sub-Saharan Africa and it is estimated that by 2025, 41.7% of males and 38.7% of females in this part of the world will develop HTN. To prepare nurses and physicians working with hypertensive patients, the World Health Organization (WHO) developed comprehensive HTN guidelines for low- and middle-income countries.

Little is known about the capacity of Ugandan nurses to address early detection, risk assessment, and patient education on diet, physical activity, and other lifestyle changes for hypertensive patients. Based on the WHO HTN guidelines, a nurse-led pilot project aimed at enhancing nurses' knowledge, attitude, and skills in early detection, risk assessment, and patient education was implemented at Mulago Hospital's medical outpatient clinic.

To evaluate outcomes of the project, a one-group pre-/poststudy using convenience sampling was designed and implemented. The education intervention was conducted over 3 months and consisted of 22 hours of didactic classroom sessions that focused on improving the nurses' knowledge, skills, and attitudes (KSA) related to HTN management. To enhance self-directed learning, a CD-ROM on HTN management was given to each nurse. The participants were also involved in clinic sessions that focused on using the WHO risk prediction charts, accurate BP measuring techniques, motivational interviewing for patient education on lifestyle changes, and implementation of the WHO HTN guidelines. The nurses' KSAs were measured using pre-/postintervention instruments. The measures included a researcher-developed knowledge scale, a technique skills checklist that assessed accurate BP measurement skills, and an adapted version of the *Respondents' Attitude to Assessment Strategies for Prevention of High Blood Pressure* survey.

Seven nurses working in the outpatient clinic participated in the study. All participants were female and ranged in age from 37 to 53 years. Mean years of nursing experience were 2.8 ± 4.1 and 71% received nursing education in Uganda. The study found that after the educational intervention, there was significant difference in the proportion of nurses who obtained satisfactory answers on the knowledge scale, significant difference in the proportion of nurses who correctly performed accurate BP measurements, and significant improvement in the nurses' attitudes about implementing assessment strategies to prevent and treat high BP. Findings from this study highlight the importance of using evidence-based guidelines to improve nurses' KSAs in BP management. Considering the growing incidence of high BP in sub-Saharan Africa, evidence-based strategies that improve nurses' capacity to manage high BP in a low resource primary care setting is crucial.

Katende, G., Groves, S., & Becker, K. (2014). Hypertension education intervention with Ugandan Nurses working in hospital outpatient clinic: A pilot study. Nursing Research and Practice, 2014. doi: 10.1155/2014/710702.

DISPLAY 23.5 PERFORMING

TESTICULAR SELF-EXAMINATION (TSE)

- TSE should be performed monthly.
- TSE should be done right after a hot shower or bath. The scrotum is most relaxed then, which makes it easier to examine the testicles.
- Examine one testicle at a time. Use both hands to gently roll each testicle (with slight pressure) between your fingers. Place your thumbs over the top of your testicle, with the index and middle fingers of each hand behind the testicle, and then roll it between your fingers.
- The epididymis, which feels soft, rope-like, and slightly tender to pressure, is located at the top of the back part of each testicle. This is a normal lump.
- One testicle (usually the right one) is slightly larger than the other; this is normal.
- When examining each testicle, feel for any lumps or bumps along the front or sides. Lumps may be as small as a piece of rice or a pea.
- If there are any swellings, lumps, or changes in the size or color of a testicle, or if there is any pain or achy area in your groin, let your doctor know right away.
- Lumps or swelling may not be cancer, but a physician should be consulted.

Adapted from American Cancer Society. (2015). Testicular self-exam. Retrieved from http://www.cancer.org/cancer/testicularcancer/moreinformation/doihavetesticularcancer/do-i-have-testicular-cancer-self-exam

The choices a young adult man makes during these years establish healthy eating, work, rest, and exercise habits that will benefit him for a lifetime. A man should follow the dietary food guidelines that are recommended by U.S. Department of Agriculture (2016) when considering personal likes and dislikes. He and his family will benefit if he is able to balance work and home, doing his best in both settings. Establishing a pattern of rest that allows his body to recover and refresh from a day full of meaningful activities will help him look forward to each day. He should establish an exercise routine that meets his personal needs, fits his skills and talents, and includes some physical activities that involve his family. These choices provide him with the knowledge that he is doing everything he can to keep himself healthy and to prevent the two major killers of men—heart disease and cancer. However, there are additional considerations. Typically, young adult clients have few interactions with health care providers in any given year. It is often assumed that young adult males in this age range are not at risk for physical or psychological disease. This is a myth. It is important for people in this age group to have regular health checkups, be assessed for early signs of disease, and engage in health promotion activities (Fig. 23–13).

FIGURE 23–13Adult men are encouraged to maintain good health through eating a healthy diet and getting regular exercise.

Adult Men (35 to 65 Years)

Men in the developmental stage between 35 and 65 years of age are often faced with caring for their own families and children, as well as aging parents and in-laws. The physical, economic, and emotional demands can be great: older adults may have extended care needs while, simultaneously, the family must bear the economic burdens of putting children through college. Meanwhile, men are adjusting to the reality that their career path is probably set and many of their life choices have been made.

The term "midlife" is applied to the first half of this age period, 35 to 49 years. It is a time when many men focus on a reappraisal of values, priorities, and personal relationships. As the term "midlife crisis" implies, this can be one of the more difficult stages of life. It can be an emotional time of doubt and anxiety when a man becomes uncomfortable with the idea that his life is half over. He may believe that he has not accomplished enough, or he may struggle to find new meaning or purpose in his life. Men may experience boredom with their personal life, job, or partners, and a desire to make changes in these areas may occur (Lachman, 2015; Robinson & Wright, 2013).

The later years in this stage, ages 50 to 64, involve preparation for retirement. In anticipation of retirement, these years are marked by expanded social relationships and pursuit of new hobbies to fill increased leisure time, along with anticipating finishing a career and accumulation of the best retirement benefits. The decisions made during these

years will play out over the rest of a man's life and could alter how a spouse or long-term partner lives out their years. Health problems that were left undiagnosed when the man was younger begin to emerge. Peers may be suffering and succumbing to diseases, and a man begins to adjust to the potential loss of loved ones, particularly a spouse or long-term companion (Cahill, Giandrea, & Quinn, 2013; Wang & Shi, 2014).

Successful navigation of this stage can be fulfilling but may require a man to enhance his self-care skills. This includes having a positive attitude toward aging, one that examines the benefits of maturity, finds a balance between work and home, and maintains a healthy lifestyle by eating balanced meals and obtaining regular exercise. The community health nurse can provide anticipatory guidance to men approaching this stage and provide them with information on ways to manage life more effectively.

Reproductive Health

During this stage, especially when a man has decided that his family is complete, he may choose a permanent form of birth control. For men, permanent birth control can be obtained through a surgical procedure called *vasectomy*. A vasectomy entails removal of all or a segment of the vas deferens, so that sperm cannot be released. The procedure is routinely conducted on an outpatient basis, is minimally invasive, and takes about 30 minutes. Vasectomies are considered permanent; however, with the advent of microsurgical techniques, vasectomy reversals are now possible (Rayala & Viera, 2013) (Fig. 23–14).

FIGURE 23–14Reproductive health is also an important consideration for men.

Compared to tubal ligation (a surgical form of contraception for women), vasectomy is equally effective in preventing pregnancy. But, vasectomy is simpler, faster, safer, and less expensive. When compared to the expense of a tubal ligation, a vasectomy is about one fourth of the cost. Despite its advantages, vasectomy has low utilization as a form of contraception. In the United States, only 5.7% of all couples that use some form of contraception rely on a vasectomy (Sharlip et al., 2012). Among married couples, the prevalence of vasectomy as a form of birth control is higher, at 13.1% (Anderson et al., 2012). Reasons for low use of vasectomy include lack of knowledge, misconceptions, lack of access, provider bias, and patient preferences (Shih, Zhang, Bukowski, & Chen, 2014). Men who select vasectomy are largely a homogenous group of older White, well-educated men of high economic status who have children (Eeckhaut, 2015; Sharma et al., 2013).

Erection problems are common among men of all ages but especially in men as they age. Erectile dysfunction (ED), sometimes called *impotence*, is the repeated inability to get or keep an erection firm enough for sexual intercourse. The word impotence may also be used to describe other problems that interfere with sexual intercourse, such as lack of sexual desire and problems with ejaculation or orgasm. Using the term *erectile dysfunction* makes it clear that these other issues are not involved (Corona, Rastrelli, Maseroli, Forti, & Maggi, 2013; Mola, 2015).

Because an erection requires a specific sequence of events, ED can occur when any of the associate events are disrupted. The sequence includes nerve impulses in the brain, spinal column, and areas around the penis, as well as response in muscles, fibrous tissues, veins, and arteries in and near the corpora cavernosa. Damages to nerves, arteries, smooth muscles, and fibrous tissues, often as a result of disease, are the most common causes of ED. Comorbidities such as diabetes, kidney disease, chronic alcoholism, multiple sclerosis, atherosclerosis, vascular disease, and neurologic disorders are primary health risk factors for ED (Besiroglu, Otunctemur, & Ozbeck, 2015; McMahon, 2014).

Lifestyle choices that contribute to heart disease and vascular problems also increase the risk of ED. Smoking, being overweight, and lack of exercise are possible causes of ED. Surgery (especially radical prostate and bladder surgery for cancer) can injure nerves and arteries near the penis, causing ED. Injury to the penis, spinal cord, prostate, bladder, and pelvis can lead to ED by harming nerves, smooth muscles, arteries, and fibrous tissues of the corpora cavernosa. In addition, many common medicines—antihypertensives, antihistamines, antidepressants, tranquilizers, appetite suppressants, and cimetidine—can produce ED as a side effect (Maiorino, Bellastella, & Esposito, 2015; Meldrum et al., 2012).

In diagnosing ED, the medical history should include whether or not erections occur at other times. If an erection can be achieved with masturbation or upon awakening, the problem is probably not physical and is related to stress or an emotional problem. Treatment for ED usually proceeds from least to most invasive. For some men, making a few healthy lifestyle changes may solve the problem. Smoking cessation, weight loss, and increased physical activity may help some men regain sexual function. Cutting back on any

drugs with harmful side effects is considered next. For example, drugs for high BP work in different ways. If a particular drug is causing problems with erection, a different class of BP medicine might work just as well. Psychotherapy and behavior modifications in some men should also be considered (Maiorino et al., 2015; McMahon, 2014).

Drugs for treating ED can be taken orally, injected directly into the penis, or inserted into the urethra at the tip of the penis. In March 1998, the U.S. FDA approved sildenafil citrate (Viagra), the first pill to treat ED. Since then, vardenafil hydrochloride (Levitra [oral], Staxyn [sublingual]), tadalafil (Cialis), and avanafil (Stendra) have also been approved. The aforementioned medications all belong to a class of drugs called phosphodiesterase (PDE) type 5 inhibitors. These medications are currently the first line of therapy for treating ED. The drugs work by relaxing smooth muscles in the penis during sexual stimulation and allow increased blood flow. They can be taken as needed before sexual activity, up to once a day. Low-dose daily dosing rather than "on-demand" dosing has been found to be beneficial for some couples (Smith et al., 2013).

Heart Disease and Men

Cardiovascular disease is a term that refers to the broadest category of diseases that affect the heart and blood vessels. About one in three adult men have some form of CVD and it is the leading cause of death among males in most racial/ethnic groups. Despite a decline in the overall death rate from CVD, the burden of disease among men remains high. In 2009, CVD caused 386,436 deaths in men, a rate of 236.1 deaths per 100,000. It was estimated in 2010 that 74.9% of all coronary artery bypass surgeries and 67.1% of percutaneous coronary interventions (angioplasty) procedures were performed on men. Additionally, in 2011, 68.7% of all heart transplant recipients were male (AHA, 2013b; CDC, 2015t).

Approximately 70% to 89% of sudden cardiac events occur in men, and 50% of these men have no previous symptoms of disease. The average age for a first heart attack among men is 66 years. About 8.5% of White men, 7.9% of Black men, and 6.3% of Mexican American men have some coronary disease. The rate of a first cardiovascular event rises from 3 per 1,000 men at 35 to 44 years of age to 74 per 1,000 men at 85 to 94 years of age. It is interesting to note, if all forms of major CVD were eliminated, life expectancy among all persons would increase by almost 7 years (CDC, 2015t; Mozaffarian et al., 2015).

Major risk factors for heart disease in men include HTN, hyperlipidemia (high LDL), tobacco use, diabetes, obesity/overweight, lack of physical activity, excessive alcohol consumption, stress, and low daily fruit and vegetable consumption. When working with adult men, the community health nurse should educate men about the importance of modifying factors that increase their risk of developing CVD (Campos-Outcalt, 2014). PHNs should discuss the signs and symptoms of a heart attack and how to access emergency medical treatment with adult males.

Prostate Health

Prostate health is another concern that may occur later in this life stage. The prostate is a doughnut-shaped gland located at the bottom of the bladder, about halfway between the rectum and the base of the penis. The prostate encircles the urethra. The walnut-sized gland produces most of the fluid in semen. Men can experience infection (prostatitis), prostate enlargement (benign prostatic hyperplasia [BPH]), and prostate cancer (ACS, 2015d).

BPH is very common among men. The primary risk factor for developing BPH is age. Nearly 50% of men over 50 years of age report symptoms that are related to prostate gland enlargement.

Symptoms of BPH are caused by an obstruction of the urethra and gradual loss of bladder function, which results in incomplete emptying of the bladder. The most commonly reported symptoms of BPH involve lower urinary tract symptoms (LUTS), such as hesitant, interrupted, or weak urinary stream, urgency or leaking of urine, and more frequent urination, especially at night. Men often report the symptoms of BPH before the physician diagnoses it through a digital rectal examination (DRE). Treatment for BPH can include medication or surgery to reduce the size of the prostate (McVary et al., n.d.).

Prostate cancer is the most frequently diagnosed cancer in men and the second leading cause of cancer death. According to the ACS, 1 man in 7 will get prostate cancer during his lifetime and 1 man in 38 will die from the disease. However, most prostate cancers grow slowly and do not cause any health problems in men who have them. More than 2.9 million men in the United States who have been diagnosed with prostate cancer at some time in their lives are still alive today. Prior to age 40, prostate cancer is very rare, but the chance of having prostate cancer rises rapidly after age 50. About 6 cases in 10 are diagnosed in men 65 years of age and older. Age is the strongest risk factor for prostate cancer, but family history and ethnicity also need to be considered. Prostate cancer occurs more often in Black men than in men of other races and occurs less often in Asian and Hispanic/Latino men. The reasons for these racial and ethnic differences are not clear. Starting at age 50, all men should talk to their health care provider about the pros and cons of screening for prostate cancer. This discussion should start at age 45 if a man is Black or has a father or brother who had prostate cancer before age 65. Men with two or more close relatives who had prostate cancer before age 65 should talk with their health care provider about screening for prostate cancer at age 40 (ACS, 2015d; CDC, 2015u). The effectiveness of the screening test, prostate-specific antigen (PSA), has been brought into question, and the U.S. Preventive Services Task Force (2015) has outlined a framework for further study and review.

Treatment for prostate cancer depends on the man's age, overall health status, and stage of disease. Treatment options include surgery to remove all or part of the prostate (prostatectomy), radiation, and hormone therapy. Surgery, radiation, and hormone therapy all have the potential to disrupt sexual desire and performance, temporarily or permanently. Urinary dysfunction and incontinence are common side effects that occur after surgery or radiation. Rather than immediate treatment, watchful waiting or active surveillance is an

option that may be appropriate for older men with limited life expectancy and/or less aggressive tumors (Filson, Marks, & Litwin, 2015). A community health nurse can reinforce or clarify information shared with the man by his health care provider, discuss his treatment options with him and his family, and provide the support they may need if prostate cancer is diagnosed.

Role of the Community Health Nurse

The community health nurse works with adults in all age groups using the three levels of prevention—primary, secondary, and tertiary—as a guide. Interventions are conducted at the individual, family, group, and aggregate levels to make progress toward the *Healthy People 2020* objectives (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

SITUATION: Breast cancer

GOAL: Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest potential is restored.

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Recovery at home with return to activities of daily living within 2 weeks	• Maintains periodic follow-up with health care provider, follow-up mammogram at 6 and 12 months, and as recommended by health care provider • Education regarding risk for other cancers (cervical, ovarian, uterine, etc.)	• Practice breast self-examination (BSE) and receive mammograms as recommended; receives screening for ovarian cancer—transvaginal ultrasonography and blood test for tumor marker CA 125

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Identification of lump in left breast, appointment made with health care provider for evaluation • Receives mammogram and sonogram	• Needle aspiration of lump followed by cytologic studies • Lumpectomy with removal of two suspicious lymph nodes • Low-dose radiation

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Education regarding for BSE and mammograms, as needed • Education regarding environmental exposure and breast cancer (smoking, alcohol, chemicals) • Education regarding low-fat diet and maintaining a body mass index <29	• Avoidance of environmental exposures that may contribute to cancer • Performs BSE and obtains mammogram when appropriate

Client teaching by the community health nurse is a major factor in preventing and managing chronic diseases. The challenge to the nurse is to be prepared to discuss issues, backed up with knowledge of and access to the appropriate community resources, to meet client needs. What the nurse can accomplish can be quite dramatic in terms of reducing days in the hospital because of chronic disease, improving quality of life for the chronically ill person, and preventing a combination of unhealthy habits from becoming causative factors in new cases of chronic disease. See Chapter 26 for more on chronic diseases and disabilities. A nursing care plan matrix can guide the community health nurse in discussing areas of health promotion and protection with the client. An example of a nursing care plan matrix for young adults can be found in Display 23–6.

DISPLAY 23.6 NURSING CARE PLAN MATRIX FOR HEALTH PROMOTION, YOUNG ADULTS: 18 TO 35

Community health nurses can use this matrix to individualize teaching, services, and/or care to young adult clients. Use the questions to stimulate the development of an individualized approach that is client focused and client driven with the community health nurse acting as the catalyst. In any or all of these areas, the community health nurse may (1) discuss issues and commend the client for positive attitudes and behaviors (e.g., when the client is making healthful decisions, such as condom use for his/her health and the health of significant others), (2) discuss the issues and guide the client to resources that will enhance more positive behaviors and decisions (e.g., flu shot clinic or healthy lifestyle program for adults), or (3) discuss the issues and inform the client that immediate changes must be made to protect the health of self or others and inform/utilize the appropriate resources as soon as possible (e.g., follow-up for symptoms related to suspected STI).

1. *Life partner*. Ascertain whether the client is looking for a life partner or is choosing to live a single life. Discuss how the single life is satisfying for the client and ways to make it richer.

Discuss settings in which client can meet others (male or female, based on sexual preference) with similar interests, philosophy, and outlook, such as work settings, school settings, faith communities, recreational communities, and the like.

Discuss what the client is looking for in a potential life partner, expectations for the relationship, what the client contributes, how the client compromises and resolves conflict, and other issues. If in a relationship, what is good, what needs improving, and how to initiate change.

1. *Life's work*. How is the client preparing for his/her life's work (education, formal training, on the job training)? Will the life's work provide resources for client's life plans? Will the work choice provide long-term satisfaction? Is the work choice a "stepping stone" to another work role? How will/does he/she handle work and rearing children? What needs changing or can be improved in the work/children arrangement?
2. *Planning for children*. What knowledge does he/she have about family planning? What methods fit best with his/her philosophy, religious beliefs, and lifestyle? What are the long-term effects of the choices? How many children is the client planning to rear? Has he/she thought through the ramifications of this number? If choosing not to have (or unable to have) children, how will he/she deal with this? Does he/she want alternative suggestions for raising a child (adoption, foster parenting) or information about interacting with children (volunteering)?
3. *Maintaining physical and mental health*. In this area, the community health nurse needs to explore all areas of health promotion and protection. This will include discussions regarding primary and secondary prevention. Primary prevention discussions could include:

- Diet and nutrition
- Physical and leisure activities
- Safe sex practices
- Periodic health examinations
- Personal safety—seat belts, protective helmets, dating violence, etc.
- Immunizations
- Regular use of sunscreen
- Stress reduction activities

Secondary prevention discussions could include:

- Breast self-examination
- Testicular self-examination
- Smoking cessation
- Pelvic exams and Pap smears
- Counseling and support at times of stress

1. *Developing a life's philosophy*. Discuss client's personal life satisfaction, which may include religiosity and spirituality, living in congruence with cultural/ethnic/family beliefs and expectations, and coming to a comfortable level of satisfaction with life choices, having few regrets.

Primary Prevention

Primary prevention activities focus on education to promote a healthy lifestyle. Much of the community health nurse's time is spent in the educator role. When working with individuals, the PHN should encourage routine health examinations, healthy eating habits, adequate sleep, moderate drinking, and no smoking. Among aggregates, the community health nurse focuses on community needs for services and programs that will keep that population healthy, such as providing flu clinics, teaching sexual responsibility, and preventing STIs.

The community health nurse may collaborate with community leaders and other stakeholders in designing programs, work with committees to secure funding, or approach the state legislature to lobby for needed changes to state laws and policies governing the health of adults. At other times, the nurse works with small groups of adults who could benefit from making healthy choices in diet, relaxation, and physical activity. Likewise, it is not unusual for the PHN to work with an individual to promote healthy living. An example of available resources on smoking cessation to those working with the veteran population is shared in Population-Focus.

POPULATION-FOCUS PUBLIC HEALTH AND THE VETERAN POPULATION

The Clinical Public Health group in the Veterans Health Administration provides expertise and leadership that is focused on preventing illness and promoting quality of life for the veteran population through sound policy and practice. The mission is accomplished through education and outreach, policy development, clinical demonstration projects, population-based surveillance, performance measurement and improvement, clinical guidelines, and research. Current focus areas for the veteran population include HIV, hepatitis C, influenza, health care–associated infections, and smoking and tobacco use. The veteran population is disproportionately affected by smoking-related illnesses. Many veterans began smoking in the military and this remains a significant public health challenge in VA clinics. The U.S. Department of Veterans Affairs Public Health Web site "Quit Tobacco" was developed specifically for the veteran population to provide evidence-based information and helpful resources for veterans interested in improving their

health by quitting the use of tobacco. The Web site is resource rich and can be accessed by any veteran or health care professional at http://www.publichealth.va.gov/smoking/quit/index.asp. One particularly meaningful resource for the veteran population is a 27-minute video episode of *The American Veteran Show* that presents the story of several veterans' experiences in a VA tobacco cessation clinic led by a VA nurse practitioner.

Bryan, Associate Director for Patient Services, VA Clinic

Secondary Prevention

Secondary prevention focuses on screening for early detection and prompt treatment of diseases. Throughout the life span, screening tests can help adults identify disease early (see Display 23–2). A significant amount of the community health nurse's time is spent in assessing the need for planning, implementing, or evaluating programs that focus on the early detection of diseases. This is followed with teaching to prevent further damage from the disease in progress or to prevent the spread of the disease, if it is communicable. Examples of secondary prevention programs include establishing mammography clinics, teaching breast and TSE, and screenings—BP, blood glucose, BMI, and cholesterol. Wherever adults gather in groups, this is a good place to provide both primary and secondary health care and prevention services (AHRQ, 2014a, 2014b).

Tertiary Prevention

The tertiary level of prevention focuses on rehabilitation and preventing further damage to an already compromised system. Many adults with whom a community health nurse works have chronic diseases, conditions resulting from another disease, or long-standing injuries with resulting disability. Ideally, negative health conditions can be prevented. If not, the next best thing is for them to be diagnosed early, without damage to an individual's health. But if negative health conditions have not been treated or brought under control, then the individual is at a tertiary level of prevention. At this level of prevention, the nurse focuses on maintaining quality of life.

Depending on the client's age, tertiary prevention can be simple or very complex. A 19-year-old man who breaks his leg while skiing needs information about using crutches safely, a reminder to eat protein foods for bone healing, and an appointment to return to his health care provider if he experiences various symptoms and to get the cast removed. He generally needs no additional help from others. Tertiary prevention in this case is uncomplicated. On the other hand, a 62-year-old woman who is 70 pounds overweight with out-of-control blood glucose levels, symptoms of congestive heart failure, and difficulty walking more than 20 feet has much to accomplish in order to feel healthy. Can the nurse help the woman lose weight? Will weight loss bring her diabetes under control and alleviate congestive heart failure symptoms? With some weight reduction, will she be able to walk more easily? Or, will the woman feel better with physical therapy and a different medication regimen? Is there a quicker, safer, and better approach? On assessment, the nurse discovers that the woman has been as much as 80 pounds overweight for 40 years. Will this information alter the nurse's approach to helping this woman? What additional information does the nurse need?

Caring for people at the tertiary level of prevention can become quite complicated because many body systems may be involved. In addition, all people function within many social systems, which may include family expectations, roles people have within the family, expected behaviors, community system knowledge and involvement, personal expectations, motivation, and support. Working at the tertiary level involves all of the nurse's skills in addition to community resources and a client who can be or wants to be motivated.

SUMMARY

The 20th century saw a shift in the leading causes of death, from communicable to noncommunicable diseases. Currently, the five leading causes of death in adults are diseases of the heart, malignant neoplasms, CLRDs, cerebrovascular diseases, and unintentional injuries—none of which are communicable. The health care needs of adults are of great concern. Many needs are the same for both women and men, but the important differences were addressed in this chapter.

Adults have health care needs that change as they age. Diet and exercise, obesity, substance use, safety, and healthy lifestyle choices are issues that adults must consider throughout their lives. Heart disease and cancers remain important concerns for both men and women, and health decisions made as a young adult can have a major impact on persons as they age.

Chronic illness is an issue of increasing concern for both men and women as life expectancies increase. Community health nurses should use the three levels of prevention to promote health across the life span. Primary prevention activities focus on education to promote a healthy lifestyle. Secondary prevention focuses on screening for early detection and prompt treatment of diseases. The community health nurse's role at this stage is to assess needs; to plan, implement, or evaluate programs that focus on the early detection of diseases; and to educate clients to prevent further damage from or spread of disease. The tertiary level of prevention focuses on rehabilitation and prevention of further damage to an already compromised system. At this level of prevention, the nurse focuses on maintaining quality of life.

Activities to Promote Critical Thinking

1. Using the newspaper or online news sources, select three articles that relate to a preventable chronic disease. For each article, summarize the content, identify the likely cause, and describe how the disease may have been prevented.
2. You are asked to offer a weight control program for 12 young adults who are residents in an apartment complex that has monthly programs related to health and wellness. The ages of the intended participants range from 20 to 30. What steps would you take to develop a successful program? What would be important to emphasize with this age group? What resources (e.g., smartphone apps, online information) might be useful to them in adhering to a healthy diet and exercise program?
3. Using nursing and other health care databases, research a chronic disease associated with men or women aged 35 to 65. In a small group discussion with your classmates, identify selected concerns and discuss both personal responsibility and societal responsibility regarding management of this health problem.
4. Access the Web site for the Nurses' Health Study 3 at (http://www.nhs3.org/). If you were to join the study what would be the benefits to you personally and to your nursing practice? Would you encourage other nurses to participate? What strategies might you use to encourage participation? What research findings from this study may have personal benefits to you or members of your family?
5. Arrange to have a discussion with a nurse leader in the Veteran's Administration (VA) health care system to gain a better understanding of the role they play in improving the health of veteran populations.

   - When completing health histories or screening veterans for health-related issues, what are important things to look for and/or ask about? What health issues are prevalent in the veteran population? How does diversity within the veteran population relate to prevalence of critical issues?
   - Think about how nursing assessment, planning, intervention, and evaluation can be applied to address functioning across all dimensions when working with veterans attempting to reintegrate into their community. How might you be able to impact community responsiveness to the veteran culture and needs of returning veterans?

6. Visit a local veteran's organization (e.g., VFW, American Legion) in your community and discuss the resources available in the community. Explore veteran online resources (www.va.gov) and review the history and programs available.

   - What are family health considerations for veterans? Do these differ from the general population? What community resources are available for family health needs and concerns? Are there any access challenges for veterans and their families for the services they need?
   - What resources are available to the veteran population to address health-related

issues? How well do those resources provide culturally competent, evidence- based care for this population? What resources are needed that might not be available in the community? What options do veterans have for accessing needed resources?

- What are the mechanisms through which coordination of services occurs for veterans in the community? Are there formal structures that facilitate coordination across agencies? Are there particular issues or segments of the veteran population that are "falling through the cracks" or are underserved?

24 CHAPTER

Older Adults: Aging in Place

"We are always the same age inside."

—*Gertrude Stein* (1874–1946), Poet and Novelist

KEY TERMS

Ageism
Aging in place
Alzheimer's disease (AD)
Arthritis
Assisted living
Case management
Centenarians
Continuing care retirement communities (CCRCs)
Custodial care
Elder abuse
Geriatrics
Gerontology
Hospice
Long-term care
Nursing home
Obesity
Oldest old
Osteoporosis
Palliative care
Polypharmacy
Respite care
SenilitySkilled nursing facilities
Supercentenarians

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the global and national health status of older adults.
- Identify and refute at least three common misconceptions about older adults.
- Describe characteristics of healthy older adults.
- Provide an example of primary, secondary, and tertiary prevention practices in the older adult population.
- Identify four chronic conditions most commonly found in the older adult population.
- Identify four types of elder abuse.

- Discuss four primary criteria for effective programs for older adults.
- Describe various types of living arrangements and care options as older adults age in place.
- Describe the difference between hospice and palliative care.
- Describe the future of an aging America and the role of the community health nurse.

Older Americans constitute a large and rapidly growing population group. If you aren't already part of it, you will be in the future. Perhaps your parents and grandparents are in that group now. Improved medical care, advances in public health standards, and focus on prevention have contributed to dramatic increases in life expectancy in the United States. A child born in 2013 could expect to live 78.8 years, about 30 years longer than a child born in 1900 (Administration on Aging, 2014). A second reason for the huge growth in the number of older adults began in 2011 as the baby boomers (people born after World War II between the years of 1946 and 1964) reached age 65.

- Between 2003 and 2013, the population aged 60 and over increased 30.7% from 48.1 to 62.8 million (Administration on Aging, 2014).
- Older adults represent 14.1% of the U.S. population, about one in every seven Americans (Administration on Aging, 2014).
- The result is that in the time period between 2011 and 2029, when the last of the baby boomers turns 65, there will be an era of unprecedented growth in the older population.

The number of older adults is projected to more than double to 98 million by 2060 (Administration on Aging, 2014). Looking forward to the changing health needs of the nation, *Healthy People 2020*, the road map for health in the United States, lists four overarching goals:

1. Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
2. Achieve health equity, eliminate disparities, and improve the health of all groups.
3. Create social and physical environments that promote good health for all.
4. Promote quality of life, healthy development, and healthy behaviors across all life stages (U.S. Department of Health and Human Services, 2016).

The future older population is expected to be better educated than the current one. The increased levels of education will most likely accompany better health, higher incomes, more wealth, and consequently a higher standard of living in retirement. As people retire at younger ages and in better health, they will require programs and services that support preventive health measures. The programs provide opportunities for continued well-being and enhanced quality of life and contribute to overall longevity. This group's potential for longevity could result in impending poor retirement planning and dwindling finances, increased living costs, increasing chronic disease and disability, diminishing functional capacity, and ongoing losses (Holland, 2014; National Institute on Aging, 2015c).

Health care costs in the United States continue to rise:

- The cost of providing health care for an American 65 years and older is three to five times greater than the cost for someone younger (CDC, 2013c).
- The total national health expenditures (NHEs): $2.9 trillion (CDC, 2015e).
- Total NHEs as a percent of gross domestic product: 17.4% (CDC, 2015e).
- Annual per capita NHEs: $9,255, up from $147 in 1960 (CDC, 2015e; Kaiser Family Foundation, 2013).

Of the total health expenditures:

- 32.1% are spent for hospital care.
- 5.3% for nursing home facilities and continuing care retirement communities.
- 20.1% for physician and clinical services.
- 9.3% for prescription drugs (Kaiser Family Foundation, 2013).

The growth of the aging population presents opportunities for public health nurses to work with communities to strengthen and expand programs and services targeted to seniors, to advocate for the needs of the aging population with government agencies and other organizations, and to assure access to quality health care services that address their unique and complex problems (United Nations, 2015).

This chapter first examines the characteristics of the aging population in the United States and the global challenge of an aging society. Some myths and misconceptions about

older adults are described, and ageism is discussed. Next, the primary, secondary, and tertiary health needs of older adults are explored. Diseases common among older adults are reviewed. Several types of elder abuse are described along with factors that contribute to the abuse of seniors. Finally, population-based health services and nursing interventions applied to the health of the aging population are discussed in light of cost containment and comprehensive care.

GERIATRICS AND GERONTOLOGY

Geriatrics is the medical specialty that deals with the health and social care of the older adult. A geriatrician is a medical doctor with specialized training in geriatrics. Geriatrics includes the physiology of aging, diagnosis and treatment of diseases affecting the aged and resulting from the aging process, and the complex psychosocial issues associated with the aging population. Geriatrics, like other medical specialties with the exception of palliative care, focuses on abnormal conditions and the treatment and cure of those conditions. In the past, geriatric nursing focused primarily on the sick aged. As the nursing profession has grown, its scope has broadened. Many nurses choose to be involved with community-based nursing, focusing on prevention and improved health behaviors for the growing aging population.

Gerontology refers to the study of all aspects of the aging process, including economic, social, clinical, and psychological factors, and their effects on the older adult and on society. Gerontology is a broad, multidisciplinary practice, and gerontological nursing concentrates on promoting the health and maximum functioning of older adults.

PHNs work with many types of older people. In one instance, the nurse may work to promote and maintain the health of a vigorous 80-year-old man who lives alone in his home. As another example, the nurse may give postsurgical care at home to a 69-year-old woman teaching her husband how to care for her and helping them contact community resources for assistance with shopping, meals, housekeeping, and transportation services. Perhaps, nursing intervention focuses on teaching nutrition and maintaining a healthful lifestyle for an extended family that includes a 73-year-old grandmother. The nurse may also lead a bereavement support group for senior citizens whose spouses have recently died. The possibilities are limitless and ever expanding.

A PHN works with older adults at the individual, family, and group levels. However, a community health perspective must also concern itself with the aggregate of older adults. There are many groups of seniors with whom the nurse may choose to work, such as those who attend an adult day care center, belong to a retirement community, live in a nursing home, or use Meals on Wheels. Other groups include residents of a senior citizens' apartment building, retired business and professional women, older post–cataract surgery patients at risk for glaucoma, the older poor, Alzheimer's disease (AD) sufferers, and the homeless. Work with clients can also involve political advocacy.

HEALTH STATUS OF OLDER ADULTS

The growth in the number of older adults in the United States is due to two factors—longer life spans and aging baby boomers These two factors will combine to double the population of Americans aged 65 years or older during the next 25 years to about 72 million. By 2030, older adults will account for roughly 20% of the U.S. population (CDC, 2013c).

The proportion of individuals aged 65 and older is projected to increase from 12.4% in 2000 to 20.23% by the year 2050 (HelpGuide, 2015d). People are living longer as a result of improved health care, eradication and control of many communicable diseases, use of antibiotics and other medicines, healthier dietary practices, safer global water supplies, regular exercise, and accessibility to a better quality of life including education and social services. Increased life expectancy reflects, in part, the success of public health interventions, but public health programs must now respond to new challenges including the growing burden of chronic illness, injuries, and disabilities; increasing concerns about future caregiving; and rapidly rising health care costs.

The rising number of older adults increases demands on the public health system and on medical and social services and health care delivery. Currently, 50 million older adults have some type of disability (Healthy People.gov, 2015a). Chronic diseases that affect older adults disproportionately contribute to disability, diminish quality of life, and increase health care costs:

- Of those, over 65, 59% report arthritis as the leading cause of disability (CDC, 2013a).
- Diabetes and AD affect one in four and one in nine, respectively, of those aged 65 and older and are expected to have even greater effects on the U.S. health care system in the next few decades (Alzheimer's Association, 2014; CDC, 2013c).

Two key challenges that are new to the public health arena, although they have long been the target of health care and aging services professions, are preventing and treating cognitive decline and addressing end-of-life issues. Meeting these challenges, along with the increasing number of individuals with chronic conditions, is critical to ensuring that the aging population can look forward to their later years. As more and more Americans reach age 65, society is increasingly challenged to help them grow old with dignity and comfort.

Global Demographics

The unprecedented growth in older adults is not limited to the United States but is happening worldwide. In 2010, an estimated 524 million people were aged 65 or older—8% of the world's population. By 2050, this number is expected to nearly triple to about 1.5 billion, representing 16% of the world's population (National Institute on Aging, 2015b). Life expectancy at birth around the world now is 67. Life expectancy has increased in developing countries since 1950, although the amount of increase varies (Central Intelligence Agency [CIA], 2015). The high percentages of older adults are in part the result of a longer life span, but they also reflect low birth rates in many countries (National Institute on Aging, 2015b).

Although more developed countries have the oldest population profiles, the vast majority of older people—and the most rapidly aging populations—are in less developed countries. Between 2010 and 2050, the number of older people in less developed countries is projected to increase more than 250%, compared with a 71% increase in developed countries (National Institute on Aging, 2015b). In most of the world, the population of those over 85 years of age is the fastest growing segment of the population and is projected to increase 151% between 2005 and 2030 (National Institute on Aging, 2015b). Because of this demographic shift along with altered societal expectations, changes in attitudes and social policies worldwide are needed; many countries have few or no social programs, pensions, or health care services available for their older adult populations.

National Demographics

As a result of demographic transitions including declining infant and childhood mortality, lower fertility rates, and improvements in adult health, the shape of the global age distribution is changing. The age distribution in developed countries, such as the United States, represents a larger proportion of older to younger populations. By 2025, the United States is expected to have 80% more older adults than in 2000, but working-age adults will grow by only 15% (Ortman, Velkoff, & Hogan, 2014).

There are disparities in life expectancy among various subgroups in the population. Life expectancy is highest for White Americans and lowest for Black Americans, who have the highest death rates of any of America's racial and ethnic groups. Although life expectancies have been increasing for all Americans in general, a variety of factors have caused those figures to level off in recent years. These factors include unhealthy lifestyles and societal problems, such as deaths caused by firearms, substance abuse, and human immunodeficiency virus in older adults.

The Hispanic, Black, and Asian populations have been expanding and are projected to grow substantially through 2025 (*Healthy People.gov, 2015b*). Although the older population is not expected to become majority–minority in the next four decades, it is projected to be 42% minority in 2050, up from 20% in 2010 (*Healthy People.gov, 2015b*). Thirty-three percent are projected to be minority in 2050, up from 15% in 2010.

The health status of racial and ethnic minorities of all ages lags far behind that of nonminority populations. For a variety of reasons, older adults may experience the effects of health disparities more dramatically than any other population group. In an effort to help address these health disparities, the Racial and Ethnic Approaches to Community Health (REACH, 2015) program supports community-based coalitions in the design, implementation, and evaluation of innovative strategies to reduce or eliminate health disparities among racial and ethnic minorities. Methods utilized include "capacity building, targeted actions, community/system change, widespread risk/protective behavior change, and health disparity reduction" (p. 2). An example of one of these programs, along with other public health nursing research targeted to the older adult population, is highlighted in Evidence-Based Practice. The goal of REACH is to achieve health equity, eliminate disparities, and improve the health of all groups (CDC, 2015r).

DISPLAY 24.1 EVIDENCE-BASED PRACTICE

These are only a few examples of research that may benefit your elderly clients.

A Racial and Ethnic Approaches to Community Health (REACH) study conducted in 16 disadvantaged black communities looked at 5-year trends in self-reported vegetable and fruit consumption and compared results with trends among other black populations and white populations in 14 states. Participatory interventions were used with the REACH participants to improve their consumption of vegetables and fruits. After interventions, there was a 7.4% increase in consumption in the REACH participants and no change among the comparison groups. Researchers estimated that the disparity between the 16 disadvantaged REACH communities and the comparison groups decreased 33% over the course of the study.

Liao, Y., Siegel, P., Zhou, H., Grimm, K., Njai, R., Kent, C., & Giles, W. (2015). Reduced disparity in vegetable consumption in 16 disadvantaged Black communities: A successful 5-year community-based participatory intervention. Journal of Racial & Ethnic Health Disparities, 2(2), 211–218.

Improving the health status of immigrant populations has not always been an easy task. Two nurse researchers examined health care utilization and management of hypertension in a group of elderly Korean immigrants recruited from a senior center and a church. Baseline blood pressures were taken and participants completed a health care utilization questionnaire. Findings noted 87% of participants had regular health exams and were aware of their hypertension diagnoses as well as were taking their prescribed antihypertensive medications. About 63% of the elderly Korean participants had hypertension, but not all hypertension was managed effectively. Most had health insurance (95.7%), a much higher number than other elderly ethnic groups (e.g., 29.2% Hispanics, 14.8% Asian/Pacific Islanders). This may help explain higher rates of health care exams and medication compliance in this group. Also, the senior center offered regular blood pressure checks, had assigned meal coordinators for this specific population, and offered social support for this specific group of older adults. This is an example of community agencies and community health nurses targeting programs and interventions to specific populations.

Sin, M. K., & Hirsch, A. (2013). Health care utilization and hypertension management in community-based elderly Korean immigrants. Journal of Immigrant & Minority Health, 15, 1090–1095.

Assisted living facilities are not always well regulated, making their elderly residents more vulnerable. Two gerontology nurse researchers examined neglect and neglect-related outcomes in these facilities based on complaint investigations. They specifically examined elder neglect (medical, personal, environmental), the frequency of neglect-related outcomes (health services, physical psychosocial), and the degree to which practices of the facilities (inadequate staffing, hiring, and business practices) and staff insufficiencies (qualifications, education, attitudes) were associated with neglect. They looked at citations that were issued during routine inspections of facilities and the narrative reports done for investigation of complaints. A total of 165 facilities were included, mostly in urban areas, with a total of 616 complaints. Citations were given for inappropriate care, hiring, staffing, and business practices

and inadequacies in staff education, attitude of staff, and staff qualifications. For neglect outcomes, injuries were the most common and some deaths occurred. Psychosocial outcomes were found in 23.6% of facilities; more than half of facilities had elderly patients relocated because of neglect. When comparing citations and types of neglect, all were statistically significant except for inappropriate business practices. Staff attitudes and inappropriate staffing were associated with a higher number of citations and all three types of neglect. Personal neglect was found to be the most common type in this study, and <10% of facilities had no reports involving neglect. Neglect often resulted in infections, injuries, and death and increases health care costs. Failure to complete background checks on staff, overcrowding, and improper financial transactions were noted as inappropriate institutional practices. Public health nurses need to participate in research on assisted living facilities and not succumb to the preconceived ideas that these are private-pay, well-run places for older adults needing assistance. National databases are needed to help families determine best placements for their loved ones, and public health nurse surveyors could be helpful in this endeavor. This vulnerable population needs PHN services; they remain members of the communities served by PHNs and deserve protection.

Phillips, L. R., & Ziminski, C. (2012). The public health nursing role in elder neglect in assisted living facilities. Public Health Nursing, 29(6), 499–509.

Current research has shown that although many efforts—such as aspirin use for high-risk adults, tobacco use screening and brief intervention, colorectal cancer screening for adults over age 50, and immunization for pneumococcal disease for those aged 65 and older—can be very effective, they are not always implemented or consistently utilized. Nevertheless, older people are healthier than ever before. Increasing numbers of capable older adult people are living independently. Hearty older adults—people older than 65 years of age who maintain a level of wellness and activity, well above present expectations for that age—are increasing in number. Many continue to work and stay involved in community programs and activities. Some have become valuable volunteers, helping others in such community activities as hospice and literacy programs for adults, serving as foster grandparents, working in libraries and homeless shelters, or providing services such as Meals on Wheels. Research has shown a connection between positive health effect and community involvement/participation, volunteering, and other forms of social capital.

Not only are more people living into old age but also, once they get there, they are living longer. In 2010, slightly more than 14% of the older population will be 85 and older. By 2050, that proportion is expected to triple (U.S. Census Bureau, 2015). Because of this expansion, subcategories of the over-65 age group are being used. Oldest old refers to people who are 85 and above (Segen's Medical Dictionary, 2015); it is the fastest growing age group in the United States and worldwide. Those 100 years old or older are called centenarians. A new category for those who have lived 110 years is called supercentenarians (Gerontology Research Group, 2015).

Growth in the number of older adults will significantly affect health care resources, housing options for older adults, and national longevity statistics. As the number of older people increases, so, too, will their need for assistance with activities of daily living (ADLs) and other services. Many people will be involved with the care of a family member who needs assistance in attending to ADLs such as dressing, eating, toileting, and bathing; and researchers are seeking effective methods of providing respite to caregivers and reducing costs. In the United States, approximately 80% of older adults have one chronic condition and half of older adults have two chronic conditions. It is estimated that health care costs for chronic disease treatment account for more than 75% of national health expenditures (Kaiser Family Foundation, 2013). Approximately 7 of 10 deaths are from chronic conditions such as heart disease, cancer, and respiratory deaths (CDC, 2015j). Death is only part of the picture of the burden of chronic disease among older Americans. These conditions can cause years of pain, disability, and loss of function and independence before resulting in death. In addition to chronic conditions that require ongoing monitoring and management, the PHN should anticipate the needs of many older adults who will face the loss of a spouse, helpmate, or companion and who may experience loneliness, social isolation, and depression.

Many older adults live in poverty; over 4.2 million older adults (9.5%) were below federal the poverty level in 2013. This poverty rate is statistically different from the poverty rate of 9.1%, only a year earlier in 2012 (Administration on Aging, 2014). However, in 2013, the Supplemental Poverty Measure (SPM) from the U.S. Census Bureau adjusted for regional costs of living and nondiscretionary expenses and revealed another calculation of poverty level for older adults at 14.8% (over 5% points higher than the official 9.5% rate). This increase is mainly due to adding in medical out-of-pocket expenses that were not included in the original poverty level calculations (Administration on Aging, 2014).

The education level of the older population is rising. Between 1970 and 2014, the percentage of older persons who had completed high school increased from 28% to 84%. In 2014, about 26% had a bachelor's degree or higher. Considerable racial/ethnic differences were found in the proportion completing high school (i.e., 88% of non-Hispanic Whites, 76% of Asians, 74% of African Americans, 76% of American Indian/Alaska Natives, 54% of Hispanics). Only 30% of older Whites, and 9% of older African Americans, had high school diplomas in 1970 (Administration on Aging, 2014). With higher levels of education should come broader health consumerism and improved quality of life.

DISPELLING AGEISM

Ageism is a term that describes negative stereotyping of older adults and discrimination because of older age. In America, ageism is a major problem (Ageism Hurts.org, 2015). These stereotypes often arise from negative personal experiences, myths shared over time, and a general lack of current information. Unfortunately, health concerns and symptoms in older adults are often overlooked or dismissed as part of the normal aging process. By becoming more aware of myths and realities, PHNs can better improve the health and quality of life of the growing population of older adults. Ageism can interfere with effective practice and prevent the kind of comprehensive and interdisciplinary services and care that aging persons need and deserve. Ageism has an impact on both society and culture, even though most individuals are not aware of it. Ageism objectifies older adults and can create needless fear, waste, illness, and misery. "Ageism is to old age as racism is to skin color and sexism is to gender….In its worst form, ageism leads to elder abuse, mistreatment, and neglect" (Robnett & Chop, 2015, p. 22). Most people know little about aging and may have negative stereotypes about older adults. PHNs must guard against ageism in their practice by dispelling common myths and misconceptions.

The Myth of Senility

Myth: It is normal for older adults to become more confused and childlike and forgetful and to lose contact with reality as they age. They become "senile."

Reality: Senility is an obsolete term used to describe deterioration in the mental functions of some older people. The word implies that with growing old come symptoms of forgetfulness, confusion, and changes in behavior and personality. This term is stereotypical, implying that older people are mentally deficient. Memory loss is *not* an inevitable part of the aging process (Alzheimer's Association, 2015b). The brain is capable of producing new brain cells at any age, so significant memory loss is *not* an inevitable result of aging. But, just as it is with muscle strength, you have to use it or lose it. Lifestyle, health habits, and daily activities have a huge impact on the health of the brain. At any age, there are many ways you can improve your cognitive skills, prevent memory loss, and protect your gray matter (HelpGuide, 2015b).

Certainly, Alzheimer's and arteriosclerosis cause memory loss and altered behavior in the older adult, but many older adults have similar symptoms as a result of anxiety, loss, depression, or grief or simply from side effects of medications or changes in their routines. These reactions need to be diagnosed by health care providers and differentiated from disease processes. A recent review of the available literature on the relationship between exercise and cognition indicates that social engagement and physical activity may help maintain cognitive functioning in older adults (Bherer, Erickson, & Liu-Ambrose, 2013; HelpGuide, 2015b). Age-related memory loss can be the result of several physiological factors.

First, the hippocampus, a region of the brain involved in the formation and retrieval of memories, often deteriorates with age. Second, growth factors—hormones and proteins that protect and repair brain cells and stimulate neural growth—decline with age. Third, older people often experience decreased blood flow to the brain. This can impair memory and lead to changes in cognitive skills (Pavlopoulos et al., 2013). Intelligence, learning ability, and other intellectual and cognitive skills do not decline with age. Cognitive deficits are often caused by reversible factors (Gutchess, 2014). Sometimes, even what looks like significant memory loss can be caused by treatable conditions and reversible external factors such as medication side effects, depression, vitamin B_{12} deficiency, thyroid problems, alcohol abuse, or dehydration (HelpGuide, 2015b). Generally, older people are capable of making their own decisions; they want and need the freedom to make choices and to be as independent as their limitations will allow.

The Myth of the Rocking Chair

Myth: *As age increases, older adults withdraw, become inactive, and cease being productive.*

Reality: Whereas some older adults do become disengaged, many remain active for as long as possible. Diminished capabilities and personal preferences affect the level of activity. As age advances, older adults do not necessarily become inactive and sit in rocking chairs on the porch. The average American retires at age 63. Prior to the 1990s, the average age of retirement had been declining. Now, it is moving upward. A recent trend has been for retirees to return to work; in 2012, almost 27% of 65- to 74-year-olds were working and this number is expected to rise to 31.9% by 2022 (Pew Research Center, 2014).

Labor force participation rates of those over 60 (not retired) have been increasing over the past decade for men and women age 62 to 64 (4% increase for men and 12% increase for women). The Center for Retirement Research at Boston College found that older workers who are more productive remain in the workplace for a longer period than do those who are less productive (Burtless, 2013). Millions of Americans older than age 65 choose to work full- or part-time, and many others, who are not included in labor statistics, work but do not report their earnings. An example is the grandmother who chooses to give up full-time employment in an unsatisfying job to babysit for three preschool grandchildren and is paid in cash by her two children. The grandmother gets to spend time with growing grandchildren and supplement her retirement income, the parents feel comfortable that their mother is caring for their children, and the grandchildren are experiencing the joy of being with their grandparent. In another situation, active retired older adults assist with their two children's businesses. The mother types legal documents for the son's law practice during busy times, and the father helps out on Saturdays at the daughter's pool supply store. Everyone wins in these situations.

Meaningful activity remains important to seniors. Healthy older people usually do not disengage or withdraw and isolate themselves from society; rather, they are active and involved. Remaining active—through a daily routine, purposeful behavior, and a positive view of life—produces the best psychological climate.

The Myth of Homogeneity

Myth:

As older adults age, they lose their individual differences and become progressively more alike.

Reality: As a person ages, his/her personality remains fairly constant. Not only are individual differences retained, these differences become even more pronounced with age. Generally, an older adult becomes more like the person he or she was in youth (i.e., a talkative teenager, e.g., becoming a talkative older person or a stubborn youngster carrying the trait of stubbornness into old age). Except for changes in physical appearance and experiencing more physical problems, being "old" feels no different from how we feel now or when we were young. In reality, an old person is a young person who has just lived longer. Not all elderly drive slowly or are cantankerous or politically conservative (Storlie, 2015).

The aging process is quite distinct among older people, and they age at widely disparate rates. Some people still play golf, drive a car, and participate in social and community activities at age 85; others are frail and cannot move about well, needing assistance with their ADLs. Some prefer to equate "real age" with biological age, not chronological age; this depends on how well an individual promotes self-care, both physically and mentally. Exercise, nutrition, vitamins, seat belt use, and other factors are thought to play a role in healthy aging. Physical, social, and mental health parameters; life experiences; and genetic traits all combine to make aging an individualized process (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

SITUATION: Making a healthy transition into a satisfying old age

GOAL: Using the three levels of prevention: health promotion improves overall health and well-being and prevents or delays chronic diseases, whereas secondary prevention ensures prompt early diagnosis and treatment of conditions, and tertiary prevention aids in rehabilitation and continuing health promotion, preventing or delaying chronic diseases, to promptly diagnose and treat conditions, until the fullest possible potential is restored

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Adapt to changed roles with spouse and significant others. • Maintain health while assessing increasing dependency needs, including alternative housing, modifications in transportation, and changing health care needs.	• Periodically review and update will, insurances, and other important documents as needed. • Keep beneficiaries or executors aware of changes in and location of documents and personal wishes regarding end-of-life care and funeral/burial arrangements.	

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Follow the U.S. Task Force Recommendations for regular screening of potential health problems. • Reflect on past successes and contributions to the workforce.	• Allow time for adaptation to this life transition. • Organize new free time into satisfying and enriching activities.

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Early preparation—emotionally and financially. • Plan ahead for changes in health status and potential need for long-term care. • Complete documents, such as a will and a living will.	• Regularly assess health status. • Follow the U.S. Task Force Recommendations for immunizations. • Implement a health-promoting regimen that includes diet and exercise. • Assess living environment for safety hazards.

The Myth of Inability

Myth: Older adults are forgetful, are unable to learn new things, and are set in their old ways of doing things.

Reality: Learning is a lifetime ability that continues into old age. Although older adults may experience some difficulty with short-term (or working) memory as they get older, their long-term memory generally remains sound. People at any age can learn new information and skills. Research indicates that older people can learn new skills and improve old ones, including cognitive training and exercise interventions, as well as how to use a computer and the Internet (Bherer, 2015; Rose et al., 2015). Learning occurs best in a self-paced, supportive environment. Studies have demonstrated that exercising the brain improves memory (HelpGuide, 2015g). Older adults have spent a lifetime adapting to change, with varying measures of success. People older than 65 years grew up during a time when having an automobile was a luxury, and many did not have a microwave oven, computer, or utilize social media until they were in middle adulthood. Older adults learned to adapt to these changes, and they are becoming increasingly computer literate today. The ability to change does not depend on age but rather on personality traits acquired throughout life or, sometimes, because of socioeconomic difficulties. For example, elders living on fixed incomes may be faced with inflationary costs. This may cause them to vote against a school levy that would increase taxes, although they otherwise would be very supportive of schools because they value education.

MEETING THE HEALTH NEEDS OF OLDER ADULTS

No one knows conclusively all of the variables that influence healthy aging, but it is known that a lifetime of healthy habits and circumstances, a strong social support system, and a positive emotional outlook all significantly influence the resources people bring to their later years. Most people recognize a healthy older person when they meet one. See From the Case Files I for an example of healthy aging.

From the Case Files I

I am a PHN and live next door to Minerva Blackstone, affectionately called Minnie by her friends. Minnie is a lively 87-year-old woman who enjoys life. Every day, except in bad weather, she walks a half mile to visit her granddaughter Karen. There, she works on the quilt she is making for Karen. In addition, twice a week, Minnie takes the city bus to the senior citizens' center to join her friends in an exercise class. Although her eyesight has somewhat diminished, Minnie enjoys reading in the evening or crocheting while she watches television. Mysteries and comedies are her favorite kinds of stories.

Minnie is a happy person but is not content unless she is up on the latest political developments. She always has opinions on current events and expresses them with vigorous shakes of her curly white hair at her monthly group meeting on women and politics. She has a good appetite and generally sleeps well. Minor arthritis does not hamper her activities, nor does the hypertension that she controls by taking her medication with conscientious regularity. Minnie is enjoying a healthy, successful old age.

Carole Stokes, District PHN

What is healthy old age? As was mentioned earlier, the vast majority (94%) of our older adults, even those with chronic diseases or other disabilities, are living outside institutions and are relatively independent. Their ability to function is a key indicator of health and wellness and is an important factor in understanding healthy aging. Good health in the older adult means maintaining the maximum possible degree of physical, mental, and social vigor. It means being able to adapt, to continue to handle stress, and to be active and involved in life and living. In short, healthy aging means being able to function, even when disabled, with a minimum of help from others.

Wellness among the older population varies considerably. It is influenced by many factors, including personality traits, life experiences, current physical health, and current societal supports and personal health behaviors including smoking, obesity, and excessive alcohol use. One way to measure healthy aging on a large scale is the degree to which states have met or exceeded targets on the *Healthy People 2020* older adult health indicators. The National Report Card on Healthy Aging tracks 15 indicators of older adult health, 8 of which are identified in *Healthy People 2020*, the national health agenda of the U.S. Department of Health and Human Services. These 15 indicators are grouped into four areas: Health Status, Health Behaviors, Preventive Care and Screening, and Injuries. In addition, the report assigns a "met" or "not met" score to states on the basis of their attainment of *Healthy People 2020* targets (CDC, 2013c, 2015j; *Healthy People 2020,* 2015c). As of 2013, goals for mammograms, colorectal screening, and taking blood pressure medications have been met. Also, rates of smoking have dropped for older adults, as have rates for obesity and those not engaging in leisure time physical activity within the last month (CDC, 2013c). In addition, the report assigns a "met" or "not met" score to states on the basis of their attainment of *Healthy People 2020* targets (CDC, 2013c). The United States has met six of the *Healthy People 2020* targets in this report (p. ii to iii):

- Having no leisure time physical activity in past month (31.4% vs. goal of 32.6% reporting leisure physical activity)
- Obesity (24.5% vs. goal of 30.6% reported that they are obese)
- Current smoking (8.4% vs. goal of 12% reported that they are currently smoking)
- Taking medications as directed for high blood pressure (94.1% vs. goal of 77.4%)
- Having mammograms within past 2 years (81.9% vs. goal of 70%)
- Screenings for colorectal cancer (72.2% vs. goal of 70%)

However, every state has considerable work to do on other indicators for older adults.

- Flu vaccine in past year—no states met the 2020 target of 90% (total was 66.9%)
- Ever had pneumonia vaccine—no states met the 2020 target of 90% (total was 68.1%)

Other actions that can increase healthy aging include addressing health disparities among older adults, encouraging people to plan for end-of-life care and communicate their

wishes through advance directives, improving oral health and increasing physical activity among seniors by promoting environmental changes, increasing adult immunization levels, and preventing falls. Some older adults demonstrate maximum adaptability, resourcefulness, optimism, and activity. Others, often those from whom we tend to draw our stereotypes, have disengaged and present a picture of dependence and resignation. Most older adults fall somewhere in between these two extremes. Although the level of wellness varies among older adults, that level can be raised. The goals in community health nursing are to maximize the wellness potential of older adult clients and to support their highest level of functional ability enabling them to remain independent. Nurses must analyze and build on an older person's strengths rather than focus on the difficulties or deficits. The goal for an aging population is to enable older people to thrive and have the highest quality of life for as long as possible, not merely to survive (Altarum Institute, 2012).

Effective nursing among any population requires familiarity with that group's health problems and needs. Aging, in and of itself, is not a health problem. Rather, aging is a normal, irreversible physiologic process. Its pace, however, can sometimes be slowed, as researchers are discovering, and many of the problems associated with aging can be prevented. The aging process is subtle, gradual, and lifelong. One can see remarkable differences among individuals in the rate of aging. Even in a single individual, various systems of the body age at different rates. Therefore, chronologic age cannot readily be a reliable indicator of health needs. Methods for calculating your "real" or biological age can give you a better picture of your body's true state of health (see http://www.biological-age.com/about.html for a calculator you can use for yourself and your clients).

However, the proportion of people with health problems increases with age, and as a group, older adults are more likely than younger ones to suffer from multiple, chronic, and often disabling conditions requiring ongoing care and management.

LEVELS OF PREVENTION

Older adults, like any age group, have certain basic needs: physiologic and safety needs, as well as the needs for love and belonging, self-esteem, and self-actualization. Their physical, emotional, and social needs are complex and interrelated. The following sections discuss these needs according to primary, secondary, and tertiary prevention activities.

Primary Prevention

As discussed previously in this text, primary prevention activities involve those actions that keep one healthy. Such primary prevention activities as health education, follow-through of sound personal health practices (e.g., flossing, seat belt use, exercise), recommended routine screenings, and maintenance of an appropriate immunization schedule ensure that older adults are doing all that they can to maintain their health. The list in Display 24–1 includes strategies for successful aging. It provides primary prevention activities the PHN can use when working with older adults, either individually or in groups.

DISPLAY 24.1 STRATEGIES FOR SUCCESSFUL AGING

- Do at least 30 minutes of sustained, rhythmic, vigorous exercise four to five times a week.
- Use complementary/alternative therapies (e.g., meditation, yoga, Tai Chi).
- Eat "like a bushman" (a healthy diet of fruits, whole grains, vegetables, and lean meat).
- Get as much sleep and rest as needed.
- Maintain a sense of humor and deflect anger.
- Set goals and accept challenges that force you to be as alive and creative as possible.
- Do cognitively challenging activities for at least 6 hours each week (e.g., crossword puzzles, playing cards, reading).
- Don't depend on anyone else for your well-being.
- Be necessary and responsible; live outside yourself (give to others, become involved).
- Don't slow down. Stick with the mainstream. Avoid the shadows. Stay together. Maintain energy flow in a purposeful direction; aging need not be characterized by losses. Maintain contacts with family and friends, and stay active through work, recreation, and community. Find meaning in your life.
- Get regular checkups. Maintain good dental health.
- Don't smoke—it's never too late to quit.
- Practice safety habits at home to prevent falls and fractures. Always wear seat belts when traveling by car.
- Avoid overexposure to the sun and the cold.

- If you drink, moderation is the key—when you drink, let someone else drive.
- Keep personal and financial records in order to simplify budgeting and investing—plan long-term housing and financial needs.
- Keep a positive attitude toward life—do things that make you happy.

Adapted from Shapira, E. Z. (2011). A new wrinkle: What I learned from older people who never acted their age. Bloomington, IN: iUniverse; Harmell, A. L., Jeste, D., & Depp, C. (2014). Strategies for successful aging: A research update. Current Psychiatry Reports, 16(10), 476.

Nutrition and Oral Health Needs

People who have maintained sound dietary habits throughout their life have little need to change in old age. The USDA replaced the food pyramid with MyPlate as a visual to guide the food intake of Americans (U.S. Department of Agriculture, 2015). Tufts University has modified MyPlate for older adults (see Fig. 24–1). The modifications include an emphasis on drinking plenty of fluids such as water and/or fat-free milk and high-fiber intake, as well as adding multivitamins to the diet. Also emphasized is the importance of regular exercise with icons depicting common activities that include daily errands and household chores (Tufts University, 2015).

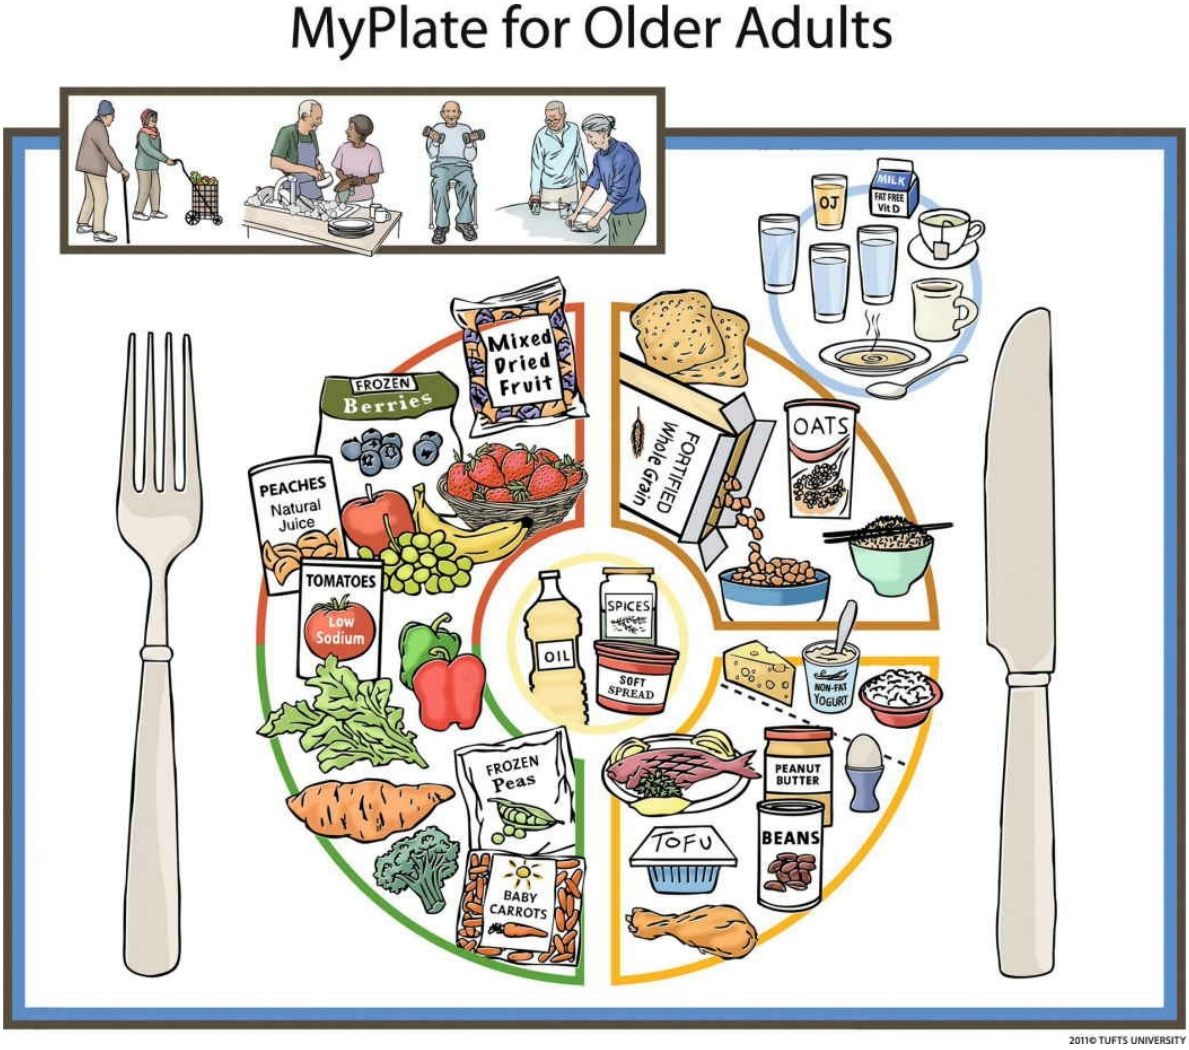

FIGURE 24–1 MyPlate for older adults. (Copyright (Tufts University, 2011). Used with permission.)

Many older adults have not established such habits but may be required to do so because of disease processes such as diabetes or cardiovascular disease. It is generally believed that older people need to maintain their optimal weight by eating a diet that is low in fats, moderate in carbohydrates, and high in proteins with a daily calorie count of 1,200 to 1,600. Foods with "empty calories," such as salty snacks, candy, fatty foods, and alcohol, should be limited; they meet hunger needs by satisfying appetite only, while providing little nutrition. Cereals and whole grains, dried beans, and nuts can provide fiber needed by seniors, and eating colorful fruits and vegetables (rather than fruit juice) also contributes to fiber and may help to prevent macular degeneration. Another important thing to remind older adults to do is to drink adequate amounts of liquids, especially water. Eight glasses a day are recommended, and many older adults have a diminished feeling of thirst and can easily become dehydrated if they do not purposefully plan their fluid intake. Older adults need less vitamin A but more calcium and vitamin D (for healthy bones), more folic acid, and more vitamins B_6 and B_{12} (for cognitive health) than younger adults. Many communities offer meals to seniors, either at senior centers or by way of Meals on Wheels,

through grants provided by the Older Adult Nutrition Program (Administration on Aging, 2015).

Major advances in the field of oral health including community water fluoridation, advanced dental technology, better oral hygiene, and more frequent use of dental services have had a substantial impact on the number of older adults who retain their natural teeth. Before the time of widespread fluoride use, it was common for people to lose most or all of their teeth by midlife. The percentage of older adults who have lost all their natural teeth has declined to 18%, surpassing the *Healthy People 2020* target of no more than 20% (CDC, 2015k). Severe tooth loss in older adults compromises the quality of their nutrition. Most people can keep their natural teeth for a lifetime with preventive oral health (CDC, 2015l). The percentage of adults ages 65 and over with a dental visit in the past year was 60.6% (CDC, 2015k). Oral health is integral to general health and well-being throughout one's life. A good deal of research has demonstrated the connection between oral health and general health due to chronic inflammation that releases cytokines and C-reactive protein causing endothelial damage and cholesterol plaque attachment in cardiovascular disease and stroke. Poor oral health has also been associated with peripheral vascular disease, diabetes, and risk for death caused by pneumonia in nursing homes (Igari, Kudo, Toyofuku, Inoue, & Iwai, 2014). Even those with dentures must be vigilant in maintaining oral health, as they are still at risk from inflammatory processes leading to diseases like pneumonia. The oral health of older adults, however, is often neglected. Many older adults especially those who are disadvantaged and with limited incomes have decreased nutritional and fluid intake, changes in gums and increased periodontal disease, as well as a higher incidence of dry mouth. Saliva contains minerals for rebuilding of tooth enamel as well as antimicrobial components (Carpenter, 2013; CDC, 2015i; National Institute on Aging, 2015b). Fluid intake and oral hygiene are appropriate topics for anticipatory guidance from PHNs working with older adults.

Oral health and hygiene needs do not decrease with age. Eating, chewing, and swallowing should be an uncomplicated and natural process. Eating should remain a pleasurable social experience, preferably taking place in the company of others. PHNs can assist older adults with meal management by following the suggestions outlined in Display 24–2 and Figure 24–1.

DISPLAY 24.2 MEAL MANAGEMENT CONSIDERATIONS

- Complete a safety check with the older adult to assess the ability to operate

stoves and microwave ovens. Include the elder's ability to reach and put things on and off stove burners.

- Arrange kitchen shelves so that commonly used items can be reached from an easy standing level.
- Suggest use of turntables and long-handled "grabbers" while discouraging use of step stools or ladders.
- Assess the elder's typical meal for quality and availability—can be accomplished for all meals by doing a 24-hour dietary recall—begin with the most recent meal and work backward.
- To ensure that elders eat an appropriate number of times a day, suggest that they "eat by the clock" or with a certain TV show.
- Help older adults build support system for sharing grocery shopping, cooking, and meals.
- Suggest they bake once a week for an activity or shop with another elder.
- Suggest buying convenience foods, making sure they have nutritional value, such as frozen vegetables or dinners.
- Consider community resources to assist with shopping, transportation, or meal preparation as needed. Keeping a continuous shopping list helps elders to remember needed grocery items and provides a reference if someone offers to assist with shopping.
- Help older adults consider increasing socialization by eating together with friends—rotating among three to four friends each week or eating out with friends and selecting restaurants that are physically and financially accessible.

In addition to maintaining a healthy diet, older adults are cautioned to limit the use of alcohol, avoid tobacco, drink fluoridated water or use fluoride toothpaste, practice good oral hygiene, and have regular dental checkups (CDC, 2015k). They should also avoid the habitual use of laxatives, instead adding more fiber and bulk to their diet with fresh fruits and vegetables. Also, inadequate fluid intake can contribute to bowel and bladder problems. Following a diet that includes eight or more 8-ounce glasses of fluid daily assists the gastrointestinal and genitourinary systems in their functions. Increased physical activity and exercise helps maintain regularity of bowel function in older adults.

Physical activity, drinking plenty of water, and adding fiber and bulk to their diet with

fresh fruits and vegetables are healthy ways seniors can assure good bowel patterns.

Exercise Needs

Older adults need to exercise; in fact, they thrive when exercise is incorporated into their daily routine (National Institute on Aging, 2015b). Research demonstrates that exercise and increased physical activity have multiple benefits for the older adult including arthritis relief, restoration of balance and reduction of falls, strengthening of bone, proper weight maintenance, improved glucose control, and overall mortality (Beherer, Erickson, & Liu-Ambrose, 2013; Kokkinos, 2012; Reiner, Niermann, Jekauc, & Woll, 2013; Taylor, 2014). It also contributes to a healthy state of mind, improved sleep, and reduces the risk of heart disease (CDC, 2014). Aging does not and should not involve passivity; instead, physical activity and movement contribute to the quality of intellectual and physical performance in old age. Exercise, such as a daily walk, can keep muscles in good tone, enhance circulation, and promote mental health and adequate sleep (Healthy People 2020, 2015d; National Institute on Aging, 2015b). Exercise may occur in connection with such activities as homemaking chores, gardening, hobbies, or recreation and sports. Often, such physical outlets are enjoyed in the company of other people, meeting social and emotional needs as well as physical ones. Even among the very old, an exercise routine that includes activities to improve strength, flexibility, and coordination may indirectly, but effectively, decrease the incidence of osteoporotic fractures by lessening the likelihood of falling. Resistance training (with small dumbbells or resistance bands), along with either Tai Chi or regular walking, has been shown to increase muscle strength, stability, and functional ability among seniors (healthfinder.gov, 2015; National Institute on Aging, 2015b). Community health nurses can encourage exercise among clients and examine factors that prevent them from regularly exercising. Physical disabilities need not be a barrier to exercise, as there are specialized exercise programs (e.g., chair aerobics, wheelchair fitness).

Sleep

Sleep is another area of focus in *Healthy People 2020* (*Healthy People 2020,* 2015d). Sleep is essential for health, productivity, energy, and emotional balance. In older adults, adequate sleep is necessary to fight off infection and support the metabolism of sugar to prevent diabetes or to work effectively and safely. Sleep timing and duration affect a number of endocrine, metabolic, and neurological functions that are critical to the maintenance of individual health. Untreated, sleep disorders and chronic short sleep are associated with an increased risk of heart disease, high blood pressure, obesity, diabetes, and all-cause mortality (*Healthy People 2020,* 2015d).

Some changes in sleep are natural with aging. The body produces lower levels of growth hormone, resulting in a decrease in slow wave or deep sleep. Illness often means more fragmented sleep (more rapid sleep cycles) and more awakenings between sleep cycles. As circadian rhythms (the internal clock that tells you when to sleep and when to wake up)

change, the older adult may want to go to sleep earlier in the evening (HelpGuide, 2015i). Also, many medications can alter sleep patterns, and snoring, which may worsen with age, is a common cause of sleep disturbance (National Sleep Foundation, n.d.).

Economic Security Needs, Poverty

Economic security is another major need for older adults. Worrying about finances is often one of the most debilitating factors of old age. Fearing the potential cost of major illness and not wanting to be a burden on family or friends, many older people conserve their limited finances by establishing frugal eating patterns, using health resources sparingly, not taking their medications or only taking medications in partial doses, reducing costs for home heating and cooling, and, in general, spending little on themselves. People sometimes have to choose between food, housing, and medications. Another factor that is driving up the cost of health care for the aging population is that many clients wait until they are more seriously ill before seeking health care. In waiting for conditions to improve or go away, they often miss out on important preventive health measures and community-based programs that can maximize function and help the client maintain health at a higher level (U.S. Preventive Services Task Force [USPSTF], 2015). Too often, the fear—let alone the reality—of financial difficulties prevents older adults from leading full and active lives (Wallace, 2014–2015).

For older adults today who have lived many years past retirement and perhaps have not planned for sufficient financial security to maintain them throughout these additional, unexpected years, the fears are not unfounded. The official poverty rate in 2013 was nearly three times larger among Hispanic adults than among White adults ages 65 and older (20% vs. 7%) and two and a half times larger among Black adults ages 65 and older (18%). Rates of poverty for all three groups were higher under the SPM, with 28% of Hispanic adults, 22% of Black adults, and 12% of White adults ages 65 and older living below the SPM poverty thresholds in 2013 (Kaiser Family Foundation, 2015b).

Putting older people in touch with appropriate community resources can do much to help relieve the source of that stress and anxiety. The PHN can also provide information about potential consumer fraud (e.g., telemarketing schemes) targeted to elderly. This is a form of financial abuse perpetrated by criminals who have no personal relationship with the victims, and seniors with retirement income, savings accounts, or property are disproportionately targeted. Losses from this type of fraud can wipe out a lifetime of savings and leave the older adult feeling foolish and helpless.

Psychosocial Needs

All human beings have psychosocial needs that must be met for their lives to be rich and fulfilling. Lacking healthy relationships with other people, life can be very lonely and diminished in quality. With advancing age, the psychosocial issues are many; a major issue that confronts the majority of our aging population is coping with multiple losses (McCoyd

& Walter, 2016). In addition, maintaining independence, social interaction, companionship, and purpose is necessary for a healthy old age. Older adults who have maintained good health and have developed a supportive system of family and friends have more fulfilled lives. Programs such as Friendly Visitors, where volunteers regularly meet with isolated seniors either in their homes or long-term care facilities, can be an effective method of increasing social support for those who have no family members nearby.

A supportive system of family and friends helps older adults meet their psychosocial needs.

Spiritual Needs

Holistic nursing is a hallmark of community and public health nursing. This means a focus on body, mind, and spirit. The word spirit comes from the Latin meaning "breath" and refers to the core of an individual, the part that gives meaning to life (New World Encyclopedia, 2015). Spirituality is far more encompassing than religion, though we often see the two used interchangeably. Many people think that spirituality and religion are the same; religion and spirituality may exist together; however, a spiritual component exists in all people, but not everyone is religious (Center on Aging Studies Without Walls, n.d.). Religion is generally recognized to be the practical expression of spirituality, or the organization, rituals, and practice of one's beliefs. Religion includes specific beliefs and practices, whereas spirituality is far broader.

Religion and associated activities are common among older adults. Older adults may turn to spirituality and religion when they meet difficult life-changing events and experience personal losses. Their reaction to these events and losses may cause distress and temporary or chronic psychological conditions (Noronha, 2015). Many older persons report that religion helps them cope or adapt with losses or difficulties. While other sources of well-being decline, religion may become more important over time. At the time when religious support is most needed, older persons are often less able to access it because of failing health, immobility, or lack of transportation.

Individuals within different cultures have varying philosophies and practices of spirituality, but derive similar positive outcomes. For many, old age may be a time of life review. These years become a time of redefining self without the association of lifelong friends, spouses, or work that helped define the self during decades of adult life. This may be a time of reevaluation of what gives meaning and satisfaction in life.

Faith-based nursing is one of the community nursing roles that epitomizes this holistic approach of caring for their clients, many of whom are older adults (see Chapter 31). Faith community nursing, or parish nursing, began in the mid-1980s as a way for nurses working with church congregations to integrate healing and faith (Pappas-Rogich, 2012). Ebersole and Hess' gerontological nursing text (Touhy & Jett, 2014) elucidates, nurses can support the spiritual dimension of older clients in times of difficulty by developing the following skills:

- Listening
- Being aware of signs of mental health problems and urge professional help
- Sharing concern and observations
- Providing privacy
- Reassuring the value of the person
- Allowing decisions to be made
- Accepting without judgment
- Helping express religious, spiritual, or social needs

- Recognizing cultural differences
- Keeping separate values and spiritual beliefs that are different
- Referring to professionals when needs are beyond listener's ability to help
- Using humor as appropriate

Coping with Multiple Losses and Suicide

Older adults may experience multiple losses, including loss of income and prestige from a career once practiced or the economic stability of an enjoyable job, loss of space due to replacement of a larger residence by a much smaller home or apartment, and reductions in health and vitality that may result in limited movement or pain as a daily concern or may necessitate another move to a more dependent living environment. Repetitive losses occur as significant others, relatives, friends, and acquaintances die. There are no right or wrong ways to grieve, but there are healthy ways to cope with the pain. Assisting older adults to handle with these losses is an important role of the public health nurse. To do this, PHNs need to be aware of some of the facts about grief.

First, it is not true that ignoring pain will help it go away faster. In the long run, ignoring pain will only make it worse. It is necessary to face grief and deal with it in order to experience real healing; and feeling sad, or frightened, or lonely is a normal reaction to loss. Second, crying does not mean you are weak. Crying is a normal response to loss, but this does not mean that someone who does not cry does not feel the loss. It may just be shown in a different way. Third, there is no set time for grieving. It will differ from person to person (HelpGuide, 2015d). For about 15% of the bereaved population, grief becomes an endless "loop of suffering"; this is described as prolonged grief disorder, and it requires specialized psychological counseling techniques much like posttraumatic stress disorder (Maercker & Lalor, 2012; Schumer, 2009, p. 2). The most important tip for assisting older adults in coping with grief and loss is making sure they have the support of other people. Wherever it comes from, connecting with others helps the healing process.

As Kübler-Ross (1969) stated in her classic work, there are five stages of grief: denial, anger, bargaining, depression, and finally acceptance. Inadequate coping with the compounding losses can make an older person believe that life holds no meaning. Depression may be a difficult problem for older adults. Social and emotional withdrawal can often occur, as can suicide. Although older populations have a much lower rate of suicide attempts than younger age groups do, the rate of completed suicide is high.

- In 2013, the highest suicide rate was among people 45 to 64 years old (19.1 per 100,000). The second highest rate (18.6 per 100,000) occurred in those 85 years and older.
- For many years, the suicide rate has been about four times higher among men than among women. In 2013, men had a suicide rate of 20.2 per 100,000, and women had a rate of 5.5 per 100,000.

- Of those who died by suicide in 2013, 77.9% were male and 22.1% were female.
- In 2013, Whites had the highest U.S. suicide rate (14.2) and American Indians and Alaska Natives had the second highest rate at 11.7 (American Foundation for Suicide Prevention, 2015).

Because most persons who commit suicide have visited their primary care provider in the last month of their lives, recognition and treatment of depression in health care settings is a promising way to prevent suicide in this age group (Raue, Ghesquiere, & Bruce, 2014).

Mortality after bereavement is high and can sometimes be prevented through nursing intervention. The experience of loss and the mourning process among elders have been examined in many studies. It has been found that the ability to mourn prior states of one's self and the past is crucial to successful aging. Life review can be liberating and can provide energy for current living, including planning for the future. Although men and women experience similar levels of depression during early bereavement, it is often more difficult for men to seek and receive social support. Depression has been found to increase the risk of death for those who have lost a spouse, independent of age or bereavement. The death of a spouse has effects upon the health of the surviving spouse, and depression can exacerbate these effects. In addition to preventing early deaths after the loss of a spouse, the greater goal for the nurse in promoting successful aging can be accomplished when the nurse recognizes the significance of accepting all the losses of aging. The loss of a spouse is much more frequent for women than for men. With this knowledge, a woman who was in a more passive, dependent role may become more anxious when her spouse dies. For couples that were especially close, the wife may be more inclined to experience significant depression (Vitelli, 2015).

Maintaining Independence

Older people need independence, and those who stay independent are happier. As much as possible, they need to make their own decisions and manage their own lives. Even those with activity limitations because of disability can still exercise decision-making options about many, if not most, aspects of their daily living. Unfortunately, because many older adults have chronic diseases, it can be more difficult for them to maintain their independence.

The number of disabled U.S. adults is increasing; 47.5 million U.S. adults report a disability. More than one third of these are aging baby boomers. Arthritis is the most common cause of disability. The number of people reporting a disability increases with age, with women having a higher prevalence of disability than men at all ages. Given the size of the baby boomer generation, the number of adults with disabilities is likely to increase dramatically as they enter into higher-risk age groups over the next 20 years (CDC, 2013c).

The need for autonomy—to be able to assert oneself as a separate individual—is important for all people. Independence helps to meet the need for self-respect and dignity.

They need to have their ideas and suggestions heard and acted upon, and they ought to be addressed by their preferred names in a respectful tone of voice. Respect for the older adult is not a strong value in American society, but it is highly valued in Asian, Italian, Hispanic, and Native American cultures. Older people represent a rich resource of wisdom, experience, and patience that is often unacknowledged in the United States.

Interaction, Companionship, and Purpose

Older people need companionship and social interaction, particularly if they live alone. The company of other people and the companionship of a household pet offer avenues for expression along with response and it adds meaning to life. As people age, their social networks weaken, and PHNs and others can help to improve their psychosocial health by working at individual, family, and community levels. The problem is of greatest significance for women, who outnumber men considerably in the later years and who more frequently live alone.

It is also important for older adults without companions to discover and develop a friendship with someone who can be considered a *confidante*, someone in whom the older adult can confide, share reflections on the past, and trust. It could be a close friend, a sibling, a son or daughter, or an acquaintance. This person is usually seen daily or is engaged on the telephone each week. In particular, mothers and daughters form confidante bonds. Many women consider a sibling a confidante, especially if that person lives close by; this is especially true for childless and single women.

Meaningful activity is another need of the older adult that adds purpose to life. Some kind of active role in community life is essential for mental health, satisfaction, and self-esteem. These activities can range from involvement in hobbies, such as gardening or crafts, to volunteer work or even full-time employment. Examples include the federally supported Foster Grandparents and Senior Companions programs, which engage millions of Americans in service. These older adults work part-time offering companionship and guidance to handicapped children, the terminally ill, and other people in need (Corporation for National & Community Service, n.d.).

Additional volunteering opportunities abound. Internationally, many older professionals join the Peace Corps, which was initiated in the early 1960s. In this program, people of all ages work for 2-year periods in global communities that are in need of services to improve personal health, education, environment, and the larger community (Peace Corps, 2015). On the national level, the AmeriCorps program is similar but with a 10-month commitment volunteering with local and national nonprofit and government agencies. Retired people can volunteer to help others, donating their skills at a time in their lives when they are in transition from employment to retirement or to fill active retirement years (AmeriCorps, 2015). Through the Corporation for National and Community Service, older adults can volunteer in the Retired and Senior Volunteer Program (RSVP) or the Foster Grandparent Program. The Senior Companion Program and Senior Corps

program engage seniors in a bevy of activities designed to improve people's lives and the environment (Senior Corps, 2015). Environmental Alliance for Senior Involvement (EASI) is a nonprofit coalition of aging, volunteer, and environmental organizations that began in 1991 (Environmental Alliance for Senior Involvement, 2015). It sponsors various environmentally focused programs, such as assisting the Hawk Mountain Sanctuary to protect birds of prey or monitoring streams and other waterways for cleanliness.

Volunteering can be a rewarding experience for older adults.

Many older adults choose not to engage in long-term volunteering, and other programs are more appropriate for them. Elderhostel, Inc., the not-for-profit world leader in lifelong learning since 1975, is the creator of Road Scholar educational adventures providing high-quality, affordable, educational adventures for adults who desire lifelong learning. It is the nation's first and the world's largest education and travel organization for older adults,

offering more than 7,000 learning adventures in all 50 states and more than 150 countries (Road Scholar, 2015). Their theme-based, short-term (3 days to 3 weeks) educational programs are infused with a spirit of camaraderie and adventure. The success of this program is based on recognizing that learning is a lifelong process that is rewarding at any age—and it is learning without any test or term papers! Elderhostel is inspired by the youth hostels and folk schools of Europe but guided by the needs and interests of older citizens.

Safety Needs

People of all ages have safety needs, and safety issues are a major concern for older adults and the PHNs who work with them. Several areas of focus are discussed here: personal health and safety, home safety, and community safety.

Personal health and safety includes three major areas: immunizations, prevention of falls, and drug safety.

Immunizations

Older adults are at increased risk for many vaccine-preventable diseases. Preventable illnesses cause substantial morbidity and mortality in older patients, who tend to have more medical comorbidities and are at higher risk for complications. Acute respiratory infections, including pneumonia and influenza, are the eighth leading cause of death in the United States, accounting for 56,000 deaths annually. On average, influenza leads to more than 200,000 hospitalizations and 36,000 deaths each year (Greenberg, 2012; CDC, 2015p).

Each year in the United States, about 9 out of 10 flu-related deaths and more than 6 out of 10 flu-related hospital stays occur in people over the age of 65. Nonetheless, vaccination rates in the United States do not meet targets. In the United States, the majority of deaths from influenza occur among those over 65, yet only 65% of older adults were immunized against the flu; this is short of the *Healthy People 2010 and 2020* targets of 90%. Only 60.6% of Americans 65 and older were immunized against pneumococcal pneumonia (Greenberg, 2012). The CDC recommends that all adults over 50 receive three immunizations, one each for influenza, pneumonia, and shingles (CDC, 2015m). While influenza does kill an estimated 36,000 people per year, in older adults, it is the exacerbating effect on other conditions (e.g., pneumonia, congestive heart failure, or chronic obstructive pulmonary disease [COPD]) that makes flu of great concern in older adults (National Foundation for Infectious Diseases, 2015). Racial and ethnic disparities exist among older adults receiving influenza vaccines; therefore, it is important to include outreach efforts, such as culturally targeting communication, reaching out to those providers serving this population, and offering vaccination clinics in underserved sections of the community.

Pneumococcal vaccine coverage rates have also increased steadily from 38.4% in 1995 to 66.8% in 2009, but improvement is still needed. In 2012, only 60% were vaccinated,

even further from reaching the *Healthy People 2020* goal of 90% vaccine coverage for those aged 65 and older (Alliance for Aging Research, 2015). However, incidence rates for pneumonia have been generally decreasing since 2000, largely because of more people being vaccinated. Similar to flu vaccination, certain racial and ethnic groups remain substantially below those of the general population. Attempts to improve immunization coverage involve changing provider knowledge, attitudes, and behavior through reminders and standing orders, so that "missed opportunities" when seeing clients are prevented. One simple method is to ask clients about their beliefs and fears related to immunizations and then to address them directly and honestly. Additional opportunities for vaccinating people exist beyond the primary care setting, as PHNs are well aware. People can be reached during emergency department visits, during screening procedures such as colonoscopies, at neighborhood and senior centers, at religious facilities, and in other settings where elders may gather. Regardless of the site, a method for tracking and communicating vaccinations is needed so that vaccination information may be documented and shared with the elder's primary care provider. Clinicians often fail to document immunizations for adult patients. Immunizations protect more than the at-risk population; they protect society as a whole. People of any age with a chronic illness, such as heart disease, diabetes, or chronic respiratory disease, and people older than 65 years of age should be encouraged to receive an annual flu vaccine and the pneumonia vaccine every 5 years (CDC, 2015l).

Shingles is caused by the varicella–zoster virus (VZV); this is the same virus that causes chickenpox. Anyone who has had chickenpox can develop shingles because VZV remains in the nerve cells of the body after the chickenpox infection clears, and VZV can reappear years later causing shingles. Shingles is a painful localized skin rash often with blisters. The disease most commonly occurs in people 50 years old or older, people who have medical conditions that keep the immune system from working properly, or people who receive immunosuppressive drugs (CDC, 2015m). The CDC recommends Zostavax for use in people 60 years old and older to prevent shingles. This is a one-time vaccination. There is no maximum age for getting the shingles vaccine (CDC, 2015n). In 2012, only 20% of people age 65 and older received this vaccine; this is below the *Healthy People 2020* target of 30%. The incidence of shingles was on the rise until the vaccine was developed in 2006; since 2008, it has generally been on the decline (Alliance for Aging Research, 2015).

Fall Prevention

Every year, about one third of U.S. adults age 65 and over experience a fall. Falls are the most common cause of hospitalization due to nonfatal trauma (more than 734,000) and over 21,700 deaths are attributed to falls yearly. The total costs related to fall injuries was $34 billion in 2013. Even minor falls can seriously impact the lives of seniors, limiting their social activity and leading to isolation and dependency (National Council on Aging, n.d.a). Environmental hazards (e.g., lack of nonslip surfaces and handrails) and host conditions (e.g., poor vision, problems with balance) are often the causative factors in falls. Fall

prevention includes asking older adults about their concerns related to fall risk, discussing their current health conditions (e.g., vision problems, medications that cause dizziness), asking about current vision and recent eye exams (e.g., is current eyeglass prescription being used, do bifocals cause problems when using stairs), noticing if they have difficulty getting out of chairs or are unsteady while walking (e.g., do they need someone to assist them, do they hold onto furniture, could they benefit from a consultation with a physical therapist to improve strength, balance, and gait), and asking whether they check with their physician and pharmacist regularly about the medications they take (e.g., are there drug interactions and side effects that cause dizziness or visual issues, do they take sleep medications that may affect balance) and whether their home is an obstacle course (e.g., make sure paths are free from clutter; do they need a consultation with occupational therapist to ensure good lighting, stair handrails on both sides, grab bars in shower and next to toilets, or use of shower chair). The use of a home safety checklist can give the nurse a baseline of information from which to begin teaching and providing interventions to ensure continued safety for many independent seniors who choose to remain in their homes (National Council on Aging, n.d.b). See Display 24–3 for guidelines to assess the senior client's environment.

DISPLAY 24.3 GUIDELINES FOR ASSESSING THE SAFETY OF THE ENVIRONMENT

Illumination and Color Contrast

- Is the lighting adequate but not glare producing?
- Are the light switches easy to reach and manipulate?
- Can lights be turned on before entering rooms?
- Are night-lights used in appropriate places?
- Are there working flashlights close by (bedroom, kitchen, bath, living room)?
- Is color contrast adequate between objects such as a chair and floor?

Hazards

- Are there throw rugs, highly polished floors, or other hazardous floor coverings?
- If area rugs are used, do they have a nonslip backing and are the edges tacked

to the floor?
- Are there cords, clutter, or other obstacles in pathways?
- Is there a pet that is likely to be running underfoot?

Furniture

- Are chairs the right height and depth for the person?
- Do the chairs have armrests?
- Are tables stable and of the appropriate height?
- Is small furniture placed well away from pathways?

Stairways

- Is lighting adequate?
- Are there light switches at the top and bottom of the stairs?
- Are there securely fastened handrails on both sides of the stairway?
- Are all the steps even?
- Are the treads nonskid?
- Should colored tape be used to mark the edges of the steps, particularly the top and bottom steps?

Bathroom

- Are grab bars placed appropriately for the tub and toilet?
- Does the tub have skid-proof strips or a rubber mat in the bottom?
- Has the person considered using a tub seat?
- Is the height of the toilet seat appropriate?
- Has the person considered using an elevated toilet seat?
- Does the color of the toilet seat contrast with surrounding colors?
- Is toilet paper within easy reach?

Temperature

- Is the temperature of the room(s) comfortable?
- Can the person read the markings on the thermostat and adjust it appropriately?
- During cold months, is the room temperature high enough to prevent hypothermia?
- During hot weather, is the room temperature cool enough to prevent hyperthermia?

Overall Safety

- How does the person obtain objects from hard-to-reach places?
- How does the person change overhead light bulbs?
- Are doorways wide enough to accommodate assistive devices?
- Do door thresholds create hazardous conditions?
- Are telephones easily accessible, especially for emergency calls?
- Would it be helpful to use a cordless portable phone or a cellular phone?
- Would it be helpful to have some emergency call system available?
- Does the person wear sturdy shoes with nonskid soles?
- Are smoke alarms present and operational?
- Is there a carbon monoxide detector (if the house has gas appliances)?
- Does the person keep a list of emergency numbers by the phone?
- Does the person have an emergency exit plan in the event of fire?

Bedroom

- Is the height of the bed appropriate?
- Is the mattress firm at the edges to provide enough support for sitting?
- If the bed has wheels, are they locked securely?
- Would side rails be a help or a hazard?
- When side rails are in the down position, are they completely out of the way?
- Is the pathway between the bedroom and bathroom clear of objects and adequately illuminated, particularly at night?
- Would a bedside commode be useful, especially at night?
- Does the person have sufficient physical and cognitive ability to turn on a light before getting out of bed?
- Is furniture positioned to allow safe use of assistive devices for ambulation?
- Is a telephone situated near the bed?

Kitchen

- Are storage areas used to the best advantage (e.g., are objects that are most frequently used in the most accessible places)?
- Are appliance cords kept out of the way?
- Are nonslip mats used in front of the sink?
- Are the markings on stoves and other appliances clearly visible?
- Does the person know how to use the microwave oven and other appliances safely?

Assistive Devices

- What assistive devices are used?
- Is a call light available, and does the person know how to use it?

- Would the person benefit from any assistive devices that are not being used?
- Are assistive devices being used safely and properly, or do they present additional hazards?

Adapted from Miller, C. A. (2015). Nursing for wellness in older adults (7th ed.). Philadelphia, PA: Wolters Kluwer.

Medications

Medications are often prescribed to control the effects of chronic conditions, and older adults' bodies can react differently than those of younger people (on whom most new drugs are tested). A significant safety issue for the older adult arises from the use of prescription and over-the-counter (OTC) drugs. Problems can arise from a single difficulty or a combination of issues such as (1) number of medications taken daily, (2) absorption rate of medications, (3) drug interactions, and (4) side effects.

Older adults often have multiple chronic diseases for which they take prescription medications. It is not unusual for older people to be taking 4 to 6 medications daily and fill 13 prescriptions or more each year. Although older adults constitute only 13% of the population, they account for approximately one third of all medications prescribed in the United States (National Institute on Drug Abuse, 2014). In addition, many older adults take OTC medications and/or dietary supplements.

Older adults often receive multiple prescriptions from multiple providers and sometimes from multiple pharmacies. This puts them in danger of receiving double doses of the same or similar medications. Polypharmacy involves the use of multiple medications (more than is medically necessary). Almost 50% of older adults take at least one medication that is not medically necessary (Maher, Hanlon, & Hajjar, 2014). This can happen, for instance, when one health care provider prescribes a brand-name medication and a second one writes a prescription for the same medication but in generic form. Often, the person has no idea that they are taking two doses of the same medication Also, common medications like acetaminophen can be found in a variety of OTC and prescription medications (e.g., cold remedies, arthritis topical ointments), and inadvertent overdosing can be a real problem.

Absorption time is usually slower in older adults, and distribution changes as drugs may stay in the body longer because of a higher percentage of fat stores, along with reduced liver and kidney function that affect clearance time. Most adverse drug events (ADEs) are due to drug interactions. The greater number of medications taken, the more likely there will be side effects. Polypharmacy is linked to adverse clinical outcomes such as drug interactions, ADEs, diminished functional capacity, multiple geriatric syndromes (e.g., cognitive impairment, falls, urinary incontinence), and it also leads to increased health care costs (Maher et al., 2014). Multiple medications or complicated drug regimens for many older people can lead to unexpected and dangerous drug interactions or drug–disease

interactions; sometimes, medications are prescribed for symptoms that may actually be a side effect of an original medication.

Medication side effects or drug interactions can lead to falls and further disability. Older adults need education about the drugs they take and their possible effects. They also need proper supervision of their overall medication intake, including complementary and alternative therapies (e.g., herbal treatments) and OTC drugs (Public Citizen's Health Research Group [PCHRG], 2015). It is also important for all seniors to keep a list of their current medications and doses, and to have this available in the event of an emergency. However, many hospitals and providers prefer the "brown bag method" of determining accurate medication information; patients are asked to bring everything they take with them. One study of hospital discharges among elderly patients found that over 41% were taking 5 to 8 medications and over 37% had 9 or more prescriptions. This earlier study also found that 58.6% took at least one prescribed medication that was unnecessary (Hajjar et al., 2005). This is an area in which the community health nurse can intervene very effectively (see Display 24–4).

DISPLAY 24.4 PROMOTING POLYPHARMACY SAFETY IN THE OLDER ADULT THROUGH MEDICATION REVIEW

- Ask the client to bring all of his or her medications for you to examine.
- List all medications, along with dosage and time taken.
- Note the pharmacy or pharmacies where each prescription originates. Has more than one physician prescribed medications for the client?
- Ask about medical conditions and diseases for which he or she takes medications. Does the client have a clear understanding of each medication and its benefits and potential side effects?
- Ask the client for which condition or disease each medication is prescribed. Does the client understand the basic disease process and how the prescribed medication works?
- Are there duplicate medications (e.g., contain the same active ingredient, both a generic and a proprietary form)?
- Ask if they feel that they are taking any medications that may no longer be needed.

- Ask if they are concerned about the number of medications they are taking.
- What are the most common side effects of each medication?
- Is the dosage prescribed within the recommended range?
- Is the client experiencing any symptoms of potential drug interactions (e.g., nausea, headaches, dizziness)?
- Is one medication being used to treat possible side effects of another medication?
- Ask if the client takes all medications as prescribed. Are any doses or medications skipped?
- Does the client use a daily or weekly pill box? Does the client have some system of checking off when medications have been taken each day?
- Is the client taking any medications that were prescribed for someone else?
- Is the client taking any OTC medications, nutritional supplements, or herbal remedies? For what purpose or condition? For what length of time has each been used?

Adapted from Hanlon, J., & Schmader, K. (2010). What types of inappropriate prescribing predict adverse drug reactions in older adults? Annals of Pharmacotherapy, 44(6), 1110–1111; Heuberger, R. A., & Caudell, K. (2011). Polypharmacy and nutritional status in older adults. Drugs & Aging, 28(4), 315–323; Loya, A. M., Gonzalez-Stuart, A., & Rivera, J. O. (2009). Prevalence of polypharmacy, polyherbacy, nutritional supplement use, and potential product interactions among older adults living on the United States–Mexico border. Drugs & Aging, 26(5), 428–436; Reeve, E., Shakib, S., Hendrix, I., Roberts, M. S., & Wiese, M. D. (2013). Development and validation of the patients' attitudes towards deprescribing (PATD) questionnaire. International Journal of Clinical Pharmacy, 35, 51–56.

The consequences of polypharmacy are enormous. Approximately 30% of hospital admissions of older adults are drug related. Each year, in hospitals alone, there are 28,000 cases of life-threatening heart toxicity from adverse reactions to digoxin, the most commonly used form of digitalis (i.e., drug that regulates the speed and strength of heartbeats) in older adults. Because as many as 40% or more of these people are using this drug unnecessarily, many of these injuries are preventable (PCHRG, 2015). Each year, 41,000 older adults are hospitalized—and 3,300 of these people die—from ulcers caused by NSAIDs (i.e., nonsteroidal anti-inflammatory drugs, usually for treatment of arthritis). Each year, 32,000 older adults suffer from hip fractures attributable to drug-induced falls, resulting in more than 1,500 deaths. A long-term care study showed that polypharmacy was a risk factor for falls. In another study, the main categories of drugs responsible for the falls leading to hip fractures were sleeping pills and minor tranquilizers (30%), antipsychotic drugs (52%), and antidepressants (17%). All of these categories of drugs are often prescribed unnecessarily, especially in older adults (PCHRG, 2015). Two million older Americans are addicted, or at risk of addiction, to minor tranquilizers or sleeping pills because they have used them daily for at least 1 year, even though there is no acceptable evidence that the tranquilizers are effective for more than 4 months (PCHRG, 2015).

Safety can involve many things, such as pedestrian and driving issues, crime and fear of crime against older adults, and environmental factors such as sun exposure, pollution, heat, and cold.

Because of age-related changes in vision, hearing, mobility, and the effects of polypharmacy, older adults are at risk in the community as pedestrians and as drivers. Automobile crashes and pedestrian injuries can be life-threatening events when elders are involved. As pedestrians, older adults must be increasingly vigilant to traffic patterns, sidewalk irregularities, and the possibility of being a victim of street crime. Often out of necessity and pride, elders drive longer than their abilities permit. As people age, they are more prone to lapses in memory and attention, problems with depth perception and gauging distance of cars in traffic, reduced manual dexterity and reaction time, and impairment of other skills critical to driving safety (Governor's Highway Safety Association, 2015; HelpGuide, 2015g). Older adults are more likely to receive traffic citations and be involved in an automobile accident than younger people. Fatal car crashes rise sharply after a person turns 70 (CDC, 2015b, 2015h, 2015i; PCHRG, 2015). In 2012, more than 5,560 older adults were killed and more than 214,000 were injured in motor vehicle crashes. This amounts to 15 older adults killed and 586 injured in crashes, on average, every day (CDC, 2013a, 2015i).

Although many older adults are fearful of being victims of crime, rates of nonfatal violent crime and property crime against the elderly are lower than in all younger age groups. See Display 24–5 for actions PHN can take to assist elders with a fear of crime.

DISPLAY 24.5 REDUCING THE FEAR OF CRIME

Allow elder adults time to discuss their fears of crime.

- Facilitate a realistic self-assessment of their ability to avoid crime and to defend themselves.
- Teach basic safety and security techniques.
- Correct the elder's sensory losses if possible, such as by getting a hearing aid or glasses.
- Correct a physical disability if possible, such as by treating the pain of arthritis or obtaining physical therapy.

- Facilitate access to safe, reliable, and affordable transportation.
- Identify family members, friends, neighbors, or caregivers who can support efforts to leave the home on a more regular basis.
- Encourage an elder to make a daily telephone or e-mail contact with at least one supportive person.
- Encourage the elder to get to know his or her neighbors.
- Encourage elders to travel and conduct community activities and errands together.
- Encourage participation in local senior centers and other community-based programs.
- Refer to alternative housing options available for older adults.
- Provide information on local services that assist and support crime victims.

The ratio of property crime to violent crime is higher among the elderly (13 to 1) than for younger ages (2 to 1 for 25 to 49, and 5 to 1 for 50 to 64). Also, there is more identity theft among those age 65 and older (5%) than for those 16 to 24 (3.8%). The incidents of identity theft are higher in the age groups 25 to 49 and 50 to 64 (7.9% and 7.8%, respectively). Over 59% of elderly report being victimized in or near their homes (Morgan & Mason, 2014).

Environmental factors can affect health and safety of elders when outside their homes. Sun exposure, pollution, and heat and cold can have negative effects on older adults. Like infants and children, they are vulnerable to climatic changes, and preventive measures should be taken. Sunblock should be used when gardening or reading and walking outdoors for longer than 10 minutes, even on days when the sky is overcast. Hot and cold weather can negatively impact older adults. Even in their homes, the elderly need to be aware of the temperature. In warm weather, they may not realize that they are thirsty or feel that they are hot. They may not want to run their air conditioning (or their heaters in cold weather) in an effort to reduce their expenses (UC Davis Health System, 2015). Teaching geographically and seasonally appropriate safety precautions is the responsibility of PHNs providing services to older adults in the community.

Secondary Prevention

Secondary prevention focuses on early detection of disease and prompt intervention (see Chapter 1). Much of the PHN's time is spent in educating the community on preventive measures and positive health behaviors. This includes encouraging individuals to obtain routine screening for diseases such as hypertension, diabetes, or cancer, which, if identified early, can be treated successfully. Many nurses, working in collaboration with community agencies, are in positions to establish screening programs based on the desires and demographics of the community and agency focus, making them accessible to the population being served.

Older adults need to be encouraged to follow the routine health screening schedule prescribed by their clinic or health care provider. The preventive screening services described in Table 24–1 was developed by the U.S. Preventive Services Task Force and is presented here as a guide. An immunization schedule for adults is found in Table 24–2. Resources that can be utilized by the PHN working with older clients are listed in Display 24–6.

Table 24–1 Preventive Services Recommended for Older Adults

Screening	Men	Women	Grade
Abdominal aortic aneurysm	65–75 years, who have ever smoked		B
Alcohol misuse	Over age 18	Over age 18	B
Aspirin/prevention of cardiovascular disease	Ages 45–79 When benefit (CVD) outweighs potential harm (GI bleed)	Ages 45–79 When benefit (CVD) outweighs potential harm (GI bleed)	A
Mammography		Ages 50–74, screen every 2 years	B
Cervical cancer/Pap		Older than 65, do not screen	D
Colorectal cancer	Ages 50–75, screen annually with high-sensitivity fecal occult blood testing (FOBT); screening colonoscopy every 10 years	Ages 50–75, screen annually with high-sensitivity FOBT; screening colonoscopy every 10 years	A
Type 2 diabetes	Asymptomatic adults with sustained B/P >135/80	Asymptomatic adults with sustained B/P greater than >135/80	B
Hypertension	All adults	All adults	A
Lipid disorders	Age 35+	Age 45+	A
Lung cancer	Asymptomatic, age 55–80, 30-pack-a-year history, current smoker or quit within last 15 years	Asymptomatic, age 55–80, 30-pack-a-year history, current smoker or quit within last 15 years	B
Obesity	All adults	All adults	B
Osteoporosis		Age ≥65, no fractures or secondary causes	B
Tobacco use	All adults	All adults	A

Table 24–2 Recommended Immunizations for Older Adults

Recommended immunization schedule for adults aged 19 years or older, by vaccine and age group[1]

VACCINE ▼ AGE GROUP ►	19–21 years	22–26 years	27–49 years	50–59 years	60–64 years	≥ 65 years
Influenza[*,2]	1 dose annually					
Tetanus, diphtheria, pertussis (Td/Tdap)[*,3]	Substitute Tdap for Td once, then Td booster every 10 years					
Varicella[*,4]	2 doses					
Human papillomavirus (HPV) Female[*,5]	3 doses					
Human papillomavirus (HPV) Male[*,5]	3 doses					
Zoster[6]					1 dose	
Measles, mumps, rubella (MMR)[*,7]	1 or 2 doses depending on indication					
Pneumococcal 13-valent conjugate (PCV13)[*,8]	1 dose					
Pneumococcal 23-valent polysaccharide (PPSV23)[8]	1 or 2 doses depending on indication					1 dose
Hepatitis A[*,9]	2 or 3 doses depending on vaccine					
Hepatitis B[*,10]	3 doses					
Meningococcal 4-valent conjugate (MenACWY) or polysaccharide (MPSV4)[*,11]	1 or more doses depending on indication					
Meningococcal B (MenB)[11]	2 or 3 doses depending on vaccine					
Haemophilus influenzae type b (Hib)[*,12]	1 or 3 doses depending on indication					

*Covered by the Vaccine Injury Compensation Program

Recommended for all persons who meet the age requirement, lack documentation of vaccination, or lack evidence of past infection; zoster vaccine is recommended regardless of past episode of zoster

Recommended for persons with a risk factor (medical, occupational, lifestyle, or other indication)

No recommendation

Report all clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS). Reporting forms and instructions on filing a VAERS report are available at www.vaers.hhs.gov or by telephone, 800-822-7967.

Information on how to file a Vaccine Injury Compensation Program claim is available at www.hrsa.gov/vaccinecompensation or by telephone, 800-338-2382. To file a claim for vaccine injury, contact the U.S. Court of Federal Claims, 717 Madison Place, N.W., Washington, D.C. 20005; telephone, 202-357-6400.

Additional information about the vaccines in this schedule, extent of available data, and contraindications for vaccination is also available at www.cdc.gov/vaccines or from the CDC-INFO Contact Center at 800-CDC-INFO (800-232-4636) in English and Spanish, 8:00 a.m. - 8:00 p.m. Eastern Time, Monday - Friday, excluding holidays.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

The recommendations in this schedule were approved by the Centers for Disease Control and Prevention's (CDC) Advisory Committee on Immunization Practices (ACIP), the American Academy of Family Physicians (AAFP), the America College of Physicians (ACP), the American College of Obstetricians and Gynecologists (ACOG) and the American College of Nurse-Midwives (ACNM).

DISPLAY 24.6 PROGRAMS AND SERVICES FOR OLDER ADULTS

Resources for Community Health Nurses to Utilize with Clients

- Communication services (phones, emergency access to health care)
- Dental care services
- Dietary guidance and food services (such as Meals on Wheels, commodity programs, or group meal services)
- Escort and protective services
- Exercise and fitness programs
- Financial aid and counseling
- Friendly visiting and companions
- Health education
- Hearing tests and hearing aid assistance
- Home health services (including skilled nursing and home health aide services)
- Home maintenance assistance (housekeeping, chores, and repairs)
- Legal aid and counseling
- Library services (including tapes and large-print books)
- Medical supplies or equipment
- Medication supervision
- Podiatry services
- Recreational and education programs (community centers, Elderhostel)
- Routine care from selected health care practitioners
- Safe, affordable, and ability-appropriate housing
- Senior citizens' discounts (food, drugs, transportation, banks, retail stores, and recreation)
- Social assistance services offered in conjunction with health maintenance
- Speech or physical therapy
- Spiritual ministries
- Transportation services
- Vision care (prescribing and providing eyeglasses, diagnosis and treatment of glaucoma and cataracts)
- Volunteer and employment opportunities (Vista, RSVP)

services. Washington, DC: Agency for Healthcare Quality & Research (AHRQ).

Diseases and Conditions Common in Old Age

Alzheimer's Disease

Alzheimer's disease (AD) is the most common form of dementia in older adults, first described in 1907 by Dr. Alois Alzheimer. He depicted the symptoms that are now known as AD. Although much is still unknown about this devastating disease, we do know that:

- It's the only cause of death among America's top ten that cannot be prevented, cured, or slowed.
- Almost two thirds of Americans who have an Alzheimer's diagnosis are women.
- One in three seniors dies of Alzheimer's or dementia.
- Alzheimer's disease is the sixth leading cause of death in America.
- Only 45% of those with Alzheimer's disease or their caregivers report being told of their diagnosis. More than 90% of those with the four most common kinds of cancers report being told of their diagnosis.
- In 2015, Alzheimer's and other dementias will cost the nation $226 billion. By 2040, they could cost as much as $1.1 trillion (CDC, 2015b).
- The number of people who develop this disease doubles every 5 years as people live beyond age 65 (CDC, 2015b).
- Every 67 seconds, another person develops AD, and this will change to every 33 seconds by the year 2050 (Alzheimer's Association, 2015a).
- Age is the greatest risk factor for AD. Most individuals with AD are over age 65 (Alzheimer's Association, 2015c).
- One of three people age 85 or older has the disease (CDC, 2015a).
- AD increased 66% in the years between 2000 and 2008. It is the only major disease that increased during that time frame. Because of this growth, *Healthy People 2020* designated dementias, including AD, as one of the new focus areas (*Healthy People 2020, 2015a*).
- By 2050, this number is projected to rise to 14 million, a nearly threefold increase (CDC, 2015b).
- Among adults from the ages of 65 to 86, AD is the fifth leading cause of deaths.
- In 2013, an estimated 5 million Americans aged 65 years or older had Alzheimer's disease. This number may triple to as high as 13.8 million people by 2050 (CDC, 2015b).

The occurrence of AD is not a normal development in the aging process. Alzheimer's disease has no survivors. It destroys brain cells and causes memory changes, erratic behaviors, and loss of body functions. It slowly and painfully takes away a person's identity and ability to connect with others, think, eat, talk, walk, and find his or her way home

(Alzheimer's Association, 2015b).

As the disease progresses, these changes become so severe that they interfere with the individual's daily functioning, resulting in total dependence on others for care and eventually in death. On average, a person with Alzheimer's lives 4 to 8 years after diagnosis but can live as long as 20 years, depending on other factors (Alzheimer's Association, 2015d). Although AD is the sixth leading cause of death among all Americans and the fifth leading cause of death for 65- to 85-year-olds (CDC, 2015b), those most often diagnosed with AD are generally over age 65 (late-onset AD). However, it is possible for the disease to occur in people between the ages of 30 and 60, but early-onset AD is usually considered an inherited form of the disease; another risk factor for Alzheimer's (Alzheimer's Association, 2015c).

There is a simple way to describe the difference between the normal forgetfulness of aging and AD. From time to time, we all forget where we have put our keys, but people with early-stage AD may notice that they tend to forget things more often—especially recent activities or events, or names of familiar things or people (Alzheimer's Association, 2015d). Although these symptoms are bothersome, they are usually not serious enough to cause alarm. As the disease advances, the symptoms become serious enough to cause people with AD or their family members to recognize that things are not right and that help is needed. In the middle stages of AD, people eventually forget how to do simple tasks like brushing their teeth or combing their hair, and they begin to no longer be able to think clearly. They eventually have problems speaking, understanding, reading or writing, or recognizing people they have known for years. People who suffer from AD may become anxious or aggressive and may wander away from home, thus requiring the need for total care.

There is no single test to identify AD (Alzheimer's Association, 2015b). It is recommended that health care providers offer a comprehensive exam including a complete health history; physical exam; lab tests; neurologic, functional, and mental status assessments; along with possible brain scans. A comprehensive assessment is needed because many conditions, including some that are treatable or reversible (e.g., thyroid disease, depression, brain tumors, drug reactions), may cause dementia-like symptoms. Physicians are now able to accurately diagnose 80% to 90% of people who show symptoms, but the only definitive diagnosis of AD is done at autopsy by the examination of brain tissue (National Institute on Aging, 2015a). Probable causes of AD are many. Promising leads involve the role of neurotransmitters, proteins, metabolism, environmental toxins, and genes. Research has shown links between some genes and AD, with three gene variants identified for early-onset AD and one that boosts risk for late-onset type.

- In 2015, the direct costs to American society of caring for those with Alzheimer's will total an estimated $226 billion, with half of the costs borne by Medicare.
- Nearly one in every five Medicare dollars is spent on people with Alzheimer's and other dementias. In 2050, it will be one in every three dollars.

- Average per-person Medicare spending for those with Alzheimer's and other dementias is three times higher than average per-person spending across all other seniors. Medicaid payments are 19 times higher.
- Unless something is done, in 2050, Alzheimer's will cost over $1.1 trillion (in 2015 dollars). Costs to Medicare will increase over 400% to $589 billion.
- In 2014, 15.7 million family and friends provided 17.9 billion hours of unpaid care to those with Alzheimer's and other dementias—care valued at $217.7 billion.
- Nearly 60% of Alzheimer's and dementia caregivers rate the emotional stress of caregiving as high or very high; about 40% suffer from depression (Alzheimer's Association, 2015a, para. 12 to 24).

Several medications have been approved for use with Alzheimer's patients. Medications called cholinesterase inhibitors are prescribed for mild to moderate AD. However, these drugs only delay the progression of symptoms for a limited time. At best, available medications "turn back the clock somewhat" with the disease worsening at a slower rate, or the drugs control some of the client's behaviors that jeopardize safety, thereby promoting caregiver management.

How does this disease impact the role of the PHN? Often, the person with AD is cared for at home until very late in the disease course. Perhaps more than any other disease, AD is responsible for enormous caregiver burden. In fact, because of the physical and emotional toll of caregiving, Alzheimer's and dementia caregivers had $9.7 billion in additional health care costs of their own in 2014 (Alzheimer's Association, 2015a).

The intense care given to these clients can be a constant drain on the emotional and physical reserves of their families, which highlights the need for respite care. The client exhibits depression, agitation, sleeplessness, and anxiety, which can greatly upset the family's normal routine. In many situations, the main caregiver is an aged spouse. The stress of providing care puts the caregiver's health at risk, as well. In 1992, Congress created the Alzheimer's Disease Supportive Program to encourage states to provide support for persons and families with Alzheimer's. The intensity of caregiving is aptly described in a book written for AD family members: *The 36-Hour Day* (Mace & Rabins, 2006). Another good book is *The Theft of Memory: Losing my Father, One Day at a Time by* award winning author Jonathan Kozol. This is the personal story of his experience with his father, a brilliant neurologist who suffered from Alzheimer's (Kozol, 2015). Another good resource is Braff and Olenik's (2003) *Staying Connected While Letting Go: The Paradox of Alzheimer's Caregiving* (see What Do You Think?).

What do *you* think?

Have you heard of the *Best Friends* approach to Alzheimer's care? This method has changed the caregiving approach to AD and is changing the lives of caregivers, families, and clients. It improves the quality of life not only for clients with AD but

also for those providing care. *Best Friends* is a groundbreaking and uplifting method for the care of people with AD. It builds on the essential elements of friendship: respect, empathy, support, trust, and humor. These are the building blocks of a care model that is both effective and flexible enough to adapt to each person's remaining strengths and abilities. The *Best Friends* approach does not just prevent catastrophic episodes; it makes every day consistently reassuring, enjoyable, and secure.

From Bell, V. & Troxel, D. (2011). An overview of the Best FriendsTM approach to Alzheimer's care. Baltimore, MD: Health Professions Press. (*Best Friends*™ is a trademark of Health Professions Press, Inc.).

Because so many older adults afflicted with AD reside at home with their family members providing care to them, it is important for the PHN to monitor and assess the levels of stress on family members. The nurse can intervene as necessary and provide caregivers with methods to cope and adapt as needed, making applicable referrals. The nurse can assist with planning and preparing the caregiver for what lies ahead. Most communities have resources for clients and their families. They may provide family and caregiver support groups, respite care, counseling, and legal or financial consultation. These services are available through local agencies, such as the Area Agency on Aging, but there are also government-sponsored national resources that offer information, referral services, and educational materials (e.g., Alzheimer's Association) all of which can be accessed by the PHN, the home health/hospice nurse, or the families in need. Some may find online support groups helpful. The nurse needs to know what resources are available in order to guide families to them (see Using the Nursing Process).

USING THE NURSING PROCESS WHEN WORKING WITH OLDER ADULTS

Assessment

Mr. and Mrs. Boxwell are in their late 70s and have lived modestly on a fixed income since Mr. Boxwell's retirement. However, their budget has been strained this year as they have had $300 to $400 a month in out-of-pocket expenses for prescription medications. Mrs. Boxwell confessed to you (the community health nurse visiting them after receiving a referral from the coordinator of the senior center they attend) that at times, they will skip medication doses to "make ends meet" in some months. They both take drugs for high blood pressure; also, Mrs. Boxwell is diabetic and Mr.

Boxwell has heart failure. They live in a small, older home, and their older model car is seldom driven as they report "the traffic is getting worse" and they have "come close to having a car crash two times" while they were driving in the past 3 months. They are receptive to your suggestions and are trying to stay healthy and independent.

Nursing Diagnoses

1. The clients are at risk for an alteration in their health status due to insufficient finances to purchase needed medications for chronic diseases.
2. The clients are at risk for altered safety when driving related to chronic health problems, diminished driving skills, and a history of near automobile crashes.

Plan and Implementation

Diagnosis 1

The community health nurse will explore the clients' eligibility for Medicare Part D and Medicaid. It is possible these clients are eligible, yet unaware of these programs.

The community health nurse will consult with the clients' primary health care provider and ask for a change in prescriptions from brand names to generic. Also, ordering some medications in larger doses that come in scored tablets may be less expensive, and the client can safely break the larger pills in half. Mrs. Boxwell will

check with her present distributor of diabetic supplies about getting larger quantities, generic brands of syringes, alcohol pads, etc.

Diagnosis 2

Mr. Boxwell will look into selling the car and exploring the bus schedule and other senior shuttle services that can be used to travel to the doctor and grocery store. Mr. and Mrs. Boxwell's daughter spends a day with them monthly and takes them wherever they want to go, as long as it is "a fun outing," and they will look into coordinating errands with her.

Evaluation

The couple is eligible for Medicare Part D, and this will help defray the out-of-pocket costs for medications. They have reduced medication costs as much as possible and report not missing any prescribed medications.

They sold their car and are negotiating the bus in good weather and using a taxi in the winter or when it is raining (they figured they save $1,000 a year in auto insurance, auto maintenance, and gasoline, whereas the bus and taxi cost them about $22 a month).

Because the couple is receptive to the help you have provided, you initiate a discussion regarding their long-term plans for housing needs as they get older. They are not opposed to a senior housing option and have been talking about it with their daughter. They are going to talk with a realtor about selling their house, explore some senior apartments with their daughter on her monthly visits, and review their budget.

Arthritis

Arthritis encompasses more than 100 diseases and conditions that affect joints, surrounding tissues, and other connective tissues and is the leading cause of disability for adults in the United States (CDC, 2015c). Types of arthritis include osteoarthritis (OA), rheumatoid arthritis (RA), gout, and fibromyalgia. OA is the most common form of arthritis affecting both young and old, with two thirds of sufferers younger than age 65 (National Institute of Arthritis and Musculoskeletal and Skin Diseases [NIAMS], 2014a). However, the incidence increases with age. For those aged 18 to 44, 7.6% report physician-diagnosed arthritis. For those 45 to 64, the incidence rises to 29.8%, and for those 65 and older, 50% report physician-diagnosed arthritis. By 2030, it is estimated that 25% of the total adult population will have physician-diagnosed OA (CDC, 2013a; NIAMS, 2015). With OA, the number of cartilage cells diminishes, cartilage becomes ulcerated and thinned, subchondral bone is exposed, and bony surfaces rub together resulting in joint destruction (NIAMS, 2014b). This disease is no longer considered to be only a normal

consequence of aging. Risk factors include obesity, repetitive mechanical overuse of a joint, and heredity (CDC, 2015a). For those underweight or of normal weight, 16.4% have arthritis. Among those who are overweight, 21.4% have arthritis, and this increases to 66% for those who are obese (CDC, 2013a). Classic symptoms include aching, stiffness, and limited motion of the involved joint. Discomfort increases with overuse and during damp weather. Acetaminophen is the first drug of choice; however, clients often find a combination of medications and daily routines that helps them the most. The nurse can best assist these clients by assessing the safety of a particular regimen and suggesting treatment changes as new research becomes available, including new medications, surgical options for joint replacement, and dietary changes, such as vitamins and foods high in essential fatty acids (NIAMS, 2015). Arthritis limits ADLs and quality of life and is a costly disability. Forty-two percent of those with arthritis report activity limitations. In 2003, arthritis-related costs totaled $218 billion. This included $81 billion for medical costs and $47 billion in lost earnings (CDC, 2013a).

RA is a progressive chronic condition that begins during young adulthood and becomes disabling as the disease continues, attacking tissues of the joints and causing systemic damage in the later years (NIAMS, 2014b). It affects diarthrodial (synovial line) joints. This form of arthritis is an autoimmune disease that causes inflammation, deformity, and crippling. RA is treated with anti-inflammatory agents, corticosteroids, antimalarial agents, gold salts, and immunosuppressive drugs. Joint discomfort is often relieved by gentle massage, heat, and range-of-motion exercises (NIAMS, 2014a).

The PHN needs to be aware of the major differences between these two prevalent forms of arthritis. Recommended treatments, including physical therapy, diet, and medication, change as more evidence-based research is conducted on arthritis (NIAMS, 2014a). It is helpful to keep up-to-date on treatments, as these conditions are treated in the community and affect a large portion of the midlife and older populations that a PHN may carry in his or her caseload.

Cancer

Cancers, which are characterized by the uncontrolled growth and spread of abnormal cells, steadily increase in incidence in aging adults. Cancer causes 13% (7.6 million) of deaths worldwide. Age is a fundamental risk factor of cancer with the incidence of cancer rising dramatically with age (World Health Organization [WHO], 2012). The leading types of cancers are breast, prostate, lung, and colorectal cancers (CDC, 2012a). One popular theory is that as the body ages, the immune system declines, losing its ability to serve as a buffer against abnormal cancer cells that have been forming in the body throughout life. Tobacco use is a major risk factor for cancer. Harmful alcohol use, poor diet, and physical inactivity are other main risk factors (CDC, 2013b).

It is particularly important for the CHN to be aware of the increased incidence of cancer in older clients because older people often underreport symptoms that may be early

signs of cancer. It is vital for PHNs, through assessments at clinics, on home visits, or during participation in screening programs, to encourage clients to report untoward symptoms in order to promote early detection, which gives clients their best chance of survival (American Cancer Society, 2014). Adherence to the health care practitioner's recommended schedule for health screening should be encouraged. In addition, being aware of and educating clients about the American Cancer Society's *Signs and Symptoms of Cancer* can possibly save their lives (see Display 24–7).

DISPLAY 24.7 SIGNS AND SYMPTOMS OF CANCER

There are some general signs and symptoms of cancer that can be helpful to PHNs when working with clients:

- Unexplained weight loss
- Pain
- Fever
- Fatigue
- Skin changes (hyperpigmentation, erythema, jaundice, itching, and excess hair growth)

Other common signs and symptoms of more specific types of cancers:

- Change in bowel habits or bladder function
- White patches inside mouth or white spots on the tongue
- Sores that do not heal
- Indigestion or trouble swallowing
- Unusual bleeding or discharge
- Thickening or lump in breast or other parts of the body
- Recent change in wart or mole; any new skin changes
- Nagging cough or hoarseness

Cardiovascular Disease

Following arthritis and hearing impairment, hypertension is the third most frequent

chronic condition for people older than age 65. About 66% of those between 65 and 75 have been diagnosed with hypertension, as have about 75% of those 75 years and older heart disease (CDC, 2015j). Hypertension increases with age and affects men more frequently than women; it is more prevalent in minorities. For example, hypertension in White adult males is 61%, whereas the prevalence in Black males is 71% and it is 69% in Hispanic males. Among females, the prevalence of hypertension in White women is 47%; in Black females it is 51%, and in Hispanic females, the prevalence is 65%. Older adults have difficulty managing ADLs if antihypertensive medications lower their blood pressure too dramatically. Hypotension leads to problems of safety, including a higher risk of falls; blood pressure should be monitored by the PHN, and the client should be taught to also self-monitor. Both hypertension and hypotension can have significant detrimental effects on the health of older adults (CDC, 2015j).

Heart disease is the leading cause of death for both men and women in the United States (Centers for Disease Control and Prevention [CDC], 2015f). Risk factors in the aging population associated with cardiovascular disease (CVD) include tobacco use or exposure to tobacco smoke, inappropriate nutritional patterns, diabetes, high cholesterol, and lack of exercise. There are also regional differences in the pattern of deaths from heart disease: The southeastern coastal plains (Appalachia) and lower Mississippi River Valley (southern parts of Georgia and Alabama) have the highest death rates. Blacks and Whites generally have higher rates of heart disease death than do Hispanics or Asians and other races/ethnicities (CDC, 2015g). See Chapter 29 for more information on this and on the "Stroke Belt."

Disease prevention is an important role for the PHN. Based on the knowledge of the prevalence of hypertension in older adults, the nurse can provide primary prevention by teaching community groups and individuals about this condition and ways to prevent its occurrence and can provide secondary prevention by screening seniors on a regular basis.

Depression and Suicide

Depression is not a normal part of growing older, yet it is one of the most common, and most treatable, of all the mental disorders in older adults (CDC, 2015d). It is a major health concern in this population and can be life threatening if unrecognized and untreated. Research has shown that medical costs are much higher for older adults who have medical conditions in addition to depression (National Institute of Mental Health, 2015). Biological, psychological, and social changes place older adults at high risk for the development and recurrence of depression. It is frequently related to multiple losses, such as retirement, a health change, or the death of a significant other. Depression is reported to be more common in women than in men. However, as mentioned earlier in this chapter, depression in men is more severe, resulting in suicide at a higher rate than among women. Higher levels of perceived social support are related to lower instances of depression among all people, and women especially seem to make these supportive connections throughout

life more effectively than do men. The nurturing, reassurance, and support women get from intimate relationships with other women are not often as highly developed in men, and for this reason, men display more symptoms of depression after a loss.

The nurse needs to keep in mind the many potential causes of depression. Medical conditions, such as stroke, cancer, vitamin B_{12} deficiency, diabetes, chronic pain with dependence on prescription painkillers, or insomnia, may lead to depressive symptoms. Many prescription drugs can trigger or exacerbate depression. These include blood pressure medications, sleeping pills, calcium channel blockers, ulcer medications, and painkillers. Dementia and depression can be confused. Never assume that loss of mental sharpness is just a sign of old age. It may be difficult to differentiate whether an older adult is suffering from grief, depression, or dementia (National Institute of Mental Health, 2015). As mentioned earlier, older populations may have a lower rate of suicide attempts than younger age groups do, but the rate of completed suicide is high.

PHNs can help elders prevent the overwhelming signs and symptoms of depression related to losses by working with community groups. Through senior centers, adult housing units, senior day care centers, or men's and women's groups at religious centers, the PHN can meet with seniors to offer support, teach strategies to improve the quality and quantity of support systems, invite mental health speakers to discuss the topic of depression prevention, and generally assess the holistic health status of the elders in that setting. The increased years added to life through the advances of the past few decades in medications and treatment should lead to healthy and happy later life for seniors, filled with activities that bring joy and contentment. Years lost to depression are a wasted resource that may be prevented through early intervention and treatment.

Diabetes

According to the American Diabetes Association (2015b), 9.3% of all Americans have diabetes mellitus (DM). For those age 65 or older, the percentage jumps to 25.9%, or 11.2 million people. In 2012, $245 billion was attributable to diagnosed diabetes, including $176 billion in direct costs and $69 billion in indirect costs (disability, work loss, premature mortality). Diabetes mellitus (DM) affects the health of older people and limits their ability to perform activities.

The prevalence of diabetes varies by race:

- 17.5% of American Indians/Alaska Natives
- 16.3% of American Indians/Native Americans
- 13.2% of Hispanics
- 12.9% of non-Hispanic Blacks
- 9.1% of Asian Americans
- 7.6% of non-Hispanic Whites 18 and older (Food and Drug Administration [FDA], 2015)

The number of people with DM has increased sixfold since 1958, and 95% of these have type 2 diabetes. Type 2 diabetes can often be prevented with adherence to proper diet and regular exercise with the addition of oral medications, when needed. More Americans than ever suffer from various forms of DM, and the resulting rates of death and serious complications, such as adult blindness, kidney disease, and foot or leg amputations, are especially high for older adults and racial/ethnic minority populations (American Diabetes Association, 2015a, 2015b). In the past, DM was not always managed effectively; fear and misinformation about the disease may hinder today's elders from getting an early diagnosis or from participating in effective teaching and instruction on how to manage their diabetes.

Being diagnosed with DM can cause depression or anger, and the PHN must tailor educational programs to meet individual client needs. The plan should be comprehensive, with special emphasis placed on the areas in which each client needs information. For example, a spouse may be concerned about preparing meals that meet her husband's needs, whereas the husband may be more concerned with how the disease will affect his long days on the golf course or sexual functioning. In contrast, a single older woman may worry whether she can see well enough to draw up her insulin or can afford to pay for diabetic supplies and special foods. All newly diagnosed diabetics need a comprehensive overview of the disease process followed by an individualized approach for ongoing control and management of the disease.

Self-care behaviors (e.g., appropriate diet, glucose monitoring, medication management, foot care) are not often consistently practiced, yet they are necessary to promote good health and fewer complications (American Diabetes Association, 2015a). PHNs are ideally situated to meet group and individual needs. They have the resources and skills to plan and implement diabetic education classes for groups of elders, in addition to making home visits to address specific learning deficits that impact an individual's ability to manage his or her diabetes properly. The group setting allows elders to share their experiences, learn from each other, and benefit from the support of the group. Home visits permit the nurse to focus on an assessment of the client, home, family support, diabetic supplies and technique, and overall health management.

Obesity

The CDC defines obesity as a body mass index (BMI) of 30 or greater (2012c). Worldwide obesity has more than doubled since 1980, overtaking underweight as a cause of death. In 2014, over 600 million adults worldwide were obese (WHO, 2015). In the United States, more than one third of older adults aged 65 and older were classified as obese in 2007–2010. By 2050, the number of obese U.S. older adults is expected to more than double, rising from 40.2 to 88.5 million (WHO, 2015). Both aging and obesity contribute to increased use of health care services. Consequently, an increase in the proportion of older adults who are obese may compound health care spending.

Obesity prevalence is higher in:

- Both women and men who are 65 to 75 than those who are older than 75
    - Men age 65 to 74: 36.4%
    - Men age 75 and over: 27.4%
    - Women age 65 to 74: 44.2%
    - Women age 75 and over
    - Women age 75 and over (CDC, 2015j)

Obesity prevalence among women aged 65 to 74 was higher than in women aged 75 and older in all racial and ethnic groups except for non-Hispanic Black women. The overall prevalence of obesity among older adults and the racial and ethnic patterns are similar to estimates previously reported for the entire adult population (CDC, 2012b). Among older men, there were no differences between racial and ethnic groups in obesity prevalence. However, among older women, non-Hispanic Black women had higher obesity prevalence than older, non-Hispanic White women. Although these same patterns have been shown among middle-aged women, the values are significantly lower among the oldest adults, those aged 75 and over (CDC, 2012b). Socioeconomic disparities in obesity prevalence, as measured by educational attainment and observed in women aged 20 and over, were also found among those aged 65 to 74, but the relationship diminished and even disappeared in those aged 75 and over. Among all women, there was a significant trend in lower obesity prevalence among those with the highest education. This was also true for women aged 65 to 74, but among women aged 75 and over, no difference was observed in obesity prevalence by educational attainment (CDC, 2012b).

Osteoporosis

Osteoporosis is a disease of bone in which the amount of bone is decreased and the strength is reduced. Osteoporosis is a generalized, persistent, and disabling disease that can overshadow every facet of an older adult's overall functional level and independence. It causes acute and chronic pain, subsequent fractures, decreased physical activity, limited mobility, changes in body image, role changes, a reduction in ability to perform ADLs, and depression.

Researchers estimate that one in five women in the United States has osteoporosis and that half of the women over 50 will have a fracture of the hip, wrist, or vertebrae; it is considered a major public health threat for approximately 44 million U.S. adults over age 50 (International Osteoporosis Foundation, n.d.). In osteoporosis, calcium leaches from the bone mass and results in small holes forming in the bones. These empty spaces within the bone increase susceptibility to fractures of hip, wrist, or vertebra. The risk of osteoporosis increases with age. As the disease progresses, other characteristics appear, such as compression of the vertebrae that result in loss of height and the hunched back deformity known as dowager's hump.

Proper diet and exercise throughout life are now recognized as the most effective

measure to maintain bone health. There is growing evidence that calcium and vitamin D supplementation can help lower rates of fractures and reduce bone loss in the elderly. Higher protein intake may also help prevent bone loss (International Osteoporosis Foundation, n.d.). There are many FDA-approved drugs to treat osteoporosis that can be prescribed by a primary care provider. Therefore, identification of risk factors and regular screenings are essential to prevent the progression of this debilitating disease (National Center for Biotechnology Information, 2015).

See Chapter 23 for more on medications. PHNs can focus their teaching on primary prevention and ensure that people eat diets rich in vitamin D and calcium, and include calcium supplements as needed. Not smoking, maintaining a healthy weight, participating in weight-bearing activities, and receiving ongoing bone density screenings are all positive health behaviors that can contribute to strong bones throughout life. The value of hormone replacement therapy (HRT) in women—its benefits and possible long-term side effects—must be considered on the advice of the primary care provider, whose judgment should be based on the latest research findings along with the individual woman's needs.

Tertiary Prevention

Tertiary prevention involves follow-up and rehabilitation after a disease or condition has occurred or been diagnosed and initial treatment has begun. Chronic diseases that are common among older adults, such as heart failure, stroke, diabetes, cognitive impairment, or arthritis, cannot always be prevented but can frequently be postponed into the later years of life through a lifetime of positive health behaviors. However, when they occur, the debilitating symptoms and damaging effects can be controlled through healthy choices encouraged by the PHN and recommended by the primary care practitioner.

Although many older adults are considered generally healthy, 80% have at least one chronic condition and 50% have at least two (CDC, 2013c). A small proportion suffer more disabling forms of disease, such as COPD, cerebral vascular accidents (CVAs), cancer, or DM, with some requiring extensive care and ongoing medical management. The most common health problems of older people in the community are arthritis, reduced vision, hearing loss, heart disease, peripheral vascular disease, and hypertension. Heart disease and cancer pose their greatest risks as people age, as do other chronic diseases and conditions, such as stroke, chronic lower respiratory diseases, Alzheimer's disease, and diabetes. Influenza and pneumonia also continue to contribute to older adult deaths among older adults, despite the availability of effective vaccines (CDC, 2013c).

The tragedy of these leading killers is that they are often preventable. Although the risk for disease and disability clearly increases with advancing age, poor health is not always an inevitable consequence of aging. Even though many older adults experience relatively good health, almost all may expect to be chronically ill for an extended amount of time at the end of their lives. Chapter 26 expands on clients with disabilities and chronic illnesses and the role of the PHN working with these populations in the community.

HEALTH COSTS FOR OLDER ADULTS: MEDICARE AND MEDICAID

As the number of older adults grows, so do costs for health care:

- NHEs grew 3.6% to $2.9 trillion in 2013, or $9,255 per person, and accounted for 17.4% of gross domestic product (GDP).
- Medicare spending grew 3.4% to $585.7 billion in 2013, or 20% of total NHE.
- Medicaid spending grew 6.1% to $449.4 billion in 2013, or 15% of total NHE (Centers for Medicare & Medicaid Services, 2015).

Despite the expenditures, it is a myth that Medicare or Medicaid covers all health care costs for older adults. In actuality, an older adult spends a great deal out of pocket for health care. Individuals and their families cover 52% of long-term care costs out of pocket. The cost of paid long-term care is only the tip of the iceberg. Approximately 75% of long-term care services and support are provided on an unpaid basis by family members. This is often done at a heavy physical and financial cost, including lost opportunities for employment, health insurance, and retirement savings. Services for older adults are very expensive. Some examples of average costs in the United States for health care services are:

- $17,904 annually for adult day care services
- $44,616 annually for homemaker services
- $45,760 annually for a home health aide
- $43,200 annually for care in an assisted living facility
- $80,300 annually for a semiprivate room in a nursing home (Genworth, 2015)

Most long-term care isn't generally provided solely for the purpose of medical care but rather help with basic personal tasks of everyday life, or ADLs. Medicare doesn't cover custodial care, if that's the only care needed, and most nursing home care is custodial care. Therefore, most nursing home stays do not qualify for Medicare coverage. The average cost per year of a private room in a nursing home is $94,170, rising 3.6% annually. In many areas, it costs much more (John Hancock, 2013). Medicaid is the primary payer for long-term services (Kaiser Family Foundation, 2015a).

Medicare

Although Medicare does cover many services for older adults, there can be significant out-of-pocket costs. Some examples follow (Medicare.gov, 2015a).

NOT covered by Medicare:

- Long-term care (also called custodial care)
- Most dental care and dentures
- Eye examinations related to prescribing glasses
- Cosmetic surgery
- Acupuncture
- Hearing aids and exams for fitting them
- Routine foot care (Medicare.gov, 2015b)

Part A (hospital insurance) covers:

- Inpatient care in hospitals (such as critical access hospitals, inpatient rehabilitation facilities, long-term care hospitals)
- Inpatient care in a skilled nursing facility (limitations apply)
- Hospice care services
- Home health services
- Religious nonmedical health care institution

Services NOT covered by Part A:

- Custodial care (or long-term care).
- If beneficiaries are hospitalized, they pay a $1,288 deductible. If their stay lasts longer than 60 days, they are billed $322 per day for days 61 through 90 and $644 beyond that (Medicare.gov, 2016).

Hospitalizations and rehospitalizations are a significant expense for the Medicare program. A major theme of health care reform was the prevention of hospitalizations by providing more supportive care at home, care that is generally covered by the Medicaid programs.

Part B (supplementary medical insurance for physician visits):

- Beneficiaries pay 20% of the Medicare-approved amount for any visits to their doctor.
- Medicare premiums for medical insurance (part B) are $1,380 per person per year for most beneficiaries and are higher for those with incomes above $80,000 (Medicare.gov, 2015b).

Part C (Medigap—private health plans)

Part D (prescription drug benefits):

The Part D national base beneficiary premium for prescription drug coverage is $388 per person annually. A beneficiary's actual costs depend on the plan that is selected.

For more on Medicare, see Chapter 6.

Medicaid

Although the majority of people enrolled in Medicaid are children and families, most Medicaid spending goes for services provided to people aged 65 and over, and people with disabilities (Kaiser Family Foundation, 2015a).

For seniors, one of the most significant gaps in Medicare coverage is the cost of custodial care or help with ADLs like bathing, dressing, eating, getting into or out of a chair, or using the bathroom. Contrary to what many people believe, Medicare does not cover this kind of care, either in a nursing home or in the beneficiary's own home. Funding for this type of care is generally covered by Medicaid waiver programs and through the use of Older Americans Act funds.

It is another myth that Medicaid is a program for the poor whereas Medicare is for those who are financially secure. In FY 2010, 14% of all Medicaid beneficiaries—9.6 million—were "dual eligible" seniors and younger persons with disabilities who are covered by Medicare as well. One of every five Medicare beneficiaries is a dual eligible client. Dual eligible beneficiaries are very poor and many have high health and long-term care needs. Medicaid assists them with their Medicare premiums and cost sharing and covers full Medicaid benefits for a large majority of them—most importantly, long-term services and supports, which Medicare does not cover (Kaiser Family Foundation, 2015b).

Medicare and Medicaid are integral programs that provide quality health care for older adults across the country. Further cuts to these programs will affect the livelihood of many individuals. Given recent economic problems, increased spending in these programs is not feasible, nor sustainable. Our only chance to continue to help older adults live healthier and happier lives is to create innovations in Medicare and Medicaid that result in savings to both programs and increased efficiency and quality in the care that these programs provide.

If seniors' health and long-term services and support needs are not met, their condition ultimately can deteriorate to the point where they need to be hospitalized or admitted to a skilled nursing facility where cost of care is markedly higher.

ELDER ABUSE

Elder abuse is a problem that is underrecognized and underreported, and it has devastating consequences. Unfortunately, we simply do not know for certain how many people are suffering from elder abuse and neglect, at there are few reliable national measures of "elder" abuse. This is partially because there is no uniform reporting system for elder abuse in the United States. Additionally, the available national incidence and prevalence data from administrative records are unreliable because states have different definitions of elder and different reporting mechanisms (National Institute of Justice, 2015a). The complexity of defining elder abuse, and the debate over the classification of types of mistreatment compounds the task of evaluating the magnitude of the problem. Elder abuse or mistreatment (i.e., abuse and neglect) is defined as intentional actions that cause harm or create a serious risk of harm (whether or not harm is intended) to a vulnerable elder by a caregiver or other person who stands in a trust relationship to the elder. This includes failure by a caregiver to satisfy the elder's basic needs or to protect the elder from harm (National Center on Elder Abuse, n.d.a).

Signs of elder abuse may be missed by professionals working with older Americans because of lack of training on detecting abuse. The elderly may be reluctant to report abuse themselves because of fear of retaliation, because of lack of physical and/or cognitive ability to report, or because they don't want to get the abuser (90% of whom are family members) in trouble. Below is a sampling of findings about the incidence and prevalence of elder abuse and neglect:

- Major recent studies found that 7.6% to 10% of participants experienced abuse in the year prior to data collection. Also, for 1 in 10 adults who reported that they experienced abuse, financial abuse was included in the report.
- An increasing trend in reporting of elder abuse is seen when examining available data from state Adult Protective Services (APS) agencies.
- Even though there are APS agencies in all 50 states (programs differ by state), and most states have mandatory reporting laws for elder abuse, a large number of cases of neglect, elder abuse, and financial mistreatment are still undetected each year.
- In one study, it was estimated that the involvement of authorities is only found in 1 in 14 cases of elder abuse. A study on elder abuse prevalence in the state of New York found that there are 24 unknown cases for every case known to APS.
- Major financial exploitation is self-reported at a much higher rate (41 per 1,000) than neglect or physical, emotional, and sexual abuse (National Center on Elder Abuse, n.d.b).

The National Institute of Justice conducted a large survey of older adults. They found that 1.6% of the respondents reported physical abuse, but only 31% had reported the incident. When other forms of abuse were included, 11% of those surveyed had some kind

of mistreatment in the previous year, with over 5.2% reporting financial abuse, 5.1% citing emotional mistreatment, and 5.1% experienced potential neglect (National Institute of Justice, 2015a). Older adults are at increased risk for abuse due to social isolation, mental impairment, and dependence on others.

Physical abuse, neglect, emotional or psychological abuse, verbal abuse and threats, financial abuse and exploitation, sexual abuse, and abandonment are considered forms of elder abuse (National Center on Elder Abuse, n.d.a).

In some states, self-neglect is also considered a form of mistreatment. This occurs when an older adult neglects to take care of his or herself in a way that leads to illness or injury. Self-neglect includes such behaviors as failing to take medications, refusal to seek medical attention for a serious illness, leaving a burner on the stove on and unattended, poor hygiene, dressing inappropriately for the weather, or confusion. Self-neglect is the form of abuse most commonly reported to APS (National Center on Elder Abuse, n.d.b).

It is notable that financial abuse often accompanies one of the other forms of abuse. The financial abuse of seniors is a growing problem, often called the "crime of the 21st century." It is one of the most sinister forms of abuse. A senior can be financially stable and living independently one day, and become destitute and forced to live in a facility the next as a result of abuse. Sadly, most elder abuse occurs in the elder's own home, and the abuser is usually a family member. In states reporting in a survey of APS agencies, almost half of all cases investigated were substantiated. Most victims of elder abuse are White (77.1%), and the majority of victims are reported to be over age 80 and female (American Psychological Association, 2012). The most common perpetrators of elder abuse are spouses or partners of elders, often in a relationship with long-term domestic violence. Family members account for 76% of reported mistreatment. Abusers, particularly adult children, are often dependent on the victim for financial assistance, housing, or because of personal problems such as mental illness, alcohol, or drug abuse (National Institute of Justice, 2015a). The most common types of financial mistreatment were having someone steal or spend their money, sell or take their property, or forge their signature. The risk of financial mistreatment was higher for individuals who engaged in fewer social or other activities outside of the home (e.g., participating in social activities away from home, getting together with people who do not live in the home, going to the movies), had low self-control, were male and identified as a racial minority (National Institute of Justice, 2015b).

An elder person in immediate danger should be removed from his or her environment; however, elder abuse does not often come to the attention of PHNs or other providers of services to older adults. It is estimated that five occurrences of neglect, abuse, exploitation, or self-neglect go unreported for every case that is reported. Therefore, nurses working in the community with older adults must be vigilant for signs of elder abuse and knowledgeable about reporting laws.

Various state, local, and county agencies investigate and enforce elder abuse laws. The first agency to respond to a report of elder abuse in most states is APS. In some states,

certain professionals are required or encouraged to report elder abuse; there are generally doctors and nurses, psychologists, police officers, social workers, and employees of banks and other financial institutions. The National Institute of Justice (2013, para. 1) has identified four areas that are potential markers for identifying elder abuse:

- Physical condition and quality of care (e.g., unreported injuries, malnourishment)
- Facility/housing characteristics (e.g., unchanged linens, strong odors)
- Inconsistencies in statements/records (e.g., statements given vs. what you see)
- Staff/family member behaviors (e.g., evasiveness, lack of knowledge or concern)

APPROACHES TO OLDER ADULT CARE

In general, nursing service to seniors can be divided into two approaches: geriatrics and gerontology. In addition, healthy older adults can be effectively cared for in the community through case management approaches, which focus on all three types of services: primary, secondary, and tertiary. The ultimate goal of community-based case management for the aging population is to enhance the quality of care by decreasing fragmentation, maximizing resources, and providing the highest quality of care possible.

Case Management and Needs Assessment

Case management involves assessing needs, planning and organizing services, and monitoring responses to care throughout the length of the caregiving process, condition, or illness. This concept, which has been practiced by PHNs for many years, focuses primarily on the health needs of clients. Social workers use case management to address their clients' social needs, including their financial problems. Some HMOs provide a coordinated system of services for their enrolled clients. However, many communities provide no such advocate for their older residents, and a more comprehensive, community-wide system approach needs to be developed in order to serve the entire older adult population. Such a system might be based in an agency specifically designed to serve as case manager or agent to assess clients' needs and assemble existing agencies and services to meet those needs.

Various techniques or tools are available to assess the needs of older adults:

- The Older Americans Resources and Services Information System (OARS), developed by Duke University Center for the Study of Aging and Human Development (2014), utilizes two sections of one tool—OARS Multidimensional Functional Assessment Questionnaire (OMFAQ)—to determine levels of functioning in five areas (mental health, physical health, economic resources, social resources, and ability to perform ADLs), along with the extent and intensity of utilization, as well as perceived need, of services. Administration time is about 45 minutes, and this tool is commonly used in research and to determine effectiveness of services, as well as assessment of functional status.
- The Barthel Index assesses functional independence and is often used to determine the levels of disability or dependence of stroke victims with respect to ADLs (Mahoney & Barthel, 1965).
- The Modified Rankin Scale (MRS) is another common tool used for this purpose (Bonita & Beaglehole, 1988; Sulter, Steen, & De Keyser, 1999).
- The Katz Index of ADLs is based on an evaluation of the functional independence or dependence of clients with respect to bathing, dressing, toileting, and related tasks (Katz, 1963).
- The Instrumental Activities of Daily Living Scale looks at an older adult's ability to perform such activities as using the telephone, shopping, doing laundry, and handling finances (Graf, 2013).
- Other tools sometimes used with clients include the Stanford 7-day Physical Activity Recall (PAR) questionnaire (Sallis, Buono, Roby, Micale, & Nelson, 1993) and the Physical Activity Scale for the Elderly (PASE) (Washburn, Smith, Jette, & Janney, 1993). All of these tools measure physical activity and functioning.

A frequently overlooked area of assessment is the client's spiritual needs. Religious dedication and spiritual concern often increase in later years. Limited ability or lack of transportation may prevent older people from attending religious services or engaging in

spiritually enhancing activities. Self-health ratings, including clients' reports on their spiritual needs, provide another useful assessment technique.

HEALTH SERVICES FOR OLDER ADULT POPULATIONS

How well are the needs of older adults being met? To answer this question, other questions must be raised. Do health programs for older adults encompass the full range of needed services? Are programs both physically and financially accessible? Do they encourage clients to function independently? Do they treat senior citizens with respect and preserve their dignity? Do they recognize older adults' needs for companionship, economic security, and social status? If appropriate, do they promote meaningful activities instead of overworked games or activities such as bingo, shuffleboard, and ceramics? Are health care services and other social services provided based on evidence and research?

Effective services for older adults should be comprehensive, coordinated, and accessible and demonstrate evidence-based quality.

Criteria for Effective Service

Several criteria help to define the characteristics of an effective community health service delivery system. Four, in particular, deserve attention. In order to be effective, it should be *comprehensive*. Many communities provide some programs, such as limited health screening or selected activities, but do not offer a full range of services to more adequately meet the needs of their senior citizens. Gaps and duplication in programs most often result from poor or nonexistent community-wide planning. Furthermore, such planning should be based on thorough assessment of the needs of the population in that community. A comprehensive set of services should provide the following:

1. Adequate financial support
2. Adult day care programs
3. Access to high-quality health care services (prevention, early diagnosis and treatment, rehabilitation)
4. Health education (including preparation for retirement)
5. In-home services
6. Recreation and activity programs that promote socialization
7. Specialized transportation services

A second criterion for a community service delivery system is *coordination*. Often, older people go from one agency to the next. After visiting one place for food stamps, they go to another for answers to Medicare questions, another for congregate dining, and still another for health screenings. Such a patchwork of services reflects a system organized for the convenience of providers rather than consumers. It encourages misuse and discourages effective use. Instead, there should be coordinated, community-wide assessment and planning. Communities must consider alternatives that can meet many needs in one location, such as multiservice agencies and interdisciplinary collaborative programs.

A coordinated information and referral system provides another link. Most communities need this type of information network, which contains a directory of all resources and services for the older adult and includes the name and telephone number of a contact person with each listing. Such a network is available in many communities and should be developed in those without one. A simplified information and referral system that includes one number (i.e., an "800 number") that can connect seniors with available resources and services is particularly helpful to older people. In most communities, coordination is not present, or it is not done with any regularity or thoroughness. Many agencies in a given community do not coordinate services but instead deliver their own services in a patchwork and uncoordinated fashion. Collaboration among those who provide services to seniors can provide vital information for planning and implementing needed programs.

A third criterion is *accessibility*. Too often, services for seniors are inconveniently

located or are prohibitively expensive. Some communities are considering multiservice community centers to bring programs and services for elderly closer to home. The Program of All-Inclusive Care of the Elderly (PACE) is one example of this (National PACE Association, 2015). Comprehensive services are offered to eligible nursing home patients, including personal, health care, and housing services (e.g., adult day care, meals, social workers, nurses, primary care physicians, dentists, podiatrists, optometrists, prescriptions, medical specialists, and acute and nursing home care). More convenient, and perhaps, specialized transportation services and more in-home services, such as home health aides, homemakers, and Meals on Wheels, may further solve accessibility problems for many older adults. Federal, state, and private funding sources can be tapped to ease the burden on the economically pressured population.

Finally, an effective community service system for older people should promote *quality* programs. This means that services should truly address the needs and concerns of a community's senior citizens and be based on scientific evidence. In evaluation of the quality regarding the needs of today's elders and in anticipation of the larger numbers to come, many options are becoming available. A range of housing types, from luxurious retirement communities with all amenities for the active and healthier senior to secure and more modestly priced or low-income apartments for independent senior living, are being built in most communities.

The concept of continuing care retirement communities (CCRCs), sometimes referred to as total life centers, allows seniors to "age in place," with flexible accommodations designed to meet their health and housing needs as these needs change over time (American Association of Retired Persons [AARP], 2015a). CCRCs are the most expensive long-term care solution available to seniors; however, they provide all levels of living, from total independence to the most dependent, and are designed to meet the continuous living needs of older aging adults. Residents entering CCRCs sign a long-term contract that provides for housing, services, and nursing care, usually all in one location. Many seniors enter into CCRC contracts while they are healthy and active, knowing they will be able to stay in the same community and receive nursing care should this become necessary. Seniors who invest in a CCRC have adequately planned for housing and care for the remainder of their life and have the financial means to support it. Entrance fees can range from $3,000 to $5,000 to 1,000,000 and monthly fees from $3,000 to $5,000 (AARP, 2015b). Others may choose to remain in their own home because they do not desire living arrangements that include only older adults or because they have not planned adequately for the expense. Nevertheless, demand is increasing for this type of housing option.

Although only 1.4 million people in the United States live in skilled nursing facilities, such organizations remain the most visible type of health service for older adults (CDC, 2015q). These facilities provide skilled nursing care along with personal care that is considered nonskilled or custodial care, such as bathing, dressing, feeding, and assisting with mobility and recreation. Currently, approximately 2 million people are receiving

nursing home care.

Some struggle to maintain the appearance of doing well in order to maintain their independence. Often, they fear that their children or others will make decisions for them that include leaving their homes. Home, whatever form it takes, is where these people believe they are the happiest.

There is increased emphasis on providing needed services for elders at home. This trend started several years ago when it became evident that people improved more quickly and at lower cost when they were cared for as outpatients in their own homes. Today's emphasis on cost control gives added support for providing services at home. Given the increase in longevity, the potential for cost savings appears significant if care for dependent older people can be maintained at home. Doing so encourages functional independence as well as emotional well-being, but needs must be assessed. What are the needs of this specific population group in terms of nutrition, exercise, economic security, independence, social interaction, meaningful activities, and preparation for death? Planning for quality community services depends on having adequate, accurate, and current data. Periodic needs assessment is a necessity to ensure updated information, and initiate and promote quality services.

Services for Older Adults by Level of Care Required

The majority of older adults want to remain in their own homes for the remainder of their lives and be as independent and in control of their lives as possible (HelpGuide, 2015i). Partners for Livable Communities (2015) outline a blueprint for developing livable communities where peoplecan live in their own communities and grow old with all the services necessary. Aging in place is a term used for seniors who choose to remain in their own homes. To successfully remain at home, older adults need transportation, a home that can be modified if moving up and down stairs becomes problematic, a yard that can be maintained, personal care if needed, a way to safely take medications, live in a safe neighborhood, and have family or friends who can assist when needed (HelpGuide, 2015f).

Maintaining functional independence should be the primary goal of services for the older population. Assessment of needs, ability to function and the use of tools, such as the previously cited OARS, the Instrumental Activities of Daily Living Scale, or other tools, form the basis for determining appropriate services. Although many of the well seniors can assess their own health status, some are reluctant to seek needed help. Therefore, outreach programs serve an important function in many communities, as they locate people in need of health or social assistance and refer them to appropriate resources.

Health screening is another important program for early detection and treatment of health problems among older adults. Conditions that are easily screened include hypertension, glaucoma, hearing disorders, cancers, diabetes, anemia, depression, mild cognitive impairment, and nutritional deficiencies. At the same time, assessment of clients' socialization, housing, and economic needs, along with proper referrals, can prevent further problems from developing that would compromise their health status. Health maintenance programs may be offered through a single agency, such as an HMO, or they may be coordinated by a case management agency with referrals to other providers. These programs should cover a wide range of services needed by the senior population, such as those listed in Display 24–6.

At times, seniors who remain in their own homes or apartments need home care services brought to them. Other seniors live with family members and go to an adult day care center during the day. The third category of living arrangements includes those that are short term. It may be a rehabilitation hospital for recovery and physical therapy related to a hip fracture, or respite care, which gives the usual caregiver a much-needed rest from 24-hour-a-day caregiving and helps prevent "burnout." Families of terminally ill clients and those with severe dementia cared for at home often use respite services.

Adult Day Care

Day care services offer a place where older adults can go during the day for social activities, nutrition, nursing care, and physical or speech therapies. They can be publicly or privately funded, nonprofit or for-profit. The average price for adult day care is $64.00 per day, and

Medicare does not cover this service (HelpGuide, 2015a).

Home Care Services

Home care provides services such as skilled nursing care, psychiatric nursing, physical and speech therapies, homemaker services, social work services, and dietetic counseling (see Chapter 32). These services are useful for families who are caring for an older person, especially if the caregivers work and no one is at home or available during the day. One disadvantage to those remaining in their homes is that services for dependent older adults in the community are often fragmented, inadequate, and inaccessible, and at times, operate with little or no quality control.

Independent Living

This is a general term for any housing arrangement designed exclusively for seniors. Types of independent living facilities include subsidized senior housing, retirement communities, and senior apartments restricted to those who are older (usually 55+) (HelpGuide, 2015h). These facilities provide minor assistance with ADLs and maintenance for the housing facility.

The *Village Concept* is a relatively new solution for independent living in which older adults live in their own homes in a village, giving them access to services such as transportation and grocery shopping or helping with household chores provided by the village. This means that the older adult is not dependent on family or friends. This option requires a membership fee, often more than $500 a year, based on services needed (AARP Public Policy Institute, n.d.).

The dependent older adult needs someone in the community to assess their particular needs; assemble, coordinate, and monitor the appropriate resources and services; and serve as their advocate. Some communities have ombudsmen to serve in this role. But PHNs can easily fill the role of case manager for clients. This case management approach tailors services to the long-term needs of clients and enables them to function longer outside of institutions.

Assisted Living

Assisted living or assisted living facilities (residences) provide supervision or assistance with ADLs, coordination of services by outside health care providers, and monitoring of resident activities to help to ensure their health, safety, and well-being. Assistance may include the administration or supervision of medication or personal care services provided by trained staff. It is less costly than care in a nursing home (Medline Plus, 2015).

Assisted living as it exists today emerged in the 1990s as an alternative on the continuum of care for older adults. Usually, it includes seniors for whom independent living is no longer appropriate, but who do not need the 24-hour medical care provided by a nursing home. Assisted living is a philosophy of care and services promoting

independence and dignity. Other names for assisted living are residential care, board and care, congregate care, sheltered housing, adult congregate living care, adult living facilities, supported care, enhanced care, adult homes, retirement residences, adult foster care, and community-based retirement facilities. There is no nationally recognized definition of assisted living. Regulation and licensing of these facilities occur at the state level, and each has its own definition of the term it uses to describe assisted living. More than two thirds of the states use the licensure term "assisted living." Other licensure terms used for this type of care include residential care home, assisted care living facilities, and personal care homes. Because the term assisted living has not been defined in some states, it is often a marketing term used by a variety of senior living communities, licensed or unlicensed. The difference in licensing is usually based on the size of the facility or the services it can offer.

Services that are provided include help with ADLs, health care management and monitoring, housekeeping and laundry, transportation, security, recreation, and either reminders or help with medications. Although skilled nursing care is not provided, assisted living is an expensive option ranging in cost from <$10,000 to over $50,000 a year with an average rate of $1,800.00 per month (Genworth, 2015). Medicare does not cover the costs of assisted living; therefore, almost all of the expenses must be paid for out of pocket (HelpGuide, 2015c). Medicare only pays for medical care, not housing costs. Medicaid may help pay some assisted living costs and limited custodial home care but not generally for housing costs related to personal care homes. Those facilities focusing on the care of people with AD are physically designed with clients' safety and individual needs considered, and are staffed with trained paraprofessionals.

Nursing homes/long-term care/skilled nursing facilities include those services that provide care for people at different stages of dependence for extended periods of time. New choices are now available and provide housing for larger numbers of older adults than do nursing homes. The average nursing home cost is over $90,000 for a private room, and Medicare only covers limited stays in long-term care. For 100 days following a hospital stay, Medicare covers a nursing or rehabilitation center. Medicare does not, however, pay for custodial care (care that includes help with ADLs but not skilled nursing care). Medicaid will pay for nursing home care for those with limited assets (HelpGuide, 2015c, 2015e).

Medicare and Medicaid generally pay only for care in skilled nursing facilities. Medicaid may pay for care in intermediate care facilities but only after the client meets income and asset tests that leave them essentially indigent. Medicaid coverage of assisted living services is available in a few states that can grant Medicaid waivers. The average length of time a senior remains in an assisted living residence is about 28.3 months (National Center for Assisted Living, 2015). Because of licensing restrictions, when someone becomes bedridden or needs additional assistance or skilled nursing care, they generally must move from assisted care into another facility.

Nursing home reform was legislated in the late 1980s, putting increased demands on facilities to provide competent resident assessment, timely care plans, quality improvement,

and protection of resident rights (Omnibus Budget Reconciliation Act, 1987). This increased complexity of services has resulted in increased costs in these facilities. Staffing needs increase as care becomes more complex and the resident population grows. Licensed personnel must be knowledgeable decision-makers, managers of unskilled staff, staff educators, and role models, as well as efficient and effective administrators in an essentially autonomous practice setting. And, as the population grows, the need for greater numbers of both licensed and attendant staff becomes more evident. Because many of these jobs offer low pay and are without substantial benefits or a career ladder, it is projected that it will remain difficult to staff for rising demand.

In the past, nursing homes had stigmas attached to them. Many people saw them as places that enforced dehumanizing and impersonal regulations, such as segregation of sexes, strict social policies, and sometimes overuse of chemical and physical restraints. Media attention to such conditions, together with current licensing regulations, should make these types of practices the rare exception. In addition, as competition comes from facilities offering lower levels of care (e.g., assisted living centers), residents in nursing homes who are receiving minimal care may be able to find other types of housing.

Even in institutions in which the quality of care is outstanding, costs are so high that family resources are soon depleted if not planned for long in advance of the need. Although Medicaid pays for skilled nursing costs if the client meets low-income and asset requirements, and Medicare pays for a limited period of care, clients and families pay more than half of the total costs. Life savings that older parents had hoped to leave to their children may be quickly consumed, forcing them into indigence.

END OF LIFE: ADVANCE DIRECTIVES, HOSPICE, AND PALLIATIVE CARE

A final need of older adults is preparing for a dignified death. In her classic work, *On Death and Dying*, Elisabeth Kübler-Ross (1969) described death as the final stage of growth and one that deserves the same measure of quality as other stages of life. Although death is a natural part of life, many older people fear death as an experience of pain, humiliation, discomfort, or financial concern for loved ones. Sometimes, very aggressive and heroic medical treatments are offered to those near the end of their lives, often at the urging of family members. Planning for a dignified death is an important issue for many older people, and PHNs can facilitate conversations among family members and provide necessary information and resources.

Advance Directives

Living wills and advance health care directives (AHCDs), sometimes referred to as *advance directives*, are legal documents that instruct others about end-of-life choices should an individual be unable to make decisions independently. The forms for advance directives are available for every state online through CaringInfo.org (National Hospice and Palliative Care Organization, n.d.). An AHCD only becomes effective under the circumstances specified in the document. This document allows for appointment of a health care agent who will have the legal authority to make health care decisions on behalf of the patient and for specific written instructions for future health care in the event of any situation in which the patient can no longer speak for himself or herself. Examples include:

- The use of dialysis and breathing machines
- Use of resuscitation if breathing or heartbeat stops
- Tube feeding
- Organ or tissue donation

Having such documents prepared and making them known to significant others can ensure that wishes will be honored. These documents can provide clear directions for families and health care professionals and are gaining more recognition and importance as a result of increasing ethical dilemmas and challenges brought on by advances in technology (American Medical Association, 2015). Advance directives can be revoked or replaced at any time, as long as the individual in question is capable of making his or her own decisions. It is recommended that these documents be reviewed every 2 years or so, or in the event of a change in health status, and revised to ensure that they continue to accurately reflect an individual's wishes.

Hospice

Hospice is an option that takes a multidisciplinary approach to end-of-life care and needs. Hospice is more a concept of care than a specific place, although some hospice organizations provide individuals with a place to die with dignity if they have no home or choose not to die at home. Hospice is an option for people with a "projected" life expectancy of 6 months or less and often involves palliative care (pain and symptom relief) as opposed to ongoing curative measures. Staff is on call 24 hours a day, 7 days a week. In 2011, $1.65 million patients received services from hospice, and 44.6% of deaths occurred under hospice care. Over 39% of hospice patients were over age 85, and 66.4% of all hospice care is given in the patient's own home (National Hospice and Palliative Care Organization, 2015). The Medicare hospice benefit, enacted by Congress in 1982, is the predominant source of payment for hospice. The number of hospice programs nationwide continues to increase—from the first program that opened in 1974 to approximately 5,300 programs today. The majority of hospices are independent, freestanding agencies, whereas the remaining agencies are either part of a hospital system, home health agency, or nursing home. Hospices may range in size from small, all-volunteer agencies that care for fewer than 50 patients per year to large, national corporate chains, employing nurses and other staff members that care for thousands of patients each day (National Hospice and Palliative Care Organization, 2015).

Hospice enables many clients to live their end days to the fullest, with purpose, dignity, grace, and support; in fact, one recent large-scale study found that hospice patients survived 29 days longer than nonhospice patients (National Hospice and Palliative Care Organization, 2015). Hospice care focuses on all aspects of an individual's life and well-being: physical, social, emotional, and spiritual. Individuals are permitted to go on and off hospice care as needed or if they change their mind and decide to return to curative treatment. Some community health nursing agencies offer hospice programs staffed by their nurses. It is a service that has been well received by older adults, meets important needs, and is growing in use (eldercare.gov, 2015). See Chapter 32 for more on hospice and palliative care in the community.

POPULATION-FOCUS ON ADVANCE DIRECTIVES

Advance-directives are a very personal and individual matter. Whenever you or I go into the hospital or surgery center for a procedure, we are usually asked by an

admitting nurse or clerk if we have an advance-directive (no matter our age or health status). How many people actually answer in the affirmative? Autonomy is a hallmark of ethical thought. We believe that people should be able to choose for themselves and have their choices respected; hence, the right to leave the hospital against medical advice (AMA). Therefore, we wait for patients to express their preference about advance directives (or the choice to have none).

Have you ever considered this from a population perspective? When someone does not choose a plan for end-of-life care, the option by default generally becomes full medical treatment and lifesaving measures to delay death, despite the futility of the pending outcome. Often, this causes needless suffering and is costly in terms of manpower and resources. But, do individuals truly understand their options? Can we offer better explanations of the alternatives? Behavioral economists explain that people are not always good at systematically looking at best evidence in order to make decisions. We rely on what others think or on rules of thumb because we are often faced with "decision fatigue." We are programmed to avoid loss and seek immediate rewards. Taking this into consideration, and the knowledge that terminal patients want comfort and quality of life at the end of life, researchers gave participants three options: (1) advance directives for comfort-oriented care (where life might be shorter), (2) advance directives for a longer life (where there might be more pain and suffering), and (3) no directives. Because of the way choices were structured, twice as many people chose the option with comfort as the goal over the other two choices. They termed this "choice architecture," as this reframing of the choices to draw attention to outcomes helps to "nudge" people toward their definitive goals (Hostetter & Klein, 2013, June–July, para.17).

The argument could be made that evidence supports advance directives for comfort-oriented care, but is it ethical to influence behavior in this way? The elderly are a growing population, and the lack of advance directives does lead to more economic burden on the healthcare system. Population-focused initiatives are needed to educate the elderly about advance directives and the potential outcomes of the choices they make. Can you think of creative ways of addressing this issue on a population level?

Hostetter, M., & Klein, S. (2013, June–July), In focus: using behavioral economics to advance population health and improve the quality of health care services. Matters Quality. Retrieved from http://www.commonwealthfund.org/publications/newsletters/quality-matters/2013/june-july/in-focus

Palliative Care

Palliative care consists of comfort and symptom management and does not provide a cure. For most chronic ongoing health conditions—such as diabetes, high blood pressure, congestive heart failure, arthritis, and COPD—there are no cures, only symptom relief. Relative to the senior population, which suffers from more chronic conditions than the rest of the population, palliative care should not be viewed as synonymous with hospice or end-of-life care. Rather, palliative care should be viewed as any care primarily intended to relieve the burden of physical and emotional suffering that often accompanies the illnesses associated with aging. Palliative care should be a major focus of care throughout the aging process, regardless of whether death is imminent within 6 months (National Hospice and Palliative Care Organization, 2015). Many seniors are now "preplanning" their funerals. This option is gaining momentum in the senior population and allows individuals to make arrangements with a funeral home of their choice, selecting interment or cremation, a memorial service or a celebration of life gathering, music to be played, and other personal details. All options are chosen by the senior rather than leaving these choices and decisions solely to their family members. Other older adults may place less emphasis on the rituals, as was demonstrated by one older adult who left these choices to her children by telling them, "Surprise me!"

CARE FOR THE CAREGIVER

The burden of caregiving is receiving more attention in recent years because it is such a demanding and costly role. An increasing number of older people are cared for in their home by a spouse or other family member on an unpaid basis. Almost 75% of persons receiving care at home rely exclusively on informal caregivers, usually women between the ages of 45 and 64. The demands of caregiving exact a toll on the caregiver, who not only may miss important screening and health care visits for self but also often give up a social life. Caregiving has been associated with increased levels of depression and anxiety, as well as increased use of psychoactive medications, poorer levels of self-reported health, compromised immune function, and increased mortality. For example, there are nearly 15 million Alzheimer's and dementia caregivers providing 17 billion hours of unpaid care valued at $202 billion (AARP, 2015b). These caregivers suffer not only emotionally but also physically. Because of the toll of caregiving on their own health, caregivers for those with AD and dementia had $7.9 billion in additional health care costs. More than 60% of family caregivers report high levels of stress because of the prolonged duration of caregiving and 33% report symptoms of depression (National Alliance for Caregiving and the AARP Public Policy Institute, 2015). Their own decline in health compromises their ability to be a caregiver unless they get some relief (see Chapter 32).

Respite care is a service that is receiving increasing attention. It provides time off for caregivers, including family members, who care for someone who is ill, injured, or frail. Respite care can take place in an adult day center, in the home of the person being cared for, or even in a residential setting such as an assisted living facility or nursing home. Although there are different approaches to respite care, all have the same basic objective: to provide caregivers with planned temporary, intermittent, substitute care, allowing for relief from the daily responsibilities of caring for the care recipient (AARP, 2015b). Respite care is sometimes available through agencies that provide volunteers to relieve caregivers; neighbors, churches, or volunteer organizations may be potential sources of assistance. Some skilled nursing facilities provide an extra room to give temporary institutional housing for the older adults while caregivers take a break over a weekend, for instance. Clients may also need a change from the constant interaction with their caregivers. Long-term care insurance may cover some costs of respite care. The 2000 Older Americans Act Amendments provided funding for states to work through the National Family Caregiver Support Program (NFCSP) to address respite care specifically on the local level (CDC, 2015o).

THE COMMUNITY HEALTH NURSE IN AN AGING AMERICA

PHNs can make a significant contribution to the health of older adults. Because these nurses are in the community and already have contact with many seniors, they are in a prime position to begin needs assessments and mutual planning for the health of this group. Case management is often a critical aspect of the nurse's role because the PHN must know what resources are available and when and how to make referrals for these older clients (see From the Case Files II).

From the Case Files II

Johnny Jessup is 94 years old and lives with his wife, age 86, in a small mobile home on some acreage in a rural area of our county. He had mastoiditis as a child and lost a good deal of hearing. His vision is good, though, and he only wears glasses for reading. He was diagnosed with prostate cancer 20 years ago and still suffers from the radiation treatments he had at that time. He wears a protective "diaper" because he is often bowel incontinent. He is generally in good health, with no hypertension or evidence of heart disease. He spends most of his days outside, watering his berries, flowers, and fruit trees. He worked as a farmer and laborer—always outside—and he enjoys being in the sun and away from the television that his wife, Maude, likes to watch. He has difficulty hearing it, and when he turns up the volume, it "hurts her ears" and they argue over that. They have one son who lives in the same town, but he works long hours at his job. They speak by phone every other day, and he comes by to visit when he can. Their three grandsons are all away at college and they rarely see them.

As a young man, Johnny liked to dance, and he occasionally will go to the local

senior center dances. Maude does not like to dance and will not accompany him there. Sometimes, this is a source of stress. Johnny likes to drink an "occasional cold beer," but he never drinks "hard liquor." He quit smoking 25 years ago, but he had been a heavy smoker from the age of 20. His appetite has usually been good, but he sometimes has difficulty eating fresh fruit or nuts because of his bowel problems. Maude has recently been having memory lapses and some difficulty remembering to turn off the stove and close the refrigerator door. She has trouble with a number of daily tasks. She likes to have someone bring them fast food as a treat every week, and they now require assistance with errands and most housekeeping tasks.

Recently, Johnny noticed that he was having more difficulty doing his outside chores. He seems more "weak" and "tired" and he has recently had quite a bit of "nausea and vomiting." Maude and Johnny's son took them for an appointment with his urologist, and it was determined that his prostate-specific antigen (PSA) was elevated.

You are a district PHN and have recently been assigned to the Jessup family to assess their functional limitations and provide them with information on resources they might need over the next few months. How would you begin your visit? How can you best determine their functional and physical limitations? What other assessments could be helpful (social, spiritual, mental/cognitive, etc.)? What resources and services might be helpful to them?

Older adults are changing dramatically. The numbers and types of home care services, for example, are mushrooming. Many entrepreneurs, including nurses, who recognize the potential of this growing market, have begun offering goods and services targeted to older adults. PHNs must keep abreast of new developments, programs, regulations, and social and economic forces, along with their potential impacts on the provision of health services.

More importantly, PHNs need to be proactive, designing interventions that maximize nursing's resources and provide the greatest benefit to clients. For example, nurses might develop an older adult case management program that consists of a community-wide assessment, information, and referral service. Such a program might contract with existing agencies to serve as a clearinghouse for the older adult and to channel clients to appropriate services. Financing of such a program might be based on tax dollars (if it is a public agency), grants, or some innovative fee-for-service reimbursement system.

Many of the older population's health problems can be prevented and their health promoted. Changing to a healthier lifestyle is one of the most important preventive measures the nurse can emphasize. Education and support are two keys to the success of these changes.

The role of the PHN as a teacher is an important one. Educating older adults about their health conditions, safety, and use of medications is another important way to prevent problems. Influenza and pneumonia can be prevented through regular health maintenance,

which includes immunizations. Other problems associated with environmental conditions and the aging process, such as arthritis, diabetes, and some cancers, can be diagnosed and treated early, thereby minimizing their deleterious effect on functional independence.

Many types of accidents that frequently happen to older adults are preventable. PHNs can make a difference through their work with individuals, families, and aggregates in promoting and teaching safety measures to prevent such accidents. As discussed earlier, falls are a leading cause of injury and death for the older adult and result from a combination of internal factors (e.g., diseases, effects of medicines) and external factors (e.g., lighting, area rugs, lack of handrails) that are preventable or controllable. Nurses can make a difference in the lives of older clients by using available materials and their own resources when teaching about safety.

PERSPECTIVES VOICES FROM THE COMMUNITY

Continuing Care Centers—A Solution for Aging Adults

I am really sold on continuing care retirement communities! We have one in our area that is a big hit with our middle- and upper-income folks. The Otterbein Lebanon Retirement Community is a model continuing care center and is one of five Otterbein homes located in Ohio. With housing options for 1,200 residents on a 1,500-acre campus in rural southeastern Ohio, older adults can choose housing options that include freestanding two- and three-bedroom homes, one-bedroom cottages, or apartment-style one- or two-bedroom or one-room studio units, where they live

independently.

They are licensed for 296 beds, including assisted living options from one-room studio apartments (with limited facilities for meal preparation) to semiprivate rooms in which nurses oversee medication and staff is available to assist with personal care. If caregiving needs become greater, additional services are available. Both skilled nursing services and a freestanding 30-bed Alzheimer's living unit exist for the frailest older adults. This is a real advantage for my clients who want to remain in the same place, even as their physical condition may worsen.

Regardless of the living arrangement, the residents are free to come and go as they wish and all have access to congregate dining in their large and attractive restaurant-style dining room.

The retirement community is expanding. One hundred and ten patio homes were built in 1999–2000 with additional expansion planned.

The Otterbein Lebanon Retirement Community also provides a health clinic, adult day care, and the other usual services found in a community: a bank, post office, ice cream parlor, a small convenience store, hairdresser, library, a church (with a 70-member choir, a bell choir, and men's and women's clubs), a thrift shop, and an arts and crafts shop open to the public. Because of the popularity of this Otterbein Lebanon Community, there is a waiting list for some independent living areas.

Many of the assisted living and skilled nursing beds are occupied by residents who moved into the independent living areas 10 to 15 years ago while they were in their 70s or 80s. Their ages now range from the late 80s to older than 100, and care needs have increased. This is wonderful because, in this type of setting, frail people do not have to leave their community to get the care they need, and longtime friends are nearby to care for them or offer companionship. It is not unusual to see many of the independent seniors volunteering to help feed the frail patients in the skilled nursing care units. In fact, residents volunteer more than 85,000 hours a year to the Otterbein Lebanon Retirement Community. They know that when they need the care, a senior friend will be there for them.

Judy, PHN

PHNs face a serious challenge in addressing the needs of the growing and aging population. At the same time, nursing can be at the forefront of developing innovative health services for seniors, rising to meet the opportunity and the challenge.

SUMMARY

The number of older adults (age 65 and older) is increasing and becoming a larger percentage of the total U.S. population. Women commonly outlive men by a number of years, making women a larger part of this older population. With improved medicines and medical technology, many people are now living well into the 80s and 90s, and in relatively good health. This extended life expectancy is good news; however, it has also created a myriad of new health needs and concerns, not only for the older population but also for health care facilities and professionals who deliver services to older adults.

Healthy longevity is the goal for the aging population and is a focus of *Healthy People 2020*. This means being able to function as independently as possible; maintaining as much physical, mental, and social vigor as possible; and adapting to life's changes while coping with the stresses and losses and still being able to engage in meaningful activity.

To promote and maintain health and prevent illness, older people need to be educated about their own health care needs. In particular, they should understand the potential hazards of drug interactions if they are taking multiple medications. They also need good nutrition and adequate exercise; they need to be as independent and self-reliant as possible; they need coping skills to face the possibility of financial insecurity and the loss of a spouse or other loved ones; they need social interaction, companionship, and meaningful activities; and they need to resolve anxieties regarding their own eventual death.

The most common health problems of older adults are chronic and often progressive conditions such as arthritis, vision and hearing loss, heart disease, hypertension, and diabetes, all of which can become disabling conditions. Other major causes of death or disability include cancer, CVAs, AD, along with accidents and injuries resulting from falls, fires, or automobile crashes. Older adults also often suffer adverse side effects from polypharmacy (multiple medications prescribed for various chronic conditions), making this a danger. Many of these health problems, along with accidents and injuries, associated with old age are preventable to some extent, and early diagnosis and treatment of some conditions can minimize their adverse effects.

Too frequently, older adults suffer from the emotional side effects of aging, such as feelings of distress and anxiety regarding their future, loneliness and social isolation when loved ones or friends die, and even depression, feeling that life is over and they have no purpose or meaningful function in life. However, older people can also enter this phase of life determined to keep physically and mentally healthy, interacting with others and making viable contributions to others and society.

Many programs are available to older adults, both for those who are healthy and active, along with those needing some level of dependent or semidependent care. Programs for hearty older people include health maintenance programs that cover a wide range of health services, wellness programs, health screening, outreach programs, social assistance programs,

and information about volunteering and educational opportunities in the community. A variety of living arrangements and care options are available from which to choose and can be tailored to the older person's desires and needs. These include continuing care centers, which offer a full range of living arrangements—from totally independent living to skilled nursing services—all within one community. There are also facilities that provide skilled nursing and custodial care, assisted living, home care, day care, respite care, and hospice.

The community health perspective includes a case management approach that offers a centralized system for assessing the needs of older people and then matching those needs with the appropriate services. The PHN should also seek to serve the entire older population by assessing the needs of the population, examining the available services, and analyzing their effectiveness. The effectiveness of programs can be measured according to four important criteria (targeted to the specific needs of the population): comprehensiveness, effective coordination, accessibility, and quality.

The PHN can make significant contributions to the health of the older population as a whole by being aware of new developments and programs that become available, new regulations, and innovative social and economic forces and their impacts on the provision of health services. More importantly, the nurse can design interventions that maximize nursing resources and provide the greatest benefit to the older adult population.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. On the Internet, search for and download instructions for filling out your own advance directive. Complete the form for your state and discuss your wishes with someone who is likely to be involved in your health care.
2. Picture an older adult you know well or know a great deal about. Make a list of characteristics that describe this person. How many of these characteristics fit your picture of most senior citizens? What are your biases (ageisms) about them?
3. If you were Minnie Blackstone's community health nurse (see From the Case Files I), what interventions would you consider using to maintain and promote her health? Why?
4. As part of your regular community health nursing workload, you visit a senior day care center one afternoon each week. You take the blood pressures of several people who are taking antihypertensive medications and do some nutrition counseling. The center accommodates 60 senior clients, and you would like to serve the health needs of the aggregate population. List five potential health needs of this group. What actions might you consider taking at an aggregate level? With whom would you consult as you plan programs at the center?
5. Assume that you have been asked by your local health department to determine the needs of the older adult population in your community. How would you begin conducting a needs assessment? What data might you want to collect? How would you find out what services are already being offered and whether they are adequate?
6. Visit a continuing care center in your community. Assess the housing options, services, and health care provisions. Would you live here when you are older? How would you feel about a family member living here? What would you change if you could?
7. Search the Internet for examples of innovative programs for elders in the community at the primary, secondary, and tertiary levels of care. Determine whether such programs could work in your own community.
8. Discuss with a group of your classmates how you may be able to assist older adults with their spiritual health. What are important considerations to keep in mind? Pair with another student and practice how you would open a conversation about this with an elderly client.
9. In From the Case Files II, how would you address the subject of advance directives? Where could you locate information specific to your state? Who else should you include in this conversation? Why is it important to have current advance directives in place?

7 UNIT

PROMOTING AND PROTECTING THE HEALTH OF VULNERABLE POPULATIONS

25 CHAPTER

Working with Vulnerable People

"How far you go in life depends on your being tender with the young, compassionate with the aged, sympathetic with the striving, and tolerant of the weak and the strong—because someday you will have been all of these."
—*George Washington Carver* (1860–1943), Botanist and Scientist

KEY TERMS

Differential vulnerability hypothesis
Empowerment strategies
Environmental resources
Health disparities
Human capital
Racial/ethnic disparities
Racism
Relative risk
Social capital
Social determinants of health
Socioeconomic gradient
Socioeconomic resources
Vulnerability
Vulnerable populations

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the term "vulnerable populations."
- Describe and explain a conceptual model of vulnerability.
- Discuss the effects of vulnerability and relative risk.
- Differentiate between the concepts of social capital and human capital.
- Identify the key premise of the differential vulnerability hypothesis.
- List three of the most common factors related to vulnerability.
- Explain the socioeconomic gradient in health.
- Describe three types of health disparities.
- Describe four PHN roles or behaviors that help promote client empowerment.

Vulnerability is susceptibility to poor health. The public health nurse (PHN) caseload often consists largely of vulnerable populations. Often, vulnerable populations are subpopulations, such as ethnic or racial minorities, the uninsured, those with HIV/AIDS, children, the elderly, the poor, and those who are homeless (Shi & Stevens, 2011; Stremikis, Berensohn, Shih, & Riley, 2011). These subpopulations

often have higher morbidity and mortality rates, less access to health care (and disparities in outcomes of health care), shorter life expectancy, and an overall diminished quality of life than does the population in general (Agency for Healthcare Research and Quality [AHRQ], 2015; Shi & Stevens, 2011).

In this chapter, we examine popular models and theories of vulnerability, important concepts, and contributing factors. We also briefly discuss health disparities that are more common among vulnerable members of society and the role of PHNs working with these groups. This chapter provides an overview of this subject and lays the foundation for other chapters in this section.

THE CONCEPT OF VULNERABLE POPULATIONS

Models and Theories of Vulnerability

Flaskerud and Winslow (1998) developed a popular conceptual framework of vulnerability that contains three related concepts: resource availability, relative risk, and health status (de Chesnay & Anderson, 2016). The authors posited that a lack of resources (e.g., socioeconomic and environmental) increases a population's exposure to risk factors and reduces individuals' ability to avoid illness. A community's health status can be observed by noting disease prevalence along with morbidity and mortality rates. Within this framework, the more risk a population faces, the greater the effect on their health status (e.g., higher morbidity and mortality rates). A feedback loop exists from health status to resource availability as higher morbidity and mortality further deplete community resources (Fig. 25–1). The central point of the model demonstrates the importance of nursing research and practice, along with ethical and policy analysis, in affecting resources, relative risk, and health status. This can occur by direct interaction with one or more of these three factors (e.g., reducing risk factors through education) or indirectly through intervention at the junction of two factors (e.g., working to minimize morbidity related to a specific risk factor such as encouraging the consistent use of statins for hypercholesterolemia).

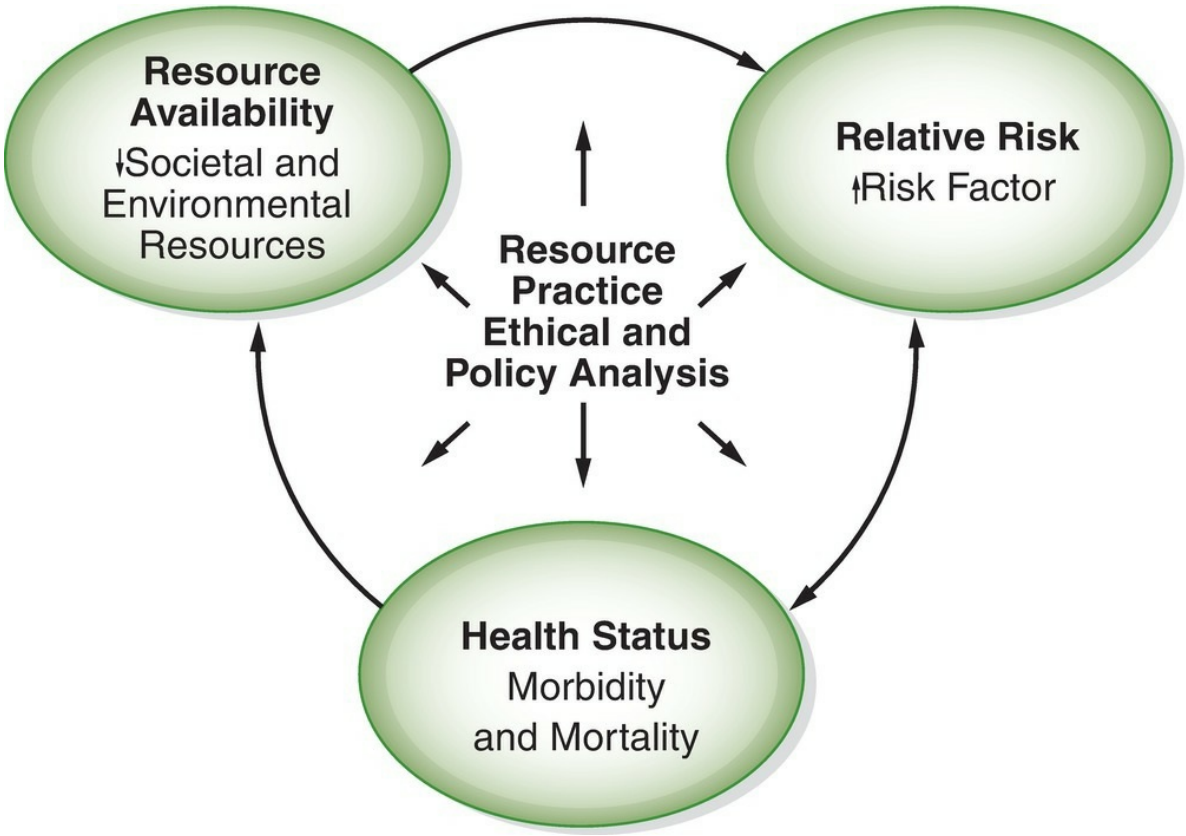

Figure 25–1 Vulnerable populations conceptual model. (Adapted from Flaskerud, J. H., & Winslow, B. J. (1998). Conceptualizing vulnerable populations health-related research. Nursing Research, 47(2), 69–78.)

To further define model components, Flaskerud and Winslow explained that socioeconomic resources include human capital (e.g., jobs, income, housing, education), social connectedness or integration (e.g., social networks or ties; social support or the lack of it, characterized by marginalization), and social status (e.g., position, power, role). Environmental resources deal mostly with access to health care and the quality of that care. The authors noted the differential access to health care among the poor, different ethnic and racial groups, and other underserved populations. Limited access or lack of access to care can arise from many sources, including crime-ridden neighborhoods, insufficient transportation systems, lack of adequate numbers and types of providers, limited choices of health care plans, or no health insurance. Relative risk refers to exposure to risk factors identified by a substantial body of research as lifestyle, behaviors and choices (e.g., diet, exercise, use of tobacco, alcohol and other drugs, sexual behaviors), use of health screening services (e.g., mammogram, colonoscopy), and stressful events (e.g., crime, violence, abuse, firearm use). The authors noted, for instance, that in populations of single-parent female-headed homes in poverty with little or no access to social programs, violence and homicide are more prevalent. Flaskerud and Winslow provided evidence of the link between poor health status and socioeconomic resource availability through the loss of income, jobs, and health insurance. In the case of environmental resources, high morbidity in an already underserved population will only exacerbate access problems. See Figure 25–1 for Flaskerud and Winslow's Vulnerable Populations Conceptual Model.

This conceptual model has generated a large body of research. Selected studies are displayed in Display 25–1. Adaptations of the model and extensions to newer conceptual frameworks include a framework to develop advocacy and promote empowerment in African American grandmothers caring for their grandchildren (Carr, 2011), a model for risk reduction among older adults vulnerable to nursing home placement (Palmer et al., 2014), living with spinal cord injury (Fyffe, Botticello, & Myaskovsky, 2011), and developing a Caregiver Empowerment Model for family members caring for aging parents (Jones, Winslow, Lee, Burns, & Esther-Zhang, 2011).

DISPLAY 25.1 SELECTED STUDIES USING FLASKERUD AND

WINSLOW'S VULNERABLE POPULATIONS CONCEPTUAL MODEL

Author(s) (Year)	Vulnerable Population	Focus of Study
Flaskerud and Nyamathi (2000)	Low-income Latina women	HIV education, counseling, and testing

Rawlett (2011)	Medically underserved, rural populations	Vulnerability
Palmer et al. (2014)	Older adults	Risk reduction of vulnerability to nursing home placement

Gelberg, Andersen, and Leake (2000) advanced another classic model, the Behavioral Model for Vulnerable Populations, looking at population characteristics (predisposing and enabling factors and needs) as an explanation for health behaviors and eventual health outcomes (Burg & Oyama, 2016). Predisposing factors included demographic variables (e.g., gender, age, marital status), social variables (e.g., education, employment, ethnicity, social networks), and health beliefs (e.g., values and attitudes toward health and health care services, knowledge of disease). Social structures (e.g., acculturation and immigration), sexual orientation, and childhood characteristics (e.g., mobility, living conditions, history of substance abuse, criminal behavior, victimization, or mental illness) were also considered predisposing factors. Enabling factors included personal and family resources, as well as community resources (e.g., income, insurance, social support, region, health services resources, public benefits, transportation, telephone, crime rates, social services resources). Perceived health needs and population health conditions also were considered, as were health behaviors including diet, exercise, tobacco use, self-care, and adherence to care. The use of health services (e.g., ambulatory and inpatient care, long-term care, alternative health

care) and personal health practices (e.g., hygiene, unsafe sexual behaviors, food sources) combined with the other factors to produce outcomes such as perceived and evaluated health and general satisfaction with health care services. The model has been used in research with homeless adults (Stein, Andersen, Robertson, & Gelberg, 2012) and in examining barriers to interconceptual care (Hogan et al., 2012), with mixed results. See Figure 25–2 Interrelated Pathways Linking Education to Health.

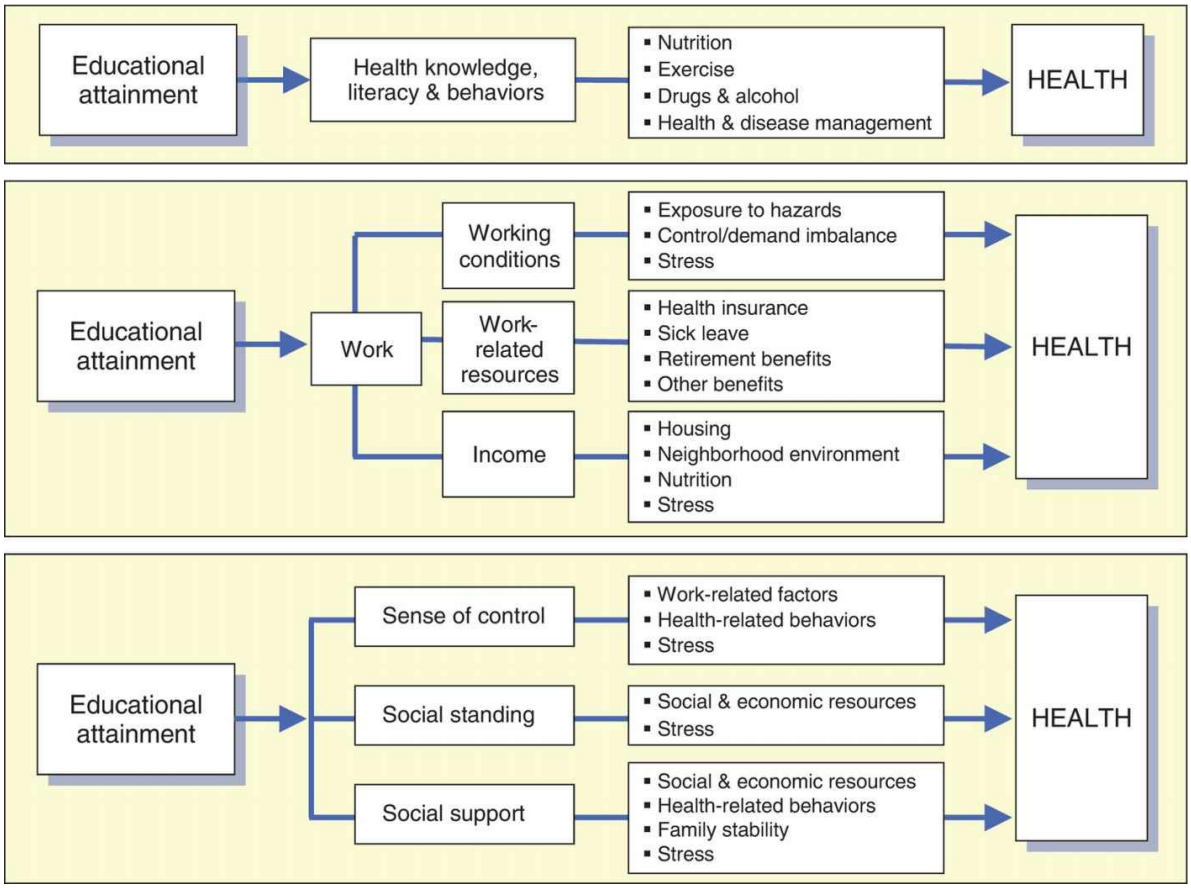

Figure 25–2 Interrelated pathways linking education to health. (From Braveman, P., Ergerter, S., & Williams, D. R. (2011). The social determinants of health: Coming of age. Annual Review of Public Health, 32, 381–398, 386, used with permission.)

LuAnn Aday (2001) advanced the well-known Framework for Studying Vulnerable Populations that includes both macro- and microperspectives (Burg & Oyama, 2016). Aday described the effects of policies on both communities and individuals, including social and economic policies, community-oriented health policies, as well as medical care and public health policies. She noted that community resources (e.g., strong neighborhoods, close ties between citizens) have a direct effect on individual resources (e.g., social status, social ties, human capital). For instance, a community with a high proportion of children, adolescents, and elderly and a majority of single female-headed households will likely also be characterized by lower education levels, higher unemployment, and lower income levels along with a subsequently higher relative risk of poor health status. When strong social networks are present and housing is adequate, the relative risk of poor psychological, social, or physical health decreases.

Aday subscribed to a differential vulnerability hypothesis that "negative or stressful events (such as unemployment, divorce, or death of a loved one) hurt some people more than others" (2001, p. 4). Even though we all are subjected to stressful events (nursing school, for instance), Aday cited research showing that low socioeconomic status (SES) groups, for example, are more adversely affected by stressful or negative events than are

those with higher SES. Chronic stressors manifested by the lack of material resources and social marginalization experienced in childhood and early adolescence can lead to real physical changes and are the basis of vulnerability to poor health in adulthood. The relationship between lower SES and poor health persists throughout childhood and adolescence into adulthood (Cheng, Goodman, & Committee on Pediatric Research, 2015; Doubeni et al., 2012). Childhood traumas are associated with an increase in "inflammatory transcription" in later adulthood (Levine, Cole, Weir, & Crimmins, 2015, p. 16). Childhood traumas also potentiated the effect of low SES in adulthood on elevated "inflammatory gene expression" (p. 16); researchers believe that early childhood traumas may affect the stress response throughout life and influence health outcomes in later adult life, especially for those who have lower SES. The expression and interaction of these developmental genes with physical and social environments can produce long-term poor health outcomes. In other words, early chronic stressors can induce physiological changes that lead to later negative health outcomes.

Like Flaskerud and Winslow, Aday noted that social status (e.g., age, gender, race, ethnicity) affects social capital and human capital. Social capital consists of marital status, family structure, social ties and networks, and membership in voluntary organizations, such as a church or clubs. Aday linked human capital to investments in individuals' capabilities and skills (e.g., education, job training) and noted that human capital encompasses jobs, income, housing, and education. Aday described research showing that better health status is associated with higher education levels and noted that the personal and political power of individuals and communities differentially affect their efforts to gain access to adequate schools, housing, and employment. "The social status and social capital resources of individuals and groups in a community influence the level of investments that are likely to be made in the schools, jobs, housing, and associated earning potential of the families and individuals living within it" (2001, p. 8).

Social capital can include social ties and networks afforded by religious affiliations.

The importance of social capital is sometimes missed, as it can be subtle and less obvious than the lack of money or jobs. But the presence of friends and family or someone to rely on in case of an emergency can be invaluable in assisting individuals through many of life's difficulties. Social support, or a close confidante, can promote social and psychological health and help counteract the effects of stressful events. In our mobile society, many people live great distances from family members and have difficulty establishing new friendships. Those who live alone or who are socially isolated are at greatest risk of vulnerability, increased morbidity and mortality, and decreased overall health (Lubben, Gironda, Sabbath, Kong, & Johnson, 2015); thus, PHNs should be aware of this and strive to provide additional support and resources.

A general model of vulnerability helps to explain individual and community risk factors that lead to vulnerability, as well as problems with access to care and quality of care received that impact health outcomes on both an individual and community level as described in a

seminal article by Shi, Stevens, Lebrun, Faed, and Tsai (2008). Vulnerable populations often experience clusters of risk factors, and these are viewed as cumulative. The specific combinations of risks (e.g., low income, low education) are more detrimental to health outcomes, as is the greater number of risk factors that accumulate over time.

Most nursing students are familiar with Maslow's Hierarchy of Needs (Maslow, 1987), with physiological needs (e.g., water, food, air) as the base of a pyramid, and the needs for safety, belonging, esteem, and self-actualization building from the basic needs. Chronic poverty, environments of crime and violence, or disenfranchisement, racism, and discrimination (vulnerability) can keep people from meeting the higher needs (Bates, 2016). Racism is largely defined as believing that race is the primary factor of our capacities and traits as humans and that any racial differences result in feelings of either superiority or inferiority.

Who Is Considered Vulnerable?

In her classic book, Aday (2001) included the following factors and populations in the description of who is considered vulnerable:

- Income and education
- Age and gender
- Race and ethnicity
- Chronic illness and disability
- HIV/AIDS
- Mental illness and disability
- Alcohol and substance abuse
- Familial abuse
- Homelessness
- Suicide and homicide risk
- High-risk mothers and infants
- Immigrants and refugees

Other authors considered the uninsured and underinsured as vulnerable populations because of their difficulties with health care access and the potential for poor health outcomes, as well as victims of bullying and crime, children in foster care, those in the gay/lesbian community, veterans and returning military personnel, and victims/survivors of torture and terrorism (Gitterman, 2014; Shi & Stevens, 2011). Although many segments of the population may be considered vulnerable at some point in their lives, some population segments are more often identified as vulnerable because of their long-term situations (de Chesnay & Anderson, 2016). The very young and the very old have particular risk factors that increase their chances of poor health, as well as unique issues with access to health care. An extensive body of research substantiates the reality of higher morbidity and mortality rates for racial and ethnic minorities than for the White population, thus demonstrating racial/ethnic disparities in health (Cantu, Hayward, Hummer, & Chiu, 2013; Dubowitz, Basurto-Davila, & Lurie, 2011; Institute of Medicine [IOM], 2003; Neumayer & Plümper, 2015).

Prevalence of Vulnerable Populations and Causative Factors

Because many of the previously listed conditions and categories have overlapping populations, it is difficult to access accurate data and statistics for each group or category. For example, someone with little education and low income may also be a member of a racial or ethnic minority and may have inadequate housing along with a chronic illness and high-risk births. Rates of low birth weight and infant mortality, along with teenage pregnancy and inadequate prenatal care for mothers, are indicators of substantial problems in that particular area. For example, racial and ethnic differences have been found in studies of perinatal outcomes among mothers with gestational diabetes (Nguyen et al., 2012) and in birth outcomes studies in New York City (Almeida, Mulready-Ward, Bettegowda, & Ahluwalia, 2014).

Root causes of vulnerability, such as low SES, lack of insurance coverage, racism, and discrimination, have been widely researched. Which cause or causes are considered most important? The exact weight of the interaction of these causes has been difficult to ascertain. The current approach to understanding the complex interrelationships among the causes and factors related to vulnerability is to examine multiple determinants of health (Freudenberg & Olden, 2010; Krewski et al., 2014); this chapter focuses on the social determinants of health. See From the Case Files.

From the Case Files I

Natalie and the Social Determinants of Health

My mother's high school friend, Natalie, had her first baby at age 16. He was 10 weeks early, and weighed a little over 2 lb. Her family was poor and mostly ate meals with a lot of fried meat and potatoes. They rarely bought fresh fruits and vegetables, and she worked at a nearby fast-food restaurant for minimum wage and no health insurance was available. She didn't know about family planning services, so she and her boyfriend had unprotected sex and she got pregnant. At that time, "no smoking" ordinances were not common, and even though she was not a smoker at the time, she was exposed to secondhand smoke at home and at work. Her older siblings had problems with substance abuse and her father was often violent with her mother. My mother helped her buy a pregnancy test at the local pharmacy, and she tried to find an obstetrician, but the closest one was 50 mi away. She had no car, and there was no bus service available. She didn't know about prenatal vitamins but wanted to have a healthy baby, so she "ate for two," especially when she could have free burgers and fries at work. It was difficult for her to exercise after dropping out of school, because

the rural roads where she lived had no sidewalks; also, there were no parks or recreation facilities. She ended up with terribly severe headaches and saw bright stars in her visual field. She had to be rushed by taxi to the regional hospital, and they diagnosed her with preeclampsia; her son was born prematurely. He had to be on a ventilator in the NICU and had some cognitive deficits that caused him a lot of later problems in school. He dropped out at the beginning of high school and then got into problems with substance abuse and the legal system. He is about 8 years older than me, and I hear about him from my mom. Natalie later developed respiratory problems and is now disabled, living on a fixed income from Social Security. She never married, but had two more children. I am now in nursing school and learning about vulnerable populations and social determinants of health in my public health nursing course. I talk with my mother every weekend by phone, and I asked her about her friend, Natalie. I now feel that I could begin to understand all of the things that were stacked against her in life. My mother finished high school and married my father, whose family owned a large farming interest in our county. She had a very different life than her friend, Natalie. She uses a treadmill every day at home and tries to cook healthy meals. My mom and dad have a good relationship, and my family lives a comfortable life. I have seen a real-life example of vulnerability and how social differences (e.g., poverty, education, social support) can affect health and social outcomes. I hope to learn more about how to change things for people who are more vulnerable, like my mother's friend, Natalie.

Brynn, Senior Nursing Student

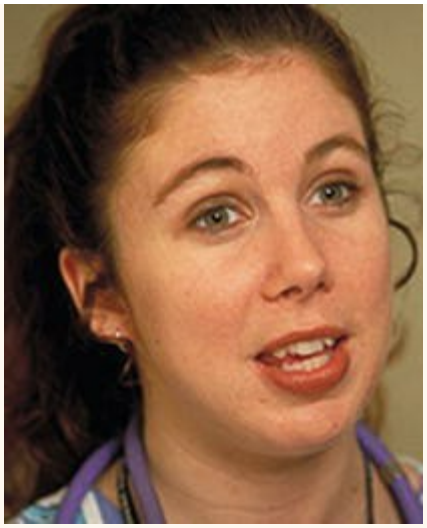
Poverty

If only one indicator is measured—poverty—it is evident that vulnerability touches a large segment of the American population, as well as the global one. An estimated 896 million people worldwide lived on or below $1.90 a day in 2012 (World Bank, 2015). Data indicated that in 2014, about 46.7 million people in the United States (14.8%) lived in poverty (Center for Poverty Research, University of California, & Davis, n.d.). For 2015, the poverty thresholds were $11,670 for a single individual, $15,730 for a family of two, and $23,850 for a family of four (U.S. Department of Health and Human Services [USDHHS], 2014). In 2013, about 15.6 million (22%) of all American children under 18 years of age were in families living in poverty. However, there are racial/ethnic disparities as 39% were Black children, 36% American Indian and Alaskan Native, 32% Hispanic, 13% White, and 13% Asian. The percentage of children living in poverty increased 4% from 2008 to 2013 (Institute of Education Sciences & National Center for Education Statistics, n.d.).



How does poverty make one vulnerable to poor health outcomes? The answer to this

question is complex and is being addressed by many investigators to provide a complete answer. One supposition is that having less money means being less able to afford most aspects of a quality life, including adequate housing in a safe neighborhood. This living situation may lead to fewer opportunities for exercise, especially if walking outside puts one at risk of becoming a victim of violence. Fewer community resources are usually available, such as grocery stores, quality schools, recreation facilities, and health care providers. Lower income level is associated with lower levels of education and often results in a person having to work at jobs where he or she is exposed to higher risks (e.g., mining), or the need to work at more than one job in order to make ends meet, and often without health insurance coverage (Centers for Disease Control & Prevention [CDC], 2015a). Because of the lack of free time, one may be less likely to shop for fresh fruits and vegetables and to cook healthy meals, with a consequent reliance on fast foods. Inadequate childcare, lower social class, and stigmatization can cause ongoing psychological stress. There may be less control over transportation and work schedules, along with a greater degree of stress on the job and at home. Chronic stress takes a toll on one's body as it can lead to health problems through neuroendocrine and immune pathways (Heffner, 2011). The resulting consequences of chronic stress may lead to rapid aging and damaged health through such behaviors as smoking and excess drinking (see Perspectives: Student Voices). Neighborhood characteristics (e.g., high levels of poverty/physical disorder, low levels of safety) have been linked to significantly higher serum cortisol levels in European American (White) children, but not for African American children. Researchers thought that this reflected an adaptive mechanism for coping with stress, as the differences disappeared as both groups of children approached puberty. They noted that disruption in cortisol levels has negative effects on mental and physical health (Dulin-Keita, Casazza, Fernandez, Goran, & Gower, 2012).

PERSPECTIVES STUDENT VOICE

A Nursing Student's View of the Aftermath of Hurricane Katrina

I was beginning my last year of nursing school when Hurricanes Katrina and Rita hit the Gulf Coast of Louisiana and Mississippi. Like most people, I was fixated on the television coverage of this natural disaster. A lot of the round-the-clock coverage focused on New Orleans, and much of that city seemed to be under water. People in flooded areas were stranded on housetops, while families could be seen walking on highways to get to Red Cross shelters. A horrifying image that I recall clearly was one of yellow school buses, mostly underwater, that were a key part of the city's disaster plan and were supposed to be used to assist those without personal means of transportation to move to higher ground.

It was like watching a very bad dream. We have had disasters in this country, but I did not expect to witness the lack of organization and preparation that seemed to abound with Katrina. I couldn't understand why masses of people didn't leave the area before the storms hit and why it took so long for the federal government to respond to the needs of American citizens. Those people who tried to leave found themselves delayed by the slowly moving parking lots that had once been interstate freeways. Even with personal transportation, evacuation was difficult!

What seemed very clear after Katrina was that there are large numbers of poor and vulnerable people in this country; I had not been previously aware of this. Did you know that most of those who died were poor and Black? This doesn't seem right. Didn't we abolish segregation and advance civil rights? In our community health nursing class, we discussed vulnerable populations and read some articles about this disaster. We talked about health disparities. I had never really thought about that before, but it rings true to me now. Some groups of people have higher numbers of deaths and more problems with certain diseases than do other groups. We do have different levels of health care for different groups, and some people can only access the health care system by coming to the ED.

I now have a better understanding of how things happened with Katrina. When you have little money, no reliable transportation, no extended support systems, and inadequate information about an impending disaster, you are vulnerable and at the mercy of government systems that often cannot respond quickly. I often wonder how

> I would fare if something happened suddenly, and I couldn't access cash from my bank account, or my car was low on gas, and I hadn't bought groceries in a couple of weeks. Would I be able to survive a natural disaster like an earthquake? I have family close by and many friends, some in nursing school, who could help me. That makes me less vulnerable, but I still should do a better job of being prepared.
>
> Brooke, Nursing Student

Research has shown that those groups with the lowest income and with the least education were consistently less healthy than were those with the most income and most education (World Health Organization, 2016a). Lower SES can affect health outcomes throughout life (Cheng et al., 2015). As one example, poor prenatal nutrition can lead to learning and memory problems in childhood, as well as type 2 diabetes and cardiovascular disease in later life (de Souza, Fernandes, & Tavares do Carmo, 2011; Finney-Brown, 2012; Martin-Gronert & Ozanne, 2010). Another example is the risk posed by environmental lead to exposure the intellectual development of children. Studies have shown reduced IQ scores for children with lead poisoning and the potential influence of exposure to lead on health and SES of affected populations (Jakubowski, 2011). Poverty and race/ethnicity are often intertwined, but SES is considered a consistent and robust variable related to health and death (Krieger et al., 2014; Montez & Berkman, 2014; Montez & Zajacova, 2013; Neumayer & Plümper, 2015).

If we examine just one aspect of poverty—access to healthy food—research has found that race and environment play a significant role. Neighborhood disparities in access to fruits, vegetables, and other healthy foods have been documented in a large-scale nationwide study and in studies in various parts of the United States (Carroll-Scott et al., 2013; Dubowitz et al., 2011; Hilmers, Hilmers, & Dave, 2012). Other researchers have noted the association of greater access to supermarkets (and limited access to convenience stores) with healthier diets and lower rates of obesity. They conducted a later study, finding that convenience stores and fast-food restaurant workers were concentrated in the South and Midwest where obesity prevalence is higher than in the Northeast and West (Michimi & Wimberly, 2010, 2015). The researchers concluded that the food environment landscapes at the metropolitan area level help explain the patterns of obesity.

Income and race/ethnicity influence access to healthy food.

Another risk factor for the poor is the finding that the highest amount of pollution is most often found in neighborhoods where there is more poverty, lower education levels, and higher rates of unemployment (CDC, 2015a). Others noted an association between SES and poorer respiratory health, often due to living conditions, such as ambient air pollution and smoking (Hajat, Vardoulakis, Heaviside, & Eggen, 2014; Kanervisto et al., 2011), and because of a higher smoking prevalence among those with lower SES (Hiscock, Bauld, Amos, Fidler, & Munafo, 2012). Also, research has shown that lower SES groups are as likely as higher ones to attempt smoking cessation but are less likely to be successful in their efforts (Hiscock, Dobbie, & Bauld, 2015). The lower success in quitting smoking is being examined to find more effective evidence-based treatment for low-income populations (Evans et al., 2015).

At the population level, increases in total income and reductions in poverty levels are "strongly associated with subsequent improvements in population health" (Aday, 2005, p. 190). This is proven out in an examination of maternal mortality outcomes in Cambodia over the past 15 years. Maternal mortality declined from 472 per 100,000 live births in 2000 to 2005 to 206 in the period 2006 to 2010. Factors that contributed to this were noted to be reduction in poverty associated with economic growth and the country's increased stability and peace, as well as improved education levels (particularly for girls), greater access to health information and services, more births at facilities or with birth attendants, expanded midwifery education, and provision of antenatal care, along with free health care (Liljestrand & Sambath, 2012). Income affects health, and poor health can affect the income of an individual as well as that of a nation (see Chapter 6).

Uninsured and Underinsured

If the uninsured is also classified as a vulnerable population, even more Americans join the ranks, because the majority of those without health insurance are working adults who are not eligible for Medicaid or Medicare. The percentage of uninsured in 2013,was estimated at 16.7%. In 2015, 10.7% of people in the United States were without health insurance (Kaiser Family Foundation, 2015). The percentage of uninsured in 2013 was estimated at 16.7. The decline in the percentage of uninsured is attributable in great part to the Patient Protection and Affordable Care Act (ACA), signed into law by President Barack Obama on March 23, 2010. This law requires most U.S. citizens and legal residents to have health insurance coverage, along with many other provisions (Knickman & Kovner, 2015). See Chapter 6 for more on the ACA. Although the improvement in health insurance coverage is encouraging, disparities in access to health care continue. In 2014, 31 million people were underinsured in the United States, which was unchanged from 2010. In 2003, 1% of privately insured adults had a deductible of $3,000 or more, but that increased to 11% in 2014 (Collins, Rasmussen, Beutel, & Doty, 2015). Also, most health care experts feel that there will still be disparities in quality, access, and outcomes for those who are more vulnerable (Stremikis et al., 2011).

How does having inadequate or no health insurance lead to poor health outcomes? As

explained in Chapter 6, those with few or no resources in this area do not utilize early screenings and preventive measures, and they delay getting treatment in an effort to save money. Those without health insurance receive care only for the problem at hand and not always for underlying causes. They do not get regular physical examinations and may be inadequately immunized against common diseases. Thus, they are at risk for poorer general health. Also, when examination and subsequent treatment are delayed, diseases, such as cancer or cardiovascular illness, may result in earlier death.

Race and Ethnicity

The United States is a multiracial, multiethnic country. About one third of the population belongs to a racial or ethnic minority group, and this proportion will continue to increase as minorities are projected to constitute more than half of all children by 2023 (U.S. Census Bureau, 2008, 2011). Hispanics represent the largest minority group (16% of the total population, up from 13% in 2000 census), and they are also the fastest growing group with a lifetime average number of children per woman of 2.53, compared to 1.71 for White women (Ennis, Rios-Vargas, & Albert, 2011; Pew Research Center, 2015).

Blacks and Hispanics report higher levels of metabolic and vascular diseases, as well as cognitive impairment (Apridonidze, Shaqra, Ktaich, Liu, & Bella, 2011). In 2010, Blacks represented 12% of the population, but they have accounted for 44% of new HIV infections; Blacks have the "most severe burden of HIV of all racial/ethnic groups" (CDC, 2015b, para. 2). Preterm births are more prevalent among Blacks, and infant mortality rates for Blacks have been consistently more than twice the rate for Whites (Office of Disease Prevention and Health Promotion, 2015a). Life expectancy for all minority races has been consistently lower than that of Whites since 1901. Life expectancy for Blacks was only 33.7 years in 1901, whereas for Whites, it was 49.4 years. The gap narrowed, but the racial/ethnic disparity still exists. In 2010, the life expectancy at birth for the White population was 78.7 years, for the Black population was 75.1 years, and for the Hispanic population was 81.4 years (Arias, 2014).

Why does simply being a member of a racial/ethnic minority group make someone vulnerable? The reasons are complex and are beginning to be understood. Williams and Mohammed (2013) found in a review of the scientific research that racism affects the health of minority racial populations in multiple ways. The authors found that institutional racism in policies and procedures reduced access to housing, neighborhood and educational quality, employment opportunities, and other societal resources. A second type of racism is cultural racism that affects economic status and health by creating a policy environment adverse to equal policies. A third finding from the review indicated that experiences of racial discrimination are a type of psychosocial stressor that can increase health risks.

Recent immigrants have healthier exercise and dietary patterns than do those born inside the United States. For Asian Americans, one study found that native language retention was associated with lower rates of obesity in first- and second-generation

participants when compared with those who become fully acculturated (Wang, Quong, Kanaya, & Fernandez, 2011). Others note the generational link between minority group membership and low educational attainment (e.g., father's education level) and the tie between education and health (Cutler & Lleras-Muney, 2010). A majority of Hispanics and Blacks have spent a lifetime at a lower level of educational attainment and continue to lag behind in most areas. One bright spot is that 2012 college enrollments for Hispanics rose to 49%, above those for Whites at 47% (Krogstad & Fry, 2014).

VULNERABILITY AND INEQUALITY IN HEALTH CARE

Social Determinants of Health

The World Health Organization has defined the social determinants of health as "the conditions in which people are born, grow, live, work, and age," including the health system (World Health Organization, 2016b, para. 1). Commonly acknowledged factors, such as social norms or attitudes (e.g., discrimination, racism), exposure to crime, violence, and social disorder; and concentrated poverty, are associated with health outcomes and are recognized as social determinants of health (CDC, 2015a; USDHHS, n.d.). The unequal distribution of these factors among certain groups is thought to contribute to health disparities that are persistent and pervasive. The IOM report *For the Public's Health: The Role of Measurement in Action and Accountability* called for addressing the underlying factors, not only the data on morbidity/mortality (2010). When we address health disparities, we must consider these social determinants and work on all levels—individual, aggregate, community, and population—to reduce them. For instance, a safe and nourishing diet is needed to be healthy. Safe and accessible drinking water is also required, as are adequate housing, a supportive environment, and appropriate levels of exercise. The distribution of health care providers (e.g., nurses, physicians, dentists) across the United States leaves many areas and populations underserved. Political resources and social structures can also influence health, and health policies are needed to address multiple inequities and disadvantages that are associated with poorer health (Boyce & Olster, 2011; Embrett & Randall, 2014). You can check your own county's health ranking at http://www.countyhealthrankings.org/.

Social determinants of health are related to both morbidity and mortality. Quantified deaths that could be attributed to social factors in the United States were recently reported. The authors found that in 2000, about 245,000 deaths were attributable to low education, 176,000 to racial segregation, 162,000 to low social support, 133,000 to individual-level poverty, 119,000 to income inequality, and 39,000 to area-level poverty (Galea, Tracy, Hoggatt, DiMaggio, & Karpati, 2011). Moreover, it is estimated that only 10% to 15% of the increase in length of life in Western nations can be attributed to improved medical care, according to Raphael's classic treatise (2003).

In an effort to improve the health of disadvantaged groups, early public health efforts addressed determinants of health such as sanitation and poverty, along with living conditions and other environmental issues, as noted in Chapters 2 and 7. The present need to address underlying social conditions to improve health status is borne out by current research on race and socioeconomic class (Williams & Mohammed, 2013). It is now widely acknowledged that to truly have an impact on the health of the population, there is a need to improve social conditions (Bharmal, Derose, Felician, & Weden, 2015; Braveman &

Gottlieb, 2014; CDC, 2016; County of Los Angeles Public Health, 2013; IOM, 2003). Political action and participatory action research are vital tools in reducing the effects of these conditions, as are methods of community empowerment (Commission on Determinants of Health Knowledge Networks, Lee, & Sadana, 2011; Sadana & Blas, 2013; see Chapters 4 and 13). See Figure 25–3 *Healthy People 2020* and Social Determinants of Health.

Figure 25–3 *Healthy People 2020* and Social Determinants of Health. (From U.S. Department of Health and Human Services. (2016). Social determinants of health. Retrieved from http://www.healthypeople.gov/2020/topics-objectives/topic/social-determinants-of-health)

Socioeconomic Gradient of Health

A series of large-scale, longitudinal studies in England, the now classic Whitehall studies, divided British civil servants into socioeconomic groups based upon their occupational status (e.g., executives to unskilled workers). What the investigators discovered was an improvement in mortality and morbidity rates as the level of occupation and pay increased. Those at the lowest levels had the poorest health, but as they moved up the salary scale and occupational level, their health improved. What makes this so interesting is that all of the workers had basic health insurance coverage and free medical care—no real problems with access to health care existed. Although less pronounced, even when the researchers adjusted for diet, exercise, and smoking, the gradient persisted (Marmot, Ryff, Bumpass, Shipley, & Marks, 1997; Marmot & Wilkinson, 2006). The investigators of one study found higher prevalence of heart disease for all participants at the lower end of the social stratus. The researchers also found death rates for diabetic participants to be about 200% higher in the lowest social group when compared to the highest (Chaturvedi, 1998). A U.S. study, following up on children of Framingham study subjects, found the association between lower socioeconomic position and coronary heart disease; a later study found higher odds of smoking, excess consumption of alcohol, and obesity that "may contribute to adult cardiometabolic disease" by the predisposition of these unhealthy behaviors (Loucks et al., 2009; Non et al., 2016, para. 5).

This inverse relationship between social class or income and health has been termed the socioeconomic gradient (Blazquez, Cottini, & Herrarte, 2014). It has been found in populations around the world, although not always unfailingly, and has been related to poor health outcomes regarding cardiovascular disease among the Greek population (Naska, Katsoulis, Trichopoulos, & Trichopoulou, 2011); cancer incidence, mortality, and survival in Western countries (Merletti, Galassi, & Spadea, 2011); injury rates, such as blunt and penetrating injuries (Zarzaur, Croce, Fabian, Fischer, & Magnotti, 2010); increased burden of chronic illness among Argentine citizens, especially those in urban areas (Fleischer, Roux, Alazraqui, Spinelli, & De Maio, 2011); and outcomes of adult asthma and rhinitis (Trupin et al., 2013).

The socioeconomic gradient has also been noted in behaviors, such as smoking, that are highest among those who are from the working class and who have low income and low educational levels (Hiscock et al., 2012; Yarnell et al., 2012). The gradient is also apparent in studies of hospital deaths. A large English study found a socioeconomic gradient with a 29.5% difference for in-hospital mortality (Wu, Jen, Bottle, Liaw, Ayulin, & Majeed, 2011). Other studies found higher rates of in-hospital mortality in U.S. pediatric patients and Iranian acute coronary syndrome patients (Abbasi et al., 2015; Colvin et al., 2013). Low birth weights and breast-feeding also demonstrate a socioeconomic gradient. Lower levels of education and income are associated with higher rates of low birth weight, whereas those at the higher levels of occupation and income are more likely to breast-feed their infants than are those at the lower levels (Madden, 2014; Yang, Platt, Dahhou, & Kramer,

2014).

Health Disparities

Health disparities are differences in the quantity of disease, burden of disease, and other adverse health conditions present in different groups (Braveman & Gottlieb, 2014). Health disparities may be unavoidable, such as health-damaging behaviors that are chosen by an individual despite health education and counseling efforts, but most are thought to be due to inequities that can be corrected (Sadana & Blas, 2013). A long-held belief about health inequities, adopted by the World Health Organization, is that health differences that are avoidable and unnecessary are patently unfair and unjust (Whitehead & Dahlgren, 2006). Health disparities can be objectively viewed as a disproportionate burden of morbidity, disability, and mortality found in a specific portion of the population in contrast to another.

The topic of social determinants of health was added to *Healthy People 2020* (Office of Disease Prevention and Health Promotion, 2015b). The *2014 National Healthcare Quality and Disparities Report* revealed that disparities persist, but several racial disparities in rates of childhood immunizations and adverse events associated with procedures have been eliminated (AHRQ, 2015). Reported disparities exist in the areas of quality of health care, access to care, levels and types of care, and care settings; they exist within subpopulations (e.g., elderly, women, children, rural residents, disabled) and across clinical conditions. Thus, to continue the work on eliminating health disparities, one goal for *Healthy People 2020* is to "achieve health equity, eliminate disparities, and improve the health of all groups" (USDHHS, 2016, para. 5).

Poor access to quality care and overt discrimination are examples of disparities. Discrimination can occur during service delivery if health care providers are biased against a specific group or hold stereotypical beliefs about that group. Providers may also not be confident about providing care for a racial or ethnic group with whom they are unfamiliar. Language may be a problem, as can cultural values and norms that are unfamiliar to providers. Patients can also react to providers in a way that promotes disparities; patients may not trust the information given to them and may not follow it as explained, leading to inadequate care (AHRQ, 2014b; Barkauskas, Pohl, Tanner, Onifade, & Pilon, 2011; Kaiser Family Foundation, 2012).

Access to Care

The IOM (2003) report *Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care* noted a large body of research highlighting the higher morbidity and mortality rates among all racial and ethnic minority groups when compared with Whites. This report drew attention to an issue that continues today and remains relevant. Differences in health care access were also explained, be it in the form of inadequate or no health insurance, problems getting health care, the quality of care, fewer choices in where to go for care, or the lack of a regular health care provider. For instance, because there are fewer numbers of health care providers in minority neighborhoods, finding a primary care provider is more difficult for those living in these areas. Often, sufficient transportation is not available, or clinic hours may be unrealistic for individuals working long hours (AHRQ, 2014b; Benatar, Garrett, Howell, & Palmer, 2012; IOM, 2003).

Residential segregation, although illegal, still exists and can play a role in health disparities. Many vulnerable populations, especially racial and ethnic minority groups and low-income populations, find health care at safety-net hospitals and community clinics where they are at the mercy of balanced budgets and vast bureaucratic systems (AHRQ, 2015; IOM, 2003). However, more recent data showed that the ACA is improving access for uninsured individuals to safety-net clinics in states with expanded Medicaid coverage (Angier et al., 2015). Other geographic factors can affect access to health care services. For example, a classic study by O'Mahony et al. (2008) found that only 25% of pharmacies in non-White neighborhoods, compared with 72% in predominately White neighborhoods, stocked sufficient opioid drugs to meet the needs of palliative care patients in different New York neighborhoods. Disparities were also found in hospice care among 8,211 older women dying from ovarian cancer; researchers found that a larger percentage of Black women, and those receiving fee-for-service Medicare, as well as those in the lowest income bracket, never received any type of hospice care (Fairfield et al., 2012). This lack of access to proper medication and care represents a disparity in health care.

Health care access is also problematic for other vulnerable groups. For example, services and resources for the mentally ill and substance abusers are often fragmented and inadequate, as are those for abusing families and homeless persons. Refugees and immigrants may have difficulty finding affordable and easily accessible health care, largely because of their lack of health insurance and the need to find care at free clinics or emergency rooms (Edberg, Cleary, & Vyas, 2011). When vulnerable individuals cannot get appropriate health care or treatment for illness or disease, for whatever reason, they are more likely to have health deficits.

Quality of Care

Quality of care should result in an "increased likelihood of desired health outcomes" and should be "consistent with current professional knowledge" (IOM, 2003, p. 31). Care quality can include areas such as patient safety issues, timeliness and effectiveness of patient care, and patient centeredness. Inequalities in the quality of care persistent (AHRQ, 2015). Research indicates that racial and ethnic minority clients feel more comfortable and satisfied with care from a health care provider who comes from the same racial and/or ethnic group (AHRQ, 2014b). However, a shortage of ethnically diverse health care providers exists. Despite racial and ethnic minorities constituting 37% of the U.S. population, only 19% of registered nurses (RNs) are from minority racial and ethnic groups (American Association of Colleges of Nursing, 2015).

Racial and ethnic minority clients often prefer health care providers from the same racial and ethnic background.

Lack of access to quality health care services is common among racial and ethnic minority groups. Significant disparities in the quality of care were found in a study of over 2.3 million racial and ethnic minority patients receiving care in 4,450 hospitals for myocardial infarction, heart failure, and/or pneumonia, thought to be due to receiving care in hospitals that were lower performing in quality care (Hasnain-Wynia et al., 2010). More recent research looked at 17 quality performance measures among patients with over 12 million hospitalizations for three conditions (i.e., myocardial infarction, pneumonia, heart

failure) over a 6-year period beginning after the Centers for Medicare and Medicaid Services instituted their Hospital Inpatient Quality Reporting System (Trivedi et al., 2014). Performance rates increased for all racial/ethnic groups, and the performance gap between White and Black patients over the course of the study dropped to 3.8% from 12.3% initially. For Hispanics, the performance improved to 1.1% from a high of 5.6%. Researchers also examined between hospital differences, a concern in the previous study, and found "greater improvement among hospitals that disproportionately serve minority patients" noting that when quality care is a focus, everyone benefits (Trivedi et al., 2014, p. 2306). A smaller 3-year study of more than 400 clinic patients with diabetes found improvements for hemoglobin A1c levels and no significant differences related to race or gender. Lee, Palacio, Alexandraki, Stewart, and Mooradian (2011) posited that having a medical home was the critical factor in decreasing health disparities for this population.

Communication can be a factor in poor quality of care. Marginalized vulnerable populations, such as substance abusers, at-risk mothers and infants, abusing families, suicide- and homicide-prone individuals, and the mentally ill or disabled, may feel they are treated as "second-class citizens," and cultural barriers and misunderstandings can lead to a discontinuation of recommended regimens. Poor health outcomes may result as effectiveness of health care for vulnerable populations is not often considered or even well defined (AHRQ, 2014b; Sadana & Blas, 2013).

WORKING WITH VULNERABLE POPULATIONS

The Role of Public Health Nurses

Community and PHNs often focus their efforts on the most vulnerable populations. In Lillian Wald's time, PHNs lived and worked among their clients, living in tenements or slums (see Chapter 2). Today, most PHNs travel a good distance to reach the homes of vulnerable clients, knowing that they can leave and go back to their own circumstances. Recognizing that demeaning or dehumanizing behaviors or language that may be directed toward clients or neighborhoods exemplifies disrespect and is often fear based can help us all to focus our efforts (see Fig. 25–2 Dimensions of Meaning). See Perspectives: One PHN's Opinion.

PERSPECTIVES ONE PHN'S OPINION

All of us, at some level, have some apprehension of the disenfranchised, whether it's because we worry that we could be in that place or because we feel that there may be some potential for harm to us. I love working with my clients and have adapted a more realistic perspective of the vulnerable and disenfranchised. I try to picture myself in their shoes. What would I do if I had all of those things working against me that they are forced to deal with on a daily basis? I have tried to reframe what some people see as their weaknesses and view them as strengths. For instance, the ability to "not sweat the small stuff" and ignore less important things that they can do little about could be a good quality for many of us hardworking mothers to embrace. I see working with vulnerable clients as an important component of students' clinical experiences, and as their preceptor, I encourage them to become engaged with my vulnerable families. I strongly feel that it is necessary so that they can better understand client circumstances and needs. It also helps them to be competent nurses, no matter where they work. My clients are admitted into the hospital and use the emergency department and outpatient clinics. They may need assistance and encouragement in following through with health care interventions, and I want students working with me to understand how to be most effective in providing quality outcomes for them. Helping vulnerable clients is part of our rich nursing heritage, exemplified by Lillian Wald and many others. We are part of a long chain of caring, safety-net nurses who work with some of the most vulnerable among us.

Jamie, PHN

What is the PHN's role with vulnerable populations, and how can nurses learn to be most effective when working with vulnerable groups?

Effective Caring

One nursing goal for clients is to help them develop their capabilities to make choices and be in charge of their lives. Achieving this goal can be challenging for nurses when working with the most vulnerable clients because they are often the most disenfranchised and fearful of others. PHNs often must tailor interventions to vulnerable clients' specific needs, and these clients often require periods of intense support (Monsen, Radosevich, Kerr, & Fulkerson, 2011). One nurse described vulnerable individuals as being behind a locked door: "the door is shut and you can't get back in" (Zerwekh, 2000, p. 50). Opening that door is the first step to working effectively with these clients. Engagement and development of rapport are essential. See Figure 25–4.

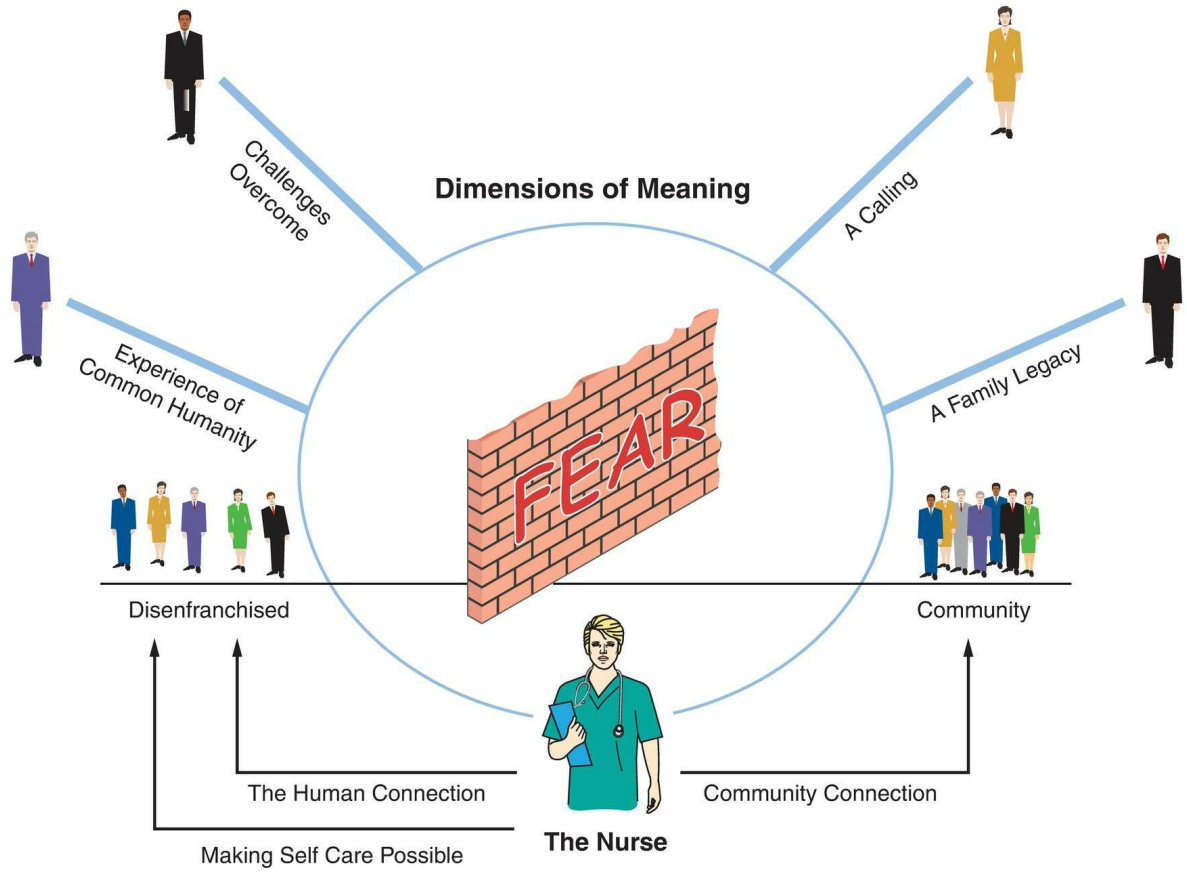


Figure 25–4 Breaking through the wall. Fearless caring with separated and often frightened clients has 10 themes that can be organized into three meta-themes: the human connection, the community connection, and making self-care possible. The nurse goes around the separating wall of fear. (Adapted from Zerwekh, J. (2000). Caring on the ragged edge: Nursing persons who are disenfranchised. Advances in Nursing Science, 22(4), 47–61.)

Because vulnerability often equates with feelings of powerlessness, the actions of PHNs can either promote engagement or destroy chances for rapport. Empowerment strategies can be used by PHNs in their work with clients, once trust and rapport have been established. An often-cited Canadian study found three phases of PHN–client engagement: getting past the fear, working to build trust, and seeking mutual ground (Jack, DiCenso, & Lohfeld, 2005). The personal values, experiences, characteristics, and actions of both nurses and clients influenced the speed at which this process took place and the eventual level of connection. Helping clients identify their fears and clearly defining the PHN role with the client and family were also important. Building and preserving relationships with clients is a central focus of PHN home visits. An Australian nurse, Margaret McAllister (2010), cites three important phases: joining, building, and extending. Joining involves getting to know your client—their strengths and weaknesses and their vulnerabilities and needs. It also includes building trust and rapport and helping them to feel accepted, engaged, and ready. The building phase involves working with individual clients to improve their social connections, build their strengths, and work toward their goals. Building self-efficacy, motivation, and health literacy are essential in this stage, as are helping them with coping

skills and giving encouragement as they build resilience. Extending strategies include helping clients to use new strategies and apply them in other situations. Phone calls and other methods of checking in with clients are used to help them change behaviors and access services. Negotiation and teamwork approaches are helpful in this stage. Keeping a focus on solutions rather than problems helps build client strengths. Six principles of solution-focused nursing, built upon mental health nursing concepts, are helpful (McAllister, 2010).

1. The person, not the problem, is your focus.
2. Strengths, not just problems, can be found and further developed. Begin with an emphasis on strengths, as this can build client hope and self-confidence.
3. Resilience is equally as important as vulnerability.
4. Move beyond an individual focus to examine unjust societal and cultural forces, and actively work toward to alter these.
5. Nurses are not only concerned with illness care but with helping clients adapt/grow.
6. A proactive, not reactive, approach is needed that involves the three stages of client involvement (i.e., joining, building, extending).

These solution-focused nursing principles of client empowerment are exemplified in a study directed by the American Academy of Nursing. In examining the commonalities of nurse-designed models of health care, the authors of this study found four common elements: health defined holistically; individual-, family-, and community-centric approaches to care that put the people and their concerns ahead of provider-defined priorities; relationship-based care that enabled individual/family/community engagement and partnerships that were time-consuming to develop, but crucial for building action and behavior change; and interventions incorporated ongoing group and public health approaches to improve health of vulnerable and underserved populations (Mason, Jones, Roy, Sullivan, & Wood, 2015).

Working with disadvantaged populations can be challenging and exhausting. Often, novice community health nurses feel overwhelmed and suffer "compassion fatigue" when confronted with the crushing realities that their vulnerable, disenfranchised clients face on a daily basis. Feelings of guilt sometimes surface when nurses contrast their own life experiences with those of their clients. To be effective in working with vulnerable populations, it is often more helpful to donate money and items on a group level rather than an individual level and to work for substantial changes in community attitudes and policies. Also, it is vital to remain grounded to continue to have the necessary energy and compassion. See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

Caring and Compassion

Dmytryshyn Jack, Ballantyne, Wahoushm, and MacMillan (2015), studying PHNs working with a Nurse–Family Partnership program, found that compassion fatigue could be problematic for nurses working with vulnerable young mothers in this long-term home visiting program (described in more detail in Chapter 4). PHNs generally found the nurse–client relationship rewarding, but needed to adapt their philosophy and definition of client success to see clients as the experts of their own individual lives. In this qualitative study, PHNs expressed personal costs of worrying about clients and doubting their own effectiveness in their ability to address concerns of clients. When they were able to shift the focus to the client, they reported greater satisfaction in the nurse–client relationship and in watching the successes of their clients over time.

Dmytryshyn, A., Jack, S. M., Ballantyne, M., Wahoushm O., & MacMillan, H. L. (2015). Long-term home visiting with vulnerable young mothers: An interpretive description of the impact on public health nurses. BMC Nursing, 14, 12.

Empowerment

In Chapter 13, the author discussed the concept of empowerment and applied it to the PHN's role when working with communities. In Falk-Raphael's classic article (2001), empowerment is defined as "an active, internal process of growth" that is reached by actualizing the full potential inherent within each client, and this occurs "within the context of a nurturing nurse-client relationship" (p. 4). PHNs described the process of empowerment as a two-way street, with clients not only gaining knowledge and skills and "acting on informed choices" but also further empowering the nurse to continue the work of empowerment (p. 6). Client empowerment is a vital role of PHNs and community health nurses working with specific populations (Ortega, 2016; Shin, Kim, & Choi, 2015).

Which community health nursing activities/actions are most effective in promoting empowerment among nurses' vulnerable clients? In Falk-Raphael's (2001) well-known qualitative study of PHNs and their clients, several themes were noted as components of the PHN role:

- *Having a client-centered approach*, denoted by flexibility in dealing with clients, for example, "meeting them where they are," "communicating at their level," and "backing off and following client's agenda" (p. 6)

- *Developing a trusting relationship* based on mutual respect and dignity, for example, clients as active partners with the PHN assuming more or less responsibility as needed; being empathetic, nonjudgmental, and "creating a safe environment" (p. 7)
- *Employing advocacy*, both at an individual level as well as political advocacy, for example, using their role and power as a professional to cut through bureaucratic red tape, connecting clients with available community resources, supporting clients in reaching their health goals, making their expertise available, and being a client resource as someone who is open and "available" (p. 8)
- *Being a teacher and role model*, using a variety of strategies and providing opportunities for clients to safely practice new skills. For example, using strategies such as teaching classes, providing individual coaching, providing positive reinforcement and support, demonstrating skills such as assertiveness, and encouraging community action/participation are helpful
- *Capacity building* through encouraging and supporting of clients' work toward attaining health goals, for example, "reflective listening and an empathetic approach" focusing on strengths, not limitations; facilitating client "self-exploration" and providing encouragement for them to "act on their choices" while being "realistic about barriers to success"; or having expectations for client accountability regarding their decisions and actions (p. 9)

Outcomes of empowerment for clients included increased self-esteem and confidence, improved self-efficacy, and the ability to "reframe situations in a positive way" (Falk-Raphael, 2001, p. 10). Clients also subsequently made better choices regarding their health and utilized resources more appropriately. They were better able to seek information and services and became more politically active. Clients' focus became more proactive than reactive, and they felt that they could communicate more effectively to define boundaries or express feelings. Consequently, clients were also better able to collaborate with their health care providers, becoming more trusting partners in care by demonstrating ownership for their actions and their health. Some clients noted a newfound ability to see their communities in a more holistic way and looked for ways to change things for the better. A large part of PHN practice is to work with the vulnerable and encourage them to become more self-reliant and responsible for their health (Cawley, 2012). Both the client and the PHN undergo a "transformation" when empowerment strategies are employed (Dowling, Cooney, & Casey, 2011, p. 476). Literature on client empowerment was searched and interviews conducted with key informants (e.g., health researchers, patients, patient care representatives, primary care clinicians) in research conducted to produce a conceptual map of patient empowerment (Bravo et al., 2015). Some indicators of patient empowerment included self-efficacy and a sense of personal control over their health as well as the care they receive, along with health literacy, and feeling respected. These led to a more active role in decision-making and management of care, eventually leading to better health outcomes.

Making a Difference

External support, along with temperament and other individual factors, has been associated with coping with stress and adverse situations. The support can be from family members, neighbors, friends, teachers, or others. PHNs can provide external support at both the individual and population levels (see Perspectives: Voices from the Community). For example, research has shown the effectiveness of social support provided by nurses in promoting consistent program participation and positive social and health outcomes among low-income pregnant women and their children, not only in America but around the world (Coalition for Evidence-Based Policy, 2015; Mejdoubi et al., 2013; Mejdoubi et al., 2015; Nurse-Family Partnership, 2011a, 2011b, 2011c, Olds et al., 2010; USDHHS, 2011; 2015). PHNs can assist vulnerable individuals in several ways.

PERSPECTIVES VOICES FROM THE COMMUNITY

A View of Katrina's Aftermath: Nurse Volunteer

I had never been a Red Cross volunteer before, but Katrina touched my heart, and I signed up. Suddenly, I was headed to New Orleans to help in a shelter. The sheer number of people streaming into the shelter astounded me—people who had lost everything. Some of these people had waited on housetops to be rescued. Others had walked for hours to reach the shelter. A common theme among them was their vulnerability. Many were members of vulnerable populations even before Katrina struck.

At first, most were relieved to be safe and dry. However, that changed as they realized what they had lost and how uncertain their futures were. Many of the older people and those with chronic illnesses had significant health problems that worsened while they were residents of the shelter. Although they were provided with food, it was sometimes difficult

for them to get the exact food they needed for their special diets. Some of them did not have all of their medications, and it took some time to complete health histories and secure necessary prescriptions. The weather was very muggy and hot, and there was little privacy. Even though the governor had called out the National Guard, people had to protect their few belongings, as theft was rampant. Toilet and bathing facilities were inadequate, space was limited, and fights often broke out between people who had been pushed to the limits of their composure. People had to show identification to apply for emergency loans or to receive other assistance. Some of them had lost all documents in the flooding or had lost things on the way to the shelter. Standing in line was physically difficult for many people, but lines were long and standing was necessary in order to get assistance.

Many people were displaced, and a good number of them were separated from their families and friends, with no idea whether they were dead or alive. It was difficult to reconnect people, as individuals were evacuated to diverse locations. Communication was often a problem until phone lines and cell towers were back up and running.

I was there to help and to listen and provide care, but sometimes I felt frustrated and ineffective. I wanted to advocate for people and improve on systems of care, but this was almost impossible in such an erratic and crisis-driven system. Better systems need to be in place before the next disaster strikes, especially for the most vulnerable. All in all, it was a rewarding experience, and I was able to make a difference for some people on an individual basis. But there were so many who needed significant and long-term assistance!

Helena, RN, PHN, Red Cross Volunteer

Adapted from Saunders, J. M. (2007). Vulnerable populations in an American Red Cross shelter after hurricane Katrina. Perspectives in Psychiatric Care, 43(1), 30–37.

Through work with individual clients, PHNs can expand their own empowerment strategies to serve the community. Being aware of the community's pulse is vital and can be accomplished not only through home visits but also by attending community-level meetings and through the development of partnerships organized around specific health issues or community problems. Early detection of problems at the community level can lead to the development of programs and services to provide early intervention and avert costly tertiary care or to actively meet the needs of specific groups, such as low-income elderly and new parents (Breitenstein et al., 2012; Cawley, 2012; Marek, Stetzer, Adams, Popejoy, & Rantz, 2012; Rantz et al., 2011).

Using Evidence to Reduce Vulnerability

Community health nurses can assist vulnerable populations, communities, individuals, and families to reduce their vulnerability by using evidence from research, expert opinion, and best practices (see Chapter 4 on Evidence-Based Practice). Often, evidence is embedded in policies, procedures, and clinical guidelines. Thus, the first place to locate evidence for practice is in the specific agency documentation for nursing practice. Sometimes, a

community need is discovered that requires creative thinking and evidence-based interventions. See Population Focus—Reaching Out to the Underserved Poor in Rural Communities.

POPULATION-FOCUS REACHING OUT TO THE UNDERSERVED POOR IN RURAL COMMUNITIES

Community Preventive Health Collaborative (CPHC) is a program developed by nursing faculty from a university in California's southern central valley. The program was designed to address the serious burden of chronic diseases including obesity, diabetes, heart disease, and hypertension in the large, agricultural county by expanding the reach of the health care workforce through the participation of nursing students and utilizing evidence-based practice interventions. Students enroll in an elective CPHC service-learning course in order to provide health education and health screening tests for blood pressure, blood sugar, total cholesterol, and body mass index.

Rural community residents face many struggles including poverty and lack of access to health care. Long and laborious work schedules, cultural values and priorities, and limited finances may influence when and how often health services are sought out. Chronic diseases may go on for a long period of time without detection. Therefore, services that can reach at-risk populations at no cost to the client are greatly needed in rural communities.

When CPHC began providing services in the rural areas of the county, the population of interest was agricultural workers. An agricultural company in our region partnered with us to provide the services. Clinics were held in a variety of locations including outdoors at an operations plant, indoors in an employee break room, and at a community health center. The process began with a health history interview that examined social factors such as diet and exercise, smoking and other substance use, and clients' health insurance status. Student nurses were able to provide health education and brochures to clients in an effort to encourage healthy lifestyle modification. Then screening tests were performed, and if elevations were found, the client was educated about his or her risks and a referral was given. The client was encouraged to seek follow-up care from a primary care provider. If the client did not already have a primary care provider, students provided information

about the employer's clinic and a list of community clinics in the area. Some clients consented for follow-up contact from student nurses and received phone calls one month after their health screening to provide additional information and resources and to determine if a primary care visit had been made.

Since 2011, CPHC has provided health screenings to over 4,000 individuals. The program continues to benefit the community by reaching out to medically underserved regions and provides health promotion and preventive health services to community members that most likely would not have received these services if it weren't for student nurses. CPHC provides services at community locations such as senior centers, community centers, and health fairs and at swap meets in our region. Most recently, CPHC has implemented referrals to PHN home visiting services. Student nurses who are currently in their community health nursing rotation now accept the referrals and visit clients in their homes to provide continuity of service. They offer in-depth health teaching related to their diagnosed health conditions and work with clients to link them with community resources (e.g., available nutrition or exercise classes).

Not only do community members benefit from the services provided by student nurses, it also greatly enhances the student nurses' experience as they reach out to medically underserved communities with health promotion and preventive health strategies. Students shared what the experiences meant to them; here are a few examples:

- *CPHC program was beneficial to my perspective as a health professional. I am now able to appreciate the role of the PHN through community outreach, health promotion, advocacy, and empowering individuals through awareness.*
- *CPHC has really enabled me to interact with the public, especially the underserved community. I have gained knowledge on barriers to healthcare that populations encounter.*
- *CPHC has helped me to have an open mind regarding barriers that prevent clients from achieving optimal health outcomes.*

Nurses in the community setting are able to conduct a community assessment and develop strategies and evidence-based interventions that address problems in order to improve health outcomes at the community level. CPHC is an example of nurses and nursing students joining with the community to offer evidence-based care to those who are most vulnerable to poorer health outcomes.

Judy H. Pedro, MSN, RN, APHN-BC
Community Health Nursing Faculty

Many areas for improvement of the lives of vulnerable populations lie in areas related to prevention and health promotion, as described above. Primary prevention is readily

available in the form of immunizations for children, adolescents, and adults. Nursing activities to promote increasing immunization levels among vulnerable people will result in greater economic and social returns for the whole community. Similar is the involvement of nurses in smoking prevention and smoking cessation activities. Also, some vulnerable subpopulations require additional insight and experience. See Perspectives: Picking up on Clues.

PERSPECTIVES PICKING UP ON CLUES

I have been a PHN for many years and been fortunate enough to work with various populations. I remember a case when I learned that although experience is a valuable asset, sometimes this contributes to assessment miscues. I had an established relationship with a socioeconomically disadvantaged postpartum client, who was experiencing anxiety, feelings of being overwhelmed, and insomnia. The interventions that I had successfully used for so many other moms in similar situations with postpartum depression had failed with this client. It was not until I inquired about a picture of my client, Nancy, in her military uniform that she shared with me that she had served for a few years in the Middle East. She further stated that she did not like to discuss her past, she regretted not being physically able to continue her military career, and she just wanted to "get some sleep." Long story short, we were able to get Nancy into a Veteran's Administration (VA) residential treatment program for substance abuse and medical treatment for traumatic brain injury (TBI). I learned through this encounter that experience coupled with a patient-centered assessment, minus my internal preconceptions, results in the best outcomes for patients. Nancy had more than the usual stressors affecting her, and I was glad that I was finally able to pick up on those clues and address her needs more completely.

Tessa, PHN

In addition to immunizations, smoking cessation, and other preventive interventions, the following topics are highlighted as evidence-based concepts shown to improve the health status of vulnerable populations: health literacy, access to nursing services, and policy.

Improving Health Literacy

People living in low-income communities often have low educational levels that are related to low literacy and low health literacy levels. An estimated 80 million Americans have limited health literacy. Because clients have difficulty obtaining, processing, and understanding health information, it is not surprising that low health literacy is associated with poorer health outcomes and poorer use of health care services (Berkman, Sheridan, Donahue, Halpern, & Crotty, 2011; IOM, 2014). Limited skills in health literacy can negatively impact client health behaviors, as well as decisions related to health, and health outcomes (Ferguson & Pawlack, 2011). A systematic review found that low health literacy was associated with more emergency care use, higher hospitalization rates, fewer instances of influenza vaccine and mammography, poorer ability to read labels and interpret health messages, and greater inability to demonstrate appropriate medication administration, as well as higher mortality and poorer overall health status among senior citizens (AHRQ, 2014a). In addition, low literacy or illiteracy is a contributing factor to unemployment and underemployment within vulnerable groups, thus increasing risk for low income and poverty. The implications of health literacy for public health are as important as those for acute care settings (IOM, 2014). See Chapter 10 for more on health literacy.

Assisting vulnerable groups and communities to improve health literacy is one approach for reducing vulnerability and improving health outcomes. Many cities have literacy programs that use volunteers to provide tutoring. This is an excellent way for nurses to give back to the community. Literacy training contributes to health literacy by improving reading, writing, and comprehension skills. A crucial aspect of improving health literacy is improvements in public schools so that more students graduate with adequate skills for higher education and employment. In addition, it is estimated that tens of millions of U.S. adults are unable to read complex texts, which includes many health-related materials (Roundtable on Health Literacy et al., 2015).

Some research shows that low-literacy clients may learn better with the use of multiple methods for teaching, such as pictures, small group classes, and audiovisual materials (Horowitz, Clovis, Wang, & Kleinman, 2013; Wolf et al., 2009). Written material should be carefully reviewed for reading level before it is given to clients. Many tools, such as Fry Readability Graph and Gunning-FOG formula, are available for testing reading levels of written material (Medline Plus, 2015). The CDC has developed the Clear Communication Index that provides a set of evidence-based criteria for developing and assessing public communication material for diverse populations (Baur & Prue, 2014). See Chapter 11.

A special challenge for nurses is preparing or locating material for clients who do not speak English. Health care agency resources need to be devoted to meeting the needs of clients who have no or few skills in English. This area of need is usually beyond the ability of the individual nurse, but the need can be made known to agency administration. A number of health literacy resources are available from the American Medical Association

(Coleman, 2011).

Improving Access to Nursing Services

Results from over three decades of research have demonstrated that home visiting by RNs is effective in improving outcomes for low-income women and children. David Olds and his research team, including Harriet Kitzman, an RN, have conducted much of the work done to demonstrate these dramatic results. Studies show that home visiting to low-income women and their children results in fewer cases of child abuse and neglect, longer spacing between pregnancies, avoidance of substance abuse and criminal behavior, and less dependence on government assistance. For the children of low-income, unmarried women, the children had fewer arrests and convictions, smoked and drank alcohol less, and had fewer sexual partners than did the children who did not have nurse home visits (Olds et al., 1997). More recently, the Olds team found that families who were visited in their homes by PHNs demonstrated lasting positive effects (Eckenrode et al., 2010; Olds et al., 2010) and a promising means of reducing mortality among mothers and children (Olds et al., 2014), as well as reducing intimate partner violence (Mejdoubi et al., 2013).

Other research demonstrating the benefits of PHN interventions and nurse home visiting includes studies on managing clients with HIV (Haley et al., 2014), new mothers released from the hospital (Paul et al., 2011), and transitional care programs for the elderly (Ornstein, Smith, Foer, Lopez-Cantor, & Soriano, 2011). See Chapter 4 for more on this line of research.

Home visiting has been shown to have positive outcomes for a variety of vulnerable

populations.

Home visiting can be provided from almost any setting that provides services to communities. The usual settings are local health departments, home health care agencies, community-based hospice agencies, and visiting nurse associations. In addition, school nurses, ambulatory nurses, parish or faith-based nurses, and nurses have recently provided limited home visiting services to clients or families seen in a variety of settings, including outpatient clinics, Head Start programs, places of worship, and health centers. Expanding home visiting to all vulnerable groups holds promise for improving the health of many individuals and communities.

School-based clinics have improved access and outcomes for preventive care like immunizations, chronic disease management (e.g., diabetes, asthma, obesity), and adolescent reproductive health services and have been associated with improved academic achievement (Keeton, Soleimanpour, & Brindis, 2012). These clinics are included in health care reform funding, largely because of their proven track record for accessibility and quality. Nurse-managed clinics have also increased access to care for communities, and they may be able to access funding through the ACA (Hansen-Turton, 2012; Holt, Zabler, & Baisch, 2014). See Chapters 30 and 31. Improving access to nursing care in the community has been shown to have benefits for population and individual health.

Improving Health and Public Policy

Policies to reduce vulnerability for individuals, families, and communities have been shown to be effective at all levels: local, state, and national. Policy based on evidence is an important component of reducing vulnerability for communities and individuals. This section of the chapter addresses health and public policy, including policy in schools, cities, counties, and health care settings. Policy includes social, economic, environmental, and health aspects. See Chapter 13 for an expansive discussion of policy.

Small changes in policy can make a big difference in outcomes for vulnerable communities. For example, policies to provide healthy foods in school vending machines provide healthier choices for all students, not just those considered vulnerable. Mandatory activity time for all school children contributes to preventing obesity and enhancing learning in all children as well as those who are most vulnerable because of low income and ethnicity (Beets, Tilley, Kim, & Webster, 2011; Cradock et al., 2011).

Communities that lack safe places for physical activities need to have attention directed to the appropriate governing bodies, such as the city council or the department of recreation. Community residents can be effective in bringing about change that improves a total community (Gortmaker et al., 2011). One model that addresses both individual and social determinants of health in a straightforward manner is the County Health Rankings Model (see Fig. 25–5).

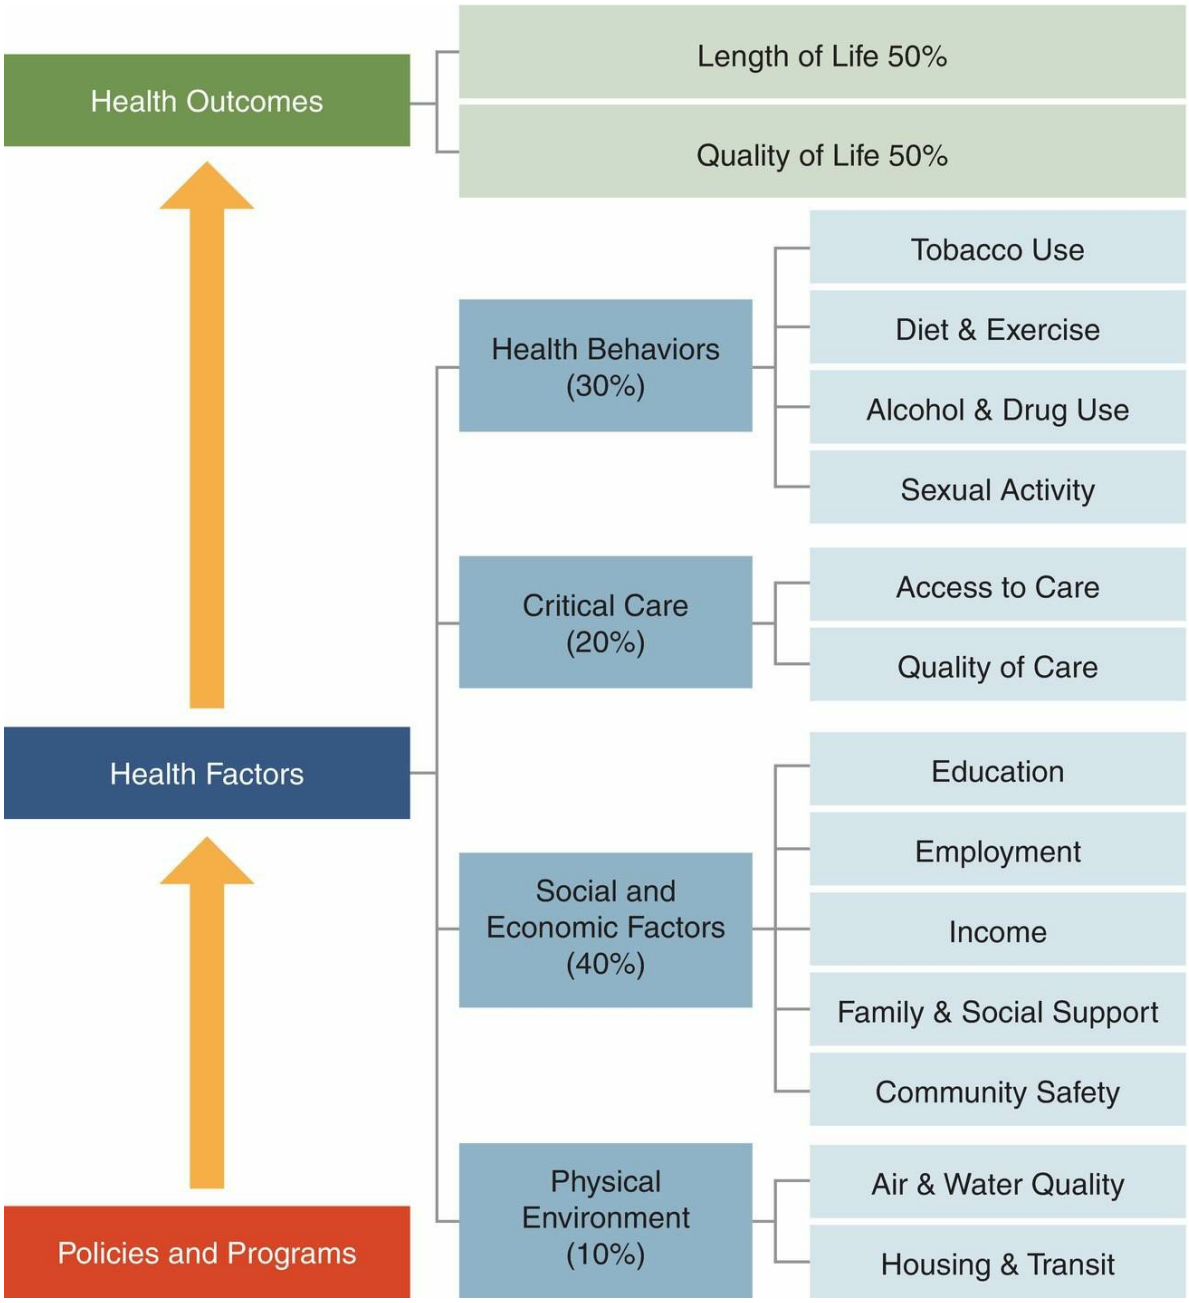

Figure 25–5 County Health Rankings Model. (From County of Los Angeles Public Health. (2013). Social determinants of health: How social and economic factors affect health. Retrieved from http://publichealth.lacounty.gov/epi/docs/SocialD_Final_Web.pdf, used with permission.)

SUMMARY

Vulnerable populations are at risk for poor health outcomes. Various models or theoretical frameworks examine personal and environmental resources and risks relative to vulnerability. Vulnerability is associated with increased risk for morbidity and mortality. Poverty, age, gender, and race or ethnicity are leading factors that make aggregates vulnerable, as can being uninsured or underinsured, a single parent, and those with little or no education. Vulnerable groups can include chronically ill or disabled, high-risk mothers and infants, those with HIV/AIDS, and the mentally ill or disabled. Alcohol and substance abusers, those prone to suicide and homicide, the homeless, abusing families, and immigrants or refugees can also be characterized as vulnerable.

It is difficult to calculate the exact numbers of Americans who are members of vulnerable groups largely because of the overlap in populations, but it involves a significant proportion of the total population. As an example of overlap in populations, low-income status is often associated with underinsurance or race and ethnicity and may also be related to homelessness and high-risk births.

Social determinants of health are strongly associated with health outcomes. Examples of social determinants of health are social norms or attitudes, such as discrimination and racism; exposure to crime, violence, and social disorder; and concentrated poverty. The socioeconomic gradient, an inverse relationship between social class/income and health, has been repeatedly demonstrated in research conducted around the world.

Health disparities are defined as differences in access to quality health care and in health outcomes and are usually characterized as avoidable and unfair. One of the goals of *Healthy People 2020* is to achieve health equity, eliminate disparities, and improve the health of all groups. Many disparities occur along income/class or racial/ethnic lines. A good deal of research is under way to determine more specifically the causes and consequences of health disparities.

Community health nurses often work with vulnerable populations, and nurses must learn to break through barriers of fear—their own and that of their clients. To be effective, PHNs must establish a sense of trust and rapport with their clients by finding common ground. Connecting with clients and connecting clients to the community and available resources are key factors in successful PHN–client relationships. Coaching and mentoring clients to solve their own problems and make necessary changes are also effective behaviors of PHNs.

Empowerment strategies with individual clients can help them to meet their full potential while also providing empowerment to the nurses working with them. Flexible, client-centered approaches, based on trust and mutual respect, have been found to be most effective. A nonjudgmental attitude and openness with clients lay the foundation for development of effective relationships. Community health nurses who work at empowering

clients are advocates at the individual level as well as the political level. The nurse is a resource to clients without being paternalistic. Nurses provide a safe place for clients to try out skills and demonstrate new, healthier behaviors. PHNs build capacity through active, reflective, empathetic listening and serve as role models and teachers. Empowered clients have greater self-confidence and are better able to collaborate with health care providers. Often, empowered clients become more engaged with their communities and neighborhoods.

Community health nurses can provide individual support as well as support and leadership for vulnerable communities. Political action can involve not only health policy issues but also political activism on the part of underserved populations to improve housing, education, and employment. Action at the community or population level is an effective and efficient way to have the "biggest bang for the buck" when improving the health of vulnerable populations.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify at least four vulnerable groups within your community. Using the Flaskerud and Winslow (1998) model depicted in this chapter, determine the health status for each of these groups. Describe the relative risk for each group.
    a. Find available community resources for each of the identified groups. Where are the resources located? How easily accessible are they? What outreach services do they provide for the vulnerable population they serve? Describe some socioeconomic resources. What areas are most deficient?
2. Pick a client from your community health nursing clinical assignment. In a respectful way, discuss your apprehensions about working in the community (e.g., very different from hospital setting) and ask about any concerns your client may have experienced in permitting you access to her or his home. Outline ways in which you could build upon this mutual sharing to achieve mutual trust and rapport.
3. Discuss how you might apply the principles of solution-focused nursing with either one of your community health nursing clinical clients/families or with someone with whom you have a relationship (acquaintance or family member who may fall within the definition of vulnerable). How might you discern a difference in their responses to your conversations and interactions with them? What behaviors would you expect to change?
4. Talk to two expert PHNs and discuss the concept of empowerment with them. What strategies have they used with clients? Ask each to share an example in which they feel that they made a real difference in the lives of their clients. Note any similarities with the roles and behaviors of PHNs and client empowerment described in this chapter.
5. Check with the health department about any interagency groups or committees that may be addressing the needs of vulnerable populations in your community. What issues are most important to this group? Who are the members? Note the agencies represented. Are there any community members present? If possible, attend a meeting or access minutes of a recent meeting and determine the types of issues being discussed. Is there a sense of community involvement and participation?
6. With a group of students, each of you search for a current evidence-based article on vulnerable populations based on ideas from this chapter. Discuss the main points of each article and how they may relate to vulnerable populations (e.g., health disparities, socioeconomic gradient), as well as individual clients you may be seeing in your clinical rotations (e.g., empowerment, health literacy). Based upon the research findings, what interventions might be most helpful? Are they feasible in your area? With your specific populations?

26 CHAPTER

Clients with Disabilities and Chronic Illnesses

"I choose not to place 'DIS,' in my ability."

—*Robert M. Hensel* (1969–, Disability Advocate)

KEY TERMS

Activity
Activity limitations
American Sign Language
Americans with Disabilities Act
Assistive devices and technology
Body functions
Body structures
Braille
Built environment
Chronic disease
Disability
Environmental factors
Functioning
Handicaps
Impairments
Participation
Participation restrictions
People with disabilities
Personal factors
Secondary conditions
Universal design

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Discuss the national and global implications of disability and chronic illness.
- Describe the economic, social, and political factors affecting the well-being of individuals with disabilities and chronic illness.
- Provide an example of primary, secondary, and tertiary prevention practices for disabled individuals.
- Describe the Americans with Disabilities Act.
- Discuss the benefits of universal design for all persons.

At some point in our lives, many or even most of us will be diagnosed with a chronic illness or develop some type of disability. We may be fortunate enough to be diagnosed early and treated promptly for our health conditions and receive sufficient and effective disease and symptom management. But on the other hand, we might become temporarily incapacitated, become unable to manage our daily lives, and require assistance from others. In these situations, we will hope that a swift recovery will assist us to resume our normal activities. Currently, over 53 million persons report living with some sort of disability in the United States (Courtney-Long et al., 2015). This represents approximately 22% of the population and includes 13% of people reporting mobility issues, 10.6% of people reporting cognitive disabilities, 6.5% of people reporting disabilities that inhibit independent living, 4.6% of people reporting vision deficits, and 3.6% of people reporting self-care deficit disabilities. In 2015, one of every five adults in the United States had been doctor-diagnosed with arthritis, mostly commonly osteoarthritis. With population growth and an aging population, by 2030, the number of adults with arthritis is expected to increase to 67 million (Centers for Disease Control and Prevention [CDC], 2016).

In addition to the human burden of disability and chronic illness, the related financial costs of direct medical care and associated indirect costs had significant impact on public and private payers of health and social insurance. A 2011 report (Anderson, Wiener, Finkelstein, & Armour, 2011) found that national disability-associated health care expenditures were $397.9 billion in 2006, or 26.7% of all U.S. national spending for health. Individuals with disabilities have higher health care costs because they have more chronic conditions, and secondly, they have poorer health status that requires more health care services. It is difficult to separate the costs of disability from the costs of chronic conditions, because it is often challenging to identify which occurred first (Smith, Molton, & Jensen, 2016). But it is clear that reducing both types of costs will be facilitated by improved health promotion and preventive services, as well as by expanding coordinated care and targeted disease management programs (Kyounghae et al., 2016).

Healthy People 2020 document details the continued impact of chronic and disabling diseases and conditions on Americans. For example, arthritis remains the leading cause of disability in the United States, with a direct impact on approximately 43 million individuals, including more than 20% of the adult population (Office of Disease Prevention and Health Promotion [ODPHP], 2016). Asthma is a national health concern for all ages, especially for those under 18 years of age, and represents one of the four most common causes of chronic illness in children. Of particular concern are health disparities in asthma morbidity and mortality, particularly for low-income and minority populations (ODPHP, 2016). The prevalence of chronic kidney disease (CKD) and end-stage kidney disease (ESKD) continues to increase; diabetes is the most common cause of kidney failure. Treatment of CKD and ESKD is expensive, with nearly 25% of the Medicare budget needed to treat Americans with these two diseases (ODPHP, 2016). Back pain impacts

80% of all Americans at some time in their lives; at any point in time, three to four percent of the population is temporarily disabled because of back pain. Chronic back pain has diverse risk factors, including age, fitness level, race, ethnicity, and occupation. Among those 50 years and older, 16.5% are estimated to have osteoporosis and have risk factors for additional serious injury or death following a potential fall (ODPHP, 2016). Addressing the complex and interrelated issues of disability and chronic illness is vital to the well-being of affected individuals and families and ultimately crucial to the financial health of the nation and its health care delivery systems.

This chapter discusses important and necessary health promotion and preventive efforts at every level. Although the treatment of chronic conditions has long been a mainstay of health care in the United States and globally, much less attention has been paid to health promotion approaches required to prevent, maintain, and improve overall well-being of individuals with chronic conditions and those at risk for these conditions. In addition, too little attention has been directed toward health promotion approaches for those with physical or psychological disabilities.

This chapter begins with an overview of disabilities and chronic illnesses, followed by a discussion of current national and global trends in addressing these issues. The various organizations that focus on improving the well-being of those affected by chronic and disabling conditions, the impact on their families, and the role of the community/public health nurse in addressing the related needs of individuals, families, and aggregates are discussed. The benefits of universal design and issues of easy access for all ages and abilities are introduced.

PERSPECTIVES ON DISABILITY, CHRONIC ILLNESS, AND HEALTH

Do you know someone living with a disability? Have you cared for a patient living with a disability? What have you learned about their lives? What does the word *disability* mean to you? Do you have thoughts or images that come to mind when you think about disability as it applies to an individual person? Disabilities may be congenital, developed early in life, or developed later in life. This can be a chronic condition or acquired through things like trauma (Krahn, Walker, & Correa-de-Araujo, 2015). Although in the past, people living with disabilities may have been invisible to most because they were often "shut-in" their family's home or institutionalized in a long-term state facility, today, those who face added physical challenges in their daily lives now emphasize their abilities, over what was viewed in the past as their incapacities, inabilities, or handicaps, and studies show that those with disabilities are able to engage in positive health behaviors when motivation is internal (Wilroy, Knowlden, & Birch, 2016).

The negative connotations embedded in public perceptions about disability evoke the prevalent societal views and stereotypes faced daily by people with disabilities. The negative views and blaming remarks that can be directed toward persons living with disabilities have been challenged by those living with disabilities, as well as their families, their allies, and their advocates. New and more positive approaches continue to emerge that view individuals and their needs from a more person-centered, holistic standpoint. The diverse personal narratives of those living with disabilities emphasize the individual circumstances and unique responses to disability, and social support and potential inclusive care for the individual have a positive impact on engaging those with disabilities in settings such as work (Cook, Foley, & Semeah, 2016).

The separate, but related, concept of chronic disease or chronic illness is any disease process that is prolonged, does not resolve spontaneously, and is rarely cured completely (Goodman, Posner, Huang, Parekh, & Koh, 2013). Chronic illness and disability-related needs differ from one individual to another and may differ from day to day or over time for one individual. An individual's needs may require different degrees or modes of accommodation. Chronic diseases may require regular self-care to avoid exacerbations and increased risks of complications, which could pose a significant burden in terms of mortality, morbidity, and personal and societal cost.

Because chronic diseases may be and are increasingly preventable, individuals living with a disability must be included in clinical and population health strategies to prevent acquisition of additional chronic diseases or threats to their health (Mahmoudi & Meade, 2015; Reichard, Gulley, Rasch, & Chan, 2015). In the landmark U.S. Surgeon General's *Call to Action to Improve the Health and Wellness of Persons with Disabilities* placed the health of persons living with disabilities equal in importance to the health of the nation,

and today, disability remains a priority for the nation reflected in *Healthy People 2020* (ODPHP, 2016).

International Classification of Functioning, Disability, and Health

The *International Classification of Functioning, Disability, and Health* (ICF) supports the more positive, emerging approaches to understanding chronic and disabling conditions (World Health Organization [WHO], 2001). Although dated, this is the relevant guide to classification of disability worldwide. The ICF replaced the outdated *International Classification of Impairments, Disabilities, and Handicaps (ICIDH)*. The significant shift in the classification's title and framework concretely reflects the profound shifts in professional thought that led to removal of concepts such as *impairments* and *handicaps*. In what remains the current version of the ICF, "disability" serves as a broad term for impairments, activity limitations, and participation restrictions. Disability is linked to "functioning," a term that encompasses all body functions, activities, and participation (WHO, 2001).

The ICF (WHO, 2001) is a universal classification system using standardized language that views the domains of health from a holistic viewpoint. It takes into account body functions and structures, activities and participation, environmental factors, and personal factors. This multidimensional approach supports a complex evaluation of an individual's circumstances in terms of functioning, disability, and health. Through combining the "medical model" of health and health care for disabled persons with the "social model," the ICF provides a biopsychosocial approach for assessing people with disabilities. Its approach emphasizes that no two people with the same disease or disability have the same level of functioning: diseases and disabilities are conditions, not persons. Yet, a client may be referred to inappropriately as "the paraplegic" or "the amputee," rather than by the given name. This type of disrespectful designation or stereotype should be avoided: a disease or disability is something one has, not something one is. The individual context and status of each person must be identified as a first step.

The key aims of the ICF are the following:

- Provide a scientific basis for understanding and studying health and health-related states, outcomes, and determinations
- Establish a common language for describing health and health-related states to improve communication between different users such as health care workers, researchers, policy makers, and the public, including people with disabilities
- Permit comparison of data across countries, health care disciplines, services, and time
- Provide a systematic coding scheme for health information systems (WHO, 2001, p. 5)

Contributing to these emerging perspectives, the following concepts and related definitions further clarify the ICF view of health:

- Body functions are the physiologic functions of body systems and include

psychological functions.

- *Body structures* are anatomic parts of the body such as organs, limbs, and their components.
- *Impairments* are problems in body function or structure, such as a significant deviation or loss.
- Activity is the execution of a task or action by an individual.
- Participation is involvement in a life situation.
- Activity limitations are difficulties an individual may have in executing activities.
- Participation restrictions are problems an individual may experience when involved in life situations.
- Environmental factors make up the physical, social, and attitudinal environments in which people live and conduct their lives (WHO, 2002a, p. 10).
  Personal factors are the features of an individual's background, life, and living that are not part of a health condition or health status, such as gender, race, age, other health conditions, fitness, lifestyle habits, upbringing, coping styles, social background, education, profession, past and current experience, overall behavior pattern and character style, individual psychological assets, and other characteristics —which may play a role in disability at any level.

For public health nursing practice, application of the ICF reinforces that disability and disease are additional factors to be considered in planning and implementing a care plan for individual clients and for population groups in the community. For individual clients, the ICF guides and facilitates assessment across a wide range of variables. Although two individuals may have the same apparent disability, such as a below-the-knee amputation, their health status and personal well-being can be quite different. One may have a more positive outlook, one may have more social supports than the other, or one may suffer more than the other from additional health issues that complicate rehabilitation. The public health nurse must always consider the totality of the situation, including the biologic, psychological, sociocultural, and environmental realms of the whole person.

Figure 26–1 depicts the interactions among the various components of the ICF, in relation to evaluation and assessment of clients with disabilities. It can also serve as a useful model for public health nursing practice in the overall assessment of people with disabilities.

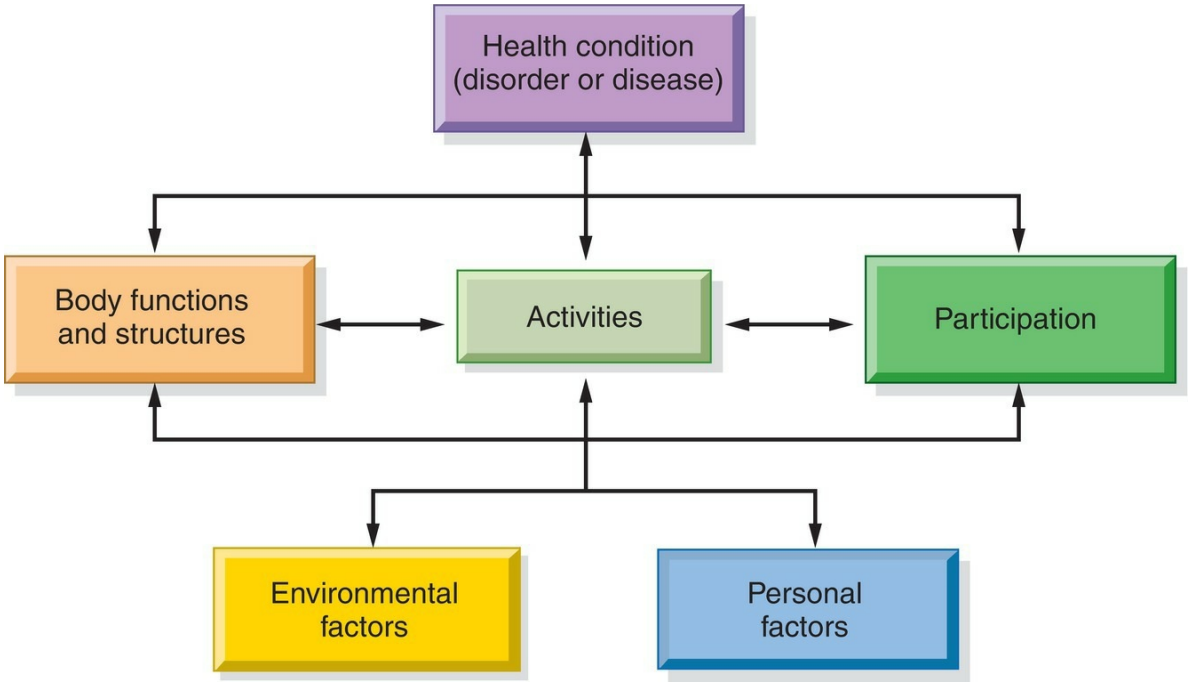

FIGURE 26–1 Model of functioning and disability. (From the World Health Organization (WHO). (2001). ICF introduction. Geneva, Switzerland: Author.)

The World Health Reports

The World Health Report (WHR) 2002: Reducing Risks, Promoting Healthy Life (WHO, 2002b) document heightened the standard for addressing global health. The World Health Organization challenged the global community to increase the focus on unhealthy behaviors that can ultimately lead to chronic disease, disability, and early mortality. Although infectious diseases and malnutrition require continuing surveillance because of their ongoing impact on populations in many parts of the world, WHO has stressed that these are not the only threat. Lifestyle choices are also one of the key contributors to morbidity and mortality levels in both affluent and poor countries. In heightening the focus on unhealthy lifestyle choices, the 2002 report underscored a twofold purpose: to quantify the most important risks to health and to assess the cost-effectiveness of interventions designed to reduce those risks. The World Health Organization's overall goal was to help all governments lower health risks and increase healthy life expectancy within their country (WHO, 2002b). A high priority was to target interventions at local, national, regional, and international levels.

The *WHR 2002* (WHO, 2002b) emphasized that health care providers worldwide should broaden their clinical and population health practices, rather than continue a narrow focus on acute illness. Changes in lifestyles and behaviors that have key impacts on increasing healthy years of life should be emphasized. Some of the health risks detailed in 2002, as well as in the 2009 WHO report, highlight factors that are the direct result of economic poverty. Other factors result from excesses, especially among some populations in more affluent countries. The ten leading health risks identified by the WHO are (1) underweight; (2) unsafe sex; (3) high blood pressure; (4) tobacco consumption; (5) alcohol consumption; (6) unsafe water, sanitation, and hygiene; (7) iron deficiency; (8) indoor smoke from solid fuels; (9) high cholesterol; and (10) obesity (WHO, 2002b, 2009). Across the globe, these ten health risks contribute to more than one third of all deaths and a significant proportion of disability. Half of these risk factors—tobacco and alcohol consumption, high blood pressure, high cholesterol, and obesity—are directly related to lifestyle and behavioral choices (WHO, 2009). The 2011 report noted the importance of service delivery, technology and continued research, along with use of evidence-based practice in designing and evaluating services (WHO and The World Bank, 2011).

Given the vital link between nutrition and health, nutritional imbalances can contribute to severe chronic illness, disability, and premature death. Of the leading 10 health risks (above), five are directly related to consumption: underweight, hypertension, iron deficiency, high cholesterol, and obesity (WHO, 2009). The worldwide prevalence of adult overweight is estimated at 1.9 billion, including 600 million adults classified as obese. Being overweight increases the risk of coronary heart disease, stroke, diabetes, musculoskeletal disorders, and some types of cancer (WHO, 2016).

In stark contrast to global patterns of overweight and obesity, an estimated 103 million

children under 5 years of age (18%) were underweight in 2013 in developing countries, even though the number of affected children decreased 11% between 1990 and 2010 (WHO, 2016). In developing countries in 2011, an estimated 35% of all deaths in children 5 years of age and younger had underweight as an underlying cause (WHO, 2016). For underweight children who survive, malnutrition and deficits of important nutrients can lead to a wide array of preventable disabilities. For example, the leading cause of acquired blindness in children is vitamin A deficiency, and the leading cause of mental retardation and brain damage is iodine deficiency (Andersen, Olsen, & Laurberg, 2015; Stevens et al., 2015).

The health outlook for these at-risk populations would dramatically improve if national and local governments would make minimal strides toward improving the health of their citizens. Governments must take a proactive role in addressing the preventive health care needs of their citizens (Display 26–1). A shift away from the narrow focus on curative services for the most high-risk individuals, and a recentering on preventive interventions for the general population is essential (Moore, 2013). For decades, public health professionals have stressed that the main focus should be on primary and secondary prevention. As difficult as it has been in the United States to implement a shift in emphasis from treatment to health promotion efforts, it will be interesting to see if advocacy, education, and global health interventions can rebalance efforts between primary and secondary prevention against tertiary prevention. Preventing chronic disease and limiting disabilities are vital to improving global health. Although the cost of health care treatment is high, total costs are disproportionally higher when the human burden leading to lost productivity and decreased quality of life is considered. The adage "an ounce of prevention is worth a pound of cure" applies to these burdens as well.

DISPLAY 26.1 BETTER HEALTH FOR PEOPLE WITH DISABILITIES

WHO. (n.d.). Disability and rehabilitation: Advocacy material. Retrieved from http://www.who.int/disabilities/facts/Infographic_en_pdf.pdf?ua=1.

Better health for people with disabilities

World Health Organization

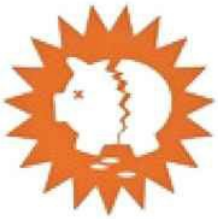
Over **1 BILLION** people globally experience disability

1 in 7 people

People with disabilities have the same general health care needs as others

But they are:

- **2x** more likely to find health care providers' skills and facilities inadequate
- **3x** more likely to be denied health care
- **4x** more likely to be treated badly in the health care system



1/2 of people with disabilities cannot afford health care

They are:

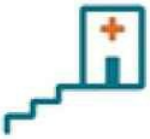
50% more likely to suffer catastrophic health expenditure

These out-of-pocket health care payments can push a family into poverty

Rehabilitation and assistive devices can enable people with disabilities to be independent

200 MIL people need glasses or other low-vision devices and do not have access to them

70 MIL people need a wheelchair. Only **5-15%** have access to one



360 MIL people globally have moderate to profound hearing loss

Production of hearing aids only meets:

10% of global need **3%** of developing countries' needs

Making all health care services accessible to people with disabilities is achievable and will reduce unacceptable health disparities

remove physical barriers to health facilities, information and equipment

make health care affordable

train all health care workers in disability issues including rights

invest in specific services such as rehabilitation

Source: World report on disability: www.who.int/disabilities/world_report

The United Nations Convention on the Rights of Persons with Disabilities

An estimated 1 billion people across the globe (15% of the worldwide population) live with disabilities, with between 110 and 190 million (2.2% to 3.8%) people 15 years and older having significant difficulties in functioning (WHO, 2016). Factoring in the over 2 billion family members affected by disability, the WHO stressed that almost one third of the world population is directly impacted by disabilities. The sheer magnitude of this issue and the recognition that people with disabilities are a developmental challenge that is significantly overlooked across the world led to the 2006 United Nations (UN) Convention on the Rights of Persons with Disabilities (CRPD). To date, 160 countries have signed the Convention or its Optional Protocol (United Nations [UN], 2016). This document remains the standard for considering the rights of those with disabilities, regardless of age, race, gender, or other demographic considerations.

Specific principles of the UN Convention on the Rights of Persons with Disabilities (UN, 2016, para. 4) include the following:

- Respect for inherent dignity and individual autonomy, including the freedom to make one's own choices and independence of persons
- Nondiscrimination
- Full and effective participation and inclusion in society
- Respect for difference and acceptance of persons with disabilities as part of human diversity and humanity
- Equality of opportunity
- Accessibility
- Equality between men and women
- Respect for evolving capacities of children with disabilities and respect for the right of children with disabilities to preserve their identities

The U.S. National Council on Disability (NCD) has advocated for U.S. ratification of the Convention to provide leadership in the arena of disabilities and disability advocacy (NCD, 2014). Although the U.S. Congress passed legislation in support of the UN Convention on the Rights of Persons with Disabilities in 2009, this positive effort proved symbolic, because the effort fell short of the needed step to ratify the Convention. This happened because only Congress can ratify treaties. Wishing to take a concrete step that would be visible to other nations, President Barack Obama publicly signed the United Nations Convention on the Rights of Persons with Disabilities Proclamation. In doing so, he recalled his father-in-law's battle with disability secondary to multiple sclerosis and the beneficial contributions of the Americans with Disability Act (White House, 2009). By mid-2012, the U.S. Senate was still discussing the Convention's ratification (McCain, 2012). In mid-2016, despite a wide variety of successful legislation and program

development at the national level in the United States (see Table 26–1), the United States has been unable to ratify the United Nations Convention on the Rights of Persons with Disabilities Proclamation. Many reasons are cited as to why this document has not been ratified, and supporters and opponents continue to heavily debate the ratification.

Table 26–1 Disability Rights Laws

Law	Summary	Contact
Americans with Disabilities Act (ADA)	Prohibits discrimination in (1) employment, (2) state and local government, (3) public accommodations, commercial facilities, transportation, and telecommunications	(1) U.S. Equal Opportunity Commission (2) Civil Rights Division (3) U.S. Department of Justice (USDOJ) (4) Office of Civil Rights, Federal Transit Administration
Telecommunications Act of 1996	Telecommunication equipment and services are accessible	Federal Communications Commission (FCC)
Fair Housing Act (amended 1988)	Prohibits housing discrimination	U.S. Department of Housing and Urban Development (HUD)
Air Carrier Access Act	Prohibits discrimination in air transportation by domestic and foreign carriers	U.S. Department of Transportation (DOT)
Voting Accessibility for the Elderly and Handicapped Act of 1984	Requires polling places to be physically accessible for federal elections	USDOJ, Civil Rights Division
National Voter Registration Act of 1993	"Motor Voter Act"—makes it easier to vote by increasing low registration rates by minorities and persons with disabilities	USDOJ, Civil Rights Division
Civil Rights of Institutionalized Persons Act (CRIPA) 1997	Right to receive care in the least restrictive setting	USDOJ
Individuals with Disabilities Education Act	Make available free public education in the least restrictive environment for all children with disabilities	U.S. Department of Education, Office of Special Education Programs
Rehabilitation Act	Prohibits discrimination in all federal programs or programs receiving federal financial assistance	(1) Employer's Equal Employment Opportunity Office (2) U.S. Department of Labor, Office of Federal Contract Compliance Programs (3) USDOJ
Architectural Barriers Act	Buildings constructed or altered with federal funds must meet federal accessibility standards.	U.S. Architectural and Transportation Barriers Compliance Board

The World Report on Disability

In 2011, the WHO and the World Bank reassessed global progress on disability since the 2006 *Convention on the Rights of Persons with Disabilities* (UN, 2016). The *Convention* provided guidance to governments globally, that it was their responsibility to improve the lives of individuals and families living with disability. Citizens of every country must and need to participate in their country's development. People living with disabilities must advocate for the removal of barriers that prevent their full participation in their communities, including access to health, education, employment, transportation, and information services. To assure full participation of people with disabilities in their communities, stakeholders in each country—and globally—must establish an inclusive world characterized by enabling environments, rehabilitation and support services, adequate social protection, and relevant policies, programs, standards, and legislation (WHO and World Bank, 2011).

Specific recommendations of the 2011 *World Report on Disability* directed governments to

- Enable access to all mainstream systems and services
- Invest in specific programs and services for people with disabilities
- Adopt a national disability strategy and plan of action
- Involve people with disabilities
- Improve human resource capacity
- Provide adequate funding and improve affordability
- Increase public awareness and understanding
- Improve disability data collection
- Strengthen and support research on disability (WHO and World Bank, 2011)

Citizens of every country, including Americans at every level, can become engaged in translating the recommendations of the *World Report on Disability* into action. Even though government at every level must play a significant part, operationalizing the *World Report* affords important roles for service providers, academic institutions, the private sector, communities, and especially people with disabilities and their families (The Arc, n.d.).

Healthy People 2020

In the United States, *Healthy People* is the most influential series of planning documents that seek to address health promotion and disease prevention as a basis for improving the health of all Americans (ODPHP, 2016). *Healthy People* strives toward a vision of a society in which all people live long, healthy lives. Through its clearly delineated, science-based, and measurable objectives, the decennial *Healthy People* has had far-reaching influences on national and state health initiatives, health care policy, research priorities, and funding since its first efforts in 1979. The evolving American perspectives on disability and on chronic illness have been reflected in the changing focus of the Healthy People series. Following the decades influenced by *Healthy People 1990* and *Healthy People 2000*, *Healthy People 2010* provided guidance during the 2000s, and *Healthy People 2020* guided public health interventions in the 2010s (ODPHP, 2016).

The four overarching goals of the current *Healthy People 2020* are to

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death
- Achieve health equity, eliminate disparities, and improve the health of all groups
- Create social and physical environments that promote good health for all
- Promote quality of life, healthy development, and healthy behaviors across all ages (U.S. Department of Health & Human Services [USDHHS], 2016, para. 5)

A comparison among Healthy People plans since its inception underscores the emergence of new approaches to both identifying priority areas and planning to improve the health of individuals with disabilities and chronic illness. In *Healthy People 2000*, only one priority area was devoted to disability and chronic illness. The priority "Diabetes and Chronic Disabling Conditions" emphasized diabetes, with only limited attention to the broader range of other disabilities, including asthma, CKD, arthritis, deformities or orthopedic impairments, mental retardation, peptic ulcer disease, visual and hearing impairments, and overweight (USDHHS, 2016).

The development of *Healthy People 2010* (implemented 2001 to 2011) reflected the accelerating interest in addressing the health promotion and disease prevention needs of those living with disabilities. In this light, *Healthy People 2010* defined disability as a barrier for those with a heath condition to interacting with their environment (ODPHP, 2016). Individuals with disabilities were classified as those with activity limitations that prevent them from interacting successfully with their environment or the perception that the individual cannot react without difficulties within their environment (ODPHP, 2016). *Healthy People 2010* focused directly on disability and chronic illness in the section "Disability and Secondary Conditions," with frequent attention to these topics across almost all the focus areas of *Healthy People 2010*. In terms of disability and chronic illness, *Healthy People 2010* increased the emphasis on conditions expected to take a future toll on

the nation's health in the coming years, as well highlighted conditions expected to become an economic burden to the nation and for individual Americans and their families.

One of the most influential aspects of the decade of *Healthy People 2010* was to promote a change in thinking within the health care community about the health promotion and disease prevention needs of people with disabilities. This shift was essential to remedy the lack of existing health promotion and disease prevention activities for this population. The previous degree of neglect of health promotion and disease prevention for people with disabilities led to an increase in the number and extent of secondary conditions, and this is a great concern, especially considering the impact on the medical, social, emotional, mental, family, or community problems that a person with a disability may experience (Froehlich-Grobe, Jones, Businelle, Kendzor, & Balasubramanian, 2016). Approaching the health needs of disabled persons from the traditional standpoint of asking what medical, rehabilitative, or long-term care is needed failed to reduce illness or improve the overall well-being of the disabled or chronically ill. In fact, misconceptions about those with disabilities and chronic illness impeded progress in this area. Examples of misconceptions include the following: (a) all people with disabilities have poor health or may have chronic pain, (b) those with disabilities should be treated as different and special, (c) public health activities need to focus only on preventing disability, (d) people with disabilities are similar, (e) there is no need for a clear definition of "disability" or "people with disabilities" in public health practice, and (f) environment does not play a significant role in the disability process (Together We Rock, n.d.).

Increased national attention to the needs of the disabled has improved and should continue to do so as the needs specific to disabled persons are seen as less specific to that population and more universal to all Americans. This changing focus in public perspectives on disability and health is clearly evident in the definition of health promotion used in *Healthy People 2010* to create healthy lifestyles and environments (USDHHS, 2016). It is important to note that *Healthy People 2020* does not list this as a separate component because the purpose of *Healthy People 2020* is to focus on health promotion (Bolin et al., 2015).

Implementation of *Healthy People 2010* led to improved documentation of the lack of parity between disabled and nondisabled populations for several *Healthy People* objectives, including (a) leisure-time physical activity, (b) use of community support programs, and (c) receipt of clinical preventive services. For example, people with disabilities reported engaging in some type of leisure-time physical activity less frequently than any other group, even less frequently than those with low rates of physical activity compared to the general population, such as individuals 65 years of age and older, as well as low-income persons. People with disabilities also have challenges in relation to additional *Healthy People 2010* objectives, including an increased likelihood of being overweight, increased adverse effects from stress, and reduced user rates for preventive services such as receiving tetanus boosters, Pap tests, breast examinations, and mammograms. Halfway between *Healthy People 2010* and *Healthy People 2020*, the 2005 *Midcourse Review* analyzed changes since

implementation of *Healthy People 2010*. It recognized the issue with accommodations for those with disabilities in disaster management and disaster settings (USDHHS, 2016). Two objectives moved further away from their 2010 targets. A 7% increase occurred in the proportion of adults who expressed that negative feelings were impacting their lives—32% in 2003 versus the 28% level reported in 1997. Secondly, in relation to employment, the proportion of adults with disabilities who were employed dropped between 1997 and 2003. As during the recession of 2001, there was a further disproportionate impact on adults with disabilities of the economic instability beginning in 2008, resulting in decreased progression toward the employment goals for 2010 (USDHHS, 2006).

Preventive services, like immunizations, are sometimes forgotten among the disabled population.

Healthy People 2020 was released in late 2011, based on an extensive review of recent and evolving research and national surveys and public and professional reviews and input (Fielding, Kumanyika, & Manderscheid, 2013). In *Healthy People 2020*, the section "Disability and Health" further strengthens *Healthy People*'s approach to disability to emphasize the principles of health promotion and disease prevention for those currently experiencing disabilities and/or chronic illnesses. Rather than narrowly defining individuals with disabilities and/or chronic illnesses through their limiting conditions, *Healthy People 2020* developers understand that individuals with disabilities and/or chronic illnesses have the potential to meet and exceed health promotion and disease prevention goals set for the nation's population as a whole. This approach is consistent with the multifaceted national goal of improving parity across all groups and among all individuals. For example, the goal of "Disability and Health" in *Healthy People 2020* is to engage those with disabilities of all ages to maintain the optimal state of health and prevent chronic conditions so that the highest quality of life can be maintained (ODPHP, 2016). Twenty main objectives were

identified across four broad categories, including (1) systems and policies, (2) barriers to heath care, (3) environment, and (4) activities and participation (see Table 26–2). These objectives reflect a growing emphasis on holistic approaches that recognize that life satisfaction is just as important to human health and well-being as are preventive services (ODPHP, 2016). It also indicates a growing realization that healthy life-years for persons with disabilities equate to decreased health costs at local, state, and national levels, just as they do for persons without disabilities. See Table 26–2 for objectives.

Table 26–2 *Healthy People 2020:* Disability and Health—Objectives

Systems and Policies

- DH-1 Increase the number of population-based data systems used to monitor ***Healthy People 2020*** objectives that include in their core a standardized set of questions that identify people with disabilities.
- DH-2 Increase the number of Tribes, States, and the District of Columbia that have public health surveillance and health promotion programs for people with disabilities and caregivers.
- DH-3 Increase the proportion of U.S. master of public health (M.P.H.)-granting programs that offer graduate-level studies in disability and health.

Barriers to Health Care

- DH-4 Reduce the proportion of adults with disabilities aged 18 years and older who experience delays in receiving primary and periodic preventive care due to specific barriers.
- DH-5 Increase the proportion of youth with special health care needs whose health care provider has discussed transition planning from pediatric to adult health care.
- DH-6 Increase the proportion of people with epilepsy and uncontrolled seizures who receive appropriate medical care.
- DH-7 Reduce the proportion of older adults with disabilities who use inappropriate medications.

Environment

- DH-8 Reduce the proportion of adults with disabilities aged 18 years and older who experience physical or program barriers that limit or prevent them from using available local health and wellness programs.
- DH-11 Increase the proportion of newly constructed and retrofitted U.S. homes and residential buildings that have visitable features.
- DH-12 Reduce the number of people with disabilities living in congregate care residences.

Activities and Participation

- DH-13 Increase the proportion of adults with disabilities aged 18 years and older who participate in leisure, social, religious, or community activities.
- DH-14 Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs.
- DH-15 Reduce unemployment among people with disabilities.
- DH-16 Increase employment among people with disabilities.
- DH-17 Increase the proportion of adults with disabilities who report sufficient social and emotional support.
- DH-18 Reduce the proportion of with disabilities adults aged 18 years and older who report serious psychological distress.
- DH-19 Reduce the proportion of people with disabilities aged five and older who in the previous 3 months experience nonfatal unintentional injuries that require medical care.
- DH-20 Increase the proportion of children with disabilities, birth through age 2 years who receive early intervention services in home or community-based settings.

From U.S. Department of Health and Human Services. (2016). Healthy people 2020, topics and objectives: Disability and health objectives. Retrieved from https://www.healthypeople.gov/2020/topics-objectives/topic/disability-and-health/objectives

Plans for the next decade of Healthy People, *Healthy People 2030*, began in March 2016, under the supervision of the U.S. Department of Health and Human Services (USDHHS), Office of Disease Prevention and Health Promotion (ODPHP). Work on *Healthy People 2030* will review, revise, and establish disease prevention and health promotion objectives for the Nation for 2020 to 2030 (Federal Register, 2016; ODPHP, 2016). Many additional research and health organizations will participate in developing *Healthy People 2030*.

The health of people with disabilities is influenced by many social and physical factors. Using the ICF and the WHO principles of action for addressing health determinants, *Healthy People 2020* identified three areas for public health action. These areas, with accompanying suggested applications, are listed below:

1. Improve the conditions of daily life by

- Encouraging communities to be accessible so all can live in, move through, and interact with their environment
- Encouraging community living
- Removing barriers in the environment using both physical universal design concepts and operational policy shifts

2. Address the inequitable distribution of resources among people with disabilities and those without disabilities by increasing

- Appropriate health care for people with disabilities
- Education and work opportunities
- Social participation
- Access to needed technologies and assistive supports

3. Expand the knowledge base and raise awareness about determinants of health for people with disabilities by increasing

- The inclusion of people with disabilities in public health data collection efforts across the lifespan
- The inclusion of people with disabilities in health promotion activities
- The expansion of disability and health training opportunities for public health and health care professionals (ODPHP, 2016, para. 5)

HEALTH PROMOTION AND PREVENTION NEEDS OF THE DISABLED AND CHRONICALLY ILL

Misconceptions Impede Improvement

The emphasis on "secondary conditions" in *Healthy People 2010* has been replaced in *Healthy People 2020* with a concern for health disparities for people with disabilities. Compared with people without disabilities, people with disabilities are more likely to experience difficulties accessing health care, dental services, mammograms, Pap tests, and fitness activities and more likely to use tobacco, be overweight or obese, have hypertension, and have lower employment rates (ODPHP, 2016). Key to addressing these barriers is for people with disabilities to have an opportunity to participate in public health activities, receive appropriately timed health interventions, engage with the environment without restrictions, and be able to participate in life without limitations (ODPHP, 2016).

Missed Opportunities by Health Care Providers or Missed Opportunities to Affect Quality of Life

All of us, whether healthy, disabled, or chronically ill, require basic elements to maintain health, including clean air and water, a safe place to live, sunshine, exercise, nutritious food, socialization, and the opportunity to be successful in life's pursuits. As self-evident as these health-promoting elements may seem, for the millions of persons who deal with disability, chronic disease, or both, such basic needs may too often take second place to other issues. It is equally problematic that health promotion and disease prevention measures, most notably at the primary and secondary levels, are often nonexistent or lacking. The CDC is making an effort to reduce health disparities among the disabled population. Surveillance, or use of surveys, helps to determine the needs and problems experienced, and research programs help to prevent the development of secondary conditions. Secondary conditions may include mental, emotional, social, medical, or family/community issues that may be experienced as a result of having a disabling condition. For instance, inadequate transportation was reported by 31% of disabled adults compared with only 13% of adults without disabilities; poverty is also a concern, as 26% of disabled adults report an annual income of under $15,000 compared to 9% of those without disabilities (CDC, n.d.). Programs in 16 states work to improve health outcomes and quality of life for this population.

The issue of missed opportunities in health promotion and prevention is depicted in Figure 26–2. The focus of the health care delivery system is increasingly skewed toward secondary and tertiary prevention efforts, and limited emphasis is placed on the health promotion and primary prevention needs of the population. Although this is a concern for all persons, it is of particular importance for persons with disabilities and chronic illnesses because they are more likely to have these needs ignored altogether. As Figure 26–2 shows, an entire area of issues may be addressed with a basically healthy person but not with a disabled or chronically ill individual. Some areas of secondary and tertiary prevention unique to persons with disabilities or chronic illnesses may be completely ignored. This nonreceipt of health-promoting or preventive education or actions vital to the health and well-being of those with disabilities or chronic illnesses is a grave concern (CDC, n.d.; Kung, Tsai, & Li, 2012). For example, issues such as sexuality are often not explored with the disabled or chronically ill. This skewed view of the lifestyles, behaviors, and needs of the disabled as "different" from those of the "able-bodied" is a clear example of lack of understanding by health professionals and the public alike and leads directly to health disparities between the able-bodied and the disabled populations.

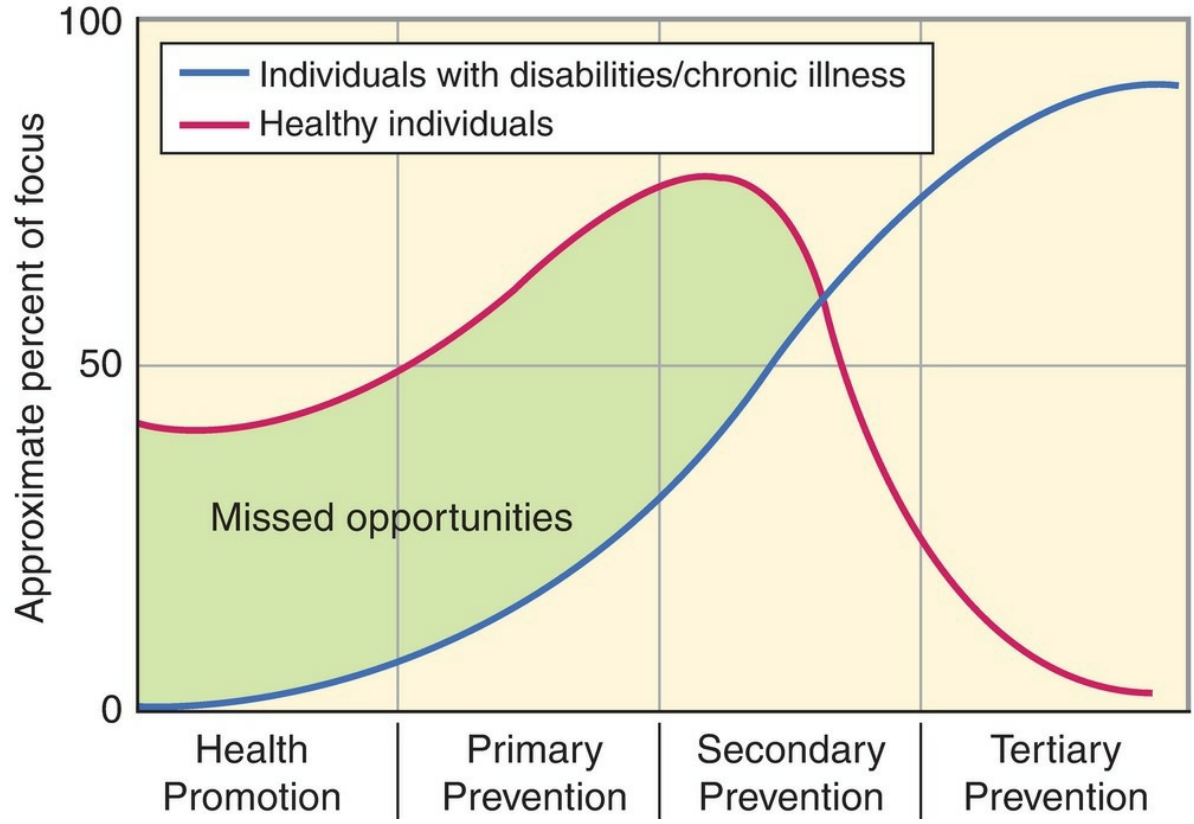

FIGURE 26–2 Difference in client focus between individuals with and without a chronic illness or disability.

It is likely that disability or chronic illness serves as the presenting reason for an individual's encounter with the health care community, including the public health nurse. As a result, the disability or illness often drives the selection of prevention efforts to the possible exclusion of other, equally important health issues. For example, for an individual with a primary diagnosis of type 2 diabetes, secondary prevention efforts often center on that disease (e.g., screening for diabetic retinopathy, peripheral neuropathy). The need to refer the client for a Pap test or a baseline mammogram may be overlooked. Likewise, the treatment plan may include a consultation with a dietitian but fail to address the basic needs for leisure-time activities, regular physical activity, a varied and interesting diet, fresh air and sunshine, and socialization—all of which may help prevent the development of depression, a common result of chronic illness. Display 26–2 offers several examples of missed opportunities in the areas of primary and secondary prevention. It is of particular concern to the practice of community/public health nursing that the broad range of health promotion and prevention needs of all clients be addressed.

DISPLAY 26.2 MISSED OPPORTUNITIES

Example 1

A 60-year-old woman, blind since birth, self-sufficient, and active all of her life, has developed severe arthritis. She encounters a health care system that far too often focuses on her "disabilities" and not her "abilities." The focus is placed squarely on her tertiary health promotion needs, often at the expense of health-promoting or lifestyle-enhancing needs. The result is a failure to recognize that the "disability" of arthritis is likely no less and no more an issue for her than for a sighted person. She receives the same medication therapy as does a sighted person but may not be offered a physical therapy program because of her disability. Her need for physical therapy is no less important, but locating an appropriate, safe, and easily accessible program requires some additional work on the part of her provider. At issue is that options potentially discussed with a sighted person are more apt to be omitted completely, which may negatively affect the client's overall health and well-being.

Example 2

A 20-year-old man with learning disabilities, who is employed at a local factory, receives a regularly scheduled physical examination with a new provider. He lives in a congregate care facility, which is an out-of-home facility that provides housing for people with disabilities in which rotating staff members provide care for 16 or more adults or any number of children/youth younger than 21 years of age. It excludes foster care, adoptive homes, residential schools, correctional facilities, and nursing facilities (U.S. Department of Health and Human Services [USDHHS], 2016). The major finding of the examination is that he is due for a tetanus booster and should also begin the series for hepatitis A, because he lives in a high-risk area of the western United States. He takes the referral slip and leaves the office. One year later, at his regularly scheduled visit, it becomes clear that he never received his immunizations. Apparently, he didn't know what he was supposed to do with the paper, because he has difficulty reading, and he had no idea where to go to get his "shots." The primary prevention elements were provided, but clearly not in a manner appropriate for this individual. With additional explanation and follow-up, perhaps the outcome would have been quite different.

Example 3

A 34-year-old woman, who has been severely obese since the birth of her last child (4 years ago), has not had a gynecologic examination since that birth. She is aware of the need to have regular examinations, yet she cannot bring herself to make an appointment. The reason is that she knows she will have to be weighed, and this terrifies her, especially because it is done in an open area where others can see. She finally gets the courage to call for an appointment and tells the clerk that she does not want to be weighed. The clerk's response is less than helpful, and she is essentially told that it is "policy." She makes the appointment but does not keep it. This situation could have been handled in a compassionate manner, recognizing the painful experience that weighing is for many individuals and suggesting alternatives, one of which could have been simply to bypass the scales until after the interview and examination. At that point, the woman may have been more amenable to the measurement and a more discrete area could have been offered. In this case, the opportunities to provide primary, secondary, and tertiary prevention were lost.

Iezzoni, Kurtz, and Rao (2015) documented the risk of missed opportunities for clinical preventive services among disabled women. Women with disabilities were less likely to receive routine mammograms compared to women without disabilities. Further, women with disabilities were less likely to receive routine cervical cancer screenings, and this is more disparate in rural settings (Horner-Johnson, Dobbertin, & Iezzoni, 2015). In light of the *Healthy People 2020* guidelines, these studies indicate a need to focus concerted efforts for improving preventive health screenings and services for those with disabilities. Specific lifestyle risk factor behaviors in those with disabilities were identified in several studies (McPherson, Keith, & Swift, 2014; An, Andrade, & Chiu, 2015). Study findings suggest that adults with disabilities with accompanying activity limitations and use of assistive devices may be at increased risk for poor lifestyle behaviors related to weight and physical activity. On the other hand, these same adults have lower use of alcohol consumption and increased vaccination rates than the nondisabled respondents. With the challenges faced by those with disabilities to maintain employment, it is vital that health care providers screen for lifestyle behavioral risks in all routine health care visits. A large population study in Taiwan revealed that only 15.8% of disabled adults (n = 785,746) over a 2-year time period used preventive health services that had been available through the public health department for many years (Kung et al., 2012). These studies suggest the need for ongoing attention to the health promotion needs of vulnerable individuals, as well as the value of identifying and taking every opportunity to address those needs.

Health Care Disparities and Discrimination

Individuals living with disabilities, and their families and advocates, have embraced concerns about the type and quality of the health-related services and the referral process. There are also concerns about the care received being appropriate to individual circumstances. This can result in increased illness and disability, as well as potentially decreased quality or length of life. It is important to consider the impact that access to care can have in the continuum of health. When considering the risk for unmet care in those with disabilities versus those without disabilities, the inability to access medical, dental, and prescription drug care is between 57% and 85% higher in those with disabilities (Mahmoudi & Meade, 2015). This is magnified in females, those without health insurance, and those living near or at the poverty level.

Additional disparities may exist in services received by those with chronic illness and disabilities. In children with cerebral palsy, vaccination rates were found to be lower (Greenwood, Crawford, Walstab, & Reddihough, 2013). In this population, protection from vaccine-preventable disease is vitally important and represents the difference between maximum health and complications from their increased vulnerability. Cody and Lerand (2013) noted that vaccination disparities occur because of many factors but cited that provider and parental attitudes toward disabled children can be a barrier to compliance with vaccination recommendations. Human papillomavirus is a sexually transmitted vaccine-preventable disease, and it is important to consider providing those with disabilities with the same health protection as nondisabled counterparts. Reducing disparities between those with disabilities and those without disabilities provides an opportunity for maximal health of those with disabilities, as well as the general U.S. population.

When an individual receives unequal, inappropriate, or limited services compared with those received by others, this is categorized as discrimination. Although the difference in treatment can be due to a lack of understanding of the needs of disabled persons, it is nonetheless discriminatory. Even when such bias is not intentional, it can dramatically affect the health of clients and must be addressed through provider education and health policy requirements. The good news is that the incidence of unequal and inappropriate practices can be reduced with education and training of health care providers, agency staff, and insurance carriers. A crucial aspect of community/public health practice is to ensure that those individuals with disabilities or chronic illnesses are afforded the best possible care, treatment options, and opportunities to improve their health—the same options made available to nondisabled persons and those who do not suffer from chronic illness (Brolan et al., 2012).

Health promotion and primary, secondary, and tertiary prevention activities are essential aspects of quality care for all persons. Those with disabilities require specialized attention to needs resulting from or related to their disabilities, yet they also require the same attention to health and well-being as the rest of the population (Kung et al., 2012).

PHNs are in a prime position to advocate needed changes for those with disabilities and chronic illnesses. Such changes can include increased attention to health promotion and disease prevention needs, accessible and appropriate delivery of those services, and specialized treatment plans that incorporate the latest knowledge of a specific illness or disability (see Perspectives: Student Voices).

PERSPECTIVES STUDENT VOICES

For as long as I can remember, I have wanted to work with children. When I was finally accepted into the nursing program, I was so disappointed when I learned that we would only have 7 weeks in our pediatric rotation. Then, I found out about an opportunity to work with children at a school in my community health practicum—I thought that was great. I just knew I'd be giving immunizations, physical assessments, and performing hearing checks. Then I found out that I would actually be working with school-aged children with disabilities and their parents in a special after-school health promotion program. The nurse I was assigned to asked me to come in before the program started so that she could fill me in on the program and my role. It actually sounded great, and I was confident that I could handle this. Then she asked me something that made me worried; she asked if I had ever worked with a child who used a wheelchair, or had a continuous insulin pump, or had seizures. I told her that I had some experience in the hospital and that I was sure that I would be prepared for any health care issues that might occur. "You misunderstand," she said, "that's not what I meant. Have you *ever gotten to know a child* with a disability?" I really hadn't, and it suddenly made me a bit worried. She explained to me that many people don't treat children with disabilities just like any other child. They also don't always know how to talk to the parents about their child. She suggested that one way to give me a bit of information was to go home and do some reading and look at some Web sites she recommended. The National Organization on Disability (http://www.nod.org/) had a great feature called "Disability Etiquette Tips" that I have already found to be a big help with the kids and their parents. She also directed me to the Easter Seals Disability Web site (http://www.easter-seals.com), which has a great deal of information on programs that are currently available for children and adults. I even learned that this organization used to be called the National Society for Crippled Children—I'm really glad they changed the name.

Eileen S.

CIVIL RIGHTS LEGISLATION

Policies such as *Healthy People 2020* are important elements in addressing the health and overall needs of people with disabilities and chronic diseases in the United States. Although it has a great deal of influence on the direction and type of programs initiated, health policies alone cannot assure that individuals with disabilities will find and receive needed services and accommodations. An act of legislation is vital to ensure that every individual's rights are protected and that there is legal recourse to secure needs that have been denied. As is often true for other issues of equality, legislation is only one of many steps that must be taken. The struggle to achieve civil rights for disabled persons in this country has gained momentum and continues to seek the influence and public attention that will improve the health and lives of those having disabilities, handicaps, and chronic illnesses. The Americans with Disabilities Act (ADA) was signed into law in 1990 to protect the civil liberties of the many Americans living with disabilities (Massey, 2015). This legislation was the result of a long and difficult struggle. Individuals with disabilities and their advocates made their voices heard by repeatedly demanding an end to inferior treatment and lack of equal protection under the law, which have impeded their daily lives. The ADA has set the standard for a number of subsequent laws that, together with pre-ADA legislation, have become a broad spectrum of protections for people with disabilities. These laws are listed in Table 26–1 and cover a variety of issues, including telecommunications, architectural barriers, and voter registration.

The ADA was written to protect those with disabilities by prohibiting any form of discrimination in the realm of employment, government, public accommodations, transportation, telecommunications, and commercial facilities (Edie, 2016). This federal law protects those with a disability, which is defined as a physical or mental impairment that substantially limits one or more major life activities with documentation of the impairment or being thought of to have the impairment (Kanter, 2015). The ADA does not list specific diagnoses, but instead, the ADA focuses on the impact the disability has on daily living. This includes things like the ability to care for self, perform manual tasks, see, hear, eat, sleep, walk, stand, lift, bend, speak, breathe, learn, read, concentrate, think, communicate, and work. This impacts the function of the immune system, normal cell growth, digestive, bowel, bladder, neurological, brain, respiratory, circulatory, endocrine, and reproductive functions (Chen, 2015). Despite this specificity, there remains a broad range of interpretations and legal challenges with respect to who is actually covered by the ADA.

In addition to the uncertainty about who is actually protected by the ADA, there can also be confusion about who is required to comply with the provisions of the Act and what specific remedial actions are necessary. The ADA currently applies to all employers with 15 or more employees (including religious organizations), and all activities of state and local governments irrespective of their size. Public transportation, businesses that provide public

accommodation, and telecommunications entities are also required to provide access for individuals with disabilities. It is important to note that the ADA does not override federal and state health and safety laws. However, successful legal challenges to those statutes have been made when they were clearly outdated or when it could be argued that the public safety was not actually at risk in a specific situation. Yet considerable gray areas exist in the application of the ADA, leaving open the prospect of challenges by those who are subject to the law and those who are protected by it (U.S. Department of Labor [USDOL], n.d.a).

Employers may hire the most qualified candidate of their choosing, provided that an individual's disability is not a factor; employers may also fire a disabled individual if the employee doesn't meet job requirements after appropriate accommodations have been made, and it is not related to the disability. Employees may also be terminated if their disability "poses a direct threat to health or safety" of others in the workplace (USDOL, n.d.a, para. 23). Individuals who believe that their legal rights under the ADA have been violated may seek remedy by filing a lawsuit or submitting a complaint to one of four federal offices, depending on the specific type of alleged violation: (1) the USDOJ, Civil Rights Division; (2) any U.S. Equal Employment Opportunity Commission field office; (3) the Office of Civil Rights, Federal Transit Administration; or (4) the Federal Communications Commission. The process for filing a complaint is not a simple task, and many seek the assistance of attorneys, legal aid societies, or various private organizations, some of which are discussed later in this chapter (see Display 26–3).

The ADA includes provisions and safeguards regarding employment (e.g., reasonable accommodations, discrimination based solely on disability), public services (e.g., opportunity to participate, technology accessibility), and public accommodations (e.g., design standards, reasonable modifications, service animals, tax credits/deductions). Telecommunications services must also provide telecommunications relay services, closed captioning, and equal access for disabled individuals to emergency services. The ADA also prohibits "retaliation and coercion" (Disability.gov, n.d., para. 16). The ADA Amendments Act of 2008 overturned some court rulings, broadening and clarifying the ADA definition of disability.

DISPLAY 26.3 OFFICE OF CIVIL RIGHTS: COMPLIANCE WITH ADA

The responsibility of the U.S. Department of Justice, Office of Civil Rights (OCR), is to investigate complaints of alleged violations of the Americans with Disabilities Act (ADA). An example of one of those complaints involved a 22-year-old

Connecticut woman with cerebral palsy. She had been placed in a nursing home because of changes in her living situation and health care status, but wanted to move back into the community. The OCR intervened to ensure that the woman secured appropriate housing and that counseling and intensive case management services were in place when she moved back into the community. Another example involved a man with traumatic brain injury (TBI) who was told he must remain in a hospital when he requested home health care services. OCR intervened and secured physical, occupational, and speech therapy for the client, as well as physical modifications needed for his home. A 32-year-old quadriplegic man had lived independently in his own apartment with a health aide's assistance, but suddenly lost his apartment and was transferred against his will to a facility. He was able to get a wheelchair accessible apartment, but could not get health aide services. OCR intervened on his behalf and secured a personal care assistant so that he could live in his new apartment. Without the protection afforded under the ADA, the outcome could have been much different.

Source: USDHHS, Office for Civil Rights. (2006, September). Delivering on the promise: OCR's compliance activities promote community integration. Retrieved from http://www.hhs.gov/civil-rights/for-individuals/special-topics/community-living-and-olmstead/compliance-activities-promote-integration/index.html

The National Council on Disability discovered in the years following legislative changes that many federal agencies charged with protecting the civil rights of disabled persons were limited by insufficient funding and a lack of coherent and unifying national strategies. The NCD recommended clarification of the basis for evaluating agency performance to improve the intended full expression of the law. The 2008 study, *The Impact of the Americans with Disabilities Act: Assessing the Progress Toward Achieving the Goals of the ADA* by the NCD, continued to find that many people with disabilities, businesses, and employers still did not understand the requirements of the ADA in relation to employment. And Americans with disabilities continued to face barriers to becoming economically self-sufficient. But the NCD also found many areas for optimism: public transportation was more accessible, especially for wheelchair users. Ramps and sidewalks had been made more accessible, although full access still lagged. Access in public accommodations continued to improve, as did public attitudes toward those with disabilities. Many people with disabilities perceived improved quality of life, which they attributed to the ADA (NCD, 2008b).

In a yearly progress report, *National Disability Policy: A Progress Report*, the importance of accurate statistical data collection and reporting in order to address program effectiveness and policy development was discussed. Civil rights were addressed, in relation to court decisions weakening the ADA, and technology accessibility, as well as voting and improvements made by the U.S. Department of Justice in protecting institutionalized individuals with disabilities. The report also called for "genetic nondiscrimination" legislation to ensure rights of the disabled in regarding privacy, confidentiality, and

potential adverse selection in health insurance, employment, and housing because of one's disability (NCD, 2008a, p. 59). Recommendations included educational accommodations, especially for standardized testing, technology accessibility in schools and universities, and better monitoring of private schools' Individuals with Disabilities Education Act (IDEA) compliance. Health recommendations included mental health parity in health insurance, and improvement in programs and services from the CDC and the Centers for Medicare and Medicaid. In the area of employment, it was recommended that substantially more research and a thorough "examination of the issues" be supported (p. 139).

The 2014 progress report highlighted the gains made in education but encouraged further improvements to meet "the unique learning needs…for students with disabilities" (NCD, 2014, p. 10). The area of employment was a significant concern, as technology, workplace culture, and transportation represent potential barriers. The report also called for the U.S. Department of Labor to end the subminimum wage for disabled employees, and addressed the need for better engagement and "system refinement" in state Medicaid systems (p. 10). The employment gap for disabled individuals is 42.8%, and the income gap is $6,000 annually. Recommendations also included support for ratifying the Conventions on the Rights of Persons with Disabilities (CRPD), mentioned earlier in this chapter. Also, the shortage of community-based mental health services profoundly affects this population, and recommendations were made for more resources in this area and for veterans with mental health issues (NCD, 2014).

It is important to those with disabilities, their families, and the professionals who serve them that a structure is in place to provide protection under the ADA, but a law does not prevent discrimination, nor does the existence of a structure such as the ADA provide immediate remedies. The most challenging aspect of providing services for persons with disabilities is to alter the perceptions and misunderstandings of others about people with disabilities (Yee, 2016). The perspective of one community member offers one such example (see Perspectives: Voices from the Community).

Currently, the NCD focuses its policy initiatives on civil rights, cultural diversity, education, emergency management, employment, financial management and incentives, health care, housing, international issues, long-term services and support, technology, transportation, and youth issues (2014). This organization provides tool kits for parents of those with disabilities, deinstitutionalization, and disability in Indian country. It is important to note that the policy and advocacy for those with disabilities is maintained through this organization as part of its charge run through the federal government.

PERSPECTIVES VOICES FROM

THE COMMUNITY

"I was always such an active and healthy person, so when I was diagnosed with multiple sclerosis, it hit me like a ton of bricks. Here I was with two small children and I was only 30 years old; it just wasn't fair. Some days are good, and some days are just awful. I finally broke down and applied for one of those disabled parking stickers. The doctor had to approve it, and he said it was a good thing to help me save my energy for the important things, like taking care of my family. I hated to use it, but I was just getting so tired. It is so frustrating to see the looks on people's faces when I park in the handicapped parking areas near the door. I know I don't look like I'm sick. I just hate those looks—I can hear them saying under their breath, "She can't be sick … I'll bet that sticker is for a family member and she's just abusing it—how lazy!" If I weren't so tired I'd park in the regular parking places."

Pat N, Tampa, Florida

FAMILIES WITH A DISABLED OR CHRONICALLY ILL MEMBER

The Family's Role in Advocacy

Families that include a member with a chronic illness or disability face many challenges. They are required to navigate a health care system that they may know little about and with which they often feel at odds. They serve as advocates for their family member in need (whether child, spouse, or parent) and may become exhausted or frustrated with their efforts, especially if they have been less than successful in achieving their goals. Many are forced to ask for or demand assistance from health care agencies, social services, or transportation sources to achieve the level of care needed by the family member (Brolan et al., 2012). Many are required to open their home to others (e.g., community/public health nurses, social workers) to access the services. Families may also have little understanding of what services they are entitled to because of language barriers, difficult agency policies, or disjointed service delivery.

The PHN is usually not the first health care professional that the family encounters. They may already have been through a lengthy struggle to receive assistance. In these circumstances, the nurse may be confronted with a frustrated family, reluctant to trust yet another health care provider. Nurses must earn the trust and confidence of the family by practicing consistency, following through with promised actions, and always being truthful. Not all problems that the family faces can be remedied, and even for problems that do have solutions, time and effort may be needed to obtain the desired result.

The Impact on Families

Caring for a family member who is disabled, whether it is a child or an adult, is stressful. High levels of anxiety, stress, depression, and illness are often reported in families of disabled children (Dykens, 2015). Families caring for a member with epilepsy and intellectual disabilities report unsettled family dynamics, emotional and physical burdens, and practical concerns such as finances, the nonstop responsibility for caregiving and coordination of care, social isolation, and difficulty showing equal attention to all family members because of the increased needs of a disabled family member. However, they also note positive aspects of care, including family closeness and showing an example to other family members of caring behaviors and altruism (Thompson, Kerr, Glynn, & Linehan, 2014). In a study of parents of deaf and hard-of-hearing children, it is important to note that parental involvement and support is an essential aspect of the process for mitigating disabilities in this group (Lam-Cassettari, Wadnerkar-Kamble, & James, 2015). Parents who participated in a family-focused psychosocial video intervention program geared toward guiding them in proper communication with their child improved parental sensitivity, structuring, nonhostility, child responsiveness, and child involvement. This also improved parental self-esteem and a more connected parent–child relationship. It is important for nurses to support the family unit, not just the disabled patient. Nurses should be especially cognizant of the needs of families of children with disabilities and their unique needs. This was echoed in a study where parent–child interaction therapy was used to support the relationship between children with autism and their parents. By supporting the parents and the disabled child, parents were able to use appropriate interventions to support the child (Sheperis, Sheperis, Monceaux, Davis, & Lopez, 2015).

Hamilton, Mazzucchelli, and Sanders (2015) also examined parental support for children with disabilities. In the adolescent years, the needs of the disabled child dramatically shift from needs as a child as parenting styles that worked at a younger age were no longer effective. Parents report struggling to understand the needs and making accommodations for the transitions of their adolescent children, and this frustration leads to increased stress and feelings of grief. The study suggested that a targeted, evidence-based parenting program should be tailored toward this special population. Nurses should be prepared to provide parenting support and referrals to parental support groups and educational programs that can assist the parents in providing the best care possible to their disabled children.

Nurses should also be aware of the physical needs of parents caring for disabled children. In a study by McCann, Bull, and Winzenberg (2015), the researchers noted that parents report sleep deprivation as a direct result of the child's illness. Based on the particular disability, parents reported varying amounts of sleep deprivation, but at the core of the research is the need for parents to be especially vigilant while their children are sleeping. This can result in failing health among parents, and nurses should consider the amount and quality of sleep in order to assure that parents of disabled children are able to

provide the care that is needed.

Geographic differences were noted in a large-scale study of children with special health care needs. Regional differences were found in access to mental health care, genetic counseling, specialist care, and physical/occupational therapy, for instance, in the West, and respite care, vision and dental care services were lacking in the South (Fulda, Johnson, Hahn, & Lykens, 2013). Also, for families with a disabled child, access to locations is an important consideration. For those with a physical disability, for example, a family may want to vacation at the beach. For those children who are wheelchair bound, this may not be a possibility for the family, or the child may be excluded while the other family members enjoy the location. Dickson (2016) reports that a city offered disabled access to the beach, but even this intervention was still problematic for complete access to this recreational pastime. Despite the ADA, many locations remain isolated from those with physical and mental disabilities creating a challenge for families that are trying to engage the disabled child and keep them included as part of the family. Even at home, when modifications are made to accommodate to improve access for a disabled child, families report dissatisfaction with the process, and a need to be inclusive with the family at all phases of the remodeling process was noted. Morgan, Boniface, and Reagon (2016) indicated that without family involvement in this process, the adaptations to improve access may not be utilized, and families may have a negative perception of their home.

Access to resources related to financial support is an important issue. In fact, the Disability Tax is a model that addresses the high cost of care of the disabled (Shick, 2015). The cost of care of a disabled child is high and is a financial burden to families as they navigate paying for obvious costs, such as doctor and hospital bills, diagnostic testing, medical treatments, and prescription medicines (Price & Oliverio, 2016). However, the cost of care is more than just the obvious costs. The cost of care of a disabled child may include 24-hour supervision for activities of daily living, and this does not end for many disabled children at the age of 18, rather the cost of care for a disabled child often requires a lifetime of services. Therapy, health care professionals, financial planners, support group facilitators, educational advocates, special education attorneys, and other professionals may be required for care. Whiting (2014a) found that parents of children with complex health needs identified that people, processes, and resources are the most important support needs. For instance, families may need a tracking or alarm system to ensure the safety of a disabled child who wanders; special equipment, such as wheelchairs, special vans, medical transportation, orthopedic devices, therapeutic beds, and lifting equipment, may be required, and this may need to be purchased multiple times as the child outgrows existing devices. Indirect costs can include medication changes, nutritional supplements, special diets, sensory considerations, and respite care—all of which can burden families with disabled children. While *Healthy People 2020* directly addresses obstacles to obtaining assistive devices and technologies in objective 10, under Disability and Health, it may still be problematic. This objective states that people with disabilities should be able to obtain assistive devices, technology and accessibility services, and service animals (ODPHP, 2016).

This can be more difficult for children with disabilities, and advocates are often needed. This may be especially true in the school setting (see Chapters 22 and 30).

With repeated changes in available equipment, financing, and technology, it is little wonder that families struggle to find the best alternatives. Just because a technology exists does not mean that it can be obtained. The insurance carrier, whether private or governmental, will often set limits on which products can be obtained or which brands are acceptable. The overriding issue of financing is no small hurdle. It is often left up to the family to learn about options and legal rights through a process of trial and error. Interventions by the community/public health nurse can greatly reduce the burden on the family. With so many product lines available online, the nurse can assist families to weigh and select among options, especially for families with limited access or experience with the Internet. It is equally helpful for the nurse to intervene with insurance providers if coverage of equipment is not easily obtained or to seek sources of funding for the equipment from private agencies. Referring families to community groups or charitable organizations that provide specific assistance can be very helpful. Other families experiencing similar struggles can provide their experience and links to needed services and self-help/support groups. In addition, the community/public health nurse can provide expertise on available community resources and referral processes. Families that are just beginning to adjust to having a child with a disability or a complex health problem identify the "impact" of the diagnosis and the "need for help and support" as very important factors as they process the information and move forward. They often refer to the experience as a battle, and PHNs should consider this when working with these clients (Whiting, 2014b, p. 26).

Respite care is another resource of great importance for families of the disabled and the chronically ill. It was most often cited as an unmet need by parents of disabled children in a qualitative study by Whiting (2014a). Because it can be emotionally draining to meet the daily needs of a relative or friend who cannot perform self-care, in this situation, caregivers are at risk for related fatigue and stress. It is also important to recognize the effect of the situation on noncaregivers in the family, particularly nondisabled siblings of a disabled child. When focus is placed on the needs of one family member, other children may feel that their own needs are not as important, which can lead to behavioral and health-related problems. Respite care can be provided for the family member with disability, in the home or through admission to a hospice facility. Respite offers needed relief to families and allows for uninterrupted attention to the nondisabled children. Respite care may also be provided free of charge by a charitable organization or reimbursed by the health insurance provider. Sometimes families are able, and choose to, pay directly for hospice care. Whatever the source, respite care can be vital to the family's health and should be a considered a priority in the overall treatment plan of families of the disabled and chronically ill (see Using the Nursing Process).

USING THE NURSING PROCESS WITH VULNERABLE POPULATIONS

Assessment

Anna Lopez is a mother of three children aged 2 to 9 years old. The eldest, Ernesto, was diagnosed with severe Down's syndrome at birth. He is confined to a wheelchair, requires total care, and remains at home with his mother and younger siblings, who are not yet in school. Anna's husband works long hours as a computer repairman for a large company. They have health insurance, but it does not cover additional expenses, such as day care for Ernesto. The family has done very well in providing for Ernesto's needs, and they receive periodic visits from you, the community health nurse, to evaluate his condition and check on the feeding tube used for his nourishment. Physically, Ernesto is stable, but you notice that Anna has slowly become more withdrawn at the visits and rarely offers information, even though she continues to respond to questions appropriately. She also seems less engaged with her other children and only occasionally smiles at them.

Nursing Diagnoses

1. At risk for depression related to ongoing caregiver demands and lack of respite care
2. At risk for altered health status due to limited focus on self-care needs

Plan/Implementation

• DIAGNOSIS 1

The community health nurse will discuss with Mrs. Lopez the need for a thorough physical assessment, including an evaluation for depression. The community health nurse will contact the insurance provider and charitable groups to seek day care/respite options for Ernesto. If unavailable, local community organizations will be contacted for other types of appropriate referrals. In addition, the need for more frequent visits to the family will be discussed with the insurance carrier to address the needs of the mother as caregiver.

• DIAGNOSIS 2

The community health nurse will discuss with Mrs. Lopez the nurse's concerns about her overall physical and mental health, some self-care options that may improve Mrs. Lopez' well-being, and possible improvements in nutrition, physical activity, leisure-time options, and adjustment of family schedule to accommodate more free time for self-care for Ms. Lopez.

Evaluation

Mrs. Lopez was at first very reluctant to make an appointment for an evaluation, but after thinking it over for a week and discussing it with her husband, she did so. Her husband was relieved that she had suggested the appointment, because he was growing increasingly concerned over her withdrawal but did not know how to bring up the subject. The family physician referred Mrs. Lopez to a psychologist for evaluation of the depression. The insurance carrier agreed to increase home visits on a short-term basis but did not have a respite care option available for Ernesto. Fortunately, a local faith-based community group was able to provide limited but appropriate assistance to the family. The group identified several members who had raised children with similar disabilities and who were willing to stay with Ernesto and the other children once a week for 4 hours. This allowed Mrs. Lopez some free time to make appointments with her psychologist, shop, or visit friends. After several months, Mrs. Lopez has begun to smile more and seems much more relaxed at the home visits. The children are all doing fine, and the respite care is expected to continue for at least the next 6 months. The community health nurse continues to emphasize to Mrs. Lopez the need for ongoing attention to her own self-care need.

The issue of employment is generally of great significance to families of the disabled and chronically ill, as employment options may be quite limited when a family member has special needs. The family may have to remain in a particular location to access needed health and social services, reducing the possibility of increased earning potential at a different location or in another field of employment. Family members who are working may choose less favorable employment options because the position is convenient or has more flexible hours. For instance, a person may take a part-time position at a local convenience store that does not pay particularly well in preference to a higher-paying, full-time factory position, because the store is close to home and allows for frequent adjustments in schedule. Baillargeon, Bernier, and Normand (2011) found in a study of almost 4,000 caregivers that parents of those most severely restricted in performing daily activities were more likely to report being unable to get childcare services and having to work fewer hours or quitting jobs in order to care for children with impaired psychological functions.

Having a chronically ill family member can mean that working individuals must take time off from work. Although some legal protections are provided under the Family and Medical Leave Act of 1993, it does not apply in all situations. For instance, it is only

available in companies with more than 50 employees and is most often used for birth and care of a newborn or newly adopted child or for temporary care of a family member with a serious health problem (spouse, parent, child). More importantly, it allows only for time off; it does not mandate that employers continue a salary during those periods (USDOL, n.d.b). Family members may have to choose between taking unpaid time off and continuing to work while dealing with the needs of the family member as best they can. Some individuals choose to work part-time or not to work at all so that they can care for family members (Baillargeon et al., 2011). At a time when many families have two wage earners to help meet financial commitments, families engaged in caregiving may have to rely on only one income. Limitations in income are particularly challenging, considering the myriad needs of those who are disabled or chronically ill, needs that may not be covered by any insurance.

There are many financial programs to help individuals with disabilities and families caring for those with disabilities. Programs include Temporary Assistance for Needy Families (TANF) and Social Security's Supplemental Security Income (SSI). Families receiving financial and other assistance from TANF also face work-related pressures. The 1996 welfare reform legislation, the Personal Responsibility and Work Opportunity Reconciliation Act, introduced regulations that often impact families with a chronically ill child, especially those families living in poverty. Those now receiving TANF have a 5-year lifetime limit on receipt of benefits (and states may opt to reduce years of eligibility further), institution of work requirements, and elimination of entitlement to cash benefits (USDHHS, 2016; Wen, 2014). Those with disabilities and families caring for those with disabilities often are unaware of eligible programs and confusion about the rules and regulations of each program. Some SSI recipients manage their own money, but others cannot. Concern about how "financial capability assessments" are made, or judging when a beneficiary is not capable of managing their own benefits, has given rise to calls for reforms in that area (Appelbaum, Birkenmaier, & Norman, 2016, p. 704). Another concern is that the SSI program has grown substantially, whereas the number of disabled children on TANF rolls has decreased. Wen (2014) reports that SSI numbers have almost doubled since 2012, as broader disability classifications were accepted, and it now disburses more money than welfare programs largely because benefits are higher and continue longer and rules are more flexible. About 60% of children on SSI now have speech delays, depression, learning disorders, and autism spectrum disorder as well as ADHD. However, Ghosh and Parish (2015) noted that families of disabled children on SSI experienced significant hardships compared to families receiving SSI without disabilities, indicating a need to revise the policies around SSI.

Falk (2016) explored the relationship between welfare status and health. The researcher noted that families receiving Temporary Aid to Needy Families (TANF) often were eligible for many programs and that the different policies and requirements are difficult for families to navigate. While some families that receive TANF have children with disabilities and are eligible for other support programs, there is a need to establish policies that can offer

guidance for these families to maximize the support and benefits obtained.

Public health nursing support for families with disabled children can be critical in helping them access resources and services.

Caregiver health needs and mental health status are another area of concern for families who must provide for a disabled or chronically ill family member. The mental health of the mother as caregiver is documented to be an area of concern, and the expression of depression in this population is concerning (In Sook & Hyun Sook, 2015; Yamaoka et al., 2015). While research often focuses on the mental health of the mother as caregiver, a line of research exploring paternal mental health when caring for a child with an intellectual disability is growing. This research supports that the child's behavior problems, father's daily stress, low parenting satisfaction, and childcare needs are the biggest predictor for father mental health difficulties (Giallo et al., 2015). A study exploring family health of parents caring for a child with disabilities indicated that parent caregivers who experienced activity restriction and low social support and those families in the lowest quartile of monthly expenditure were more likely to experience psychological distress (Yamaoka et al., 2015). It is important for nurses to provide detailed information about the child's health needs, disease, disability, medical services available, and social support available to meet the needs of the disabled child to decrease parental mental health stress and disorders.

Recognizing that caregivers within a family are at increased risk for poor health outcomes, it is important that the PHN select appropriate interventions to address the health needs of all family members.

Families may suffer from financial difficulties, poor physical or mental health, and a variety of other challenges. For instance, a classic study on loss of family income related to having a child with autism spectrum disorder found an average decrease in annual income of 14% for these families (Montes & Halterman, 2008). Families are often ill prepared to deal with the complicated systems that must be accessed to obtain needed care. The PHN is in an optimal position to interpret those systems to the families and to advocate for the needed care, services, and equipment. The nurse must view the family holistically, recognizing additional needs that may develop as a result of the situation currently faced, and include an assessment of caregiver and family work patterns when caring for families with a disabled or chronically ill family member.

Disabled individuals may also seek employment, and a number of them have difficulties finding jobs. However, for those who do gain employment, benefits to their mental health have been demonstrated in research studies. Milner, Krnjacki, Butterworth, Kavanagh, and LaMontagne (2015) found that like those with no disabilities, disabled individuals show "significant mental health benefits" when "psychosocial job quality" was good (p. 104).

ORGANIZATIONS SERVING THE NEEDS OF THE DISABLED AND CHRONICALLY ILL

The impact of civil rights legislation would not have been achieved without the chorus of voices from advocates who deal on a daily basis with the issue of disability—the individuals themselves, their families, coworkers, employers, and advocates. Much of the credit for the legislative successes belongs to advocacy groups. This section provides an overview of some of the advocates for disabled and chronically ill individuals and their families. In addition to serving these specific populations, they also provide others opportunities to learn more about the lives and struggles of disabled persons. Each of the organizations noted offers a wide range of information, much of which can be accessed online. These organizations provide nurses with a starting point for exploring specific topics pertinent to practice. As clients and families may also be accessing online content through personal or public Internet access, it is important for nurses to prescreen and make recommendations to clients and families about reliable and accurate sites.

Government

The NCD is a small, independent federal agency tasked with making recommendations to the President, the U.S. Congress, and other federal agencies about issues facing Americans with disabilities. The NCD staff is led by 15 presidential and senate appointees. In 1986, the NCD recommended that Congress enact a civil rights law for people with disabilities and provide the initial draft legislation, which led to the passage of the ADA in 1990. NCD currently fulfills its advisory roles regarding disability policies, programs, procedures, and practices that enhance equal opportunity by gathering stakeholders to create recommendations and direct appropriate steps, review relevant data sources, network and collaborate with other groups regarding the appropriate direction, create solutions to problems, and provide tools for implementation (NCD, n.d.).

Private

Many private organizations—local, national, and international—address a variety of disabilities and chronic diseases. Many of the better-known organizations such as the American Heart Association and the American Cancer Association are discussed in other chapters of this book and therefore are not covered here (see Chapters 23 and 24). This discussion includes examples of groups that deal most directly with disability and chronic illness.

A conversation in sign language.

The National Association of the Deaf (NAD), headquartered in Washington, DC, is a private, nonprofit organization established in 1880. As the oldest U.S. organization serving the deaf community, it serves to protect and promote the rights of all deaf Americans, including civil, human, and linguistic rights (NAD, 2016). NAD's Vision 2020 Strategic Plan detailed the organization's beliefs and decade-focused goals, including ensuring that American Sign Language is at the core of all that are hard of hearing or deaf. NAD's programs include advocacy, captioned media, certification of American Sign Language (ASL) professionals and interpreters, legal assistance, and policy development and research. ASL uses precision hand movements to communicate without using any verbal or auditory-type communication (Fink, 2016). Display 26–4 offers a brief summary of the purpose and use of ASL and other signed languages.

DISPLAY 26.4 SIGN LANGUAGES IN BRIEF

- Sign language is the use of "handshapes" and gestures to communicate ideas or concepts.
- American Sign Language is a unique language with its own rules of grammar and syntax.
- American Sign Language is primarily used in America and Canada and is the natural language of the deaf community; in Britain, British Sign Language (BSL) is used.
- Sign languages are not universal.
- International Sign Language (Gestuno) is composed of vocabulary signs from various sign languages for use at international events or meetings to aid communication.
- Systems of Manually Coded English (i.e., Signed English, Signing Exact English) are not natural languages but systems designed to represent the translation of spoken language word for word.

The National Organization on Disability (NOD) headquarters is in Washington, DC, and NOD acts on a mission to facilitate the active participation and contributions of the 56 million disabled people in the United States (NOD, 2016). The NOD Web site connects visitors to a rich variety of sources on community involvement, economic/employment topics, and access issues (http://www.nod.org/). An important contribution of NOD is the periodic *Kessler Foundation/NOD Survey by Harris Interactive* (NOD, 2016). These surveys seek to describe the gaps between people with and without disabilities in terms of employment, income, education, health care, access to transportation, entertainment or going out, socializing, attending religious services, political participation/voter registration, life satisfaction, and trends. Although improvements in all indicators have been demonstrated over the 24-year period of survey activity, progress is described as both slow and modest. The NOD has many programs to promote employment and created the Disability Employment Tracker to encourage companies to support the hiring and

retention of those with disabilities (NOD, 2016).

The American Council of the Blind was founded in 1961 and has a current mission to work toward improving quality of life, security, equality, and independence for all visually impaired and blind people (American Council of the Blind, 2013). Services noted by the organization include information and referral, scholarship assistance, public education, and industry consultation, as well as governmental monitoring, consultation, and advocacy. Some of the major issues currently being pursued by the organization include improved education and rehabilitation for the blind and increased production and use of reading materials for the blind and visually impaired. The American Council of the Blind recognizes companies that work toward increasing access for blind and visually impaired individuals and provides publications and resources, policy advocacy, and forums for issues that concern the needs of this population.

Guide Dogs for the Blind is a nonprofit charitable organization established to train and make available guide dogs for the visually impaired, especially in the western United States. Its mission is to work toward improved mobility to individuals that would benefit from the partnership with a dog. This volunteer-driven organization works to train and nurture dogs to provide these services to qualified individuals (Guide Dogs for the Blind, 2015). Both the dogs and services are free (with an adoption fee), and the organization relies substantially on donations. It currently has two training sites, one in California and one in Oregon, with puppy raisers located throughout the Western states. The organization can be reached through its Web site (http://welcome.guidedogs.com).

The National Federation of the Blind (NFB) works toward equality and integrating the blind into society. Founded in 1940, its objective is to remove legal, economic, and social discrimination. It also works to educate the public about new concepts concerning blindness and to highlight the achievement of blind people based on talents and capacities as they function to their fullest abilities (National Federation of the Blind, 2016). Citing the need for assistance to the more than 1.1 million children and adults in the United States who are blind, the organization provides public education, information and referral, and support for increased availability of materials in Braille (Display 26–5).

DISPLAY 26.5 WHAT IS BRAILLE?

Braille takes its name from Louis Braille, an 18-year-old blind Frenchman who created a system of raised dots on paper for reading and writing by modifying a system used on board sailing ships for night reading. The six raised dots of each Braille "cell" vary to form palpable letters and punctuation. Persons experienced in

Braille can read at speeds of 200 to 400 words per minute, comparable to print readers. Braille text can be written (1) by hand with a slate and stylus, (2) with a Braille writing machine, or (3) with specialized computer software and a Braille-embossing device attached to the printer.

Source: National Federation of the Blind. (n.d.). Braille–What is it? What does it mean to the blind? Retrieved from http://www.nfb.org/images/nfb/Publications/fr/fr15/Issue1/f150113.html

More information about Braille is available at: http://nfb.org/search/node/braille

The oldest organization devoted to eliminating barriers for the blind and visually impaired is the American Foundation for the Blind (AFB), founded in 1921. The AFB advocates for the visually impaired through increased funding at the federal and state levels in areas such as rehabilitation research for older, visually impaired persons; improved literacy for the visually impaired, including use of Braille and assistive technology; improved employment opportunities; and increased accessibility of technology. In addition, AFB houses the Helen Keller Archives, which contain her correspondence, photographs, and various personal items and documents (AFB, 2016).

The Obesity Society seeks to increase the science-based knowledge related to obesity regarding the causes, consequences, prevention, and treatment (Obesity Society, 2016). The organization addresses such issues as the need for attention to the impact of obesity on death and disability and for increased research, improved insurance coverage, and elimination of discrimination and mistreatment of people with obesity. The Society's Web site (http://www.obesity.org/home) offers informational literature ranging from obesity as a global health problem to treatment of obesity-related disability.

With growing awareness that HIV/AIDS has become a chronic condition for most individuals affected, their long-term needs are gaining increased attention. Hundreds of Web sites and organizations are available to provide information, assistance, and support. One Web site (http://www.thebody.com/; *The Body: The Complete HIV/AIDS Resource* [The Body, n.d.]) offers state-by-state links to a variety of Internet and print resources. The site also includes resources in Canada and specific sites for American Indians and Alaskan Natives.

Begun in the aftermath of World War I, the Disabled American Veterans organization has provided free services to military veterans seeking to obtain benefits for service-related injuries (Disabled American Veterans, n.d.). The organization is not a government agency and receives no federal funds, instead providing services through membership dues and public contributions. The mission of the organization is to help disabled veterans build better lives for themselves and their families. With the growing number of military injuries resulting from the Iraq and Afghanistan conflicts, the organization finds its service delivery even more stretched. The volunteers provide transportation to Veterans Administration (VA) medical facilities and provide ongoing service at VA hospitals, clinics, and nursing homes.

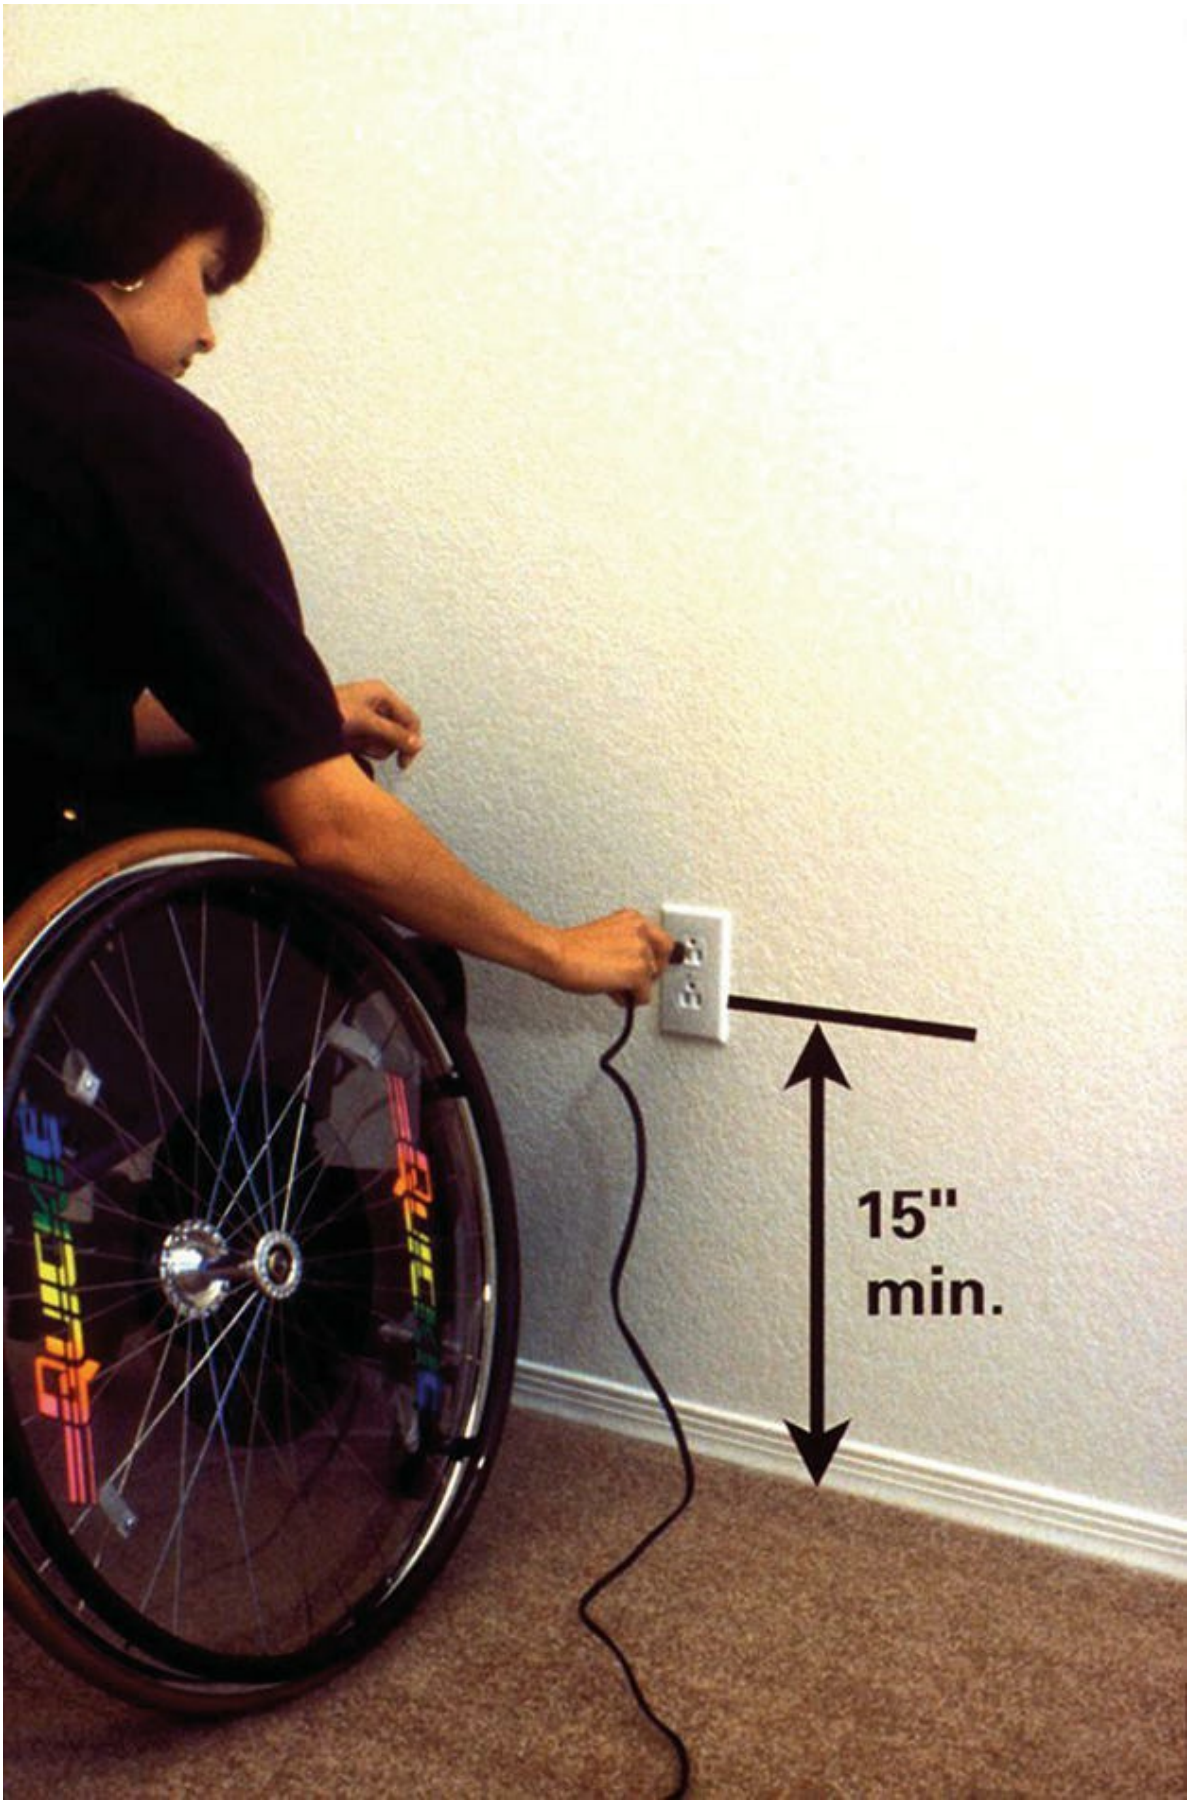
Universal Design

For those living with a disability or chronic disease and their family members, the issue of access is of utmost importance. As noted earlier, the cost to a family to accommodate the needs of a disabled person can be enormous. Considering that as the U.S. population ages, more and more of us will have need of accessibility in housing, business, and recreation in order to remain active and healthy as long as possible. In the concept of universal design, accessibility has been extended toward making tools, houses, and workplaces accessible to all. The cost of building our environments in a way that promotes access for all can be far less than the cost of remodeling those environments after the fact.

Universal design is the purposefully created environments so that things can be accessible by all without the need for modifications. The term "universal design" has been attributed to Ron Mace, founder of the Center for Universal Design, based out of North Carolina State University. Mace, who had suffered from polio as a child, died suddenly in 1998 leaving behind a long legacy of advocacy on behalf of accessibility in design (Center for Universal Design, 2016). Universal design is at the core of the ADA, and the important relationship between these two is important to note as inclusiveness and reduction of barriers to access are considered (Hums, Schmidt, Bocak, & Wolff, 2016). It is important to note that universal design is for all people, and research focusing on universal design has been instrumental in improving the quality of life of visually impaired individuals (Huang & Chiu, 2016) and disabled older adults (Mustaquim, 2015).

The issue of accessibility is not new. The ADA, as discussed earlier, addresses issues of access in employment, governmental building, and public accommodations. The Fair Housing Accessibility Guidelines, effective beginning in 1991, provide for design and construction of multifamily dwellings (four or more units) in accordance with accessibility requirements (United States Department of Housing and Urban Development [USDHUD], n.d.). The specific provisions include the following (Fair Housing Accessibility First, n.d.):

- Public use and common use portions of the dwellings are readily accessible to and usable by persons with handicaps.
- All doors within such dwellings that are designed to allow passage into and within the premises are sufficiently wide to allow passage by persons in wheelchairs.
- All premises within such dwellings contain the following features of adaptive design:
  1. An accessible route into and through the dwelling2. An accessible building entrance that is connected to accessible public transit stop route, as well as accessible parking, loading zones, public sidewalks, and streets3. Light switches, electrical outlets, thermostats, and other environmental controls in accessible locations (see Fig. 26–3)4. Reinforcements in bathroom walls to allow later installation of grab bars5. Usable kitchens and bathrooms such that an individual in a wheelchair can maneuver about the space (see Fig. 26–4)



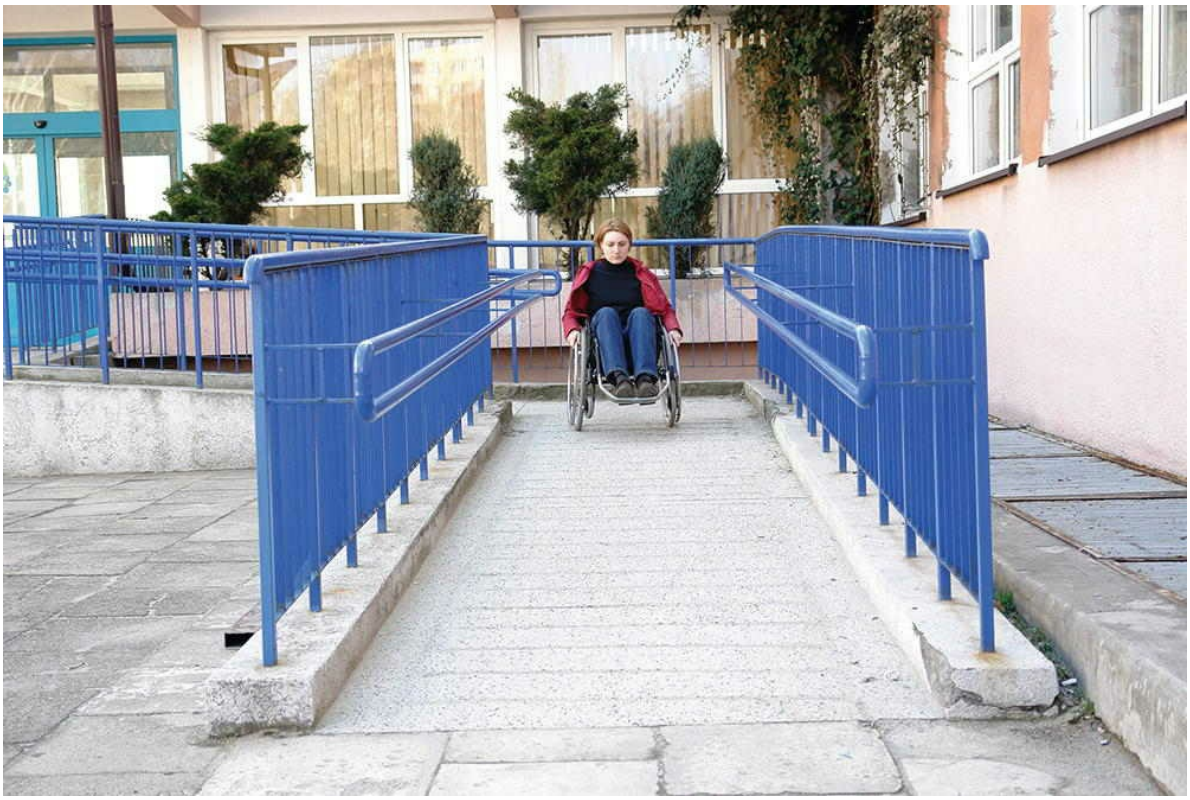


FIGURE 26–3 Recommended height of electrical outlet for ease of access for wheelchair-

seated person. (From CDC Image Library. Retrieved from http://phil.cdc.gov/Phil/quicksearch.asp)

FIGURE 26–4 Universally designed raised dishwasher. (CDC Image Library. Retrieved

from http://phil.cdc.gov/Phil/quicksearch.asp)

Ramps are needed for those using wheelchairs in order to gain access to buildings.

Universal design incorporates access, but access does not necessarily imply universal design. The design of a community's built environment and its impact on individuals plays a role in the overall health and well-being of those living there. Universal design and access play a key role in this discussion, but the importance of accessible design is more far-reaching. According to the CDC, the built environment creates a health environment and health places whereby the quality of life for all, regardless of disability status, is adequate to live, work, play, learn, and worship. This can be achieved through a variety of choices that are healthy, available, accessible, and affordable to all (CDC, 2015).

For those with existing disabilities, assuring ease of access to all types of recreation and exercise options is of paramount importance. For those who may develop disabilities or chronic illnesses, having the opportunities for healthy participation in physical activity may forestall or prevent the development of illness. For the community, having an environment that promotes rather than restricts a healthy lifestyle can be economically advantageous (see Fig. 26–5). Even schools have a role to play (CDC, 2015). Building new schools away from residential areas decreases opportunities for exercise and after-school activities. As parents are increasingly forced to drive their children to school, the children remain sedentary, the pollution from cars is increased, and the risk of automobile accidents increases. Community design is a complicated and evolving issue, but the point remains: a healthier population may be achieved with attention to the environmental barriers that impede healthy lifestyles

for all persons, including those with chronic or disabling conditions.

THE ROLE OF THE COMMUNITY/PUBLIC HEALTH NURSE

This chapter has discussed a number of areas in which the PHN plays a key role. It is important to review those roles in the context of the individual, the family, and the community. Chapter 3 first examined the broad spectrum of roles that the professional nurse assumes within the community (i.e., clinician, educator, advocate, manager, collaborator, leader, researcher). It is helpful to review those roles and think about their application to disabled and chronically ill clients, their families, and the communities in which they live.

Consider an example of the variety of roles and multilevel practice that the PHN assumes with respect to a 55-year-old female client who uses a wheelchair. The client has difficulty obtaining a gynecologic examination because of the lack of accessible examination tables at the local clinic; as a result, she has not had an examination for more than 20 years. Recognizing the need for a complete examination, the public health nurse arranges with the clinic to find appropriate alternatives that will aid the client in receiving the needed examination, possibly by ensuring that additional personnel are provided (advocate role, individual level).

Because this solution is temporary and less than optimal, the nurse contacts a number of clinics in neighboring communities and finds one that has appropriate equipment for people who have difficulty transferring to a standard examination table. Unfortunately, this clinic is 1 hour away. The nurse then contacts a number of other community/public health nurses and discovers that they also have a significant number of women clients with this problem who have not received a gynecologic examination in many years (research role, community level).

Through a coordinated effort with a local transportation company and the clinic, the nurse is able to arrange a twice-yearly gynecologic screening program for women in the community who require special accommodations (advocate and coordinator roles, community level). Information sheets that discuss the need for annual gynecologic examinations and advertise the program are distributed to area public health nurses, employers, and health clinics (educator role, community level). Data collection on examinations provided over the next few years shows a 65% increase in the number of women with special needs who have received a gynecologic examination within the past year (research role, community level).

This is not an uncommon scenario in the practice of community/public health nursing. Often, the needs of an individual may open the door to areas of concern for many in a community and provide a basis for intervention that can benefit a larger population. Just as for nursing practice in general, the role of the public health nurse with respect to disabilities and chronic illness requires a broad and holistic practice. The complexity of issues

surrounding these conditions requires creativity, tenacity, honesty, and, most of all, knowledge. Public health nurses who are informed about the issues that affect the disabled and chronically ill at local, state, and national levels are prepared to offer assistance to their clients and to their communities. Knowledge and advocacy for the civil rights of people living with disabilities, handicaps, and chronic diseases are crucial for nurses serving as their advocates (Mafuba & Gates, 2015).

The issues facing individuals and families with disabilities require strong and sustained efforts to achieve results. Although successes at the individual level are laudable, the extent to which the health and well-being of those affected are improved must be the ultimate goal. Public health nursing is in a prime position to initiate and support efforts to improve the health status of those populations. We can either leave the issues to other professionals or use our expertise and long history of caring for those less fortunate to make major and lasting changes. It is up to us. See an example of one PHN's experience with an individual who became disabled very late in life (From the Case Files: Annie's Story).

From the Case Files I

Annie's Story

Annie married young and had a couple of kids, but ended up divorced and supporting them on her own. She eventually married the love of her life, but he died from medical complications during a routine procedure. She worked very hard and had made a good living on her own. Her children were grown when she met her third husband. She was 80 when he died, and she continued to work at her business and taking care of her many rental properties. She worked most days, was fiercely independent, and was generally in good health.

This is where I enter the story. I met Annie at a community event and we hit it off instantly. She was interested in my work as a PHN, and I enjoyed working with seniors and hearing their life stories. Annie certainly had an interesting one. Hearing I was a nurse, she talked to me about her osteoporosis and having broken an arm and an ankle. She was still jet skiing with friends and family into her 80s, and she drove her large RV to scenic spots—often traveling alone (except for her beloved dog, Emily). She lived alone, too, in a large two-story house on a golf course. She also liked to golf, refusing to use a golf cart, and enjoying the exercise. She exemplified what I wanted to be when I reached my "golden years." She was happy, energetic, positive, and generally healthy (no hypertension, arthritis, or diabetes) and had many friends and colleagues who cared about her. Her kids lived out of state, but she talked with them often and visited when she could. She was well known in the

community and loved by all who got to know her.

When Annie turned 90, she slipped and fell getting out of the shower. She broke her hip and lay on her back unable to get up or even to roll over onto her stomach. She was there for 5 days before being discovered. She lived in a desert area, and the air is very dry. The air conditioning was on, but it wasn't very cool on the second level. She had bowel movements and urinated while on the floor, and scooted on her back to get to some toilet paper and attempted to clean herself. She prayed—a lot. She said she knew that there was a God who was listening to her. She worried for her little dog, but she had done something that morning she didn't usually do. She had filled Emily's water dish with extra water. Each time Emily would drink water, she would go over to Annie and lick her mouth with her moist tongue. Annie lost track of time and felt like this ordeal would go on forever. The fall happened on Friday morning of a holiday weekend, but on the fifth day after her fall, she didn't show up for work at her business raising concern. Her colleagues called emergency personnel and they broke into her house, finding her lying naked on the floor. She was so embarrassed, and she told the young paramedics that she was sorry for "giving them that mental picture for life." Amazingly, her sense of humor was still there.

Annie spent a long time in the hospital, dealing with her fractured pelvis, dehydration, and an electrolyte imbalance, among other things. I went to see her, but this vibrant, independent woman was very confused and "different." She was transferred to three different skilled nursing facilities and was never able to return to her beautiful home. She had planned for her life to end independently—living in one of her smaller houses, maybe with some part-time help. It was so difficult for her to end up in a "nursing home." What happened to her on that floor in those 5 days caused so much damage to her heart and her body, as well as to her spirit, that she ended up in a downward spiral. She died in a nursing home shortly before her 93rd birthday.

Annie had lived a very long life in good health and thought that she could continue to do so until "something gave out." This is an example to me that we are all just a quick fall or an accident away from being disabled. If it could happen to Annie, it could happen to any of us!

Nell, PHN

It is important for PHNs to consider population health among the disabled. As Grady (2011) reminds us, our U.S. population is living longer, is suffering multiple chronic illness and disabilities, and needs nurses trained to meet the requirements of this aging population. Population health promotion and prevention of secondary disabilities is also a public health concern across age groups and conditions (Ouellette-Kuntz, Cobigo, Balogh, Wilton, & Lunsky, 2015). Community-based interventions that help support disabled populations with self-management skills, improve health behaviors, and prevent secondary disabilities

have been shown to be popular and can result in cost savings as well as improved health outcomes (Ravesloot et al., 2016). See Population-Focus.

POPULATION-FOCUS ON ADVANCE DIRECTIVES

Advance directives are a very personal and individual matter. Whenever you or I go into the hospital or surgery center for a procedure, we are usually asked by an admitting nurse or clerk if we have an advance directive (no matter our age or health status). How many people actually answer in the affirmative? Autonomy is a hallmark of ethical thought (see Chapter 4). We believe that people should be able to choose for themselves and have their choices respected; hence, the right to leave the hospital against medical advice (AMA). Therefore, we wait for patients to express their preference about advance directives (or the choice to have none).

Have you ever considered this from a population perspective? When someone does not choose a plan for end-of-life care, the option by default generally becomes full medical treatment and lifesaving measures to delay death, despite the futility of the pending outcome. Often, this causes needless suffering and is costly in terms of manpower and resources. But, do individuals truly understand their options? Can we offer better explanations of the alternatives? Behavioral economists explain that people are not always good at systematically looking at best evidence in order to make decisions. We rely on what others think or on rules of thumb because we are often faced with "decision fatigue." We are programmed to avoid loss and seek immediate rewards. Taking this into consideration, and the knowledge that terminal patients want comfort and quality of life at the end of life, researchers gave participants three options: (1) advance directives for comfort-oriented care (where life might be shorter), (2) advance directives for a longer life (where there might be more pain and suffering), and (3) no directives. Because of the way choices were structured, twice as many people chose the option with comfort as the goal over the other two choices. They termed this "choice architecture," as this reframing of the choices to draw attention to outcomes helps to "nudge" people toward their definitive goals (Hostetter & Klein, 2013, para. 17).

The argument could be made that evidence supports advance directives for comfort-oriented care, but is it ethical to influence behavior in this way? The elderly are a growing population, and the lack of advance directives does lead to more economic burden on the healthcare system. Population-focused initiatives are needed

to educate the elderly about advance directives and the potential outcomes of the choices they make. Can you think of creative ways of addressing this issue on a population level?

Hostetter, M., & Klein, S. (2013, June–July). In focus: Using behavioral economics to advance population health and improve the quality of health care services. Quality Matters. Retrieved from http://www.commonwealthfund.org/publications/newsletters/quality-matters/2013/june-july/in-focus

SUMMARY

The issues of disability and chronic illness are of growing importance in public health and to community/public health nursing, both nationally and internationally. Through the efforts of the WHO, the international community has been challenged to provide increased attention to health promotion and disease prevention. Even in less developed countries, behavioral patterns linked to excesses in consumption (overweight and tobacco/alcohol use) have an impact on the quality and quantity of healthy years of life. The health promotion and disease prevention needs of the disabled and chronically ill must be given the same emphasis as the needs of those who are not disabled or ill.

The aging of the U.S. population and the rise in lifestyle-related illnesses such as diabetes and obesity are often linked with increasing rates of disability. Prevention of disability and disease is emphasized in *Healthy People 2020*, and it alerts Americans over the decades about the need to give serious attention to health-promoting and disease prevention activities. *Healthy People* has placed increasing focus on health promotion and disease prevention needs of those with disabilities and chronic illness. It is no longer acceptable that these individuals receive care solely for tertiary health needs. Research has shown that when health-promoting (lifestyle) issues are addressed with these clients, the rates of secondary conditions are reduced, including medical, social, emotional, mental, family, and community problems. Disabilities and chronic conditions are not universally debilitating, and the overall well- being and health of these individuals must be a priority.

Legislation is but one step toward equality for those affected by disabilities and chronic illnesses. The IDEA and ADA secured many improvements in accessibility and specific legal protections for the disabled, but it is only the beginning. Discrimination can occur at many levels; some is hurtful and intentional, but most results from misunderstanding of the needs and desires of disabled persons and their families. This may even occur in relation to the provision of health care because of lack of education. Improvement can be found only with increased community education programs for professionals and the public that target the myths and misunderstandings about those with disabilities and chronic illnesses.

The next time you have difficulty opening a door that is unusually heavy or struggle to open the lid of a jar or feel that you were treated differently than someone else in the receipt of services, take a moment to think. Think about the challenges, struggles, and pain that face so many citizens. Consider the impact of universal design at improving your life or the life of a family member or friend. Although many argue against improving accessibility of city streets and sidewalks because of the expense, those same people may one day find that they, too, are faced with trying to master a curb that is just a bit too high.

Public health nurses are in a prime position to advocate for the health needs of the disabled and chronically ill. With a long history of serving those who are most vulnerable, public health nurses can help make needed changes at the individual, family, and community levels. Although it is often easier to focus on the needs of the individual, those

needs are most often shared by many others, thus making it a population-level concern. Nurses have long recognized the need to collaborate with other professionals in reaching the goal of improved health care for their clients; this continues to be an important aspect of successful efforts on behalf of the disabled and the chronically ill. It will take the concerted efforts of many to implement the changes necessary to improve the lives of those most affected, their families, and the communities in which they live.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Interview an individual with a disability (e.g., hearing, vision, mobility) about the challenges that he or she has faced in interactions with nondisabled persons and in everyday activities.
2. Search the Web for sites related to disabled individuals and read some of the personal stories posted there. Discuss with a classmate how you might feel if you suddenly found yourself in these circumstances. How would you cope and adjust?
3. Take an inventory of your house or apartment and make a list of modifications you would need to make if you were abruptly confined to a wheelchair. Would you even be able to stay in your current residence (e.g., are you living in a building with only stairs to your second floor apartment)? What resources are available in your community to assist disabled individuals and families?
4. As part of your regular clinical assignment in community health clinical working with clients and families who are either disabled or have a chronic illness, assess how often you or other PHNs have addressed health promotion activities (e.g., healthy eating, physical activity, leisure-time activities) with those clients. Does the public health department have any outreach services for disabled clients to encourage them to get routine preventive services? Ask some of your clients with disabilities and chronic illnesses about their experiences and feelings about preventive services.
5. Review your family history for chronic health conditions. Are you at risk? If so, what have you done to reduce your risk over the past 12 months? Can any of these chronic health conditions lead to impaired visual, hearing, or motor functions?
6. Using the public health nursing roles of clinician, educator, advocate, manager, collaborator, and leader, research and record specific examples of the roles that PHNs assume in relation to disabilities and chronic illnesses. Take note of each role that you participate in or observe while completing your clinical experience. If you cannot find examples of the various roles at each level, interview a PHN during your clinical experience and find examples of how the nurse performs activities in each of those roles. You will most likely find that while addressing a single issue with a client, the public health nurse serves in a variety of roles and at different levels.

27 CHAPTER

Behavioral Health in the Community

"Mental health and mental disorders are not opposites, and mental health is not just the absence of mental disorder."

—World Health Organization

"Addiction is a primary, chronic disease of brain reward, motivation, memory, and related circuitry. Dysfunction in these circuits leads to characteristic biological, psychological, social, and spiritual manifestations."

—American Society of Addiction Medicine

KEY TERMS

Addiction
Alcohol-related disorders
At-risk alcohol use
Behavioral health
Community mental health
Community mental health centers
Community mental health nurse
Craving
Intoxication
Mental health
Mental health care system
Recovery
Relapse
Screening
Self-stigma
Serious mental illness (SMI)
Social stigma
Structural stigma
Substance-related disorders
Tolerance

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Discuss the incidence and prevalence of mental illness and substance use in the United States.
- Identify the *Healthy People 2020* objectives for reducing substance use and addressing mental health needs.
- Describe the role of the community health nurse across the continuum of care individuals and populations with mental and substance-related disorders.
- Implement individual-, community-, and policy-level interventions to promote behavioral health and

recovery.

This chapter provides an overview of behavioral health, a term used to refer to both mental health and substance use. A comprehensive approach to behavioral health recognizes a continuum of care, from promotion to prevention, treatment, and recovery. Community health nursing practice with a focus on individual-, community-, and policy-level interventions is discussed. The community health nurse has a key role in working with individuals, families, and communities to promote optimal behavioral health and thereby decrease the prevalence and incidence of mental and substance-related disorders. See Display 27–1: Behavioral Health Terminology.

DISPLAY 27.1 BEHAVIORAL HEALTH TERMINOLOGY

- Addiction: A complex neurobiobehavioral disorder characterized by impaired control, compulsive use, and repetition despite the consequences (Merlo, Wandler, & Gold, 2014).
- Alcohol-related disorders: A category of alcohol-induced disorders including a pattern of alcohol use leading to clinically significant impairment or distress (alcohol use disorder), intoxication (i.e., clinically significant problematic behavioral or psychological changes that develop during or shortly after alcohol ingestion), withdrawal (problematic behavioral change with physiological and cognitive concomitants that is due to the cessation of or reduction in heavy and prolonged alcohol use), and other alcohol-induced mental disorders (symptom profiles resemble independent mental disorders as describe in the *DSM*) (APA, 2013).
- At-risk alcohol use: Any level of alcohol consumption that increases the risk of harm to a person's health or well-being or that increases the risk of harm to others. The thresholds, listed below, are based on population studies among healthy adults (21 years and older) and are a starting point for evaluating risk in individuals. Various health conditions and activities may warrant lower levels or no alcohol consumption at all (Finnell, Mitchell, & Savage, in press).
    - Within a short period of time (i.e., 2 hours), which typically brings the average adult's blood alcohol concentration above 0.08 g/dL (also considered binge alcohol use) for the following is:
        - Women (healthy ≥ 21 years): consuming more than 3 drinks within a 2-hour period

        - Men (healthy ≥ 21 to 65 years): consuming more than 4 drinks within a 2-hour period
        - Men (healthy > 65 years): consuming more than 3 drinks within a 2-hour period
    - In a single day:
        - Women (healthy ≥ 21 years): consuming more than 3 drinks a day
        - Men (healthy ≥ 21 to 65 years): consuming more than 4 drinks a day
        - Men (healthy > 65 years): consuming more than 3 drinks a day
    - In a week:
        - Women (healthy ≥ 21 years): consuming more than 7 drinks a week
        - Men (healthy ≥ 21 to 65 years): consuming more than 14 drinks a week
        - Men (healthy > 65 years): consuming more than 7 drinks a week
- Behavioral Health: A term used to refer to both mental health and substance use. A comprehensive approach to behavioral health recognizes a continuum of care, from promotion to prevention, treatment, and recovery.
- Community mental health: A field of practice that seeks to promote the mental health of the community by preventing mental disorders and addressing the needs of persons with a mental disorder.
- Community mental health centers (CMHCs): Facilities that provide comprehensive, publicly funded services to the mentally ill population.
- Community mental health nurse: An individual whose practice is centered on the mental health needs of the populations served.
- Mental health care system: The collective programs designed for anyone with a mental illness. These programs may include treatments, services, or other types of supports, such as housing, employment, or disability benefits through government, private nonprofit, or private for-profit systems.
- Mental health: As defined in *Healthy People 2020*, mental health is "a state of successful performance of mental function, resulting in productive activities, fulfilling relationships with other people, and the ability to adapt to change and cope with challenges" (U.S. Department of Health and Human Services [USDHHS], 2016, para. 2).
- Mental disorders: "Health conditions that are characterized by alterations in thinking, mood, and/or behavior that are associated with distress and/or impaired functioning. Mental disorders contribute to a host of problems that may include disability, pain, or death" (USDHHS, 2016, para. 3).
- Recovery: A process of change through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential (http://www.samhsa.gov/recovery).
- Relapse: Continued use of a substance after a period of abstinence. Return to

heavy alcohol, tobacco, or drug use after a period of abstinence or moderate use (Douaihy, Daley, Marlatt, & Donovan, 2014).

- Serious mental illness (SMI): As defined by SAMHSA, "adults aged 18 or older who currently or at any time in the past year have had a diagnosable mental, behavioral, or emotional disorder (excluding developmental and substance use disorders) of sufficient duration to meet diagnostic criteria specified within DSM-IV (APA, 1994) that has resulted in serious functional impairment, which substantially interferes with or limits one or more major life activities" (SAMHSA, 2014).
- Substance-related disorders: Encompassing 10 separate classes of drugs that, taken in excess, have in common direct activation of the brain reward system, producing such an intense activation that normal activities may be neglected. This system is involved in the reinforcement of behaviors and the production of memories (APA, 2013).
- Screening: A mechanism used to detect health risks or problems using an established measure (i.e., psychometrically sound questionnaire such as the DISPLAY 27–1Behavioral Health Terminology (Continued)Alcohol Use Disorders Identification Test) or method (i.e., laboratory test such as drug toxicology using breath, blood, urine, hair).
- Tolerance: A need for markedly increased amounts of alcohol or drug to achieve intoxication or the desired effect or a markedly diminished effect with the continued use of the same amount of alcohol or drug (APA, 2013)

DEFRAGMENTING HEALTH CARE

Over the past several years, efforts have been undertaken to bridge the separate systems of care for persons with mental disorders, substance use disorders, and primary health. These changes are particularly relevant for community health nurses who have public health knowledge and skills to address the needs and problems of communities and vulnerable populations (see Chapter 1). Community health nurses, from their perspective of community-based and population-focused practice, understand that the communities in which people live and work have a profound influence on the collective health and well-being of the population.

The fragmented mental health service delivery system was identified by the president's New Freedom Commission on Mental Health (TPNFCMH, 2003) as a major impediment to the provision of quality mental health care. A person with medical, mental health, and substance use concerns moves between separate systems to receive needed care and among multiple health care providers within those systems. The best outcome can be promoted by integrating behavioral health and medical care for people with multiple health care needs. The shift to both improving and integrating behavioral and medical care has been facilitated by the Affordable Care Act (ACA) of 2014, the Mental Health Parity and Addiction Equity Act (MHPAEA) of 2008, and health coverage offered through Medicaid Expansion and the Marketplace requiring provision of mental health and substance use disorder benefits. Integrative care, according to the Agency for Health Care Research and Quality, "is derived from a practice team of primary care and behavioral health clinicians, working together with patients and families, using a systematic and cost-effective approach to provide patient-centered care for a defined population" (Peek & National Integration Academy Council, 2013, p. 2). The field of community health nursing has an integral role in assuming responsibility as a full professional partner in integrated care for the health of the community.

In considering the health of the community, it is important to keep in mind the continuum of health to illness. The World Health Organization (2014) defines mental health as "a state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community" (p. 1). Behavioral, biological, and environmental mechanisms are linked to various human responses, such as anxiety, depression, and substance use. Community health nurses can intervene at three levels of prevention taking measures to keep illness or injuries from occurring (primary prevention), to detect and treat existing health problems at the earliest possible stage when a disorder or impairment is already present (secondary prevention), and to reduce the severity of a health problem to minimize disability, restore or preserve function, and promote recovery efforts (tertiary prevention).

Several documents address the need for prevention and treatment of mental health

disorders, such as *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2016b), *Mental Illness Surveillance Among Adults in the United States* (Centers for Disease Control and Prevention [CDC], 2011), and the classic *Report of the Surgeon General on Mental Health*, submitted by David Satcher (USDHHS, 1999). This 1999 report on mental health was the first Surgeon General's report ever published on the topic of mental health and mental illness. That report concluded that mental disorders are among the most prevalent and costly conditions and that effective treatments can reduce their prevalence and decrease their adverse effect on other health conditions.

The health care goals addressed within *Healthy People 2020* (USDHHS, 2016b) are relevant to community mental health nursing (see Tables 27–1 to 27–3). The overall goal for mental health and mental disorders is to improve mental health through prevention and by ensuring access to appropriate, quality mental health services. Only one of the indicators (MHMD11.1) met the target, and that was for a single year in 2013. A decrease in all indicators is needed to fully meet the targets. According to the 2014 progress report, from 2006 to 2010, the suicide rate increased about 7%, from 11.3 per 100,000 people (age adjusted) to 12.1, moving away from the *Healthy People 2020* target of 10.2 per 100,000 people. Additionally, between 2008 and 2012, the percentage of adolescents aged 12 to 17 reporting having had a major depressive episode in the past 12 months increased about 10%, from 8.3% to 9.1%, moving away from the *Healthy People 2020* target of 7.5% (Department of Health and Human Services Office of Disease Prevention and Health Promotion, 2014). Nearly a decade and a half later after the 1999 Surgeon General's Report and several years since *Healthy People 2020* was launched, the Substance Abuse and Mental Health Services Administration (SAMHSA, 2013a) reported that not all people are receiving treatment and not all people receive the appropriate type or adequate quantity or quality of care. Thus, greater efforts are needed to address the behavioral health needs of the nation.

Table 27–1 *Healthy People 2020*—Summary of Objectives for Mental Health and Mental Disorders (MHMD)

Goal: Improve mental health through prevention and by ensuring access to appropriate, quality mental health services

Number	Objective
Mental Health Status Improvement	
MHMD-1	Reduce the suicide rate
MHMD-2	Reduce suicide attempts by adolescents
MHMD-3	Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight
MHMD-4	Reduce the proportion of persons who experience major depressive episodes (MDEs)
MHMD-4.1	Reduce the proportion of adolescents aged 12 to 17 years who experience MDEs
MHMD-4.2	Reduce the proportion of adults aged 18 years and older who experience MDEs
Treatment Expansion	
MHMD-5	Increase the proportion of primary care facilities that provide mental health treatment onsite or by paid referral
MHMD-6	Increase the proportion of children with mental health problems who receive treatment
MHMD-7	Increase the proportion of juvenile justice facilities that screen admissions for mental health problems
MHMD-8	Increase the proportion of persons with serious mental illness (SMI) who are employed
MHMD-9	Increase the proportion of adults with mental health disorders who receive treatment
MHMD-9.1	Increase the proportion of adults aged 18 years and older with SMI who receive treatment
MHMD-9.2	Increase the proportion of adults aged 18 years and older with MDEs who receive treatment
MHMD-10	Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders
MHMD-11	Increase depression screening by primary care providers
MHMD-11.1	Increase the proportion of primary care physician office visits where adults 19 years and older are screened for depression
MHMD-11.2	Increase the proportion of primary care physician office visits where youth aged 12 to 18 years are screened for depression
MHMD-12	Increase the proportion of homeless adults with mental health problems who receive mental health services

From U.S. Department of Health and Human Services (USDHHS). (2016). Healthy People 2020: Mental health & mental disorders objectives. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicId=28

Table 27–2 *Healthy People 2020*—Summary of Objectives for Substance Abuse

Goal: Reduce substance abuse to protect the health, safety, and quality of life for all, especially children

Number	Objective
Policy and Prevention	
SA-1	Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol
SA-2	Increase the proportion of adolescents never using substances
SA-3	Increase the proportion of adolescents who disapprove of substance abuse
SA-4	Increase the proportion of adolescents who perceive great risk associated with substance abuse
SA-5	(Developmental) Increase the number of drug, driving while impaired (DWI), and other specialty courts in the United States
SA-6	Increase the number of states with mandatory ignition interlock laws for first and repeat impaired driving offenders in the United States
Screening and Treatment	
SA-7	Increase the number of admissions to substance abuse treatment for injection drug use
SA-8	Increase the proportion of persons who need alcohol and/or illicit drug treatment and received specialty treatment for abuse or dependence in the past year
SA-9	(Developmental) Increase the proportion persons who are referred for follow-up care for alcohol problems, drug problems after diagnosis, or treatment for one of these conditions in a hospital emergency department (ED)
SA-10	Increase the number of level I and level II trauma centers and primary care settings that implement evidence-based alcohol screening and brief intervention (SBI)
Epidemiology and Surveillance	
SA-11	Reduce cirrhosis deaths
SA-12	Reduce drug-induced deaths
SA-13	Reduce past month use of illicit substances
SA-14	Reduce the proportion of persons engaging in binge drinking of alcoholic beverages
SA-15	Reduce the proportion of adults who drank excessively in the previous 30 days
SA-16	Reduce average annual alcohol consumption
SA-17	Decrease the rate of alcohol-impaired driving (0.08 + blood alcohol content [BAC]) fatalities
SA-18	Reduce steroid use among adolescents
SA-19	Reduce the past-year nonmedical use of prescription drugs
SA-20	Decrease the number of deaths attributable to alcohol
SA-21	Reduce the proportion of adolescents who use inhalants

From U.S. Department of Health and Human Services (USDHHS). (2016). Healthy People 2020: Substance abuse. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicId=40

Table 27–3 *Healthy People 2020*—Summary of Objectives for Tobacco (Selected)

Goal: Reduce illness, disability, and death related to tobacco use and secondhand smoke exposure

Number	Objective
Tobacco Use	
TU-1	Reduce tobacco use by adults
TU-2	Reduce tobacco use by adolescents
TU-3	Reduce the initiation of tobacco use among children, adolescents, and young adults
TU-4	Increase the smoking cessation attempts by adult smokers
TU-5	Increase recent smoking cessation success by adult smokers
TU-6	Increase smoking cessation during pregnancy
TU-7	Increase smoking cessation attempts by adolescent smokers
Health Systems Changes	
TU-8	Increase the comprehensive Medicaid insurance coverage of evidence-based treatment for nicotine dependency in states and the District of Columbia
TU-9	Increase tobacco screening in health care settings
TU-10	Increase tobacco cessation counseling in health care settings
Social and Environmental Changes	
TU-11	Reduce the proportion of nonsmokers exposed to secondhand smoke
TU-14	Increase the proportion of smoke-free homes
TU-17	Increase the Federal and State tax on tobacco products

From U.S. Department of Health and Human Services (USDHHS). (2016). Healthy People 2020: Tobacco use. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicId=40

Despite advances in health coverage for mental health and substance use treatment and efforts undertaken to integrate behavioral and primary health care, stigma continues to be a major barrier to treatment. Stigma is manifest at the self, social, and structural levels:

- Self-stigma is a subjective experience characterized by negative feeling about one's self or maladaptive behavior resulting from one's own experiences, perceptions, or anticipation of negative reactions (Livingston & Boyd, 2010).
- Public or social stigma is a phenomenon of large social groups endorsing stereotypes about and acting against a group that is stigmatized, such as persons with mental disorders (Corrigan, Kerr, & Knudsen, 2005).
- Structural stigma refers to institutional rules, policies, and procedures that restrict rights or opportunities for members of stigmatized groups (Corrigan et al., 2005; Corrigan, Roe, & Tsang, 2011).

A systematic review found limited evidence for empirically evaluated interventions for substance use–related stigma (Livingston, Milne, Fang, & Amari, 2012). Despite the limited evidence to reduce stigma, community health nurses can help mitigate stigma by leading primary prevention strategies such as educational interventions enhanced by

facilitated interactions between the public and persons who live with stigmatized health conditions. Programs that focus on educating nurses and other health care providers about mental and substance use disorders are also needed, given the limited content in formal curricula. For example, a survey study of nursing schools identified a mean of 11.3 hours of alcohol-related content; a gap signifying that nurses may not have the knowledge and competencies to care for this population (Savage, Dyehouse, & Marcus, 2014). Teaching providers and the public about the neurobiological basis of these disorders may help to dispel attitudes toward and beliefs about persons with these disorders (Finnell & Nowzari, 2013). The terminology used relative to these stigmatizing health conditions also matters. The language that is used should respect the worth and dignity of all persons, that is, people-first language (Broyles et al., 2014). Language frames what the individual thinks and how they can be affected (i.e., self-stigma) and what the public thinks and promotes (i.e., social stigma) and informs the rules, policies, and procedures of institutions (i.e., structural stigma). Community health nurses can model the use of people-first language, such as the person with depression or the person who is at risk because of alcohol use.

INCIDENCE AND PREVALENCE OF MENTAL DISORDERS, SUBSTANCE USE, AND SUBSTANCE USE DISORDERS

Mental and substance use disorders are a worldwide problem. The World Health Organization measures burden of disease using the disability-adjusted life years (DALYs). This metric combines years of life lost (YLLs) because of premature mortality and YLLs because of time lived in states of less than full health. Findings from the most recent Global Burden of Disease Study were released in 2012. Mental and substance disorders were the fifth leading causes of disease burden in 2010 (Whiteford et al., 2013).

Suicide, defined as deaths caused by intentional, self-inflicted poisoning or injury, was the 13th leading cause of YLLs worldwide in 2010 (Lozano et al., 2012; Wang et al., 2012). When suicide is taken into account as a risk factor, mental and substance use disorders were responsible for two thirds of the suicide burden in 2010, elevating them to the third leading disease category of global burden in 2010. In developed countries, suicides are the largest source of intentional injury burden (Ferrari et al., 2014; World Health Organization [WHO], 2014). According to the CDC (2015), suicide was the 10th leading cause of death for all ages in 2013. Males take their lives at nearly four times the rate of females, with firearms being the most commonly used method among males (56.9%). Females are more likely than males to have suicidal thoughts and the most common method for suicide for females is poisoning. Among U.S. students in grades 9 to 12, 17.0% seriously considered attempting suicide in the previous 12 months, 13.6% made a plan, 8% attempted suicide, and 2.7% made an attempt that required medical attention (CDC, 2015).

Three large surveys, supported by the Department of Health and Human Services, provide national prevalence estimates of diagnosable mental illness. These surveys include the National Comorbidity Survey Replication (NCR-R), the National Comorbidity Survey Replication Adolescent Supplement (NCS-A), and the National Survey on Drug Use and Health (NSDUH). The NSDUH is a primary source of information on the use of illicit drugs, alcohol, and tobacco among U.S. citizens aged 12 years or older. Prevalence data for mental illness in the United States varies depending on the survey and methodology used. A 2015 report by Bagalman and Napili (2015) summarizes prevalence data from the three different surveys. For the NCR-R survey administered in 2001 to 2003, estimates of mental illness among adults were reported to be 26.2% and 32.4%, and when substance use disorders were excluded, the 12-month prevalence of mental illness was 24.8% among adults. The 12-month prevalence of SMI was estimated to be 5.8%. Using NCS-A data gathered from 2001 to 2004, the 12-month prevalence of mental illness among adolescents was 40.3% with SMI estimated to be 8.0% among this age group. Based on the NSDUH survey, the estimated 12-month prevalence of mental illness, excluding substance use

disorders, was 18.5% among adults aged 18 or older with SMI estimated to be 4.2% among adults. Estimates of mental illness for adolescents aged 12 to 17 are not reported from the NSDUH survey (Han, Hedden, Lipari, Copello, & Kroutil, 2015). Regardless of the statistical caveats, a large proportion of the population is impacted.

Depression, bipolar disorder, schizophrenia, panic disorder, alcohol, and drug use were among the top 20 leading causes of disability according to the most recent study by the World Health Organization. Depression was also the one of the leading cause of DALYs, with the burden of depression 50% higher for females than males. Among women 15 to 44 years, depression is the leading cause of disease burden in both high-income and low- and middle-income countries. Compared with males, females were also noted to have a higher burden from anxiety disorders (WHO, 2008).

In 2013, about 24.6 million Americans surveyed with the NSDUH had used an illicit drug during the past month. This is about 9.4% of the population aged 12 years or older, a rate slightly higher than 8.9% reported in 2010. Across age groups, illicit drug use decreased slightly among youths aged 12 to 17 from the previous surveys (9.6% to 11.6% in 2002 and 2007) to 8.8% in 2013. Among adults aged 50 to 64, illicit drug use increased from 2.7% in 2002 to 6% in 2013. Results for illicit drug use among other aged groups (18 to 25 and adults aged 26 or older) in 2 to 13 were similar to rates in previous years (SAMHSA, 2014).

Among the illicit drugs, marijuana was the most commonly used (80.6% of those currently using illicit drugs) in 2013, with an increase from 5.1 million in 2005 to 2007 to 8.1 million persons in 2013 (SAMHSA, 2014). Cocaine use estimates of 1.5 million in 2013 were similar to those in 2012 (1.7 million) and 2009 (1.4 million). Heroin use in 2013 (681,000) was similar to the number in 2012 (669,000) and 2009 (582,000). Concerning, however, is that heroin use, even when it is not sustained, has been shown to predict a 3- to 4-fold excess risk of dying prematurely (Lopez-Quintero et al., 2015).

Methamphetamine use in the early 1990s was primarily a problem in the Western United States; however, the use has spread across the United States. In 2014, almost 569,000 people in the United States ages 12 and up reported using methamphetamines in the past month (Center for Behavioral Health Statistics and Quality, 2015). The most recent financial report from the RAND Corporation noted that methamphetamine abuse cost the nation approximately $23.4 to $48.3 billion in 2005 (Nicosia, Pacula, Kilmer, Lundberg, & Chiesa, 2009). Injuries, as a result of the illegal manufacture of methamphetamine, are also a major concern because its production can cause fires, explosions, injuries, and environmental contamination. A recent study examined injuries from methamphetamine-related chemical incidents in five states. A total of 1,325 meth-related chemical incidents were reported in the five states from 2001 to 2012 with 16% of injuries occurring in children. The percentage of injured persons who went to a hospital increased over time, from 75% (2001 to 2004), to 86% (2005 to 2007), to 90% (2008 to 2012) (Melnikova, Orr, Wu, & Christensen, 2015).

The rise in the nonmedical use of prescription opioids is also of concern. In the 2013 NSDUH survey, the percentage of persons aged 12 or older who used prescription drugs nonmedically in the past month was 2.5%, similar to the percentages in 2012 (2.7%) and 2010 (2.4%). However, among this age group who used pain relievers nonmedically in the past 12 months, 53% reported that they obtained the drug from a friend or relative for free and 10.6% brought the drug from a friend or relative. Other means of obtaining the prescription drug was from one physician (21.2%), from a drug dealer or stranger (4.6%), or about 0.1% purchased from the Internet (SAMHSA, 2014).

In the 2013 NSDUH Survey, more than half (52.2%) of Americans aged 12 or older reported current alcohol use, similar to the rate in 2012 (52.1%). Alcohol use among those aged 12 to 17 was 11.6% in 2013. This underage population reported obtaining alcohol by purchasing it (7.8%) or giving money to someone else to purchase it (20.5%). Among this age group who did not pay for alcohol, 36.6% got it from an unrelated person aged 21 or older; 24.5% from a parent, guardian, or other adult family member; and 16.4% from another person younger than 21 years old (SAMHSA, 2014). The Centers for Disease Control and Prevention (CDC, 2014b) reports that about 2 in 3 high school students who drink do so to the point of intoxication, that is, they binge drink (defined as having five or more drinks in a row), typically on multiple occasions. The NSDUH Survey defined binge use as having five or more drinks on the same occasion on at least 1 day in the 30 days prior to the survey (SAMHSA, 2014). From the NSDUH data, nearly one quarter (22.9%) of persons aged 12 or older reported binge alcohol use in 2013, with youth binge rates of 6.2%, lower than those in 2012 (12.9%). A growing concern is alcohol use among the older adult population with alcohol accounting for more than 21,000 deaths among adults 65 or older each year in the United States, and from the NSDUH Survey, 41.7% of people aged 65 and older reported current alcohol use with 9.1% reporting binge use (CDC, 2013; SAMHSA, 2014).

Social inequalities are associated with increased risk of many common mental disorders. A review of 115 studies conducted in low- and middle-income countries sought to explain the relationship between poverty and common mental disorders. In community-based studies, over 70% reported positive associations between a variety of poverty measures and common mental disorders, and 6% reported negative associations (Lund et al., 2010). Disparities are also evident in access to and receipt of mental health care. Using data from the National Health Interview Survey 2010 to 2013, researchers compared non-Hispanic Black and Hispanic men with non-Hispanic White men on mental health symptoms and mental health treatment utilization. Racial and ethnic differences were observed only for men aged 18 to 44 with non-Hispanic Black and Hispanic men nearly 30% less likely than non-Hispanic White men to have daily feeling of anxiety or depression. Among men aged 18 to 44 who had anxiety or depression, non-Hispanic Black and Hispanic men (26.4%) were less likely than non-Hispanic White men (45.4%) to have used mental health treatment. The disparity in treatment utilization was associated with lack of health insurance coverage (Blumberg, Clarke, & Blackwell, 2015).

There is a 13- to 30-year reduction in life expectancy for persons with SMI; the vast majority of deaths are due to physical illness. A review of the literature examined the association between physical illnesses and schizophrenia, bipolar disorder, and major depressive disorder. Researchers identified many physical disorders (e.g., obesity, diabetes, cardiovascular disease, viral diseases, respiratory tract diseases, metabolic syndrome, cancer, musculoskeletal diseases, urological, male/female genital diseases and pregnancy complications, stomatognathic diseases) that are more prevalent in individuals with SMI. The authors note that modifiable lifestyle factors and psychotropic medication side effects, as well as poor access to and quality of received health care contribute to the morbidity and mortality for persons with SMI (Hert et al., 2011).

Data from the 2007 National Health Interview Survey was used to compare sociodemographic and health characteristics, health care utilization, and participation in government assistance programs among adults with and without SMI. Over 2% of adults reported having a diagnosis of an SMI. Compared with their counterparts, those with SMI were younger, less educated, more likely to be poor and to live alone, and less likely to work. Further, 36% of adults with SMI reported having spent at least 24 hours either homeless or incarcerated during their lifetime, in contrast to 5% of other adults reporting that experience (Pratt, 2012). The homeless population with SMI faces many challenges. A descriptive study of mostly males in a state-operated mental health transitional shelter identified that 60.8% had a prior episode of homelessness and half had a history of incarceration. More than one third (36.5%) had a history of physical, sexual, or verbal/emotional abuse, and 23.0% had experienced adverse events in childhood. Co-occurrence of substance use disorders, mental disorders, and chronic medical illness was common; 36.5% had one or more diagnosis from each category. High rates of substance use disorders (44.6%) and chronic medical illnesses (82.4%) were noted (Viron, Bello, Freudenreich, & Shtasel, 2014).

Age influences the patterns of mental disorders in the community. Using data from the NCS-A survey of 10,123 adolescents aged 13 to 18 years in the United States, researchers found that anxiety disorders were the most common condition (31.9%), followed by behavior disorders (19.1%), mood disorders (14.3%), and substance use disorders (11.4%). The median age of onset was earliest for anxiety (6 years), followed by behavior disorders (11 years), mood disorders (13 years), and substance use disorders (15 years). Attention deficit/hyperactivity disorder (ADHD) is thought to be more common in boys than girls with estimated ratios ranging between 2:1 and 9:1 (Merikangas et al., 2010; Rucklidge, 2010). Prevalence estimates of ADHD vary depending on the person reporting symptoms for diagnostic evaluation, what instrument is used, and when more than one informant is used, as well as how the information is combined. A systematic review and meta-analysis was conducted using 175 unique studies including a majority conducted within school populations (74%) and 10% using a whole population approach. The overall pooled prevalence of ADHD was 7.2% (Thomas, Sanders, Doust, Beller, & Glasziou, 2015). ADHD can persist into adulthood, though is often underdiagnosed and untreated. ADHD

prevalence in the adult population is 2.5% to 5% worldwide. In the United States, the most recent large-scale prevalence study noted 4.4% of adults have ADHD; however, other researchers note that adult ADHD is often underdiagnosed (Fayyad et al., 2007; Ginsberg, Quintero, Anand, Casillas, & Upadhyaya, 2014; Kessler et al., 2006; Simon, Czobor, Bálint, Mészáros, & Bitter, 2009).

Autism spectrum disorder (ASD) is a neurodevelopmental disorder that typically manifests early in development, often before the child enters grade school. ASD is characterized by persistent deficits in social communication and social interaction (American Psychiatric Association [APA], 2013). In 2014, the CDC reported that 1 in 68 children have been diagnosed with ASD and that it is almost five times more common among boys (1 in 42) than among girls (1 in 189). Considered to be chronic and permanent in conditions, data from the 2011 Survey of Pathways to Diagnosis and Services were used to better understand the path to diagnosis for children with ASD. The study by Blumberg et al. (2015) suggests that some children may be diagnosed with ASD though their symptoms (e.g., developmental delays, problems with attentional flexibility) may not meet diagnostic criteria. There may be variability in the quality of screening and evaluation leading to imprecise diagnosing (CDC, 2014a; Fenikile, Ellerbeck, Filippi, & Daley, 2014). Thus, rates of ASD need to be viewed with caution.

Asperger's syndrome has been absorbed into the diagnosis of ASD in the current fifth edition of the *Diagnostic and Statistical Manual* (APA, 2013). This disorder is marked by social interaction and verbal difficulties as well as difficulties with nonverbal communication. The prevalence of ASD is not well established, and while no studies have yet been conducted to determine the incidence of Asperger's syndrome in adult populations, studies of children with the disorder suggest that their problems with socialization and communication continue into adulthood (National Institute of Neurological Disorders and Stroke, 2015).

For American adults, according to the National Institute of Mental Health, the 12-month prevalence rate of anxiety is 18.1% of the U.S. adult population with women being 60% more likely than men to experience an anxiety disorder over their lifetime. On average, the lifetime prevalence rate for anxiety in people ages 18 to 59 years is 32%. The 12-month prevalence rate of mood disorders is 9.5% of the U.S. adult population with women 50% more likely than men to experience a mood disorder over their lifetime. On average, the lifetime prevalence rate for mood disorders for persons ages 18 to 59 years is about 23%. The 12-month prevalence for schizophrenia, a chronic, severe, and disabling mental disorder, is 1.1% of the U.S. adult population, with men and women affected equally (NIMH, n.d.).

Older adults tend to have lower rates of frequent mental distress compared with other age groups. According to the National Institute of Mental Health, adults 60 years or older have a 15.3% lifetime prevalence rate for an anxiety disorder and an 11.9% lifetime prevalence rate for a mood disorder (NIMH, n.d.). The Federal Interagency Forum on Aging-Related Statistics (2012) reported that men had higher suicide rates than women,

with the largest difference occurring at age 85 and above (43 deaths per 100,000 for men compared with 3 per 100,000 for women). From the same report, non-Hispanic White men over age 85 had the highest rate of suicide overall at 47 deaths per 100,000. National prevalence estimates of Alzheimer's disease and other age-related cognitive impairment in older adults are lacking, likely because of the use of various measures or instruments to screen and assess for these disorders/conditions, but also because of differences in definitions and criteria used.

Mental and substance use disorders affect families, for whom support is available and accessible. Founded in 1979, the National Alliance on Mental Illness (NAMI) serves to provide advocacy, education, and support for persons affected by mental disorders. A survey conducted by NAMI assessed the experiences of 2,720 people living with mental disorders and their families who had private health insurances. The survey results identified a number of barriers that people with mental and substance use disorders encounter in their efforts to obtain quality care, including finding providers, accessing prescription medications, high out-of-pocket costs, and lack of access to information needed for informed decision making related to health plans (NAMI, 2015). Additional family-focused programs include classics such as:

- Community Reinforcement and Family Training (CRAFT), designed for families who were trying to encourage their family member to go into treatment. A 12-session structured program is available (Smith & Meyers, 2007), as is a CRAFT self-help book (Meyers & Wolfe, 2004).
- Free and easily accessible mutual support groups provide support for friend and families of persons with alcohol problems such as Al-Anon (www.al-anon.org), based on the twelve-step model, and Learn to Cope, Inc., a peer-led support network that offers support, education, recourses, and hope for families affected by mental and substance use disorders (www.learn2cope.org).
- Family psychoeducation is a means to provide information about mental disorders and learn problem-solving, communication, and coping skills. The Substance Abuse and Mental Health Services Administration (SAMHSA) provides an evidence-based family psychoeducation kit that is accessible at http://store.samhsa.gov/product/Family-Psychoeducation-Evidence-Based-Practices-EBP-KIT/SMA09-4423.

Cost of Mental and Substance Use Disorders

In addition to the human costs of mental and substance use disorders, the economic costs are also substantial. In describing the burden of mental, neurological, and substance use disorders, researchers point out that the total economic output lost to these disorders globally was about $8.5 trillion; if unabated, the cost will double by 2030. Further, the economic costs attributable to alcohol use and alcohol use disorders alone are about 1.3% to 3.3% of the gross domestic product of high- and middle-income countries (Patel et al., 2015). Despite evidence-based treatments focusing on prevention and early intervention, inpatient treatment accounts for a high proportion of the costs. In 2012, for example, 8.6 million inpatient stays in the United States involved at least one mental disorder or substance use disorder diagnosis, accounting for 32.3% of inpatient stays. Further, among stays with one of these disorders, 13.9% lacked insurance; this is more than two times greater than that among the 6% of stays without those diagnoses (Heslin, Elixhauser, & Steiner, 2015).

The Patient Protection and Affordable Care Act (PPACA) and the MHPAEA of 2008 are two sentinel pieces of legislation helping to reform health care. In analyzing data from a national survey of commercial health plans after the implementation of the MHPAEA, Horgan et al. (2015) concluded that the law had the intended effect of eliminating the quantitative limitations that applied only to behavioral health care without eliminating behavioral health coverage. This study provides support that the main goals of MHPAEA are being realized for increasing access to behavioral health services and ensuring equity with general medical services. Further promise lies with the implementation of integrated medical and behavioral health care. Melek, Norris, and Paulus (2014) suggest that a savings of $40 to $50 billion dollars annually could be realized with such integration, surpassing what is currently spent on mental health care in the United States.

Promotion, Prevention, Treatment, and Recovery for Mental and Substance Use Disorders

The Institute of Medicine (IOM) commissioned an investigation on mental health interventions that resulted in the development of the IOM "protractor" depicting a continuum of care as prevention, treatment, and recovery (Mrazek & Haggerty, 1994). The model, shown in Figure 27–1, explicitly includes promotion as a key component. This model provides a systematic framework for community health nurses to view the nature and degree of risk faced by persons with behavioral health issues as diagnosable disorders. Promotion strategies reinforce the entire continuum of behavioral health services. Promotion is aimed at supporting behavioral health and assisting individuals in withstanding challenges they encounter across the continuum.

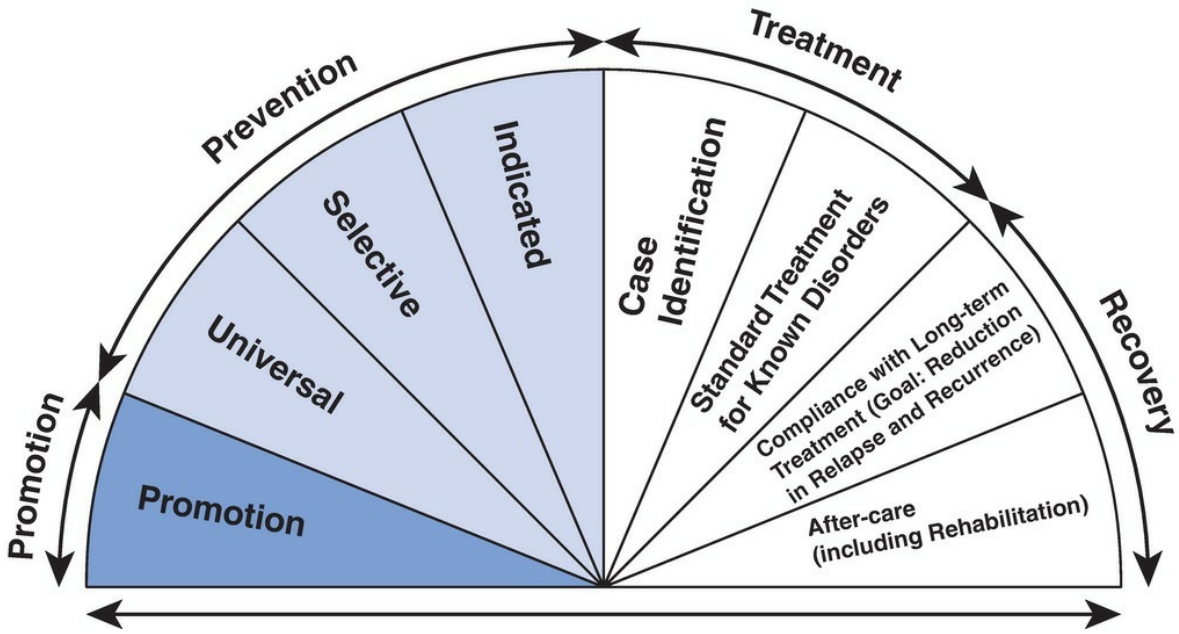

FIGURE 27–1 Behavioral health continuum of care model. (From Substance Abuse and Mental Health Services Administration (SAMHSA). (2015). Prevention of substance abuse and mental illness. Retrieved from http://www.samhsa.gov/prevention.)

Prevention strategies include three distinctions: universal, selective, and indicated as different levels of risk characterized by Gordon (1983) in a classic article on prevention. *Universal prevention* includes those strategies delivered to broad populations wherein the benefits outweigh the costs and risks for everyone. Examples of this include public health campaigns related to suicide prevention, legislation related to impaired driving, and minimum age for purchase of alcohol.

Selective strategies are indicated when a person's risk of becoming ill is elevated. Through detection of risk, vulnerable subgroups of individuals can be identified. As a result, programs and practices can be provided to reduce the risk. An example of a selective

strategy would be a program to address binge alcohol consumption among college students. Selective strategies for depression among adolescents include school-based, cognitive–behavioral, and family-based intervention programs (Gladstone, Beardslee, & O'Connor, 2011).

Indicated strategies address specific risk conditions, focusing efforts on individual risk factors or behaviors that put individuals at high risk for developing a behavioral disorder. Examples of indicated strategies include personalized normative feedback, an approach for reducing alcohol consumption among college students and the use of acceptance and commitment therapy in reducing suicidal ideation and depression among veterans (Dotson, Dunn, & Bowers, 2015; Walser et al., 2015).

Case identification entails the ability to correctly identify those individuals who have a behavioral disorder with minimal false positives. Thus, it is important to have measures with a high degree of sensitivity and specificity. Relevant optimal measures are presented later in this chapter. Yet, case identification will have limited benefit if there are no effective treatments in place.

Greater understanding of the mechanisms that underlie behavioral disorders (e.g., genetics, biological, behavioral, environmental) has resulted in established evidence-based treatments. A wide variety of pharmacological, psychotherapeutic, and social interventions have been established. For example:

- Antipsychotic, antidepressant, anxiolytic, and mood stabilizer medications are used to treat various mental disorders (Stahl, 2013).
- Medications used for alcohol use include those that produced adverse effects when alcohol is consumed (e.g., disulfiram) and those that modify the neurotransmitter systems that mediate alcohol reinforcement (e.g., naltrexone, acamprosate) (Myrick, Kranzler, Ciraulo, Saxon, & Jaffe, 2014).
- The principle opioid medications are those that act as μ-opioid receptor antagonists (e.g., naloxone and naltrexone), full agonist (e.g., methadone), partial agonist (e.g., buprenorphine), and the nonopioid α_2 adrenergic agonists (e.g., clonidine) (Stein & Kosten, 2014).
- Pharmacologic interventions for tobacco dependence include nicotine replacement therapy (e.g., gum, lozenge, nasal spray, nasal inhaler, patch), reuptake inhibitor of both norepinephrine and dopamine (i.e., bupropion), and partial nicotine agonist/antagonist (i.e., varenicline) (Hurt, Ebbert, Hays, & McFadden, 2014).

There are a number of evidence-based psychotherapies with procedures defined in manuals and efficacy established as single treatment or in combination with pharmacotherapy (Weissman, 2015). Although a wide variety of these interventions have a major role in the treatment of mental and substance use disorders, a report from the IOM states that they are not used routinely in clinical practice or taught in educational programs preparing health professionals to deliver them. Further, no standard system is in place to

ensure that the psychosocial interventions delivered to patients/consumers are effective. Despite the availability of treatments and efforts to increase access to treatment though the PPACA, only 39% of the 45.9 million adults with mental health disorders used mental health services in 2010 (England, Butler, & Gonzalez, 2015). In 2014, among the 4.1 million people in the United States aged 12 or older that received substance use treatment in the past year, the majority (2.2 million) reported receiving treatment though self-help groups. Outpatient treatment was the next highest modality for treatment, either in a rehabilitation facility (1.7 million) or mental health center (1.2 million). About 1.1 million received inpatient treatment in a rehabilitation or hospital setting (Han, Hedden, Lipari, Copello, & Kroutil, 2015).

In 2014, about 22.5 million people in the United States aged 12 or older needed substance use treatment, but only 11.6% received treatment at a specialty substance use treatment facility. Thus, the needs of 88.4% of this subgroup of the U.S. population, who warrant indicated strategies, were not addressed. Reasons for not receiving substance use treatment included not ready to stop using, no health coverage and could not afford, and not knowing where to go for treatment (Han et al., 2015). Community health nurses can have a significant role in removing such barriers to treatment.

Recovery is the final component of the Behavioral Health Continuum of Care Model. In their systematic review on personal recovery, Leamy, Bird, Le Boutillier, Williams, and Slade (2011) summarize personal recovery with the acronym CHIME (connectedness, hope, optimism about the future, identify, meaning in life, and empowerment). These aspects are aligned with SAMHSAs' guiding principles of recovery that focus on promoting a high-quality and satisfying life in the community for all people. Community health nurses can engage in partnership with individuals in supporting and promoting recovery goals, monitoring progress toward and recognizing movement away from goals, tailoring support, and supporting transitions throughout the recovery process. Community health nurses can engage in recovery movements, calling attention in order to educate the public on how stigma, including associated stigma, impedes help seeking and treatment participation (Ricci & Dixon, 2015; Yarborough, Yarborough, Janoff, & Green, 2015).

Substance Use and the Community Health Nurse

A survey of schools of nursing identified that about 11 hours of alcohol-related content was included in baccalaureate nursing curricula. Further, <10% required student competency in strategies to detect risk that would prompt the need for further indicated actions, such as brief interventions (BIs) (Savage et al., 2014). This gap in the curricula of BSN programs carries serious implications, in that nurses may not have the requisite understanding of alcohol and other drugs. Reductions in substance use (including tobacco) are 2 of the 44 focus areas in *Healthy People 2020*. See Table 27–2 for a list of substance abuse objectives. The goal is to "reduce substance abuse to protect the health, safety, and quality of life for all, especially children" (USDHHS, 2016a, para. 1). Among the 21 objectives listed are reducing the consequences of use, reducing actual use, reducing risk factors associated with harmful use, increasing access to treatment, and supporting policy initiatives.

The community health nurse plays a vital role in developing successful prevention and treatment programs related to substance use in a community. These prevention programs should be aligned with the Behavioral Health Continuum of Care Model previously discussed. The community health nurse focuses on the target population. For instance, *Monitoring the Future* is a yearly survey of drug and alcohol use among 8th, 9th, and 12th graders. Existing data such as these help determine the magnitude of the problem. Given a defined target geographic area, local health departments may have county-specific prevalence rates. The *Healthy People 2020* objectives related to substance use (Table 27–2) and tobacco use (Table 27–3) provide target benchmarks that can be used by the community health nurse in planning and developing prevention programs.

Whether providing individual-, community-, or policy-level interventions for substance use, the community health nurse must begin with a basic understanding of alcohol and other drugs; signs of use, intoxication, and withdrawal; and associated health risks. This understanding can help the community health nurse select an effective strategy (i.e., universal, indicated, targeted) that meets the particular needs of the population, subgroup, or individual. Table 27–4 lists some of the most commonly used substances.

Table 27–4 Substances Commonly Used

Substance	Facts	Signs of Use	Possible Health Risks
Alcohol			
Standard drink contains about 14 g of pure alcohol (about 0.6 fluid ounces or 1.2 tablespoons)	A small, water-soluble molecule that is rapidly absorbed into the bloodstream from the stomach, small intestine, and colon. Metabolized primarily by enzymatic pathways; small amounts are excreted through the lungs as vapor.	Acutely acts as central nervous system depressant. When blood levels are rising, a period a disinhibition often occurs and signs of behavioral arousal are common (e.g., relief of anxiety, increased talkativeness, feelings of confidence and euphoria, enhanced assertiveness). As blood levels increase, there are impairments in judgment and reaction time, increased emotional outbursts, and ataxia. At higher blood levels, alcohol acts as a sedative and hypnotic, but quality of sleep is often reduced after alcohol intake.	A carcinogen associated with 44% of some cancers A teratogen contributing to increased risk of fetal alcohol spectrum disorders, which include physical, behavioral, and learning disabilities Negative effects on many body systems (e.g., central nervous system, cardiovascular, immune, gastrointestinal, hepatic, hematopoietic) In patients with sleep apnea, alcohol increases the frequency and severity of apneic episodes and the resulting hypoxia.
Cannabis			
Hashish (hash, herb, kif) Hashish oil (hash oil, honey) Marijuana (grass, weed, dope, ganja, reefer, pot, Acapulco gold, Thai sticks)	Synthesized from the hemp plant, *Cannabis sativa*. Tetrahydrocannabinol (THC) is the major psychoactive ingredient in cannabis. Binds to cannabinoid receptors in the brain. Inhalation produces the most rapid onset. Marijuana and hash may also be taken orally via food products with slower onset of effect and slower offset of action. Tolerance and physical dependence can develop. Sinsemilla is a highly potent form of marijuana.	Relaxation and euphoria Altered perceptions of time and space Hallucinations or anxiety attacks with use of highly potent cannabis (sinsemilla)	Major effects on respiratory system. Complex effects on immune system, with host resistance impaired by THC administration. Increases heart rate, produces orthostatic hypotension, may worsen congestive health failure, and increases hypertension Deleterious effects in patients with liver disease Marijuana can disrupt the female reproductive system and induce galactorrhea. In male animals (effects in human are unclear), disrupts reproductive function, reducing the secretion of testosterone and sperm production, motility, and viability
Nonalcohol Sedative Hypnotics			
Barbiturates (downers, barbs) Benzodiazepines (Valium, Librium, tranquilizers) Chloral hydrate (knockout, Mickey Finn) Glutethimide (Doriden) Methaqualone (Quaalude, Ludes) Other depressants (Equanil, Miltown, Noludar, Placidyl, Valmid)	Depressants act on major neurotransmitter systems in the brain. Benzodiazepines exert clinical effects trough the Gamma-aminobutyric acid (GABA) receptor, leading to the sedative, anticonvulsant, hypnotic, and amnestic effects of the drug. Barbiturates and sedative–hypnotic drugs have similar action, but different binding affinities to the GABA receptors.	Produce effects on a continuum from sedation to obtundation. Barbiturates have a greater risk for respiratory depression than do benzodiazepines. High doses of benzodiazepines—ataxia and impaired gag reflex	Mild withdrawal: anxiety, headache, insomnia, dysphoria, tremor, muscle twitching Severe withdrawal: autonomic dysfunction, nausea, vomiting, depersonalization, derealization, delirium, hallucinations, illusions, agitation, grand mal seizures
Hallucinogens			
Lysergic acid diethylamide (LSD) Phencyclidine (PCP, angel dust) Mescaline and peyote (Mesc, buttons, cactus) Psilocybin (mushrooms) Amphetamine variants (MDMA/Ecstasy, MDA/love drug, TMA, DOM, DOB, PMA, STP, 2,5-DMA) PCP analogues (PCE, PCPy, TCP) Other hallucinogens (bufotenine, ibogaine, DMT, DET)	Hallucinogens are psychedelic, mind-altering drugs that affect a person's perception, feelings, thinking, self-awareness, and emotions. A "bad trip" may result in the user's experiencing panic, confusion, paranoia, anxiety, unpleasant sensory images, feelings of helplessness, and loss of control. A "flash back" is a reoccurrence of the original drug experience without taking the drug again.	Dilated pupils, increased body temperature, heart rate, and blood pressure; sweating; loss of appetite; sleeplessness; dry mouth; tremors; hallucinations; disorientation; confusion; paranoia; violence; euphoria; anxiety; and panic	Agitation; extreme hyperactivity; psychosis; convulsions; mental or emotional problems; death
Inhalants			
Amyl nitrate (poppers, snappers) Butyl nitrate (rush, bolt, bullet) Chlorohydrocarbons (aerosol sprays, cleaning fluids) Hydrocarbons (solvents, airplane glue, gasoline, paint thinner) Nitrous oxide (laughing gas, whippets)	Breathable chemicals that can be self-administered as gases or vapors. Products can be gases, liquids, aerosols, or, in some cases, solids. Toxicologic effects of the compounds differ. Subdivisions of abused inhalants include (1) volatile alkyl nitrates, (2) nitrous oxide, and (3) solvents, fuels, and anesthetics. Once inhaled, solvents rapidly enter the brain and distribute to lipid-containing membranes within the CNS.	A diverse array of acute effects, depend on the produced used. These effects may be euphoria and light-headedness; excitability; loss of appetite; forgetfulness; weight loss; sneezing; coughing; nausea and vomiting; lack of coordination; bad breath; red eyes; sores on nose and mouth; delayed reflexes; decreased blood pressure; flushing (skin appears to be reddish); headache; dizziness; and violence.	CNS depression, respiratory problems, or suffocation, which may lead to death Neurotoxicity Irritation of the eyes, nose, and mouth; localized skin rash Inflammation of the lungs Effects on major organ systems (i.e., liver, kidney) Use during pregnancy—decreased fertility, spontaneous abortions, adverse effects on infant (low birth weight, facial and other physical abnormalities, microcephaly, delayed neurologic and physical maturation), fetal solvent syndrome
Opioids			
Heroin (H, harry, junk, brown sugar, smack) Morphine and synthetic compounds (oxycodone, codeine, meperidine, pentazocine, hydromorphone, hydrocodone, methadone, levo-alpha-acetyl, buprenorphine)	Narcotics are composed of opiates and synthetic drugs. Opioids refer to all compounds, natural and synthetic, functionally related to opium derived from poppies and endogenous opioid neuropeptides chemically developed to produce the effects of opiates. Act primarily on the brain's mu opioid receptor, which mediates both analgesic and rewarding effects of opioid compounds as well as their effects on many systems in the body (e.g., hypothalamic–pituitary–adrenal axis, immune, gastrointestinal, and pulmonary).	Acute opioid overdone: stupor or coma, respiratory depression, pinpoint pupils Cough, nausea, vomiting Euphoria; restlessness and lack of motivation; drowsiness; lethargy; decreased pulse rate; constricted pupils; flushing (skin appears to be reddish); constipation; nausea and vomiting; needle marks on extremities; skin abscess at injection sites; shallow breathing; watery eyes; and itching	CNS: depression of the mental status, depression of respiratory activity, suppressed gag reflex, generalize seizures Pulmonary: frothy, pink bronchial secretions, cyanosis, rales, bronchospasm Cardiovascular: orthostatic hypotension, mild tachycardia, with IV use—bacterial endocarditis, venous thrombosis, septic pulmonary emboli, emboli of cornstarch and talc (additives) to the retina, lungs, kidney, and liver, with high doses of methadone—prolongation of QT interval and torsades de pointes Gastrointestinal: nausea, vomiting, slowing of GI motility (constipation and fecal impaction)
			Renal: rhabdomyolysis, glomerulonephritis Musculoskeletal: muscle rigidity of chest and abdominal wall, with IV use—osteomyelitis, septic arthritis, polymyositis, fibrous myopathy Infectious diseases: injection—transmission of IVE, hepatitis B, hepatitis C, cellulitis, skin and neck abscesses, endocarditis, botulism Fetal and neonatal: premature births; stillbirth, and acute infections among newborns, neonatal abstinence syndrome
Steroids			
Anabolic–androgenic (roids, juice, D-ball)	Compounds that possess anabolic or tissue-building effects The acceleration of physical development is what makes steroids appealing to athletes and young adults. Anabolic–androgenic steroids are chemically related to the male sex hormone testosterone. Steroids are injected directly into the muscle or taken orally.	Sudden increase in muscle and weight; increase in aggression and combativeness; violence ("roid rage"); hallucinations; jaundice; purple or red spots on body, inside mouth, or nose; swelling of feet or lower legs (edema); tremors; and bad breath. For women: breast reduction, enlarged clitoris, facial hair and baldness, deepened voice. For men: enlarged nipples and breasts, testicle reduction, enlarged prostate, baldness	Acne; high blood pressure; liver and kidney damage; heart disease; increased risk of injury to ligaments and tendons; bowel and urinary problems; gallstones and kidney stones; liver cancer. For men: impotence and sterility. For women; menstrual problems. For users who share or use unsterile needles to inject steroids: hepatitis, tetanus, AIDS
Cocaine, Amphetamines, and Other Stimulants			
Amphetamines (uppers, pep pills) Cocaine (coke, flake, snow) Crack (rock) Ephedra Khat Methamphetamines (ice, crank, crystal) Methylphenidate (Ritalin) Phenmetrazine (Preludin, Preludes) Other stimulants (Adipex, Cylert, Didrex, Ionamin, Melfiat, Plegine, Sanorex, Tenuate, Tepanil, Prelu-2)	Stimulants include both naturally occurring plant alkaloids (e.g., cocaine, ephedra, khat) and synthetic compounds (e.g., amphetamines, methylphenidate). Smoked stimulants are rapidly absorbed through the lungs and reach the brain in 6 to 8 s, followed by a rapid decline in effect. IV administration produces brain effect in 4 to 7 min. Intranasal and oral stimulants have slower absorption and onset of effect (30 to 45 min).	Intense pleasurable feeling; increased energy, alertness, and sociability; elation or euphoria; and decreased fatigue, need for sleep, and appetite Increased pulse rate, blood pressure, and body temperature; insomnia; loss of appetite; sweating; dry mouth and lips; bad breath; disorientation; apathy; hallucinations; irritability; and nervousness	Cardiovascular: increased heart rate, blood pressure, and systemic vascular resistance Pulmonary: acute and chronic pulmonary toxicity (smoked); cough, shortness of breath, wheezing, chest pain, hemoptysis, exacerbation of asthma Gastrointestinal: reduced gastric motility and delayed gastric emptying Endocrine: decreased (acute cocaine use) or increased (chronic cocaine use) plasma prolactin levels

Detecting Risk and Intervening

This section discusses the use of screening in behavioral health as a means for identification of mental health issues and substance use and providing early intervention. The U.S. Preventive Services Task Force, for over a decade, has recommended screening and *brief intervention* to reduce alcohol use by adults (USPSTF, 2015; Whitlock, Polen, Green, Orleans, & Klein, 2004). Given recommendations and mandates from multiple federal agencies and large health care organizations, nurses have been called upon to actively engage in integrating this health initiative into practice (American Public Health Association [APHA], 2008; Finnell et al., 2014). Given their major roles as clinician, educator, advocate, manager, collaborator, leader, and researcher, community health nurses can be instrumental in helping to reduce the harms associated with alcohol and other drug use through the use of the strategies described below. The section that follows discusses how to screen for risk for mental disorders, alcohol, drug, and tobacco use and, based on the evidence, what interventions are recommended based on the identified risk.

Screening is the presumptive identification of an unrecognized disease or defect by the application of tests, examinations, or other procedures that can be applied rapidly. Table 27–5 lists established measures for screening mental health problems, alcohol, and other drugs. From an apparently well population, screening tests separate persons who potentially have or are at increased risk for a disease from those who probably do not have the disease. A positive screening test result should be followed by a comprehensive assessment and, if indicated, evaluation to determine if a mental or substance-use disorder is present.

Treatment should be initiated when a diagnostic determination has been made.

Table 27–5 Screening Tools

Measure	Description	Source
Adapted-SAD PERSONS (sex, age, depression or affective disorder, previous attempt, ethanol drug abuse, rational thinking loss, social supports lacking, organized plan, negligent parenting, significant family stressors, suicidal modeling by parents or siblings, school problems)	10-item scale for suicide risk	Juhnke, G. A. (1996). The adapted-SAD persons: A suicide assessment scale designed for use with children. *Elementary School Guidance & Counseling, 30*(4), 252–258.
Alcohol Use Identification Test: 1–3 (U.S.)	3-item scale to identify alcohol consumption that is in excess of recommended guidelines	Babor, T. F., Higgins-Biddle, J. C., Dauser, D., Burleson, J. A., Zarkin, G. A., & Bray, J. (2006). Brief interventions for at-risk drinking: Patient outcomes and cost-effectiveness in managed care organizations. *Alcohol and Alcoholism, 41*(6), 624–631.
AUDIT (U.S.)	10-item scale to identify persons likely to be at risk, those at risk because of excessive alcohol use, those who have already experienced problems related to alcohol use, and those who may have an alcohol use disorder	See above.
Beck Depression Inventory	21-item measures characteristic attitudes and symptoms of depression	Beck, A. T., Ward, C. H., Mendelson, M., Mock, J., & Erbaugh, J. (1961). An inventory for measuring depression. *Archives of General Psychiatry,* 4, 561–571.
Brief Psychiatric Rating Scale (BPRS)	16-item scale screening for schizophrenia or other psychotic disorder	Overall, J. E., & Gorham, D. R. (1962). The brief psychiatric rating scale. *Psychological Reports, 10*(3), 799–812.
Center for Epidemiologic Studies Depression Scale (CES-D) (10 and 20 item versions)	10-item or 20-item screen for current depressive symptomatology related to major or clinical depression in adults and children	Radloff, L. S. (1977). The CES-D scale a self-report depression scale for research in the general population. *Applied Psychological Measurement, 1*(3), 385–401.
Cornell Scale for Depression in Dementia	19-item using information from patient and nursing staff interviews	Alexopoulos, G. S., Abrams, R. C., Young, R. C., & Shamoian, C. A. (1988). Cornell scale for depression in dementia. *Biological Psychiatry, 23*(3), 271–284.
Drug Abuse Screening Test (DAST)	10-item measure to determine the extent of drug use	Skinner, H. A. (1982). The drug abuse screening test. *Addictive Behaviors, 7*(4), 363–371.
Edinburgh Postnatal Depression Scale	10-item measure for coping with life changes of pregnancy and childbirth	Cox, J. L., Holden, J. M., & Sagovsky, R. (1987). Detection of postnatal depression. Development of the 10-item Edinburgh Postnatal Depression Scale. *The British Journal of Psychiatry, 150*(6), 782–786.
Generalized Anxiety Disorder	7-item screening tool for anxiety	Spitzer, R. L., Kroenke, K., Williams, J. B., & Löwe, B. (2006). A brief measure for assessing generalized anxiety disorder: The GAD-7. *Archives of Internal Medicine, 166*(10), 1092–1097.
Geriatric Depression Scale	15-item yes/no screening for depression in older adults	Burke, W. J., Roccaforte, W. H., & Wengel, S. P. (1991). The short form of the Geriatric Depression Scale: A comparison with the 30-item form. *Journal of Geriatric Psychiatry and Neurology, 4*(3), 173–178.
Patient Health Questionnaire-9 (PHQ-9) PHQ-2	9-item screen for depression in adults First 2 items from PHQ-2	Kroencke, K., Spitzer, R., & Williams, J. (2001). The PHQ-9: Validity of a brief depression severity measure. *Journal of General Internal Medicine, 16*(9), 606–613.
Primary Care Posttraumatic Stress Disorder (PC-PTSD)	4-item screen for post-traumatic stress disorder	Hanley, J., & Brasel, K. (2013). Efficiency of a four-item posttraumatic stress disorder screen in trauma patients. *Journal of Trauma and Acute Care Surgery, 75*(4), 722–727.

Given the stigma associated with these disorders, it is important to spend time addressing your role and, as with any conversations related to health, seeking permission to engage in the screening process and describing what will be done. The community health nurse needs to be cognizant that his/her beliefs and attitudes toward persons with mental

and substance use disorders sets the stage for interactions with and the provision of interventions including recovery support for a person with one or more of these disorders. A government panel examining a tool to measure stigma found about only about one quarter of U.S. adults agreed that people are caring and sympathetic to people with mental illness (Kobau, DiIorio, Chapman, & Delvecchio, 2010). Community health nurses are in key positions to model therapeutic relationships with the vulnerable populations.

Behavioral health occurs along a continuum of care, from promotion to prevention, treatment, and recovery. The severity of symptoms associated with a mental disorder is variable, as are the symptoms that may never manifest as a diagnosable disorder. Similarly, substance use occurs across a continuum, from low risk to at risk to a possible substance use disorder. When developing a screening program to detect mental health and substance use, the community health nurse should be prepared to provide interventions or be able to refer persons whose screening results suggest that referral to specialty services is indicated. Therefore, a program should have links to clinically appropriate treatment services for persons across the continuum. Thus, the community health nurse should be knowledgeable of community agencies that provide mental health and substance abuse treatment. To ensure linkages to care, it is important to know the treatment capacity of the community where screening programs are being conducted. See Chapter 12.

MENTAL HEALTH DISORDERS: SCREENING, INTERVENTION, AND REFERRAL TO TREATMENT

The incidence and prevalence of mental and substance use disorders points to the importance of universal screening. For example, the National Depression Screening Day is an example of a community-level approach to screening. Resources and supplies, such as a comprehensive kit of materials, promotional information, media campaign, training, and technical assistance, are available by visiting the mental health screening Web sites (see Internet Resources found on thePoint).

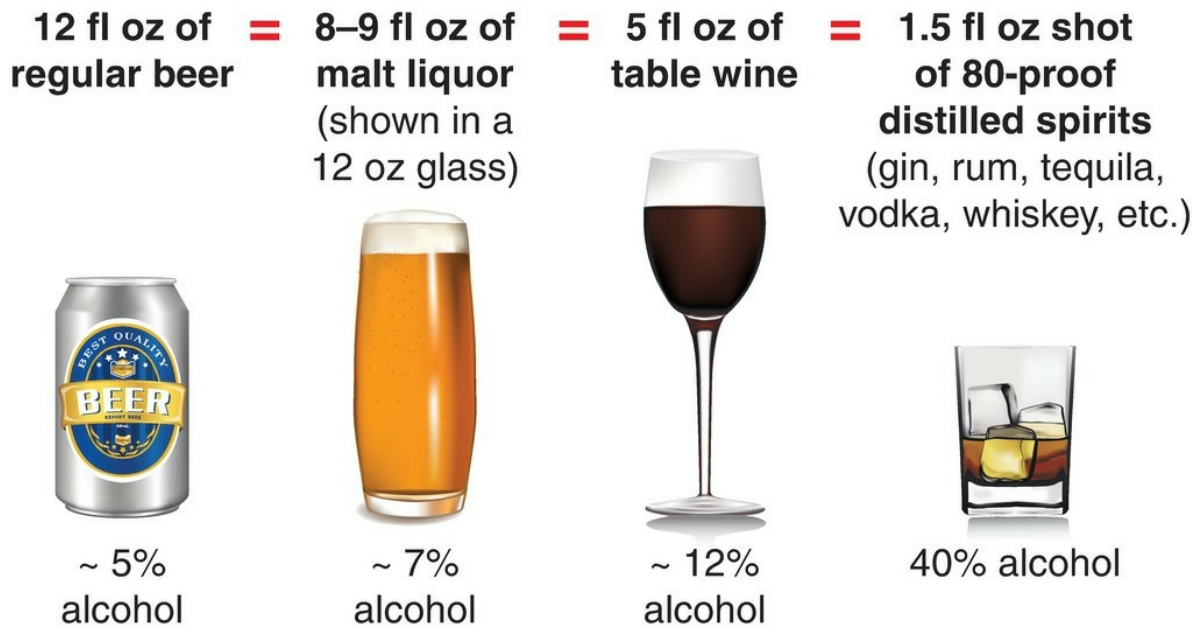
Screening Questions/Surveys

Standardized surveys and measures should be used because they are evidence-based tools for detecting risk. Table 27–5 lists commonly used screening measures for anxiety, depression, and posttraumatic stress disorder. (Note that some measures are publically available for use, whereas others may require permission or fee for use.) The severity of risk is based on the scores and their interpretation for the particular measure.

Intervention

The immediate priority for the community health nurse is to ensure safety for an individual who is at risk to self or others. It may be imperative to contact emergency services in order to ensure that the individual receives immediate and specialized care. Given the range of mental health problems and disorders, and the range of mild to severe symptomatology, referral to mental health specialists for further assessment and diagnostic evaluation is warranted (Hall, Wren, & Kirby, 2014).

Referral to Treatment



Emergency, inpatient, and outpatient levels of treatment are available for individuals with mental health disorders. A principle of treatment is to ensure adequate care in the least restrictive environment. Inpatient mental health settings provide evaluation and treatment of acute mental disorders. Inpatient mental health treatment accounts for almost 60% of all admissions to general hospitals with a length of stay in most settings from 5 to 10 days. Partial hospitalization programs are designed to prevent relapse and prevent hospital admission while providing active treatment 4 to 5 days a week until such time as the individual is stabilized and level of functioning improves (Maree, 2013). Outpatient services are provided in an ambulatory care setting such as a mental health clinic, hospital outpatient department, community health center, or practitioner's office. SAMHSA provides a behavioral health treatment services locator on their website (https://findtreatment.samhsa.gov/), an online source of treatment facilities in the United States or U.S. territories.

ALCOHOL USE SCREENING, INTERVENTION, AND REFERRAL TO TREATMENT

The National Alcohol Screening Day is an annual event that provides information about alcohol and health as well as free, anonymous screening. The National Drug and Alcohol Facts Week is an activity specifically focused on bringing alcohol information for teens across communities (National Institute on Drug Abuse, 2016). Community health nurses can engage in these activities, reaching a population in which alcohol and drug use peaks across the lifespan.

Screening Questions/Surveys

Alcohol screening questions are based on knowledge of a standard drink. A standard drink in the United States is any drink that contains about 14 g of pure alcohol (about 0.6 fluid ounces or 1.2 tablespoons). Figure 27–2 provides a graphic depicting typical alcoholic drinks and standard drink sizes. It is important to know that the NIAAA recommends no more than four standard drinks a day *and* no more than 14 standard drinks a week for healthy males ages 21 to 64. No more than three standard drinks a day *and* no more than seven standard drinks a week are recommended for healthy females and for healthy males over age 65 (NIAAA, 2015b) (Fig. 27–3).

The percent of "pure" alcohol, expressed here as alcohol by volume (alc/vol), varies by beverage.

FIGURE 27–2 What is a standard drink? Note: The percent of "pure" alcohol, expressed here as alcohol by volume (alc/vol), varies by beverage. Although the "standard" drink amounts are helpful for following health guidelines, they may not reflect customary serving sizes. In addition, although the alcohol concentrations listed are "typical," there is considerable variability in alcohol content within each type of beverage (e.g., beer, wine, distilled spirits) (NIAAA, n.d., para. 4). (From National Institute on Alcohol Abuse & Alcoholism (NIAAA). (n.d.). What is a standard drink? Retrieved from http://www.niaaa.nih.gov/alcohol-health/overview-alcohol-consumption/what-standard-drink.)

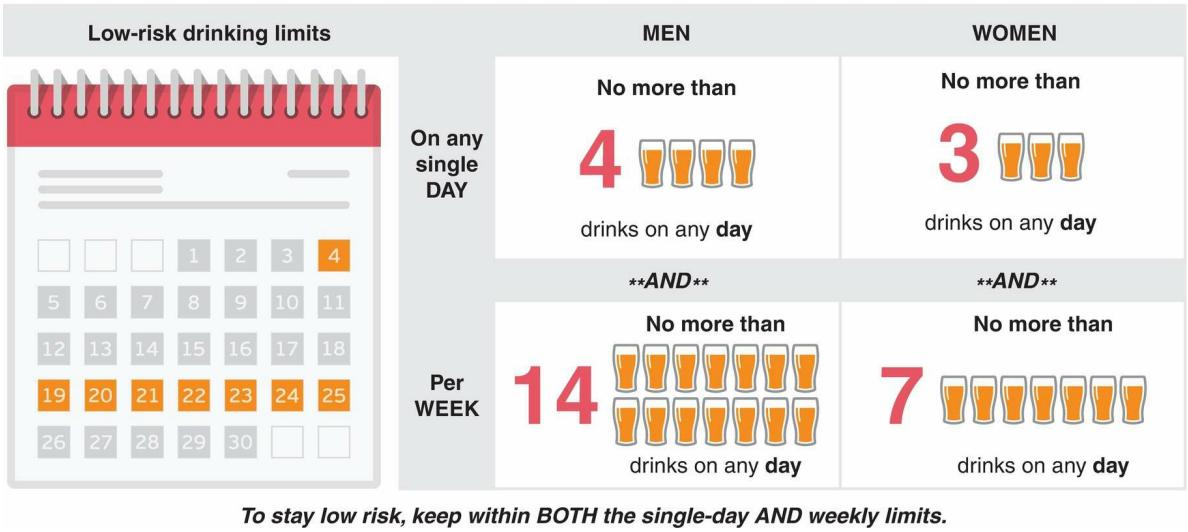


FIGURE 27–3 Low-risk drinking limits. (From National Institutes of Health (NIH). (2015). Rethinking drinking: Alcohol and your health. Retrieved form http://pubs.niaaa.nih.gov/publications/RethinkingDrinking/Rethinking_Drinking.pdf.)

The single-question alcohol screen has a sensitivity of 82% and specificity of 79%; the single question, "How many times in the past year have you had five (men) or four (women or patients over age 65) drinks or more in a day?" makes it easy to ask within the context of collecting other health information. A positive score of one or more triggers the need for a further screening for harm and possible alcohol use disorder. Given the known risks of alcohol to the developing fetus, any alcohol use reported by persons who are pregnant is considered a positive screen and constitutes at-risk alcohol use. Additionally, alcohol consumption under the age of 21 years is also considered to place the person at risk because the brain is still developing. The thresholds for alcohol consumption are based on population studies among healthy adults 21 years and older. Various health conditions and activities may warrant lower levels or no alcohol consumption at all (Fagbemi, 2011; Smith, Schmidt, Allensworth-Davies, & Saitz, 2009).

The Alcohol Use Disorders Identification Test (AUDIT) (see Table 27–5) is a 10-item screening instrument that includes questions about alcohol consumption during the past year, symptoms of alcohol use disorders, and alcohol-related problems or harm. Each response has a corresponding score and, when all 10 items are added together, results in a score ranging from 0 to 46. Scores ranging from 0 to 7 suggest abstinence or drinking below low-risk level. Scores from 8 to 15 suggest alcohol use in excess of recommended limits. Scores 16 and above suggest alcohol use above the recommended limits as well as the experience of alcohol-related harm (Rubinsky, Kivlahan, Volk, Maynard, & Bradley, 2010; Saunders, Aasland, Babor, De la Fuente, & Grant, 1993). The AUDIT-C is a three-item shorter form of the AUDIT screening tool (Fagbemi, 2011).

Underage alcohol use is also a concern, leading the American Academy of Pediatrics to recommend alcohol screening for all young teenagers. The CRAFFT (see Table 27–5) has been established to accurately screen for alcohol and other drug problems. A cutoff score of

2 has been found to be highly predictive of substance use disorder (Knight, Sherrit, Harris, Gates, & Chang, 2003; NIAAA, 2015c).

Biologic Screenings for Alcohol

Alcohol markers are not feasible for use in a community-based screening program because of the cost and the problems with obtaining biologic specimens. Andresen-Streichert et al. (2015) provided a review of various specimens used to detect ethanol use. Direct detection of ethanol in blood or breath assesses the intake of alcohol during the preceding 10 to 12 hours. Ethyl glucuronide (EtG) is a metabolic product of ethanol that is detectable in the urine or hair. Specifically, EtG can be found in the urine for up to 80 hours after alcohol consumption and allows the detection of even small amounts of ethanol ingested. A segment of scalp hair of 1 cm reflects alcohol consumption over approximately 1 month (Andresen-Streichert et al., 2015). Phosphatidylethanol (PEth), carbohydrate-deficient transferrin (CDT), glutamyltransferase, aspartate aminotransferase, and alanine aminotransferase are alcohol markers that can be measured using blood samples. In comparing these alcohol markers and correlating with data from alcohol diaries, Walther et al. (2015) found that PEth had the highest sensitivity of all biomarkers studied. Further, PEth was the biomarker with the best correlation to self-reported alcohol consumption (Walther et al., 2015).

Intervention

A negative alcohol screen (i.e., 0 for the single question and/or a score < 4 for the AUDIT) is an opportunity for the community health nurse to have a conversation about the gender- and age-related alcohol consumption limits. Information about the standard drink size (Fig. 27–2), consumption limits (Fig. 27–3), and health risks (Table 27–4) can be provided with reinforcement and encouragement to maintain low-risk alcohol use.

A BI is warranted for individuals with a positive alcohol screen and AUDIT score of 4 to 13. The BI is a short conversation (5 to 15 minutes) with the individual who is reporting harms associated with alcohol use that is above the recommended limits. The BI is a nonconfrontational and patient-centered approach to at-risk alcohol use. With this approach, the nurse engages in a motivational discussion raising awareness of alcohol-related consequences and motivating a patient toward behavior change (APHA, 2008; Sullivan & Fleming, 1997). Helpful resources for conducting a BI include:

- *Helping Patients Who Drink Too Much: A Clinicians Guide* (NIAAA, 2015a) available at http://www.niaaa.nih.gov/guide and *Planning and Implementing Screening and Brief Intervention for Risky Alcohol Use: A Step-by-Step Guide for Primary Practices* (CDC, 2014c) available at http://www.cdc.gov/ncbddd/fasd/documents/alcoholsbiimplementationguide.pdf.
- In addition to the information identified above for those with a negative alcohol screen, the booklet *Rethinking Drinking: Alcohol and Your Health* (NIAAA, 2015b) is an additional resource for individuals who are thinking about changing their alcohol use. This booklet can be downloaded from http://pubs.niaaa.nih.gov/publications/RethinkingDrinking/Rethinking_Drinking.pd
- In collaboration with the American Academy of Pediatrics, NIAAA (2015c) developed *Alcohol Screening and Brief Intervention for Youth: A Practitioner's Guide.* Screening measures for this population are included in the guide, which is available at http://pubs.niaaa.nih.gov/publications/Practitioner/YouthGuide/YouthGuide.pdf.

Community health nurses should not be hesitant to engage in these conversations with individuals who are at risk because of alcohol use. According to the CDC (2014b), only one in six adults reported that they discussed their alcohol use with a health care provider and only 17% of women who were pregnant talked about their alcohol use. These BIs are consistent with community health nursing practice that involves health teaching. But this is much more than simply giving information to individuals; it is to promote a behavior change for healthier practices.

Referral to Treatment for Alcohol

Individuals with an AUDIT score of 14 and above warrant referral for further assessment and evaluation for specialty treatment. The community health nurse should engage in conversation with the individual, again using a nonconfrontational and patient-centered approach, providing feedback about the results of the AUDIT and information about the harms associated with continued alcohol use. A menu of support options can be provided, such as those included in the *Rethinking Drinking* booklet mentioned above (NIAAA, 2015b). In the motivational discussion, the community health nurse should work toward negotiating a plan that includes referral to specialty treatment. Thus, the PHN should be aware of services available in the community and how to access those services:

- SAMHSA's Behavioral Health Treatment Services Locator (https://findtreatment.samhsa.gov/) can be helpful in identifying alcohol-related treatment in a community.
- Alcoholics Anonymous also has a Web site listing contact numbers for AA groups within and outside the United States at http://www.aa.org/pages/en_US/find-aa-resources and also provides information about online AA meetings at http://aa-intergroup.org/.

SCREENING FOR DRUG USE INCLUDING PRESCRIPTION MEDICATION FOR NONMEDICAL REASONS

A single question for screening for drug use is, "How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?" (Smith, Schmidt, Allensworth-Davies, & Saitz, 2010). Nonmedical reasons can be qualified with the explanation, "because of the experience or feeling it caused." The sensitivity for this screening question is 100% and the specificity is 74%. Any response greater than zero indicates a positive screen, meaning that the individual is at risk because of drug use. Follow-up questions are used to assess impact and whether substance use is serious enough to warrant a substance use disorder diagnosis. Additional information should be obtained about the specific drug(s) being used, frequency and quantity, and the negative impacts. A Boston University study found that for study participants, 88% of those who were alcohol dependent and 97% of those who were drug dependent could be identified by the use of a single screening question (Saitz, Cheng, Allensworth-Davies, Winter, & Smith, 2014).

The 10 questions in the Drug Abuse Screening Test (Skinner, 1982; Yudko, Lozhkina, & Fouts, 2007) provide additional information about the negative impacts and harms associated with drug use. The total "yes" responses are summed in order to obtain an overall score. A score of 0 reflects no use of drugs. A score of 1 and above indicates a level of risk that should be further assessed by a substance use specialist. This screening tool is widely used and can be found online from various sources (Counselling Resource, 2014).

Biologic Screening for Drug Use

Laboratory testing is not recommended for universal screening. Sources commonly used for drug testing include urine and blood. Other sources are oral fluid, sweat, hair, and meconium. Initial procedures for drug testing usually entail a urine immunoassay. Urine can be collected easily and noninvasively. However, urine specimens are easily adulterated or substituted. A positive test is based on a defined concentration of a component of the drug in a specimen (Warner & Lorch, 2014).

Interventions for Drug Use

Overall, there is fair evidence that people who reduce or stop drug use have a lower risk of negative health outcomes, at least those from trials conducted among treatment populations (Polen, Whitlock, Wisdom, Nygren, & Bougatsos, 2008). There are mixed results of studies on BIs for drug use. Saitz (2015) calls for well-designed studies of interventions that show efficacy, that are feasible, and that retain effectiveness in practice. A recent trial by Bogenschutz et al. (2014), among persons using drugs who were recruited from emergency departments, suggests that a BI with two boosters was not more efficacious than minimal screening. Thus, the data on BIs for drug use problems is limited. At a minimum, community health nurses should provide information about drug use treatment and support for reduction or stopping drug use.

Given the escalating number of overdoses associated with opioids, efforts have quickly been undertaken to expand naloxone access to those who may be at risk for overdose. Naloxone hydrochloride is a pure opioid antagonist that can effectively reverse the effects of opioid intoxication and overdose. Community health nurses can lead efforts to promote naloxone rescue measures. With the United States accounting for 99% of the world's hydrocodone consumption and one-quarter billion opioid prescriptions per year, this inexpensive lifesaving treatment can avert some of the damage from opioid overdose (Humphreys, 2015). SAMHSA (2013b) is a leader in addressing this significant health concern detailed in their *Opioid Overdose Toolkit*, accessible at https://store.samhsa.gov/shin/content/SMA13-4742/Overdose_Toolkit_2014_Jan.pdf.

Referral to Treatment for Drug Use

As discussed in relation to alcohol use, the community health nurse should be aware of services available in the community and how to access those services:

- The SAMHSA Behavioral Health Treatment Services Locator (https://findtreatment.samhsa.gov/) provides such information.
- The Narcotics Anonymous Web site (https://www.na.org/) provides information on locating meetings.

TOBACCO SCREENING, INTERVENTION, AND REFERRAL TO TREATMENT

The U.S. Preventive Services Task Force (USPSTF, 2009) recommends screening and providing BIs for tobacco use as part of standard routine health care for adults and women who are pregnant. The U.S. Department of Health Services clinical practice guideline provides information about screening and interventions that can be provided based on the individual's willingness to quit or not. It is recommended that all patients be asked if they use tobacco and, if so, asked, "Do you want to quit?" (Fiore, Jaen, Baker, et al., 2009, p. iv).

The five major components for treating tobacco use and dependence (5 As) are "Ask" about tobacco use, "Advise" to quit, "Assess" willingness to make a quit attempt, "Aid" the person in quitting, and "Arrange" for follow-up (Agency for Healthcare Research & Quality [AHRQ], 2012, para. 2). Community health nurses are encouraged to adopt the 5As as part of their standard care to address this major health problem in the United States and globally. Strategies for various populations are provided in the AHRQ (2015) clinical practice guideline, including those who are willing to quit, those unwilling to quit, those who have recently quit, and specific populations (e.g., LGBT, persons with medical conditions, persons with HIV).

COMMUNITY- AND POPULATION-BASED INTERVENTIONS

Community interventions move beyond single interventions and outcomes at individual levels of health behavior change. Starting with a specific framework helps planners identify why and how the intervention will work. Two theoretical frameworks used in community/public health science are *process theory* and *effect theory*. These are both part of the Model of Program Theory and used to plan, deliver, and evaluate the program (Issel, 2013). In relation to behavioral health, process theory helps the community health nurse identify the resources and structure needed to develop, implement, and evaluate the program. Effect theory provides the rationale for why the intervention will work.

Process Theory: Component of Program Theory

Three components comprise process theory: (1) an organizational plan that includes information on personnel and resources to be used (e.g., fiscal, information technology, supplies), (2) a service utilization plan that specifies how the program will reach its targeted client population (e.g., social marketing, screening procedures, logistics of availability/access), and (3) specifications of their outputs (e.g., expected outcomes). These components are continually developed throughout the process and each affects the other (Issel, 2013).

Effect Theory: Component of Program Theory

The challenge for the community health nurse in developing interventions related to behavioral health is the fact that behavior management is needed for both mental and substance use issues or disorders. Effect theory is a useful framework for developing behavioral health interventions. Effect theory encompasses the theories of causal/determinant forces, intervention mechanisms, and outcome to impact (Issel, 2013). The causal theory is an explanation of the process that currently underlies the health problem and includes relevant components directly responsible for the health problem. The intervention theory explains how the intervention alters the causal factors, describing how the program actually works. The impact theory helps explain how the outcomes lead to impacts, which is how the immediate outcomes of the program lead to long-term changes to the health problem (Issel, 2013).

Once the framework has been selected, the community health nurse conducts a community assessment drawing on primary and secondary sources such as community members. Community health nurses can utilize other data such as vital statistics or census data to develop additional insights about the health needs of the community. National sources, such as the NSDUH, can provide national and state-level estimates on the use of tobacco products, alcohol, illicit drugs (including nonmedical use of prescription drugs) and mental health in the United States. See Chapter 15 on community assessment.

The next step is to analyze the data and develop a diagnosis of the community's needs, the community responses, and expected outcomes. The health-planning phase entails designing an orderly, detailed series of specific goals and objectives. Implementing the plan for promoting the health of the community involves engaging others in the action and encouraging their ownership, sense of responsibility, and autonomy. Engaging representatives of target populations in community coalitions in various interventions has been associated with noted improvements in health status and reduction in disparities in racial and ethnic minority populations (Anderson, Adeney, Shinn, Krause, & Safranek, 2015). Evaluation occurs throughout the process, but is often seen as the final step in determining the effectiveness of the service for the community. See Chapter 12.

A case example is provided to illustrate the process of developing a smoking cessation program for mothers in a rural county (see From the Case Files I).

From the Case Files I

Smoking Cessation Program for Mothers in a Rural County

You have been working in the public health department well-child clinic in a rural Appalachian county and noticed that more than one third of the mothers you are seeing are smokers and that their babies seem to be smaller than the babies of moms who do not smoke. When you mention smoking to individual mothers, they tell you they want to stop, but just are not able to. You are interested in putting together a smoking cessation program. You decide to use Issel's (2013) effect theory as a framework for building your intervention. That is, you consider the relationships among health antecedents, causes of health problems, program interventions, and health effects. You are convincing in getting the county to fund the program. What data do you need before you begin to look at interventions (see Strategy 1 below)? What data can you get using existing databases, and what data will you need to collect yourself? Once you have reviewed the data, you decide that you want to include smoking cessation as part of well-baby visits for all mothers who are current smokers. What do you need to do before you put together the program (see Strategy 2 below)? After you have gathered all this information, what final piece is needed before you present your proposal to your public health department (see Strategy 3 below)? If you are able to implement the program what immediate impact do you expect to have and what long-term outcomes are you hoping for?

Strategies

1. Preliminary data needed:
    a. Low-birth-weight rates compared to state and national rates. (Available vital statistics public health data.)
    b. Low-birth-weight rates for smokers versus nonsmokers in your county, compared with the state and the nation. (Protected vital statistics public health data that will need approval from the state for you to access and analyze.)
    c. Comparison of asthma rates in children in your county with smoke-free homes versus homes with a parent smoking. (Available survey data using prior studies, but may not be current. Will most likely need to conduct a survey at the county level. Check with state public health department for state-level data.)
    d. County tobacco use rates based on gender and age, and trends among adolescent girls in your county schools compared to state and national rates. (Available public health survey data at state and national levels. May need to conduct a survey at the county level.)
2. A review of the evidence related to smoking cessation interventions with women of childbearing age. Were any of the studies conducted with Appalachian women? Will you need to make some adjustments to interventions that work based on culture? Are there possible economic constraints for this population in relation to pharmacologic interventions? Are the time frames reasonable in your setting?
3. You need to do an analysis of the cost to implement the program, complete a cost–benefit projection, have clear program goals and objectives, and formulate a plan to evaluate the effectiveness of the program.

The desired health impact refers to the immediate impact expected from the program. For example, if the health problem is heavy episodic (binge) alcohol consumption among college students, a logical approach may be to institute an alcohol screening program. For such a program, the immediate *impact* for the program may be that 25% of students are screened and 75% of those who require a BI and/or a referral for further assessment receive those interventions. However, the desired *outcome* of the program is an overall reduction in heavy episodic alcohol consumption on campus over a specified time period—for instance, the next 2 years. Remember that not all desired impact is related to change. The goal may be to stabilize, prevent, or maintain a health state or problem. Having a clear understanding of what a behavioral program can actually accomplish and what long-term goal it hopes to achieve prior to implementing the program will provide a

clearer picture of how to proceed with the program.

When using effect theory to design a prevention program for behavioral health, a good place to start is to identify the specific health problem and then the desired health problem impact and health problem outcome. As the program is developed, the community health nurse starts by identifying the antecedent factors that led to behavioral health problems. This provides a clear rationale for why the intervention should provide the desired impact.

Policy-Based Interventions

Not-for-profit, private for-profit, and governmental agencies play crucial roles in community health care. The provision of health care to the population requires multidisciplinary approaches that are driven by monetary reimbursements based on health care problems. Local governments may institute community mental health care policies relative to administrative processes or procedural mechanisms. Policies at the community or state levels aim to ensure the rights of individuals and public safety. Thus, cities or counties with appropriate jurisdiction over a geographic area develop policies and guidelines necessary to encourage mental health program development and implementations that address the needs of the community population.

Depending on each county, certain rules or regulations apply. It is important to learn about the community agencies and interrelationships to other county service providers to ensure the coordination of care. At the local level are freestanding programs that focus on support for individuals, families, the indigent, or the homeless. Funding may come from charitable organizations or from local governments through grant monies obtained from periodic requests for proposals (RFPs) or requests for applications (RFAs) issued by the local governing body. Other governmental agencies have roles in mental health by encouraging employee wellness in the workplace or through rules and regulations that encourage employers to provide benefits, such as mental health insurance, bereavement leave, or stress leave. The incidence of violence in the workplace has necessitated policy initiatives, resulting in business community development of strategic plans and educational programs to address these issues (Occupational Safety & Health Administration [OSHA], 2015).

Mental Health Policy and Research

The WHO 2013–2020 Mental Health Action Plan (WHO, 2013) outlines the following objectives:

1. To strengthen effective leadership and governance for mental health
2. To provide comprehensive, integrated, and responsive mental health and social care services in community-based settings
3. To implement strategies for promotion and prevention in mental health
4. To strengthen information systems, evidence, and research for mental health (p. 10)

The action plan relies on six principles and approaches: (1) universal health coverage, (2) human rights, (3) evidence-based practice, (4) life course [lifespan] approach, (5) multisector approach, and (6) empowerment of persons with mental disorders and psychosocial disabilities (WHO, 2013, p. 10). Thus, the focus is to act, unite, and empower people and countries to promote health and well-being, as well as to improve the quality of care for persons with mental disorders.

Although there is a clear need for mental health services, the proportion of people who need, but do not receive, care is especially high in low- and middle-income countries. These countries also have fewer health care professionals than required to deliver mental health and substance use interventions to everyone who needs them (Baingana, al'Absi, Becker, & Pringle, 2015). Globally, nurses represented the most prevalent professional group working in the mental health sector. Thus, there is a clear need to build capacity of nurses prepared to address mental health needs. Further, Pike, Susser, Galea, and Pincus (2013) state that this increased human capacity needs to be deployed in integrated community care settings beyond the stand-alone mental health hospital and integrated into primary health care systems.

Substance Use Policy

Alcohol and other drugs are a substantial threat to the public good. As such, drug policy should aim to promote the public good by improving individual and public health, neighborhood safety, and community and family cohesion and by reducing crime. Researchers reviewed evidence that can be used to inform decision making about drug policies related to supply control, methods to control pharmaceutical drugs, prevention programs, and health and social services for persons with drug use. A key message is that the effectiveness of these various strategies is unknown or additional research is needed. What is concerning is that programs that have widespread use, such as the Drug Abuse Resistance Education (DARE), according to meta-analyses show that the program is ineffective (Strang et al., 2012). Thus, it is important that community health nurses implement and evaluate evidence-based programs, rather than promoting programs that have widespread popularity.

Given the increase in fatal poisonings, most of which are caused by drug overdose, recent efforts have been directed to reversing opioid overdose. As of September 2015, 43 states and the District of Columbia have passed laws to increase access to naloxone. These laws are intended to increase naloxone prescribing and distribution, to increase pharmacy naloxone access, and to encourage overdose witnesses to summon emergency responders. Although these laws increase layperson access to this medication that can reverse overdose morbidity and mortality, barriers exist in terms of cost and status as a prescription medication (e.g., not an over-the-counter medication), among others things (Davis & Carr, 2015). In their role as advocates, community health nurses can take an active role in helping to remove these barriers.

Communities can set policies that restrict both alcohol availability and consumption; this is done by controlling the number of alcohol outlets, regulating the current outlets, and setting laws that will allow the community to close problem outlets. These measures are implemented through policies related to zoning and the licensing of establishments that sell alcohol. Another measure has been to require responsible alcohol-service training for bartenders. Other examples include keg registration, stricter enforcement of underage sales of alcohol and tobacco, and controlling alcohol outlet density. Major efforts in relation to

tobacco consumption in public areas have resulted in a drastic restriction of locations where tobacco users can smoke outside of their own home. In one case in Washington, DC, a judge banned smoking in a private home in response to a lawsuit brought by the homeowner's neighbor (Mendoza, 2015). In California, 69 cities have banned smoking in multiunit apartments, condominiums, and public housing complexes (Center for Tobacco Policy & Organizing, 2015).

ROLE OF THE COMMUNITY MENTAL HEALTH NURSE

The nurse's role in community mental health is multifaceted involving advocacy, education, case management, collaboration, and community involvement; this has been evident throughout the chapter. The access and use of epidemiologic data to better understand and serve the population with behavioral health issues or disorders is vital. This means identifying their incidence and prevalence of, examining the causes and risk factors associated with these disorders, and identifying and addressing the needs of people with mental and substance use disorders (see Chapter 7 on Epidemiology).

Advocacy

An important part of the nurse's role is *advocacy*. As an advocate, the nurse seeks to increase client access to behavioral health services, to reduce stigma and promote improved public understanding of this population, and to improve services in community mental health (Barry, McGinty, Pescosolido, & Goldman, 2014). The advocacy role requires being politically involved by serving on decision-making boards and committees, lobbying for legislative changes, and helping to influence mental health policy development that will better serve this population. Membership in state and national nursing organizations can be helpful in establishing collaborative partnerships to benefit the mentally ill. Membership in the National Alliance on Mental Illness (NAMI, 2011), or other advocacy groups, can also effect positive change (see Chapter 13 for more information on advocacy and policy making).

In any of these venues, the vision and expertise of the community mental health nurse can be useful to advocate for enhancing existing services, developing new services, and increasing access for the mentally ill to all services. Community health nurses can also work to confront media portrayals of behavioral disorders that are stereotypical, negative, and provide an unfavorable or inaccurate view.

Education

Another aspect of the nurse's role is *education*. The community mental health nurse teaches clients individually and in groups about their health conditions. Nurses can be instrumental in providing information about the neurobiological base of mental and substance use disorders, treatments, and self-management strategies such as taking medications consistently in order to promote optimal level of functioning in the community (Finnell & Ditz, 2007; Finnell & Nowzari, 2013). The nurse also teaches the public through community education programs and has an educational role with caregivers, family and community members, and health care decision-makers by providing information for service planning (see Chapter 11 for more on health education).

Case Management

Case management for persons with SMIs is also part of the community mental health nurse's role. This role includes screening, assessment, care planning, arranging for service delivery, monitoring, reassessment, evaluation, and discharge. Case management is often offered within the context of a community mental health center (CMHC). Case management helps the person with an SMI to access services and live as independently as possible (Townsend, 2015).

The nurse's role also involves *case finding and referral*. This means early identification of persons with mental disorders who are in need of treatment and referral of those persons to the appropriate resources for treatment. The purpose of this role is secondary prevention, because early identification and treatment help to ameliorate the severity of the mental disorder and promote a speedier recovery (Townsend, 2015). See Perspectives: Voices from the Community.

Collaboration

Finally, the nurse's role includes *collaboration*. Whether serving individual clients, groups, or populations, the nurse is part of the larger community mental health team and works in collaboration with many people to accomplish the goals of community mental health. The composition of the team—made up of clients, psychiatric nurses, physicians, social workers, nutritionists, epidemiologists, psychologists, health planners, and many more—is diverse and varies depending on the community health nurse's work setting. Collaboration allows for a pooling of professional expertise that enhances the quality and effectiveness of services for persons with mental and substance use disorders (Townsend, 2015).

PERSPECTIVES VOICES FROM THE COMMUNITY

I have been a nurse for a long time. Even though I don't work in behavioral health nursing, per se, I have had many experiences throughout the years related to both mental health and substances. When I was a student in the 1970s, I remember doing a rotation in a locked mental health facility and feeling that it was just a "revolving door." Now, there are so many medications available that can quickly address symptoms, and prevention and early intervention are the focus. Then, the same patients came back over and over again, and all staff could offer them was counseling, a few medications (mostly Thorazine), and electroconvulsive therapy (ECT). They had a "rubber room"—a padded room where they would place patients who were dangerous to themselves or others. It seemed so futile to me, at the time.

Years later, a close friend I had known since childhood was hospitalized for a suicide attempt. She had always been charming and outgoing, often talking excitedly about things and using her hands to punctuate her thoughts. She seemed to have boundless energy and there was nothing she couldn't do. I was shocked to learn that she had been suffering from a terrible depression and had tried to overdose on prescription medications. She was subsequently diagnosed with bipolar disorder and began a long road to recovery with many medication changes and years of hard work in therapy with a very kind, patient

counselor. Her marriage didn't survive and her children suffered during her so-called crazy years, but she made it through to the other side and learned a lot from her experience. I learned a lot from that "personal" experience with mental illness.

I have also worked with many public health clients who have battled various types of mental illness (often postpartum depression, or eating disorders with new moms or teens), as well as bipolar disorder and schizophrenia among drug users and homeless individuals. I have seen firsthand the problem of alcohol and substance use disorders (not only alcohol and illicit drugs, but misuse of prescription medications or huffing glue and aerosols). I have struggled to help them and their families find resources or advocated on their behalf with landlords, the school system, or law enforcement, as their illnesses led to problems in all areas of their lives.

Although I am not a mental health nurse practitioner, I feel that I have some understanding of the problems in the community, with families, and with individual clients. I realize the responsibility I have to reinforce with my students the human side of mental illness and substance abuse and to break through the fears they experience in order to help them look at the client in a different way. Brain chemistry is a powerful thing—people cannot just "will" themselves to be more cheerful/less depressed or to stop craving heroin (or chocolate, for that matter). Seeing each client as an individual and joining with them to address their issues is the best approach—that's community health nursing!

Lori, Community Health Nursing Professor

SUMMARY

Behavioral health is a key component in the health of a community. Three of the top ten leading health indicators from *Healthy People 2020* are closely linked to behavioral health issues: tobacco use, substance use, and mental health (see Display 27–2). Objectives, health indicators, and target outcomes for tobacco, illegal substances, and alcohol use guide the PHN in program planning. In every community in the United States and the world, behavioral health directly or indirectly affects every other indicator of health. Unabated, mental and substance use disorders overburden the medical, social, economic, and criminal justice systems of communities and governments. Community health nurses are critical in addressing the needs of individuals who are among the most stigmatized in society. Community health nurses have a primary role in addressing the full continuum—from promotion to prevention to treatment to recovery for persons with mental and substance use disorders.

DISPLAY 27.2 *HEALTHY PEOPLE 2020* LEADING HEALTH INDICATORS

Top 10 Health Indicators

1. Physical activity
2. Overweight and obesity
3. Tobacco use
4. Substance abuse
5. Responsible sexual behavior
6. Mental health
7. Injury and violence
8. Environmental quality
9. Immunization
10. Access to health care

Treatment related to behavioral health at the community level begins with a community assessment in order to establish a community diagnosis, followed by intervention that can address the specific public health issue identified in the diagnosis. The community health nurse can use *Healthy People 2020* objectives as a starting point in the

development of an intervention.

The community health nurse must incorporate behavioral health in the assessment, planning, and developing of community health interventions and in the evaluation of outcomes. With this comes the need for administrative, managerial, or supervisory support with commitment not only from a philosophical perspective but from a resource perspective as well. Success comes with a unified approach to mental health and substance use, requiring application of research and utilization of best practice models across the behavioral health continuum.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a community health nurse, you have been asked to design and present a 2-hour program on suicide prevention to the entire student body of the local high school. This activity is representative of which level of prevention? What are some of the considerations involved in planning this program to promote optimal success? How might you measure the effectiveness of this intervention?
2. You are part of a multidisciplinary team whose goal is to identify families in your city who are at risk for crisis (e.g., single parent, divorced, pregnant adolescents, unemployed) and develop a set of interventions. How would you locate these families? What interventions would be appropriate to meet their needs? What level of prevention would you be targeting? What might be the most effective methods of reaching them?
3. You have met a few elderly men in your area who live alone and are widowed, and you have heard that there are others. Assuming your advocacy role in community mental health, you decide to take some action to ensure that their needs are being met. How would you determine the risks and needs for this group? What interventions would be appropriate to meet their needs?
4. Select a problem that places people at risk for mental disorders (e.g., child abuse and neglect, drug abuse) and search the Internet to learn all you can about it. What is the incidence and prevalence of this problem? What interventions are most effective in addressing it? What can be done to prevent it? With a small group of students, brainstorm ideas for primary and secondary interventions.
5. Search for local treatment facilities and resources for alcohol and drug abuse clients. Call a few of them to inquire about cost, access, and types of assistance available. How many people can they serve? How does this compare to the numbers of reported alcohol and drug users in your area? Is there a waiting list? Where else can clients go when there are no more spaces available in your area?
6. Talk with a community/public health nurse working in your community. Ask questions about the available data used to assess the problems of substance abuse and mental health in the area. Ask his or her opinion on the accuracy of the data. Are adequate resources available? How does the nurse advocate on behalf of these clients?

28 CHAPTER

Working with the Homeless

"We have come dangerously close to accepting the homeless situation as a problem that we just can't solve."
—*Linda Lingle* (1953), American Politician

KEY TERMS

Chronically homeless
Continuum of care
Deinstitutionalization
Doubled up
Homelessness
Housing first
Point-in-time counts
Period prevalence counts
Single room occupancy (SRO) housing
Survival sex
Trauma informed care (TIC)
Unaccompanied youth
Unsheltered (hidden) homeless

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Define the concept of homelessness.
- Describe the demographic characteristics of the homeless living in the United States.
- Discuss factors predisposing persons to homelessness.
- Examine the effects of homelessness on health.
- Compare and contrast the unique challenges confronting selected subpopulations within the homeless community.
- Analyze the extent and adequacy of public and private resources to combat the problem of homelessness.
- Assess your beliefs and values toward homelessness.
- Propose community-based nursing interventions to facilitate primary, secondary, and tertiary prevention in addressing the problem of homelessness.

What was once considered unthinkable in a prosperous nation is now an expected occurrence in towns and cities across the United States. Drive through an inner city or suburban community on any given day, and you will see people on street corners holding signs "Hungry and homeless." Where is the public outcry in response to this scene? Has the American conscience been anesthetized to this form of human

suffering? Or is the need simply too overwhelming and the problems too far reaching to mount an effective campaign to prevent such a tragedy?

The purpose of this chapter is to define the concept of homelessness, examine the factors contributing to homelessness, analyze the major issues confronting the homeless, and examine the role of the community health nurse in addressing the needs of the homeless.

The McKinney-Vento Homeless Assistance Act (Title 42 of the U.S. Code) defines as homeless a person who lacks a fixed, regular, adequate nightly residence including supervised public or private shelters that provide temporary accommodations. Homeless individuals may also reside in institutional settings providing temporary shelter or in public or private places that are not designed for or used as a regular sleeping accommodation for human beings (e.g., cars, parks, campgrounds). Incarcerated individuals are not considered homeless under this definition (McKinney-Vento Homeless Assistance Act, 1987).

The education subtitle of the McKinney-Vento Homeless Assistance Act expands on the definition of homelessness when addressing homeless children and youth. The Act includes as homeless those children who share housing with others because of economic hardship or loss of housing, are abandoned in hospitals, are awaiting placement in foster care, or are living in motels, trailer parks, or camping grounds (National Center for Homeless Education [NCHE], 2012).

The U.S. Department of Housing and Urban Development (USDHUD, 2015) defines homeless people as those living on the streets, in vehicles, in shelters or parks, and in transitional housing; unaccompanied youth and families with children are defined as homeless under other federal statutes. Although this definition may be appropriate for the urban homeless who are more likely to live on the street or in shelters, persons living in rural areas tend to cohabit with relatives or friends in overcrowded, substandard housing (American Institutes for Research [AIFR], 2014; Housing Assistance Council [HAC], 2014). Table 28–1 outlines selected *Healthy People 2020* goals that relate to the homeless population.

Table 28–1 Selected *Healthy People 2020* Objectives Related to Homelessness

MHMD-12	Increase the proportion of homeless adults with mental health problems who receive mental health services
HIV-23 (Developmental)	Reduce the proportion of persons with an HIV diagnosis receiving HIV services who were homeless or unstably housed in the 12-mo measurement period
Related Access to Care Objectives	
AHS-2 (Developmental)	Increase the proportion of insured persons with coverage for clinical preventive services
AHS-3	Increase the proportion of persons with a usual primary care provider
AHS-5	Increase the proportion of persons who have a specific source of ongoing care
AHS-6	Reduce the proportion of persons who are unable to obtain or delay in obtaining necessary medical care, dental care, or prescription medicines
AHS-7 (Developmental)	Increase the proportion of persons who receive appropriate evidence-based clinical preventive services
AHS-8 (Developmental)	Increase the proportion of persons who have access to rapidly responding prehospital emergency medical services
AHS-9.1 (Developmental)	Reduce the proportion of all hospital ED visits in which the wait time to see an ED clinician exceeds the recommended time frame

U.S. Department of Health & Human Services (USDHHS). (2016). Healthy People 2020: Topics and objectives. Retrieved from http://www.healthypeople.gov/2020/topicsobjectives2020/default

Homeless individuals often struggle to find shelter.

SCOPE OF THE PROBLEM

It is difficult to estimate the number of people who are homeless because homelessness is a temporary condition. Rather than trying to count the number of homeless people on a given night, or point-in-time counts, it may be more prudent to gauge the number of people who have been homeless over a longer time frame such as over the course of a year, or period prevalence counts (USDHUD, 2015; National Coalition for the Homeless [NCH], 2011a).

It is also difficult to locate and account for homeless people. Most estimates of homelessness are based on the number of people served in shelters or soup kitchens or the number of people who can easily be located on the streets. People who spend time at places that are difficult to reach (e.g., cars, campgrounds, caves, boxcars, wooded areas) are considered "unsheltered" or "hidden" homeless. Many people are unable to access shelters because of overcrowding and limited capacity. In rural areas, there are fewer housing options and resources for the homeless. As a result, people may be forced to live temporarily with friends or family (a practice known as "doubling up"). While still experiencing homelessness, these individuals are not always counted in homeless statistics or considered eligible for homeless services (AIFR, 2014; HAC, 2014; NCH, 2011a).

The USDHUD, in its *Annual Homeless Assessment Report to Congress*, publishes the latest counts of homelessness nationwide. In 2015, on a single night in January, there were an estimated 564,708 sheltered and unsheltered homeless people across the nation. Overall, the number of homeless decreased by 31% since 2007, with the number of people in unsheltered locations in 2015 at estimated at 30.6% and the number of homeless veterans decreasing by 1%. Nearly two thirds (64%) of homeless are individuals. The remaining one third (36%) comprised families with children (USDHUD, 2015). Because of the transient nature of homelessness and the difficulty involved in locating and counting the homeless, it is unlikely that researchers will ever be able to estimate the exact magnitude of homelessness in America (NCH, 2011a).

There is a direct relationship between poverty and homelessness. In general, homelessness is decreasing due, in part, to the strides made over recent years to increase federal funding for homeless prevention and assistance programs. Funding for these federal programs is at its highest level in history. Despite improvements in employment and in the economy, however, those in poverty, living with friends and family, and paying over half their income for housing continue to be at risk for homelessness. Housing programs for the homeless have removed many homeless people from off the streets, but the lack of affordable housing continues to present formidable challenges to eliminating homelessness (National Alliance to End Homelessness [NAEH], 2014, 2015d).

In 2014, The U.S. Conference of Mayors Task Force on Hunger and Homelessness reported its survey findings of 25 cities across the nation. The survey revealed that, over the past year, the total number of homeless across the cities surveyed had increased by only 1%.

The number of homeless families had increased by 3%. Lack of affordable housing, unemployment, poverty, and low-wage jobs contributed to the rise in homelessness among families (U.S. Conference of Mayors, 2014).

Demographics

Poverty is directly linked to homelessness. Demographic groups more likely to be poor are also at greater risk of becoming homeless.

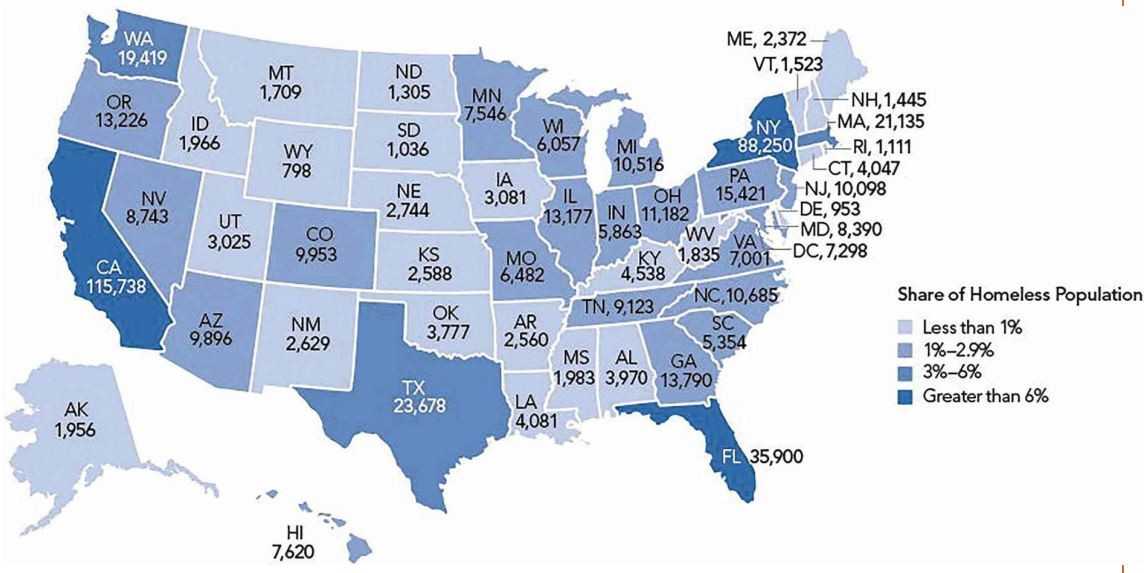
Raising awareness about homelessness is an important step in seeking community solutions.

Age

In 2015, 68% of all sheltered homeless persons were adults over 24. About 10% were between 18 and 24 and nearly 22.6% were under 18 years of age. Among the unsheltered homeless, 82.6% are over 24 and 7.7% are under 18 years of age (USDHUD, 2015).

Gender

The majority of homeless individuals are unaccompanied adult men. Single homeless adults are more likely to be male. Approximately 60% of sheltered homeless adults are men and 39.7% are women; about 2% identify as transgender (USDHUD, 2015).



Ethnicity

The racial and ethnic makeup of the homeless population varies based upon geographic location. Nationally, approximately 44.8% of the sheltered homeless are White, non-Hispanic, whereas approximately 45.9% are African American and 19.9% are Hispanic.

African Americans represent the largest minority group in shelter situations, but among the unsheltered, that drops to 27.98%, whereas non-Hispanic Whites comprise 58.6% of the total and Hispanics remain steady at 20.1%. Five states have over 50% of the American homeless population, with 21% residing in California, 16% in New York, 6% in Florida, 4% in Texas, and 4% in Massachusetts (USDHUD, 2015). See Display 28–1.

DISPLAY 28.1 ESTIMATES OF HOMELESS PEOPLE BY STATE, 2015

Source: U.S. Department of Housing & Urban Development (USDHUD). (2015). The 2015 annual homeless assessment report to Congress. Retrieved from https://www.hudexchange.info/resources/documents/2015-AHAR-Part-1.pdf.

Families

Families with children represented 36.5% of the homeless population in the United States in 2015. Approximately 60% of homeless people in families are children under 18 years of age. Nearly 9 in 10 homeless people in families reside in shelters. About 6% of homeless people in families are considered chronically homeless, but there were 2,308 fewer chronically homeless in 2015 than in 2014. The number of homeless people in families has declined by 12% since 2007 (USDHUD, 2015).

Although 60% of homeless families with children are made up of women or girls, the average homeless family household is comprised of three people. African American families with children represent 51% of sheltered families, and 55% of unsheltered families are White. New York had 26% of the total homeless families with children population (also a 9% one-year increase), and California had 11% in 2015. During recessions and periods of economic decline, more two-parent families and families headed by single fathers are likely to become homeless. Because organizations serving homeless families are generally geared to serving single women with children, it may be difficult for intact families and families headed by men to access shelter (USDHUD, 2015).

Over 36% of the U.S. homeless population in 2015 were families with children.

Contributing Factors

Persons are predisposed to homelessness because of a complex array of factors that result in individuals having to choose between necessities of daily living. Scarce resources limit choices. What would you do if you had to choose between eating and buying your child's medication? Housing consumes a huge portion of one's income and is often the first asset to be lost. Many families find they are only a paycheck away from homelessness. See What Do You Think?

Poverty

In 2013, more than 45 million people (or 14.5% of the U.S. population) were living in poverty. Approximately 20% of children under 18 live in poverty. Poverty rates are highest among single female head of households (DeNavas-Walt & Proctor, 2014). Factors impacting poverty include declining wages, loss of jobs that offer security and carry benefits, an increase in temporary and part-time employment, erosion of the true value of the minimum wage, a decline in manufacturing jobs in favor of lower-paying service jobs, globalization and outsourcing, and a decline in public assistance. As wages drop, the potential to secure adequate housing diminishes (NCH, 2011b).

Compounding the problem is a lack of affordable housing—particularly single room occupancy (SRO) housing (or housing units intended to be occupied by one person) and limited funding for housing assistance. For example, a household seeking to rent a two-bedroom apartment in Florida is estimated to need to earn an average of at least $19.35 per hour; in California, it is estimated at $25.65 per hour (National Low Income Housing Coalition, 2016). An interactive map of all 50 states is available at http://www.nlihc.org/oor. This figure for Florida is more than two times the federal minimum wage of $7.25, and it is over three times that for the California estimate. A family of four with one full-time minimum-wage earner is 17% below the poverty line. In his 2014 State of the Union Address, President Barrack Obama asked Congress to raise the minimum wage to $10.10 an hour (White House, 2014). Some politicians and business owners have also supported this idea (Correa, 2016). But, it remains unchanged at $7.25, although 29 states and the District of Columbia (D.C.) have higher minimum-wage levels (the highest is $10.50 in D.C.). Two states (Georgia and Wyoming) have lower minimum rates of $5.15 per hour (United States Department of Labor, 2016).

When rental costs increase and the number of available low-rent units decline, the housing gap widens. Moreover, federal support for housing assistance is unable to keep pace with the high demand for housing. As a result, many persons must pay high rents to obtain shelter. This situation leads to overcrowding and substandard housing.

Because the demand for housing assistance exceeds federal housing assistance resources, there are often long waiting lists. Wait lists may close when demand for housing exceeds the supply of subsidized units available for occupancy (NCH, 2014; USDHUD, n.d.).

Lack of Affordable Health Care

In the absence of affordable health care coverage, a serious illness or disability can lead to job loss, savings depletion, and even eviction. Nearly half of individuals experiencing homelessness in the United States suffer from substance abuse disorders (United States Interagency Council on Homelessness [USICH], 2013d). One third of sheltered homeless persons have a chronic substance abuse issue, and over one quarter report a severe mental illness (U.S. Conference of Mayors, 2014).

In 2013, 42 million Americans (13.4% of the population) were without health care coverage (Smith & Medalia, 2014). Individuals with income levels below the poverty line comprise 27% of the uninsured population. The Affordable Care Act has expanded Medicaid coverage to millions of previously uninsured people and has provided tax credits to other low-income individuals, making health care more affordable for many low-income families (Kaiser Family Foundation, 2014).

The uninsured are less likely to receive preventive care or care for chronic health conditions. They are more at risk for preventable hospitalizations and missed diagnoses. Nearly half of all bankruptcies in the United States are due, in part, to medical debts (Kaiser Family Foundation, 2014). Those who are able to qualify for medical assistance may be reluctant to seek employment, fearing termination of benefits. Many others have limited insurance coverage that requires higher co-pays or deductibles and does not cover major catastrophic illnesses. A catastrophic adverse health event can plunge one into a homeless condition. See Chapter 6 for more on health care economics and insurance coverage.

In a study of 300 homeless people at a day shelter, nurse researchers found 43% of them describing a serious and/or chronic health problem and 53% a significant mental health problem. Almost half revealed having a substance abuse disorder. Those with more serious health problems had some insurance and perceived better access to health care than those without insurance. This access, however, was less than they expected, and a longer duration of homelessness was associated with having insurance. They called for more research and better-matched services for this vulnerable population (Weber, Thompson, Schmiege, Peifer, & Farrell, 2013).

Employment

Low-income wage earners may hold jobs with nonstandard work arrangements. Temporary employees, day laborers, independent contractors, and part-time employees are examples of work arrangements that tend to pay lower wages, offer little or no benefits, and have less job security. For persons with little or no job skills, it is virtually impossible to compete for jobs that offer a living wage. Barriers to employment among the homeless include lack of education and job skills; lack of transportation, daycare, or other supportive services; lack of access to technology; and disabilities that make it difficult to pursue or retain employment. To overcome homelessness and maintain employment, one must not only obtain a job that

pays a living wage but must also have access to supportive services such as child care and transportation (NCH, 2012c).

Domestic Violence

Domestic violence is a major cause of homelessness among women. For victims of domestic violence, the choice is often between living in an abusive situation or leaving and facing life on the streets. Those living on the streets face assaults and rape and often seek to appear invisible in order to evade this (Colorado Coalition for the Homeless, 2012). Fifteen percent of homeless adults in cities surveyed by the U.S. Conference of Mayors were victims of domestic violence (U.S. Conference of Mayors, 2014). Victims of domestic violence are often isolated from social support networks and financial resources, rendering them especially vulnerable. They may lack a steady income or a stable employment record and often suffer from anxiety, depression, panic disorder, or substance abuse disorders. Women who are victims of domestic violence may lack the resources needed to become independent and escape an abusive environment. A major challenge facing homeless service providers of domestic violence victims is the need to ensure a safe and secure environment and to protect client confidentiality (NAEH, 2015a).

Mental Illness

The U.S. Conference of Mayors (2014) estimates that, among its 25 cities surveyed across the nation, severe mental illness is reported by 28% of homeless adults. Deinstitutionalization (being released from institutions into the community), limited access to services, difficulty carrying out essential activities of daily living, and difficulty maintaining stable relationships contribute to the number of severely mentally ill persons represented in the homeless population (NCH, 2012m).

Poor mental health adversely affects an individual's ability to make sound judgments, solve problems effectively, and make wise decisions. Persons with mental illness may neglect to take the necessary precautions to avoid or reduce their risk of illness. Some mentally ill persons self-medicate their disturbing symptoms using street drugs, placing them at increased risk of addictions and diseases transmitted through injection drug use. Mental illness and substance abuse are often comorbid conditions that, coupled with poor physical health, make it especially difficult to secure employment and safe, affordable housing (NCH, 2012m).

Addictions Disorders

Rates of alcohol and drug abuse are disproportionately high among the homeless. Nearly half of all individuals experiencing homelessness and 70% of homeless veterans have substance abuse disorders (USICH, 2013d). One study of Skid Row homeless in Los Angeles found marijuana, crack, and alcohol to be the most frequently used substances (Rhoades et al., 2011). This makes it more difficult for them to access shelters that require

abstinence for admission (Donley & Wright, 2012; USICH, 2013d).

For persons already at risk for homelessness, the behaviors associated with an addictive disorder can create instability and jeopardize family and employment support nets. The combination of substance abuse, job loss, and family breakdown often results in homelessness, especially if social support or government assistance/programs are not available. This may be further complicated with someone having little education or job skills and criminal justice system incarceration (Mago et al., 2013). Once homeless, persons may resort to drugs or alcohol to dull the pain of being homeless and ease the feelings of hopelessness that accompany such a desperate state. They may also turn to chemical substances in an attempt to self-medicate the disturbing symptoms of an untreated mental illness. Approximately half of all mentally ill homeless individuals have co-occurring substance abuse disorders (USICH, 2013d).

Although some homeless individuals may desire treatment to overcome their addictions, they often encounter obstacles that undermine their recovery and prevent them from obtaining the treatment they need. Limited access to care and lack of community resources make it difficult if not impossible to receive the services needed to achieve a successful recovery. Many shelters require sobriety to access services (USICH, 2013d). There may be long waiting lists for addictions treatment, and homeless people who do not have a phone and are difficult to locate may be dropped from the waiting list. Lack of transportation and lack of documentation needed to access programs (i.e., birth certificates, social security cards) further exacerbate the problem. Denial of Supplemental Security Income (SSI) or Social Security Disability Insurance (SSDI) to persons with substance abuse–related disabilities creates a huge barrier to achieving recovery support, proper medical care, and housing and income assistance. Moreover, the federal programs targeting homelessness, mental health, and addictions services lack the extent of funding necessary to exert an impact that could effectively address this problem on a national level (NCH, 2012o).

What do *you* think?

Many of us ask why there are so many homeless, and why they choose not to use shelters. Richard Tripp, an author who was formerly among the homeless population, gives these reasons: (a) lack of beds/overcrowding (most places require you to stand in line for hours each day in order to secure a space at night; if you have a job, you can't always get in line early enough for a bed), (b) contagious illnesses (e.g., bedbugs, tuberculosis, hepatitis) are common and those who are contagious cannot be given separate quarters, (c) having your shoes stolen (theft is not an uncommon thing in shelters; good-fitting shoes are vital to survival), (d) not being allowed to bring your pet dog or cat with you (most shelters do not permit pets, so many homeless individuals choose to sleep outside with their animals), (e) exclusion of those using alcohol or drugs (even though, in some shelters, drug dealers are

active), (f) some faith-based shelters compel their clients to listen to religious messages or sermons (this may conflict with their own beliefs, or they may feel coerced).

1. What do you think might be other reasons an individual would choose to sleep outside rather than in a homeless shelter?
2. How could some of these issues be effectively addressed?
3. How does your city address these issues and the overall problem of homelessness?

Adapted from Tripp, R. Ten reasons the homeless would rather freeze than go to a shelter. Retrieved from http://www.coppinc.com.

Additional Variables

Additional variables impacting homelessness include personal or financial crisis, natural disasters, or personal choice. For example, natural disasters may displace previously independent and self-sufficient individuals and families, rendering many homeless and in need of emergency shelter (Davidson, 2013). See more on disasters and their aftermath in Chapter 17.

Homeless Subpopulations

Although many of the struggles facing the homeless are universal, there are subpopulations within the homeless community that are uniquely vulnerable. Often, these groups face additional burdens because of their special needs and challenges.

Homeless Men

Approximately 63% of sheltered homeless adults are men (USDHUD, 2014). The majority of homeless men are single adults. Homeless men are more likely to be employed than their homeless female counterparts. However, they usually hold temporary, low-wage jobs that offer little security. They are also more likely than homeless women to have uncontrolled substance abuse issues (NCH, 2012o).

EVIDENCE-BASED PRACTICE

How do we engage homeless persons to use primary care services and to keep their medical appointments? McInnes et al. (2014) conducted a pilot study to determine the feasibility and cost-effectiveness of using mobile phone text messaging among homeless veterans frequenting an urban Veteran's Administration (VA) medical center. A purposive sample of 21 homeless individuals who owned a mobile phone and were knowledgeable in text messaging was obtained. Surveys were completed prior to and following the 8-week text messaging intervention. A semistructured interview was conducted following the intervention to evaluate the usefulness of texting as a communication device for enhancing medical appointment adherence. Patients received monetary incentives (store vouchers) for completing the surveys and participating in the interviews. The effectiveness of the intervention was determined by comparing the cost of transmitting text messages to the cost of patient cancellations, no show appointments, and ED visits.

The study found that participants reported high levels of satisfaction with the text messaging system. Appointment cancellations were reduced by 30% and no shows were reduced by 19%. There was a statistically significant reduction in ED visits post intervention and a borderline significant reduction in hospitalizations. The potential cost savings to the entire VA system, assuming the program was implemented on a national level, was $2.3 to $115.7 million.

What creative outreach approaches might the CHN develop to improve medical appointment adherence and reduce unnecessary and costly ED visits? What new technologies or communication devices might be used to enhance outreach efforts? How can creative approaches be used to improve, not only health care delivery, but the delivery of other supportive services? How might the CHN use research evidence to make a case for funding technologies that enhance communication and service delivery in the homeless population?

McInnes, D., Petrakis, A., Gifford, A., Rao, S., & Houston, T. (2014). Retaining homeless veterans in outpatient care: A pilot study of mobile phone text message appointment reminders. American Journal of Public Health, 104(54), s588–s594.

Some men find themselves in a cycle of intermittent homelessness as they move back and forth between prisons, treatment centers, shelters, temporary housing, and the streets. Other men are at risk for becoming chronically homeless. A chronically homeless adult is someone who has been homeless for long periods of time or has experienced repeated episodes of homelessness. These individuals have a diagnosed disability such as mental illness, substance abuse, or a chronic medical condition and have been homeless for at least a year or have experienced at least four episodes of homelessness in the past 3 years. Fifteen percent of the homeless population in the United States are chronically homeless (NAEH, 2015b). In 2015, the *Annual Homeless Assessment Report* to Congress recorded over 83,170 chronically homeless individuals in its point-in-time count (a 31% decline since 2007). Almost two thirds of these individuals were unsheltered or characterized as living on the street or in places not fit for human habitation (USDHUD, 2015).

Homeless men are more likely to be treated with disdain than other homeless subgroups. Some people perceive the homeless male as largely to blame for his plight, believing that he is able bodied and should be able to work. Moreover, homeless men may not suffer from disabilities severe enough to warrant eligibility for health and social services. Often health and social programs give priority to women and children, and there are estimates of 84% of the hidden homeless being males (Chalabi, 2013).

Homeless Women

Women, as single parents, lead most homeless families in the United States. About 90% of those women have experienced a minimum of one severely stressful traumatic event; for many of them, this began during childhood (AIFR, 2014). Domestic violence is a major cause of homelessness among women. Lack of affordable housing forces many women to choose between living in an abusive home and facing an uncertain life on the streets. Domestic violence victims often have poor credit and employment records because of the disruption caused by family violence. If violence is discovered in the home, landlords may evict tenants, forcing the family onto the streets (NCH, 2012a). They often have few job skills that lead to low-paying often only intermittent jobs, inadequate child care, and limited social supports; this was exacerbated during and immediately following the economic downturns of great recession (AIFR, 2014). See Population-Focus. Once homeless and on the street, a woman faces the risk of greater abuse. Moreover, the potential for exposure to violence and sexual assault on the streets increases the risk for sexually transmitted infections and traumatic injuries (Colorado Coalition for the Homeless, 2012).

POPULATION-FOCUS TENT CITIES AND SOLUTIONS FOR THE HOMELESS

After the Great Recession of 2007 to 2008, tent cities began springing up across many larger cities in the United States, some of them with mutually determined codes of conduct and social structures. These temporary communities were a similar phenomenon to the shantytowns of the Great Depression, and some cities responded with police action to clear them out or with legislation making it illegal for homeless to congregate in large numbers (Herring, 2015; National Law Center on Homelessness & Poverty [NLCHP], 2014). Cities have sometimes also sought means of controlling food sharing with the needy/homeless by passing laws to restrict the use of public property or to force agencies to meet stringent food–safety regulations (NLCHP, 2014; Stoops, 2014).

Imagine a world where it is illegal to sit down. Could you survive if there were no place you were allowed to fall asleep, store your belongings, or to stand still? Homeless people, like all people, must engage in activities such as sleeping or sitting down in order to survive. Yet in communities across the nation, these harmless, unavoidable behaviors are treated as criminal activity under laws that criminalize homelessness (NLCHP, 2014, p. 7).

The NCH, in its most recent report (2010), researched several of these large tent cities in an effort to better understand the problems facing this vulnerable population. In a good-sized tent city in Sacramento, California (n = 97), they found that a majority of the inhabitants were individuals (63%), and 37% were families. Three quarters of them were males, 23% were female, and 2% were transgender individuals. Most were between the ages of 35 and 45, and 65% had been homeless for over a year. Fifty-five percent of them had disabilities of some sort (e.g., problems walking, schizophrenia/other mental illness, PTSD, COPD, hepatitis C, back injuries), and 24% had been to an emergency room within the last 6 months. Three fourths of them had no insurance, and 19% were veterans. About 45% of them had some type of benefit income (24% general assistance/welfare, 11% SSI, 10% other).

When asked about willingness to go into an overflow winter shelter, only 33% said that they would do so. Of the majority who would not, 30% indicated an interest if the shelter provided some private space for couples or individuals, 22% were interested if there was some type of outdoor activity or open recreational space,

21% were agreeable if they were given more sleep time, and others wanted places to store their belongings or kennel their pets overnight. Sixty-five percent were willing to be sheltered if they could be placed on a waiting list for more permanent housing within a 2 to 3 month period, and 22% expressed an interest in alcohol/drug recovery housing. Reasons for not wanting to be placed in a homeless shelter included no pets allowed, not being able to make the 3 pm deadline for beds, no private showers/privacy/comfort/strict rules, no freedom/too many people, couples are unable to stay together, problem with transportation, no wheelchair access, and having to wake up too early every morning.

In California, tent cities in Sacramento, Fresno, Albany, and Ontario have been cleared out and demolished. But, in Seattle, Washington, two tent cities located in church parking lots have been maintained for a decade. Austin, Texas, put large tents, microhomes, and RVs on 27 acres of donated land and rents them at a low cost. This project also features communal garden, bees, chickens, and an outdoor cinema (Herring, 2015). Salt Lake City, Utah, established a goal to end homelessness in 10 years time. Their Housing First project has led to a 91% decrease in the city's homeless population. Even the most difficult, chronically homeless have been placed in affordable housing. One example is a 54-year-old chronically homeless man, who has lived outside for 5 or more years and who presently lives in a wooded area near a freeway. He calls it his "park" and has created a "fence" surrounding his makeshift tent. He became homeless after a back injury and has problems with alcohol and drug use and reports having had a stroke. Outreach workers say he has few remaining teeth and his speech is difficult to understand. He is now getting housing through the Housing First program and does not have to demonstrate sobriety before qualifying. He will pay either 30% of his income or $50/month (depending on which is greater). Because estimated annual costs to government (e.g., emergency room visits, incarceration) are between $30,000 and $50,000/person annually, the state saw an opportunity to help the homeless and more responsibility deal with government budgets. Although there is still limited housing in the state, each week, homeless people are placed in housing and supported by visits with outreach workers. So far, it seems to be working (McEvers, 2016).

1. Have you seen tent cities like this? What were your resultant feelings and emotions?
2. What do you think could be done to address some of the issues raised by the homeless population in this tent city? Debate the issue with classmates.
3. How could PHNs be involved in helping to design feasible population-focused interventions?

Homeless Children

One in every 30 children (2.5 million) in the United States are homeless, an increase of nearly 8% nationally. Poverty, lack of affordable housing, domestic violence, economic recession impacts, the challenges of being a parent, and racial disparities contribute to the growing trend in family homelessness (AIFR, 2014). Nearly half of all homeless children in the United States are under 6 years of age (National Center on Family Homelessness [NCFH], 2014). Unaccompanied homeless children and youth are more likely to be unsheltered than unaccompanied youth with 51% of unaccompanied youth under age 18 residing in unsheltered locations (USDHUD, 2015). These children are living in places that are dangerous and often difficult to access by service providers.

Lack of affordable housing, poverty, domestic violence, and the recent economic recession are factors leading to homelessness, especially increased numbers of homeless children.

The majority of homeless children and youth live in shelters, share housing with friends or relatives, or live in motels or campgrounds. Over 96% of homeless children under age 18

live in families (USDHUD, 2015). It is estimated that about 75% of homeless children and their families live with relatives or friends, "doubled up," especially in rural areas; they are often missed in surveys of the homeless (AIFR, 2014). When compared to their housed counterparts, homeless children are more likely to become ill, to go hungry, and to suffer from emotional and behavioral disorders. They are also more likely to experience developmental delays and to suffer from learning disabilities. Children in homeless families are more likely to experience parental separation, either by being placed in foster care or by being placed in the care of friends or relatives. More than 25% of homeless children have witnessed violent acts (Child Trends Data Bank, 2015; NAEH, 2015b; NCFH, 2015). The effect of traumatic stress among homeless families experiencing domestic violence leads to depression, fear, and aggressive and antisocial behavior (NCH, 2012o; NCFH, 2011).

Education is compromised when one is homeless. Homeless children are more than twice as likely to repeat grades in school as other children and are more likely to drop out or be suspended or expelled (Child Trends Data Bank, 2015). During the 2011 to 2012 academic year, over 1.1 million school-age children and adolescents were enrolled in U.S. schools (NLCHP, 2014). Barriers to education include transportation to and from the shelter, lack of academic and medical records required for registration, unstable living arrangements necessitating multiple moves, and urgent needs for food and shelter that take priority over education (NCH, 2012b).

Homeless children are more likely to get sick than other children. Although acute and chronic health problems are more severe in homeless children, these children are less able to access medical and dental care. Asthma, hyperactivity/inattention disorders, and behavioral problems are more prevalent in homeless children than in the general population (Child Trends Data Bank, 2015). See Chapter 22 for more on school-aged children and adolescent.

Homeless Youth

The exact numbers of homeless youth is elusive. McKinney-Vento data are only collected on children and adolescents present in schools (AIFR, 2014). Factors contributing to youth homelessness include physical and sexual abuse, family addiction, parental neglect, strained relationships, or family financial crises that lead to family separation because of inadequate shelter, housing, or child welfare resources. Foster care placement is associated with homelessness among youth. Moreover, some youth who are discharged from residential or foster care with inadequate housing or income support end up homeless (NCH, 2012k). A study conducted in the Southwestern United States examined youth perceptions of barriers and facilitators to use of homeless shelters. Ha, Narendorf, Santa Maria, and Bezette-Flores (2015, p. 25) found attitude and access barriers (e.g., shame, pride, adverse staff attitudes, "restrictive shelter rules," and other adverse conditions). Facilitators included supportive staff/others, shelters' reaching out to other services to assist them, and having a particular condition (e.g., pregnancy). Further, an examination of homeless youth's experience with primary care services in Australia found that a variety of approaches to delivery of care and

available services were accessed and that street-based clinics, which were linked to case management and counseling services, had the most impact on substance abuse and mental health outcomes for this population (Dawson & Jackson, 2013). Barriers included poor attitudes of health care providers, lack of knowledge about services, unwelcoming environments, and costs of care. The researchers highlighted the need for public health nurses to collaborate with community and social workers in order to better serve this population.

Homeless adolescents may have difficulty accessing emergency shelters because of shelter policies that prohibit older youth from the facility or because of a lack of bed space. Because of lack of education or job training skills, many resort to prostitution or survival sex (exchanging sex for food, shelter, or other basic necessities). As a result, homeless youth are at higher risk for HIV, hepatitis, and sexually transmitted infections. Homeless youth also suffer disproportionately from anxiety, depression, malnutrition, conduct disorders, posttraumatic stress, and low self-esteem (NCH, 2012k).

It is not uncommon for homeless youths to be arrested for running away, breaking curfews, or being without supervision. As young people age out of the foster care system, they find themselves on the street with inadequate support systems and little opportunity for housing or employment (NCHE, 2012).

Homeless Families

Poverty and the lack of affordable housing place families at risk of becoming homeless. Declining wages, changes in welfare programs, unstable employment, domestic violence, substance abuse, and a struggling economy have all contributed to the rise in family homelessness.

Homelessness often breaks up the family unit. Families may be separated by shelter policies that prohibit admission to older boys or men. Sometimes, parents are forced to leave their children with family or friends or to place them in foster care to shelter them from becoming homeless (Child Trends Data Bank, 2015; NCH, 2012h). One North Carolina study of homeless shelter policies found that most shelters mandated that children be kept under constant supervision by parents, and many required random alcohol and drug testing, along with set bedtimes for children and sometimes for adults. No input from homeless residents was sought in policy setting, and their feelings of empowerment and self-esteem are most likely further diminished in shelters without any type of shared governance (Spriggs, 2013).

A child is at greater risk for homelessness if his father becomes injured or ill, experiences a job loss, has a substance abuse issue, or becomes involved with the criminal justice system. Fifty percent of fathers of homeless children are unemployed, and 43% have problems with drugs or alcohol. Homeless children are at a high risk of being placed in foster care, and a personal history of foster care predicts family homelessness during adulthood. To assist homeless families, attention must be focused on promoting affordable

housing; supporting education, job training, and child care for parents; promoting access to school; expanding violence prevention and treatment services; and preventing unnecessary separation of families (NCFH, 2014; NCH, 2012h).

Homeless Veterans

According to the *2015 Annual Assessment Report to Congress*, 11% of homeless adults were veterans, and 34% of them were in unsheltered locations compared to 28% of total homeless adults. Over 90% of homeless veterans are males, and there were 4% fewer homeless veterans than in the previous year (USDHUD, 2015). In 2009, the U.S. Department of Veterans Affairs established a goal to end homelessness by 2015. Targeted funding of veteran assistance programs such as the HUD-VA supportive housing program, which provides permanent housing and treatment services to homeless veterans, along with programs funding community-based transitional housing and supportive services to low-income veterans have helped to reduce the rate of homelessness among the veteran population. Larger numbers of younger veterans of the Iraq and Afghanistan wars and projected cuts in defense spending, however, create new challenges for combating homelessness among veterans (U.S. Conference of Mayors, 2014).

Female homeless veterans represent 9% of the homeless veteran population (USDHUD, 2015). They are more likely to be married and have serious psychiatric illnesses but less likely to be employed or have addiction disorders than their homeless male counterparts. There is no difference in rates of mental illness or addictions between veteran and nonveteran homeless women (NCH, 2012j). See Perspectives.

PERSPECTIVES HOMELESSNESS FOR ONE FEMALE VETERAN

I am a female veteran, recently discharged from active duty service during which I was deployed to Iraq. I am now homeless. I am one of thousands of veterans who sleep on the streets of America every night. I did not know that I was at risk for homelessness when I joined the military; in fact, I thought a military career or enlistment would help me be successful in life. I did not know that women veterans are three to four times more likely to become homeless than nonveteran women. Or, that posttraumatic stress disorder (PTSD) is twice as likely to be diagnosed in women as in men. Considering that 14% of all deployed military personnel to Iraq and Afghanistan are women, I guess I should have known this was a possibility for me. But, I was not prepared for what happened to me. I am also a victim of sexual trauma, which is a trigger for PTSD, and this has profoundly

impacted my ability to return to a normal life as a veteran. Now, I never feel safe and I am not able to trust anyone or anything. I am afraid to fall asleep in a shelter, and I am frightened to fall asleep in my car. I am exhausted, both from the constant fear and anxiety, as well as from the seemingly impossible effort it takes to obtain the basic resources necessary to survive. I know you look at me and wonder why I am in this position. I am sure that you don't understand why I do not seem to be able to change my situation. Believe me, I have tried.

Sarah, Veteran

1. *What resources are available in the community for homeless female veterans?*
2. *Are there barriers to accessing these resources for certain veterans?*
3. *What are some of the common assumptions and stereotypes circulating in your community about homeless veterans?*
4. *What would you want to include in your assessment in order to identify risks and to implement treatment planning for homeless veterans like Sarah?*
5. *In the above example, what health issues and risks might be critical for this homeless female veteran?*

The U.S. Department of Veteran Affairs (VA) administers programs that provide long-term care, emergency shelter, 2-year transitional housing, group homes, and work therapy for homeless veterans. These programs provide case management, residential treatment, and other services to homeless veterans and improve housing, employment, and access to care for the homeless veteran population. Unfortunately, the programs are often unable to keep pace with existing needs (NCH, 2012j).

The Rural Homeless

Homeless people in rural areas are more likely to be working families who are homeless for the first time. They are less likely to be on government assistance programs. Because there are fewer shelters in rural areas, they are also less likely to live in shelters or in the streets, and more likely to live in cars, substandard housing, or "doubled up" with friends and family. As a result, they may not be considered "homeless" for reporting purposes. Higher rates of homelessness may be found in rural areas than in large cities (AIFR, 2014). Moreover, the communities in which they live may not be able to access as much federal funding, because the statistics do not adequately reflect the magnitude of the problem. Families with single mothers and children comprise the largest segment of the rural homeless population. Native Americans and migrant workers are more likely to be among the rural homeless. Like urban homelessness, rural homelessness is largely a result of poverty and lack of affordable housing. Although housing costs are lower in rural areas, incomes are also lower (National Advisory Committee on Rural Health and Human Services, 2014; NCH, 2012n).

Homelessness in rural areas may be precipitated by structural or physical housing problems that force families to relocate to safer, but more expensive, housing. In addition, the lack of job opportunities, the distance between low-income housing and job sites, the lack of transportation, rising rents, geographic isolation, and lack of resources compound the problem. To address the needs of the rural homeless, the definition of homelessness needs to be expanded to include people living in temporary or substandard housing (NCH, 2012n).

Rural housing may be structurally unsound or substandard.

The Older Homeless

Only 3.5% of sheltered homeless individuals were 62 or over in 2013 (USDHUD, 2014). Although the percentage of elderly individuals in shelters is low, it has increased over recent years from just over 4% in 2007 to over 5% in 2013 (USDHUD, 2014). The percentage of individuals aged 51 to 61 who are housed in shelters also increased from nearly 19% in 2007 to 25% in 2013 (USDHUD, 2014). It is expected to continue to rise, from 44,172 in 2010 to 58,772 in 2020—a 33% increase. And, the average age of sheltered individual homeless has been rising (National Health Care for the Homeless Council [NHCHC], 2013).

Two pathways for homelessness among the elderly have been identified. One is that chronically homeless individuals are an aging population and may be coming off the streets into shelters as their health further deteriorates, thus leading to increased numbers.

Secondly, newly homeless individuals, who have never experienced housing issues, are now finding themselves without housing because of poverty, excessive cost of housing, job loss, and problems with physical health as well as mental health issues. In some cases, loss of social support systems is instrumental (NHCHC, 2013). Many older people live on a fixed income, and this restricted income renders them more vulnerable to unexpected financial crisis and even homelessness. Isolation also contributes to homelessness. Many older people live alone and lack a support network. Some researchers define the "older homeless" as homeless persons 50 and older because of the declining physical health that accompanies street living (NCH, 2012i). Because of health issues and homelessness, they may use emergency departments (EDs) more often. Brown and Steinman (2013) found that about one third of visits to the ED by homeless individuals were for those over age 50, and these individuals often came by ambulance and were admitted. Alcohol use in the elderly homeless population is not uncommon, but drug abuse is less common than in the general homeless population (NHCHC, 2013). Because older persons tend to distrust crowds at shelters and clinics, they are more likely to stay on the streets. They are prone to criminal victimization and suffer from a variety of health conditions including chronic diseases and functional disabilities. The Social Security benefits to which many are entitled are inadequate to cover housing costs. They may also encounter difficulties applying for benefits (NCH, 2012i). Planning for end-of-life care is very difficult with this population, but providing one-on-one counseling and assistance in this area has been helpful in completing advance directives (NHCHC, 2013).

Lesbian, Gay, Bisexual, Transgender Homeless

Lesbian, gay, bisexual, and transgender (LGBT) persons often struggle to locate shelters that accept them. They are sometimes required to identify themselves as a particular gender. Transgender individuals may be turned away from shelters or subjected to physical, sexual, or verbal abuse. It is estimated that 20% of homeless youth are LGBT, although some cities have noted rates of LGB youth to range from 12% to 35% and possibly 7% identifying as transgender. These youth are over seven times more likely to experience sexual violence. They also commit suicide at much higher rates than their heterosexual homeless counterparts, with some estimates as high as 62% versus 29% for those who identify as heterosexual youth. Shelter staff may not be trained in working with the LGBT population, and discrimination does occur (NAEH, 2016; NCH, 2012l). Ream and Forge (2014) describe their work with homeless LGBT youth in New York City and the oft-cited narratives of being thrown out of their homes by family who could not accept their LGBT lifestyles, struggling on the streets with sex work and hard drug use, the risks of HIV/AIDS, and suicide. However, they note that this does not reflect the majority of this population and that "trauma, discrimination in foster care and shelters, structural barriers to exiting homelessness, and emerging adult development" are the more common issues (p. 7). LGBT-specific shelters and transitional living programs are needed for this vulnerable population, but even though they are present there, not enough capacity exists to serve all

who need these services.

HEALTH CARE AND THE HOMELESS

Homeless persons are three to four times more likely to die prematurely than their housed counterparts (NHCHC, 2011a). Acute and chronic health problems are prevalent among the homeless population. Chronic health conditions such as HIV/AIDS, diabetes, hypertension, addictions, and mental disorders require ongoing monitoring and are often difficult to treat in a population that is transient and lacks stable housing (NHCHC, 2015; NCH, 2012f). It is difficult for the homeless to adhere to complex treatment regimens. For example, where would a homeless person find a refrigerator to store insulin? Where would someone keep supplies for dressings? How could someone with no access to transportation keep regular appointments with health care providers? How does a homeless person keep track of multiple appointment dates? How is a shelter resident that is receiving the typical shelter diet high in carbohydrates, fats, and sodium able to adhere to a low-salt or diabetic diet? Where can a homeless person receive home health care if they are not allowed to stay in shelters during the day?

Many homeless people expend their time and energy trying to meet basic survival needs. Health care may take a back seat to finding food, clothing, or shelter. High cost and limited access to health care, as well as negative experiences with the health care system, can also result in avoidance or delays in seeking treatment (NCH, 2012f; NHCHC, 2011a). However, a large-scale study of 1,163 homeless adults demonstrated that their self-reports of visits to ambulatory care clinics, EDs, and hospitalizations are "quite accurate," especially visits to the ED and when they are hospitalized (Hwang, Chambers, & Katic, 2016, p. 282).

Frost bite, leg ulcers, and upper respiratory tract infections result from chronic exposure to adverse environmental conditions. The homeless are also at higher risk of trauma and criminal victimization including muggings, beatings, and rape. When one is homeless, it is difficult to maintain adequate nutrition or personal hygiene or to have access to basic first aid (NCH, 2012f, 2012g, 2012e). Communicable diseases such as TB, HIV, hepatitis, and other infections threaten not only the homeless but also the public in general.

Poverty, substance abuse, poor nutrition, and coexisting medical and psychiatric illnesses also predispose the homeless to severe oral health problems. Persons with poor access to dental treatment and preventive services have higher rates of oral disease. Poor oral health is also associated with lower levels of education and income (USDHHS, 2016). A national study of homeless adult health care needs revealed 41% requiring dental health care (Baggett, O'Connell, Singer, & Rigotti, 2010). A study of 120 homeless families found that almost half of the children had dental caries and that 43% of those families were able to get dental care when shelter-based care was provided (DiMarco, Ludington, & Menke, 2010). In an evaluation of Health Care for the Homeless programs, homeless participants reported that their dental care treatment needs were being met, and this was similar among those who were not homeless (Zur & Jones, 2014).

Persons with HIV/AIDS are at higher risk of homelessness, because HIV-related illness can impact job stability. Moreover, health care costs associated with treating the illness can exact an enormous financial burden on a low-income family. Insufficient funds to adequately house the poor with HIV/AIDS may also contribute to homelessness among HIV-infected individuals. Substance abuse and sexual exploitation among the homeless increase the risk of HIV infection. Moreover, it is difficult to maintain adherence to complex HIV/AIDS medication regimens without access to good food, bathrooms, refrigeration, and clean water (NCH, 2012g).

Health Care for the Homeless is a model for homeless health care developed through a 19-city demonstration project funded by the Robert Wood Johnson Foundation and the Pew Memorial Trust. In 1987, federal legislation (the McKinney Homeless Assistance Act) was passed that authorized federal funding for these programs. Grants are awarded to community-based organizations that deliver high-quality health care to homeless populations. Health Care for the Homeless projects can be found across the nation to address significant gaps in health care delivery for this vulnerable group in society (NHCHC, 2011b). In one study of a comparison of unmet needs among homeless and nonhomeless populations receiving care at Health Care for the Homeless programs, homeless patients reported similar rates of both medical and dental care treatment needs being met. However, they were significantly more likely to have an unmet need for mental health counseling than nonhomeless counterparts; and they had fewer problems accessing treatment for substance use disorders. Zur and Jones (2014) concluded that these programs should continue to have funding and should increase their capacity and the scope of their services. See Evidence-Based Practice.

RESOURCES TO COMBAT HOMELESSNESS

Both public and private sectors have promoted a variety of initiatives to address the problem of homelessness. These initiatives are intended to impact homelessness on the local, state, and national level and to insure a coordinated, comprehensive, and systematic approach to addressing the problem of homelessness.

Public Sector

The McKinney-Vento Homeless Assistance Act (PL100-77) was the first and only major piece of federal legislation intended to address the problem of homelessness on a national level. This landmark legislation act, passed by Congress in 1987, originally consisted of 15 programs to address the major, pressing needs of the homeless. These needs included emergency shelter, transitional housing, job training, primary health care, education, and housing (National Association for the Education of Homeless Children and Youth, 2015; NCH, 2006). The current act has been amended four times in an effort to expand its scope and strengthen its impact. In particular, the amendments made to the act in 1990 represented significant milestones in advocating for the needs of the homeless. These amendments included the creation of the Shelter Care Plus program, which provided for housing assistance for persons with disabilities, mental illness, AIDS, and drug and alcohol addiction. Another amendment created a demonstration program within the Health Care for the Homeless program to provide primary care and outreach to at-risk and homeless children. In addition, the Community Mental Health Services Program was amended and retitled: the Projects for Assistance in Transition from Homelessness (PATH). Finally, the amendments made in 1990 strengthened access to public education for homeless children and youth. For example, states were required to provide grant funding to local educational institutions to insure access to a free, appropriate education for homeless youth and children (National Association for the Education of Homeless Children and Youth, 2015; NCH, 2006).

Over the years, congress has appropriated funding to enable implementation of this federal legislation. The extent of federal funding has fluctuated over the years. In recent years, some of the programs have been repealed or restructured in an effort to contain costs. Although homeless advocates acknowledge that the act was an important step in addressing homelessness, the lack of adequate funding over recent years threatens its impact on a national level. Moreover, some homeless advocates feel that the legislation focuses more on emergency measures to address the crisis of homelessness rather than on promoting a proactive agenda to address the causes of homelessness, such as lack of good paying jobs with benefits and the lack of access to affordable health care (Homeless Hub, 2015; NCH, 2006). In Massachusetts, the number of homeless families increased 71% between 2007 and 2012. Short-term rental subsidy vouchers were developed to meet the needs of this population. After 2 years of vouchers along with supportive services to assist families in maintaining their rental homes without further subsidies, it was found that only one quarter were able to do so. Twenty percent moved in with friends/family members, 21.8% obtained a permanent housing subsidy, 23.6% were lost to follow-up, and 9% returned to homeless shelters, highlighting the need for more permanent solutions such as timelier integration of support services and "targeted workforce development" (Meschede & Chaganti, 2015, p. 85).

The USDHUD oversees a number of programs that provide supportive housing for

elderly, low-income, and disabled persons. The department also funds programs to build, buy, or rehabilitate affordable housing units for rent or ownership (NCH, 2012d). In many communities, housing is based on a continuum of care model where programs are developed to assist persons to transition from emergency to transitional to permanent housing. Emergency shelters provide temporary overnight shelter, whereas transitional housing provides up to 24 months of housing and supportive services. Rapid rehousing programs provide short-term rental assistance and supportive services, whereas permanent housing provides long-term housing and supportive services (USDHUD, 2013, 2016). In recent years, a Housing First philosophy has guided much of the publicly funded housing initiatives (NAEH, 2015c). In a Housing First approach, housing is viewed as an immediate priority. The goal of Housing First is to end homelessness by providing stable, permanent housing as soon as possible and to provide supportive services to enable people to maintain their housing (NAEH, 2015e; USICH, 2013c). Housing or supportive services are not contingent upon adherence to rigid rules or policies or to the maintenance of sobriety (USICH, 2013c). See the previous feature on tent cities and successful approaches to Housing First.

The Homeless Emergency Assistance and Rapid Transition to Housing (HEARTH) Act of 2009 increased funding for McKinney-Vento programs, which provide emergency, transitional, and permanent housing and supportive services to the homeless and provide resources to local school districts to coordinate services for homeless children (NCFH, 2014). On March 23, 2010, President Barak Obama signed federal health care reform legislation into law that extends health insurance coverage and gives states the option to expand Medicaid coverage to low-income individuals regardless of disability or family status. This legislation enables homeless individuals in many states to secure health care coverage (USICH, 2013b). See Chapter 6.

Another significant milestone in federal initiatives to reduce homelessness occurred when the federal government adopted the goal of ending chronic homelessness in 10 years. To meet this goal, annual funding was appropriated to create new permanent supportive housing. These resources helped to stimulate the production of housing. Many communities followed the lead of the federal government and developed their own 10-year plans (Burt, 2006; McEvers, 2016). In 2010, the U.S. Interagency Council on Homelessness published the nation's first comprehensive federal strategic plan to prevent and end homelessness. The document, entitled *Opening Doors*, outlined a comprehensive and ambitious plan aimed at eliminating homelessness on a national level. The goals of the plan included ending chronic homelessness in 10 years; preventing and ending homelessness for families, youth, and children in 10 years; preventing and ending homelessness among veterans in 5 years; and establishing a path to end all types of homelessness (USICH, 2010).

Table 28–2 summarizes the nine titles of the McKinney-Vento Act.

Table 28–2 McKinney-Vento Homeless Assistance Act Titles I to IX

Title I	Statement of findings by congress and definition of homelessness
Title II	Establishes the Interagency Council on Homelessness, a council comprised of 15 heads of federal agencies to address the needs of homeless populations
Title III	Authorizes the Emergency Food and Shelter Program, administered by the Federal Emergency Management Agency (FEMA)
Title IV	Authorizes the emergency shelter and transitional housing programs administered by the Department of Housing and Urban Development (HUD) including the Emergency Shelter Grant Program, the Supportive Housing Demonstration Program, Supplemental Assistance for Facilities to Assist the Homeless, and Section 8 Single Room Occupancy Moderate Rehabilitation
Title V	Requires federal agencies to make available federal land and buildings for states and local governments to use to assist the homeless
Title VI	Authorizes programs to provide health care services to the homeless, including Health Care for the Homeless program, Community Mental Health Services Block Grant Program, and two demonstration programs providing substance abuse and mental health treatment services to the homeless
Title VII	Authorizes the Adult Education for the Homeless Program, the Education of Homeless Children and Youth Program (administered by the Department of Education), the Job Training for the Homeless Demonstration Program (administered by the Department of Labor), and the Emergency Community Services Homeless Grant Program (administered by the Department of Health and Human Services)
Title VIII	Amends the Food Stamp Program to facilitate access by the homeless and expands the Temporary Emergency Food Assistance Program (administered by the Department of Agriculture)
Title IX	Extends the Veterans Job Training Act

Table 28–3 presents selected federally sponsored programs for addressing the needs of the homeless.

Table 28–3 Federally Sponsored Programs for the Homeless

The U.S. Interagency Council on Homelessness	The U.S. Interagency Council on Homelessness coordinates the federal response to homelessness and creates a national partnership with public and private sectors to reduce and end homelessness in the United States. The Council is responsible for reviewing the effectiveness of federal initiatives and programs to assist the homeless, promoting better coordination of services between programs, and informing state and local governments and private sector organizations about sources of federal homeless assistance (USICH, 2013a).
Substance Abuse and Mental Health Services Administration	The Center for Mental Health Services, a center of the federal Substance Abuse and Mental Health Services Administration (SAMHSA), supports states in facilitating access to mental health services and supports outreach and case management for the homeless mentally ill (SAMHSA, 2014).
Center for Mental Health Services	The Center for Mental Health Services operates the Homelessness Resource Center, which provides resource information and information on the latest research and best practices for addressing the problem of homelessness (SAMHSA, n.d.a, SAMHSA, n.d.b).
Projects for Assistance in Transition from Homelessness (PATH)	PATH is a grant program created under the McKinney Act to provide treatment and supportive services to persons with severe mental illnesses, including those who are homeless or at risk of becoming homeless. The grants support outreach, mental health and substance abuse treatment, and rehabilitation for the severely mentally ill (SAMHSA, 2004).
Health Care for the Homeless (HCH)	The HCH program (a provision of the McKinney Act) awards grants to community-based organizations that seek to provide quality, accessible health care to the homeless. The HCH program is administered by the U.S. Department of Health and Human Services (USDHHS). HCH projects are required to provide primary health care, substance abuse services, emergency care, outreach, and housing assistance. Many HCH projects also provide dental care, mental health treatment, supportive housing, and other services (NCH, 2012f).
The U.S. Department of Housing and Urban Development (HUD)	HUD provides funding for supportive housing for low-income families as well as low-income individuals with disabilities and low-income elderly. Funds can be used for housing development or rental assistance (to cover the difference between what a resident can afford to pay and the cost to operate the project). Grants are also provided to public housing agencies to rehabilitate or replace dilapidated public housing structures. Persons applying for public housing face a long waiting period, sometimes up to as long as 10 y (NCH, 2012d).
The White House Office of Faith-Based and Neighborhood Partnerships	The White House Office of Faith-Based and Neighborhood Partnerships promotes partnerships with faith-based and community organizations to more effectively serve individuals, families, and communities in need. This office provides information on federal grants that are available to faith-based and community organizations to address the needs of the homeless (USDHHS, 2014).

Private Sector

The private sector has made a concerted effort to organize communities in the battle against homelessness by forming coalitions, alliances, and memberships that champion the causes of the homeless. These organized efforts are carried out at the national, state, and local level to positively impact the problem of homelessness in communities across the nation. Table 28–4 presents a list and description of selected resources in the private sector to combat homelessness.

Table 28–4 Private Sector Initiatives to Combat Homelessness

National Coalition for the Homeless (NCH)	The National Coalition for the Homeless is the nation's oldest advocacy and direct service organization for the homeless. The coalition is comprised of a national network of people who are currently experiencing or who have experienced homelessness, activists and advocates, community-based and faith-based service providers, and others who are interested in its mission. The mission of the coalition is to prevent and end homelessness while ensuring the immediate needs of the homeless are men and their civil rights protected. See http://nationalhomeless.org.
The National Center on Family Homelessness (NCFH)	The National Center on Family Homelessness seeks to prevent and end family homelessness by advancing knowledge gained from research, programs, trainings, and collaborations with homeless shelter and service providers. The organization seeks to raise awareness of the causes and effects of homelessness and to inform local, state, and national solutions for the problem of homelessness. See http://www.family homelessness.org.
National Coalition for Homeless Veterans	The National Coalition for Homeless Veterans is a 501(c)(3) nonprofit organization that provides resource and technical assistance to service providers and local, state, and federal agencies that provide assistance to homeless veterans. The coalition advocates for the needs of homeless veterans and for increased funding for federal homeless veteran assistance programs. See http://www.nchv.org.
National Alliance to End Homelessness (NAEH)	The National Alliance to End Homelessness seeks to end homelessness by advocating for policies that promote solutions to homelessness, providing technical assistance to local communities, and advancing data and research on best practices and solutions for combating homelessness. See http://www.endhomelessness.org.
Commission on Homelessness and Poverty, American Bar Association	This commission is committed to educating the public and the legal community about the issue of poverty and homelessness and trains members of the legal community on how best to advocate for those in need. The commission also advocates for public policies that protect and provide for the needs of the poor and homeless. See http://www.americanbar.org/groups/public_services/homelessness_poverty/about_us.html.
National Low-Income Housing Coalition	The National Low-Income Housing Coalition is dedicated to establishing housing stability and expanding the supply of low income housing in America. A major priority of the coalition is to promote public policy that provides funding for housing for extremely low-income people. See http://www.nlihc.org.

ROLE OF THE COMMUNITY HEALTH NURSE

Community health nurses maintain a long tradition of providing care to vulnerable populations and play a vital role in addressing the health needs of the homeless. Settings for care include shelters, clinics, soup kitchens, churches, community centers, social service agencies, and even the streets.

Trust is an essential ingredient in the development of a therapeutic relationship with the homeless. A caring, consistent relationship is more likely to engage people who are homeless and get them into treatment. It is sometimes difficult to establish trust with clients who have experienced negative encounters with the health care system. Often, limited resources, inadequate access to care, or prejudicial views can intensify these negative emotions. As with other vulnerable populations, the homeless struggle with feelings of powerlessness, loss of control, and low self-esteem. Victim blaming is common. Some members of society perceive the homeless as responsible for their own fate. It is not uncommon to hear people speak about the homeless in derogatory terms or to suggest that the solution to the problem of homelessness is to simply "get a job."

USING THE NURSING PROCESS

Sheila Hendricks, a public health nurse for the Manchester City Health Department, and her colleagues were brainstorming ideas for how to reach the growing population of homeless women and children in their jurisdiction. They arranged a meeting with the director of a local rescue mission in the area. The mission provided emergency shelter to 100 homeless women and children each night. The women were allowed to remain at the shelter for 30 days provided they actively sought employment, social services, or educational opportunities. Families typically left during the day to seek jobs or other forms of assistance and returned in the evening for shelter. The community health nurses negotiated with the rescue mission to establish an on-site nursing clinic twice a week that would provide health education, screenings, and referrals on a drop in basis. The hours of clinic operation were 4 PM to 8 PM to accommodate client schedules.

Assessment

After the clinic was in operation for 2 weeks, the following priority health issues began to emerge:

- Inadequate maternal and child nutrition
- Lack of primary health care services for women and children (i.e., immunizations, screenings, treatment for upper respiratory tract infections, dermatological problems, asthma, hypertension)
- Depression
- High rate of reported sexually transmitted infections and HIV because of history of violence, survival sex, and injection drug use
- Untreated addiction disorders

Plan

The following diagnoses were developed (in order of priority):

- Impaired access to health and social services related to lack of insurance, scarce community-based resources, and lack of transportation
- Ineffective family coping related to untreated addictions, mental health issues, and history of intimate partner violence
- At risk for injury related to untreated addictions and mental health disorders, history of intimate partner violence, and hazards of street life
- Altered nutrition less than body requirements related to lack of resources to purchase nutritious foods, addictions disorders, and chronic health issues

After assessing priority needs and establishing relevant diagnoses, the nurses developed a plan of care for this population. The priority goal was to promote access to care by linking clients to essential health and social services. The rationale for establishing this goal as a top priority was that if clients were able to access needed services, the other diagnoses could potentially be addressed (i.e., need for counseling, health care, housing, education).

Implementation

A nurse practitioner was engaged from the health department to provide primary care services to the women and children at the shelter including screening and treatment for sexually transmitted infections and treatment of common acute and chronic health conditions. Conditions requiring more extensive follow-up were referred to the local federally funded Health Care for the Homeless clinic. A social worker from the local social service agency was recruited to visit the mission on a monthly basis to assist clients to apply for housing and public assistance programs. Clients were referred to the local community mental health center for counseling related to addictions and violence issues. The nurses conducted health education programs and one-on-one counseling on topics such as parenting, coping, healthy eating, basic hygiene, and safety. They also offered health screenings for blood pressure, diabetes, HIV, and tuberculosis and provided referrals to the health department clinic for cancer screenings (i.e., mammograms, colorectal screening).

Evaluation

After the clinic had been in operation for 90 days, preliminary evaluation data revealed the following:

Sixty-five women and 28 children had frequented the clinic over the past 3 months. All 65 women received health promotion teaching and a resource packet for further reference. Eighty percent of clients who required referrals to outside agencies were successful in accessing care. Twenty-five women and 15 children were under the care of the nurse practitioner for acute or chronic health conditions. Ten cases of latent TB infection were identified through TB testing, and these clients were referred to the City Health Department TB clinic for follow-up treatment. Seven abnormal PAP smears were identified, and eight clients were diagnosed with sexually transmitted infections. Fifteen clients were found to be HIV positive. Clients with positive screenings were referred to the City Health Department or the local Health Care for the Homeless Clinic where treatment was initiated. Forty women applied for social service benefits. Most of these clients are still awaiting the receipt of benefits.

Behaviors that would ordinarily be considered lawful in the privacy of one's home become criminal activity when they are exhibited in public. For example, the homeless can be arrested for loitering, sleeping, urinating, or drinking alcohol in public. These behaviors can trigger a criminal record, thereby, jeopardizing future employment or housing opportunities (NLCHP, 2014). In all 50 states, men may be incarcerated for failing to pay child support (Carmon, 2015). Consider a man who is laid off from a low-wage job. He is unable to pay child support and is arrested. His violation generates a criminal record and compromises his ability to secure employment in the future. He becomes trapped in a cycle of poverty and homelessness that is difficult to escape.

What do *you* think?

Every nurse encounters new situations with prior assumptions, biases, and preunderstandings. When considering work with the homeless, it is important to clarify one's own beliefs and values about poverty, homelessness, addictions, and mental disorders. What has been your experience with the homeless? Have you ever observed a homeless individual asking for money or holding up signs at a busy intersection? What thoughts and feelings do encounters such as these provoke? Have you ever volunteered at a soup kitchen or food pantry, fed a group of homeless people, or donated food or clothing? Have you had the opportunity to get to know a homeless individual? Do you have a personal experience with homelessness or

poverty? If so, how has it affected your understanding of what it means to be poor or homeless?

It may be helpful to interview people who work with the homeless or to visit clinics, shelters, or other settings where the homeless congregate or access services. How are homeless people treated? What is a typical day like for someone who is homeless? How often do homeless persons hear their names? How often are they looked in the eye when addressed by others? How often are they touched in a way that is therapeutic, respectful, and affirming? By reflecting on your personal values and by allowing yourself to get closer to the people and places that are a part of the experience of homelessness, you will gain a deeper understanding of the homeless condition and be better equipped to serve those suffering from homelessness.

To effectively address the multifaceted problems associated with homelessness, a comprehensive and holistic approach is needed. As such, the community health nurse is responsible for implementing primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services. See Using the Nursing Process.

Primary Prevention

Primary prevention includes advocating for affordable housing, employment opportunities, and better access to health care to prevent the downward spiral into homelessness. Strategies for preventing homelessness may include financial counseling to assist clients to better manage their money; assistance in locating sources of legal or financial aid to prevent eviction, such as loans or grants for emergency funds to help pay for rent and utilities; and assistance in accessing social services and temporary housing or health care to avoid a housing, health, or family crisis (Anderson & McFarlane, 2015; NLCHP, 2014).

Health education that addresses primary prevention may focus on positive parenting skills, violence prevention, anger management, coping skills, healthy eating, or principles of basic hygiene. Immunization programs will help to prevent communicable disease in this high-risk population. Counseling victims of intimate partner violence and helping them to locate safe shelter can also aid in the prevention of homelessness (Anderson & McFarlane, 2015). Addictions treatment is also important to prevent the likely consequences of untreated addiction (e.g., death, incarceration, institutionalization, homelessness).

PERSPECTIVES A NURSE'S VIEWPOINT ON WORKING WITH THE HOMELESS

When I first decided to visit the homeless men's shelter, I was scared to death. Here I was, a veteran nurse with over 20 years experience in community health, and I was afraid. But, I thought to myself—afraid of what? I couldn't tell you. I suppose I harbored the stereotypes and negative images that most of us associate with homeless addicts. I remember passing this shelter years ago, looking out at the men hanging out on the street corner, and thinking to myself "Please God, don't let my car break down!" I remember thinking "I would never step foot in a place like that."

Well, I believe God has a sense of humor. He was equipping me for a work I could not have ever imagined. My views about homelessness were challenged to the core when I peered into the faces of those men, heard their stories, and began to feel their pain. Theirs were stories of broken lives and lost hope but also of courage in the face of suffering and the will to survive in the midst of great adversity. These men were as diverse as their stories. They were from all walks of life. They possessed incredible gifts and talents. They were musicians, artisans, businessmen, writers, and poets. They had families who loved them and families who left them. Left because they could not continue to watch them die

a little each day and be destroyed themselves in the process.

So here I am. Doing what I can to bring hope and healing. The irony is I came to bring hope and yet I am the one who is being healed. Healed in the broken areas of my life. Healed in my narrow view of life and my internal prejudices. I am so grateful to God for giving me this unique opportunity. It is a great privilege to serve these men.

Rita, age 42

Secondary Prevention

The focus of secondary prevention measures is on the early detection and treatment of adverse health conditions. This requires a thorough assessment of client needs including the need for housing, health care, education, social services, and employment. Clients will also benefit from secondary prevention measures such as screening for communicable and chronic diseases (e.g., hepatitis, TB, STI, HIV, hypertension, diabetes, cancer).

Barriers to accessing services and the extent of community resources available to the homeless also need to be assessed (Anderson & McFarlane, 2015; NLCHP, 2014; Zur & Jones, 2014). Resources such as shelters, soup kitchens, medical clinics, social service agencies, and supportive housing should be readily accessible to the homeless population. Hauff and Secor-Turner (2014) interviewed staff from shelters and health services serving a homeless population. Shelter staff was most concerned with barriers to appropriate care, health need/problems, and lack of medical respite/support services. Health service providers echoed those concerns to some degree with health needs/barriers to management of care, discharge planning issues, and the need for support/respite services. The researchers described the need for better training of health service providers about the homeless and cultural competencies. They also noted the need for training in Trauma-Informed Care (TIC), a homeless service delivery model that recognizes the traumatic experience of homelessness as well as some of the traumatic events that led to live on the streets. TIC is based on the need for staff to be aware of and understand trauma, along with the resolve to use strengths-based interventions and skill building with homeless clients in an effort to help them regain some control in their lives.

Lack of transportation can be a major barrier to accessing care. Some programs have responded to this need by adopting mobile health vans that provide care on street corners and in neighborhoods (Gibson, Ghosh, Morano, & Altice, 2014). Clinics have also been established in shelters to facilitate client access, and nurses often manage clinics (see Chapter 31). Nursing students also play an important role in promoting access to care for the homeless (Asgary, Garland, Jakubowski, & Sckell, 2014; Bowker, Weg, & Hansen, 2013). In a study of homeless and marginally housed adults in Connecticut, 51% reported that they had used some type of primary care in the previous 2 years. Those that had used primary care services were found to have also had regular visits with community health nurses, and this was a statistically significant association (Zhuo, Khoshnood, & Forster, 2015).

The community health nurse should also consider the role of faith-based communities in providing physical and spiritual support to the homeless. Many places of worship have responded to the crisis of homelessness by offering food, shelter, counseling, medical care, and social services within the context of the faith community. Clinics have been built within faith communities to promote access to care See From the Case Files.

Tertiary Prevention

Tertiary preventive measures attempt to limit disability and to restore maximum functioning. The goal is to provide rehabilitative care and support to clients who are already experiencing the consequences of homelessness. Often, homeless individuals suffer from chronic health conditions that have gone untreated for long periods of time. This neglect in attending to health needs results in significant disease morbidity. Treating complications of advanced disease, providing rehabilitative care, and offering counseling and support are important tertiary preventive strategies. Rae and Rees (2015) asked homeless adults in the United Kingdom about their perceptions of health care needs and their experiences in receiving care. They often recognized that they needed health care, but did not place a high priority on getting care. Further, many obstacles to care were shared with the researchers in this qualitative study (e.g., poor public attitudes toward them, bad experiences with health care personnel, difficulty finding a physician). Many felt that they received substandard care, but others reported positive experiences with care. A U.S. study found lower health care expenses for homeless individuals after they moved into supportive housing (Wright, Vartanian, Hsin-Fang, Royal, & Matson, 2016).

PERSPECTIVES A PHN'S HOLISTIC APPROACH TO HOMELESSNESS

I got a referral from our communicable disease coordinator, regarding a homeless client with a lesion on his lower leg (wound botulism). I quickly learned that he had a long history of drug abuse, suicide attempts (13 known), and repeated hospitalizations for this wound. He was discharged from the hospital each time because he had no insurance, and he was also misdiagnosed. I finally located him living on a friend's property in a disheveled travel trailer with a leaky roof and broken windows. It was a rainy week, during the winter months, and he and his small dog were trying to keep warm and dry. He used the oven for heat and a nearby field as his bathroom. His only relatives lived out of state, and he dumpster dived for food. He ate food from expired cans, when he could find them. He knew about the local food lunch program and health care at our county clinic, but he was seldom able to utilize these services, because of lack of transportation and difficulties with ambulation related to his leg wound.

As a PHN, your view of the patient is holistic and goes beyond the diagnosis. My PHN partner and I did the following:

- *Reviewed his wound care.*
- *Assisted him in getting his medication, with money from the local Coordinating Council and Ministerial Association.*
- *Referred his case to two churches who provided him with assistance from their food pantries and a Pizza Hut gift card for his birthday (to cheer him up).*
- *Obtained tarps for his trailer, and a sleeping bag from a local service group.*
- *Assisted him with a disability application.*
- *Connected him to a mobile mental health unit that we are assigned to weekly for mental health assessment and drug diversion; we also updated his immunizations.*
- *After the final diagnosis from the CDC was confirmed, we arranged for transport to another hospital for treatment, as the patient refused to go back to the original hospital that had misdiagnosed him and kept discharging him.*

I remember that after I graduated with my BSN, someone asked me why I was leaving the recovery room to go into public health nursing. At that time, I told the person "I didn't want my varicose veins popping out of my support hose before I retired." But, I love public health nursing and am so glad that I made this choice. And, as I am planning my retirement, I can truly say, "It's been quite a ride"!

Susan, District PHN

Case Management

At each level of prevention, the community health nurse functions as a case manager and coordinator of care to insure seamless delivery of services as people transition from one level of care to another. It is often difficult for the homeless to keep track of multiple appointments, negotiate the bureaucracy of multiple agencies and services, or maintain communication with providers through follow-up phone calls, letters, or visits. With no permanent address or phone, homeless clients encounter obstacles to adhering to recommendations to follow up on test results or to notify their provider if symptoms persist or worsen. An Australian quality improvement project was conducted to examine how community-based palliative care services might be more effectively provided among a homeless population. MacWilliams, Bramwell, Brown, and O'Connor (2014, p. 83) reported that the "complex psychosocial and medical needs" of the homeless population, along with their inconsistent, unsafe, and often unreachable settings for care posed challenges. Also, their lack of social support and difficulty complying with treatment protocols (often because of substance abuse and mental health issues) make them especially challenging as a population. However, researchers noted that they needed to explore creative ways to meet the needs of this population who require "flexible, compassionate, and coordinated" care (p. 83). The community health nurse can help to bridge these gaps in service delivery and promote more effective adherence to therapeutic regimens.

From the Case Files

Faith-Based Outreach

As a faith community nurse working in a large church congregation, you are invited to develop an outreach program to minister to the needs of an inner-city mission that is receiving financial support from the church. You begin by visiting the mission to conduct a needs assessment of its residents and to identify priority health issues. The shelter operates as a faith-based, nonprofit organization and is dedicated to serving the needs of homeless men with addictions. The shelter provides emergency overnight services and operates a 1-year residential faith-based addictions recovery program. Approximately 300 homeless male addicts frequent the shelter daily. Staff and residents have expressed concerns regarding a recent outbreak of boils among residents.

Assessment data reveal the following issues:

Approximately 80% of clients have a history of injection drug use.
Clients sleep in dormitory-style accommodations and share bathroom facilities.

An on-site barbershop operated by the residents provides haircuts for a nominal fee.

Clients have access to a small recreational area with donated exercise equipment.

Laundry services are available and residents take their clothing to the laundry on alternative days where it is washed. Laundry is typically washed in cold water and at times the laundry runs out of detergent.

Questions:

What additional data would you wish to gather to address the outbreak of boils at the shelter? How would you collect this data?

What host, agent, and environmental factors may have contributed to the outbreak of boils?

Discuss appropriate nursing interventions to address the outbreak. Consider the following levels of prevention: primary, secondary, and tertiary.

What advocacy role might the CHN play in addressing this issue?

LEVELS OF PREVENTION PYRAMID

SITUATION: Promoting health and preventing illness among homeless male addicts

GOAL: To apply the three levels of prevention to avoid adverse health conditions, promptly diagnose and treat disorders, and assist homeless male addict population to maintain or regain optimal health

TERTIARY PREVENTION

- Provide case management of chronic health conditions.
- Advocate for expansion of counseling, rehabilitative services, and addictions treatment programs for the homeless.
- Advocate for supportive and transitional housing to enable homeless residents with addictions disorders to successfully transition back into the community.

SECONDARY PREVENTION

Early Diagnosis and Treatment

- Conduct mass screenings for diseases commonly found in homeless male population (TB, HIV, hepatitis, prostate cancer, colorectal cancer).
- Develop programs for health screening and early diagnosis and treatment in the community that are culturally sensitive and accessible to the homeless (i.e., mobile vans, faith community, or shelter-based clinics).

PRIMARY PREVENTION

Health Promotion and Education

- Support employment and job training opportunities that assist clients to obtain jobs with livable wages and benefits.
- Advocate through housing coalitions and legislative efforts to promote affordable housing, employment opportunities, and better access to health care.
- Develop culturally sensitive health education programs that promote healthy coping, positive parenting, communication and relationship building, mental health, and injury and illness prevention.
- Promote programs that offer counseling and support to prevent continued high-risk behaviors as a result of untreated addiction.

Health Protection

- Advocate for legislation to protect citizens from environmental toxins and industrial wastes common to low-income areas.
- Provide immunization services to prevent communicable disease transmission.
- Counsel clients on proper nutrition, exercise, and basic hygiene to promote healthy lifestyles and prevent disease transmissio.
- Advocate for funding for nutrition programs for the homeless and for homeless shelters that would allow for the purchase of nutritious foods.

Advocacy

Advocacy is a vital dimension of the community health nurse's role in working with the homeless. Advocacy entails working with different sectors of the community (including public officials, service providers, and persons living in the community) to develop innovative models for responding to the crisis of homelessness. Advocacy creates the broader system-wide changes needed to end homelessness (NCH, 2013). The community health nurse acts as an advocate at each level of prevention to effect positive change. For example, the nurse may advocate for mental health and substance abuse services to promote mental health and prevent homelessness (primary prevention). Alternatively, he or she may advocate for legislation to fund supportive housing, health care, or social services to benefit the homeless chronically mentally ill (tertiary prevention). The CHN can also assume an advocacy role by becoming involved in local, state, or national coalitions or organizations devoted to protecting the rights of the homeless or by speaking out on legislation that impacts the homeless (NCH, 2013).

SUMMARY

Rising poverty and lack of affordable housing have led to a dramatic rise in homelessness. Poverty, lack of housing, domestic violence, mental illness, addictions, personal crisis, and natural disasters are factors that may predispose persons to homelessness.

Homeless families represent the fastest growing segment of the homeless population. Acute and chronic health problems plague the homeless. Conditions such as HIV/AIDS, diabetes, hypertension, addictions, and mental disorders are prevalent among the homeless and are difficult to treat because of the challenges associated with being homeless.

Both the public and private sectors have launched concerted efforts to combat the problem of homelessness through the passage of federal legislation (most notably the McKinney-Vento Homeless Assistance Act) and through the formation of national, state, and local coalitions and alliances to champion the cause of the homeless. There is still much to be done.

Community health nurses maintain a long and distinguished tradition of providing care to the marginalized and underserved. As such, they play a vital role in addressing the needs of the homeless in society. At the core of community nursing practice is the development of a trusting relationship. The community health nurse needs to examine his or her values and presuppositions regarding poverty and homelessness to be more effective in rendering care that is respectful, compassionate, and nonjudgmental.

The community health nurse delivers primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services. Primary prevention includes advocating for affordable housing, employment opportunities, and improved access to health care to prevent the downward spiral into homelessness. Secondary prevention includes screening for communicable and chronic diseases and promoting access to affordable health care and social services. Tertiary prevention includes rehabilitative and supportive care and counseling.

The community health nurse also serves as a case manager to coordinate care and to assist clients to negotiate the bureaucracy of multiple agencies and services. Finally, the CHN acts as an advocate to promote the rights of the homeless and to speak out on legislation impacting homelessness.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Reflect in writing on the meaning of "home." Share your reflections with classmates. How similar are your responses?
2. Interview a homeless person regarding the most difficult choices he or she has had to make. What were the conditions surrounding these choices?
3. Volunteer to work at a soup kitchen or homeless shelter. Observe carefully the faces, sounds, attitudes, and activities. What is it like there? What would it be like to receive rather than give service?
4. Access the state information for American Institutes for Research (2014) document on homelessness available in the references. Look up your state to determine the number of homeless children, those at risk for homelessness, and your state's policy and planning regarding housing for the homeless population. How does your state compare to other states? Consider how you might address these issues in a letter or visit to your local state legislator.
5. Perform a windshield survey in a low-income community. What resources are lacking? Where is the nearest bank, school, grocery store, health clinic? What are the conditions of the roads, homes, and other buildings? How do you feel as you drive through the community? What do you think it would be like to live there?
6. Given that veterans make up 11% of the total population of homeless individuals and that problems may follow their return to civilian life, what might be the relationship between health and community integration in the population of veterans who are discharged following deployment to the Middle East?

QSEN: Quality and Safety Education for Nurses

Quality improvement—Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Knowledge—Describe strategies for learning about the outcomes of care in the setting in which one is engaged in clinical practice.

Recognize that nursing and other health professions students are parts of systems of care and care processes that affect outcomes for patients and families.

Skills—Seek information about outcomes of care for populations served in care setting.

Attitudes—Appreciate that continuous quality improvement is an essential part of the daily work of all health professionals.

It is likely that you evaluate the quality of the care given to your patients in the acute care setting every day you are in a patient care environment. Biomarkers such as improvements in blood pressure and Hgb A1C levels, reduction in pain, or changes in function such as improvement in activities of daily living may serve as indicators of success when measuring the effectiveness of one's nursing interventions. But how is success measured when one is caring for large and diverse population groups such as the homeless?

To measure change in this context, one must first define what is meant by "success." For example, what are the markers for success when working with a population of homeless teen mothers? What about a population of veterans with decade-long histories of active addiction? Literature reviews, surveys, or focus groups may help point to measures of success. Interviews with key stakeholders also provide insight as to the most important measures for evaluating program effectiveness in a population.

Nelson et al. (2012) examined the impact of a work-skills program on employment and life domains among 638 homeless clients in New England. Data were tracked from program inception to 6 months following graduation. Assessment measures included data on general health status, housing, employment, self-esteem, self-efficacy, income level, and general work-skills such as workplace technology, basic literacy, communication, and social networking. Data revealed that the program resulted in improvements in work and life skills that were associated with improved self-esteem and self-efficacy. These improvements, in turn, increased the probability of securing stable housing in the future. Tyler et al. (2014) evaluated the impact of an interdisciplinary community-based intervention on hepatitis C knowledge among homeless adults. The authors found that the nurse case managed intervention, an approach that engaged key stakeholders, outreach workers, community organizations, and the homeless, predicted the greatest gain in HCV knowledge.

In considering measures for evaluating program success, one must also consider the context in which the program is being implemented and the philosophical perspectives and values systems of participants. For example, Lashley (2013) explores the tension between sacred and secular ways of knowing when evaluating programs for the homeless in a faith-based context. Critics may contend that faith-based interventions for the homeless cannot be fully understood through a secular lens. Even the idea that a spiritually based experience can be objectively measured may be perceived as offensive. Despite these concerns, research and evidence-based practice continue to be successfully integrated into faith-based ministries to improve patient outcomes. Community-based participatory research, which involves the community as a full partner in the research process, is an effective paradigm for engaging populations in outcomes-based program improvement (Lashley, 2013).

1. How might you engage a target population to actively participate in the evaluation process?
2. What outcomes do you believe are most important to track when caring for homeless populations?

29 CHAPTER

Issues with Rural, Migrant, and Urban Health Care

"No city should be too large for a man to walk out of in a morning."
—*Cyril Connolly* (1903–1974), British Critic

"Globalization is exposing new fault lines—between urban and rural communities, for example."
—*Ban Ki-moon*, United Nations Secretary General

KEY TERMS

Built environment
Critical access hospitals
Federally qualified health centers
Frontier area
Ghettos
Health professional shortage areas (HPSAs)
In-migration
Medically underserved areas (MUAs)
Medically underserved population
Metropolitan statistical area
Micropolitan statistical area
Migrant farmworkers
Migrant streams
Out-migration
Patterns of migration
Population density
Rural
Rural health clinics
Seasonal farmworkers
Social justice
Telehealth
Urban
Urban health
Urbanized area (UA)
Urban cluster (UC)
Urban health penalty
Urban planning

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Define the terms *rural, frontier, migrant*, and *urban*.
- Discuss the population characteristics of rural residents.
- Describe five barriers to health care access for rural clients.
- Describe the migrant lifestyle.
- Identify at least three health problems common to migrant workers and their families.
- Discuss barriers and challenges to migrant health care.
- Identify common health disparities found among rural and urban populations.
- Propose intervention strategies at the aggregate or community level to assure a healthier *built environment* in both rural and urban areas.
- Explain the concept of *social justice* and how it relates to public health nursing in rural and urban areas.
- Compare and contrast the challenges and opportunities related to rural and urban community health nursing practice.

About half of the population live in what is known as the suburbs, but the remainder live in one of two diametrically opposed areas: rural or urban. There is a good chance that many of you reading this book live either in very densely populated, bustling urban areas or in sparsely populated, somewhat isolated rural areas. Public health nursing in urban and rural areas requires not only general public health nursing knowledge and skills but also a unique understanding of how these distinctive environments affect the health of the populations living there. Where you live can and does markedly affect your health outcomes, with rural and urban areas having distinctive problems and issues, as described in a seminal 2002 article by van Dis (2002). These differences are much more than just the ability to shop at "Wal-Mart versus Pottery Barn" (p. 108). Both rural and urban clients have health disparities and disadvantages, although they may be dissimilar in nature (Anderson, Saman, Lipsky, & Lutfiyya, 2015).

Boston Park Harbor. (Source: USA.gov.)

Rural nursing practice offers many opportunities. Nurses are respected community members—their judgment and opinions count. Rural nurses are key members of the health care team. They can make a difference in the lives of their neighbors, friends, and community. Rural PHNs often struggle with helping clients gain access to quality health care and the inherent transportation problems found in isolated areas. The challenges are many, but the rewards are great.

Urban PHNs often specialize in particular areas of interest. They deal with different types of problems, such as homelessness, overcrowding, bioterrorism threats, and violent crime. They are often called upon to advocate for their most vulnerable clients, and they develop collaborative relationships with other professionals. Urban community health nursing can also be very rewarding and satisfying.

This chapter addresses the special health needs and concerns of rural, migrant, and urban clients and the ways in which a community health nurse can address those needs. After reading the chapter, you may come to appreciate the many advantages that rural nurses enjoy and consider rural nursing as a practice choice or you may find that being a PHN in an urban area offers you more opportunities for specialization and networking. Either way, your contributions can improve the health of populations living at both extremes.

DEFINITIONS AND DEMOGRAPHICS

Depending on one's geographic location, professional discipline, agency or institutional affiliation, or other frame of reference, the term *rural* has different and specialized meanings. Moreover, rural populations and characteristics have changed significantly over many years. These differences and their implications are described in this chapter.

Definitions of "Rural"

The term *rural* means different things to different people. It is helpful to be aware of the precise meaning of the term as it is used in a particular agency, community, or piece of legislation because differences in semantics can affect public policy regarding rural communities. For example, federal dollars are often distributed to communities based on rural or urban status.

The U.S. government provides several definitions of rural. These can seem confusing and complicated, but it is important to understand the terms and how they are used in federal programs and grant funding. The U.S. Census Bureau (2015) classifies urban areas as densely developed land that includes commercial, residential, and any other nonresidential areas and recognizes rural areas as including "all population, housing, and territory not included within an urban area" (para. 1). Two types of urban areas are described—an urbanized area (UA) or an urban cluster (UC). A UA consists of densely settled territory with a population of at least 50,000 people. A UC has a population <50,000 but more than 2,500 (U.S. Census Bureau, 2015). Past descriptions have relied on a specific measure of density. Population density refers to the number of persons per square mile—urban areas are much more densely populated than rural areas. Some counties may include both rural and urban designations, as these designations do not follow municipal boundaries but rather denote population density (like the dense grouping of buildings that you might notice from an airplane).

A consideration in urban areas is the term *megacity*; this is an urban center with over 10 million residents. New York and Los Angeles are characterized as megacities, as are London, Tokyo, Rio de Janeiro, and others around the world (Hayes, 2011). Public health problems are intensified with larger population areas; issues with communicable disease, poverty, inadequate housing, and unemployment become even more magnified with larger populations. Since the 2000 Census, the U.S. Office of Management and Budget (OMB) reclassified the United States into metropolitan and micropolitan statistical areas. This nomenclature identifies a metropolitan statistical area as a core-based statistical area (CBSA) associated with at least one UA that has a minimum population of 50,000. Micropolitan statistical areas are CBSAs associated with at least one UC of no <10,000 and no more than 50,000 people (U.S. Census Bureau, 2013). Both metropolitan and micropolitan statistical areas comprise the central county or counties containing the core, and also included are adjacent outlying counties that have a high degree of social and economic integration with the central county (based on the number of people who commute to work). With such a broad definition, micropolitan statistical areas can include both rural and urban areas. Before 2003, the OMB defined urban and rural in terms of metropolitan and nonmetropolitan counties. By making these changes, the number of people living in what used to be considered nonmetropolitan areas decreased.

The U.S. Department of Agriculture (USDA) rural–urban continuum examines

metropolitan and nonmetropolitan areas on the basis of counties, and this provides different data apart from census reports. Nonmetropolitan areas have some type of combination that includes "open countryside," rural towns (<2,500 people), and urban areas (2,500 to 49,999 people) (See Fig. 29–1). State and federal agencies recognize county-level jurisdictions and governments and depend upon employment, income, and population data that are available on an annual basis (USDA, 2013). Many states have offices of rural health or other agencies dealing with issues specific to rural populations.

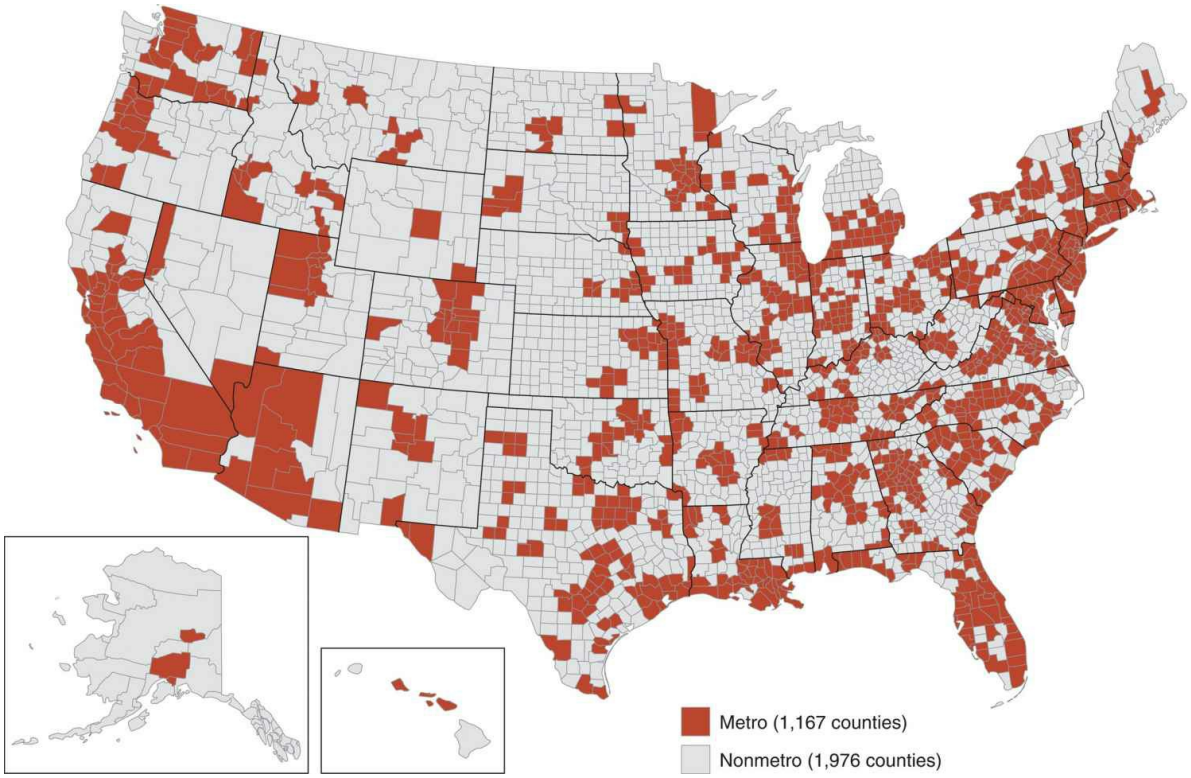

FIGURE 29–1 Metro and nonmetro counties, 2013. (Retrieved from http://www.ers.usda.gov/media/1103491/metrononmetro.png.)

For the purposes of this chapter, rural is defined as *communities with fewer than 10,000 residents and a county population density of <1,000 persons per square mile*. This definition of rural is arbitrary because rural clients do not merely consider population density or community size when defining their *ruralness*. They have a multitude of reasons for defining their community as rural, such as distance from a large city, major occupations in the area (e.g., agriculture), or number of students in the local schools. If you have access to a small community, ask some of the residents the reasons why they consider their community to be urban or rural.

The term frontier area is used to designate sparsely populated rural places that are isolated from population centers and services, but specific definitions vary (Rural Assistance Center [RAC], 2012). A common definition of a "frontier and remote area" (FAR) is one with six or fewer persons per square mile, but others include not only population density but also distance and travel time to market service areas. For instance, 60 mi. or 60 minutes of driving on paved roads to the nearest 75-bed (or greater) hospitals could constitute a frontier area. The USDA (2015) has developed FAR codes, based upon urban–rural census data and delineated by ZIP codes. There are four levels of FAR codes; level one includes a good number of people living far from city areas where higher-level goods are available (e.g., regional airport hubs, stores with major household appliances, advanced medical care), whereas level four includes fewer people with a more significant level of remoteness (e.g., access to stores selling gas or groceries, basic medical care). The other two levels may

also have access to movie theaters, car dealerships, and clothing stores. This is helpful to researchers and public health agencies in determining rural–urban status and designing programs to meet specific needs. Rural–urban commuting area (census data) is also used to designate remote areas (RAC, 2012). It is estimated that 3 million people (4% of population) live in frontier areas that comprise 56% of the U.S. land areas. States with more than 10% of their population in a frontier area include Idaho, Nebraska, Maine, Arkansas, Oklahoma, Alaska, Arizona, Montana, Wyoming, New Mexico, Colorado, North Dakota, and South Dakota (National Center for Frontier Communities, 2014).

Health issues of concern to rural areas may be of even greater concern to frontier areas. Sparsely populated areas may be less able to attract health care professionals. The term health professional shortage areas (HPSAs) is used to identify urban or rural geographic areas, population groups, or facilities with chronic shortages of medical, dental, or mental health professionals. The federal government determines which areas are HPSAs. As of 2015, there were 15,557 in the United States. Over 59 million people live in areas that have been designated as HPSAs for primary care, representing about 60% of need met (Fig. 29–2). Over 90.3 million live in mental health HPSAs, and 47.4 million are in areas with shortages of dentists (Health Resources and Services Administration [HRSA], 2015). In medically underserved areas (MUAs), residents experience a shortage of health services; these areas are determined by the federal government using a score based on the shortage of primary care physicians, high infant mortality rates, high percentage of the population living below the poverty level, and a high proportion of residents over age 65. A medically underserved population (MUP) includes those with economic and cultural/linguistic barriers to primary health care services (HRSA, n.d.a).

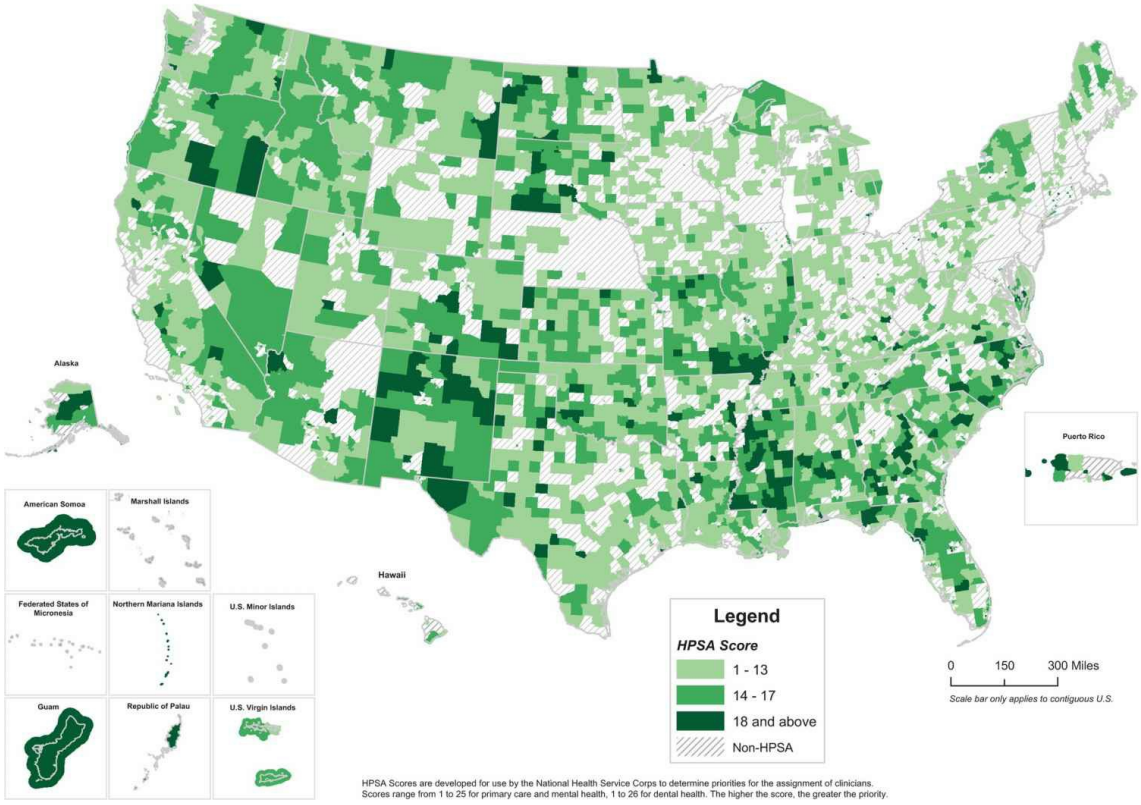

FIGURE 29–2 Health professional shortage area, primary care, 2016. (Retrieved from http://datawarehouse.hrsa.gov/ExportedMaps/HPSAs/HGDWMapGallery_BHPR_HPSAs

Population Statistics

The number of persons living in urban areas of the United States tripled since the mid-1800s, to almost 60 million in 2000, and grew 10.8% from 2000 to 2010. About 75% of the total population can be found in urban areas (Gorski, 2011). California, Arizona, and Texas showed the largest growth in suburbs of large metropolitan cities. During the same period, rural population growth was 4.5% with 46% to 60% of rural counties losing residents. An all-time high of 51% of the population live in the suburbs. Only 16% of the U.S. population is characterized as rural, the lowest ever. The primary cause for this shift is thought to be children leaving home for larger cities with better employment opportunities. Rural areas are caught in a vicious cycle, because of individuals moving away to find jobs and businesses reluctant to relocate to rural areas because of a smaller pool of potential workers. Great Plains states are at risk of losing the most population and with growth of non-white populations, with Appalachia, West Texas, Arkansas, and Mississippi also losing substantial portions of their populations (Barcus & Simmons, 2013; Nusca, 2011).

Poverty and joblessness are common among rural Americans. The average per capita income is significantly lower in rural versus urban areas, and the percentage of the population living below the poverty level is higher in rural areas (Gorski, 2011). Jobs in rural America are changing, with agriculture, fishing, and forestry declining; at the same time, government, manufacturing, and service jobs are increasing (Council of Economic Advisors, n.d.). More involuntary part-time employment is also found among rural workers (29% females, 27% males), and states with a high proportion of rural population often don't provide unemployment benefits for these workers (Glauber, 2013). Rural residents are more likely to work for small companies that pay lower wages and don't offer health insurance; there are also more unemployed workers (Gorski, 2011). Even with employer penalties that came with health care reform and the expected move to reduce employee workloads below the 30-hour threshold, this did not occur across the board (Dougherty, 2011). While an estimated one million workers between ages 19 and 64 may be affected by some employers dropping work hours below the threshold to avoid penalties associated with health care reform, the number of workers characterized by involuntary part-time employment have not increased in industries or occupations where workers aren't affected by health reform mandates (Even & MacPherson, 2015). Rural areas have high rates of uninsured and public insurance coverage (e.g., Medicaid, Medicare). There is also a higher percentage of elderly and those living in poverty, along with higher rates of chronic illness (about half have one chronic illness or more) and more rural residents reporting poor to fair health (Seright & Winters, 2015). Rural residents are less likely to receive recommended preventive services, and they make fewer visits to health care providers. They also have fewer physicians (10% of total), and there is continuous concern about physician recruitment in rural areas of the United States and other countries beyond what incentives (e.g., scholarships, forgivable loans) can offer (Fuchs & Jotkowitz, 2012). Specialized medical care is rarely found in rural areas. Of the 2,000 rural hospitals, 75% of them have

50 or fewer beds; most are designated *critical access hospitals* (CAHs) as they have 25 or fewer beds (Agency for Healthcare Research and Quality [AHRQ], 2012; Gale, 2010; Gorski, 2011). CAHs must provide 24-hour emergency care, with either MD on site or RN on site with MD on call and able to arrive within 30 minutes. They must also have 25 beds maximum and be over 35 mi from the next hospital or 15 mi if the terrain is difficult (Seright & Winters, 2015). Also, the quality and staffing levels of rural nursing homes, as determined by national survey inspection data, are below that of those in urban areas. Higher rates of contractures and lower staffing levels, along with structural and operational problems of rural facilities, accounted for most of the disparity (Bowblis, Meng, & Hyer, 2013). James (2014, p. 2122) denotes a "rural mortality penalty" that has existed for over 20 years, reversing the prior trend for higher urban mortality rates in the 19th and early 20th century because of high levels of infectious disease and water/sewage contamination.

Rural areas have a slightly higher fertility rate than urban areas (Johnson & Lichter, 2012). However, this population growth related to births (termed *natural increase*) is offset by the loss of rural youth moving to more urban areas for education, jobs, and marriage (Nusca, 2011). This has been characterized as leading to a "brain drain" from rural areas, often leaving older adults or those with less education and income remaining.

Birth rates in rural and urban areas are declining slightly overall, while there is an inflow of older adults and an already aging population (Environmental Protection Agency [EPA], 2014).

Changing Patterns of Migration

Population changes in rural areas are usually related to natural increase through births or through out-migration, the process of residents moving out of rural communities and into urban places (EPA, 2014). When America was a more rural country, there was more natural increase than out-migration, which caused continued growth in the rural population. In the 1970s, the proportion of births decreased, but many people moved into rural communities, resulting in an increase in population there. During the 1980s, the population trends shifted, when most rural areas lost population to out-migration as a result of economic recession and a serious farming crisis. During the first half of the 1990s, the population trend in rural communities changed to in-migration, an increase in residents moving into rural communities from urban places. White-collar workers were affected by changing technologies, and many young professionals with families elected to live in more rural settings. Since the beginning of the 21st century, more rural counties have experienced out-migration, and rural towns in some areas have disappeared; this trend has slowed but continued overall (Kilkenny, 2010; USDA, 2016). The lack of in-migration is related to a decrease in retirees moving to rural areas along with problems recruiting professionals and managers for local manufacturing companies. Poverty and low quality of life are also causative factors (USDA, 2013). Because of the boom in energy-related employment, Montana and North Dakota have had more in-migration (USDA, 2014). Some rural areas with few natural amenities, such as mild winters and forest areas, have also experienced out-migration, but others with beautiful landscapes, desirable climates, or proximity to tourist areas (e.g., ski slopes, lakes, beaches, national parks) have experienced more growth, and there has also been some remigration with former residents moving back to raise families in more rural environments (McGranahan Cromartie, & Wojan, 2010). Because of the boom in energy-related employment, areas in Montana and North Dakota have had more in-migration, along with some counties in Arkansas, Louisiana, Pennsylvania, and Texas (USDA, 2014).

Population trends have many implications for the health services needed by rural people. The patterns of rural migration change like shifting sand, adding to the challenge of planning resources for rural communities.

POPULATION CHARACTERISTICS

The following information is meant to describe, not stereotype, rural clients. Each rural community is unique, as are its residents. The PHN must determine whether the population characteristics discussed fit a specific rural community. The nursing student who plans to practice in the international arena will need to seek out relevant information about the specific rural population to be served. A rural culture is often very different from that found in larger cities (Eisenhauer, Hunter, & Pullen, 2010), and it is important to spend time in rural areas and to learn from our clients.

Age and Gender

Approximately 22.8% of women over age 18 live in rural areas (American Congress of Obstetricians and Gynecologists [ACOG], 2014). The proportion of females age 35 and over is higher in rural areas than in urban areas, or even the United States as a whole. Those females below age 18 (17.5%) and above age 65 (14.6%) comprise the largest percentages in rural areas, but urban areas have more females in the 18- to 34-year range (Maternal Child Health Bureau, 2011). Changes in age distribution for both males and females over three decades reveal net losses of those below age 20, and similar gains for those between the ages of 20 to 49 and over 65 in both rural and urban populations. Little change is noted for both rural and urban populations in the age group 50 to 64 (Council of Economic Advisors, n.d.). Elderly persons, those age 65 and older, are the fastest growing population in the United States in every location, including rural America.

Population trends have a direct relationship to the kinds of health services that are needed in rural communities. Growing families with young children need maternity, pediatric, and family health medical services, along with dental care and mental health services. They also can benefit from health promotion and disease prevention activities. The elderly, on the other hand, need health care to manage increased number of chronic health conditions. Rural communities need to provide access to nursing homes and rehabilitative services, as well as to hospitals, clinics, and health promotion programs that serve the elderly and the entire community.

Race and Ethnicity

Rural areas have historically had less racial diversity than urban areas. However, that is rapidly changing. Racial and ethnic groups have historically been concentrated in certain areas of the country—for example, Blacks in the rural South and American Indians in the rural Southwest and West, as well as Mexican Americans in the border states of the Southwest (McGranahan et al., 2010). Rapid Hispanic growth areas are found in the Midwest and Southeast (see Fig. 29–3) as well as the Great Plains (Barcus & Simmons, 2013). California, Texas, and Florida are home to 55% of the U.S. Hispanic population, with 14.4 million living in California. Other states experiencing growth include Illinois, New York, New Jersey, Colorado, Arizona, and Georgia (Brown & Lopez, 2013). The Hispanic population reached 55 million in 2014, but growth has slowed dropping from an annual average increase of 4.8% between 1995 and 2000 to 2.2% from 2010 to 2014. The median age for Hispanics is younger than other ethnic and racial groups, but it has been slowly rising; in 2000, it was 26; in 2010, it was 27; and it is now estimated at 29 years compared to 43 for non-Hispanic Whites, 34 for non-Hispanic Blacks, and 36 for Asians (Krogstad, 2015).

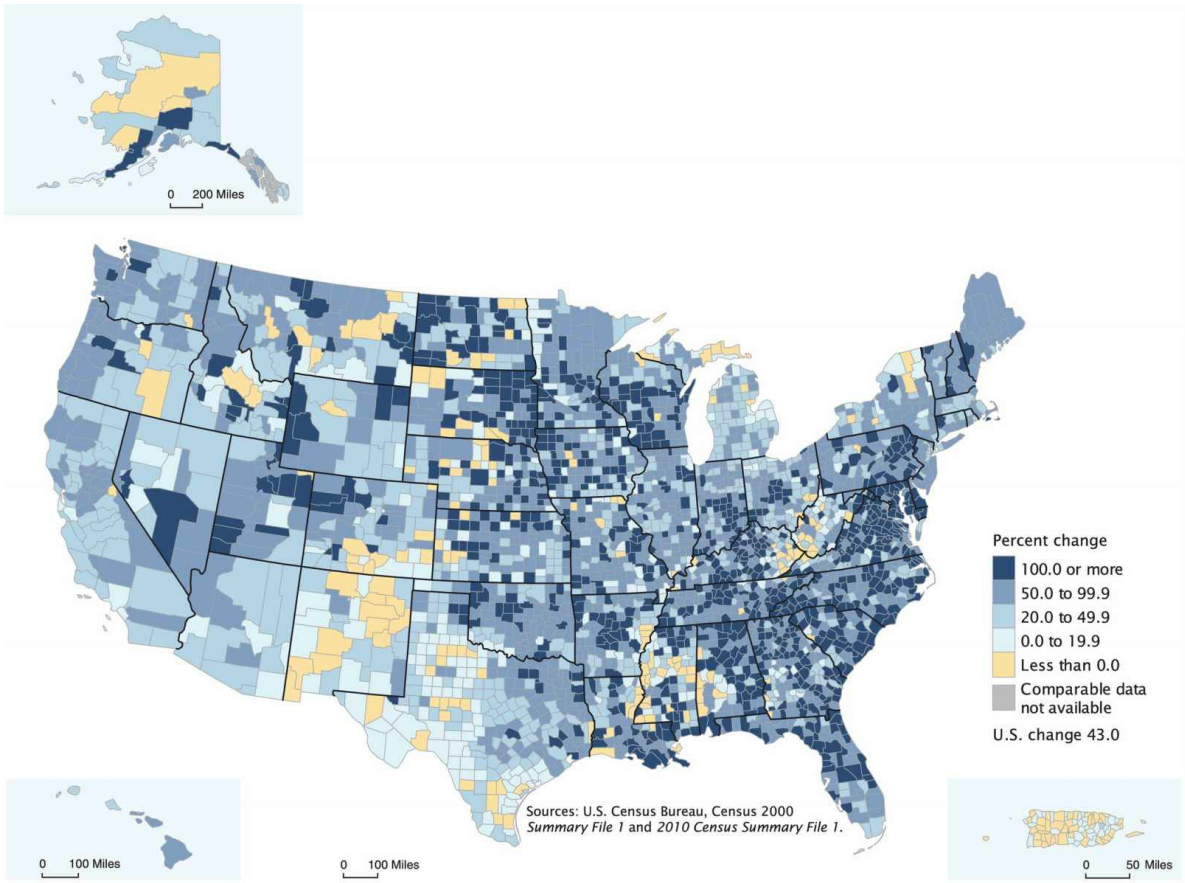

FIGURE 29–3 Percent change in Hispanic or Latino population by county: 2000 to 2010.

Higher birth rates led to faster growth of this population, and this could signal a need for changing health policies and practices. For instance, in rural counties with a high elderly population and established caseloads of chronic disease patients, an influx of younger Hispanic populations may require a shift in policies and resources to include more pediatric and obstetric care. Almost half of rural counties lacked an obstetrician in 2010, and some states have no mother/infant tertiary care centers. Because of this, Wyoming approves out-of-state providers and reimbursement for transport and care when deemed medically necessary (ACOG, 2014). All of these changes influence geographic patterns of health status.

Education

Rural clients in the United States have historically had lower educational attainment than those in urban areas. However, the gap has closed for high school completion. By 2012, 12% of urban versus 14% of rural working age adults had less than a high school education, but rural areas had a greater proportion of those with a high school education. The gap for those with college degrees was much wider (32% of urban vs. 18 % of rural working age adults), and 12% of urban versus 6% of rural had advanced degrees (USDA, 2014). In the United States, while high school graduation overall rates rose to 81% for White students, Hispanics had a 76%, and African American students a 68% rate of graduation (Moskowitz, 2014). Some studies have shown urban–rural differences overall, but Jordan, Kostandini, and Mykerezi (2012) found dropout rates to be similar and noted that many ethnic differences were more likely due to peer influences and "some location attributes" (p. 18). Some educational researchers note that Hispanic students begin with a disadvantage, as their parents often do not speak English and have low levels of education (e.g., 41.3% of mothers had less than high school education). They are also often more likely to attend "hypersegregated schools" (e.g., majority of students are non-white), and as a group, they often perform below other ethnic and racial groups throughout their K to 12 schooling (Bouie, 2016). Only 9% of 25- to 29-year-olds completed a bachelor's degree in 2012, but approximately 18% enrolled in college during the 2011 to 2012 school year (Krogstad & Fry, 2014).

Lower levels of education are associated with poverty, especially in rural areas. In 2013, for the first time in five decades, the majority of public school children live in low-income homes. This is evidenced by 51% of them being eligible for free or reduced lunches; the highest percentages (above 50%) are in the southern states, along with California, Nevada, Utah, Kentucky, and West Virginia. Mississippi had the highest percentage at 71%, with New Mexico following at 68% (Layton, 2015; Southern Education Foundation, 2015). Most of these states have significant rural populations. Rural schools provide education to some of this country's poorest children. The poverty rate in the 800 poorest rural school districts is similar to the rate in large urban districts, and 19% of all schoolchildren attend majority rural districts. Many of these children have long bus rides that take time away from homework, and the districts also have higher transportation costs (Midwest Regional Educational Laboratory, 2013). Rural clients have little access to higher educational facilities, such as community colleges or universities close to home. Travel to urban areas for educational pursuits adds to the burden of obtaining additional education beyond high school.

Income, Housing, and Jobs

Some rural communities are home to some very wealthy residents, many of them landowners, business owners, farmers, or ranchers. On the average, however, the income of people in rural communities is lower than that of persons living in urban communities. This is reflected in higher rates of unemployment and lower per capita income; for instance, per capita personal income in 2013 was $17,536 for rural Telfair County, GA, but $121,632 in New York City (Bureau of Economic Analysis, 2014). Although unemployment trends over the past decade have been similar, rates of unemployment in rural areas are generally slightly higher than in metropolitan areas; loss of jobs was slightly higher in rural areas and began earlier in the recent recession. In 2011, growth of employment in rural areas still lagged behind urban areas, and some of this is due to having an older population and a workforce with lower levels of education (Hertz, Kusmin, Marré, & Parker, 2014). Mean rates of unemployment in rural counties with lower educational attainment were 2 percentage points higher than in those with higher rates (Economic Research Service [ERS], 2016). Also, many residents of rural areas are underemployed or only seasonally employed because of the nature of agriculture or other industries (Jensen, Mattingly, & Bean, 2011). Persistent poverty, defined as 20% or more of the population living in poverty for over 30 years, is more common in rural counties than in urban ones. Of the 386 counties with this designation, 340 of them are in nonmetropolitan areas, and a large number are in the South (USDA, 2011). More rural children live in poverty than those in urban areas (24% vs. 15%), and poverty among rural non-Whites is also higher than for children living in large cities (49% Blacks, 37% Hispanics vs. 41%, 35% Whites), according to Jensen and colleagues (2011). Also, the percentage of working poor in rural areas is higher than in urban areas (Glasgow & Berry, 2013). In 2009, about 11% of poor families living in rural areas reported receiving Temporary Aid to Needy Families (TANF) income, whereas 14% of poor urban families received income from TANF (Jensen et al., 2011).

See Figure 29–4, Poverty rates by residence.

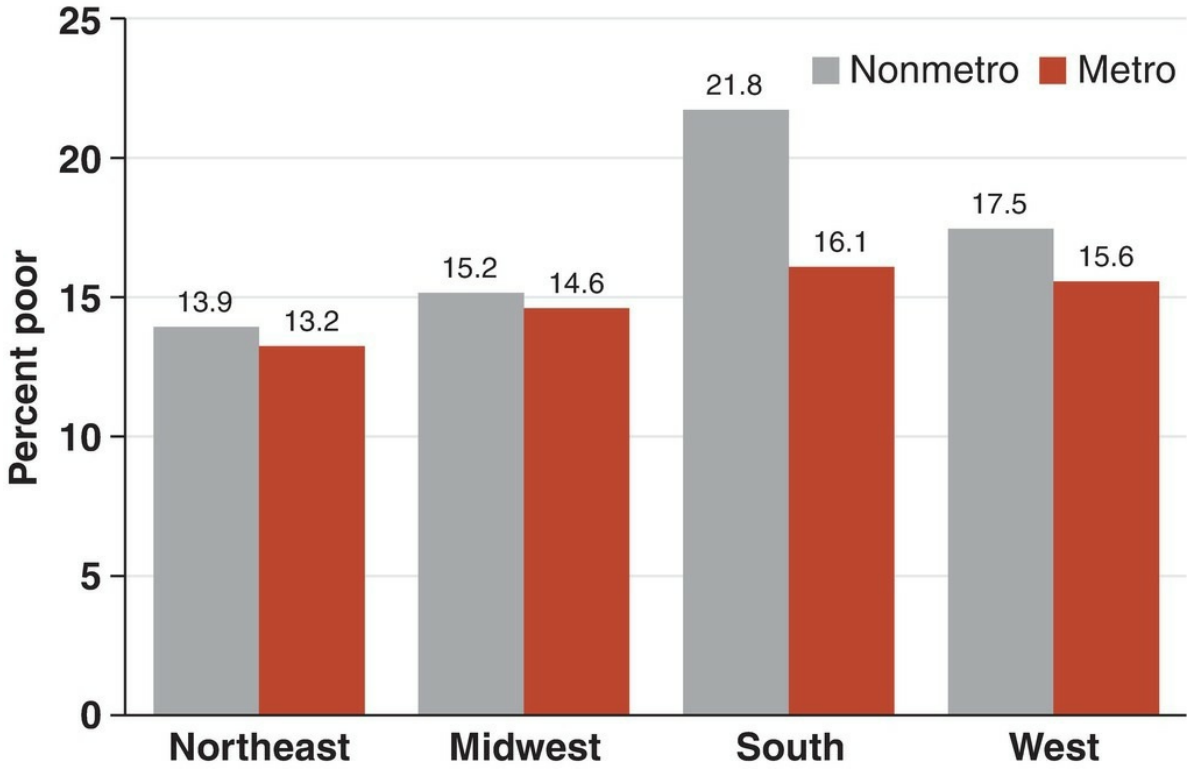

FIGURE 29–4 Poverty rates by region and metro/nonmetro status, 2010 to 2014. (From U.S. Department of Agriculture (USDA). (2015). *Geography of poverty*. Retrieved from http://ers.usda.gov/media/114604/povertyratesbyregion.png.)

Living in a rural area, however, has a number of economic advantages. The cost of land is lower than in urban areas; therefore, housing costs are also lower. The median cost of homes in remote rural areas is less than in urban areas, but the cost of goods is often similar to costs in urban areas, or may be higher, because of transportation expenses. Taxes are usually less, and restrictions on land use are not as stringent. Less expensive land is advantageous to businesses, such as manufacturing, which may need large parcels of land. However, transportation costs are higher. Home ownership is reflected in the costs of land and construction, with 83% of rural households reporting that they are homeowners, compared with 63% of urban households (Hawk, 2013). Differences are similarly noted between urban and rural areas on rental costs and mortgage interest payments. In a 2011 survey, renters in urban areas reported paying a mean of almost $700 per month, but rural average rent was reported at around $350 monthly. Urban households are twice as likely to rent than rural ones, and the total household budget reflects high housing costs in both area households, 34.1% in urban versus 28.5% in rural (Hawk, 2013). Rental units in rural areas represent over 28% of total available housing. Although rural housing costs for the most part are lower, 47% of rural renters are considered "cost burdened" with over half of these renters paying over 50% of their monthly income on rental housing (Hawk, 2013, p. 2). Most low-income housing in rural areas consists of single-family homes, not large apartment complexes, and manufactured homes comprise 12% of rental units (over twice the overall housing rate). Almost 43% of rural renters are in single-family homes. Older

housing is also common, and units are often substandard and in need of repair. Often because of high rates of poverty, those owning homes in rural areas live in houses that are old and need significant repairs. The highest small town and rural rental rates are found in Hawaii (39%), California (37.4%), Rhode Island (34.6%), and Alaska (34.3%), whereas Texas, California, North Carolina, and Ohio had the largest number of small town and rural renter–occupied units (Housing Assistance Council [HAC], 2013).

What do *you* think?

HELP FOR AILING HOMES

Many rural homes are rundown and in need of repair. Because building and construction are not always prevalent in rural areas, it is difficult for homeowners to find assistance. For instance, one woman inherited a family home built in 1949 but could not keep up with routine repairs. At first, the water pump broke and she hauled water from outside, then the heating quit working, and she began burning kindling and wood in her wood-burning stove. She had to use laundry and shower facilities at neighbors' or friends' homes. Eventually, the wind tore off a good portion of the roof. In searching for assistance, the homeowner had difficulty finding an agency that would help her repair her home. There were some programs for purchasing homes, but she didn't want to assume more debt. Eventually, she found an agency that provides assistance for rural residents. They helped her salvage her home so that she could remain there. In this case, the outcome was positive, but some individuals become frustrated and give up—living with family or friends or becoming homeless (often living in cars or camping out).

From White, G. B. (2015, January 28). Rural America's silent housing crisis. The Atlantic. Retrieved from http://www.theatlantic.com/business/archive/2015/01/rural-americas-silent-housing-crisis/384885/

Some government assistance is available to help low-income renters. Section 515, the USDA loan program for rental homes for low-income individuals, provides over 400,000 affordable rental houses. The USDA offers rent subsidies to low-income elderly or disabled residents of multifamily housing units through Section 521. Section 8, a rental voucher program administered by the U.S. Department of Housing and Urban Development (HUD), is targeted to very low–income families who can choose from privately owned rental housing (HAC, 2013; USDHUD, 2016b). However, funds for this program are limited and applicants may wait several years for approval. Both rent subsidy programs supplement participants' rental costs above 30% of their income. HUD's Healthy Homes Program, created in 1993 to decrease childhood lead exposure, has expanded priorities to include radon, asbestos, allergens, mold/moisture, pest/pesticides, drinking water contamination, injury/fire hazards, and indoor air quality (Ashley, 2015). HUD has provided grant funding for demonstration projects with nurses, environmental specialists,

and community workers targeting conditions in the home related to asthma and other conditions (Polivka, Chaudry, Crawford, Bouton, & Sweet, 2011). See Chapter 9.

The United States is unique in that it feeds its population with a small proportion of workers committed to food production and still is able to export food products to the rest of the world. Although many people equate farming with rural life, <1% of nonmetropolitan employment is directly related to agricultural farmworkers (ERS, 2015). When compared with urban areas, rural communities typically offer fewer job options. Types of rural work, such as crop agriculture, manufacturing, and forestry, vary by locale, and these employment opportunities have been diminishing along with concomitant decreases in population and the shift from a goods-based to a service-based economy. Two thirds of all rural employment is now in the service sector, often in jobs that assist retirees. Although there is more manufacturing in the South, manufacturing has decreased overall, whereas health and social service sector jobs have increased substantially. White-collar jobs have increased; examples of white-collar occupations include professional, management, and sales, as well as technical/administrative support, but hands-on occupations (e.g., construction trades, assembly/production, repair/maintenance) are often more common in rural areas (Florida, 2012).

Although the use of the Internet for commerce is now very common in urban and suburban areas, the *rural digital divide* still exists. In 2013, 70% of urban households and 73% of suburban households reported having broadband Internet access, but only 62% of rural households did. When smartphones with Internet connection are added to the mix, the percentages for urban and suburban areas each rise by 10%; the increase for rural areas is only 8%, largely because of access and older demographics (Zickuhr, 2013). Roughly 72% of Americans currently use broadband; many in rural areas find it either nonexistent or too expensive (Zickuhr, 2013). The benefits of broadband services apply not only to wider employment opportunities but also to job retraining, education, and medicine (e.g., telehealth). A national survey of U.S. households found that rural residents had less access to the Internet (59.7% vs. 69.4%), and overall use was lower for non-white respondents and those without a medical condition (Wang, Bennett, & Probst, 2011b). Where broadband Internet services are readily available, higher-skilled remote workers could remain in rural areas while still providing high-tech services to clients across the country, thus potentially reducing the out-migration of young adults.

RURAL HEALTH ISSUES

Population-level differences in health between rural and urban areas are commonly noted (Anderson et al., 2015). Health concerns of populations in rural areas are related to the environment, occupations, injuries, and distance from health care providers. Environment issues particularly relate to agriculture and the health risks that accompany farming and other rural lifestyles.

Agriculture and Health

Although farming is not characteristic of all rural areas where agricultural production occurs, both direct and indirect effects on health can exist. In an important classic book about this sponsored by the Institute of Medicine (Merchant, Coussens, & Gilbert, 2006), it is noted that pesticides and fertilizers can affect water, air, and soil, and dust created from plowing for crops can affect the air quality. For instance, an "estimated 70% of antibiotics are used for nontherapeutic purposes in intensive livestock production," placing workers at risk for developing antibiotic-resistant infections (p. 4). Occupational exposures to windblown soil, organic dust, pesticides, mycotoxins, ammonia, animal dander, and hydrogen sulfite are only some of the air quality issues in rural areas (Lee, Mulay, Diebolt-Brown, & Lackovic, 2010). In Iowa, for instance, it is estimated that for every pound of corn harvested, 2 lb of soil are "exported" (p. 7). Livestock growth-producing agents, along with radon, pesticides, and fertilizers, can contaminate ground water (Blake, 2014). Kasner and associates (2012) found an "over-representation of females among farmworker illness and injury cases" among females that did not handle pesticides but were often working on nut and fruit crops and exposed to off-target drift of pesticides (p. 571). They noted that, while females were at increased risk for acute injury and illness related to pesticides, the male farmworkers had higher total absolute numbers with these illness and injuries. Lee and colleagues (2011) examined Occupational Health and Safety Administration (OSHA) databases and found almost 3,000 cases of illnesses related to drift of agricultural pesticides in a study of 11 states. They noted that 47% had work exposures, and 9 out of 10 had a fairly low severity of illness. Fourteen percent of the exposures were found in children under the age of 15. Most often (45%), the cause was fumigant soil applications and 24% with applications by air (e.g., crop dusters). Fumigants are commonly used on agricultural crops such as strawberries, potatoes, melons, tomatoes, grapes, peanuts, cotton, and tobacco (Dow AgroSciences, 2015). Lawsuits have been filed in California, Delaware, Florida, Hawaii, and Missouri against Monsanto over its popular herbicide, Roundup, with its active ingredient now thought to be a "probable human carcinogen" (Gillam, 2016, para. 8).

Many rural residents depend on their own well water for drinking, and water quality is monitored only sporadically by well owners and then usually only for nitrates and coliform bacteria (Lee et al., 2010). About 30% of rural residents obtain drinking water from very small water systems, without the monitoring and regulations associated with large urban water suppliers. Testing of small water systems should be done at regular intervals in order to get a true picture of water quality (Wedgworth et al., 2015).

Agricultural-related morbidity and mortality are relatively high. Agriculture (grouped together with fishing and forestry) now ranked above mining in the rate of fatal occupational injuries (26.8 vs. 19.8 per 100,000) in 2010. When examining rates for specific occupations, farmers/ranchers were 41.4 per 100,000 in 2010, behind fishermen, loggers, and aircraft pilots. Occupational incidents, such as off-road tractor overturn,

increased 4% between 2009 and 2010 (U.S. Department of Labor, 2011). By 2013, agriculture was still in the top 10 occupations with the highest death rates (Smith, 2013). Tractor rollover accidents are very common and often involve older tractors (average farm tractor age is >25 years) without rollover protective structures (ROPS) (Murphy et al., 2010). Tractor injuries make up about 33% of all deaths, and farm children are at higher risk for injuries than hired farmworkers, and preschool and older male adolescents have the highest risk for fatalities from injuries (Wright, Marlenga, & Lee, 2013).

It is estimated that 33,000 injuries to children are farm related, and approximately 100 of them are fatal. Of the fatal injuries to youth, 23% were machinery related (often tractors), 19% were vehicle related (including ATVs), and drowning was to blame in 16% of fatalities. Most fatalities (34%) were in the 16- to 19-year age group (Occupational Health & Safety Administration [OSHA], n.d.). Farming injuries can result from tractor rollovers, suffocations in grain bins, exposure to harmful substances, falls, fires or explosions, accidents with other farm equipment, and on- or off-road collisions. Some injuries result in permanent disability, and worker training programs to recognize hazards and prevent injuries are rare in rural areas. A study reviewing government databases for nonfatal occupational injuries and illnesses in agriculture found significant undercounts. Leigh, Du, and McCurdy (2014) found that 73.6% of crop farm incidents and 81.8% of animal farm incidents were missed, because of the government's exclusion of small farm employees, farmers, and family members in their surveys. See Display 29–1 for two examples of common agricultural accidents.

DISPLAY 29.1 AGRICULTURAL ACCIDENTS

Farm Tractor Accident

In the old days before mechanical equipment, a farmer might be injured by one of his horses or mules, or accidently stabbed with a pitchfork. Today, tractors are involved in the majority of injuries and deaths. ROPS, or a roll cage over the tractor seat, can save lives; they were standard on every tractor manufactured in the country since 1985 (1959 in Sweden). If a farmer uses the seat belt and the tractor equipped with ROPS turns over, there is a good chance that he will survive the accident. Sadly, many farmers don't use seat belts, and many use older tractors without ROPS protection. There are many potential hazards on farms (e.g., falling bales of hay, heat stroke, dangerous equipment like hay balers, choppers, combines), but tractor rollovers and children falling from tractors are much too common and can often be prevented.

Death on the Farm

Agricultural deaths are not uncommon, as Tim Smith, an Iowan and fourth-generation farmer knows well. He almost died 26 years ago in a farm accident when as manure-pumping equipment caught his jeans and almost pulled his leg from his body. He was flown to a hospital and considers himself lucky to have his leg and his life. Tim reports that in his county with a population under 17,000, five people have died from agricultural-related accidents in the last 4 years. Some died from tractor rollovers and others in grain bins (from suffocation and crushing). Farmers face dangers of being gored by bulls, being electrocuted (as tall farm equipment hits overhead power lines), or being overcome by deadly fumes (often from manure pits

on dairy farms), among other things. Just a few months ago, Tim says that two workers who were scooping silage (animal feed) from a wagon were injured. One worker's sweatshirt got caught in the beater mechanism and he became tangled in the machinery in an instant and flipped over onto his back. He had severe cuts and had to be airlifted to a hospital where doctors were able to save his life only because one of the cuts narrowly missed his femoral artery. In manure pit incidents, four members of the same family died (farmer, wife, two daughters) as they rushed to aid a farmhand who had fallen into the pit. They all died quickly after falling/climbing into the pit. But many die from exposure to the fumes and pass out, slipping into the manure slurry and drowning. Janna Swanson, a city girl who married a farmer, had no clue about the dangerous work of agriculture. Now, she worries all the time.

Source: Hirsch, J. (2014, June 16). *Death on the farm: Agricultural jobs are the most dangerous in the world. Why aren't we talking about it?* Retrieved from http://modernfarmer.com/2014/06/farm-deaths/. (Photo source: USDA Agricultural Research Service)

Out of total farming operations, family farms account for 97.6%, and they represent 85% of all farm production (MacDonald, 2014). About 91% of farm families have a member working off the farm. Almost 36% of farmers and spouses with off-farm employment worked in management or professional occupations; other common areas of employment include construction, manufacturing, education, and health care (Brown & Weber, 2013). This contributes to the time spent in travel and its attendant problems. Because of the lack of mass transit, rural commuting increases air pollution and the incidence of injury or death from traffic accidents.

The Built Environment in Rural Areas: Relationship to Health

Even with the advances of medicine and genomics, and the staggering percentage of our gross domestic product (GDP) spent on health care, scientists feel that we will not be able to significantly improve our overall health and quality of life without addressing how we plan our living spaces.

Substantial scientific evidence gained in the past decade has shown that various aspects of the built environment can have profound, directly measurable effects on both physical and mental health outcomes, particularly adding to the burden of illness among ethnic minority populations and low-income communities (Frost et al., 2010; Hansen, Umstattd Meyer, Lenardson, & Hartley, 2015). Lack of sidewalks, bike paths, and recreational areas in some communities discourages physical activity and contributes to obesity; in those low-income areas that do have such amenities, the threat of crime keeps many people inside. Income segregation—the practice of housing the poor in discrete areas of a city—has also been linked with obesity and adverse mental health outcomes. Low-income and/or ethnic minority communities—already burdened with greater rates of disease, limited access to health care, and other health disparities— are also the populations living with the worst built environment conditions. The stress of housing insecurity has been associated with poor health status, poor mental health, and more limitations to daily activity (Stahre, VanEenwyk, Siegel, & Njai, 2015).

The built environment consists of the development of housing, highways, shopping areas, and other man-made features added to the natural environment. As populated areas expand, stresses are placed on natural habitats, water supplies, and air quality. The built environment is inextricably related to health.

Urban sprawl is a concern in some rural areas, as people move from urban centers to more suburban environments. Urban encroachment into agricultural areas creates problems with air and water pollution, access to health care, and heat islands. *Heat islands* occur when green areas are exchanged for asphalt, resulting in temperature and ecosystem changes that can extend to more rural areas (Trivedi et al., 2015; U.S. Environmental Protection Agency [EPA], 2011). Ozone levels are often highest just outside the city, because "ozone is formed relatively slowly by the action of sunlight on oxides of nitrogen and hydrocarbons" (p. 72). Urban sprawl also causes problems with water pollution and the availability of water. Encroachment of housing areas into natural habitats or farmlands can lead to wider human exposure to pesticides, herbicides, and other hazards such as mosquito-borne illnesses. Mass transit is not often available in suburban areas and almost never found in rural areas. Opportunities for health-promoting behaviors are often more limited in rural areas. Deteriorating (or no) sidewalks can be a barrier to walking in rural areas. Exercise or fitness facilities, bike paths, jogging trails, and other incentives for physical activity are also often lacking in rural communities. Trivedi and colleagues (2015) examined data from a

large national survey and found that rural adults were 1.19 times more likely to be obese when compared to urban adults. The prevalence was 35.6% in rural residents versus 30.4% for urban residents, and that difference was also found for both males and females (37.7% vs. 32.5%; 33.4% vs. 28.2%). Rural adults reported lower fiber and fruit intake, higher intake of sweetened drinks, and having no time for leisure activity than their urban counterparts (38.8% vs. 31.8%). Also, exercise levels were lower among rural adults than for those in urban areas (Trivedi et al., 2015). Obesity is prevalent in rural areas, and the physical environment, along with diet, plays a role in this epidemic (Lenardson, Hansen, & Hartley, 2015). Eating out, especially at buffets, fast-food restaurants, and cafeterias, instead of cooking at home, as well as not participating in physical activity have been associated with higher rates of obesity (Lenardson et al., 2015).

Rural roads are another concern because they are often narrow, without streetlights, and poorly maintained. More fatalities occur on rural roads and highways. While 19% of the country's population lived in rural areas in 2012, 54% of all road fatalities occurred there (National Highway & Traffic Safety Administration, 2015). Speeding, failure to use safety restraints, and alcohol are common causes of fatal crashes in rural areas. Over half of fatal crashes occurred during daylight hours in rural areas; the opposite is true in urban areas. Fifty-five percent of all fatal alcohol-related crashes occurred in rural areas, and 65% of rural occupant deaths in pickup trucks were not using restraints. Also, because time to trauma centers is much longer in rural versus urban areas, of all drivers who died en route to the hospital, 68% were from rural areas (National Highway Traffic Safety Administration, 2014). The majority of first responders in rural areas are volunteers (National Rural Health Association [NRHA], 2015). Slow-moving farm equipment traveling on rural roads, along with speeding and failure to use safety restraints, are often fatal conditions for drivers in rural areas. Researchers in North Dakota implemented a pilot program in two rural counties to "heighten awareness and safety on rural roads," but their interventions yielded "little effect on overall seat belt use" (Huseth, Vachal, Benson, & Lofgren, 2011, para. 1).

Self, Home, and Community Care

Historically, self-management of health care problems has been the most common way for rural people to cope with illness. This can be viewed as a type of strength, or it may be seen as a limitation. Mental health professionals note that the values held by those living in rural areas often include self-sufficiency, a high regard for privacy and autonomy (Smalley, Warren, & Rainier, 2012b). Rural residents are often viewed as hardworking, traditional, hardy, self-reliant, and resistant to accepting help or services from outside agencies regarded by them as welfare-type programs. Many rural clients are considered individualistic, independent, and resourceful. They often take care of illnesses or injuries on their own or have a supportive network to help them get their health needs met. Small communities commonly have strong social networks, but this type of familiarity may lead to problems with privacy and confidentiality, as well as stigma regarding mental health or substance abuse treatment. It can also exert a protective factor, as rural participants in one study reported better perceptions of physical and mental health, and less depressive symptoms, when they were more "socially connected" (Galloway & Henry, 2014, p. 43).

Life in a rural area may seem idyllic, but there are some significant risks of a rural lifestyle.

(Private author photo with permissions of Tamara Harris, Tobey Roos, & Richard Wosnik.)

Because cost, travel, weather, and distance are barriers to obtaining health services from formal health care providers, rural clients may employ a variety of folk treatments and home remedies before consulting a nurse or a physician; such clients tend to visit providers at a much later stage than do people in urban areas. A cross-sectional study, examining rural and urban differences on 2013 County Health Rankings found that those living in rural counties had poor health outcomes overall and statistically significant differences in morbidity factors, health behavior, physical environment, and clinical care (Anderson et al., 2015). Rural residents put off getting care because of problems with transportation (10% vs. 5%) and cost (25% vs. 14%) at higher levels than urban counterparts in a study examining veteran's health (Spoont et al., 2011). They are also less likely to receive home health or palliative care services and physical therapy visits at home. They are also more likely to report poor or fair health (one in three adults), to have chronic diseases such as diabetes, and to die from heart disease than are residents of urban areas (AHRQ, 2011; O'Connor & Wellenius, 2012). One large-scale study found that rural residents pay more for medications than urban residents, but consistently significant differences were found between rural and urban health care expenditures (Lee, Jiang, Phillips, & Ohsfeldt, 2014b). Rural residents, however, receive care in a less timely manner than urban residents and utilize physicians who are more likely to provide care that is outside their specialty areas. Compared with hospitals that are less rural, CAHs have been found to have significantly higher patient mortality rates and worse processes of care for patients having heart failure, acute MIs, and pneumonia (Joynt, Harris, Orav, & Jha, 2011). A longitudinal cohort study from Canada noted that rural patients recently diagnosed with heart failure had fewer physician office visits in the first year, higher rates of hospitalization, and more ED visits (Gamble et al., 2011).

The low population density in rural areas makes service delivery more difficult, especially for those with special health needs such as the elderly, the disabled, and others (AHRQ, 2011). In rural Iowa, medical oncologists have served rural patients in outreach clinics for more than 20 years (Gruca, Nam, & Tracy, 2014). While insurance rates in rural areas are problematic, the greater treatment barriers when living in an isolated area are geography and lack of adequate transportation; poverty and unemployment are also big factors. In one example from Northern California, a few residents of the tiny, isolated town of Hayfork catch a ride 30 mi through winding mountain roads to a clinic in Mad River (Hernandez, 2015).

Suicide rates in rural areas, especially the rural West, can be as much as three times those in urban areas. Young rural males have been found to have almost double the rates of suicide compared to those in urban areas; firearm suicides are most common at 51.1%, with hanging/suffocation at 33.9% (Wallis, 2015). Female rural youth rates for suicide are less than rural males but are higher than rates for young urban females. Over twice the rate

of anxiety and depression has been found in rural women, as opposed to urban women (Smalley et al., 2012b). A study of rural Midwest women found that 36.4% reported being depressed; self-report and depression screening were congruent 76.8% of the time, indicating that the women generally correctly identified their depressive symptoms (Groh, 2012). Military veterans, and those still on active duty, are more prone to higher levels of depression than their civilian counterparts. Dittrich et al. (2015) researched a national database for veterans with depressive symptoms and noted that those living in rural areas were more likely to Hispanic or multiracial, unemployed, and over age 65 or to have some type of health service deficit (e.g., uninsured, lack of routine medical exams, deferring medical care because of cost). In another study, less than half of rural community clinics or primary care settings accurately diagnosed depression in their patients; and over 85% of the rural population resides in a mental HPSA (Smalley, Warren, & Klibert, 2012a). This is another area where rural health care is lacking.

Home health care (HHC) is particularly difficult in sparsely populated areas, for both patients and nurses. Locating addresses in very rural areas often takes additional skills. (See Display 29–2 for the story of a home health nurse trying to locate a client's home.) The benefits of HHC are worthwhile; it allows people to stay at home, supports their hardiness, and compensates for the long distance between home and formal health care. An examination of rural and urban HHC patients revealed that rural patients were more ill and had more risk factors for hospitalization and generally poorer health overall. Living in a rural area was correlated with higher odds (1.16) of being in a serious or fragile condition and also higher likelihood of receiving respiratory treatments (21.1% rural vs. 14.6% urban); there is a greater prevalence of smoking among rural residents (15.5% vs. 11.9%). Also, 29.8% of rural residents were more likely than urban residents (26.7%) to have surgical wounds that required further care (Probst & Bhavsar, 2014).

DISPLAY 29.2 LOCATING A RURAL HOME HEALTH CLIENT

The following written (verbatim) directions were given by a discharge planner to a case manager (home care nurse) when making a referral for Mary, a 67-year-old woman who lived 37 mi from the hospital:

> *Drive on the gravel road east of town until you get to the third set of mailboxes. Then, turn left; drive up the road until you see the old church; cross the broken bridge toward the river. Mary lives on the third farm. Her house has some trees and a fence around it (p. 222).*

It took the home health nurse over 2 hours to drive about 30 mi on the narrow country roads after the morning rain. The nurse had to stop four times to ask residents for additional directions and hints for finding Mary's house. It was finally located, hidden in a large group of trees. The total travel time for this visit was about 4 hours.

From Bushy, A. (2003). Considerations for working with diverse rural client systems. Lippincott's Case Management, 8(5), 214–223.

Access to Acute Care

Rural hospitals have a high risk for financial problems and closures, thus leaving rural patients stranded without services nearby and forcing them to drive long distances for inpatient care. The Medicare Rural Hospital Flexibility Program encouraged states to form rural health networks, improve emergency medical services, and improve the financial performance of rural hospitals by designating them CAHs. Critical access hospitals are rural hospitals, located a minimum of 35 mi from the next hospital or 15 mi if the terrain is mountainous or the only routes are on secondary roads (RAC, n.d.). One intention of this designation was to reduce the number of rural hospital closures by providing cost-based Medicare reimbursements, which differ from the prospective payments given to larger hospitals. Most CAHs are nonprofit, have limited lengths of stay and bed capacity, and are heavily dependent on Medicare and Medicaid funding (Holmes & Pink, 2011). Higher Medicare reimbursement rates are given to CAHs, but expected decreases in Medicare payments to all hospitals over the next decade are a source of concern (Spencer, 2013). However, even though urban and rural Medicare patients receive similar amounts of care, quality of care is not always comparable to urban areas (Stensland, Akamigbo, Glass, & Zabinski, 2013). Lower-quality follow-up care after discharge was noted among rural Medicare clients and this has implications for reimbursement rates as hospitals are penalized for some readmissions (Toth et al., 2015). And "the digital divide between urban and rural hospitals that are adopting electronic health records and using the technology effectively is widening" (Sandefer, Marc, & Kleeberg, 2015, p. 1).

Major Health Problems

Among major health problems affecting individuals in rural areas are cardiovascular disease (CVD), diabetes, and human immunodeficiency virus (HIV). Geography, economics, and rural lifestyle factors may account for the higher rate of these major health problems.

Cardiovascular Disease

When it comes to CVD, geography may play a role. Geographic concentrations of CVD and other diseases vary from one rural location to the next, possibly related to inadequate health care, distance from care, environmental exposures, infectious disease in the area, and other factors. These multidimensional elements interact in such a way to cause cardiovascular mortality statistics to vary among regions and ethnic groups. However, one recent national cohort study found "geographic variation in inflammatory biomarkers among otherwise healthy women that cannot be completely attributed to traditional clinical risk factors or lifestyle characteristics" (Clark, Coull, Berkman, Buring, & Ridker, 2011, para. 3).

CVD is a leading cause of death in the United States (1 in 7 deaths), and the total direct and indirect costs of CVD and stroke were estimated at over $320.1 billion in 2015 (American Heart Association, 2015). Mortality because of heart disease is highest in the South, especially following the path of the Mississippi River (Bolin & Bellamy, 2015). Regional variations have been noted in prevalence of CVD and stroke, as well as heart failure readmissions (Cook & Lauer, 2011). Studies have found increased stroke mortality in the South (stroke belt), and many researchers are focusing on the possible underlying risk factors related to geographical variations. One group of researchers wanted to better understand the effect of length of time living in the stroke belt and age at first exposure. Howard and colleagues (2013) studied almost 25,000 residents who were stroke free at initial survey and later had strokes and found that the "risk of stroke was significantly associated with proportion of life" in the stroke belt (p. 1655). They used a proportional hazards model to determine the association of stroke incidence and with their "indices of exposure" (e.g., born in stroke belt, current residence, years in stroke belt during specific age ranges). Those individuals who were lifelong residents of the stroke belt had the strongest association with risk of stroke, but living in that area during childhood was the most predictive of future stroke, when adjusting for risk factors (p. 1655). Davis, Gebreab, Quarells, and Gibbons (2014) examined social determinants (e.g., stress, racial discrimination, socioeconomic status [SES]) of cardiovascular health (e.g., risk factors of diabetes, high cholesterol, hypertension, obesity) among black and white women in the stroke belt (defined as urban) and stroke buckle (defined as rural). They noted that black women overall had poorer cardiovascular health than white women in both rural and urban areas (odds ratio 2.68 for rural and 2.92 for urban). White women who reported high levels of daily stress were found to have poorer cardiovascular health than those who reported lower levels of stress (odds ratio 2.85). They concluded that risk reduction measures should

be tailored to specific populations in the South, targeting low-SES black women and white women with high stress levels. In a study of the predictors of uncontrolled hypertension in the stroke belt, researchers found that blacks were more likely than whites to have uncontrolled blood pressure (both systolic and diastolic). They noted that not correctly taking medications, age, and race were significant predictors of uncontrolled systolic blood pressure. Interventions could be targeted to address hypertension management in blacks and older adults in an effort to control hypertension and help prevent strokes (Dave et al., 2013). Other researchers have focused attention outside the stroke belt and noted racial and urban–rural disparities with stroke mortality. Mortality from strokes is higher among blacks and residents of rural areas (Sergeev, 2011). An Australian study also found urban–rural differences, with increased odds of death following strokes for patients treated in rural hospitals (Cadilhac Kilkenny, Longworth, Pollack, & Levi, 2011). After implementation of a Rural Stroke Project in rural hospitals (e.g., stroke units, aspirin within 24 hours of ischemic stroke, team health assessment within 48 hours, adherence to care plans, clinical coordinators), more patients were discharged home and care was improved (Cadilhac et al., 2013).

Rural areas usually have less high-tech health care equipment available, which may affect outcomes for patients with cardiovascular emergencies. Being within 60 minutes of a Primary Stroke Center (PSC) can determine outcome for many patients. Mullen and associates (2014) noted that 65.8% of Americans had that access (87% being in major cities, 59% in minor cities, and only 9% in suburbs/1% rural areas). They also noted that PSC access was generally lower in the stroke belt (44% inside vs. 69% outside) and that non-Whites and Hispanics were more likely to have access than Whites (77% vs. 62%, 78% vs. 64%). Demographics were only meaningfully associated with access in smaller cities, not major cities and suburbs. Less access was found in smaller cities with lower levels of education, income, health care resources/utilization, and higher numbers of uninsured along with Medicare/Medicaid eligible individuals. PHNs can advocate for better access to care and promote healthy lifestyle choices as well as population-targeted interventions to reduce stroke and CVD.

Rural residents may ignore early cardiovascular symptoms and give little heed to preventive interventions such as exercise and low-fat diets. A small study of women in rural Midwest states found that the participants had problems identifying symptoms associated with heart attacks in women, especially when they had no prior exposure. This may lead to delays in seeking treatment, but the women also were reluctant to call for help because of privacy concerns, thinking that an ambulance wouldn't get to them in time, and they did not want to ask relatives for help; researchers concluded that rural women may need educational programs and better information in order to seek assistance in a timely manner (Jackson & McCulloch, 2014). Other risk factors, such as smoking and poverty, affect cardiovascular health. Adults in rural counties are most likely to smoke and use smokeless tobacco, and they are more likely to be in the presence of smokers at home and work (Vander Weg, Cunningham, Howren, & Cai, 2011). Rural residents are also more likely to

be obese than urban counterparts (Trivedi et al., 2015). Lee et al. (2014a) found a higher prevalence of prediabetes in both blacks and whites living in the stroke belt than those living outside it. Also, prediabetes prevalence was higher for blacks independent of where they live. Rates of diabetes are higher in rural areas; this also plays a part in higher CVD morbidity and mortality (Bolin & Bellamy, 2015). A study of health risk behaviors of insured and uninsured patients using a rural health clinic found that the majority of all patients regularly ate fried foods, did not eat the daily recommended servings of vegetables or fruits, drank high-calorie beverages, and did not regularly exercise (Smalley et al., 2012a). Uninsured patients also were more likely to text and talk on cell phones while driving, drink alcohol, have unprotected sex, and not seek necessary medical care in a timely manner.

Diabetes

Rural populations are disproportionately affected by diabetes and CVD (8.6% and 38.8%, respectively); the prevalence is generally greater in rural areas, and this is even more pronounced among Hispanics and Blacks. Causes for these differences are not always well understood but may be due to poverty, tobacco use, and greater incidence of obesity in rural populations, all of which put them at a higher risk for chronic illness (O'Connor & Wellenius, 2012). Rural areas have been cited as promoting obesity on a population level because of fewer opportunities for walking, as residents spend a great deal of time commuting to work or driving to essential services, and rural residence was positively correlated with BMI, distance to retail food, and commute times, among other things (Calancie et al., 2015). Lower physical activity rates and greater barriers to physical activity are commonly found in rural populations, as opposed to populations living in urban settings (Bolin & Bellamy, 2015).

Rural populations also face greater barriers in diagnosis, treatment, and follow-up care. Some compliance issues with prescribed medication regimens may relate to the lack of health insurance and low-income levels in rural areas but could also be due to lower health literacy and education levels. Other problems with accessing care may involve transportation and weather. A lack of access to quality health care services has been a long-standing problem for rural Americans. The lack of appropriate services, such as certified diabetes educators or endocrinologists, is also common in rural America; expensive, up-to-date technologies requiring technical expertise are not readily available in most rural areas (Patel, Darling, Samuels, & McClellan, 2014). The U.S. Department of Health and Human Services and the United Nations have both identified rural residence as a potential barrier to better health outcomes (Sparks, 2012). Because of the significant difference in access to health care, Douthit, Kiv, Dwolatzky, and Biswas (2015) cite a need for an ongoing effort at reform to improve services, recruit health care professionals, and train them specifically for service in rural areas, as well as increasing health insurance coverage and focusing more on health promotion.

Anderson et al. (2015), in a comparison study of people living in rural counties versus

nonrural counties, found that rural residents had statistically lower scores in areas such as clinical care, morbidity factors, and general health behavior. Many factors facing rural populations create barriers to engaging in preventive services (Weaver & Gjesfjeld, 2014). For instance, a classic study by Krishna, Gillespie, and McBride (2010) highlighted the extreme complications encountered by rural residents who often have to travel great distances to access services for diabetes care, such as basic follow-up with podiatrists for diabetic foot care, ophthalmologists for retinal health, and nutritionists and health educators, as well as routine laboratory blood tests, to guide lifestyle choices. Maez, Erickson, and Naumuk (2014, p. 1) found that "nutritional patient education, motivational counseling and lifestyle modifications" were the most important factors in promoting better outcomes for rural clients. Harvey and Janke (2014) found that a chronic disease management program, using weekly group sessions, initiated positive changes in behavior among a group of rural clients. Multiple strategies were found to be effective in a systematic review of rural diabetes care (Ricci-Cabello, Ruiz-Perez, Rojas-Garcia, Pastor, & Gonçalves, 2013). PHNs, especially in rural and frontier areas, often provide follow-up for diabetic clients who may be unable to regularly access their health care providers because of problems with distance or transportation. Home visits to check on their diet/exercise, blood glucose monitoring, and foot care are important safeguards for this population. Also, interventions targeted to behavior change can be helpful.

Human Immunodeficiency Virus Infection

Human immunodeficiency virus or HIV, the virus that causes acquired immunodeficiency syndrome (AIDS), was first identified among the urban U.S. population in the early 1980s. The Centers for Disease Control and Prevention (CDC) estimates that more than 1.1 million U.S. residents have HIV, and 34,247 were diagnosed with AIDS in 2009. In 2012, almost 1.2 million people were living with AIDS in the United States (CDC, 2015). About 5% to 8% of all HIV cases in the United States were among rural populations in the early 1990s, with 56,209 diagnosed with AIDS by 2007. In the South, there are rising incidences of new cases and deaths from AIDS; in 2009, 68% of new cases were in the rural South. In 2009, the Northeast reported the highest rate of persons per 100,000 living with an AIDS diagnosis (248.7), followed by the South (169.5), the West (133.6), and the Midwest (77.2) (CDC, 2012). A study examining HIV prevalence, level of urbanization, and poverty found that racial and ethnic differences in HIV prevalence were still evident, after controlling for poverty in rural areas; this was not the case in more urban areas, where racial and ethnic differences in HIV prevalence were not significant in high-poverty areas (Vaughan, Rosenberg, Shouse, & Sullivan, 2014).

Also, 50% of rural AIDS cases are among African Americans, and young African American women are the fastest growing group infected through heterosexual exposures. In all racial/ethnic groups in rural areas, men have the highest rate of AIDS at 9.1 per 100,000 (almost three times that of women), and more than 50% are exposed through sexual contact with men. Injection drug use accounts for 20% of male AIDS cases, and over 50%

of rural HIV infections are only diagnosed within the year after advancing to AIDS. While there have been no significant differences between rural and urban populations in numbers of sexual partners, rates of unprotected sex, and being tested for HIV, rural residents were found to be less likely to change sexual behaviors or condom use in response to the AIDS epidemic (Rural Center for AIDS/STD Prevention, n.d.). Rural HIV patients were slower to adopt novel HIV therapy than urban counterparts in a Veterans' Administration study of raltegravir (Ohl et al., 2013).

Early diagnosis and treatment of HIV/AIDS are issues that must be faced by all rural communities. Physicians, nurses, and other health practitioners need to be educated about the changing face of the disease. Barriers to access among rural California HIV-infected women were similar to those noted for other health care issues: lack of transportation, problems navigating the health care system, physical health issues (Sarnquist et al., 2011). Depression is linked to lower medication adherence in HIV-positive women, and this has implications for rural care (Tyer-Viola et al., 2014). Because relatively few cases of HIV/AIDS may be present in any one rural community, specialized services are often not available, and it can be a challenge to stay up-to-date with the newest treatment protocols (National Rural Health Association [NRHA], 2016). Each state health department has resource persons who can provide information to health professionals in rural communities about the HIV/AIDS epidemic and current treatment protocols. A study of HIV testing and other treatment services in rural counties in the South found that 53% of health departments responding to the survey provided HIV testing, and 48% had HIV treatment sites. Clients had to travel an average of 50 mi to reach these services, which was considered a barrier, but facilitators included rapid HIV testing, integrating HIV testing into other services, and establishment of free/easily accessible HIV testing services (Sutton, Anthony, Vila, McLellan-Lemal, & Weidle, 2010). Communities must determine the burden of disease and tailor services to their population while at the same time providing education and case finding. For example, a study examining social service needs of HIV patient in Alabama found that case management, financial assistance, and help getting medical care were the most common needs. Women often needed help finding child care, and those scoring in the highest 25% required assistance with more than basic needs, but also legal and medical needs, as well as substance use treatment (Stewart, Phillips, Walker, Harvey, & Porter, 2011). A study of HIV-positive women in California found that 45.3% of those interviewed had problems traveling to appointments, 32.8% had physical problems that prevented them from traveling, 31.2% had no transportation, and 25% cited difficulty in navigating the health care system (Sarnquist et al., 2011).

Increased community awareness may be accomplished through faith-based organizations or by having local coaches or radio personalities raise the issue of HIV/AIDS; after-school service learning programs for youth may be helpful in reducing adolescent sexual risk-taking behaviors. Free HIV testing made available where rural populations gather (e.g., regional athletic events, colleges, health centers, church congregations) or high-risk groups gather (e.g., adult or gay bookstores, bars) can be effective. Testing incoming

and outgoing prisoners, and providing condoms, can also reach a high-risk population. Many health departments offer services through Ryan White CARE Act grant funding; these may include comprehensive care clinics or PHN case management services, as well as education/prevention.

It may be difficult for a person to seek diagnosis or treatment from a rural health practitioner. Confidentiality is an issue of concern, as is lack of anonymity. People with HIV/AIDS may fear the stigma of HIV/AIDS and the rejection that is often associated with it. They may have concern for their jobs or their position in the community if their diagnosis is divulged, and they frequently fear that health care workers will break confidentiality rules (NRHA, 2016). Instead, rural people may choose to seek out HIV/AIDS testing through an urban health care facility where they know no one. Returning to the community can be devastating because of the lack of needed support services and the fear of sharing their diagnosis with others.

Another issue that may arise is that of urban residents with rural roots who return to their home communities as their illness worsens. These people seek family support and can overwhelm their caregivers, especially if the caregivers do not seek support for themselves. Community health nurses are in a good position to assist families with any health issues and can offer to facilitate connections to other social, spiritual, financial, and health care providers. A recent study of HIV-positive women found that satisfaction with social support and coping that focused on managing HIV disease were the best predictors of adherence to medication regimens (Tyer-Viola et al., 2014). In addition, it is important for health care providers to develop interventional strategies aimed at improving quality of life while screening patients for HIV-related symptoms and depression (Vyavaharkar, Moneyham, Murdaugh, & Tavakoli, 2012). Adherence to the treatment plan was lower in patients experiencing adverse effects, thus management of these side effects is vital (Al-Dakkak et al., 2013). It is important to continue HIV/AIDS treatment even if the viral load becomes undetectable, as this is a sign that the medications are working. If patients stop taking their medications, the virus will start reproducing again and the viral load will increase (AIDS.gov, 2016).

Access to Health Care

Insurance, Managed Care, and Health Care Services

Health insurance in today's market is costly, especially for individual purchasers. Some people, therefore, forego health insurance for themselves and their families. As noted earlier, rural workers are less likely to be offered health insurance through their employers, often because they are either self-employed or because of the size or type of employers (AHRQ, 2012). Depending on their income, people may or may not be eligible for Medicaid or State Children's Health Insurance Programs (S-CHIPs). Even people who are eligible for government health assistance may not apply because of their belief that it is a sign of weakness to accept a handout. Thompson (2015) reported on farmers in Kansas and their reaction to the Affordable Care Act (ACA). Most farmers are self-employed and were often unable to pay for individual insurance or had preexisting conditions that prevented them from being eligible for insurance. One insurance agent noted that 60% to 70% of farmers still purchase through individual markets and most are in their late 50s. Because farming is considered dangerous work and many of them have some preexisting health problem, they pay higher premiums than most people. Many were uninsured and a few depended on spouses' health insurance through their employers. Since the ACA was enacted, a good number of farmers "now have health insurance for the first time in 40 years," despite being political conservatives and probably never voting for a Democrat in their life (para. 22). While some younger farmers feel that rates are too high, he goes on to explain that most farmers understand that many of their neighbors have been uninsured for a long time and that health care reform provides an opportunity for them to finally get health insurance.

Historically, a traditional fee-for-service model delivered health care in rural and urban communities (see Chapter 6). However, that is changing, and it is challenging for rural providers to deliver the cost-effective, complex health care that rural persons need via solo or small group practices. Rural patients often utilize family practice clinics. The managed care model, which attempts to control costs and improve health care delivery, has slowly diffused into rural communities. One reason for the sluggishness is that rural practitioners are reluctant to become part of organizations that negotiate to reduce their payments, as many of them already see a disproportionate number of Medicaid and uninsured patients that impact their bottom line. Another reason is the low population density, making this type of health care insurance less profitable. However, more states are moving to Medicaid managed care models, and Medicare offers this option to beneficiaries. This puts rural residents at a disadvantage, as they may have poor access to services because of distance and travel time.

Building provider networks in rural communities is both time- and effort-intensive because rural providers are often inexperienced with managed care organizations (MCOs). The federal government provides support for rural health clinics in areas designated as

underserved and nonurban; differences in effectiveness and efficiency have been noted in larger clinics versus smaller clinics (Ortiz & Wan, 2012; RAC, n.d.). These clinics have served rural clients for more than 30 years, and they are an important source of health care. However, in a study of rural health clinics and their perceptions of the ACA's Accountable Care Organization (ACO) model, researchers found that almost half of respondents had very little knowledge of ACOs (Ortiz, Bushy, Zhou, & Zhang, 2013). While a majority of clinic respondents felt that ACOs could improve patient safety and quality, many were concerned about having adequate funding to upgrade technology and were concerned about potential regulatory and legal barriers. These are valid concerns, as Bradley (2013) notes. Despite the cost savings expected with ACO's more integrated health care delivery model, the high costs for initial technology upgrades, and the potential for small rural providers to be overtaken by larger consolidated groups, in rural areas, this component of health care reform may be problematic. Some grant funding targeted to implementation of the ACA in rural areas is available (National Advisory Committee on Rural Health & Human Services, 2011). See Chapter 6.

Other specialized *migrant clinics* may also be located in rural areas with large migrant worker populations. Many of these are federally qualified health centers that provide care to underserved populations through Medicare, Medicaid, or a sliding fee scale (RAC, n.d.). Because only 9% of physicians work in rural areas (where 21% of the population resides), midlevel practitioners, such as physician assistants (PAs) and nurse practitioners (NPs), are often employed in these clinics (AHRQ, 2012). Also, specialists are most often found in metropolitan areas; rural areas are devoid of most of the smaller specialty physicians, and the population has difficulty accessing these services. For instance, 90% of geriatric specialists are found in urban areas, along with a greater proportion of internal medicine physicians. Family physicians are more evenly distributed between urban and rural areas (Peterson, Bazemore, Bragg, Xierali, & Warshaw, 2011).

Rural areas are characterized by a lack of core health care services (e.g., primary care, hospital care, emergency medical services, long-term care, mental health and substance abuse counseling services, dental care, public health services). A national survey of CEOs from rural hospitals found that over 75% reported physician shortages, most commonly family practice (58.3%) and internal medicine (53.1%). Other shortages were noted for physicians specializing in psychiatry, general surgery, neurology, pediatrics, cardiology, and OB-GYN. Over 73% reported shortages of registered nurses, and over half needed pharmacists. Thirty-five percent reported a need for NPs (MacDowell, Glasser, Fitts, Nielsen, & Hunsaker, 2013). In a comparative study of rural and urban primary care physicians, Weigel, Ullrich, Shane, and Mueller (in press) found those working in rural areas provided care to more patients per physician than their urban counterparts, as well as a wider variety of services. Population health services in rural areas may be covered by a combination of public health departments, physicians in private practice, and local hospitals, as well as various community agencies. In some rural or frontier areas, state health departments may offer services, as no local infrastructure may be present. Many rural

residents depend heavily on public health department services.

Seventeen percent of local health departments (LHDs) serve small towns (populations under 10,000), and 44% serve communities with populations between 10,000 and 49,999. These LHDs are less likely than larger health departments to provide environmental health services, but they often provide many of the other services (e.g., primary prevention, health services, epidemiology/surveillance) found in larger health departments (National Association of County and City Health Officials, 2014). Many rural public health agencies are small and isolated, with a need for connections with other agencies in the region or state. PHNs serve in a variety of capacities—often wearing many hats. The highest level of education for many PHNs is an associate degree, which generally doesn't include public health content in the curriculum (NRHA, 2011). Rural public health departments generally have lower public funding for programs and services and must guard against fragmentation of resources/programs. They also experience difficulty competing against urban agencies in access to grant funding and recruiting specialized staff. Transportation costs and adequate provision of a variety of services are other issues faced by rural public health departments, and all of these issues affect the health of the populations served. However, one study comparing willingness to respond to emergency situations revealed that rural health department workers were significantly more likely to respond than urban workers (Barnett et al., 2012). In all response scenarios provided (weather related, pandemic influenza, radiological "dirty" bomb, anthrax), rural workers were more willing to respond and report to the health department; the lowest response from both groups was found for a "dirty" bomb scenario (78.7% rural, 73% urban).

Barriers to Access

In rural areas, numerous access barriers to health care exist. The physical distance between place of residence and location of health care services can be considerable. Weather and geographical barriers may also be a factor. Rural clients may be referred to a distant urban medical center for cancer therapy or other sophisticated care. Members of the population may be frustrated if they travel to a faraway site for care and do not have their problem resolved. Rural clients must be advised before they travel to make sure that the health care provider is not behind schedule or unable to see them; see From the Case Files I for a hard lesson learned by one PHN student.

From the Case Files I

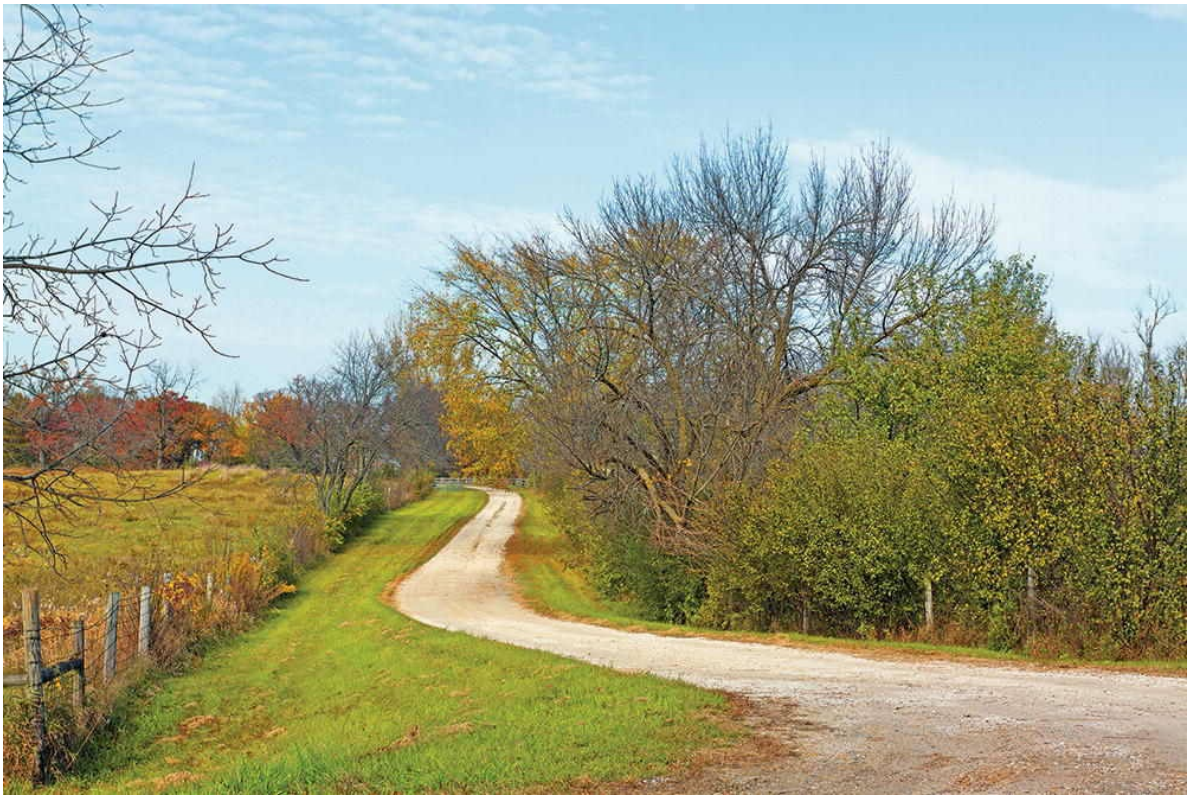
A Lesson in Rural Transportation

I live in a relatively large city of 450,000 people. When I started my community health nursing rotation, I was assigned to a rural county public health department in an adjoining county over 50 mi from my house. To make matters worse, when I got there for my first clinical day, my professor told me that I was assigned to see clients in an isolated community another hour away from the health department! There was nothing but farmland between the county seat and this small, forgotten oil town. This small town didn't even have sidewalks, much less a fast-food restaurant! After I got over my frustration about traveling such long distances, I began to visit some of my families and started to actually enjoy my time with them. They were so appreciative and open to my suggested interventions. I really seemed to be making a difference. One older gentleman, Armando, was a diabetic who spoke very little English. He lived with his wife of 50 years, who spoke almost no English. Their children had moved away in order to go to school and get better jobs. His diabetes was not well controlled, and the rural health clinic FNP suggested that he see a specialist (actually an internist) in the county seat. I helped him make arrangements with the doctor for an early afternoon visit and made sure that he could catch the county bus that ran between the smaller communities and the county seat. When I came back for a follow-up visit the next week, I was shocked to learn that Armando's appointment had been pushed back to 4:30 PM because of the doctor's involvement in hospital emergencies, and by the time Armando was finished with his appointment, the county bus service had ended. Armando, with no money and no one to call for a ride, began walking back to his home—over 52 mi away! About halfway home, a farm truck driver gave him a lift to the large cotton farm a few miles from his home. You can imagine my horror and embarrassment when I learned of this ordeal. I never realized how difficult it was for rural people to get to their medical appointments. I always had a car and could drive wherever my gas budget could take me. I thought that the bus would not be a problem, but I learned my lesson. Now, I make sure that the physician's office understands the patient's circumstances and the importance of getting them back to the bus stop in time to make the last bus.

Andrea, Senior Nursing Student

Transportation barriers can hinder access to health care services and are especially common among low-income and vulnerable populations (Syed, Gerber, & Sharp, 2013). Transportation can also be an issue, especially for people who do not drive or who lack dependable vehicles. Almost 33% have transportation disadvantages, with those earning

between $20,000 and $50,000 spending 30% of their income on a car and the costs related to driving it (American Public Health Association [APHA], n.d.a). Unpredictable weather adds to potential barriers for rural clients. Snow, ice, wind, flash floods, and rain can make travel dangerous, even over short distances. Parents may decide not to risk driving on poorly maintained roads to get their children immunized or to have their own hypertension evaluated. Elderly people may choose to delay health care when long travel times, especially in isolated rural areas, are involved. Rural populations have disproportionately high injury mortality rates, much of which is due to motor vehicle accidents (APHA, n.d.a).



According to a classic study by Branas, McKenzie, and Williams (2005), almost 47 million rural Americans do not have access to either level I or level II trauma centers within an hour's driving time, leaving them at higher risk for death from injuries. However, almost 43 million urban Americans are able to access trauma centers (level I or level II) within an hour's time. There is a noted mortality benefit of direct trauma center transport, and regional trauma systems can provide a population-based approach to provide urgent care (Haas et al., 2012). Hsia and Shen (2011a) found that 31% of those in rural areas had difficulty accessing trauma centers within one hour of driving time, and certain vulnerable populations are at an even greater risk of poor access to health care services. A good number of hospital trauma centers have closed since 2001, with a negatively disproportionate affect for rural residents (Hsia & Shen, 2011b). Inadequate phone service, dead zones in cell coverage, and the lack of adequate numbers of board-certified emergency physicians on staff are all problems frequently encountered in rural areas (Bolin & Bellamy, 2015). However, Lipsky et al. (2014) examined differences in survival among rural and urban trauma patients after implementation of the Model Rural Trauma Project. They noted, after statistical correction for differences among the 1,122 patients, that rural mortality was not significantly different from that for urban patients.

Limited choice of health care providers is a barrier for some rural residents. Fewer physicians, nurses, dentists, and other providers work in rural areas (AHRQ, 2012). Those with special needs often must travel to urban medical centers to get required care. One seminal study of disabled adults noted that they found their local rural physicians to be less familiar with their conditions, thus requiring these disabled patients to "teach" their health care provider. They also described rural public transportation as often unreliable and inaccessible (Iezzoni, Killeen, & O'Day, 2006). A literature review revealed that rural residents have diverse types of disabilities yet have barriers to accessing needed care. Children/adolescents, mentally ill, working adults, the elderly, and those with HIV/AIDS were populations of interest, and rural health care providers were often found to be lacking in training and experience necessary to treat some of the more complex medical needs of these clients. The authors also noted the need for regional specialized care services, telehealth, better training and networking for local primary care physicians, and the use of case managers and trained local paraprofessionals to bridge the gap in care (Lishner, Richardson, Levine, & Patrick, n.d.). As Medicare payments to primary care physicians are reduced and often late, there is a real threat to rural disabled and elderly clients, as some

physicians either limit the number of Medicare clients they will serve or close their offices in rural areas. As mentioned earlier, concerns about confidentiality or provider expertise sometimes cause clients to seek care from even more distant providers, but as the options for health care continue to shrink, rural clients may have few choices available locally. Those persons with disabilities who are also uninsured (more common in rural populations) have significantly more access barriers to care than those without disabilities (Iezzoni, Frakt, & Pizer, 2011).

New Approaches to Improve Access

The *Healthy People 2020* document mandates improvements in access, health education, health screening, immunizations, and disease morbidity for the United States. Creative ways of delivering these and other services to rural clients need to be explored. Access to care is a social justice issue: clients who live in rural areas should receive quality health care, regardless of where they choose to live.

A country road, often without street signs and sometimes difficult to locate.

Faith-based nursing has been a staple in rural areas, as well as with some urban communities, but is gaining momentum as more formal interventions are developed, for instance, mental health promotion for rural Latino immigrants (Stacciarini et al., 2016). Even informal support from other church members and friends may provide a compassionate environment for needed behavioral changes such as healthy diet and increased physical activity (Kegler et al., 2012). Church communities may also provide

assistance and relief to caregivers in rural areas, especially when more formal services are unavailable or geographically distant (Greene, Perkins, Scott, & Burt, 2011). See more on faith-based nursing in Chapter 31.

One approach that has been successful in numerous rural areas is the use of *mobile clinics*. These clinics bring health care providers to remote places for health screenings, immunizations, dental care, mental health visits, and other services. Mobile health clinics are frequently staffed by NPs and can improve access to health care for low-income residents. They often are available to residents on evenings and weekends and offer culturally sensitive and bilingual outreach, as well as care for uninsured clients. They may be helpful in overcoming access problems for vulnerable populations (Isler, Miles, Banks, & Corbie-Smith, 2012).

School-based clinics can improve access for schoolchildren (and sometimes their families) but may be less prominent in rural areas (see more on school-based clinics in Chapter 30). Only 27% are in rural areas and 16% in suburban areas, with the majority in urban areas. These clinics provide available, community-based, affordable, and culturally acceptable care to well and sick children. Often, grant-supported, school-based clinics facilitate the receipt of health education and primary care by children who are otherwise without easy access to health services (National Conference of State Legislatures, 2011). A study by Bains, Franzen, and White-Fresé (2014) revealed that Latino and African American male adolescents, who generally seek mental health services and obtain care at lower levels than White adolescent males, were more likely to access these services at school-based health centers because of the accepting nature of services there. See more in Chapter 30.

Telehealth, another approach to increasing access to care, provides electronically transmitted clinician consultation between the client and the health care provider. This option is especially useful for connecting home health nurses with their patients who need close monitoring at home. It is also useful for patient and professional health education, public health applications, and health administration. Specialty health care also may be accessed, with patients and providers connected via two-way audiovisual transmission over telephone lines or the Internet, thus obviating the need for patients to leave their residences. Streaming media, video conferencing, and store-and-forward imaging are just some of the applications commonly utilized (HRSA, n.d.b). Clients can also be assessed quickly by interactive communication from physician offices, hospitals, and other sites. Rural American Indians and Alaska Natives found cancer support groups offered through this technology to be helpful (Doorenbos et al., 2010). Telehealth technology may decrease visits to emergency departments and hospitalizations, if early assessment and intervention can be provided, and telehealth has been used to manage rural heart failure patients to decrease hospital readmission rates (Graves, Ford, & Mooney, 2013). Telehealth interventions for speech–language services to rural children and one systematic review of the use of technology with underserved clients acknowledged the effectiveness of the use of various methods of technology in promoting health and improving outcomes (Fairweather, Lincoln, & Ramsden, 2016; Montague & Perchonok, 2012). McIllhenny, Guzic, Knee,

Demuth, and Roberts (2011) found that a nurse educator coaching clients to access to a Web portal with diabetes-related health education resources could be useful in providing diabetes care to a rural population. Physical therapists provided physical therapy sessions to veterans through home video technology and noted significant physical improvement along with cost savings of over $1,151 and travel time of over 46 hours (Levy, Silverman, Huanguang, Geiss, & Omura, 2015). Grants and other funding are available to promote the use of this technology (HRSA, n.d.b). Rural hospitals in a health care profession shortage area that employ hospital-to-hospital telemedicine services can qualify for Medicare reimbursement; over 50% of all U.S. hospitals now use some type of telehealth, with many larger systems having telehealth networks (Kutscher, 2014). See Chapter 10.

Healthy People 2020 Goals

The four overarching goals of *Healthy People 2020* are to:

1. Attain high-quality, longer lives free of preventable disease
2. Achieve health equity, eliminate disparities, and improve the health of all groups
3. Create social and physical environments that promote good health for all
4. Promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, 2016b, para. 5)

Because of the unique health issues facing rural America, *Rural Healthy People 2020,* a rural-oriented document was developed (Bolin & Bellamy, n.d.). Using surveys, literature reviews, and other methods of data collection and analysis, top priorities for rural health were identified. The original *Rural Healthy People 2010* document also highlighted current knowledge on rural health and identified best practices, and it called for further research on rural health promotion (Bellamy, Bolin, & Gamm, 2011). Certainly, there are data to substantiate continued problems with access to health care and insurance, as well as emergency services, in rural areas. And there is a higher rate of CVD and diabetes, along with obesity and tobacco use among rural populations (NRHA, n.d.). The *Healthy People 2020* document notes specific differences in oral health and social determinants of health related to geography. A national survey (n = 688) conducted between 2010 and 2011 listed the initial top ten priorities for *Rural Healthy People 2020*, with access to quality health services as the most important priority (Bolin & Bellamy, n.d.). However, funding cuts prevented the broadened surveys first proposed, and the authors launched a second Web-based survey in 2012, that at 1,214 respondents. Again, access to quality health services was the first priority chosen, with nutrition and weight status, diabetes, mental health/disorders, substance abuse, heart disease/stroke, physical activity/health, older adults, maternal–child health, and tobacco use making up the top ten priorities (Bolin & Bellamy, 2015; Bolin et al., 2015). A large longitudinal study of maternal and infant health in Maine revealed that access to prenatal care, along with pregnancy care and outcomes, was similar for rural and urban women over an 11-year period (Harris, Aboueissa, Baugh, & Sarton, 2015). Rural mothers had higher BMIs prior to pregnancy and were generally younger, less well

educated, unmarried, and living in low-income households. They were also more likely to smoke, but less likely to drink alcohol, and were not often sure of their pregnancies until later than urban mothers, but they still accessed prenatal care at similar times (Harris et al., 2015).

Access to quality care is linked to availability of health insurance. Rural residents, when compared to urban counterparts, have higher rates of uninsured, higher out-of-pocket costs, and higher proportions of emergency room visit costs; they are also less likely to be covered through group health insurance or managed care plans and less likely to have prescription drug coverage (Bolin & Bellamy, 2015). Also, insurance instability (gaps in coverage) is correlated with increased use of emergency rooms, and this is particularly significant for rural residents who often have less access (Fields, Bell, Moyce, & Bigbee, 2015). Because of lower rates of insured rural residents, their preventive health care is often lacking (e.g., lower rates of mammograms, colonoscopies, vision exams). Also, around 65% of primary care professional shortages occur in rural counties. Rural residents are also less likely than urban residents to have a usual source of primary care, and this is especially true in the 18- to 44-year-old age group (Bolin & Bellamy, 2015).

Problems more commonly seen in rural areas include oral health and cigarette and smokeless tobacco use. Sixty percent of rural counties are considered professional shortage areas for dental health, and more dentists are over age 55 in rural areas (42% vs. 38% in urban). Rural populations are less likely to have an annual dental examination. They are also more likely to have tooth or gum disease, often because of higher rates of cigarette and smokeless tobacco use, and they are more likely to use the emergency room because of dental caries than urban residents (Bolin & Bellamy, 2015; Kronkosky Charitable Foundation, 2011). Smoking prevalence in rural areas is higher than in urban areas, and smokeless tobacco use is twice or three times higher in rural areas (Bolin & Bellamy, 2015; Borders & Booth, 2007; Kronkosky Charitable Foundation, 2011). Over one fourth of rural pregnant women smoke during their pregnancy, compared to 11.2% of urban women (Bolin & Bellamy, 2015).

Alcohol dependence is more common in rural than suburban or urban areas, and one study found that current and lifetime rates of alcohol, tobacco, and illicit drug use were significantly higher for rural adolescents than for their urban complements (Coomber et al., 2011). Some studies show that overall prevalence of illicit drug use is similar, but access to substance abuse services is better in urban areas. Methamphetamine use is often prevalent in rural areas because "cooking" is easier because of availability of ingredients such as anhydrous ammonia (farm fertilizer) and remote, isolated locations (Oser et al., 2011). Prescription opioid use and abuse is increasingly becoming a public health crisis across the United States. Nonmedical abuse of prescription opioids is often concentrated in rural areas (e.g., Alaska, Kentucky, Oklahoma, West Virginia) and is best addressed on macro, local, and micro levels (e.g., overall drug availability, family/peer stressors, genetic vulnerability/psychiatric morbidity). In 2006, it was the cause of 37% of all poisoning deaths, but in nonmetropolitan counties, there was a threefold increase; there are also more

nonmedical than medical opioid users in rural areas (Keyes, Cerda, Brady, Havens, & Galea, 2014). Depression is often associated with opioid drug abuse among rural residents, as is the number of medical comorbidities (e.g., CVD, diabetes, chronic renal disease); better screening is needed before these powerful medications are prescribed, as the potential for abuse is high (Kapoor & Thorn, 2014). Also, newer and less addictive types of pain control are needed (Dryden, 2016). The vast majority (80%) of rural residents live in counties without detoxification facilities and primary care practitioner in rural areas often lack sufficient training to effectively screen for substance use (Bolin & Bellamy, 2015; Kronkosky Charitable Foundation, 2011).

Children in rural areas are at greater risk for death and disability because of the lack of pediatric emergency services (Bolin & Bellamy, 2015). Children with special needs who live in a rural area are often lacking needed services to promote health and prevent illness. Research has also demonstrated that rural residence is a risk factor for overweight and obesity in children (Davis, Bennett, Befort, & Nollen, 2011). Rural areas also frequently have deficient physical education programs in schools, but residents have greater inactivity and calorie consumption (Bolin & Bellamy, 2015; Kronkosky Charitable Foundation, 2011).

Cancer disparities are found in rural populations. For example, cervical cancer rates for rural women are statistically higher than for Caucasian and Black women living in urban areas (Evans, Cole, & Norris, 2015). Survival rates for cervical cancer are also lower in nonmetropolitan areas, especially so for rural black women who had a 50.8% 5-year survival rate compared with 60.2% for those in metropolitan areas (Singh, 2012). Rural women are less likely to receive screening mammograms and Pap smears than urban women. Rural populations also have a lower proportion of colonoscopies to screen for colorectal cancer. Further, most rural physicians are trained as generalists, therefore not trained to perform colonoscopies (Evans et al., 2015). Rural PHNs need to consider the *Healthy People 2020* objectives and *Rural Healthy People 2020* priority areas as guides for improving the health status of clients in rural communities.

MIGRANT HEALTH

You may not have seen migrant workers, yet you are a direct beneficiary of their labor. Have you ever thought about the people who harvest the fruits and vegetables that you eat? What would happen to the complex system of agricultural production and distribution if workers were not available to pick crops at peak harvest times? Have you ever thought about who they are, where they come from, where they live, or what their health is like? A common question among Americans who have never worked with migrant populations is "Why are they here?" and the answer is often a case of simple economics. Whatever your political, social, or ethical views on this subject, migrant workers and their families often cross paths with PHNs and we need to understand them in order to effectively provide care. See What Do You Think?

What do *you* think?

There are many critics of undocumented migrant workers. Some feel that it is their willingness to work for low wages keeps overall wages lower for everyone working in agriculture. Others feel that migrants are taking jobs away from Americans. The United Farmworkers, an agricultural worker union, introduced the *Take Our Jobs* program in 2010 to address these issues. Unemployed Americans were invited to work in the fields along with migrant farmworkers, but very few accepted this invitation; those that did attempt it had a difficult time keeping up with the grueling pace of work. Stephen Colbert, a television show host and comedian, picked beans and packed corn as part of the challenge, and filmed some of his workday experiences for his late-night show. He also gave testimony to Congress on the need for better wages, living conditions, and visa programs for these workers. What do you think about the issue?

From Lerner, A. (2011). *Migrant labor, immigration, and food production*. Retrieved from http://find.galegroup.com/gic/infomark.do?&source=gale&idigest=a24509ee707e3735cde6db3e17c5304e&prodId=GIC&userGroupName=bhs&tabID=T00

Migrant farmworkers are an integral part of the farming community in the United States and across the world. The agricultural industry relies heavily on migrant workers to harvest the almost endless array of fresh produce that appears year-round in supermarkets across the United States as fresh, frozen, and canned fruits and vegetables. It is estimated that the cost of vegetables (e.g., tomatoes) would most likely increase by 25% to 40% if migrant farmworkers were not readily available to pick crops in a timely manner (Lerner, 2011). More than 3 million seasonal and migrant farmworkers provide labor for the $28 billion vegetable and fruit crops of the United States (National Center for Farmworker Health [NCFH], 2012b). Many of these workers are unauthorized or illegal immigrants to

the United States, often from Mexico. A study of Canadian migrant workers, a country with a seasonal agricultural worker program offering higher wages and shorter time periods away from home and family (up to 8 months), found that 100% of those leaving Mexico on their first entry into Canada were legal temporary workers. In contrast, only 18% of those leaving for the United States were entering legally as workers with an H-2A (work program) visa (Massey & Brown, 2011). The vast majority entered this country in an unauthorized manner. Because Canada recruited temporary workers from Mexico under a formal agreement, their workers were over age 18 (usually 22 to 45 years), had agricultural experience, and had no prior criminal records. Mexico also stipulated that they have some education (third to ninth grade) and be in a stable relationship (married or common law). Because of this program, with benefits to both countries as well as the temporary workers, Canada has a low proportion of workers becoming permanent residents and a more "circular flow" with repeat migrations. With the H-2A visa, there are restrictions against farmworkers changing employers, and this could affect their work safety climate (Arcury et al., 2015c). In the United States, undocumented workers often stay for longer periods of time because of "tighter controls on border crossing making repeated migrations more difficult than before 9/11" (Massey & Brown, 2011, p. 119).

Despite their importance to American agriculture, migrant workers are not often visible members of our society. They go unnoticed beyond the fringes of the camps and farms to which they travel in order to pursue their livelihood. Most come to the United States from other countries (72%), and of those, about 68% are from Mexico. Most have been in the United States 10 years on average. The average age is 36 years, 78% are males, and 35% stated that they spoke no English. The average level of completed education was the eighth grade (NCFH, 2012b). Approximately 42% of farmworkers are considered migrant (traveling 75 mi to obtain farm jobs), and many travel to multiple farm sites within a year. Most (34%) worked in fruit and nut crops, and 69% find employment through family and friends. Only 6% are salaried, with the majority paid low hourly wages or by the piece. California, Florida, Texas, North Carolina, Michigan, Washington, Tennessee, and Oregon currently have the highest number of migrant farmworkers (NCFH, 2012b). They come with the hope of bettering their impoverished lives. Some are legal residents, but most are undocumented aliens and live in fear of deportation. All endure backbreaking, menial labor for low wages and are often deprived of basic rights to safe working conditions, adequate sanitation/housing, health care, and a quality education for their children. See From the Case Files II.

From the Case Files II

A Case of Active TB in a Rural Community

As the PHN in a rural community, I received many types of referrals for families including maternal child, older adults, child abuse, or communicable disease cases. The small public health district office where I worked was staffed with one nurse and one aide, and we hosted clinics for immunizations, well-child care, and family planning. It was located in a small agricultural town of approximately 20,000 people, with a very large Hispanic- and Spanish-speaking population. One day I was summoned to the main office, approximately 30 mi away, to respond to a new active tuberculosis (TB) case. A 20-year-old Hispanic male was a patient in the county hospital and he was on respiratory isolation. I picked up the case file from my supervisor and we discussed the plan of action. When the patient was released, he would return to live in the small community that I covered. I would need to examine his living conditions and his contacts.

I first visited Gregorio in the county hospital. I spent time interviewing him, donning an N95 mask, and educated him about who I was, as well as the reason for my visit. Gregorio explained that he, along with other men from his home country of Chiapas, Mexico, had taken an arduous journey to come to our area in order to find work. He could no longer stand the pain in his chest and his brothers decided to drop him off at the hospital. He provided his address and the names of his brothers with whom he lived or visited with regularly, as well as most of the names of the other men with whom he worked. There were 20 names in total that were close contacts and needed follow-up. I explained to Gregorio that I would be his nurse when he was released from the hospital and that I would be helping him receive treatment for TB.

The next day, the Public Health Aide and I traveled to Gregorio's home address. It must have seemed very strange to have a nurse and an aide knock on the door of a male household of agricultural workers. Many of the men did not receive health care in their home country. They were very welcoming, and with the assistance of Gregorio's older brother, we began to complete the contact investigation. They lived in a 2-bedroom home, without furniture, and each man took a spot on the floor to sleep at night. One by one, each was interviewed for TB risk assessment and a TB skin test was placed. On return to the home in 2 days, skin tests were read and those who had positive tests were referred to the community health center for chest x-rays. Many of the men had not yet been successful in obtaining work and had no income. The County Public Health Officer (a physician) intervened to ensure that appropriate treatment would be received. The large number of close contacts and the difficulty in arranging transportation from the rural community necessitated that the Health Officer come to the rural district office to hold a TB clinic so that each close contact could be evaluated. The men could walk approximately 1 mi to the public health office to meet with the MD. The men seemed a bit bewildered regarding our very intensive efforts to get them into health care. However, they were very cooperative, and no other close contacts were found to have active TB, but many

were prescribed treatment for latent TB infection (LTBI).

Gregorio was hospitalized until he was no longer communicable, and he was picked up by the public health medical investigator to return home. By this time, some men had found work in the fields and had made other living arrangements. I had to find the new addresses where they had moved in order to ensure compliance with LTBI treatment. When I showed up at the homes of the contacts that had moved, they were neither pleased nor unhappy to see me, but they were cooperative.

Gregorio and his brothers stayed in the original home. The county public health department instituted daily Direct Observed Therapy (DOT) and assisted with transportation to medical appointments. Gregorio was cooperative with the plan of care and enjoyed the company of the public health staff including the PHNs, aides, medical investigators, and DOT workers. Five days a week, Gregorio had a visitor to assess his needs and oversee his medications. At times, this included support through food baskets and other community resources when work could not be found. In addition, we made DOT scheduling considerations for late afternoons during times when Gregorio was working, as this was highly important to him so that he could work and get paid.

Over the year that Gregorio was on treatment, he understood that we cared for his well-being and wanted to prevent him from having more serious complications. Without public health interventions, his untreated TB could have created a serious public health threat in this small community. However, because public health was present, the outcomes were such that Gregorio was able to live productively and contribute to the stability of his brothers' household, as well as that of his more family back in his home country.

Judy H. Pedro, MSN, RN, APHN-BC

Migrant Farmworkers: Profile of a Nomadic Population

Maintaining a low public profile, migrant workers are, for the most part, marginalized from mainstream society. They remain unseen, unheard, poorly understood, and excluded from many programs that provide health care assistance for low-income people. The migrant worker is a kind of disenfranchised person, for whom no one wants to take responsibility. Yet the needs of these workers are great. They are plagued with different, more complex, and more frequent health problems than the general population (Arcury & Quandt, 2011; Migrant Clinician's Network, 2016). Common ailments include infectious diseases (e.g., TB, parasites), gastrointestinal disorders, dermatitis because of pesticide exposure, emotional distress and depression, vision and eye problems, cancer, and chronic illnesses, such as asthma, bronchitis, diabetes, and hypertension. They are plagued by poverty, poor nutrition, substandard housing conditions, extended working hours, and grueling, often unsafe, working conditions. Their demographics, socioeconomic conditions, and lifestyle resemble those of a Third World country despite the fact that they live and work in one of the most prosperous nations on Earth. Although migrant families are in dire need of health resources, various economic, cultural, and language barriers prevent this aggregate from accessing available health services. Poverty, frequent mobility, low literacy, and language and cultural barriers impede farmworkers access to cost-effective health care and social services (NCFH, 2012b).

Migrant workers live and work in areas where health care practitioners are generally in short supply. In a large national study of farmworkers, only 52% had used U.S. health care services within the last 2 years, and barriers include lack of health insurance, fear of immigration consequence, low English proficiency, and access to transportation (Hoerster et al., 2011). Among Latino immigrants, common barriers include communication problems, difficulty proving financial eligibility, and long waiting periods for gaining access to health care services (Cristancho, Peters, & Garces, 2014). They often used traditional cultural remedies (e.g., herbal medications, traditional healers) and often blended both traditional and U.S. health care practices (Jostad-Laswell, Guendelman, & Castañeda, 2013). An 18-month ethnographic study of indigenous Triqui migrant workers followed them from Oaxaca, Mexico, to central California and onto the northwest area of Washington as they harvested crops. Interviews were conducted with them and the health care providers who worked in the clinics serving them. The researcher (Holmes, 2009, p. 873) found that "social and economic factors in health care and subtle cultural factors… keep medical professionals from seeing the social determinants of suffering," and this leads them to inadvertently blame the patients. Additional barriers include limited transportation, prejudice because of immigrant status, mistreatment because they are "undocumented," lack of time-efficient health care delivery methods, increasing cost of health care, and needed services not being offered (NCFH, 2012b, 2015).

Historical Background

Both historically and internationally, farmers have rarely been able to permanently employ the large workforces needed to harvest their crops. Throughout the 19th century, however, the small, family-owned farms typical in the United States got through the harvest by using schoolchildren, neighbors, and local day laborers. As time went by, this became more and more difficult to accomplish. During the decade ending in 1929, over half a million Mexicans migrated to the United States, many drawn to work in seasonal agriculture. With the Great Depression, many of the small, independently run farms went bankrupt, and citizens were concerned about scarce employment opportunities. Because of this, state and federal governments were lobbied by civic groups to "round up Mexican Americans indiscriminately … and to 'repatriate' them to Mexico" (University of California, 2012, para. 5.). Within a few years, the outbreak of World War II caused an increased need for food production and additional workers, as many U.S. workers joined the military. To keep abreast of the demand for produce, the larger surviving farms turned to migrant labor for help. The Emergency Labor Program—known as the Bracero Program—was enacted in 1942 to permit temporary Mexican immigration to provide needed workers for American agriculture and industry (University of California, 2012). Between 1942 and 1964, more than 4 million Mexican workers participated in this program, leaving their families behind and coming to work in Californian fields. When this program ended, workers continued to cross the border to seek employment, often bringing along their families. Employers hired needed undocumented workers from Mexico, as well as Central and South America. The 1986 Immigration Reform and Control Act created sanctions for employers who hired undocumented workers and made them responsible for checking documents and eligibility for potential employees (National Agricultural Law Center, n.d.).

Living apart from society, the plight of migrant farmworkers was largely ignored until exposure on a 1960 television documentary—Edward R. Murrow's *Harvest of Shame*—created a national outcry. This led to the passage of the Migrant Health Act of 1962, which addressed the specific health needs of migrant workers for the first time in U.S. history. This act authorized delivery of primary and supplementary health services to migrant farmworkers (NCFH, n.d.). Federally funded migrant health clinics serve areas in the United States where significant number of migrant farmworkers gather. In 2010, 165 migrant clinics served more than 863,000 seasonal and migrant farmworkers and members of their families, a number far below the estimated 3+ million farmworkers thought to be in this country. Eligibility for services at the clinics includes being principally employed in agricultural labor for the prior 24 months (Farmworker Justice, 2016). Services may be provided seasonally, on a temporary basis, or year-round. Staffing usually includes doctors, nurses, NPs, PAs, outreach workers, social workers, and dental and pharmacy workers, along with health educators. Transportation may also be a component in some areas. Primary and preventive health care services are provided to migrant workers and their families throughout more than 500 clinic sites. However, funding is often inadequate, and many clinics are not sufficiently staffed or operated to meet the health needs of migrant farmworkers and their dependents. Most migrant health centers receive funding from a variety of sources, including Medicaid in some instances. Additionally, although these

clinics exist throughout the United States, large geographic regions are not served well or at all. Other services, such as *promotora programs* that employ Hispanic lay health workers or nursing voucher programs providing NP services at participating clinics and nurse referrals to specialists, are available in some areas (Fiandt, Doeschot, & Lanning, 2010; Molokwu, Penaranda, Flores, & Shokar, in press; Wright et al., 2015). Migrant workers in areas without migrant clinics or other targeted services must rely on LHDs and emergency rooms for health care, or they may simply go without needed care.

In 1964, the U.S. Department of State initiated the H2 Temporary Guest Worker Program. In 2010, a total of 55,721 H-2A visas were granted to migrant farmworkers (NCFH, 2012b). The current H-2A program for temporary agricultural workers permits employers to file paperwork, demonstrating a need for temporary workers that cannot be met by U.S. workers, and then, workers from approved countries can apply for a visa. It allows them to work for up to 1 year in the United States, and they may bring spouses and children under age 21 under a companion visa program (H-4) that does not permit them to work (U.S. Department of Homeland Security, 2012). Only a small percentage of workers and employers utilize this program, approximately 1% in the last national survey. More recently, approximately 48% of migrant farmworkers were described as unauthorized to work in the United States, 33% were U.S. citizens, and 26% have been in the United States <4 years (NCFH, 2012b).

Demographics

Because migrant farmworkers constitute a mobile population with shifting composition, it is difficult to precisely determine their number or origins. Estimates of the number of migrant workers vary also because of the influx of illegal and undocumented workers. A large number of seasonal and migrant farmworkers reside in the United States, and 33% are U.S. citizens, and others have permanent resident status. Most of the estimated 3 million migrant (42%) and seasonal (58%) farmworkers tend to be either newly arrived immigrants, with few connections, or established legal residents with limited opportunities and skills, who rely on farm labor for survival (NCFH, 2012b). In addition to male workers, who make up the majority, you may also see mothers bring infants and young children to work with them, and the children spend their days strapped to their mother's back or playing among the pesticide-laden fields.

Seasonal farmworkers generally live in one geographic location and are temporarily employed in agriculture, whereas migrant farmworkers meet that classification while moving to find agricultural work throughout the year, usually from state to state, and establishing temporary residences (Migrant Clinicians Network, 2016). Some live apart from their families, forming groups of single men; others travel with their entire families. The average migrant farmworker spends from June to September doing seasonal harvesting, with about 8 weeks on the road traveling from farm to farm for work, and is then unemployed unless other work, such as hauling or canning, is found. Days begin before dawn and work continues for 12 hours or longer. Farmworkers cannot be paid for

overtime, as federal laws exclude this category of work, and 14 states don't require workers' compensation (Barbassa, 2010; NCFH, 2012b). The main reason migrant workers immigrate is to find work, and most migrant farmworkers end up in areas where they already have social networks, such as family or acquaintances from their own areas of Mexico or other countries (Cohen, 2010; Rose, 2013).

Migrant farmworkers have the potential to receive compensation below minimum wage standards. Although most are paid by the hour, 11.7% receive piece-rate pay. Eight out of ten migrant farmworkers live below the U.S. poverty line (NCFH, 2010). Since 2000, Latino migrant farmworkers have had a median annual income of around $10,000 (Lerner, 2011). Families working in the cotton fields of Texas and other states report working long hours, and children as young as 11 may work alongside adults (Coursen-Neff, 2011). The Fair Labor Standards Act of 1938 (FLSA) was amended in 1978 to mandate minimum wage for workers on large farms but has never been changed to provide overtime pay for farmworkers. Farmworkers paid at a per-piece rate may earn as little as 40 cents for a bucket of tomatoes or sweet potatoes, therefore needing to pick approximately 2 tons of produce (125 buckets) to earn 50 dollars (Student Action Farmworkers [SAF], 2011–2016).

Migrant Streams and Patterns

Migrant farmworkers usually have their permanent residence, or *home base*, in states with a traditionally high number of immigrants, like California, Texas, Florida, Washington, Oregon, and North Carolina (SAF, 2011–2016). From their home base, they move to locations where each new crop is ready for harvest. As they follow the harvest seasons of agricultural crops, migrant farmworkers move from place to place, usually along predetermined routes called migrant streams (Fig. 29–5). Some migrant farmworkers are multigenerational; that is, their families have been farmworkers for several generations, traveling the same streams for many years. It is very common for farmworkers and other foreign workers to send money back home to family members; total migrant and foreign worker remittances constitute large sums of money and provide significant support for families in other countries, like Mexico, China, India, and the Philippines (Tomlinson, 2013). Of farmworkers in the United States, 75% were born in Mexico and 60% live apart from their immediate family members. Immigrant farmworkers often leave their home country to seek a better life for their families (SAF, 2011–2016).

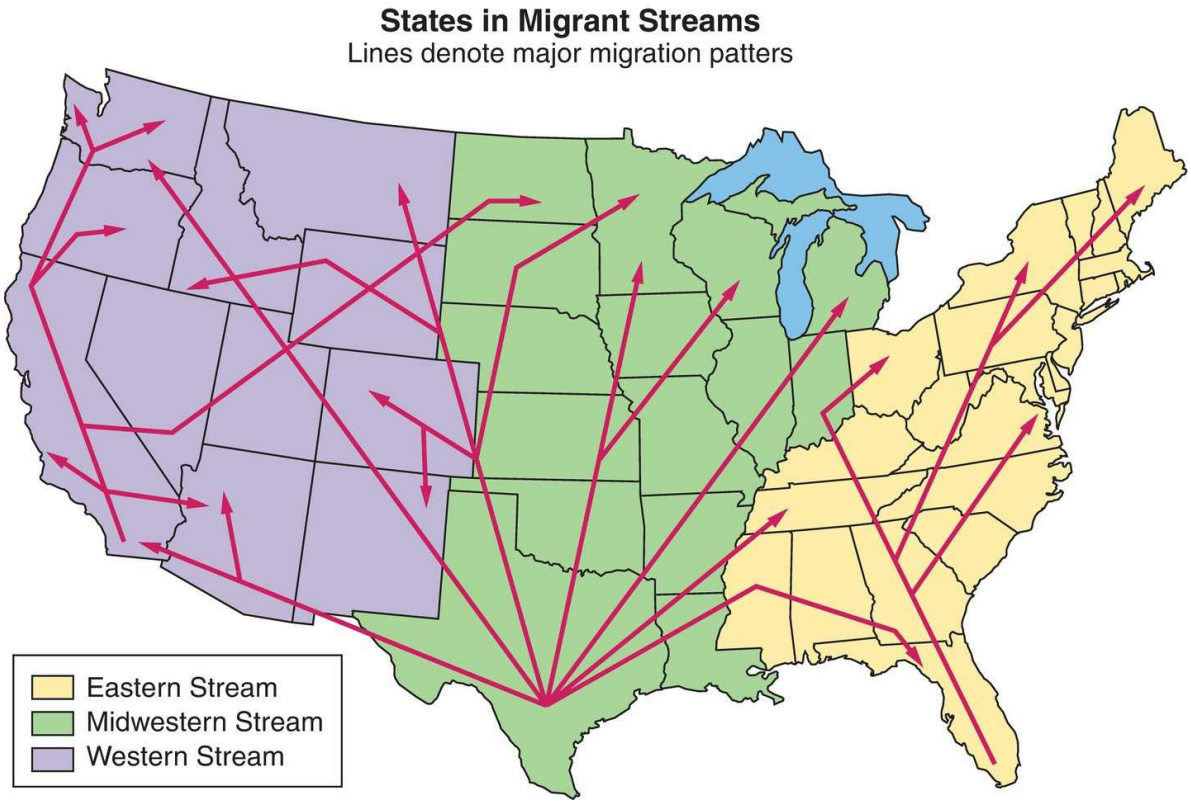


FIGURE 29–5 Migrant streams. (Source: Migrant Head Start Program, USHDHUD [same—unchanged].)

Three principal streams formulate the agricultural routes that migrant laborers follow. The *eastern stream* originates in Florida, where most of their time is spent, and extends up the East Coast through North Carolina, Tennessee, Kentucky, Virginia, and other states east of the Mississippi, as far as north as Ohio, New Jersey, New York, Connecticut, Massachusetts, New Hampshire, Vermont, and Maine. The *midwestern stream* begins in southern Texas or northern Mexico and fans out across the United States, ending in the Northwestern and Midwestern states bordering Canada, both east and west of the Mississippi. The *western stream* originates in California and moves up the West Coast to all western states and from central California into North Dakota per a seminal article by Formichelli (2008). California, Florida, and Texas are regarded as *sending states*, as they are often home states with long growing seasons where migrant streams begin and end. Male workers may travel with the crops and leave their families in these home states (USDHUD, 2016a). Workers move from areas with cotton, tree fruits and nuts, and vegetable crops to other areas where they harvest cherries, watermelons, cantaloupes, or potatoes.

Cranberry harvest in New Jersey. (Source: USDA, Agricultural Research Service.)

Weather conditions and employment opportunities affect movement and patterns of migration. Because of the unpredictable nature of farmwork, the three streams are not clearly delineated, pointing to more complex patterns of movement. In addition to the migrant streams, patterns of migration exist, with varying lengths of stay. In a *restricted circuit*, many people travel throughout a season within a small geographic area, following the crops. *Point-to-point migration* entails leaving a home base for part of the year to travel to the same place or series of places along a route during the agricultural season, usually returning on a yearly basis. Almost 40% of seasonal farmworkers shuttle back and forth this way (Loue & Quill, 2010).

Nomadic migrant workers travel away from home for several years, working from farm to farm and crop to crop and relying on word of mouth about job opportunities. Nomadic workers are often younger males who send money home to their families (Fan, Gabbard, Pena, & Perloff, 2014; Loue & Quill, 2010). Some of these workers eventually settle in the areas to which they have migrated, whereas others return to their home base. A given ethnic group usually follows its own particular stream and pattern of migration. New growth states, like Utah, Minnesota, Wisconsin, Nebraska, Kansas, Tennessee, and Arkansas, have seen immigrant populations increase. Some migrant workers find work in service sector jobs and others labor in construction or landscaping, thus ending their need to constantly move with the crops. Overall, the migration rate of farmworkers has dropped from 53% in 1998 to 23% in 2009, thought to be due to economic, institutional, and governmental changes (e.g., stricter U.S. border enforcement, improved Mexican economy), in both the

United States and Mexico (Fan et al., 2014). Married men, not living with their families, are more likely to migrate than those living with their families, often because of the need to send money back home. This drop in migrant labor has implications for American farmers, as they find it more difficult to find sufficient laborers during peak planting and harvesting periods and may need to pay higher wages that ultimately result in higher consumer prices for agricultural products (Fan et al., 2014).

Migrant Lifestyle

To understand the health needs of migrant farmworkers and their families, it is important to understand their lifestyle. Migrant workers and their families endure a transient and uncertain life, with long hours, stressful working conditions, low wages, and poor health care. Substandard housing, unsafe working conditions, and language barriers make life even more difficult (USDHUD, 2016a).

Migrant workers must confront the vagaries of an unpredictable world. Migrants typically remain in an area for only 6 to 8 weeks, working the fields 6 days a week from sunrise to sunset. Depending on weather and crop conditions, work may be plentiful 1 week and virtually gone the next. Because yearly income must be earned during the harvest season, all family members contribute to harvesting. Children are essential to the core group's economy and must help in the fields and at home (Loue & Quill, 2010). Migrant workers often drive night and day as they move from crop to crop. Typically, they travel with their children and only their most essential possessions, in aging cars, vans, and trucks. Occasionally, van loads of *solos*, or single men, migrate together. Their status is even more precarious because they lack family support systems. Male farmworkers, single or away from their families, more often engage in risk-taking behaviors of drinking alcohol, having sex with commercial sex workers, and inconsistent use of condoms (Rhodes et al., 2010).

Depending on the economy and the crop, a migrant farmworker's income varies widely. A study of migrant farmworkers in North Carolina found that 90% were paid by the hour, but 18.3% of all farmworkers reported wage violations: 45.3% of those without H-2A visas and only 3.6% with H-2A visas (Robinson et al., 2011). Men, women, and older children all work in the fields. Arcury Rodriguez, Kearney, Arcury, and Quandt (2014b) found that over one quarter of youth farmworkers were between the ages of 10 and 13, and 39.1% were 14- to 15-year-olds. Over 34% were 16- to 17-year-olds, and 78.2% of the study participants working in tobacco, sweet potato, and berry crops were born in the United States. Over 55% of them were paid piece rate, rather than hourly wages, and almost 22% had problems getting their correct pay. Because inexpensive child care is seldom available, mothers often leave very young children alone playing in fields, where they are exposed to sun, chemicals, and dangerous machinery. Sometimes, children are brought to the fields and left in cars or in cardboard boxes. Often, a teenage girl or the mother of an infant may remain in the camp to babysit all the children; she is usually stranded there, because all available cars are used to take workers to the fields. There are Head Start and Migrant Head Start programs in many areas, but they can only provide

services to a minority of children needing them.

Migrant laborers learn about employment opportunities from recruiters, farm labor contractors, and crew leaders, as well as from other migrants. About 33% of California farmworkers and 20% of those nationwide are usually employed through farm labor contractors (University of California, 2012). Migrant farmworkers may travel in crews or groups and are often employed by farm labor contractors (an individual who serves as the mediator between workers and the farmer). These contractors may also provide transportation, housing, and meals for the workers and may also supervise their work in the fields. The farmer usually pays the labor contractor, who, in turn, pays the workers (National Agricultural Law Center, n.d.). This can be viewed as a way for farmers to remove themselves from the responsibility of paying minimum wages to workers, providing worker's compensation, meeting legal responsibilities (e.g., state and federal worker safety rules), and preventing union organizing because they employ the contractor, not the individual workers. Owners may also ignore abuses, because they are not directly employing workers. The labor contractor may underreport hours of workers, or piecework, and harassment can often occur. An unscrupulous crew leader can withhold payment and keep the migrant workers in constant debt. There is often no recourse, as access to legal counsel is rare and legal aid programs funded by the federal government are prohibited from providing services to undocumented workers, and workers generally don't speak out about injustices because of fear and feelings of hopelessness. One remarkable exception is a multimillion-dollar judgment awarded to five farmworkers "kept in virtual indentured servitude by their contractors" at an organic farm supplying the upscale supermarket chain, Whole Foods. The contractors charged "smuggling fees, rent, and cleaning charges" that left workers with only $2 out of their $7 hourly wage. They were threatened with violence and the contractors carried guns to ensure compliance (Goldstein, Howe, & Tamir, 2010, p. 3).

Female migrant farmworkers comprise about 21% of the agricultural workforce in this country, and they face the same occupational hazards (e.g., respiratory, skin, and infectious diseases; pesticide exposure/illness; musculoskeletal disorders; injuries) including reproductive health problems (Habib & Fathallah, 2012). They also endure the lack of a stable home and social isolation, discrimination and fear, and the added difficulties of child-rearing and housekeeping while living a nomadic lifestyle. Despite the moves and difficulty with health care coordination, the health network providing pregnancy care to migrant women reports that 97% of those followed had babies born at the target birth weight (Migrant Clinicians Network [MCN], 2013).

Migrant Hero

César Chavez founded the National Farm Workers Association (NFWA; later changed to United Farm Workers [UFW]), the first union in agricultural labor history to successfully organize migrant farmworkers. As a child, he traveled with his family to harvest crops, but they rarely had enough food to eat and often lived in shacks. Work was frequently scarce,

wages were low, and labor contractors cheated the family out of the money they earned. Moving to California during the Great Depression, the family became part of the migrant community. Chavez attended as many as 65 different schools and dropped out of school upon completing eighth grade, to help support his family by working full-time in the fields.

Chavez organized many successful strikes and boycotts, the most famous one being the boycott of California grapes as a protest against the indiscriminate use of spraying by growers. This boycott lasted for longer than 5 years, and on two occasions, he fasted as a protest against the use of agricultural pesticides. His efforts united people who, as individuals, had no significance in the power structure. His legacy is an example of how people can unite to build power together. He achieved great recognition, although he never had the financial trappings of success (Bardacke, 2011). Throughout his life, he ignored personal hardships to continue the struggle with union victories and losses.

Health Risks of Migrant Workers and Their Families

A community with varied and profound health needs complicated by disease and social isolation, migrant farmworkers and their families are at risk. Migrant workers, often paid piecework, labor at a fast pace, largely without breaks, in order to take advantage of the short growing season (Connor, Layne, & Thomisee, 2010; Lerner, 2011). Because seasonal earnings must last the entire year, the migrant farmworker generally avoids or delays seeking health care until illness becomes debilitating. Immediate treatment is generally only sought when a worker is "completely debilitated," if a pesticide exposure has occurred, or a work supervisor has been notified (Thierry & Snipes, 2015, p. 178). Migrant farmworkers and their families suffer illnesses caused by poor nutrition, a lack of resources to seek care early in the disease process, and infectious diseases because of overcrowding and poor sanitation. A study on food security among U.S. farmworker households noted that about half were consistently in a food secure state, but 29% were in a transient state of food security; seasonal versus migrant status and having proper immigration documents versus being undocumented were predictive of food security (Ip et al., 2015). Another study found that 62.83 % of migrant workers surveyed in Georgia were food insecure, and those without H-2A visas were almost three times more likely than those with visas to be without sufficient food (Hill, Moloney, Mize, Himelick, & Guest, 2011). National statistics on migrant seasonal workers are sparse, with much of the data regional and only sporadically collected. Some of the statistics include the following:

- The life expectancy of a migrant worker is lower than the general population, with high rates of poverty, reduced access to health care, and an inverse and increasingly powerful relationship between stressors (e.g., problems speaking English, legal status, discrimination) and mental/physical health among Mexican workers (Williams, 2012; Williams & Sternthal, 2010).
- Migrant farmworkers are more likely to come from a country with higher rates of TB (e.g., Mexico 14.2/100,000 vs. United States 3.6/100,000 cases of TB in 2010). Farmworkers are six times more likely to develop active TB over their lifetime than other workers (Hernández-Garduño, Mendoza-Damián, Garduño-Alanis, & Ayón-Garibaldo, 2015; NCFH, 2013b).
- Migrant children are often delayed for immunizations and have an increased incidence of TB; intestinal parasites and infections; nutritional deficiencies and malnutrition; skin, respiratory tract, and ear infections; dental problems; and pesticide and lead exposure (American Academy of Pediatrics, 2014; SAF, 2011–2016). Almost one third of preschool migrant/seasonal farmworker children were reported to be food insecure, yet obesity was also present in these children and adults (Borre, Ertle, & Graff, 2010; Hernandez, Reesor, Alonso, Eagleton, & Hughes, 2015).
- Migrant workers have high rates of work-related conditions, such as musculoskeletal injuries, heat stress, eye injuries, hearing loss, and skin diseases, because of equipment

use and exposure to chemicals, dust, and sun (Habib & Fathallah, 2012; Quandt, Schulz, Talton, Verma, & Arcury, 2012). A study of migrant youth, ages 10 to 17, found 54% reporting musculoskeletal injuries and almost 61% having a traumatic injury (Arcury et al., 2014b). Migrant children are often exposed to heat and sun, musculoskeletal injuries, pesticides, and hazardous tools and machinery (NCFH, 2012a). Their employers are often seen as demanding and their work is sometimes dangerous. Yet, they are generally unwilling to report injuries or even complain to employers because of fear of deportation or firing. A mind-set that they must endure bad work environments as a temporary, but necessary, condition of their work life in the United States is not uncommon; they may feel that "they are undeserving of health care" (Willen, 2012, p. 807). They often continue to work while injured or ill because of perceived difficulty leaving work and pervasive *no work, no pay* employment situations (Arcury et al., 2012a; Gleeson, 2010; Hoerster et al., 2011).

Although training in occupational safety is common for many jobs, it is not always done with agricultural workers. Many Latino migrant and seasonal workers have developed an informal "occupational safety information exchange," including pesticide safety, as a way to alert new workers to occupational dangers (Spears, Summers, Spencer, & Arcury, 2012). In 2011, the U.S. Department of Health and Human Services reported that federally grant-funded health centers provided services to 803,933 farmworkers for the following reasons: dental exams, diabetes mellitus, child immunizations, hypertension, flu vaccine, contraception, fluoride treatments, and Pap tests (NCFH, 2012b).

Occupational Hazards

The hazards of agricultural employment, coupled with limited legal protection, jeopardize the health of the migrant farmworker. As mentioned earlier, agriculture (grouped with forestry and fishing) ranks in the top 10 job categories with the highest occupational death rates (Smith, 2013). Falls, cuts, muscle strains and sprains, and repetitive motion injuries (e.g., carpal tunnel syndrome) commonly afflict migrant laborers. Migrant and seasonal farmwork typically requires stooping, long hours working in wet clothes, working with sometimes contaminated soil and water, climbing, carrying heavy loads, and exposure to the sun and the elements. Failure to perform these activities on a rigid timetable dictated by seasons and weather can result in crop loss. For instance, a shortage of workers resulted in a $1 million loss for an asparagus farmer in Michigan (Schmidt, 2012). This urgency compels farmworkers to labor in all weather conditions, including extreme heat or cold, rain, bright sun, and high humidity.

It is difficult to reach this population in order to gain a full picture of their injuries but musculoskeletal injuries (e.g., back and shoulder pain, numbness/pain in hands), respiratory illnesses (because of molds, various types of dust, pesticide exposure), skin and eye problems (caused by sunburns, rashes, calluses, eye trauma/irritation), infectious diseases (because of crowded, unsanitary conditions), injuries and fatalities (because of

hazardous tools, machinery), and exposure to heat and sun (e.g., heat exhaustion, heat stroke, and pesticide exposures are common concerns (NCFH, 2013a). An interesting finding is that farmworkers with H-2A visas had fewer reports of musculoskeletal pain compared to manual laborers not working in agriculture in one North Carolina study (Tribble, Summers, Chen, Quandt, & Arcury, 2015).

In a small study of migrant workers, the incidence rate for work-related eye injuries was 23.8/10,000 worker years compared to a national incidence rate of 6.9 in 2009. Eye injuries (from tree branches, tools, or irritants) can cause serious problems and are seldom reported to employers. Treatment, if any, is often delayed, and penetrating or open wounds were common (Quandt et al., 2012). Extreme cold can lead to frostbite, and overexposure to the sun may result in heat stroke; farm laborers are more often at risk for these conditions. Some plants, like tobacco, pineapples, and garlic, release chemicals that are irritants or can be toxic to farmworkers who come in close contact with them.

Pesticide Exposure

Migrant farmworkers are at greater risk for pesticide poisoning when fields are sprayed or during initial re-entry into the field. Many migrant camps are located within large open fields or on the periphery of cropland. Overhead pesticide sprayings then endanger not only those at work in the fields but also those in the camp. If fields are not posted with warning signs, mass poisoning of farmworkers can occur: thousands of rural residents, in addition to farmworkers, have been poisoned by pesticide drift. One study of almost 3,000 cases of agricultural pesticide drift in 11 states found 47% of participants had work exposures and 14% were children under age 15. Soil fumigants comprise 45% of pesticide poisonings, and 24% are related to aerial applications (Advocate Precautionary Principle, 2011). Two nurses, who as children worked alongside their families in the fields, recalled: "as the planes sprayed the fields, you could feel the drifts" and when the spray mixed with the early morning dew "the pesticide residue would be on your clothes and your skin—it looked like a white film" (Formichelli, 2008, para. 15).

Contaminated water sources in the field enhance the absorption and spread of pesticides and organic compounds. EPA standards that bar entry to sprayed fields for at least 24 hours are often ignored. Pesticides can drift from the fields to contaminate food, yards, or children playing nearby. Children are at greater risk for pesticide-induced illnesses because of their higher metabolic rate, greater surface absorption, still developing organs, and possibility for chronic long-term exposure (Rauh et al., 2011). It is estimated that thousands of farmworkers suffer pesticide poisoning each year, but exact counts are not possible because of inadequate surveillance systems and reluctance of farmworkers to report injuries (Farmworker Justice, n.d.). Surveillance systems are only in place in 11 states; the Sentinel Event Notification System or Occupational Risk (SENSOR) is a means of reporting pesticide-related injuries as well as other occupational illnesses and injuries (National Institute for Occupational Safety & Health, 2012). Some farmworkers, primarily those without H-2A visas, were less likely to be provided pesticide safety equipment and

often were not notified when pesticides were applied (Robinson et al., 2011). Reporting of pesticide-induced morbidity and mortality is not required in every state. California has the oldest pesticide surveillance system in the United States, beginning in 1971 (California Department of Pesticide Exposure, 2013).

But, even with reporting laws, many cases are never recognized because workers do not seek medical care. Pesticide burns and rashes often go untreated because of lack of education about the dangers of pesticides and lack of available services. Migrant workers are often unaware of the hazards of pesticides. Arcury et al. (2010) found that a large number of migrant farmworkers had multiple detections for several pesticide and herbicide urinary metabolites. In a later study, Arcury et al. (2014a) noted that farmworkers had consistently greater levels of lifetime and residential exposure to pesticides than nonfarmworkers and that among both groups, education level was inversely related to lifetime pesticide exposure. An Eastern Washington state study, comparing farmworker adults and children with nonfarmworker adults and children living in close proximity to farmland, found organophosphate metabolite concentrations (urine and house dust) significantly higher among those working in the fields and their children. However, even those adults and children just living near farmland had metabolites present. Researchers found a 20% decrease in metabolite concentration for every mile of distance from farmland (Coronado et al., 2011). Pesticide drift has been shown to result in elevated levels of active compounds in both indoor air and house dust in homes near agricultural application areas. Houses closer to agricultural herbicide applications had significantly elevated levels of herbicides in house dust than in homes that were further away (Shelton & Hertz-Picciotto, 2015). Orchard air-blast applications of pesticides, along with wind direction, can influence pesticide drift from crops into agricultural residences; potential exposures can be analyzed through screening tests (Burns, Cohen, & Lunchick, 2015; U.S. Environmental Protection Agency, 2014).

Even though it may be required of health care providers to report pesticide poisoning, it is often misdiagnosed because the symptoms can mimic those of viral infections or heat-related illness. Symptoms of pesticide exposure include sore throat, runny nose, headache, fatigue, red/swollen/watery eyes, drowsiness, itchy skin, abdominal pain, and nausea or vomiting. More severe symptoms may include sweating, salivation, blurred vision or pinpoint pupils, fever, severe thirst, muscle twitching, or weakness and incontinence (especially with organophosphate or carbamate exposures). Finally, with the most severe exposures, seizures, respiratory depression, and unconsciousness or coma can occur. There are over 19,000 pesticide products registered with the EPA and more than one thousand active ingredients. Biomarkers, or signs of a specific chemical's presence in the body, are important in definitively proving exposures; however, chemical companies are not currently required to provide this information (Huber, 2011).

Only a few categories of pesticides account for more than half of the cases of acute illness; these include inorganic compounds, carbamates, pyrethroids, and organophosphates. Although the impact of acute pesticide poisoning is widely recognized, little is understood about the long-term effects of the repeated low-level exposures to which

migrant farmworkers are constantly subjected. The Florida Department of Health lists the chronic effects of long-term pesticide exposure as birth defects, cancers, blood disorders, neurological problems, and reproductive issues. Extreme exposure can lead to loss of consciousness, coma, or death (NCFH, 2013a). Several studies showed that entire families are at risk for pesticide exposure because of drift from nearby areas, poor handwashing facilities, and bringing pesticides home on clothing (Quandt et al., 2010). Numerous studies have examined the link between exposure to pesticides and various neurologic problems and cancer—most often with organophosphate-based pesticides. Some pesticides have been suspected of leading to depression, suicidal ideation, and other psychological distress (Bienkowski, 2014). Some evidence of an association between pesticide exposure and the incidence of diabetes has been found (Diabetologia, 2015). Non-Hodgkin's lymphoma, leukemia, prostate cancer, sarcomas, and multiple myelomas have been associated with organophosphates, herbicides, and insecticides (Cockburn et al., 2011). Prenatal exposure to organophosphate pesticides has been significantly associated with slightly decreased intellectual development (Bouchard et al., 2011). Today, it is more common for farmworkers to be exposed to "nonpersistent" pesticides that are metabolized in the body within days (NCFH, 2013a).

Low-flying crop duster spreads pesticide on fields.

A large body of supportive research has indicated a link between Parkinson's disease, other neurologic disorders, and pesticide exposure, and some specific pesticides (e.g., ziram,

paraquat) have been implicated (Van der Mark et al., 2012; Wang et al., 2011a). Display 29–3, Environmental Exposure History, is a helpful assessment tool for community health nurses working with migrant and seasonal workers to use to determine pesticide exposure. When a client presents with symptoms that may be suggestive of pesticide exposure, mnemonic prompts may help to clarify common symptoms (see Display 29–4).

DISPLAY 29.3 ENVIRONMENTAL EXPOSURE HISTORY

Do an Exposure History to:

- Identify current or past exposures
- Reduce or eliminate current exposures
- Reduce adverse health effects

Taking an Exposure History: Questions to Consider

Use the I PREPARE mnemonic:

I–Investigate potential exposures

- Have you ever felt sick after coming in contact with a chemical, pesticide, or other substance?
- Do you have any symptoms that improve when you are away from your home or workplace?

P–Present work

- Are you exposed to solvents, dusts, fumes, radiation, loud noise, pesticides, or other chemicals?
- Do you know where to find Material Data Safety Sheets on chemicals that you work with?
- Do you wear personal protective equipment?
- Are work clothes worn home?
- Do coworkers have similar health problems?

R–Residence

- When was your residence built?

- What type of heating system do you have?
- Have you recently remodeled your home?
- What chemicals are stored on your property?
- Where does your drinking water come from?

E–Environmental concerns

- Are there environmental concerns in your neighborhood (e.g., air, water, soil)?
- What types of industries or farms are near your home?
- Do you live near a hazardous waste site or landfill?

P–Past work

- What are your past work experiences?
- What is the longest job held?
- Have you ever been in the military, worked on a farm, or done volunteer or seasonal work?

A–Activities

- What activities and hobbies do you and your family engage in?
- Do you burn, solder, or melt any products?
- Do you garden, fish, or hunt?
- Do you eat what you catch or grow?
- Do you use pesticides?
- Do you engage in any alternative healing or cultural practices?

R–Referrals and resources (use these key referrals and resources)

- Agency for Toxic Substances and Disease Registry: www.atsdr.cdc.gov

DISPLAY 29.4 MNEMONIC PROMPTS TO DETERMINE CHOLINERGIC SYMPTOMS OF ORGANOPHOSPHATE EXPOSURE

SLUDGE	DUMBBELS
Salivation	Defecation
Lacrimation	Urination
Urination	Miosis
Defecation	Bronchorrhea
Gastric secretions	Bradycardia
Emesis	Emesis
	Lacrimation
	Salivation/seizures/sweating

The four most acute symptoms: bradyarrhythmias, bronchospasm, muscle weakness, and bronchorrhea

Pesticide exposure can be a single event, may occur multiple times, or can even be continuous. Health effects are thought to be a function of the frequency of exposure and the dose. Most migrant workers come into contact with pesticides through their work. However, exposure to pesticides does not affect only those working in the fields. "Most farmworker housing is contaminated with a broad range of pesticides," and this exposes not

only workers but also their families to pesticide-related risks. "Most workers and family members have absorbed measurable doses of pesticides" according to a seminal study by Arcury and Quandt (2009, p. 103). Organophosphates decrease the levels of acetylcholinesterase, found in nerve endings, and can be absorbed through the skin, inhaled, or ingested. Most workers have metabolites present, and farmwork and housing close to agricultural fields are common factors associated with exposure. Drifts from sprayed fields and residues on farmworker clothing, shoes, tools, and skin, as well as food brought from the fields, are all potential sources of exposure. Vehicles can also become contaminated, as can carpets and furniture. Contaminated clothing should be kept in separate hampers and laundered separately; workers need to be encouraged to leave boots and shoes outside their homes and to change clothing and shower before eating and playing with their children. Substandard housing is also a factor.

Agricultural fields are usually located in isolated areas on the outskirts of rural communities. While in these isolated fields, migrant workers often are not provided with sanitation facilities or fresh drinking water. The Occupational Safety and Health Administration (OSHA) mandates field sanitation (at least one toilet and handwashing station) and fresh drinking water for each agricultural establishment employing 11 or more hand-labor workers on any given day (OSHA, 2011).

Fields in Eastern Oregon. (Source: USDA, Agricultural Research Service.)

Substandard Housing and Poor Sanitation

Quality of housing affects farmworker health, and more comparative studies are needed (Arcury et al., 2015a; Arcury, Jacobs, & Ruiz, 2015b; Quandt et al., 2015). Formal demographic data on farmworker housing are often lacking. One cohort study of a farmworker population in Mendota, California (MICASA), employed door-to-door enumeration in a rural agricultural community. Almost 10% of the dwellings were classified as "back houses or unofficial dwellings," thought to have been missed during the last census (Stoecklin-Marois, Hennessy-Burt, & Schenker, 2011, p. 291). A survey of growers about migrant health and nutrition in the Midwest found that the median migrant camp had 23 seasonally employed residents (for 10 weeks up to 6 months), with 7 accompanying children. No consistency was reported in kitchen appliances, and most owners had little information about migrant health services. Also, they reported that migrant laborers had restricted access to fresh produce for meals and children did not have easy access to public play areas but mostly used open fields (Kilanowski, 2012). In a classic article by Cole and Crawford (1991), a vivid example of one migrant camp in Alabama highlighted workers living in a converted chicken house. An upper portion of the wall had been removed for ventilation, creating easy access for insects and birds. A dirt floor, a single light bulb, and two portable toilets located a distance away were some of the other features. Two sinks in a common living area provided the only water for the almost 60 people who lived in the chicken house. Many did not have mattresses, and because the workers were harvesting potatoes, potato baskets conveniently served as the only furniture. Such living situations still exist today. Living with 13 other workers in a three-bedroom home in Watsonville, California, a female farmworker remarked, "We have to put up with this because we can't afford anything else" (Holden, n.d., p. 40). A description of dorm-style rooms in Immokalee, Florida, revealed "the shower has filthy, crumbling concrete walls—the kind that won't come clean…(and) a metal sink held by a rotting plywood counter, and the toilet often backs up, so the tiny room reeks of sewage" (p. 41).

Migrant farmworkers move frequently and often have great difficulty securing adequate housing. In the past, many growers or owners provided housing to migrant workers and their families. This practice has now become much less common, and only limited numbers of government-sponsored housing units are available for migrant workers. Housing conditions may actually be considered hazardous in some areas, and employer-owned labor camp regulations are much less stringent than Section 8 housing standards (Summers, Quandt, Talton, Galván, & Arcury, 2015; Vallejos, Quandt, & Arcury, 2009). Many migrant farmworker camps have ongoing violations. One study found a range of 4 to 22 per camp, with the mean number of total violations at 11.4; however, those camps housing H-2A visa workers and those examined early in the season had fewer violations (Arcury, Summers et al., 2012). In another study, GIS mapping was used to determine the differences between visible and hidden farm labor camps in North Carolina (Summers et

al., 2015). Almost 38% of the camps were hidden, and hidden camps were substantially larger and more likely to have barracks-type housing. Historically, employer-owned farm labor camps were often infested with pests and had structural damage and insufficient bathing facilities. Researchers noted that hidden camps perpetuate social isolation and the potential for substandard housing.

When private housing is available, it is often only offered at prices that outpace worker's wages. Data are scant, but a large survey of migrant workers in the eastern, Midwestern, and western migrant streams conducted by the HAC revealed that over 50% of all housing units surveyed were overcrowded (only 3% of U.S. households are and 44% of mobile homes were substandard). Almost one quarter of units surveyed had at least one broken appliance or fixture, and 11% had no working stove. Between 13% and 39% of housing is owned by employers, and for those lucky enough to find employer-owned housing, over half of those units were offered without charge. Agricultural employers most commonly own single-family homes (39%) and apartments (14%), but workers and their families also are housed in barracks or dormitories, in motels, and in mobile homes (Holden, n.d..; HAC, n.d.). Forty-two percent of farmworkers lived in single-family homes and 21% in apartments; fifteen percent lived in mobile homes and the same proportion in duplex/triplex housing. About 4% lived in dorms/barracks, and 2% lived in motels. Approximately 2% reported living conditions not meant for human habitation such as in cars tents, and outdoors (NCFH, 2012b). Only 0.5% lived in tents/campsites (HAC, n.d.). The most serious housing problems were found in the Northwest region and in Florida. Over one quarter of housing units were located adjacent to agricultural fields, and more than half of these had no working shower/tub or washing machine—or both (HAC, n.d.).

Families with children occupied 65% of both severely substandard and moderately substandard units (HAC, n.d.). Structural problems, such as holes in the roof (15%), sagging frames or roofs (22%), or damage to foundations (15%), were common. Broken glass or window screens were noted in 36% of units, and peeling external paint was found in over 40% of units (Holden, n.d.; HAC, n.d.). Evidence of water damage was found in 29% of units, and 9% had exposed wiring. An examination of 183 North Carolina migrant farmworker camps in 2010 revealed 11.4 mean housing violations, with a range from 4 to 22 (Arcury et al., 2012b). Bathroom violations were most common, and camps housing workers without H-2A visas or posted state inspection certificates, or those examined later in the migrant season, had more violations. An example with serious consequences is Jensen Farms, a Colorado cantaloupe grower, who was fined for substandard housing provided to migrant workers in their fields and packing facility. The owner of Jensen Farms also owned the Gateway Motel, used for migrant housing during harvesting season, where workers each paid $25 per week for space in overcrowded rooms without beds (and no laundry facilities). The owner claimed that he was an "innkeeper" and did not fall within the purview for migrant and seasonal worker housing laws, but he was found out of compliance and fined $4,250. In 2011, Jensen Farms shipped out *Listeria*-contaminated cantaloupes that resulted in "the deadliest outbreak of food-borne illness in nearly 100 years" (Flynn, 2012, para. 2).

Although unsanitary worker housing may not be directly related to the outbreak, this may be just another indication of overall carelessness that led to unsafe farming practices.

Substandard housing is not the only concern. Crowding is also a problem, as many farmworkers, unable to find sufficient numbers of rental units, share housing—sometimes paying per-person costs. One of the few studies on migrant housing found that Minnesota seasonal vegetable workers' construction trailer barracks, housing 15 to 20 single migrant workers, rented for $90 per month per person. The California Migrant Housing Authority reported two-bedroom housing units available for $345/month (Migrant Housing, n.d.). In the HAC study, almost one third of migrant workers paid rental costs that were in excess of 30% of their gross incomes—defined as a housing cost burden (HAC, n.d.). The costs led to further crowding, as families doubled up to save expenses. When housing cannot be found, workers and families may have to resort to paying rent to live in garages, barns, sheds, or chicken coops, or they may be forced to stay in their cars. One Michigan farmer with 65 acres of blueberries describes the migrant workers he has employed for 7 to 9 weeks of every year for the past 25 years as "the hardest workers I know," stating that "we would not be here if it wasn't for the migrant workforce." Each year, around 90,000 migrant workers come to Michigan, but employer-provided housing only can accommodate about 22,000 of them (Schmidt, 2012, para. 3). More permanent, though seasonally occupied, housing is needed to accommodate these workers.

Migrant Family Health

Migrant workers have higher rates of obesity than season farmworkers, and females are more likely to be obese and have diabetes than males. However, males were more likely to smoke than females (Castañeda, Rosenbaum, Holscher, Madanat, & Talavera, 2015). Despite often working among fruit and vegetable crops, migrant families often have difficulty procuring food and maintaining a sufficient supply. The lack of food supplies was often due to limited access to resources and isolation, but parents attempted to sacrifice in order to feed their children, and when eligible utilize government food sources (Quandt, Grzywacz, Trejo, & Arcury, 2014). Because of frequent moves, migrant children are often educationally, socially, and physically disadvantaged; many migrant parents have an eighth grade education or less and the majority of migrant children who meet criteria for special services at school are actually receiving them (Habib & Fathallah, 2012; Waldman, Cannella, & Perlman, 2010). The children have "some of the lowest socioeconomic and educational indicators," and their parents are frequently viewed by school personnel as difficult to reach and not involved in their children's education (Jasis & Marriott, 2010, p. 126). One explanation for their lack of participation is their extended work hours, beginning early in the morning and ending long after school hours. But some programs have been successful in reaching out to migrant parents. A community-based adult education program that improved migrant parents' self-actualization and promoted changes in interactions between parents and school personnel also led to improved school outcomes for migrant children; the process of engaging Latino immigrant families includes

encouraging participation, leadership development, and organizing activities (Jasis & Marriott, 2010; Jasis & Ordoñez-Jasis, 2012). Migrant education programs, especially with Mexican American resource teachers as role models, have also been helpful.

Migrant children are often called upon by their families to stay home from school to work, care for younger children, or attend to other household chores. They may feel socially estranged, be constantly moving, and have difficulty finding health-promoting recreational activities and have difficulty assimilating (Portes & Rivas, 2011). A large seminal California study found significantly higher odds of developmental risk among children of undocumented Mexican parents but not for children of documented Mexican parents (Ortego et al., 2009). This may indicate stressors related to immigration status. There has been a 45-fold increase in the number of undocumented workers taken into custody by the U.S. Immigration and Customs Enforcement (ICE) agency between 2001 and 2007. And highly publicized ICE raids have led migrant parents to withdraw their children from Migrant Head Start programs, noticeably decreasing enrollments across the country and further placing migrant children at risk for academic problems (Mather & Parameswaran, 2012). Connor, Layne, and Hilb (2014) note that despite the many trials facing migrant children, they show great strength and resilience that helps them face their challenges.

A survey of over 2,000 migrants (ages 12 to 65) found an increased risk for depressive symptoms among returning migrants and anxiety and depressive symptoms among migrant relatives (Familiar, Borges, Orozco, & Medina-Mora, 2011). A program available for migrant farmworkers or their children is CAMP, the College Assistance Migrant Program, serving about 2,000 students annually (U.S. Department of Education, 2015).

The children of migrant farmworkers receive only fragmented health care. Common health problems of migrant children include general poor nutrition, anemia, vitamin A deficiency, increased risk for respiratory and ear infections, dental problems, lead and pesticide poisoning, intestinal parasites, skin infections, TB, and delayed development (American Academy of Pediatrics, 2014). Migrant farmworker children (ages 0 to 16) in Georgia were assessed and found to have a higher prevalence of obesity and stunting than nonmigrant children; among the 6- to 12-year-old group, migrant children had higher prevalence of elevated blood pressures, and elevated blood pressures were found in older migrant teens (Nichols, Stein, & Wold, 2014). Another study found that migrant boys were more likely to be obese than girls, and hypertension and anemia were more prevalent among obese migrant children (Gonzalez, Billings, Shin, Rosenbaum, & Song, 2013). Lack of awareness that minor symptoms, such as diarrhea or fever, may indicate a more serious underlying problem can cause delays in seeking medical attention, as can poverty and a lack of health insurance. An earache is minor, but it can lead to a major problem, such as deafness, if left untreated.

Studies on the impact of Head Start enrollment on migrant children's health outcomes revealed that higher rates of health treatments were obtained for those attending one or more years and for lower rates of obesity for those attending Migrant Head Start program

for multiple years (Lee & Pond, 2015; Lee & Song, 2015).

A systematic review of migrant children and adolescents compared with nonmigrant counterparts did not find a significant difference in behavioral or emotional problems (Belhadj Koulder, Koglin, & Petermann, 2015). Migrant adolescents are less likely to abuse substances when they first arrive, but the likelihood increases as they remain in this country and is higher for second-generation Hispanics (The Future of Children, 2011). Overall, they are less likely to graduate from high school, because their education is often interrupted. Globally, children between the ages of 7 and 14 who live in a rural setting are less likely to attend school but more likely to work. Also, migration causes educational interruption and difficulty "catching up." The average level of education completed was the eighth grade (NCFH, 2012a). Stress from acculturation, poor working conditions, deficient social support, and poor family functioning have been associated with greater anxiety and depressive symptoms among farmworkers (Winkelman, Chaney, & Bethel, 2013). Research on children whose parents have been arrested, detained, and/or deported has found increased economic and social instability leading to parental depression and poor cognitive and behavioral outcomes for children (Chaudry et al., 2010; Migration Policy Institute, 2015). The situation becomes even more complicated when one parent of legal children is born in the United States and is a legal citizen and the other is not; approximately 4.5 million children live in mixed status families (Brabeck, Lykes, & Hunter, 2014).

Mixed methods research by Winkelman et al. (2013) showed that about 25% of migrant farmworkers experienced stress, depression, or anxiety in their lifetime from sources such as (1) physical stress because of working conditions; (2) psychological stress because of family situations, work environment, documentation status, and lack of resources; (3) depression because of separation from family; and (4) use of both positive and negative coping mechanisms to deal with stress and depression. Acculturative stress, workload, and depression have been found among migrant workers in other countries, such as Korea (Lee, Ahn, Miller, Park, & Kim, 2012). This study by Winkelman et al. (2013) suggests that stress and depression are significant mental health issues among Latino migrant farmworkers because of a lack of permanent employment and continued work uncertainty. Behaviors used to cope with stress included (1) watching TV (75%), (2) sleep (73.3%), (3) family support (66.7%), (4) listening to music (56.7 %), (5) humor (50%), and (6) prayer (48.3%). Negative coping behaviors used by migrant farmworkers included (1) smoking or use of tobacco products (16.7%), (2) eating unhealthy foods (16.7%), (3) playing the lottery (15%), (4) drinking alcohol (15%), and (5) gambling (11.7%).

Display 29–5 lists some stressors from the Hispanic Stress Inventory evaluation tool. Social isolation factors ranked slightly lower, but being away from friends and family was often mentioned. In this study of farmworkers, migrating mostly from Mexico, almost 42% met the classification as depressed, and over 18% had anxiety levels consistent with impaired functioning. The researchers concluded that social isolation had a stronger potential effect on anxiety, whereas poor working conditions were associated more with

depression. The need for migrant workers to congregate in neighborhoods with others from their cultural background is an attempt to counter this social isolation. When surrounded by others who share their culture and speak their language, and when they can find familiar music, television, entertainment, and food, it helps to allay feelings of anxiety and depression. It is easy to understand why many migrant workers in specific migrant streams originate from the same states or communities in Mexico or other countries; it is an attempt to hold onto some semblance of their social networks as they migrate to the United States (Loue & Quill, 2010).

DISPLAY 29.5 EXTRAFAMILIAL AND INTRAFAMILIAL STRESSORS FOR HISPANIC ADULTS

Common Extrafamilial Stressors

Difficult interactions with others because of not being able to speak English
Feeling an expectation to work harder because of being a Latino
Feeling pressures to learn English
Difficulty finding work I want to do because I am Latino
Forced to take low-paying jobs
Continually concerned with quality of my work so that others do not consider me lazy
Being treated badly because of my poor English
Difficulty getting promotions or salary increases because I am Latino
Not having sufficient income to support my family

Common Intrafamilial Stressors

Conflicts among my family members
Physical violence among my family members
Serious arguments among my family members
Children have too liberal ideas about sexuality
Children talk about leaving home
Children receive bad school reports or grades
Spouse and I disagree about how to raise our children

Children do not respect my authority as I think they should

Adapted from Cavazos-Rehg, C., Zayas, L., Walker, M., & Fisher, E. (2006). Evaluating an abbreviated version of the Hispanic Stress Inventory for Immigrants. Hispanic Journal of Behavioral Sciences, 28, 498–515.

Alcohol use has been noted to be common among male migrant workers, and the stressors migrant farmworkers face related to their employment and acculturation put them at a higher risk for drug and alcohol abuse, as well as other high-risk behaviors. Arcury et al. (2016) compared interview data from male Latino migrant farmworkers and Latino nonfarmworkers in North Carolina and found that 48.5% of farmworkers reported heavy episodic drinking in the past 3 months; 23.8% admitted that this behavior was frequent. However, no significant differences were noted between the two groups regarding behavior related to alcohol consumption. Stress and being a farmworker, however, were significant factors for being at risk for alcohol dependence; reduced risk was noted for farmworkers who were married. Drugs and alcohol may be used as a means of coping with separation from family and social isolation.

Problems with substance abuse may also be associated with violence. Respondents with higher stress levels also reported greater interpersonal violence and depression (Kim-Godwin, Maume, & Fox, 2014). Aggression at migrant farm labor camps was often tied to alcohol use and was more common as the work season progressed; while acts of aggression were prevalent among male migrant workers, the frequency was low (Kraemer-Diaz et al., in press). In a San Diego, California study of intimate partner violence (IPV) among farmworkers, researchers found that 16% of women interviewed, and 32% of males reported victimization, perpetration, or both (Duke & Cunradi, 2011). Male drinking and female impulsivity were significant correlates to IPV. Although research on migrant children and violence is almost nonexistent, one classic article reported that 46% of children have witnessed some form of violence, 20% had witnessed a shooting, and 11% had witnessed a murder (Triantafillou, 2003). Many migrant families come from areas where violent crime levels (e.g., murder rates) are high, and gang activity, along with domestic violence, are widespread (Thale, 2014). In a classic study conducted in Texas border counties, verbal abuse was the most frequently reported form of IPV (72%). Only 22% reported knowledge of a shelter where they could go to gain assistance (Kugel et al., 2009). While health care provider screening for IPV increases the rates of identification, many providers do not effectively screen (Wilson, Rappleyea, Hodgson, Hall, & White, 2014; Wilson et al., in press). One large California study of migrant farmworkers found a 5% prevalence of being a victim of personal violence within the past year. Males experienced violence in workplaces, or other public settings, whereas over 80% of self-reported violence reported by females was the result of violence (Villarejo et al., 2010). Research on domestic violence among this vulnerable population is scant, but more than 1,000 battered farmworker women in a multicenter study were interviewed and researchers identified the typical profile as:

- Childbearing age (15 to 40)
- Hispanic
- Afraid of their partner
- Married or living with partner
- Drug or alcohol use by partner

The overall incidence was 20.6%. Fifty percent of abused women were pregnant at the time of the abuse (MCN, n.d.). Nationally, just over 35% of women report sexual, physical abuse, or stalking by an intimate partner during their lifetime (Black et al., 2011). See Chapter 20 for a more complete discussion of domestic/IPV. What makes farmworker domestic violence so significant is the fact that these women often experience language barriers, do not have adequate access to health care, live isolated lives with little social support, and fear deportation if they report the abuse—all factors that lead them to endure their violent situation in silence. One example is a migrant woman, who shared a one-room dwelling with her husband, infant, and five single men. Her husband became increasingly violent and unpredictable. He began to beat her and the baby, and she was unable to predict what would initiate a violent attack. She finally fled when one of the men living with them also began beating her. She attributed the aggressive behavior to the powerlessness felt by the men. The Violence Against Women Act of 1994 affords protection for undocumented battered women and children by allowing them to seek legal immigration status without the help of their abusers (Migrant Clinician's Network, n.d.). PHNs must be aware of these issues and what resources are available in the community (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

SITUATION: Domestic violence in the migrant population. Research is scant; however, informal discussions occur among women and health care providers. Outreach workers sometimes possess lists of men who are abusive and their victims. Although the migrant lifestyle and experience are difficult for the entire family, women and children suffer most from family violence that the migrant way of life promotes. Isolation and subjugation to a patriarchal system usually prohibit migrant women from seeking help if they are abused. Fear of consequences and difficulty expressing negative views about husbands prevent women from speaking out (Migrant Clinician's Network, n.d.).

GOAL: Using the three levels of prevention, negative health conditions are avoided,

promptly diagnosed, and treated, and/or the fullest possible potential is restored.

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Promote family rehabilitation, with or without abuser in the home. • Encourage ways to eliminate or reduce social and geographic isolation among vulnerable women.	• Alleviate stressors of the migrant lifestyle, such as overcrowding and substandard living conditions. • Provide emotional support and educate on what constitutes abuse. • Promote self-esteem to the point where a woman can take control of her situation.	• Encourage women to contact health care providers as they migrate. • Encourage women to find appropriate lay community outreach workers for support. • Encourage migrant women to unite and create an environment that allows them to speak up and out while supporting one another against abuse.

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Promptly identify an abused woman—through self-identification or by other family members or professionals—and remove her from the dangerous situation.* • Keep communication lines open, be culturally sensitive, and examine for injuries.	• Secure the victim in a safe battered women's shelter. • Assist victim to regain self-esteem.

*Secondary prevention is difficult because of limited financial resources, lack of transportation, no nearby friends or relatives for support, language barriers (e.g., non–English speaking), and limited safe shelters for battered women in rural areas.

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Create awareness of the harsh living conditions that migrant families endure. • Advocate for improved and safe living conditions on state and national levels. • Provide adequate housing that eliminates overcrowding and offers privacy.	• Train bilingual and bicultural lay migrant women on the issues of spousal abuse and help them form support groups. • Provide opportunities for women and men to improve self-esteem that will change attitudes toward each other.

The World Health Organization (2014) addressed the health sector's role in migrant IPV prevention, and the following lists are recommendations for the policy, health system, health facility, and health care provider levels of care.

At the health policy and health system levels

1. Promote social participation in the design of health policy.
2. Strengthen coordination between the health system and other sectors.
3. Develop a multisectoral approach.
4. Promote evidence-based policy-making.
5. Identify objectives and indicators for monitoring and evaluation.

The World Health Organization (2014) addressed the health sector's role in migrant IPV prevention, and the following lists are recommendations for the policy, health system, health facility, and health care provider levels of care.

At the health policy and health system levels

1. Promote social participation in the design of health policy.
2. Strengthen coordination between the health system and other sectors.
3. Develop a multisectoral approach.
4. Promote evidence-based policy-making.
5. Identify objectives and indicators for monitoring and evaluation.

1. Address and prevent institutional discrimination.

2. Identify and address access barriers.
3. Address language and cultural barriers to health services.
4. Address administrative and practical barriers.
5. Identify relevant program adaptations that respond to health needs of migrant and ethnic minority women facing IPV.
6. Develop systems for organizational learning relating to IPV among migrant and ethnic minority women.
7. Explore opportunities for prevention activities within primary care.

At the health provider level

1. Engage in training to better understand the IPV vulnerability of migrant and ethnic minority women.
2. Know the legal implications of health services work with regard to IPV.
3. Become familiar with research literature on health provider bias and discrimination in medical decision-making with respect to migrant and ethnic minority women.
4. Create and participate in networks of health care professionals to address IPV with migrant and ethnic minority women during medical encounters.
5. Share best practices and engage in program coordination with organizations that work directly with migrant and ethnic minority women experiencing IPV.

World Health Organization. (2014). *Preventing and addressing intimate partner violence against migrant and ethnic minority women: the role of the health sector*. Retrieved from http://www.euro.who.int/__data/assets/pdf_file/0018/270180/21256-WHO-Intimate-Partner-Violence_low_V7.pdf

Infectious Diseases

As noted earlier, TB is a common infectious disease among farmworkers. Some studies find that farmworkers are six times more likely to develop active TB over their lifetime than other workers, with 48.8 cases per 100,000 detected among agricultural workers seen at migrant health centers in 2011; this is higher than the rate for nonagricultural workers at all health centers at 33.1 cases per 100,000 (NCFH, 2013b). Because of their migrant patterns, it is difficult to complete treatment regimens. Because of frequent moves, poor access to health care, and social isolation, it is often difficult for migrant farmworkers to be accurately diagnosed and treated. Many factors may prevent them from successfully completing a treatment regimen, and language barriers, along with cultural differences, may preclude them from fully understanding the impact of their disease on themselves and others. For instance, a Mexican migrant worker may be diagnosed with TB in California and begin treatment there but may move to Washington state to pick cherries and run out of medication before completing treatment. Moving back to California for summer work, he may again start treatment but may travel home to Mexico during the winter, only to be

reinfected by an older, untreated member of his extended family.

Migrant workers are at greater risk of HIV infection for many of the same reasons. Albarrán and Nyamathi (2011) found that Mexican migrant workers were at higher risk for HIV infection because of limited health care access, multiple sexual partners, low levels of condom use, injection practices, and men having sex with men. They also note that there is now a higher prevalence of HIV found in rural areas of Mexico, as workers bring the infection back to their homes. HIV-positive status may be misunderstood and, because of stigmatization and fears of deportation, may be purposely hidden from health officials. Estimated HIV rates are reported to be between 2.6% and 13%, depending on geographic area and personal risk factors like drug abuse; however, accurate national prevalence rates are almost impossible to attain (NCFH, 2011). High-risk behaviors, such as sex while under the influence of alcohol and drugs, sex with commercial sex workers, inconsistent use of condoms, performing sex works, and sex with a male partner, were increased in male migrant farmworkers, elevating their risk for HIV/AIDS (Sanchez et al., 2012). A larger proportion of male migrant farmworkers reported condom use after migration to the United States, demonstrating an increase in preventative measures; this is an encouraging report, as overall, loneliness has been negatively associated with condom use in a study of rural men having sex with men (Hubach et al., 2015; Sanchez et al., 2012). There is a great need for more effective outreach and education strategies (Hernandez, Mata, Vasquez, & Martinez, 2014). Other infectious diseases (e.g., hepatitis, enteric diseases, parasites) may commonly afflict migrant workers, often because of inadequate sanitation and hygiene facilities.

Economic Barriers and Limited Health Resources

Most migrant workers are unable to qualify for basic health and disability benefits such as Workers' Compensation, Social Security, occupational rehabilitation, and disability compensation because of undocumented status. One California survey found that between 27% of male and 11% of female migrant workers had been paid Workers' Compensation claims over the course of their work history, with about 40% of undocumented migrant workers having any knowledge of this program even though there is universal coverage (Kresge Foundation, 2012; Villarejo et al., 2010). Federal legislation passed in 2006 requires proof of U.S. citizenship (e.g., passport, birth certificate) when applying for or renewing Medicaid coverage, so undocumented workers are generally unable to qualify (Farmworker Justice, n.d.). As a group, migrant farmworkers have more difficulty accessing Medicaid than any other population.

Medicaid benefits have little value in the face of constant mobility, because they are not transferable from state to state. On one hand, although the low income of migrant workers meets the guidelines for state medical assistance, few families remain in one state long enough for the 30-day residency requirement. On the other hand, farmworker families may not qualify for Medicaid because, during certain months of the year, they earn more than the state's poverty limits. Ironically, migrant workers suffer from preventable and treatable

diseases covered under Medicaid, but they are frequently unable to obtain treatment. Some undocumented workers may be eligible for emergency Medicaid—a very limited benefit (Farmworker Justice, n.d.).

Although many are eligible for public programs such as food stamps, S-CHIP, and the Women, Infants, and Children (WIC) program, migrant farmworkers as a whole generally do not participate. They may fear immigration penalties or be totally unaware of the available benefits. Some are eligible for Social Security benefits but do not possess the ability to process their claim (NCFH, 2012b). Workers who do not have valid Social Security numbers, but still have taxes withheld from their wages, are estimated to contribute $7 billion in Social Security taxes and about $1.5 billion in Medicare taxes.

Some think that undocumented workers are a drain on the U.S. economy and illegal immigration is a hot-button topic. However, a substantial amount of research demonstrates that immigrants generally pay more money into the system than they extract from it. While they may earn better wages, it may come at a high personal cost. A large, longitudinal study of Mexican migrant farmworkers noted that those returning to live in Mexico have a higher prevalence of obesity, smoking, heart disease, and mental health disorders than nonmigrants. Researchers posit that migrant workers discard more traditional nutrition patterns for unhealthy behaviors (e.g., consumption of fast food, overeating), possibly because of their increased income level. Also, the stress of migration (e.g., discrimination, fear) may be associated with increased levels of depression and anxiety. They may also be returning home to Mexico for family support and to seek medical treatment for health problems (Ullmann, Goldman, & Massey, 2011). Researchers surveyed 186 unauthorized and temporary migrant workers returning to Tijuana, Mexico, and found that 71% were uninsured in the United States, but 42% did use some health care services while there. However, approximately 11% did not seek needed medical care (Martinez-Donate et al., 2014). Others have noted that increased access to "culturally-specific mental health services, especially in rural areas" is needed (Garcia, Gilchrist, Vazquez, Leite, & Raymond, 2011, p. 500).

Whatever your viewpoint on this issue, it is important to the public's health that basic health care services be available to vulnerable populations. Continued efforts must be made to conduct research assessing risks and hazards, especially those of pesticide exposure. Many government publications document the despair and isolation of migrant workers, yet very little has been done to address the living and working environments that contribute to diminished health. Although migrant workers are a mobile population and difficult to study, they represent an important, integral part of our economy; infectious disease among this population increases health risks for all (Flynn, 2012; NCFH, 2012b).

Unique Methods of Health Care Delivery and Primary Prevention

Because migrant health centers do not adequately meet the health needs of the entire migrant community, several innovative methods of health care delivery have been developed and implemented by community health nurses.

Mobile health vans staffed with bilingual community health nurses and lay workers can travel directly to migrant camps and are an effective strategy for outreach health screening and education. By going to migrant camps and delivering care where the clients live and work, especially during nonwork hours such as evenings and weekends, community health nurses increase health access and overcome barriers of culture and lack of child care. Although migrant families receive only fragmented acute care, a nurses' outreach team can succeed in encouraging migrant farmworkers to prevent illness with immunizations, good nutrition, and healthy lifestyles. A viable alternative to traditional medical clinics, the mobile nursing clinic provides primary care to an underserved population through health promotion, disease prevention, and early treatment. In Georgia, a mobile health clinic reported the most common diagnoses as back pain, high blood pressure, and musculoskeletal and GI problems, along with eye and skin problems (Luque et al., 2012).

Mobile dental vans also provide services to migrant worker's children, often with arrangements made through school nurses and dental care provided by dental schools or through partnerships (Luque & Castañeda, 2013). Migrant workers suffer from dental problems at a rate higher than the national average and one California study found that 36% of men had dental caries, 30% had broken or missing teeth, and 18% had gingivitis (Villarejo et al., 2010). Another California survey noted that 36% of male and 29% of female farmworkers reported having dental cavities (Kresge Foundation, 2012). Migrant farmworkers were reported to have low levels of knowledge about oral cancer risk factors and signs/symptoms and to be less likely to seek preventive care (Dodd, Schenck, Chaney, & Padhya, 2016). For migrant children, over 87% of those accessing a mobile dental clinic had untreated caries (Mulligan, Seirawan, Faust, & Habibian, 2010). Migrant preschoolers were found to have overall low-quality diets, with fewer than recommended levels of vegetables, fruits, and whole grains in one study (Quandt et al., 2016).

Promotoras (i.e., lay community outreach workers), or *doulas* (i.e., usually trained childbirth assistants), have promoted health in migrant communities (Lucio et al., 2011). Some programs use *doulas* to provide classes on childbirth and other perinatal subjects in an interactive manner; these provide extensive case management services along with the traditional duties of childbirth coach. Because *doulas* and *promotoras* are generally members of the migrant community, they are readily accepted. Some *promotoras* teach parenting classes to avert child neglect/abuse; others may work with special populations to deter domestic violence or substance abuse or promote breast-feeding (Blanco, 2011). Some deal with interventions and education to control hypertension, and others facilitate early

screening and treatment for cancer (Nuno, Martinez, Harris, & Garcia, 2011). One program in a rural area on the United States–Mexico border showed statistically significant improvement in reports of mammograms (two times more likely with the educational intervention from *promotoras*), and there was an even stronger result for those who had not had either mammograms or Pap smears at baseline or within the last year (Nuno et al., 2011). Some *promotoras* migrate with workers and families to provide year-round support and resources. In the United States prior to the Affordable Care Act, many migrants had only limited access to health care (Ingleby, Chiarenza, Deville, & Kotsioni, 2012).

Information Tracking Systems

Mobility impedes continuity of care, and the inadequate system of medical record keeping for the migrant population is particularly frustrating and challenging. Data information systems are vital components for monitoring the health status of individual farmworkers as they migrate. Furthermore, these data are essential for generating research and follow-up care as well as long-range health planning. They also help justify appropriation of monies to migrant health agencies. The MCN has instituted several tracking systems. *TBNet* promotes the completion of TB treatment among migrant populations, and *Diabetes Track II* is geared toward those with diabetes and helps with monitoring and control. *CAN-Track* is a system for coordination of cancer care, and the newest tracking system, *Prenatal Health Network Project*, offers greater continuity for pregnant migrant women. *Heart Fax* is another system of tracking for those with CVD.

Migrant children are susceptible to medical "feast or famine" and may be either over- or undertreated simply because their medical histories are unknown to current providers. One now defunct method for tracking the health status of migrant school-age children was through the Migrant Student Record Transfer System (MSRTS), a computerized system that collected and maintained health and academic records for migrant children. School nurses collected data on migrant children about personal and family history; immunization status; visual, auditory, and dental problems; nutritional status; and general physical condition. The U.S. Department of Education (2014) now offers Migrant Student Information Exchange (MSIX) that permits states to transfer health and educational information on migrant students. However, the ability to track these children in the migratory lifestyle from work location to work location is often inconsistent. Early intervention for migrating children is not always feasible, but it can greatly improve outcomes.

MiVIA ("my way" in Spanish) is putting health records online and making them available to migrant workers and their health care providers. Workers get a photo identification card, and their records can be accessed only by the use of a personal password. They can access their medical files, medications, a medical reference guide (bilingual), and other resources, such as local clinics and doctors, public transportation, and housing online, no matter their location (Hou, 2010; MiVIA, 2013). The program began in California's wine country but is spreading to more distant locations.

THE ROLE OF COMMUNITY HEALTH NURSES IN CARING FOR A MOBILE WORKFORCE

Beyond barriers to health care, such as lack of health services, language, and cultural impediments, inadequate to nonexistent transportation, financial strains, underinsurance, and questionable residency status, which are by themselves formidable obstacles, the migrant lifestyle is fraught with challenges. Because of the insecurity and instability inherent in a mobile lifestyle, long-term health goals are difficult to establish and long-term follow-up of any chronic illness is doubtful. Nonetheless, PHNs provide much-needed services using community resources, innovative thinking, tenacity, and sensitivity.

Strategies for improving the health status and resource use of migrant workers and their families include:

- Improving existing services
- Advocating and networking
- Practicing cultural sensitivity
- Using lay personnel for community outreach
- Utilizing unique methods of health care delivery
- Employing information tracking systems

Community health nurses are the major providers of migrant health services and have a crucial role in the development and management of interventions. In response to the growing need for available, accessible, and affordable health care for farmworker families, nurses are called on not only to understand the migrant lifestyle but also to help migrant families overcome the barriers to health care (see Perspectives: Voices From the Community).

PERSPECTIVES VOICES FROM THE COMMUNITY

"I spoke with one of my students after clinical last week, and she told me about her work this semester with a 35-year-old single mother of two who had been discharged from the hospital following a lupus flare-up. The student felt that her client was a devoted mother, but she let her 8- and 12-year-old children stay home from school to help with family

farm tasks in order to make ends meet. After weekly visits with her client for almost 2 months, she told me—I was finally able to get her to trust me enough to help her trust others. She has reached out to her neighbors and asked for help and they are more than willing to lend a hand. Now, her children can return to school and go back to being children instead of day laborers! I told her that sometimes, it takes a strong person to reach out for help and that she is a strong woman!

—Kevin, Nursing Faculty Member, faith-based college, Western Massachusetts

I was having a conversation with students about how to "break the ice" when making home visits to families who have never had home health services. One student mentioned that at the beginning of the semester, she was afraid that her shyness would be her downfall. But in the week that followed, it occurred to her that the best way to establish trust with anyone is to express an interest in answering questions they have before you pose your own. The student now makes it a habit to ask every patient the three things they would like her to know about them that will help her to personalize their care. During week 8 of the clinical semester, the student stated—This was a real "icebreaker" and my patients have been much more open to listening and learning from me once I listen and learn about them!

—Betsy, Community Health Nursing Instructor, Northern California School of Nursing

"First of all, a nurse should expect the unexpected. Because of the migratory way of life… clients do not always know where they will be next week or next month. Therefore, we must understand that they do not always have their medical records, immunization records, or income records. Hours are very irregular, depending on what time the workers get in from the fields and what time the shifts are. Because of the distances we travel, we work anywhere from 8 to 12 hours a day. The most rewarding part of the job is bringing health services to the underserved and uninsured. The people are so gracious and appreciative of whatever services we provide."

—J. S., RN, Michigan

"Since farmworkers come to our area for only 4 months of the year, it is rare that I care for a migrant woman through her entire pregnancy. I may diagnose her pregnancy, I may see her for three or four prenatal visits, or I may meet her only once before she goes into labor and delivers her baby. I struggle with the desire to make a difference in a short period of time and with the disappointment of not being able to follow through."

—C. K., CNM, RN, Pennsylvania

"Be warm and interested in the whole family. If you do not speak Spanish or Creole, work with translators who understand how you work. Use translators as…vehicles to get the information out and in. Eye contact and touch are crucial. Learning to be clinically relevant as well as competently utilizing a translator is an art and takes time and experience to hone. Learning some phrases or some of the most frequently asked questions in the language of the farmworker should be encouraged. Even the attempt to speak the

patients' language will build trust and confidence. These harvesters of the nation's food are very bright and resourceful people who travel great distances and undergo severe deprivation in order to work. The nobility of this pursuit is getting short shrift in the press and legislative bodies today, but the sheer enormity of the service [that] this group of oppressed people do for the rest of us needs to be acknowledged and honored by the clinicians who will provide primary health care to them and theirs."

—W. H., RN, Michigan

"I worked as a Head Start nurse for many years in an agricultural area of California. One of my assignments was a state/county migrant farm labor housing project. I was asked to make a home visit to check on a 4-year-old who hadn't come to preschool in a few days. When I arrived at the family's duplex, I found the sixth grader there, caring for all five of her younger siblings, including the 4-year-old and an 8-month-old baby. When I asked why she was home with all of the children, she guardedly informed me (after some coaxing) that her parents had been picked up in a raid at the tree farm where they worked and had been taken back to Mexico. The children were now alone, with no family nearby. I worked with a nun at Catholic Social Services to provide care for the children until the parents returned to the United States so that the children, who were all U.S. citizens, would not be placed in foster care. The parents had not been allowed to contact their children before being placed on the bus to Mexico, but other workers, who were not undocumented, had seen them go and told the children about their plight. It was heartbreaking to see the fear in their eyes. I quickly went to work looking for resources for them. A nun from Catholic Social Services stayed with the children until the parents returned and helped them with food."

—Holly, Head Start Nurse, California

"I'm dealing right now with Hispanic women, migrant workers, who do not have any access to prenatal care, none whatsoever. What I'm doing is creative financing, a lot of begging, a lot of pleading, a lot of being nice to people I don't even want to be nice to because it means that much to me for them to get help. So I find myself in situations that are sometimes uncomfortable, but nonetheless, I do it because I feel that as a nurse that's my job. Having been a farmworker myself, I would want someone to do that for my mother, and they did."

—Unidentified female nurse, Idaho Falls, Idaho

"I was appalled and dismayed by the comments of one of my students on the course discussion board. When discussing at-risk populations in urban and rural centers, the point was made that a diagnosis of HIV often imposed an additional barrier for residents who were trying to get themselves and their loved ones out of poverty and into safer and healthier living situations. One student responded that the diagnosis was a result of —'irresponsible choices and these patients need to own their own behaviors.' This spurred further discussion about the need for all health care professionals to self-reflect on a regular basis to assess for the presence of prejudices and biases that may impact our care. Although

these were difficult discussions, I believe that this student was able to turn an incidence of bias into an exemplar of a teachable moment."

—Maggie, novice PHN faculty member from a large state university in the Southwest

An aggregate at risk, migrant workers suffer higher frequency of illness, more complications, and more long-term debilitating effects. Exacerbated by a magnitude of environmental and work stressors, the health of migrant families is also compromised by limited access to health care, mobility, language and cultural barriers, low educational levels, and few economic and political resources. Because migrant health needs are largely manageable within community settings, community health nurses are ideal health providers. Implementing health education at migrant camps, training lay health workers, and providing clinic hours to accommodate late workdays are successful interventions. Learning the language of the migrant workers and their unique cultures is also helpful in reaching this population. PHNs must advocate for the health of migrant workers, who have very little economic or political power, and also guide them through the complexities of a changing health care system.

In the past, male migrant workers traveled primarily in organized crews; now, they may travel in family units with women and children. Added attention must be given to family members exposed to the hazards of the migrant lifestyle. Even as many migrant workers settle into communities, the cycle of poverty continues as other workers arrive from impoverished countries. With a paucity of health resources, the PHN is sometimes the only health provider who can and will care for this population.

Providing care for migrant workers presents a challenge, requiring nurses to be innovative and to go beyond the boundaries of traditional health services (see Using the Nursing Process). Although many resources and programs exist to help migrant families, the needs are still overwhelming. By aligning with the goals of *Healthy People 2020* to improve the health of one of the most underserved populations, the community health nurse will also be improving the health of the nation as a whole.

USING THE NURSING PROCESS WHEN WORKING WITH MIGRANT FAMILIES

Background Data and Assessment

Tom Reynolds is a community health nurse in central Montana. He has three migrant camps in his service area that are homes for primarily Mexican residents. The men primarily work in strenuous construction jobs–masonry, landscaping, and in agriculture, cherry orchards, dairy farm, and ranches. The women work as housekeeping staff in private homes, motels, and hotels in the area. One evening, he made it a point to stop by one of the camps that he could catch up with residents and assess any health concerns that need to be addressed. At the end of a three-week period, Tom had made a conscious effort to meet with the residents in each of the three camps. The feedback from these informal conversations assisted Tom in the formulation and implementation of a nursing plan of care targeting the health promotion needs of this unique population of residents.

Nursing Diagnoses

1. Alteration in family health status secondary to language, transportation barriers, and health literacy barriers.
2. Fear related to risks of deportation and separation from family members.
3. At risk for occupational and situational injury, illness, and stress because of extended work hours and poverty-level living conditions.

Plan and Implementation

Tom researched funding options for a demonstration project that was sponsored by the LHD. The Director of the Health Department agreed to support the project for 6 months if Tom could find matching funds for the project from a local foundation, recruit the personnel he needed, and the results were positive.

Tom was able to recruit three other community health nurses, one of whom was bilingual and familiar with the cultural values and practices of the migrant workers. In addition, Tom reached out to the university's undergraduate nursing program and the community health instructor agreed to utilize the three camps as clinical sites for the upcoming semester. The nurses, students, and staff social worker from the public health department coordinated weekly evening and weekend visits to each of the three camps. The teams completed a family assessment for each family: established a health record, completed a community-based assessment for each of the three camps, administered immunizations, assisted with arranging transportation to and from medical appointments, and enrolled families in the Women, Infants, and Children Supplemental Food Program (WIC). In addition, the teams completed short teaching sessions on topics such as oral care, hand hygiene, family planning, and infant safety.

The students were inspired by Tom's energy and they asked to utilize this

experience to develop their Capstone Projects that centered on meeting an unmet need of the unique group of residents. The local farmworkers heard about all of the activities at the camp and they began to organize food and clothing drives to assist the residents in meeting the challenges of the warm Montana summers and very snowy winters.

Evaluation

The evaluation of the interventions was so positive that the program became a permanent service of the health department. In the months that followed, a NP was added to the team and a volunteer dentist who provided on-site oral care and evaluations. With optimal health and a decrease in issues related to health disparities, several families were able to leave the camps and establish a permanent home in the local community.

COMMUNITY HEALTH NURSING IN RURAL AREAS

The Health Resources and Services Administration (HRSA) completed the last national public health workforce study in 2012, and no PHN to population ratio was reported. However, local public health workforce data for three states were collected: Georgia, New Mexico, and New York. Urban public health worker ratios were respectively reported at 41, 16, and 30 per 100,000 people. Rural public health worker ratios were 216, 111, and 96, respectively (HRSA, 2013). It is difficult to estimate the total number of PHNs and to provide accurate estimates of those working in rural areas (Washington State Nurses Association, 2011). PHNs, though, make up12% to 20% of the public health workforce, second only to administrative/clerical personnel at 18% to 23% (HRSA, 2013). No average age was provided; however, the average age of PHNs was reported at 46.6 years in 2005. Most rural nurses working in the community are thought to have little education in public health, as the associate degree in nursing is often accepted by health departments in rural areas (Knudsen & Meit, n.d.). Working urban nurses with a BSN numbered 51%, whereas only 36% of those working in rural areas had a baccalaureate degree, in the most recent comparison study (Rural Health Research Center, 2007). However, rural areas promote a broad scope of PHN practice, as these nurses deal with a wide variety of issues—immunizations, home health, school nursing, maternal–child health, emergency preparedness, as well as communicable disease/epidemiology. While no differences were found in regard to education level, overall perception of competency was associated with years of professional practice experience in one seminal study of rural and frontier PHNs (Bigbee, Otterness, & Gehrke, 2010). Highest levels of competency were reported in the areas of culture, communication, and leadership/systems, whereas lower levels of competency were noted for basic public health, finances, policy/program planning, and analytic assessment in another classic study of PHN rural and frontier one-nurse offices (Bigbee, Gehrke, & Otterness, 2009). Rural health departments are often lacking in technological and communication systems, but there is an even greater need for reliable communication capability and training opportunities for rural PHNs who provide the majority of care in rural and frontier communities (Knudsen & Meit, n.d.). Place, MacLeod, John, Adamack, and Lindsey (2011) found that a Rural Nursing Certificate Program was well received despite technological and distance obstacles. Advanced nursing degrees are also offered through the use of distance technologies, making them more accessible to rural nurses (Rutledge, Haney, Bordelon, Renaud, & Fowler, 2014).

Working in a Rural Community

Rural community health nurses most often grew up in rural areas or lived for a time in small communities. They frequently have extended family there. Rural PHNs are active members of their community and are highly respected professionals. The need for registered nurses in rural areas is rated at approximately 74% nationally. In addition, rural areas demonstrate a significant shortage of health care professionals including physicians, nurses, physical therapists, occupational therapists, and pharmacists (MacDowell et al., 2013).

The rural community health nurse plays many roles:

1. *Advocate*: Assists rural clients, families, and populations in obtaining the best possible care
2. *Coordinator/case manager*: Connects rural clients with needed health and social services, often assisting with information on transportation
3. *Health teacher*: Provides education to individuals, families, or groups on health promotion or other health-related topics (e.g., prepared childbirth, parenting, diabetes maintenance, home safety)
4. *Referral agent*: Makes appropriate connections between rural clients and urban service providers
5. *Mentor*: Guides new community health nurses, nursing students, and other nurses new to the rural community
6. *Change agent/researcher*: Suggests new approaches to solving patient care or community health problems based on research, professional literature, and community assessment
7. *Collaborator*: Seeks ways to work with other health and social service professionals to maximize outcomes for individual clients and the community at large
8. *Activist*: With a deep understanding of the community and its population, takes appropriate risks to improve the community's health

See From the Case Files III for a day in the life of a rural PHN.

From the Case Files III

A Day in the Life of a Rural PHN

Lisa S. arrives at Sampson County Public Health Department in rural North Carolina. She reviews the seven case files of the patients and families that have been assigned to her caseload for the day and begins her work. Prior to leaving the office,

she contacts the Director of the Senior Center to confirm that she will be able to speak at the Alzheimer's and Dementia Caregiver Support Group next week about safety proofing home settings when a loved one has a progressive dementing illness (*health promotion/primary prevention educator*). Then, she calls the family of a hospitalized patient (*care coordinator/case manager*) to assist in the coordination of the discharge of their family member. At 11:00, Lisa makes a home visit to the O'Brien family. Mr. O'Brien explains that he does not understand the process of applying for Meals on Wheels and he can't get anyone at any agency to call him back. Lisa gives Mr. O'Brien an informational handout with telephone numbers, addresses, and Web site information so that he or his daughter can contact the appropriate agency (*referral agent*) and even calls her friend from church who works at the office to let him know that the family may need some special attention to navigate the process (*advocate*). At lunch, Lisa runs into the physical therapist and they discuss concerns about the hospitalized individual with whom Lisa spoke with earlier in the day (*collaborator*). Both question whether the family will be able to manage the care needed for the patient with only minimal outside support. After lunch, Lisa returns to her office for a staff meeting and discusses an update to the electronic medical record (EMR) (*change agent/researcher*) that she is recommending for implementation by all disciplines within the department. At the same meeting, she agrees to work with a graduate public health nursing student during his rural practicum (*mentor*). That evening, as a concerned member of the local community, Lisa participates in a meeting at the town hall about issues related to the growing numbers of opioid overdoses within the local community. She addresses the group, giving them data and expresses concern (*activist*), then volunteers to lead a task force that will examine the issue and propose a plan for a "Prescription Give-Back Day" that would allow residents to turn in old/unused prescriptions at the health department offices. It is quite apparent that PHNs working in rural settings take on many roles during the course of a typical workday. As a nursing student working in a rural community, you may have the opportunity to "try on" many of these roles and demonstrate your creativity, compassion, and skills.

Rural PHNs have the opportunity to use autonomy in daily practice. Nurses must rapidly assume independent and interdependent decision-making roles because of the small workforce and large workload. For nurses who live and work in rural areas, resources are limited and demands are many. These health care professionals are highly visible, stating "As a nurse, you are kind of in a fishbowl….people know who the nurses are and you will be approached in various places for advice and information" (Zibrik, MacLeod, & Zimmer, 2010, p. 25). This visibility in the rural community can make confidentiality a preservation of client anonymity challenging. The role of the PHN is similar to being "a specialist in general nursing" (Zibrik et al., 2010). Rural PHNs learn to prioritize tasks quickly and work efficiently with others to get the job done. Referrals to other rural providers are

facilitated because providers frequently know one another. The rural community health nurse has an advantage over urban nurses in that the rural health care system is smaller and easier to influence and change, but specialization is seldom possible and long-distance travel is generally a necessity (Cant, Birks, Porter, Jacob, & Cooper, 2011).

Rural PHNs may experience the challenge of physical isolation from personal and professional opportunities associated with urban areas. Rural nurses may also feel isolated in their clinical practices because of the scarcity of professional colleagues. See From the Case Files IV for examples from nurses working in frontier areas.

From the Case Files IV

Frontier Nursing, Then and Now

As described in Chapter 2, Mary Breckinridge founded the Frontier Nursing Service in 1925, with nurse–midwives providing care to clients in their own homes. Nurses traveled by horseback and on foot into the sparsely populated hollows of Kentucky (Stone, 2011). Today, NPs working in nurse-managed clinics in rural Appalachian communities in Virginia were interviewed about their practices, in a classic study by Caldwell (2007), and spoke about their connections to the people and communities

they serve. One said, "Here you get to know the whole family and that is rewarding…you know what is important to them…what their worries and concerns are….so you probably get closer to your patient in this area than you might outside here. It becomes an extended family, which is very rewarding" (p. 76).

Another NP described a man with severe COPD who visited her clinic. He was also a patient of another area provider, but when the NP examined the man, she noticed the gauze 4 × 4 he had on the back of his neck and inquired about it. The man said he "cut himself shaving." The NP pressed the man to see the wound and found that he had "cancer with the bone exposed," describing it as "the most awful thing that I had ever seen in my life. I could put my fist in there. And you could see his carotids pulsating." She told the patient how serious this was and arranged for a plastic surgeon to see him right away. He had a total neck resection and recovered completely. She reflected, "What if I had accepted his story about the sore and it being all right? It was not what he was coming to see me for…I look at more than just the chief complaint" (p. 77).

For these nurses, isolation was considered a positive aspect of their professional practice. It encouraged connection and caring relationships with their patients (Stone, 2011).

The rural community health nurse often receives a salary that is lower than that of urban nurses in comparable positions (Knudsen & Meit, n.d.). However, there are benefits to rural nursing. Housing costs are usually lower than in larger cities, and long commutes to and from work on congested highways are often avoided, although rural driving can be hazardous. As a place to live and raise a family, rural communities offer a slower pace of life, open spaces, and friendly atmosphere. The smaller system of health care in a rural community can be advantageous to the PHN. It may be easier to understand the system and initiate planned change. There are many possibilities to enhance rural nursing practice, including continuing education through distance learning or at satellite campuses, partnerships with larger medical centers, and invitations to clinical experts to provide on-site workshops (Place et al., 2011). Grants can be written to facilitate these endeavors, and private sponsors may be approached to provide assistance. Given a smaller, more manageable community, it may be easier for PHNs to organize collaborations between private and public agencies, as well as key stakeholders within the community; collaboration is a cornerstone of public health nursing in any setting (Keller, Stroschein, & Schaffer, 2011).

However, many rural areas find it difficult to recruit nurses and need to more effectively advertise their benefits (Prengaman, Bigbee, Baker, & Schmitz, 2014). When RN to population ratios are high in both rural and urban areas, years of potential life lost and rates of poor health are significantly improved, as well as rates of teen births and mammography; however, this association was shown to improve even more as the level of

rurality increased demonstrating the importance of adequate nurse staffing in all areas (Fields, Bigbee, & Bell, in press).

URBAN HEALTH

Urban health considers those characteristics of the environment as they relate to the health of the population living within large cities. According to Vlahov, Boufford, Pearson, and Norris (2010), the factors responsible for the health of urban residents reflect three broad themes: the physical environment, the social environment, and access to health and social services. As opposed to rural areas, there may be less of a feeling of community connectedness in urban life, along with lower overall levels of trust and weaker family and community ties. Connectedness has been shown to be a protective factor, especially for adolescent risk behaviors. Inner-city neighborhoods are often observed to have "high unemployment levels, lack of educational and jobs skills, broken families, alcohol and drug abuse, and low incomes conducive to the growth of street gangs and their culture of violence" (Vlahov et al., 2010, p. 195). Community involvement and social networks, often deficient in densely populated areas, are components of social capital (discussed in Chapter 25), and community participation, social trust, and sense of belonging were significantly associated with positive health outcomes, such as mental and physical health (Ryff et al., 2015). Population turnover, racial/ethnic diversity, and poverty in urban cities are thought to contribute to the "lowered ability of individuals and communities to control crime, vandalism, and violence" (de Snyder, Friel, Fotso, & Khadr, 2011, p. 1183). Urban communities may be marked by negative social support, such as that found associated with drugs and gangs. Moreover, the social exclusion stems from the high concentration of poverty in central cities as well as high stress levels from violence and social isolation (Vlahov et al., 2010). Urban communities are made up of multiethnic and diverse racial communities, and these groups are often socially and economically separate from what one might believe to be mainstream urban communities. Poverty, especially within black urban communities, has remained stable over time despite many social programs to address poverty and jobs; recent analysis of the socioeconomic quality of racial and ethnic neighborhoods found some narrowing of this black–white gap, as more whites live in poorer neighborhood and more blacks live in neighborhood with less poverty (Firebaugh & Farrell, 2016; Lewis et al., 2013). Urban areas have been associated with *food deserts*, or areas with few or only small stores, and food insecurity has been found in urban families spending more than 30% of their income on private, rather than public, housing (Kirkpatrick & Tarasuk, 2011; Walker, Block, & Kawachi, 2012). Both housing and food are more expensive in large cities. Hodson (2016) notes that we are currently experiencing the largest urban growth period in history, with over half of the world's population living in cities. Even more growth is expected; thus, it is important to examine the health of urban dwellers.

In 2000, the Johns Hopkins University founded the Urban Health Institute as a means to bolster support among an inner-city population. This interface between the university and the Baltimore community was created to improve the health and well-being of the

residents of East Baltimore (Johns Hopkins University, 2016). Its mission is to promote evidenced-based interventions to solve local as well as national, health problems encountered in urban America. The New York Academy of Medicine (2016) has organized the Institute of Urban Health to promote research that improves the health and well-being of urban populations and decreases health disparities by studying the social, biologic, and environmental influences on health. The academy sponsors the *Journal of Urban Health,* a publication that focuses on population-based research with low-income, disadvantaged populations living in urban areas. But how did the health of these urban communities evolve to such a state that targeted efforts are now required? It began in the 1800s.

History of Urban Health Care Issues

Urban living has a long and checkered history in the United States. Arriving immigrants increased population density, especially in the large Eastern and Midwestern cities. Millions of immigrants arrived in the United States between the mid-1800s and the early 1900s. Because most had some family or distant relatives who had arrived here earlier, they made their ways to where these people lived, hoping to receive temporary shelter while they sought work (Dolkart, 2008). Many came with large families and roomed with other large European and Eastern European families in tenements. Others came alone or as a nuclear family without close ties to others already living here. Nonetheless, they gathered in ghettos, thickly populated sections of cities inhabited predominantly by members of the same minority group. This enabled them to be with people from their homeland—people who knew the same language and the same ways (Bial, 2002). The 1893 World's Columbian Exposition in Chicago introduced the "city beautiful" concept of replacing crumbling urban cities and tenements with more classical buildings and parks/lakes to address the crime and social problems of the day (Pain, 2016).

As time went on, many families left ghetto communities and found housing in smaller towns or in the beginnings of suburbs. As described in the classic work by Minetor (2010), the Irish left New York City in the early 20th century; then Blacks, coming from the South, moved in. Many Black families later left for outlying suburban areas, and Puerto Rican families moved in. Today, Haitian and Middle Eastern families inhabit some of the same neighborhoods. After 100 years, many of the same buildings continue to provide less than optimal shelter for a new group of immigrants. Although ghetto living provides a sense of belonging, for many, it is temporary because it engenders more negatives than positives. Children and grandchildren of the original immigrants seek different lives for themselves, away from the urban areas that are often riddled with crime, unsafe housing, and disease. Others, because of poverty, drugs, or fear of being homeless, remain in urban slum areas.

In a classic position paper, the American College of Physicians used the term urban health penalty to describe the "concentration of economic decline, job loss, and major health problems" afflicting inner-city populations experiencing health problems when healthier and wealthier residents moved to the suburbs, leaving poverty zones of economic and physical deterioration that act as determinants of health (1997, p. 485). As discussed earlier, that health penalty is now more prevalent in rural areas. An urban health penalty has historically been associated with large cities because of economic inequalities that often prevented subpopulations of poor from having the basic quality of life found in mainstream society (Vlahov et al., 2010). These unhealthy environments were thought to lead to inequality in health. However, more careful statistical analysis of population size and the death counts of four major diseases found both an urban health penalty when looking at total counties and an urban health advantage when examining subgroups, noting that there is a tipping point that must be considered (Choi, Lee, & Chang, 2015).

Who has been responsible for addressing the needs of these communities over the last hundred or more years? Who has been, or should have been, addressing the needs evolving among the urban communities? Two connected disciplines, urban planning and public health, have addressed these issues from the 19th century to the present. Urban planning worked to improve the welfare of individuals and communities by creating more healthful, efficient, attractive, and equitable places. The activities of urban planners often include addressing the community's needs related to diversification of the transportation system, housing, reducing air pollution and greenhouse gases, street network design, and built environment site design; in some large cities, these tasks are handled by separate departments that do not often interface with environmental or public health (Nieuwenhuijsen, 2016).

Public health, of course, is directed at improving human well-being through assessing and ensuring the delivery of services at the community level. Together, these disciplines both addressed the needs of the identified vulnerable populations. Initially, during the late 19th and early 20th centuries, these two systems were linked in promoting health by facilitating physical activity through the creation of green space. They also designed cities to be less vulnerable to contagions (Owens, 2016). They joined together in preventing infectious diseases by ensuring healthful drinking water and sewage systems. They also protected the community from exposure to hazardous substances related to industry by monitoring land uses and instituting zoning ordinances (Boarnet & Takahashi, 2011). During the middle of the 20th century, the focus of planning and public health agencies drifted apart, partly because of their successes in limiting injury and health risk caused by inappropriate mixing of land use. The target of public health agencies shifted from investigating ways to improve the infrastructure to a focus on germ theories and immunizations, challenges that were easier for physicians to address than changing environments. On the other hand, urban planning switched its energy to aiding economic development with large transportation and infrastructure (Viel, Hägi, Upegui, & Laurian, 2011). At about the same time, Rachel Carson's book *Silent Spring,* published in 1962, described the effects of pesticides on wildlife and the eventual effects on human health, thus initiating the *environmental justice movement* and focusing environmental health professionals largely on toxic chemical exposures. See Chapter 9.

According to Boarnet and Takahashi (2011), the disciplines of urban planning and public health are collaborating once again, working together to improve transportation and air quality and addressing national health issues such as injury prevention, physical activity, health care access, energy use, and greenhouse gas emissions, along with disaster preparation and response. A Canadian example brought agencies together, led by a land use/transportation consultant, to build a sustaining and collaborative relationship between agencies and local government and to prioritize land use and transportation planning while keeping in mind the built environment in order to better align with population health goals (Miro et al., 2014). This team effort is a natural partnership when addressing such concerns as physical activity and the provision of safe and accessible spaces, for instance. Several

studies demonstrated a positive association between the built environment and physical activity. Land use mix, "connectivity," population density, and neighborhood design were also determinants of physical activity (McCormack & Shiell, 2011). These factors are significant in reaching the *Healthy People 2020* objectives directed at the prevention of chronic disease, injury prevention, and health promotion. Leaders at the CDC are concerned with factors that affect people and their environments and support efforts that address the improvement of both physical and social environments as related to places to live, work, and play. The CDC's *Healthy Places* describes the components involved: interaction between environment and health, poorly planned growth leading to sprawl and increased used of vehicles, and healthy community design that promotes health and well-being (2016).

The World Health Organization's Healthy Cities movement emphasizes health in planning and policy development. It encompasses economic and urban development and considers health inequality and urban poverty, as well as the vulnerable populations living in urban areas (World Health Organization, 2012) (see Chapter 1 for more on Healthy Cities). Health care reform also offers opportunities to address urban health issues, especially related to health care access. Policy development to address the unique challenges of urban areas is part of public health advocacy for urban PHNs and other public health officials. And the move toward quality health care in the public health system will positively affect the health of all populations, including urban residents (Honoré et al., 2011).

Urban communities must be given the opportunity to participate, particularly in activities that focus on change at the community and systems levels of prevention and public health practice. An example is the building of coalitions among key neighborhood stakeholders and agencies, as well as the individuals and families residing in those neighborhoods. Tapping into already existing neighborhood networks can facilitate health promotion efforts through capacity building and common goals that develop through collaborative partnerships. Such interventions reflect many of the key public health nursing interventions, as demonstrated in Chapter 14 through the use of the Minnesota Wheel and other models.

The *Healthy People 2020* document addresses societal determinants of health that include both physical and social environments. Notwithstanding the complexity of urban areas, particularly in large metropolitan cities, health promotion efforts and a focus on healthier environments are key components of this national health effort. Reduction of inequalities in the physical environment (e.g., transportation, parks, healthy food access) and the social environment (e.g., crime) can lead to improvement in key health indicators and aid in meeting the goals and objectives of *Healthy People 2020* (Secretary's Advisory Committee on Health Promotion and Disease Prevention Objectives for 2020, 2016). Urban development, transportation, housing, education, and agriculture must be addressed, as well as health promotion and disease prevention, in order to affect substantive change. Research and data collection are important to guide our progress.

Emerging Issues in Access to Health Services

Access to health care in the United States is regarded as "unreliable" because many people do not receive the appropriate and timely care they need. The U.S. health care system, which was already overwhelmed, has faced an even greater influx of patients because health care reform was fully implemented in 2014; this was when 32 million Americans obtained health insurance for the first time (U.S. Department of Health & Human Services [USDHHS], 2016a). Health care issues that should be monitored over the next decade include (1) increasing and measuring access to appropriate, safe, and effective care, including clinical preventive services; (2) decreasing disparities and measuring access to health care for diverse populations, including racial and ethnic minorities and older adults; and (3) increasing and measuring access to safe long-term and palliative care services and access to quality emergency care (USDHHS, 2016a).

Urban Populations and Health Disparities

An example of urban housing.

The majority of the world's populace now lives in cities, which is a change from long-held rural dominance. Along with urban living, other global challenges including economic globalization, climate change, financial difficulties, food and energy insecurities, armed conflicts, and changing patterns of diseases (Friel et al., 2011a). The greatest growth of large cities around the world is among less-wealthy nations, where urban slums are developing at a rapid rate (Ieri, 2015; Vlahov et al., 2010). Depending upon the classification used, more than one third of the U.S. population lives in central cities. This is the highest number since 1950 (Mather, Pollard, & Jacobsen, 2012). However, suburbs of metropolitan areas had the fastest growth, especially in the West and the South; over half of the populace lives in *suburban areas*. More than 84% of the U.S. population lives in what are characterized as central-city or metropolitan areas (Mather et al., 2012).

Although some metropolitan areas have recorded substantial population losses in central-city areas (e.g., Pine Bluff, AR, at 5.53%; Farmington, NM, at 4.81%; and Johnstown, PA, 4.14%), others exhibited substantial population growth (The Villages, FL, at 22.4%; Midland, TX, at 13.85%; Austin, TX, at 13.23%; and Odessa, TX, at 12.23%) between 2010 and 2014 (Demographia, 2012; Wikipedia, 2016).

One example of how changes in population can adversely affect large cities can be found in Detroit, Michigan. Between the 2000 and 2010 censuses, the population dropped

25% (or 237,500 people) to the lowest level since 1910. This is a lower proportion than the 29% population loss experienced by New Orleans because of Hurricane Katrina. However, the total number of people was much less in New Orleans (only 140,000). The dramatic losses in Detroit pulled down the numbers for the state of Michigan, and it was the only U.S. state to show a net population loss. Auto and other industrial losses, combined with large numbers of home foreclosures, are thought to be at the root of the problem. Population loss leads to a smaller tax base and a greater proportion of poor residents, yet the city had the same maintenance expenses for sewers, water lines, and streets (Seelye, 2011). With the loss of jobs, many people moved to the suburbs, and unemployment and welfare rates increased in Detroit. The poverty rate jumped from 10.4% in 2000 to 17% in 2010 (Davis, 2012).

Historically, movement to the suburbs began with the housing boom and highway expansion occurring after WWII. People moved from large cities to more suburban areas, and shopping malls and schools followed. Cars became even more essential, because public transportation did not always extend into suburban areas thereby leading to long commute times and traffic congestion. Although not all suburban areas have remained attractive and vital, an income gap persists between city and suburban residents. Poverty is two times greater in large central cities than in corresponding suburban areas (18.8% vs. 9.4%), but in total population, there were 1 million more suburban poor in 2005. By 2012, 59 of the top 95 metropolitan areas in the United States found the majority of their region's poor located in the suburbs. In addition, this demonstrated an increase in 93 of 95 metropolitan areas between 2000 and 2012 (Kneebone, 2014). This is indicative of a "suburbanization of poverty" (p. 12). Poverty rates were highest in metropolitan areas in the Midwest and South, and almost half of all large cities had significant increases in poverty rates. Only about one third of suburban areas recorded poverty rate increases.

Today, the declining urban situation is not confined to a few large cities. To achieve the vision of creating "social and physical environments that promote good health for all" as an overarching goal of the *Healthy People 2020* document, more must be done to promote health and prevent disease in urban areas (USDHHS, 2016b, para. 5). The primary reason for health disparities, as mentioned in Chapter 25, is the disproportionate burden of certain health and social problems among different populations—in this instance, urban areas. Environmental exposure to air pollution contributes to illness and mortality including heart disease, cancer, and respiratory diseases. Consumer products (e.g., fast food, alcohol, tobacco) are more readily available in urban and low-income areas and have been shown to be significant health risks that contribute to health disparities (Freudenberg, & Olden, 2011). Other environmental issues, such as extreme heat events where temperatures rise and lead to climate-related deaths, may amplify public health stressors and primarily affect vulnerable populations. When examining urban form and its relationship to this weather phenomenon, Stone, Hess, and Frumkin (2010) found an increase in annual extreme heat events between 1956 and 2005, with more than twice the number of events in sprawling metropolitan areas when compared with compact metro

regions; urban planners are urged to consider construction limits in order to help with thermal regulation (Wu & Lung, 2016). Urban cities are often heat islands because of fewer green spaces and a larger proportion of asphalt. Extreme heat events not only lead to increased ED visits for heat-related illness, they can lead to increased hospitalizations for those with asthma and other chronic conditions, as well as death for elderly and other vulnerable populations (Matte et al., 2016; Soneja et al., 2016; Winquist, Grundstein, Chang, Hess, & Sarnat, 2016). Cities provide interventions such as extreme heat warnings and cooling centers, but not all residents avail themselves of these services (Hess, McCowell, Luber, 2012). Canadian researchers (Bélanger et al., 2016) interviewed almost 3,500 people in 1,647 buildings in disadvantaged areas across nine of the largest cities to determine their perception of adverse health effects of urban heat. Those with negative health impacts relied more on adaptation methods (e.g., eating iced foods, visiting air conditioned places, taking showers to cool down, turning off appliances), indicating that these measures were more reactive in nature. As with rural areas, the built environment greatly impacts urban neighborhoods.

Friel et al. (2011a, p. 861) show that "social patterning in health outcomes within and between cities," suggesting that urban physical environments, social environments, and living conditions are causing health changes. Urban health equity depends on political empowerment of the people to strongly represent their interests and needs in order to challenge unfair distribution of resources. Further, with most of the world living within the built environment, this poses a major opportunity to improve urban health and equity (APHA, n.d.b; Friel et al., 2011a). Poor social conditions and health inequalities have been recognized in urban areas around the world. Urban slums in low- and some middle-income countries provide social exclusion for many living in poverty and threaten development (de Snyder et al., 2011). In this country, overcrowding and poor-quality housing have been found to have a direct relationship with poor mental health, developmental delay, and even to shorter stature (Vlahov et al., 2010). Inadequate urban housing and neighborhood disorder are related to poor-quality sleep among Latino adults (Chambers, Pichardo, & Rosenbaum, 2016). Prenatal exposure to particulate matter (diesel fuel, perchloroethylene) has been shown to affect math scores when the children reach third grade; researchers suggest "individual pollutants may additively impact health" (Stingone, McVeigh, & Claudio, 2016, p. 144). Urban housing and neighborhoods have been linked to childhood asthma morbidity. Indoor area pollutants (e.g., nitrogen dioxide, particulate matter) have been associated with asthma symptoms in children, and reduction of indoor allergens and pollutants has shown improvements in asthma symptoms (Matsui, 2014). Adamkiewicz et al. (2014) demonstrated that urban indoor environments in multifamily housing units were very common; over 50% of those tested had 3 or more exposures to problems such as pests, mold, ventilation, or combustion and noted that cumulative exposure could be linked to poor health.

In addition to concerns about housing, hazardous waste landfill sites are often located in or near urban areas. Air pollution and noise exposure, often associated with large inner

cities, have been linked to asthma, cardiovascular death, hypertension, ischemic heart disease, and hearing impairment (Vlahov et al., 2010). Also, Ard (2015) examined industrial air toxins over a 9-year period and found that African Americans were consistently exposed more often than Whites and Hispanics even though air toxins decreased overall during that time; income level was not a protective factor for them. In Flint, Michigan, following pollution of their water system, soil lead data show higher lead values in the metropolitan city center, and seasonal blood lead variations indicate that resuspension of lead dust may be to blame (Laidlaw et al., 2016). See Chapter 9 for more on environmental health.

Continued exposure to higher sound levels found in large cities can lead to noise-induced hearing loss as well as decreased levels of work performance, among other things (Recio, Linares, Banegas, & Diaz, 2016). Significantly lower psychomotor speed and reduced working memory were found in a sample of healthy adults when subjected to urban noise levels (Wright, Peters, Ettinger, Kuipers, & Kumari, 2016). Lead poisoning and hazards related to asthma have been more often reported in older, larger cities (Maring, Singer, & Shenassa, 2011).

A national study found that traffic-related air pollution (measured by nitrogen dioxide levels) was significantly associated with small for gestational age births and lower birth weights and may be a source of air pollution related to poor pregnancy outcomes in Canada (Stieb et al., 2016). Another study examined the effects of long-term air pollution exposure on survival rates for acute myocardial infarctions (Chen et al., in press). Researchers concluded 12.4% of deaths could have been prevented if the lowest measured concentration of ambient fine particulate matter in urban areas had been consistently achieved over the study period.

The risk for major depressive disorder has also been shown to increase as exposure to particulate matter increased; this was true in the general population but was even more highly significant in people with chronic diseases (Kim et al., in press). Suicide rates in New York City have declined from 8.1 per 100,000 to 4.8 per 100,000 and remained stable through 2006 (Nandi et al., 2012). While global data have often suggested that urban residents have better health on average than their rural counterparts, this benefit is truly only greater for those at the high end of the income scale. This only magnifies the disparities in urban areas between rich and poor or the social gradient. A more current view is that those living in urban slums, often in megacities outside the United States, have health outcomes that are either similar to or worse than those of their rural neighbors (Friel et al., 2011a; Vlahov, 2015; Vlahov et al., 2011). Using the social determinants of health, researchers in Toronto, Canada, modeled both short- and long-term interventions (Mahamoud, Roche, & Homer, 2013).The Rockefeller Foundation funds two projects that will further examine ways to improve urban health equity and develop a global research agenda, as well as identify better ways of measuring and evaluating population health in urban settings (Friel, Vlahov, & Buckley, 2011b).

Air pollution is a common problem in metropolitan areas, as seen in this view of San Pedro in Los Angeles County. (Source: California Department of Transportation.)

Violence is often associated with large metropolitan cities. The U.S. Department of Justice (Langton & Truman, 2015) revealed that the overall rate of violent crime was 20.1 per 1,000 in 2014, not significantly different from the previous year. The rate of violent crime in metropolitan areas is over two times that reported in nonmetropolitan (rural) areas: 410.3 versus 188.1 per 100,000. Cities outside metropolitan areas have higher rates of property crimes than both urban and rural areas, although vehicle thefts were highest in urban areas (U.S. Department of Justice, Office for Victims of Crime, n.d.). Kneebone and Raphael (2011) note that, with community diversification, the association between community demographics (e.g., race/ethnicity) and crime significantly weakened. For example, Black or Hispanic population density associated with property crime or violent crime was significantly reduced or almost disappeared. Over a four-decade period, Parker and Stansfield (2015) found that increased population diversity in U.S. cities contributed to declining homicide rates; racial differences were noted with growing Hispanic presence in Black areas leading to lower Black homicide rates, but no differences were found in White homicide rates. Black and Hispanic growth rates, however, have been shown to strongly affect socioeconomic changes in urban areas, decreasing the per capita income growth rate and increasing poverty rates (Park, 2011).

Social disorganization theory is thought to predict relationships between delinquency rates and neighborhood social structures and processes (e.g., poverty, residential instability,

overcrowding), and one study of Chicago neighborhoods found that individual-level risk factors (e.g., lack of adult supervision, individual/peer alcohol use, depression) were a more consistent predictor of physical aggression than neighborhood factors baseline levels of aggression were taken into account (Jennings, Maldonado-Molina, Reingle, & Komro, 2011). They also cited previous research on programs such as Head Start, residential relocation efforts, and neighborhood supervision of teen peer groups as having shown some effectiveness in dealing with individual risk factors; they further noted the need for interventions that address multiple causal factors.

Among youth, Latinos/Hispanics are disproportionately represented among youth gangs, and substance use and sales are gang-related activities. Gang violence and bullying are making its way onto social media sites (Patton et al., 2014), and a study of over 16,000 adolescents found that those reporting being bullies or having been bullied were at greatest risk of becoming involved in violence, having academic problems, and using multiple substances (Bradshaw, Waasdorp, Goldweber, & Johnson, 2013). Individuals who are exposed to urban violence may develop PTSD, and a study examining health-related quality of life among those with PTSD who were exposed to urban violence found that they had higher levels of anxiety and depression, more childhood traumas, and more new trauma experiences (Pupo, Serafim, & deMello, 2015). Supportive family members were shown to be associated with lower reported involvement with violence during adolescence. While those living in low-resource urban areas may not be able to avoid witnessing violence, having one supportive parent had significantly less violence involvement, and those with a supportive mother only or two supportive parents had a significant inverse correlation with violence involvement (Culyba et al., in press).Van Dommelen-Gonzalez, Deardorff, Herd, and Minnis (2015) chose as positive deviance framework to study the relationship between positive peer networks associated with aspirations for college, along with frequent marijuana/alcohol use, among gang-affiliated youth in San Francisco. Having close friends with plans to attend 4-year colleges was positively related to lower frequency of alcohol/marijuana use. How adolescents perceive their communities can also influence behaviors and health. A Baltimore study found that girls perceived vacant homes and few recreational facilities as having an influence on sexual health, but boys felt there was more of an influence on violence and drugs (Mmari et al., 2014). Mmari, Marshall, Lantos, and Blum (in press) noted that adolescent trust of authority (e.g., institutions) was lacking, as over half of the study participants did not trust police and a good percentage had no trust in any type of authority. Levels of trust were found to correlate with risk behaviors.

Inner cities are often thought to be places with low-income residents living in large, poorly maintained government housing projects. Dilapidated housing in central cities exposes residents to cracks in walls and ceilings, peeling paint, broken windows, leaking pipes, and pests such as cockroaches and rats. There is often limited access to adequate rental properties, and rent is often higher in large cities, making it difficult for low-income residents to find adequate housing. Nationwide, about one third of households live in rentals, but 43% of rental properties are in central cities. Most rental property in this

country (80%) is considered private, with landlords not receiving any government subsidies. Rents in large metropolitan areas rose 9% between 2000 and 2005, but household incomes of renters fell 5% during that time period. As the recession began in 2008, "rent-to-income ratios were higher than they had been" since the early days of the Depression (DiPasquale, 2011, p. 58). Vacancy rates in 2009 peaked at 10.6%, and rents declined across the country (DiPasquale, 2011). However, Dewan (2014) reports that median rents in 90 cities were over 30% of the gross median income; no more than 30% of one's household income is considered to be affordable rent. In Chicago, the average rental percentage increased from 21% to 31%, and New Orleans reported 35%, from a low of 14%. Miami rent is now 43% of the typical household income, despite efforts to increase the number of apartment buildings. Apartment vacancy rates are now very low, and rents will most likely continue upward.

Low-income housing, when available, is often plagued with construction and maintenance problems and is characterized by crowding, poor quality, high population density, and attendant health problems. Over 1.3 million U.S. households are located in public housing. Over one third of rental housing was built before 1960, and owners of multifamily rental properties that have lost tenants and income may scrimp on maintenance that decreases property values even more (DiPasquale, 2011). Gielen et al. (2012) examined low-income urban housing quality and found that 99% of 246 homes studied failed on HUD's housing quality standards. Heating and cooling, walls/ceilings/floors, and sanitation/safety issues were areas with the highest failure rates. Homelessness is more prevalent in urban areas than in rural areas, and some of the community-level determinants include high rent levels, lower level of home ownership, high-poverty levels, aging population, a growing Hispanic population, and proportion of recently moved or single-person households (Boozer, 2014). Byrne, Munley, Fargo, Montgomery, and Culhane (2013) estimate a 15% to 39% increase in homelessness for every $100 increase in rent in metro, suburban, or rural areas. See Chapter 28 for more on the homeless and promising interventions.

Urban poor are often forced to live in neighborhoods that do not facilitate outdoor activity or have markets that provide healthy foods, such as fresh fruits and vegetables. A walk through most urban corner markets reveals that they do not always offer low-fat dairy products or fresh produce but generally do their best business selling lottery tickets, liquor, sodas, and cigarettes. A study of urban food environments and residents' shopping behaviors noted that healthful food inventory scores were lowest for convenience or corner stores, but these were the most common type of retail food outlet (78.6%). Almost 95% of participating residents did "primary food shopping" at chain supermarkets with higher scores, but most shopped at a store further from their home in order to find healthier foods (Cannuscio et al., 2013, p. 606). Distance to store and the price of food items were both found to be positively correlated with obesity (Ghosh-Dastidar et al., 2014). In New York City, it is estimated that only half of residents consume two or more servings of fruits and vegetables daily, and typical interventions aimed at increasing consumption are not likely to

be effective in neighborhoods with low education levels (Li, Zhang, & Pagán, 2016).

In a Philadelphia study of patients with high hospital utilization (≥3 inpatient admissions within 12 months; ≥6 chronic illnesses), 30% were found to be food insecure, and 25% were marginally food insecure (Phipps, Singletary, Cooblall, Hares, & Braitman, in press). In the past 30 days, 40% were concerned that their food would run out, 17.5% said that they did not eat for a full day, and 10% reported being hungry and not eating some or all of the time. Food insecurity can have negative impacts on health, especially for those with chronic conditions. In a qualitative study of San Francisco area individuals with HIV/AIDS, participants discussed living on insufficient food supplies and being hungry, as well as having concerns about the potential poor health effects of eating a "cheap diet" (Whittle et al., 2015, p. 154). Some reported having to use socially and personally unacceptable means of getting food (e.g., trading sex for food, depending on friends/family/charities). High rents related to gentrification of their neighborhoods were cited as a cause of their food insecurity.

Alcohol availability is higher in areas with greater concentrations of lower-income minority residences and the concentration of liquor stores and other alcohol outlets in disadvantaged communities has been found to contribute to increased alcohol consumption, especially among teens, in a systematic review of 26 studies (Bryden, Roberts, McKee, & Petticrew, 2012). In a study of California cities, adolescents had a greater increase in past-year use of alcohol and heavy drinking when higher levels of adult drinking were also found. Bar density was also associated with higher levels of past-year use of alcohol (Paschall, Lipperman-Kreda, & Grube, 2014). Youth exposed to higher-density levels of alcohol outlets were found to be at risk for both recent heavy alcohol use and lifetime alcohol use (Shih et al., 2015). Restricting the number of alcohol outlets in urban areas and making it more difficult for youth to enter clubs and bars are important to addressing this problem. In a study of national survey data on alcohol consumption, Jones-Webb and Karriker-Jaffe (2013) found that significantly more individuals from disadvantaged neighborhoods reported negative consequences from drinking alcohol than those in higher-income areas. Being a resident of an African American neighborhood was associated with increased liquor consumption and more negative consequences from drinking. The researchers called for an examination of tax policies and advertising practices in minority neighborhoods that support the easy availability of alcohol and problem drinking.

Urban substance abuse follows a similar pattern as rural, except that those admitted for treatment are more often Black and Hispanic, rather than White, and more often unemployed with no reported primary source of income; a greater proportion of those in urban areas use heroin and cocaine, whereas those in rural areas have higher percentages of alcohol, marijuana, and nonheroin opioid use (Substance Abuse and Mental Health Services Administration, 2012). As drug use increases, financial resources decrease (Ompad et al., 2012). A Baltimore study of 3,245 injection drug users (former, current) over a 22-year period found that 57% were incarcerated at least once and that incarceration was

positively related to subsequent injection drug use among those who were former, not current, users in this largely African American sample (90%). Genberg, Astemborski, Vlahov, Kirk, and Mehta (2015) also reported that 29% of their participants were females and about one third were HIV positive. Weiss et al. (2014) reported on outcomes of the Cessation of Heroin: A Neighborhood Grounded Exploration (CHANGE) study and noted that those heroin users wanting to stop and who are successful use a combination of approaches: treatment, strategies to avoid heroin triggers, engaging in some type of alternative activity (e.g., support groups, faith-based practices, exercise), and motivations (e.g., wanting a better quality of life and relationships, fear of incarceration, illness, or death).

Drug overdose deaths are becoming a national epidemic, rising from 9 to 15 per 100,000 between 2003 and 2014 (Park & Bloch, 2016). Heroin deaths quadrupled between 2002 and 2013; heroin use increased 63% overall, and there was a 50% increase among men (Fox, 2015). For women, the numbers doubled. It is no longer urban poor who are addicted; heroin has made its way into the suburbs and higher-income white populations. Analgesic (not heroin) overdose deaths occur in higher-income, less unequal neighborhoods than heroin overdose deaths (Cerdá et al., 2013). An interesting study of a particular opioid receptor gene (OPRM1) found that those individuals with a particular allele (118G) had over five times greater odds of suffering respiratory or cardiac arrest with acute drug overdose (Manini, Jacobs, Vlahov, & Hurd, 2013). The Food and Drug Administration (2015) approved a nasal spray form of Narcan, to make it more easily accessible as a lifesaving measure for opioid drug overdoses. Other interventions are needed to address this problem in urban areas and across this country (see Chapter 27).

Sociologists Wilson and Kelling first proposed the *broken window theory* in 1982, noting that if a broken window goes unrepaired, soon more windows are broken, and this sends a powerful message to residents that no one cares. A classic research study by Keizer, Lindenberg, and Steg (2008) tested this theory in six-field experiments where neighborhoods, characterized by broken windows, litter, unreturned shopping carts, and graffiti, were studied. They found that when residents see others violating social norms or rules (e.g., disorderly or petty criminal behavior), they are then more likely to also violate norms and rules and that this is a cause for the spread of disorder. Gau, Corsaro, and Brunson (2014) studied the causal path of broken window theory and found that fear is the result of disorder, partially because of poor neighborhood cohesion and lower expectations for social control. Welsh, Braga, and Bruinsma (2015) note that the theory is helpful in measuring neighborhood disorder and in developing interventions to address the problems related to it. Research has demonstrated that crime and safety were more significant predictors, walkability measures, in a study of behaviors affecting mental health outcomes and health status of low-income urban women (DeGuzman, Merwin, & Bourguignon, 2013).

Population density, complexity, and racial/ethnic diversity are associated with urban areas. Central cities are often home to a large proportion of poor people and those from

different racial and ethnic groups. Less than half of all Hispanics lived in the top ten metropolitan areas in 2005, with 22% living in Los Angeles and New York. These two large cities are also home to 27% of the Asian population, with 56% living in the top 10 metro areas. Over the past 15 years, there has been significant movement of blacks to Southern metropolitan areas, but movement to other areas (e.g., Las Vegas, Phoenix, Sacramento, Minneapolis) has also occurred. In the 21st century, America has evolved into a metropolitan nation with >8 out of 10 Americans living in metropolitan areas of varying sizes. Between 2000 and 2010, the fastest growing cities included Las Vegas, NV; Raleigh, NC; Cape Coral, FL; and Provo, UT. Conversely, the cities with the greatest rates of decline included New Orleans, LA; Youngstown, OH; Detroit, MI; and Cleveland, OH. During the latter part of the decade, though, there were major shifts that occurred because of the economy and the housing market collapse (Frey, 2012).

Urban poor have health problems characterized by accidental and violent injuries, as well as noncommunicable diseases and chronic stress (Kliewer & Lepore, 2015; Maxmen, 2016). In a classic comparison of neighborhood characteristics in the Multi-Ethnic Study of Atherosclerosis, researchers found that distinct neighborhood features, not associated with race or ethnicity, had health modifying effects. Increased levels of smoking, depression, and not walking for exercise were found in less socially cohesive neighborhoods, whereas individuals living in neighborhoods with the fewest problems had less smoking, depression, and drinking (Echeverria, Diez-Roux, Shea, Borrell, & Jackson, 2008). As noted in Chapter 25, poverty makes a significant difference in health status. Gilster (2014) found an association between neighborhood stressors and depressive symptoms in low-income, non-white neighborhoods in Chicago. Neighborhood factors were also associated with inner-city school children performance on math and reading tests and behavioral problems and being held back in school (Kim, Mazza, Zwanziger, & Henry, 2014). Neighborhood disadvantage and disorder (drug activity, violent crime) have been related to the rapid transition from no drug involvement to problem drug use (Reboussin et al., 2015). Neighborhood poverty has been associated with HIV diagnosis in a New York City study (Wiewel et al., 2016). Goldsmith and Blakely (2010) note that political and economic forces, especially for poor city dwellers, generate poverty. Working class urban residents no longer can find industrial jobs, and a concerted effort to improve conditions in urban America is needed in the form of urban policy development.

Over the past 25 years, cities and their suburbs have become more alike, and the demographic and health profiles that were previously uniquely urban are now shared by "edge cities" and suburbs populated by poor and minority families. Political power has shifted to more affluent suburban areas, where the tax base and spending practices are greater, at the expense of these cities. Monies that once came to cities to support new resources have also declined. Hanlon (2012) studied 5,000 U.S. "inner-ring" suburbs, many early suburban areas of large metropolitan cities. These developed just prior to or immediately after WWII and are often considered to be very similar in composition. She found, however, that this was not the case and that many were sliding into decline with

higher levels of poverty, foreclosures, and significant fiscal problems.

This aerial view of New York City shows Central Park and other green areas interspersed among densely populated areas, an example of good urban planning. (Source: National Aeronautics & Space Administration.)

Urban health disparities present a challenge that can be addressed only by the joint effort of public health and urban planning bodies. Coalitions of public health professionals, planners, builders, and architects, along with transportation engineers and government officials, are needed to promote healthy, sustainable communities (Boarnet & Takahashi, 2011). There is a move to make cities and their suburbs *sustainable communities*. These are seen as healthy places where both natural and historic resources are protected, employment is available, urban sprawl is contained, neighborhoods are safe, air pollution is minimized, lifelong learning is promoted, health care and transportation are easily accessible, and all citizens have the opportunity to improve their quality of life. A federal collaborative program, the Partnership for Sustainable Communities (n.d.), is a nonprofit organization that helps American cities become more socially, economically, and environmentally sustainable while focusing on land use planning, affordable housing, community development, energy use, and transportation.

As with all good plans, the sustainable development plan requires that the recipient of the planning be involved. Democratizing the practice of urban planning is vital to its success. Communities that have been victimized through ineffective planning must be included in the decision-making process. This process will require the inclusion of the

practical experience that residents bring to the table, alongside expert input. However, to ensure equitable participation and to level the discussions, the community must have access to all the necessary resources, such as technical, medical, legal, and financial assistance, and crowdsourcing, health portals, and Web-based tools may be helpful (Gottlieb, Hoehndorf, Dumontier, & Altman, 2015; Jiao et al., 2015; Wong et al., 2015). The health of communities must be addressed from all levels of environmental impact (individual, community, and systems), and population health in the urban setting must be studied (Gottlieb et al., 2016). Data must be included from the various environments, such as homes, workplaces, schools, and community spaces. These approaches then bring such action in line with what is often referred to as *environmental justice* or the marriage of environmental health and civil rights (Walker, 2012). A framework to ensure such justice requires that all individuals and communities have the right to work, play, and live in environments that are safe and healthy. It also requires that polluters are punished and required to provide compensation for damages and/or renovation.

Community Health Nursing in an Urban Setting

Urban public health nursing can be very rewarding, and many nurses are drawn to urban areas where salaries are higher and opportunities for advancement or additional education greater. In urban areas, there are a larger number of nurses, more schools of nursing, and more intensive recruitment efforts than in rural areas, although inner-city areas, much like rural settings, can have problems filling PHN vacancies. While there were 41,290 PHNs working at local, state, and federal levels in 2012, it is difficult to determine how many work primarily in urban settings (Public Health Foundation, 2013). However, RN workforce studies reveal a higher rate of nurses (934.8 vs. 852.7 per 100,000 population) and a greater proportion of nurses with a BSN (46.6% vs. 33.9%) in urban areas when compared with rural areas (HRSA, 2013).

PHN practice is population-focused care that requires unique knowledge, competencies, and skills. PHN roles have always extended beyond sick care, also encompassing advocacy, health education, community organization, as well as political and social reform (Kulbok et al., 2012). Contemporary public health nursing also involves collaboration with both community agencies and community members as equal partners. Primary prevention (health promotion) is a major focus. PHNs have a key role of working with populations to improve health and social conditions of vulnerable populations (Kulbok et al., 2012). These nurses practice in diverse settings such as community nursing centers, home health agencies, housing developments, local and state health departments, neighborhood centers, churches, schools, and worksites. PHNs can develop sustainable programs and build community capacity for health promotion in collaboration with community members. By utilizing a community-based participatory research (CBPR) model, PHNs can collaborate with community members, leaders, and stakeholders to identify resources and solutions to problems. Specific public health roles include advocates, collaborators, educators, partners, policy-makers, and researcher (Kulbok et al., 2012).

Bond, Jones, Ompad, and Vlahov (2013) report on the interest of faith-based organizations in working with LHDs to provide influenza vaccination programs (60% were interested in providing on-site vaccinations, and 16.5% had contacted LHDs). This collaboration may be especially helpful with black congregations, as other studies have shown low interest and vaccination rates among this population (Vlahov, Bond, Jones, & Ompad, 2012). A seminal study by Schulte (2000) demonstrated that urban PHNs create connections through caring processes and an underlying sense of regard for their clients as human beings. Community health nurses collaborate with their clients to develop their facility for long-term health promotion and improvement of their quality of life. Their ultimate goal is to empower clients to be self-sufficient. The centrality of caring is noted in the following PHN comment:

"Public health nursing is more than a job…. When I'm out there, I care about the people, about what happens to them. I don't think I'd make a really good PHN if I didn't

care. You get results if they know you care—they're willing to make some change. If they don't think you care at all about them, why should they take a risk for you? I think public health nursing is all about caring about people" (p. 8).

This type of caring is typical of public and community health nursing in all settings, including urban and rural health departments (Keller et al., 2011).

There are many points at which the community health nurse can make a difference in people's lives. Nurses provide services in deteriorating urban areas, with those living in poverty in all settings, and among all vulnerable populations. Nurses first need to assess themselves for their attitudes and preconceptions. Although access to care can be improved for many low-income people in urban areas, many clients simply need an advocate. Our ability to envision solutions and join together with clients aids us in helping to create a healthier environment for our clients (Fullilove & Cantal-Dupart, in press). The urban communities, and the poor or vulnerable people living in them, need strengthening and interventions that can be initiated by PHNs using the nursing process as a guide. See Chapter 25.

Self-Assessment

Confronting poverty and caring for vulnerable people from diverse backgrounds, whether in rural or urban areas, necessitate reflective assessment of one's own assumptions and beliefs. Because poverty may be prevalent over a lifetime, a good number of nursing students have personal or family experience of living in poverty. However, because the stigma is so great and faultfinding so pervasive in American society, acknowledging and reflecting on this experience may well be painful. In contrast, because poverty is so hidden and frequently denied, some nursing students have lived apart from any knowledge of the human experience of poverty. They may have come to believe many of the negative stereotypes about poor people. Nursing students and practicing nurses need to ask such questions as "How have my judgments been shaped? How can I open myself to caring for those from whom most of society turns away?"

We learn from one another's stories. First, learn from your classmates, friends, and neighbors who are courageous enough to tell you their own experiences of living in poverty. Ask them and listen intently. Then, let your clients teach you. One honor that nurses have is the opportunity to work with people from all walks of life. During your clinical experiences in community health, you are particularly likely to meet impoverished, vulnerable individuals and families living outside the mainstream. And you can join with them to empower them by helping to build skills and confidence and connecting them to resources. See From the Case Files V about experiences of students through the eyes of their professors.

From the Case Files V

Examples from Community Health Nursing Instructors

- Ann, a nursing faculty member at a small Roman Catholic college, had a one-to-one postclinical conference with a student and relays this conversation. The student had made many visits to an African American teen mother of two thriving children. The young mother lived in a dangerous housing project, and, although she locked him out of her second-floor apartment, her abusive boyfriend had been known to climb up the drainage pipe and over the porch roof. Sometimes, he forced open a window and beat her. The mother worked every day at a fast-food establishment; her grandmother took care of the children. After a couple of months of weekly visits, the student exclaimed, "When I read her chart, I saw her as an immoral girl—a slut—and I expected her to be a loser. Now, I can't believe what I've learned about how strong she is. She just keeps fighting for herself and for her kids to survive! She's a great mom and I told her so!"
- Another faculty member, Sharon, who taught community health nursing in a Midwestern school of nursing was having an informal discussion with a student who related her experience of trying to get comfortable making home visits with low-income young women. She was making brave attempts at home visits to a pregnant woman, about her age, living in the deteriorating outskirts of a major city. She thought she had established rapport and was making headway developing trust with the client. One day, the client asked the student, with concern in her voice, if she had "broken off her engagement." The flustered student then had difficulty explaining the absence of her engagement ring, which she had never mentioned, but the client had obviously noticed. During the previous week, she had suddenly realized she was wearing this special ring in marginal neighborhoods and thought it best to leave it at home. Of course, she thought that she had to fabricate another reason to tell the client but felt badly for being so judgmental when the client was identifying with the student and believed they had something in common.
- Lynn, a new public health nursing faculty member from a large state university in the West, was shocked and repulsed by the comment of one of her students during lecture one day. When discussing vulnerable populations in urban centers and rural areas, the point was made that poverty can be a generational phenomenon and that many of our clients may find it difficult to dig out of this circumstance. Social justice was discussed, along with the need for PHNs to become social activists in order to change political and socioeconomic

factors that keep the status quo. One student, a Hispanic female from a middle-class family, spoke up stating "they should all get jobs at McDonalds." This spurred further discussion about population-focused versus individual-focused interventions and approaches and the need for all of us to be aware of our prejudices and stereotypical viewpoints.

Improving Access

Even with ACA and government-sponsored health insurance and services, extensive barriers prevent many people from accessing services. The community health nurse serves as an advocate and bridge for families who need to gain access. Barriers to access associated with the clients themselves include reluctance to seek coverage because of feelings of powerlessness; being unaware that such services exist or are worthwhile; lacking resources such as a telephone, transportation, or fare for children who need to go along because no babysitter is available; being illiterate; and preoccupation with meeting survival needs and competing life priorities instead of health needs.

Barriers associated with applying for health insurance include a system that is unfriendly and complicated. Paperwork is overwhelming and may be returned for correction; presentation of paid utility bills or other statements that are not often saved may be required. Informative materials may be too difficult to understand; programs may seek to restrict enrollments by restricting information. The process may require a car, a phone, and appointments at inconvenient times. Also, service interruptions are not uncommon, as wages vary over time. Wait times for reinstatement may be long. The nurse can intervene as a coach and guide, interpreting the system to the client and the client to the system. Likewise, nurses can serve as change agents to improve the system whenever possible.

Strengthening Communities

We are all connected. All of us as citizens have a stake in preventing the adverse hardships of poverty and ill health. All of society pays to support community members that do not contribute, to house those who are incarcerated, and to ignore the vulnerable. This weakens us. We fear crime in our homes, schools, businesses, and communities in general. Society, as a whole, is impacted when adults are incapable of providing nurturing environments for their children. And the alienation of many groups in society erodes our sense of community as a nation.

The common good is enhanced by strengthening community resources, including investing in people of historically low status, developing and strengthening ties within families and among people involved in neighborhood mutual support, and redeveloping neighborhood resources (Latkin, German, Vlahov, & Galea, 2013; see Chapter 13). Whenever possible, the PHN voices support of economic redevelopment of neighborhoods to enhance schools, housing, and employment. The nurse can also work to promote

subsidized carpools, school-to- work transition programs, and inner-city economic development programs. Reflecting community priorities and needs as well as focusing on population health are two examples of cornerstones of public health nursing (Keller et al., 2011).

Many caution well-intentioned professionals to beware when seeking solutions to vulnerability through the use of service programs alone. For instance, a whole population of people can become defined in terms of their problems instead of their strengths. In addition, citizens acting to help themselves within their community can be weakened when they are seen as clients requiring professional services. Also, being dependent on multiple human services often has a disabling effect, reducing self-worth, and leads to feelings of powerlessness.

Because human service interventions can have negative as well as positive effects, it is important to consider whether more community agencies are the answer to resolving community hardship. Community health planning should seriously consider an organizing process that builds community and that focuses on developing neighborhood competence to solve problems and create solutions for itself (see the discussion of community development in Chapter 15).

SOCIAL JUSTICE AND PUBLIC HEALTH NURSING

Justice is concerned with treating people fairly. *Distributive justice* refers to the justified distribution of burdens and benefits throughout society (see Chapter 4 for a discussion of distributive justice). In the United States, the marketplace largely determines the distribution of goods and services. Although equality is claimed as a social ideal, dramatic inequities are accepted as being determined by the law of the marketplace. In contrast, community health nursing is grounded in commitment to a just distribution of primary goods for all members of society (Falk-Raphael & Betker, 2012). The founder of American public health nursing, Lillian Wald (1915/1971), was in the forefront of social reform movements emphasizing just allocation of resources for the immigrant and poor laborer. At the start of the 21st century, PHNs have inherited her legacy but are we living up to it?

Social justice occurs when a society provides for the overall health and well-being of all people by treating people fairly. It involves an equal societal bearing of burdens and reaping of benefits, and it is a widely held view that social justice is the foundation of public health nursing (Drevdahl, 2013). Community health nurses who practice social justice have broad and holistic views of health; they have strong convictions that health care is a basic human right and that improving the health of communities is an example of social justice. For instance, PHNs concerned with social justice will include socially marginalized and vulnerable populations (e.g., prisoners, undocumented aliens) in their influenza pandemic planning processes. Not to do so would constitute discrimination and would be morally indefensible (Rosoff & DeCamp, 2011). Social justice ensures the distribution of resources that benefits marginalized populations and holds in check the self-interest of more privileged populations. Impartiality is the goal.

PHNs must have a heightened sense of the value of cultural, racial, and socioeconomic differences and awareness that these differences are often turned into discrimination in health care services and policies. They must be determined to extend the bonds of community so that everyone has a firm place to stand and is equally entitled to health care services with a high standard of care for all.

Where is nursing's role within the concept of social justice? Social justice can be both an individual- and a population-based concept, but it is through the population lens that PHNs must focus their greatest attention. Urban health nursing directs its practice to the systems and community- or population-based level, at which both political and economic solutions must be considered. Although most nurses in urban settings continue to provide service on the individual level, nurses should step back and analyze their practice and synthesize recommendations for a plan of action at the level of community planning to better address the needs of the city or neighborhood (Kulbok, Thatcher, Park, & Meszaros, 2012).

Therefore, although day-to-day practice usually includes individual services, the overall planning for change and improvement must occur from the perspective of the population level. From this level of practice, the construct of *person* incorporates the population level of aggregates, institutions, communities, states, and nations—not solely the individual. The concept of the *environment* at the individual level is often associated with physical and psychosocial influences. With a population focus, it incorporates economic and political structures that can influence health or illness and addresses community and global systems that must be utilized to initiate change and solutions.

Like the other constructs, *health* is expanded to include a population focus that recognizes sociopolitical influences. By acknowledging the health issues encountered at the individual as well as the population level, the urban nurse can incorporate interventions that address the more dynamic societal level. In order to combine critical caring theory with public health nursing practice, PHNs contribute to creating "supportive and sustainable physical, social, political, and economic environments" (Falk-Raphael & Betker, 2012, para. 1).

Nursing practice requires cultural and racial competence in order to advocate for the diverse communities served by nursing. The standards of practice for culturally competent care are based on the framework of social justice. It is through the application of social justice and culturally competent care that inequalities in health outcomes may be decreased (Douglas et al., 2011). This should lead to an enhancement of the practice and research needed to contribute solutions for addressing health disparities in all settings.

The urban nursing profession must focus, much like public health nursing, on including both primary and secondary prevention—not only at the local or community level but also include the state, national, and international levels—to enact change for the common good. The role of advocate in these practice settings must include not only the individual level but also the community or population and systems levels. Examples of such actions would include advocating for adequate funding of government health systems, such as Medicare and Medicaid, and helping to ensure that all communities are safe and healthy environments in which to live and work. To connect all populations to fair and just, systems requires that health care is accessible, affordable, available, and sustainable and that it is distributed both impartially and equitably, without any regard to personal advantage. Good health not only should belong to those who are blessed with the means of paying for health care, education, and safe working environments but should be a benefit for all of us living together on this planet.

SUMMARY

Rural clients are a unique aggregate. Community health nurses are key to ensuring the delivery of appropriate health services to this population. There are numerous definitions of the term *rural*. In this chapter, rural is defined as communities with fewer than 10,000 residents and a county population density of fewer than 1,000 people per square mile. Between the 2000 and 2010 censuses, urban population growth was about twice than in rural areas. The elderly are a rapidly growing population in rural communities. Rural areas often have less diversity than urban cities, but that is changing in many areas. Rural clients generally have lower educational levels than urban clients, due in part to less access to higher education and lower-paying jobs. Income levels and housing costs are frequently lower than in larger cities.

Rural Healthy People 2020 initiative identifies national goals applicable to rural communities. Many at-risk populations live in these communities, where there are often fewer employment opportunities, a lack of adequate housing, and limited access to health and social services. Rural elders may have more limited alternatives for housing if they can no longer live alone. Mental health services are inadequate, even though the need may be great. Numerous risks are associated with agriculture. The community health nurse can help this population identify hazards and practice injury prevention.

A PHN needs to engage in community assessment of the rural area as a part of orientation. It is helpful to identify the strengths of the community. Rural clients are frequently resourceful and often have a supportive network of people to meet their needs.

Access to health care is an important issue in rural communities. Health insurance may not be easily available, but some progress has been made through the Affordable Care Act. Barriers to access include distance, weather, transportation, and limited choice of providers. Some ways to improve access in these communities are school-based clinics, mobile health vans, faith-based nursing initiatives, and use of the latest technologies. University-sponsored nursing centers that could serve rural populations should be expanded.

Migrant farmworkers are an integral part of the farming community in the United States and across the world; however, they are rarely visible members of our society. As members of a community with varied and profound health needs complicated by disease, social isolation, and occupational hazards such as pesticide exposure and working with dangerous farm equipment, they also endure substandard housing and poor sanitation, and migrant farmworkers and their families often live in high-risk environments. Migrant children are often educationally, socially, and physically disadvantaged. Because migrant health centers do not adequately meet the health needs of the entire migrant community, several innovative methods of health care delivery have been developed and implemented by community health nurses, including mobile health vans and information tracking systems.

Rural PHNs are key members of the professional community. Their roles include advocate, coordinator/case manager, health teacher, referral agent, mentor, change agent/researcher, collaborator, and activist. Community health nurses have challenges and opportunities related to their clinical practices. Confidentiality and personal/professional boundary issues may exist. Salaries for rural nurses may be lower than for nurses in urban areas. But rural community health nurses are highly respected individuals who make a difference in the communities they serve.

Urban health issues have existed for hundreds of years in the United States, and they continue today. Many disenfranchised and minority groups call inner cities home. Air pollution, poverty, discrimination, substandard housing, crime, substance abuse, and social disorganization often characterize life in urban settings. The built environment is an important consideration in urban as well as rural settings and can contribute to greater health risks. Some large cities have had marked decreases in population and significant problems with unemployment, although more people around the world live in urban areas now than in rural areas.

Although nursing services may often be delivered at the individual level, the true impact on health must be addressed at the community or population level, as well as the system level. Key to recognizing the potential impact for improvement in existing health disparities is the acceptance of a social justice orientation that will empower nurses to address the required changes needed within the existing social, political, and economic systems.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Search for six recent articles in both rural and urban newspapers relating to access to health care or quality of care. After summarizing the content, identify barriers to access that are common to both, and those that are different. What are the main themes relating to health and access to care?
2. Discuss with your clinical group the common characteristics of rural, migrant, and urban clients. How can the PHN be better prepared to meet their unique needs? What are some specific challenges facing the PHN working in a rural area? In an urban area?
3. Describe some of the benefits of rural public health nursing. Do the same for urban public health nursing.
4. Compare and contrast health, living, and working concerns between migrant workers and recent immigrants. Discuss how many recent immigrants from places such as Asia, Russia, or the Middle East experience the same hardships as migrant workers do. How does a nomadic lifestyle affect and differentiate the needs of migrant workers and recent immigrants?
5. If you are from a rural area, interview a peer who was raised in an urban setting (or vice versa). Compare your experiences with family, school, friends, entertainment, etc.
6. Search the Internet for examples of community needs assessment from both rural and urban areas. What are the main findings of each? How do planned interventions differ? How are they similar?
7. Debate with a classmate the need for ready access to specialist medical care and sophisticated diagnostic equipment in all communities. Is this feasible? If not, how can services best be made available to urban and rural clients?
8. Search YouTube for videos related to rural public health nursing, migrant workers, urban health, social justice, or other topics described in this chapter. Discuss key points with your clinical group and highlight the major issues.

8 UNIT

SETTINGS FOR COMMUNITY HEALTH NURSING

30 CHAPTER

Public Settings for Community Health Nursing

"A [community nurse] must first nurse. She must be of yet higher class and yet of fuller training than that of a hospital nurse because she has no hospital appliances at hand at all and because she has to take notes on the case for the doctor who has no one but her to report to him."

—*Florence Nightingale*, 1876 (as cited in Edgecomb, 2001)

KEY TERMS

Block grant funding
Correctional nurses
Indian Health Services (IHS)
Individualized education plans (IEPs)
Individualized health plans (IHPs)
Local health departments (LHDs)
Public health nurse (PHN)
School nurse
School nurse practitioners
School-based health centers (SBHCs)
Section 504 plans
U.S. Public Health Service Commissioned Corps

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Explain the focus of the nursing process and how public health nurses (PHNs) and other nurses working in the publicly funded sector use it to provide care in their communities.
- Describe how federal, state, and local public health infrastructures influence the population's health.
- Evaluate the potential benefits of school-based health centers (SBHCs) and discuss possible parental or community objections.
- Compare and contrast common roles and functions of PHNs, school nurses, and correctional nurses.

Many nursing students are not aware of the vast employment opportunities available outside the hospital in publicly funded settings. This chapter discusses several of these publicly funded health settings and the opportunities nurses can garner, particularly in services such as public health nursing, school nursing, or correctional nursing. This chapter is a practical explanation of the work of these nurses in the public sector.

Although each of these nursing opportunities differs greatly, they have several

characteristics in common. First, community nurses who work in a setting supported through public funds (e.g., taxpayer-funded) still use the nursing process, but their client is a population or group of people, rather than an individual. Second, emphasis is placed on prevention of disease or disability. Third, community nurses employed in publicly funded settings work with a variety of people, usually vulnerable populations. They must be able to network and collaborate with other agencies and disciplines. For example, a nurse working in a correctional facility often collaborates with mental health workers and correctional officers. A nurse working in the public setting has many opportunities to be an advocate for individuals and the community and may serve on regional task forces or advisory boards. In addition, PHNs focus on population-based care. Nurses may perform individual care, especially correctional nurses; however, most of the focus is placed on the population as client. Finally, nurses who work in the public setting must be autonomous, flexible, creative thinkers who are self-directed and able to prioritize and use the nursing process to make educated decisions and plan care for their respective populations. Nurses who work in public settings must have the highest level of nursing, communication, problem-solving, and intellectual skills.

Nurses working in the public sector generally need to be very self-directed, autonomous, and creative thinkers.

PUBLIC HEALTH NURSING

A public health nurse (PHN) is a nurse who works to promote and protect the health of an entire population (American Nurses Association [ANA], 2013a). The 2012 data specify the highest enumeration estimate of 516,193 workers comprising the U.S. public health workforce (University of Michigan Center of Excellence in Public Health Workforce Studies, 2013). This workforce consists of epidemiologists, nurses, environmentalists, laboratory professionals, nutritionists, dental workers, social workers, and other health care providers.

Looking at public health from a nursing perspective, approximately 7.8% of all registered nurses (RNs) work in public/community health settings (Health Resources and Services Administration [HRSA], 2010). Public or community agencies are the third largest employer of RNs, after hospitals (employing 62.2% of nurses) and ambulatory care (employing 10.5% of nurses). However, with the struggle to find adequate access to health care, along with its increased costs, more nursing care is being performed in a public or community setting. Unfortunately, you may not know of these wonderful employment opportunities available in the public sector. This section describes the role and opportunities for RNs at the local, state, and federal levels of government. The focus will be on governmental agencies, because these agencies employ the majority of PHNs.

Education

The ANA (2013b) recommends that an entry-level PHN should have a bachelor's degree in nursing. This is important because baccalaureate programs provide additional training in public health and leadership. Some states, such as California, require nurses to take additional classes and obtain certification beyond a bachelor's degree if the BSN program does not offer specific content (e.g., child abuse, public health didactic, and practicum). PHNs working with specific populations, or in administration, should hold a master's degree. A PHN with a master's degree in community/public health nursing may take a national certification examination offered by the American Nurses Credentialing Center (2015). Many, but not all, master's programs offer dual nursing and public health degrees. The emphasis on national certification is due to an ever-increasing need to keep the population protected from health threats, such as bioterrorism (especially after September 11, 2001), emerging diseases (e.g., pandemic flu), or natural disasters (e.g., hurricanes, earthquakes).

Key Functions of the PHN in the Public Setting

Public health nursing practice consists of many areas of expertise, including:

- Focusing on the health of populations
- Reflecting the needs and priorities of the community
- Requiring caring relationships with individuals, families, communities, and systems
- Being grounded in cultural sensitivity, compassion, social justice, and a belief in the worth of all people (e.g., vulnerable populations)
- Encompassing all aspects of health (e.g., physical, emotional, mental, social, spiritual, and environmental)
- Using strategies to promote health that are motivated by epidemiologic evidence
- Involving individual, as well as collaborative, strategies to achieve results
- Knowing that Nurse Practice Act provides authority for independent action (Keller, Strohschein, & Schaffer, 2011)

In brief, the role of the PHN is to focus on the health of the public. PHNs combine their nursing and clinical knowledge of disease and the human response to it, along with public health skills, in order to accomplish their goals (ANA (2013b); Swider, Krothe, Reyes, & Cravetz, 2013). They apply the nursing process, not only with individuals but also with populations. PHNs are a critical link between data tracking (e.g., epidemiology) and clinical understanding of a disease or condition (Kroelinger, Kasenhagen, Barradas, & Ali, 2012; McCulloch & Prieto, 2008). PHNs use the data to prioritize their interventions to stop the spread of diseases, such as measles, and also to intercede with other concerns (e.g., childhood obesity). For example, PHNs may develop a campaign for children to wear bike helmets after an increase of fatal head injuries is noted in their area. A key emphasis of the PHN is prevention, and a key focus is educating and empowering the community. Several other differences exist between PHNs and nursing in general (see Table 30–1 for a comparison). In 2010, the Quad Council (comprised of the Association of Community Health Nurse Educators/ACHNE, the Association of State and Territorial Directors of Nursing/ASTDN, the PHN Section of the American Public Health Association/APHA, and the American Nurses Association's Congress on Nursing Practice and Economics/ANA) developed the Quad Council Competencies for Public Health Nurses as a tool in education and for agencies in orienting new public health nurses (Swider et al., 2013).

Table 30–1 Comparing Public Health and General Nursing

Public Health Nursing	General Nursing
Population based	Individual based
Grounded in social justice	Grounded in a relationship of caring
Focuses on the greater good	Focuses on individual good (patient)
Health promotion and disease prevention	Restoration of health and function
Utilize and organize community resources	Manage resources at hand
Seek out clients in need	Take care of clients who come to them
Commitment to the community as a whole	Commitment to individual patient

Adapted from *Cornerstones of Public Health Nursing* (Minnesota Department of Health, 2007).

PHNs may focus on a population that is a geographic community (e.g., a state or municipality) or a focus group (e.g., adolescents or the elderly) spanning all socioeconomic levels. To accomplish this, PHNs often work with individuals or families at highest risk, and their motive is to improve, protect, and promote the health of the entire population. One of the goals that characterize PHNs, and differentiate their goals from those of other specialty disciplines, is achieving the greatest good for the majority of people (ANA, 2013b). See Chapter 13 for an in-depth discussion of social justice. This requires priority planning and a basic knowledge of the community. It can also create ethical dilemmas for PHNs who may have personal and passionate issues that they would like to pursue, but which may not be the top priority for the majority of community members.

For example, many issues exist in a community. In one community, one child may have been hit by a car while riding his bike without a helmet, while at the same time, in the same community, there may be 10 births to teen moms, 20 instances of drug overdose, and an outbreak of pertussis. The PHNs in that community must prioritize which issue to address first by deciding which issue impacts the most people and what interventions will

help the population thrive (ANA, 2013b). Because each community is different, once all factors are taken into account, the priorities will vary among communities. Hence, *assessment* is a critical component of public health and a key tool for the nurses who work in the public sector (ANA, 2013b; Institute of Medicine [IOM], 1988; Turnock, 2016). See Display 30–1.

DISPLAY 30.1 THREE CORE FUNCTIONS OF PUBLIC HEALTH (IOM, 1988)

1. Assessment
2. Assurance
3. Policy development

Another way public health nursing differs from other areas in nursing is that PHNs must actively seek out and identify potential problems and situations (ANA, 2013b). Nurses who work in a hospital setting address the issues that come to them. If a nurse works in the intensive care unit (ICU) of a hospital, she will work with her assigned patient load. PHNs, on the other hand, are out in the community identifying the problems, not waiting for problems to come to them. For example, PHNs may participate in visits to childcare centers to note any safety hazards, ensure that rules and regulations are being followed, and that children are properly immunized. These visits are part of the priority of *assurance* identified by the IOM (1988) and Turnock (2016), noted in Display 30–1.

PHNs cannot perform all these activities alone. They need to collaborate with other partners and optimally use often limited resources. PHNs are in a unique situation because they work with their populations (i.e., clients) and with others to find the best solutions for a situation or problem. For instance, PHNs may notice an increase in the number of measles cases in their community. They may then work with families to identify where and how the children were exposed to the disease and with local health care providers to provide treatment and vaccinations for those at highest risk of exposure to and damage from measles. PHNs also work with school nurses and other school personnel to exclude from school attendance those children who are not adequately immunized against measles. This helps decrease the spread and potential harm because of measles. PHNs educate a variety of groups, such as parent–teacher associations (PTAs) and city or school officials, as to how measles spreads, what can be done to treat the disease, and the importance of herd

immunity in protecting the public. Education thus empowers each group to be part of the solution. Finally, PHNs can work with public health officials to develop a policy for all new school entrants to receive a second booster of measles vaccine. *Policy development* is the third critical component of public health identified by the IOM (1988) and Turnock (2016). See Display 30–1.

PUBLIC HEALTH FUNDING AND GOVERNMENTAL STRUCTURES

PHNs can work at any and all levels of government. Hence, it is important to understand the organizational structure, communication, and funding streams between the federal, state, and local levels of government (see Chapter 6 for more on the structure of the public health system). At each level, all three branches of the government are involved in public health, although often the legislative and executive branches play the most important roles, and this discussion focuses on these areas.

The legislative branch (meaning Congress, state legislatures, or local councils) mandates laws or policies and decides how much of the funding in its jurisdiction will be appropriated to public health. Much of the work for public health is carried out in the executive branch of government (Fig. 30–1). Because state and local organizations can be set up in a variety of ways, nurses need to contact local health departments (LHDs) for specifics. Public health services are delivered by centralized (28%), decentralized (37%), or combined authority (35%) of local, state, and federal government agencies or nongovernmental organizations (Hyde & Shortell, 2012).

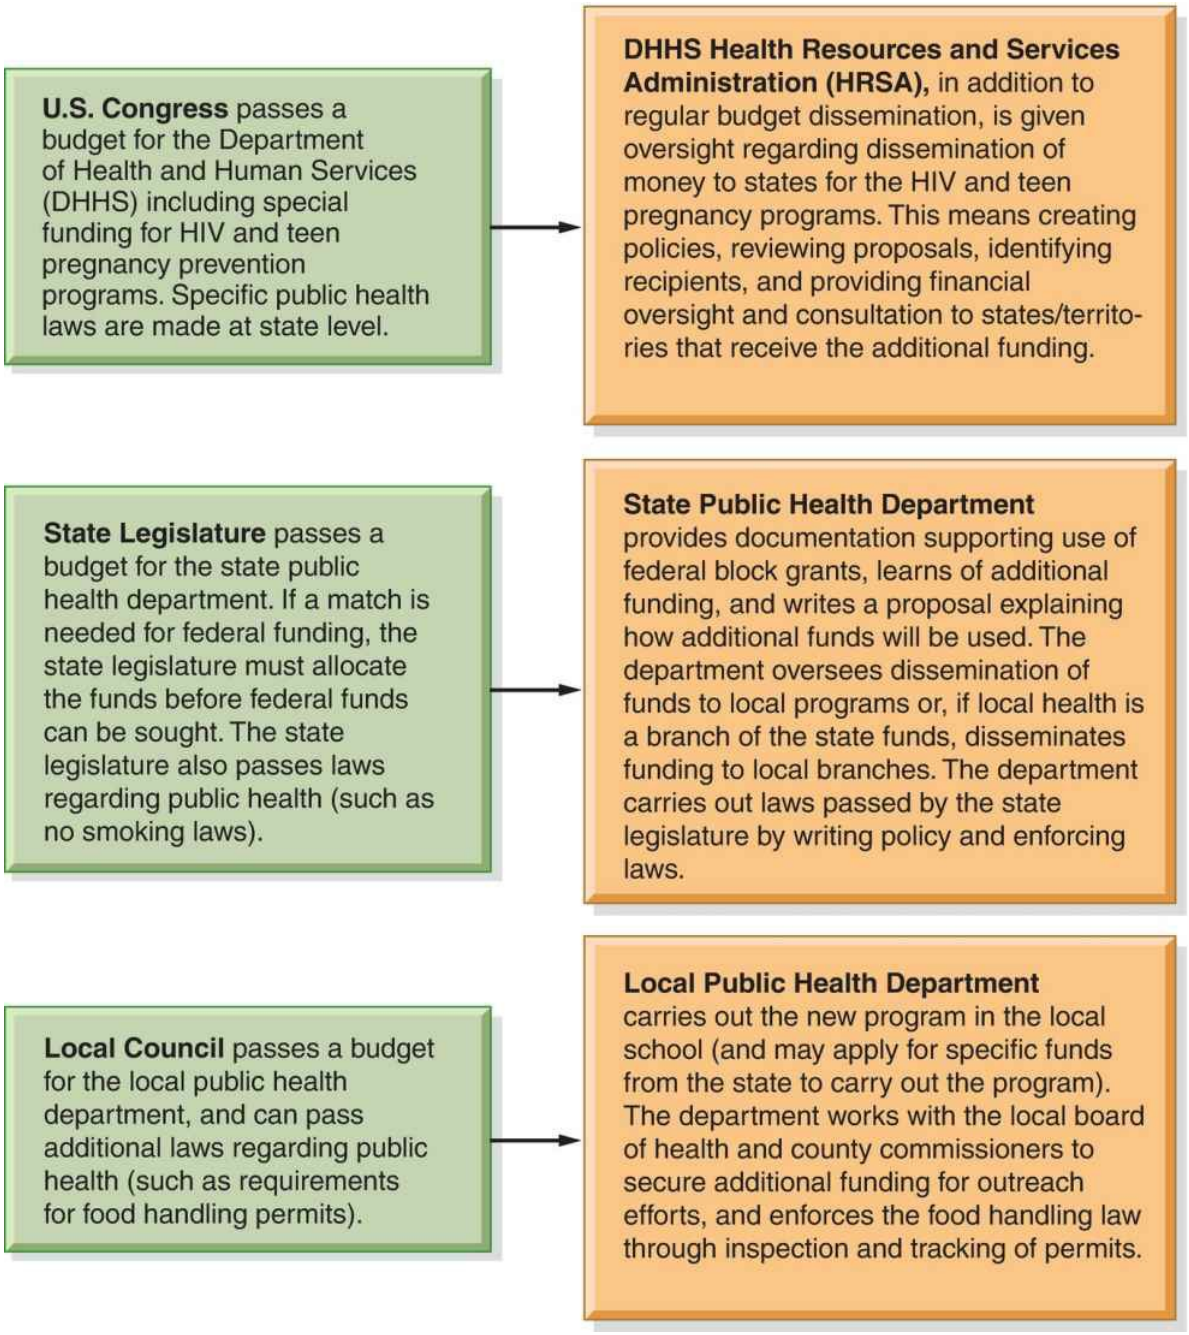

FIGURE 30–1 Examples of government organization in relation to public health.

Federal Agencies

The federal government oversees national policy and funding, provides expertise, and sets a national agenda (Shi & Johnson, 2014). Several federal organizations are part of the executive branch that oversees the health of the nation. The main organization involved with public health is the Department of Health and Human Services (DHHS), which is overseen by the Secretary of Health and Human Services. The Secretary of DHHS is appointed by the President and is a member of the President's cabinet. Within DHHS are many agencies, including eight that specifically impact public health (U.S. Department of Health and Human Services [USDHHS], 2015). Table 30–2 provides additional detail regarding these eight agencies. Other federal agencies that also impact public health include the Environmental Protection Agency (EPA), the Department of Homeland Security, the Department of Agriculture, the Department of Education, and the Department of Veterans Affairs.

Table 30–2 Agencies within Department of Health and Human Services

Agency	Headquarters	Responsibility and Bureaus
Health Resources and Services Administration (HRSA)	Rockville, Maryland	Medically underserved—includes Medicare/Medicaid, HIV/AIDS, maternal and child, health professions, primary health care
Indian Health Services (IHS)	Rockville, Maryland	Provides health services for Native Americans (including Alaskan Natives)
Centers for Disease Control and Prevention (CDC)	Atlanta, Georgia	Health surveillance and prevention of disease and bioterrorism
National Institutes of Health (NIH)	Bethesda, Maryland	Medical research
Food and Drug Administration (FDA)	Rockville, Maryland	Ensures safety of food, medication, medical procedures, and equipment
Substance Abuse and Mental Health Services Administration (SAMHSA)	Rockville, Maryland	Oversees prevention, diagnosis, and treatment for mental health and substance abuse
Agency for Toxic Substances and Disease Registry (ATSDR)	Atlanta, Georgia	Protects public from environmental exposures
Agency for Health Care Research and Quality (AHRQ)	Rockville, Maryland	Includes research on health care quality and effectiveness
Center for Medicaid/Medicare Services (CMS)	Baltimore, Maryland	Provides oversight of the Medicare program, the federal portion of the Medicaid program and State Children's Health Insurance Program, the Health Insurance Marketplace
Agency for Children and Families (ACF)	Washington, District of Columbia	Promotes the economic and social well-being of families, children, individuals, and communities
Administration for Community Living (ACL)	Washington, District of Columbia	Increases access to community support and resources for the unique needs of older Americans and people with disabilities
U.S. Public Health Service Commissioned Corps	Rockville, Maryland	An elite team of 6,500 health care professionals working in several federal agencies protecting, promoting, advancing the health, and well-being of the nation

Turnock, B. J. (2016). Essentials of public health: What it is and how it works (6th ed.). Burlington, MA: Jones & Bartlett Learning.

These various organizations receive funding and directives from the Congress (i.e., the legislative branch of the federal government) as part of the DHHS budget process. It is the prime responsibility of DHHS and other agencies to ensure that legislative mandates are followed, policies carried out, and funds appropriately disseminated. State health entities receive a large portion of funds as part of block grant funding. These funds are lumped together to pay for some general use that states have identified (see Chapter 6 for more detailed information). *Healthy People 2020* and state needs assessments help set priorities for state funding. For example, the maternal and child health (MCH) block grants received by states are then used for reproductive health, child health, and immunizations. States with LHDs also disseminate a portion of these funds to the local level. In addition, state and local tax dollars are used to supplement various programs (Knickman & Kovner, 2015). Thus, the political leanings of state and local officials can strongly influence local health initiatives.

State Agencies

The U.S. Constitution bestows states with the responsibility to safeguard the health of their citizens (Turnock, 2016). Much of public health is overseen at a state level. However, the structure of where public health fits into the executive branch of state government varies. More than half of the states have an independent state-level public health agency; another third of the states are part of a "super agency" that may include human services and other state programs (Madamala, Sellers, Beitsch, Pearsol, & Jarris, 2011; Shi & Johnson, 2014). The governor appoints a commissioner, or leading health official, to oversee public health and serve as a member of the governor's cabinet. These cabinet members are usually medical doctors, appointed by the governor. In recent years, state directors have also included social workers (e.g., Michigan) and public health professionals (e.g., Arkansas). In 2007, Governor Phil Bredesen appointed Susan Cooper, RN, MSN, as the first nurse to serve as public health commissioner for the state of Tennessee. The first nurses appointed to director of state offices of public health were Barbara Sabol and Gloria Smith in the states of Kansas and Michigan (Feldman, 2012).

The purpose of state agencies is to carry forth regulations and policies determined by the federal government. Examples of these programs are the Medicaid, Medicare, and State Children's Health Insurance Programs (SCHIPs). Many of these programs may have specific federal requirements, but they also allow states the ability to personalize the programs to fit the state's individual needs. An example of such a program is the MCH block grant, which provides funding and guidelines for the states. However, states determine which programs (e.g., reproductive health or children's health) will be funded and how they will be implemented. See Chapter 21.

Another example of federal leadership is the *Healthy People 2020* document that provides goals for a variety of health outcomes. States can use these outcomes, or develop additional performance measures, according to state characteristics and needs. In addition, the state agency is influenced by the state legislative body, which oversees the state budget and can pass laws specific to the state. Each state is different because of varying needs, cultures, and political environments. Examples of public health laws at a state level include immunization requirements for school entrance, seat belt safety laws, and regulations regarding parental rights concerning birth control and abortion services for teens. Other health policies that influence public health include laws to quarantine persons with communicable diseases, especially during times of outbreaks. State laws must be in place outlining legal jurisdiction of containing and reporting communicable disease; such laws often need to be updated as new threats occur. This was recently exemplified during the early 2000s when smallpox became a bioterrorist threat. State laws allowing persons to be quarantined for smallpox had expired, and new laws had to be passed in order to prepare for potential outbreaks. Without these laws in place, public health officials and law enforcement do not have the power and authority required to maintain the health of the public (Turnock, 2016).

Local Public Health

Local health departments (LHDs) carry out state laws and policies (Turnock, 2016). They provide the most direct, immediate care of the population (Shi & Johnson, 2014). For example, they may provide immunization clinics, track and treat cases of tuberculosis (TB) and other communicable diseases, and provide education on a variety of subjects (e.g., HIV/AIDS, smoking cessation). They often carry out programs with funding from federal and state agencies. For instance, federal funding to address asthma may be obtained through the state agency, and local agencies may organize an educational program on asthma triggers in a local business where many community members work. State and local agencies do not work alone in such endeavors, however. Collaboration is very important in addressing the public health needs of a community. Public health agencies work with private organizations, hospitals, nonprofit groups, universities, and government agencies that oversee food and housing to meet citizens' needs.

LHDs work with state health departments, some independently and some as dependent branches of the state agency. The size and services offered by a local agency also differ depending on state laws, structure, and wealth (Turnock, 2016). A total of 61% of LDHs serve communities of 50,000 or less population. Most (68%) are county agencies, but 20% are city or town agencies. Almost 77% of LHDs are locally governed, most often a local board of health. The majority of LHDs collaborate with other community agencies: 67% on emergency preparedness and 47% on community assessment/planning. Over 60% of LHDs in the United States have fewer than 25 employees. Along with clerical/administration personnel, registered nurses are the most common occupation found in LHDs at 96%. The number of LHDs per state can vary dramatically. For example, Delaware has only 2 LHDs, California has 61, and Massachusetts has the most with 329 (NACCHO, 2014). Nearly all LHDs (96%) employ nurses, who make up 19% of the total public health workforce at the local level (NACCHO, 2014).

NURSING ROLES IN LOCAL, STATE, AND FEDERAL PUBLIC HEALTH POSITIONS

Nurses can work in a variety of capacities at the various levels of government, which may cover most aspects of public health (Shi & Johnson, 2014; Turnock, 2016). Generally speaking, nurses who work at the local level of public health tend to provide direct service care. For example, they often administer immunizations, monitor patients with TB, provide education to school groups, provide cancer screenings, and track communicable disease rates. Local PHNs are the eyes and ears of their communities. Many PHNs working at the local level, especially in rural or small public health departments, may have a variety of responsibilities. For instance, a PHN may be a full-time employee whose time could be split into 50% cancer screening; 25% with the Women, Infants, and Children (WIC) program; and 25% on Medicaid outreach (see Display 30–2 for an example of a PHN's day). PHNs also serve in administrative roles within agencies, as well, where they may oversee an entire bureau or program, for example, or serve as supervisors for a group of PHNs (Kulbok, Thatcher, Park, & Meszaros, 2012).

DISPLAY 30.2 A TYPICAL DAY IN THE LIFE OF A PUBLIC HEALTH NURSE

8:00 AM Staff reproductive health clinic. Provide counseling regarding family planning services, as well as breast and other cancer screenings.

10:30 AM Make a home visit to a mother and baby who is not thriving. Conduct an examination of the baby and assess the living situation. Assist the mother regarding breast-feeding, nutrition, newborn care, and parenting.

12:30 PM Attend a lunch meeting of a newly formed coalition that is concerned about the increased rate of teen pregnancy in the city. Provide community statistics as well as firsthand knowledge of teens participating in the Women, Infants, and Children (WIC) program and the Nurse-Family Partnership home visiting program. Offer information on how to approach the problem.

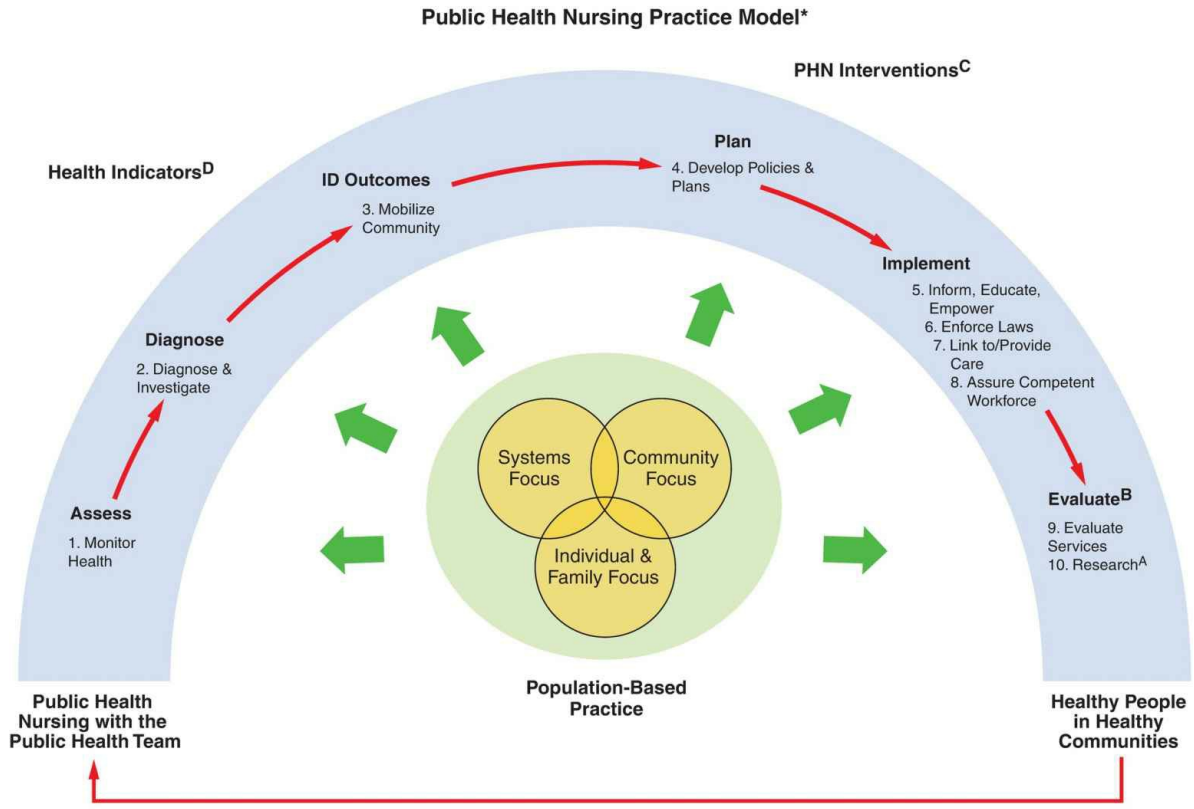
1:15 PM Respond to phone messages from local school nurses about possible round worm infection of preschoolers in one local school.

2:00 PM Investigate the case of a third grader who has TB. With the help of the school nurse, check immunization records of other students and staff. Contact the

family to learn who else is exposed and at risk. Provide proper testing and education regarding the signs and symptoms of TB, the need for regular testing, and following the treatment regimen.

3:30 PM Staff cancer screening clinic performing Pap smears and providing counseling to women regarding risks of breast and cervical cancer. Follow up with patients from last week's clinic whose results were questionable.

4:45 PM Call environmental health sanitarian to discuss possible water system contamination at a farm labor camp and arrange for testing and follow-up.



5:00 PM Finish paperwork and head home.

Public health nurses working for local health departments are the eyes and ears of their communities.

Within each of the governmental agencies, programs may be arranged according to a particular subject area. For example, a PHN may work in the cardiovascular disease program, overseeing cholesterol screenings and promoting physical health and nutrition. A PHN could also work in epidemiology, tracking diseases, or be part of a community emergency response team to prepare for a natural or manmade disaster. A PHN could also work in the immunization program, promoting and tracking the immunization requirements of school-age children. The nurse may also be in charge of day care licensure requirements, traveling throughout the state and conducting inspections or writing policies. Or, the nurse could oversee a program to decrease sudden infant death syndrome (SIDS) in

the state and track SIDS-related deaths. Thus, the variety of locations and programs are limitless for PHNs (Swider, Levin, & Kulbok, 2014). The following is a brief overview of some of the main roles of nurses working at state health department and LHD. Specific options and means by which PHNs serve as advocates and change agents to protect and promote the health of all are discussed, using the nursing process as an outline. Figure 30–2 provides a practical model of how PHNs use the nursing model and public health principles in their everyday functions.

FIGURE 30–2 Public health nursing model from Los Angeles County.

Assess

An assessment of the situation is key to any nursing care. PHNs assess the situation in a variety of ways. They observe a great deal when they are in the community and when they conduct home visits. They also assess data to identify trends. Often, nurses work with other public health personnel when assessing and tracking data, although nurses may serve as specialists in epidemiology. For example, PHNs can use morbidity and mortality statistics to determine the leading causes of death nationally and locally. They can assess communicable disease rates to identify an outbreak before it becomes too widespread. They track how many people in the community are in compliance with immunizations to keep the herd immunity high and decrease the chance of outbreaks. PHNs use census data to determine population growth. As an example, global reports indicate that the number of individuals aged 60 years or older will grow from 841 million in 2013 to over 2 billion worldwide by 2050. Estimates indicate that in 2050, approximately 21.1% of the world's population will be over the age of 60 (United Nations, 2013). This is important in planning for future activities and resources. PHNs also use prevalence data to determine which ethnic groups are at higher risk than others. For example, PHNs at a county health department notice increased cases of TB. Upon further investigation, they learned that the greatest increases were within the immigrant Hispanic population. By using data and conducting an assessment, they were able to successfully target interventions for this population (Community Tool Box, 2016). See Chapters 12 and 15.

Environmental risks are important to the public's health and are often assessed by nurses. For example, a PHN conducting blood tests noticed that students living in a mining community had elevated blood lead levels. This assessment information forms the basis for the nurse's intervention. Each nurse must assess his or her own community, because each has specific characteristics and needs. A community positioned next to a factory that emits fumes will have different issues than a rural community 90 miles away from any industry. At the same time, an outbreak of *Escherichia coli* in one town may identify a risk to the PHN in the neighboring town. See Chapter 9.

Diagnose

Assessment is key to diagnosing a situation or problem. For a PHN, diagnosis also includes identifying priorities for the many concurrent issues. Nurses who work in public settings may perform skin tests or simple blood work in public clinics to determine TB exposure, or risk of high blood pressure, or other conditions (see From the Case Files I). Other nurses utilize microscopes to identify cases of vaginitis and cervicitis. This could all occur on the same day.

From the Case Files I

Tuberculosis (TB) Exposure (Compare Your Local Response With That Outlined Here)

As a public health nurse (PHN), you are alerted to a person who has an active TB case. He present into the health department for a chest x-ray after he failed his tuberculin skin test. The person has recently arrived by plane from another state. He stayed for a few weeks with family members in a small house but now lives with friends in a small apartment. When talking to the patient, you note that he coughs often and does not cover his mouth.

- As a PHN, what steps would you take to determine exposure?
- How will you determine who was exposed and will need to be tested?
- What questions can you ask to help determine when and how the patient was exposed to TB?
- What type of education will you provide to him?
- How can you ensure that the patient is compliant with medication treatment?
- Imagine that you are the school nurse of the patient's 8-year-old daughter who has also tested positive. What steps would you take?
- What would you do differently if you were a correctional nurse and the patient was an inmate?
- What are the ethical and legal issues related to TB?

See example of a PHN caring for a new TB client in Chapter 29.

As nurses diagnose individual needs, they apply this information and watch for increased or decreased rates (e.g., of disease or injury) among the population. For instance, a nurse working in a public health clinic may notice an increase in the number of people diagnosed with diabetes. The nurse further assesses the situation to determine if it is a population need and also the degree of the problem. Another PHN may assist with newborn genetic testing. Nurses are in the perfect position to identify issues and trends early on. As more is known regarding genetic trends, the PHN can use this information to advocate policies and laws that will impact a particular population (Community Tool Box, 2016).

Constant assessment and diagnosis are tools by which PHNs identify critical situations and prioritize issues that must be addressed first. Several documents have helped PHNs prioritize issues. *Healthy People 2020*, a guide to identifying many of the nation's top priorities, is a valuable tool (USDHHS, 2016). See Display 30–3. Public health performance standards also assist nurses in prioritizing needs (Centers for Disease Control and Prevention [CDC], 2015f); Swider et al., 2013). The IOM (2015) has also identified a need for a greater focus on informatics and genomics in improving patient care and health

research.

DISPLAY 30.3 HEALTHY PEOPLE 2020—PUBLIC HEALTH PRIORITIES

Healthy People 2020: Public Health

Healthy People 2020 provides the direction and goals for all public health nurses (PHNs). *Healthy People 2020* is used to guide prioritizing activities for PHNs. Specifically, PHNs focus on the ten leading indicators, which include:

- Access to health services
- Clinical preventive services
- Environmental quality
- Injury and violence
- Maternal, infant, and child health
- Mental health
- Nutrition, physical activity, and obesity
- Oral health
- Reproductive and sexual health
- Social determinants
- Substance abuse
- Tobacco

Healthy People 2020: Educational and Community-Based Programs (School Nursing)

One objective directly relates to school nurse staffing:

ECBP-2	Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS), and sexually transmitted disease (STD) infection; unhealthy dietary patterns; and inadequate physical activity
ECBP-4	Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: handwashing or hand hygiene, oral health, growth and development, sun safety and skin cancer prevention, benefits of rest and sleep, ways to prevent vision and hearing loss, and the importance of health screenings and checkups
	Healthy People 2020: Adolescent Health
AH-6	Increase the proportion of schools with a school breakfast program

Other objectives that school nurses can use to help prioritize activities include:

Healthy People 2020: Disability and Health

DH-5	Increase the proportion of youth with special health care needs whose health care provider has discussed transition planning from pediatric to adult health care
DH-14	Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs

Healthy People 2020: Environmental Health

EH-16	Increase the proportion of the nation's elementary, middle, and high schools that have official school policies and engage in practices that promote a healthy and safe physical school environment

Healthy People 2020: Family Planning

FP-8	Reduce pregnancy rates among adolescent females
FP-9	Increase the proportion of adolescents aged 17 years and under who have never had sexual intercourse
FP-12	Increase the proportion of adolescents who received formal instruction on reproductive health topics before they were 18 years old

Healthy People 2020: Immunization and Infectious Diseases

IID-10	Maintain vaccination coverage levels for children in kindergarten
IID-11	Increase routine vaccination coverage levels for adolescents
IID-12	Increase the percentage of children and adults who are vaccinated annually against seasonal influenza
IID-18	Increase the proportion of children under 6 years of age whose immunization records are in fully operational, population-based immunization information systems

Healthy People 2020: Injury and Violence Prevention

IVP-27	Increase the proportion of public and private schools that require students to wear appropriate protective gear when engaged in school-sponsored physical activities

Healthy People 2020: Mental Health and Mental Disorders

MHMD-2	Reduce suicide attempts by adolescents
MHMD-3	Reduce the proportion of adolescents who engage in disordered eating behaviors in an attempt to control their weight

Healthy People 2020: Nutrition and Weight Status

NWS-10	Reduce the proportion of children and adolescents who are considered obese

NWS-15	Increase the variety and contribution of vegetables to the diets of the population aged 2 years and older

Healthy People 2020: Oral Health

OH-2	Reduce the proportion of children and adolescents with untreated dental decay

Healthy People 2020: Respiratory Diseases

RD-5	Reduce the proportion of persons with asthma who miss school or work days

Healthy People 2020: Substance Abuse

SA-3	Increase the proportion of adolescents who disapprove of substance abuse

Healthy People 2020: Tobacco Use

TU-2	Reduce tobacco use by adolescents
TU-3	Reduce the initiation of tobacco use among children, adolescents, and young adults

Healthy People 2020: Vision

V-2	Reduce blindness and visual impairment in children and adolescents aged 17 years and under

Healthy People 2020: Correctional Nursing

IID-27	Increase the percentage of persons aware that they have a hepatitis C infection
IID-29	Reduce tuberculosis (TB)
MHMD-7	Increase the proportion of juvenile residential facilities that screen admissions for mental health problems

MHMD-10	Increase the proportion of persons with co-occurring substance abuse and mental disorders who receive treatment for both disorders
SA-8	Increase the proportion of persons who need alcohol and/or illicit drug treatment and received specialty treatment for abuse or dependence in the past year
TU-13	Establish laws in states, District of Columbia, territories, and tribes on smoke-free indoor air that prohibit smoking in public places and worksites (13.13 correctional facilities)

Improved medical technology has supplied immunizations that have decreased the rates of many communicable diseases. This led to the emergence of new issues and priorities for PHNs, specifically, injury prevention and the management of chronic diseases (Madamala et al., 2011). World events have also placed additional emphasis on public health roles,

including the global spread of TB, bioterrorism, pandemic influenza, and natural disasters (Madamala et al., 2011). Because of their nursing and epidemiologic skill, PHNs serve as critical members of emergency preparedness and response teams (Association of Public Health Nurses, 2014). The nursing and epidemiologic skills they use when tracking outbreaks of communicable diseases, such as TB, are easily transferable to the communicable agents of bioterrorism (e.g., smallpox, anthrax).

Plan and Implement

Once PHNs have diagnosed and prioritized the needs of their community, they develop and carryout plans to address those needs. Development of care plans is an important function for nurses. Many interventions require collaborating and working with other agencies. Education is also a key to many public health nursing interventions. However, education alone will not change behavior; thus, it is important to address the issue from many different angles, as well as at different levels. PHNs cannot solve all issues, but they can serve as advocates to influence those who can make the changes (Swider et al., 2013). The interventions are endless, but here are a few examples:

- Nurses conduct home visits to mothers at risk. They conduct family assessments to determine the level of psychological issues and education needed by the family regarding specific needs, such as responses to medication. They also help mothers receive needed psychological counseling by linking them to a local mental health agency.
- A community nurse working in risk management develops and teaches an education program about workplace safety and ergonomics. She develops policies regarding shift hours and heavy lifting.
- A school nurse serves as an advocate for a program that will assist children with special health care needs attend a clinic closer to home.
- A PHN develops a campaign for social media sites (e.g., Twitter, Facebook), television, radio, and local newspapers regarding the need to receive a flu shot. The nurse also includes incentives that target the elderly community who are at additional risk for developing complications from this illness.
- The community health nurse organizes a health clinic at local shelters providing foot care and screenings for blood pressure, diabetes, TB, and cholesterol, as appropriate.
- The school nurse works with schools to educate teens regarding birth control and the impact of teen pregnancy. She includes counseling regarding STDs. She works with the community to ensure that a variety of teen-focused activities are available for this population.
- The community outreach nurse conducts home visits to new mothers who need assistance with breast-feeding and newborn care. The nurse also contacts the housing authority to report hazardous conditions in the housing project she has visited.
- The PHN helps identify resources for families without insurance to ensure that well-child and adult screenings are performed regularly in order to reduce health care costs associated with illness.
- The school nurse organizes an immunization clinic at the local school after an outbreak of measles. The nurse also conducts classes at the school regarding communicable disease prevention and tobacco cessation.
- The PHN organizes a bicycle fair to educate the community regarding the need for bicycle helmets, in hopes of decreasing head injuries. She also works to develop

public policy related to child car seat/booster seat usage and collaborates with local businesses in providing vouchers for discounts on child restraints for low-income parents.
- The nurse, who is a paid lobbyist, works to change laws regarding e-cigarettes.
- A nurse, who is an elected member of the state legislature, sponsors a bill to increase funding for school nurses.
- After a hepatitis outbreak at a local business, the nurse conducts an assessment of the business and provides education classes, as well as suggesting policy changes to help guard against future outbreaks.

The following interventions are based on evidence-based practice (see Chapter 4). Below are some examples of EBP in public health nursing:

- Media campaigns targeting specific populations have been successfully used to educate and promote healthy behavior (Atusingwize, Lewis, & Langley, 2015).
- Improving work-based health literacy through educational programs to improve musculoskeletal pain (Larsen et al., 2015).
- School-based program to increase physical activity among sedentary middle school girls (Robbins Pfeiffer, Maier, Lo, & Wesolek, 2012).
- Bike helmets (and legislation requiring helmet use) have been proven to be effective in decreasing head injuries (Walter, Olivier, Churches, & Grzebieta, 2011).

Evaluate

The world in which PHNs work is always changing. It is crucial to constantly evaluate programs and interventions to determine if goals are reached. For example, a nurse may visit childcare facilities or senior centers to ensure that laws regarding licensure are being followed. Evaluating is often equated with assessing. PHNs also can evaluate data to determine whether various rates (e.g., infant mortality or other health indicators) increase or decrease as a result of their interventions.

Another way that PHNs can determine if their interventions are effective is by becoming involved in research. The Quad Council supports research studies about the impact that PHNs have on improving population health and societal outcomes (Swider et al., 2013). Kulbock et al. (2012) describe the interrelatedness of the core competencies and evidence supporting PHN role expansion that can increase the health benefits of the population served.

LEVELS OF PREVENTION PYRAMID

HEALTH ISSUE: Cervical cancer community setting

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Provide nursing support groups after hysterectomy and other treatment.		

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Promote regular Pap smears • Provide Pap smear and high-risk screening counseling at local health fairs	• Provide resources of medical services available for women diagnosed with cervical cancer

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Promote healthy lifestyle choices that will decrease risk of human papillomavirus (HPV) (use of condoms, decrease tobacco use, food containing vitamin C and beta carotene) • Provide HPV vaccine at appropriate age • Educate public on risks related to cervical cancer (HPV vaccine, multiple sex partners) • Educate women to get regular Pap smears	

PUBLIC HEALTH NURSING CAREERS

Nurses who work at the state and federal levels tend to have consultant, or oversight-type roles, and some nurses head programs that are specifically funded at the state and/or federal levels (e.g., HIV/AIDS, immunization programs). Some state-employed nurses may work in clinics for children with special health care needs. Some federally employed nurses may provide direct care through ambulatory care clinics. PHNs at all levels may also be called upon to help during a disaster or communicable disease outbreak. See Perspectives: PHN Nursing Instructor.

PERSPECTIVES PHN NURSING INSTRUCTOR

As an instructor of undergraduate nursing students, I want students to realize that public health nursing is a wonderful and rewarding employment opportunity. Many students often enter the nursing program not knowing much about public health nursing. They may only get minimal exposure to public health and thus do not often understand who or what is involved in public health nursing. In so doing, they miss out on a wonderful opportunity to work with a variety of people. It may be helping new moms, or working with children and adolescents, or the elderly. They may help give vaccinations or prepare for community disasters. They might teach about breast-feeding or conduct cancer-screening clinics. They are out working directly with the people, ensuring the public's health.

Public health nurses (PHNs) are able to use the science of nursing because they need to understand the pathophysiology, anatomy, human development, and disease transmission. They may not do as many hands-on procedures as hospital nurses, but they still must keep up-to-date in knowledge, as they are often teaching. In addition, they must be quick and receptive thinkers who can work independently and creatively. PHNs also are the essence of the "art" of nursing. They must understand and relate to people and grasp social systems and human behavior. They are the voice for the most vulnerable and the champion of all.

Although PHNs may not see an immediate reward for their actions, as a nurse who works in the hospital does, PHNs make a long and lasting impact not just to an individual but also for an entire society. They have the opportunity to really be a patient advocate. They do this by helping well people stay well and by preventing illness. They also help those who are sick obtain medical access. PHNs can also be involved in public policy change that can help an entire community. Public health

nursing encompasses the entire art and science of nursing.

Erin M.

Among distinct opportunities at the federal level are those associated with the Department of Veterans Affairs and the U.S. Department of Health and Human Services (USDHHS, 2014d, 2015). Agencies headed by the USDHHS include the National Institutes of Health (NIH), the Indian Health Service, the Health Resources and Services Administration (HRSA), the Center for Medicaid/Medicare Services (CMS), U.S. Food and Drug Administration (FDA), the Administration for Community Living (ACL), the Substance Abuse and Mental Health Services Administration (SAMSHA), the Administration for Children & Families, and the Centers for Disease Control and Prevention (CDC).

PHNs in these agencies oversee and carryout the initiatives of *Healthy People 2020*, along with other program initiatives. Many of their functions are similar to those mentioned earlier. For example, they may oversee and develop programs, such as national surveys, that collect data used to determine priorities. Examples of these surveys include the Behavioral Risk Factor Survey (BRFS), the Youth Risk Behavior Survey (YRBS), and the National Health Interview Survey (NHIS). Federally employed PHNs at HRSA may review state funding proposals for projects and ensure that guidelines are met. They are a resource for state health department and LHD and often are called upon as consultants. Nurses working at the NIH may assist in conducting research, or work with legal and bioethics staff in evaluating the impact of research on participants, monitoring patients for adverse reactions, or coordinate care for specific groups of patients (NIH, 2016). In addition to these opportunities, PHNs may work as clinicians for the Indian Health Services (IHS), Federal Bureau of Prisons (BOP), and Immigration Customs and Enforcement within the Department of Homeland Security (DHS).

Indian Health Services

Indian Health Services (IHS) started from special relationships between the federal government and the Native American tribes. This relationship is based on information found in the Constitution (Article I, Section 8) and was started in 1787. Over time, other treaties, policies, and laws have influenced the present structure of the IHS. The main goal of IHS is to ensure that comprehensive, culturally acceptable personal and public health services are available and accessible to American Indian and Alaska Native people (IHS, 2015). IHS is responsible for providing health care to Native Americans (American Indians and Alaska Natives). The IHS provides services for members of 566 federally recognized Tribes, or 2.2 million American Indians and Alaska Natives in 170 IHS and tribally managed service units (IHS, 2015). Employment with the IHS allows a nurse to live in a variety of rural and urban settings and to work specifically with Native Americans, a vulnerable population. These nurses work and oversee health care services in clinics run by IHS. The clinics are usually focused on primary care and on general practice. They may work with patients who have diabetes, providing nutritional counseling and education; they may also provide immunizations, perform well-child examinations, or conduct HIV/AIDS screenings. Unique aspects of these jobs are that most clinics are located in remote areas of the country and face unique challenges. Some houses on Native American reservations may not have a telephone or consistent electricity, and these clients may have numerous special needs (IHS, 2015). This type of nursing is very challenging but can also be extremely rewarding.

Uniformed Public Health Nursing

Nurses can serve in each of the seven uniformed services of the U.S. Department of Defense (e.g., Army, Navy, Marine, Air Force), U.S. Department of Homeland Security (Coast Guard), U.S. Department of Commerce (National Oceanic and Atmospheric Administration [NOAA] Commissioned Corps), and the U.S. Public Health Service Commissioned Corps (USPHSCC).

The U.S. Public Health Service Commissioned Corps is a group of more than 6,500 specially trained public health members who serve their country with the goal of protecting

and promoting the health of the nation. The Corps was established in 1798, as part of an act to treat sick seamen in Marine hospitals. Over the years, the Corps expanded to oversee the health of immigrants entering the country and to assist in preventing/treating communicable disease outbreaks. The U.S. Surgeon General, 2016 oversees the Commissioned Corps and supports the officers stationed in more than 20 federal agencies or departments across the nation, often in very remote areas, filling essential public health leadership and clinical service roles within the nation's federal government agencies (USDHHS, 2014a).

The U.S. Surgeon General, Vice Admiral Vivek H. Murthy, M.D., M.B.A., talking to staff.

Nurses are an integral part of the Corps. They provide nursing care and health care leadership around the world. Their focus is on improving health for the entire community by providing care, conducting research, or reviewing new medications. These nurses work in a variety of federal agencies, many of them listed earlier. On a daily basis, they may perform tasks similar to civilian nurses. However, as commissioned officers, they can also be deployed to protect the nation's health. For example, USPHSCC nurses were some of the first on the scene to assist in the aftermath of the 2010 earthquake in Haiti. Nurses may also be deployed in the case of a widespread communicable disease outbreak. Their activities can be international as well, in providing expertise and support on global issues such as the Asian tsunami or the worldwide spread of HIV/AIDS. A unique opportunity presented itself to the USPHS Commissioned Corps during the height of the Ebola Virus global epidemic. The President of the United States called upon the USPHS

Commissioned Corps to deploy to West Africa to provide care to the health care workers who had been exposed to or infected with the Ebola virus (White House, 2014). Four teams of approximately 70 officers composed of clinicians (physicians, nurses, behavioral health specialists), pharmacists, infection control and laboratory officers, and administrative management personnel rotated to Liberia for 60 days at a time beginning in October 2014 (Lushniak, 2014). Upon the departure of these specially trained teams of PHS officers in May 2015, Liberia was declared Ebola-free. Concurrently, smaller teams of PHS officers served to combat the Ebola outbreak in Guinea and Sierra Leone and remained on site educating the community on Ebola treatment and prevention. President presented the USPHS Commissioned Corps with the Presidential Unit Citation, the highest award for a uniformed service, for their contributions in the fight against Ebola. For more information and a video on the presentation, visit the C-SPAN Web site (http://www.c-span.org/video/?328326-3/president-obama-meets-public-health-officials).

As commissioned officers, USPHSCC nurses are compensated with regular salaries based upon rank following the military pay system. In addition to a potential signing bonus, TRICARE health insurance, eligibility for veteran's benefits, and access to military base lodging and recreational facilities are available. Officers are supported with opportunities to further their education and advance their careers. Student tuition reimbursement and loan payment options are also available through select federal agencies (USDHHS, 2014c).

To qualify as a nurse in the Commissioned Corps, one must be a U.S. citizen, under age 44, able to pass a physical examination and security suitability clearance, possess a bachelor's or higher degree from an accredited nursing program, and hold a valid nursing license from one of the 50 states, the District of Columbia, Puerto Rico, Guam, or the U.S. Virgin Islands (USDHHS, 2014b). For more information on the USPHSCC, visit their Web site (www.usphs.gov).

School Nursing

School nurses save lives and assist in helping children so that they are able to learn and reach their greatest potential. School nursing is a specialized practice of professional nursing that advances the well-being, academic success, and lifelong achievement of students. School nurses are a link between the school, families, community, and health care stakeholders. These nurses (between 2.1% and 2.8% of RN population) are tasked with serving as advocates for health and healthy school environments (National Association of School Nurses [NASN], 2014e). In a qualitative study examining how school nurses provide health care to students, Rademacher (2012, p. 242) describes the school nurse "caring for" and "caring about" children's health needs and being motivated to assist students in achieving their best at school.

A school nurse works primarily with the students who attend the nurse's assigned schools, as well as with the families of those schoolchildren, members of the school staff and administration, health care providers, and other helping professionals within the school and community. In fall 2015, approximately 50.1 million students were expected to attend public elementary and secondary schools (National Center for Education Statistics, 2015). These children are the parents, workers, leaders, and decision-makers of tomorrow, and their future success depends in good measure on achieving their educational goals today. Their school success is intertwined, to some degree, with the state of their health (American School Health Association, n.d.; CDC, 2011). See Chapter 22.

Think back to your own elementary and secondary schooling. Did you have access to a school nurse? If so, how did that person influence your health and the health of your peers? If you did not have a school nurse, how do you think a school nurse might have improved your school environment or educational experience? The school nurse is a key provider of a variety of services.

History of School Nursing

Beginning in the mid-1800s and continuing through the early years of the 20th century, mandatory education was instituted in the United States. The early years included health services often conducted by "medical inspectors," usually physicians. In New York City, where communicable disease was rampant, inspectors sent notes home with children with the message "you are sick—go home" and citing the reason for their exclusion from school (Vessey & McGowan, 2006, p. 255). The reasons for exclusion were largely the contagious illnesses commonly found among the tenements and crowded slums of the growing city. However, parents often did not receive these notes, or couldn't read them, and because families lacked resources, most children were left untreated and simply remained out of school as truants. No efforts were made by medical inspectors to follow up on excluded children. Because these excluded children played with healthy children after school hours, the levels of contagious illness actually worsened (Vesey & McGowan, 2006). As noted in

Woodfill and Beyrer's classic text (1991), the absentee children promoted the spread of various communicable diseases. In 1902, the practice of school nursing began when the New York Board of Education contracted with Lillian Wald's Henry Street Settlement to provide a PHN to work with the families and schools to facilitate the return of healthy children to school. The nurse was Lina Rogers. She made home visits to follow up on excluded children and was assisted by other Henry Street nurses in providing care, educating families about diseases and the need for hygiene, and working with other organizations to provide needed food, shoes, and clothing (Hawkins & Watson, 2010; Rollins, 2011; Vessey & McGowan, 2006). In the first month of the school nurse experiment, 98% of children previously excluded from school for medical reasons were treated and readmitted (Woodfill & Beyrer, 1991). Lina Rogers, who later married and was known the last name of Struthers, described her first school "dispensary" as an "unused stair closet" where she was unable to stand fully erect, but still provided treatment for skin and eye diseases, as well as draining ears (Struthers, 1917, p. 19). The board hired 12 more school nurses, and over the next few years, other cities and states began hiring nurses to work in the schools. School nurses have historically advocated for hot lunches, breakfast programs, better social conditions, and the need for increased health education in schools and for families (Abrams, 2005; Rollins, 2011). See Chapter 2.

School nurses continue as a specialty branch of professional nursing that serves the school-age population. Approximately 61,000 to 70,000 RNs are working in elementary and secondary schools (K-12) currently (NASN, 2014e). However, according to the recent School Health Policies and Programs Study (SHPPS), the nationally recommended ratio of one school nurse for every 750 students has not been achieved at the elementary and middle/high school levels, with only 85.2% and 78.4%, respectively, reporting that they had a school nurse. However, about half of all schools reported having an RN for 30 or more hours per week, and around 60% of all schools had licensed practical nurses available and not RNs. Many schools still report having an insufficient amount of school nursing services (CDC, 2015g). Several school sites serving adolescent students provided a cell phone app to those interested in contacting school nurses with questions or concerns; they receive a return text with information on where to access information and resources, as well as a call from the nurse if it is during school hours. Students and school nurses have found this innovative approach helpful (Penfold, 2013).

School nurses deliver services to students from birth through age 21 years. They also work with students' families and the school community in regular and special education schools, as well as other educational settings (e.g., preschools, court, and other community schools). Studies show that having a school nurse present increases health and social services and improves absentee rates (Hill & Hollis, 2011). The role of the school nurse has expanded over the years, along with the increase in chronic conditions and challenges in accessing health care (Kennedy, 2014). It is estimated that 8% of children aged 3 to 17 years have a learning disability, about 9% have ADHD, and 14% have ever had an asthma diagnosis (Bloom, Cohen, & Freeman, 2012). Federal law requires school systems to

provide care for children with disabilities. The Individuals with Disabilities Education Act (IDEA, 1975), the Rehabilitation Act of 1973, and Title II of the Americans with Disabilities Act all mandate equal educational opportunities for all students, including children with complex medical conditions. In 2012, 95% of 6- to 21-year-old students with disabilities were being educated in regular schools, and only 3% received services in a separate school (National Center for Education Statistics, 2016). Legislative mandates and technology that has allowed low-birth-weight babies to survive have led to a steady increase in the number of children with special health care needs attending school (American Academy of Pediatrics [AAP], 2016). It is now commonplace for children to attend school accompanied by feeding tubes, catheters, insulin pumps, glucose monitors, and ventilators. There is a growing population of adolescent and preadolescent children who are within 6 months of dying from chronic disease and are routinely attending school (NASN, 2014c).

According to Kennedy (2014, p. 7), over the past 15 years, the school nurse role has dramatically changed, as has the student population. "There are more immigrant students, more children living in poverty, more children likely to have food insecurity and poor health because of lack of access. And there are more students with chronic conditions who need support to manage their illness so they can stay in school. Schools can't afford *not* to have a school nurse" (Kennedy, 2014, p. 7). The lack of access to health care has added extra burdens on schools, and school nurses are often "the sole provider of access to health care" (Sonnenberg, 2013 para. 20). Also, children often come to school sick or miss additional days of school resulting from complications of illnesses that could have been easily treated in earlier stages. In 2012, 7% of U.S. children had no coverage for health insurance, and 4% had no usual source of health care. Some children access health care services only at school, and 12% made at least one visit to the ED, whereas 5% had two or more visits (Bloom, Jones, & Freeman, 2013). Results from the 2011–2012 National Health Survey indicate that 6.2% of children missed 11 days of school or more in the past year because of illness, and this was more of a problem in children with special health care needs as the proportion increased to 14.9% (CDC, 2013a; National Quality Measures Clearinghouse, 2013). Children from families of lower socioeconomic status were twice as likely to miss 11 days of school or more than were children from families with higher income levels (9% vs. 4%).

In their survey of almost 400 school nurses in 35 states, Krause-Parello and Samms (2011) found that school nurses "very frequently" worked with students having asthma (59.2%), allergies (58.7%), ADHD (52.7%), diabetes (29.6%), depression (13.5%), and seizure disorders (8.8%). Although asthma was the most common condition observed, only a little over 20% reported having asthma action plans for 100% of their students with asthma. Seasonal allergies were most common, followed by nut and dairy allergies.

School nurses spend a good deal of time on health promotion, and 87% in one survey saw a "direct correlation with student academic outcomes" and health-promoting activities (Krause-Parello & Samms, 2011, p. 34). Most school nurses promote self-care and safety education (87.8%), and 64.4% did environmental assessments of their schools. School

nurses, administrators, teachers, parents, and community stakeholders are all vital in coordinated school health program and in developing health-promoting schools (Hung, Chiang, Dawson, & Lee, 2014). School wellness programs often incorporate education on healthy nutrition and increasing physical activity, for instance (Avery, Johnson, Cousins, & Hamilton, 2013). Walker (2014) reminds us that the school nurse is also a role model for wellness promotion, in addition to providing individual and group health education. Some of the health school nurse behaviors include drinking water, eating a healthy lunch in the teacher's lounge (often filled with unhealthy snacks), walking during recess or free time, eating healthy snacks (e.g., fresh fruit, vegetables), and limiting consumption of unhealthy foods and beverages.

School nurses are also involved in emergency preparedness and disaster planning. The National Association of School Nurses (NASN, 2014d), in their position statement on this issue, noted that school nurses are a crucial link between local public health agencies and emergency services. School nurse roles include prevention/mitigation, preparedness, response, and recovery; their role with special needs children is especially vital. Epidemics (e.g., influenza), weather-related emergencies (e.g., hurricanes, tornadoes, earthquakes, flooding), and other sudden crises (e.g., school shootings, terrorism) are all potential issues facing school nurses. The Federal Emergency Management Institute (a division of the Department of Homeland Security and the Federal Emergency Management Administration [FEMA]) offers training courses for school administrators, school nurses, and teachers to aid them in preparing for various emergencies (see Chapter 17). Additionally, school nurses must consider emergency evacuation plans, especially for disabled students, and determine the best way to reunite students with their families.

Key Roles of the School Nurse

The school nurse's main role is to provide both individual and population health care and coordination for school-age children and adolescents. School nurses utilize their knowledge of normal growth and development, social determinants of health, safety and health (including environmental health), and the educational system in providing services. They clearly understand the connection between health and learning and promote health among students, families, and staff. They provide case management for children with chronic illnesses (e.g., diabetes, asthma, severe allergies), immunization monitoring/access, and collaborate with parents, teachers, and psychologists in providing appropriate educational plans for students requiring special education services. They work with school staff to ensure a healthy and safe environment (e.g., nutrition, physical activity, playground safety). They also collaborate with community agencies (e.g., public health departments/other health agencies, charitable groups/service clubs), physicians, dentists, parent groups, and child protective services in order to meet students' and families' needs. They often conduct screenings and work with school staff to promote their health and wellness. School nurses may also work with school-based clinics to provide direct health care to children and their families. They are an integral leader in coordinated school health programs (AAP, 2016).

The National Association of School Nurses (NASN, 2016) describes the broad role of the school nurse as a "specialized practice of professional nursing that advances the well-being, academic success and lifelong achievement and health of students" (para. 8). The school nurse:

- Facilitates the normal development of students and promotes positive intervention outcomes
- Provides leadership in the areas of health promotion, safety, and a healthy school environment
- Provides high-quality health care and promotes early intervention for actual and potential student health problems
- Uses sound clinical judgment in the provision of case management for students
- Collaborates actively and professionally with others to promote student/family capacity for self-management and adaptation, as well as learning and self-advocacy (NASN, 2016)

Parents of schoolchildren cite first aid/emergency care, teacher education about special needs students, parent/school/health care provider communication, control/prevention of disease, and provision of medical treatments to special needs children or those with chronic illnesses as the most important roles and duties of the school nurse (Lineberry & Ickes, 2015). The partnership between school nurses and families is important for the child's health outcomes, and the use of problem-based communication strategies helps promote this collaboration (Mäenpää, Paavilainen, & Åstedt-Kuri, 2012).

Liaison with the Interdisciplinary School Health Team

School nursing services are part of a coordinated school health program that provides school health services, health education, and health promotion programs for faculty and staff (American School Health Association, n.d.). Although the school nurse plays a central role, collaboration with many other individuals is important. School nurses must be familiar with the education setting and work closely with teachers/aides, special education teachers/staff, principals, administrators, school office staff, health aides, psychologists, speech therapists, as well as parents and families. The Whole School, Whole Community, Whole Child (WSCC) model focuses on the child and emphasizes a school-wide approach and acknowledges learning, health, and the school as being a part and reflection of the local community (CDC, 2015a, 2015l). See Figure 30–3 for the WSCC Model. It includes 10 components:

FIGURE 30–3 Whole School, Whole Community, Whole Child (WSCC) model. From Centers for Disease Control and Prevention. (2016). Whole School, Whole Community, Whole Child. Retrieved from http://www.cdc.gov/healthyyouth/wscc/

- Community involvement

Positive Working Relationship with School Team Members

The school principal influences all phases of the school health program by promoting good school health through active support of the school's health services, participation in setting health-related policies, and tapping into community resources. The principal can reinforce positive efforts within the school, ranging from the health teaching in the classroom to the cleaning activities of the custodian. Because of the principal's influential position, it is absolutely essential for the nurse and principal to maintain a positive and cooperative working relationship. Studies have noted that parents, principals, teachers, and school staff have positive attitudes toward school nurses and find that having a school nurse present saves time for school administrators, teachers, and staff (Baisch, Lundeen, & Murphy, 2011; Lineberry & Ickes, 2015).

Teachers, whether they are involved in regular instruction, physical education, or special education, play a major role in school health. Because they spend the most time with students, their observations, health teaching, and personal health habits have a profound effect on student health and the quality of school health services. The school nurse and teachers must collaborate constantly, as the school nurse provides information and guidance to teachers regarding students in their classrooms with specific health conditions and concerns and teachers report on students' health concerns and behaviors. Teachers, in particular, feel that they have more classroom teaching time and that students with chronic illnesses are safer with school nurses on school grounds (Hill & Hollis, 2011. Biag, Srivastava, Landau, and Rodriguez (2015) found that teachers had higher levels of satisfaction when nurses were available on campus full time and appreciated nurses' help with students having chronic conditions, managing medical emergencies, and providing first aid when students were injured. They also found benefits when school nurses followed up on hearing and vision problems, making necessary referrals and getting services for students having problems. Student Study Teams (SSTs), where teachers, administrators, psychologists, school nurses, and others meet to discuss students identified as having learning or health problems, were also noted as an important collaborative opportunity (Biag et al., 2015).

The school nurse is part of a team providing a coordinated school health program.

Other health team members, such as health educators, health coordinators, psychologists, audiologists, speech therapists, occupational therapists, physical therapists, counselors, health care providers, dentists, dental hygienists, social workers, security and juvenile justice personnel, health aides, and volunteers, may also be involved, depending on size and financial resources of the school. All team members, including students, parents, bus drivers, and custodians, have a specialized role complementary to that of the school nurse.

School-based health centers (SBHCs) provide an access to health care services for youth confronted with barriers to social determinants of health and are often sponsored or funded by public health departments, community health centers, or hospitals. They often provide care for children, and sometimes their families, who otherwise do not have access to health care. SBHCs "bring critical, developmentally appropriate services to children and adolescents where they spend most of their waking hours; at school" (Keeton, Soleimanpour, & Brindis, 2012, p. 132).

If the school system desires such services, a physician may work on a part-time consultative basis; however, physicians are not consistently or effectively used in schools (AAP, 2013). This role focuses largely on advising and consulting related to policy and medical–legal matters. A community physician may serve on a school advisory panel, acting as a liaison between the community, other health agencies, and the school. A physician or a nurse practitioner (NP) may become involved in student health appraisals, rescreenings,

health problem interventions, sports physical examinations, or first aid support at sporting events.

Responsibilities of the School Nurse

The primary responsibilities of the school nurse are to prevent illness and to promote and maintain the health of the school community. The school nurse serves not only individuals, families, and groups within the context of school health but also the school as an organization and its membership (students and staff) as aggregates. The school nurse identifies health-related barriers to learning, serves as a health advocate for children and families, and promotes health while preventing illness and disability (NASN, 2016). "School nurses must understand the culture of education in order to build professional relationships with administrators and be seen as valuable members of the school team" (Maughan & Adams, 2011, p. 355).

School nursing activities are comprised of nursing care of children with special health needs, including nasogastric tube feedings, catheterization, insulin pumps, and suctioning; general and emergency first aid; vision, hearing, scoliosis, and TB screenings; height, weight, and blood pressure monitoring; oral health and dental education; immunization assessment and monitoring; medication administration; assessment of acute health problems; health examinations (especially for athletic participation or school entry); and referrals (DuChateau, Beversdorf, & Wolff, 2015; Jones & Boyd, 2011). School nurses also assess and are the frontline providers for identifying communicable diseases, such as outbreaks of influenza or meningitis. A systematic review of research on the impact of school nurses noted that fewer absences occurred when school nurses were present and that rates for immunization compliance were also improved (Lineberry & Ickes, 2015).

Medication administration is another common school nurse duty. In one study, 91.9% of school nurses reported giving ADHD medications, 88.8% gave bronchodilators, 88.6% gave over-the-counter (OTC) medications, 86% gave antibiotics, and almost 71% gave insulin. This study also found that medications may be given by school nurses (92.7%) and unlicensed assistive personnel (UAP; 31.9%), such as health aids or school clerks (Krause-Parello & Samms, 2011). Administrators, teachers, and others may also give medications depending upon state laws. For instance, only school nurses and physicians may administer medications in Massachusetts, but many other states (e.g., Pennsylvania, California) allow UAPs to give medications in the nurse's absence (Krause-Parello & Samms, 2011).

School nurses perform first aid, help students with inhalers and nebulizer treatments, and some may do gastric tube feedings and ventilator/tracheostomy care. They are responsible for documenting their care, but this can be difficult because of time constraints, educational regulations, and lack of a functional standardized data set or method of collection. A study by Johnson, Dewey Bergren, and Westbrook (2012) collected and evaluated data from six states. They found that most school nurses and school districts reported on staffing, risk management, case management, episodic care, and health

promotion activities. However, applying existing data classification systems (NANDA, NIC, NOC) did not "adequately describe the scope of school nursing practice" (p. 103). They called for a nationally standardized school nursing/health database to improve care coordination and more efficient delivery of care to school-age children and youth.

Other duties of a school nurse may include training school staff in cardiopulmonary resuscitation (CPR), universal precautions and first aid, as well as overseeing the health and wellness of school staff members. They also participate in emergency planning and disaster drills, as well as school evacuation plans. Many of these activities may be performed concurrently (Sonnenberg, 2013). Lineberry and Ickes' (2015) systematic review noted four main areas of school nurse activity: (a) "health promotion and disease prevention," (b) "triage and treatment" of acute infectious diseases and injuries, (c) managing "chronic conditions," and (d) offering "psychosocial support" (p. 31). See Display 30–4 for a typical day in the life of a school nurse. Each school nurse must assess and prioritize how to address the specific needs in each individual school and determine the order. As you can see, there are a wide variety of activities involved in school nursing. This largely autonomous practice requires specific skills and training.

DISPLAY 30.4 A DAY IN THE LIFE OF A SCHOOL NURSE

6:00 AM This morning, I texted one of my nurses to make sure that she was going to be well enough to come to work. If she was still too sick to work, I would have had to get an early start contacting one of our two district nursing substitutes to see if they could cover again (nursing subs are rare gems within our profession).

8:00 AM At school, I stopped to say hello to the office staff, to see how they were doing, and to ask if they did anything fun since seeing them last. I have learned during my time with the district that it is vital for the office staff to like and respect you because they are the heart of each and every school. They know all of the students, including home and health issues, who the regulars are in the health room, when there are field trips, and anything else that may be important for me to know. They are also my health room assistants, because it is impossible for me, or my support nurses, to be present at each school all day, every day. I always carry a personal phone and a work phone to be easily reached when not on site.

8:15 AM As I walked into my office, I had a call from my support nurse at the high school. She updated me on a student having an allergic reaction to the latex that the science room was using for an experiment. There was enough of an exposure that

the student was given her EpiPen and staff called 911. It was decided that the student would be removed temporarily from the classroom during the 6-day experiment, and arrangements would be made to make it safe for the student to return to the classroom at that time.

8:25 AM After that call, I had another nurse call asking about one of her diabetic students who wanted to begin participating in an after school program provided by the school. I asked her to send me the student's daily schedule for monitoring and treating his blood glucose (BG) levels as well as some history of his BG highs and lows. Fortunately, the support nurse and I had time in the coming week to put something together. A triage list is necessary in school nursing!

8:45 AM Finally, I was able to get caught up with my email. At one of my other elementary schools, we had an upcoming field trip for the 5th grade classes. I emailed all the teachers to request a day and time to do a basic med training before the big day and to answer any questions the teachers might have. One of the classes has a diabetic student in it so I also called the parents to see if one of them would be able to go on the trip as a chaperone and to care for their student. If they couldn't, a nurse would have to go. This would mean having one less support nurse for much of the day. I then checked in with my nurse that helps to cover three of my other elementary schools to see how she was doing and to send her a to-do list for the day.

10:45 AM Before checking on our two diabetics for their lunches, I had just enough time to print out DISPLAY 30–4A Day in the Life of a School Nurse (Continued)a report that shows which students are noncompliant with their vaccinations. I then stopped by the lunchroom to see how one of the diabetic student's lunch went. His blood glucose numbers were high, but when he rechecked after recess, his blood glucose was on the way back down to normal range again. I made it back just as my younger diabetic walked into my office for her BG check. I love being able to have time to talk to my diabetic students because not only do I enjoy the conversation, I can also get an idea of how their week is going to go based on their experiences over the weekend, if they are sick, if they have any big plans coming up, etc. I can also pick up on when things are a little off. This diabetic student was acting a little more goofy than normal. I discovered that her blood glucose level was 71 and her dex had two arrows facing downward. Fortunately she was a few minutes late for her check so she was able to go straight to lunch. I walked her to the lunchroom so that I could see what she picked to eat for hot lunch. I always check her again after her lunch is complete to see how many carbohydrates she consumed for dosing her insulin.

11:30 AM Once back in the health room, a student came in very upset, clutching his arm. He had fallen off of the playground set and landed on his arm. My assessment revealed that his forearm was oddly shaped. It was clearly broken. While I assessed him, I had an office staff member call 911 and his parents to update them about the situation. Fortunately, it was not a compound fracture, and he still had

sensation and capillary refill. Because we are not at a hospital, there are many things we do not have available to us when caring for patients in the schools. I improvised a splint, using my clipboard with an ice pack resting on his arm to help reduce swelling until the paramedics arrived.

11:35 AM To distract the student from the pain, I asked what educational show they liked, and loaded it up on my computer to distract him. The office staff completed the paperwork to report the injury and emailed me a copy.

11:35 AM My diabetic came in to have me check her food tray so that she could get her insulin dose. Usually, I go out to meet her but in this situation, I had her bring her tray to my office where I checked and dosed her.

11:45 AM After everyone left, I debriefed with the office staff about how things went, what they did well, and to answer any questions or concerns that they might have had.

12:00 PM I checked the immunization list to see who might be excluded from school for being noncompliant with vaccinations. I will determine which students will need reminder letters mailed home and prepare them for mailing.

1:00 PM A diabetic student came in again because her dex was alarming. When we checked her again, she was at 49. I gave her a juice and a snack while I called her mom to let her know what was happening. I had her stay with me for 15 minutes after she finished her snack and then retested her. She was up within range by her next check but, with her mom's permission, I gave her a protein snack to keep her going on the way home.

1:30 PM I checked in with my nurses. The nurse with the student using the EpiPen was able to find information about how to clean out the room for the student, and she let me know that the teachers had been informed of the situation, a report had been filed, and the family called saying the student was fine.

2:00 PM One of the teachers stopped in to see me. She had been sick for a while and was showing signs of pneumonia. She knew she was very sick, but she needed encouragement to go see her provider. Usually, people think that school nurses focus on just the students but in reality, we care for the adults as well. School staff and families rely on us to give health care advice.

3:00 PM It's the end of the school day! I only made a dent in my to-do list by the end of the day but, more importantly, the students were safe and we had all made it through another day. Things may be hectic at times but knowing that I am helping keep people safe and making them feel better when they are ill makes it all worthwhile.

Heather D., Lead Nurse, Spokane WA

Education: Special Training and Skills of the School Nurse

School nurses operate from one of two administrative bases: the school system or the public health department. In most localities, public or private school systems or districts hire school nurses, and they maintain a specialized, school-based practice. Private schools and universities also hire school nurses (NASN, 2014f). In this specialized role, the nurse can concentrate time and effort solely on the school health program and develop specialized skills in school health assessment and intervention. Today, with the emphasis on delivery of health care at community sites where clients spend most of their time (e.g., schools for children, the workplace for adults), the nurse whose specialty is school health care seems better prepared to meet the complex needs of the school-age population. In contrast, the school nurse who operates under the board of health's jurisdiction provides services to schools as one part of generalized public health nursing services to the community. The community health nurse working through the health department usually devotes only a portion of the workday to the school; she may have additional responsibilities, such as clinic nursing and home visits. This broader base allows contact with preschoolers and their families, provides a stronger knowledge of the community and its resources, and promotes integration of in-school and out-of-school care (Selekman, 2013).

Depending on the state of residence, a school nurse is usually an RN—frequently with additional education beyond the bachelor's degree in nursing, sometimes including a master's degree—that has primary responsibility for the health care of school-age children and school personnel in an educational setting. In some areas of the country, licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) may be hired by school districts, but they must generally work under the supervision of an RN. *School nursing: Scope and standards of practice* (ANA & NASN, 2011) indicates that school nurses should, at minimum, possess a bachelor's degree. As the needs of school-aged populations become increasingly complex, some states require even more specialized training for school nurses. In California, for instance, school nurses are expected to hold a school health services credential. This credential is obtained through a postbaccalaureate program that includes course work in audiology, guidance and counseling, exceptional children, school health principles and practice, a practicum in school nursing, child psychology, and health curriculum development, in addition to other courses. However, most California school nurse credential programs are now available only as part of a master's degree program. A national certification is available as well (NASN, 2014a).

School nurse practitioners (SNPs) are RNs with advanced academic and clinical preparation (generally certification and a master's degree in nursing), along with a guided experience in physical assessment, diagnosis, and treatment, so that the SNP may provide primary care to school-age children. Many school districts see the advantage of having an SNP on staff, rather than using the limited services of a physician. Assessment, diagnosis, treatment, and referral of injuries, communicable diseases, or other health problems can be managed more efficiently by a NP who is educationally prepared to work holistically with

the school-age population and is part of the educational setting. If this arrangement is impractical, an SNP who is available to school nurses for consultation or who is employed on a part-time basis can become the impetus for comprehensive school-based health services. Some school districts utilize SNPs to provide services to teachers and staff to promote wellness or to handle job-related injuries. Some research findings cite cost savings related to SNP services, as students and staff served by them experience fewer days of absenteeism (Kerr et al., 2011). As the population continues to become more diverse and the problems of children and their families grow in complexity, the school nurse with specialized training in school health, the education system, case management, and advanced practice nursing (e.g., NPs, clinical nurse specialists) becomes even more essential.

Functions of School Nursing Practice

The three main functions of school nursing practice are health services, health education, and promotion of a healthy school environment. Health services include caring for individual students who have chronic conditions or acute situations while at the same time thinking of the entire population and tracking trends (Rollins, 2011). For example, the school nurse observes an increase in the number of students diagnosed with asthma and investigates ways to help all students with asthma. One way of doing this may be to organize an *Open Airways* course (developed by the American Lung Association, 2016) to assist students in identifying triggers and managing their own care. The goal of this course would be to decrease student asthma attacks.

Health Services for Children with Chronic Conditions

Chronic health conditions are commonly considered to involve having medical needs that are greater than those usual for a child of similar age, or functional limitations, and to last longer than 3 months to a year (Crump et al., 2013). The number of children afflicted with chronic diseases is rising and is thought to affect over 5 million children and adolescents (Compas, Jaser, Dunn, & Rodriguez, 2012; Crump et al., 2013). Common chronic conditions include hay fever, sinusitis, dermatitis, tonsillitis, asthma, diabetes, seizure disorders, and hearing difficulties (Goodwin et al., 2013). In addition, acute illnesses such as stomachaches, headaches, colds, and flu are frequent complaints of school-age children. A retrospective cohort study of almost 23,000 children and adolescents found that having a chronic health condition was associated with lower English language and math performance, despite socioeconomic status or ethnicity. In this study, absences did not significantly change the low performance scores for children with chronic conditions; conditions such as autism, ADHD, and seizure disorders had the strongest associations (Crump et al., 2013). Although, reducing absenteeism is a common function for school nurses, and chronic absences have often been linked with chronic conditions like asthma and diabetes (Jacobsen, Meeder, & Voskuil, 2016). School nurses need to "develop and maintain a high level of clinical expertise" with these common chronic conditions of

children and youth and may need additional resources in the case of neurological conditions, such as seizure disorders, brain cancers/injuries, and Tourette syndrome (Sprague-McRae & Rosenblum, 2013, p. 276). See Quality and Safety Education in Nursing (QSEN).

For students in special education programs, school nurses can coordinate individualized education plans (IEPs) with individualized health plans (IHPs) to develop health management goals for students. Medically fragile or technology-dependent students, who may require procedures such as suctioning or tube feeding, would have IHPs developed for *specialized physical health care procedures* (Galemore & Sheetz, 2015). School nurses utilize additional reference books and Web sites in order to keep up to date with current procedures (DuChateau et al., 2015). Because these students are often hospitalized, interrupting their education, the school nurse needs to assist with transition planning. Collaboration with school psychologists and school and health team members is important to transition planning that is also needed as students move from elementary to middle school, from middle school to high school, and as they move out of public schools and on to other educational or job training settings (Finch, Finch, McIntosh, Thomas, & Maughan, 2015; NASN, 2015). School nurses develop individualized health plans (IHPs) to ensure that students with special needs (e.g., chronic conditions) have these needs met. If these students attend the regular classroom and do not fall under the IDEA, the plans may be known as Section 504 plans, named after the section of the Rehabilitation Act and the accompanying statute, the Americans with Disabilities Act (ADA), that specifically allows for school accommodations with this population. Some examples might include severe peanut allergies that lead to anaphylaxis, serious asthma complications, diabetes, or heart disease. Students are to be provided with a "free and appropriate public education" (FAPE), and some students may be covered under both IEPs and Section 504 plans (Zirkel, Granthom, & Lovato, 2012, p. 425). See Table 30–3 for a list of IEP eligible disabilities.

Table 30–3 Individuals with Disabilities Education Act (IDEA)

Thirteen Eligible Disabilities (Galemore & Sheetz, 2015, p. 86):

- Autism
- Deaf-blindness
- Deafness
- Emotional disturbance
- Hearing impairment
- Intellectual disability
- Multiple disabilities
- Orthopedic impairment
- Other health impairment
- Specific learning disability
- Speech or language impairment
- Traumatic brain injury
- Visual impairment, including blindness

QSEN: Focus on Quality for School Nurse Working with Student Returning to School After a Concussion

QSEN Definition	SN Knowledge	SN Skills	SN Attitudes and Judgment
Patient-centered care: Recognize the student and parent as the source of control and full partner in providing compassionate and coordinated care based on respect for child's preferences, values, and needs.	Comprehension of pathology related to concussions, including symptoms/comorbid conditions, coping, complications, affect on academic functioning, pain control, and absences.	– Basic neurological assessments and baseline testing. – Symptom recognition, adaptive strategies. – Medical clearances, returning to sports.	– Expectations of time needed to return to full function or new state of functioning. – Encourage counseling and other services, if needed. – Recognize student and family connection to sport; discuss change to lower impact sport, and risks/long-term complications of repeated concussions.
Teamwork* and *collaboration: Function effectively within nursing and interprofessional teams, fostering open discussion, mutual respect, and shared decision making to achieve quality patient care.	Utilize effective communication with student, parents, teachers, coaches, neurologist and other professionals.	– Work closely with neurologist and school team to assist student in school reintegration, making up work, and gaining needed accommodations (e.g. rest breaks, reduced homework). – IEP, Section 504 plans, if needed.	– Be proactive in educating school team members about injury, be open to questions and strive for effective communication.
Evidence-based practice: Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.	Explain evidence regarding postconcussion syndrome, medications, sports safety, student health plan, where to find reliable evidence and practice guidelines.	Discuss variables that can affect a student's return to playing sports (e.g., previous concussions, severity of injury, expected time for recovery) and potential timetable. – Use evidence to update concussion plan.	– Rely on critically appraised current evidence and not personal examples or anecdotes. – Discuss the lack of evidence in some situations.
Quality Improvement: Use data to monitor outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.	Utilize national and other databases on head injuries, including information on types of sports involved, circumstances of injuries, prevention measures, and implications of negative outcomes.	– Work with school and district on developing a concussion database. – Educate school staff about student health issues. – Help to infuse new evidence into school sports program and academic practice standards.	– Work with students, parents, coaches, and trainers to encourage sports safety in schools. – Share information on potential for poor outcomes, and long-term financial/legal considerations.
Safety: Minimize risk of harm to patients and providers through both system effectiveness and individual performance.	Review safety principles on repeated concussions, serious sequelae (e.g., brain swelling, bleeding, sudden-impact disorders, sudden death).	– Utilize acute and continuing neurological assessment skills and teach coaches about initial concussion assessment/management. – Work with staff on PE modifications and using new technology to decrease injuries.	– Use change theory to promote a safety culture in schools, recognizing potential barriers. – Employ the use of personal stories from athletes who have had concussions.
Informatics: Use information technology to communicate, manage knowledge, mitigate error, and support decision-making.	Assert vigilance in following media coverage of concussions, current academic literature, and updated web sources.	– Promote computer literacy in locating resources, and communicating with parents/staff. – Use email and other electronic methods to provide information to staff and others.	– Teach others about reliable sources of information on the web. – Recommend caution when seeking information from unrecognized sources.

Using principles of Quality and Safety Education for Nurses in school nurse continuing education. *Journal of School Nursing, 30*(2), 97–102.

The five chronic conditions most often seen in school-age children are asthma, diabetes, seizures, severe food allergies, and attention deficit/behavioral disorders. A recent survey of New Jersey school nurses by Krause-Parello and Samms (2011) found that chronic conditions most often seen by the school nurse included allergies (87.3%), asthma (74.6%), ADHD (47.6%), diabetes (20.6%), and depression (9.5%). They also found that the most common procedures done by school nurses included first aid (98.4%), nebulizer treatments and inhalers (96.8% and 95.2%, respectively), along with wound care (90.5%), and glucose monitoring (87.3%). Urinary catheterizations, insulin injections, and

gastrostomy tube feedings were less common, but were done by many school nurses.

ASTHMA. Asthma is often deemed the most common chronic disease of childhood. Although reports indicate that morbidity and mortality from asthma have stabilized in the past few years, in 2010, an estimated 17% of children aged 17 years and younger have been diagnosed with asthma (Sondick, Madans, & Gentleman, 2011). Non-Hispanic Blacks exhibit the highest asthma attack rates, and boys more often than girls reported an episode within the past year (Sondick et al., 2011). An estimated 10.5 million school days are missed annually because of asthma, the condition that is the leading cause of absences. Children with asthma also tend to show comorbidities, such as learning disabilities (Hauptman & Phipatanakul, 2015). School environmental factors (e.g., mold, allergens, indoor air quality) also exacerbate asthma symptoms in children and youth. Asthma management programs are useful in helping students manage symptoms and reduce asthma triggers. School nurses work with students, their families, and their doctors to develop an *asthma action plan* to control, prevent, or minimize untoward effects of acute asthma episodes. This can extend beyond the school into the students' homes. For instance, in Ohio, public health nurses collaborated with other professionals through a Healthy Homes Program Grant to perform housing control assessments, education, and interventions (e.g., home visits, education) in housing units. Results showed reduced asthma symptoms, fewer schools days and workdays missed, and the number of emergency room visits for asthma events were decreased (Polivka, Chaudry, Crawford, Bouton, & Sweet, 2011). A Healthy Homes program headed by public health nurses in Baltimore, Maryland, focused upon home assessments for environmental health risks (lead, asthma triggers, carbon monoxide, pesticide use, environmental tobacco smoke) as well as source of heating in the home. They also included educational sessions to review home environmental health risks and a targeted hazard reduction intervention (U.S. Department of Housing and Urban Development, 2015a, 2015b).

Peak flow meters can be used regularly to determine early signs of asthma problems. The activities of nurses acting as case managers have been found to decrease the number of ER visits and hospitalizations of school-age children with asthma (Toole, 2013). Noyes et al. (2013) found that a daily dose of preventive asthma medication, given while the child was at school, was both cost-effective and effective in reducing inner city children's symptoms. Monitoring asthma medications and teaching proper methods of inhaler use are also vital school nursing functions. It often falls to school nurses to ensure that proper protocols and training are in place.

School nurse assisting a diabetic child with their insulin.

DIABETES. Diabetes is another common chronic illness in young people: approximately 215,000 under age 20 have diabetes. This translates into 0.26% of youth having diabetes (National Diabetes Education Program, 2011), and experts now conclude that both type 1 and type 2 diabetes mellitus are found in school-age children. It is estimated that there are 13,600 newly found youth under the age of 20 annually diagnosed with type 2 diabetes (National Diabetes Education Program, 2011). Type 2 diabetes is rising almost exponentially in adolescents, leading some scientists to frame it as a major public health crisis caused largely by obesity, sedentary lifestyle, and the predisposition of certain ethnic groups to diabetes.

Working with families and health care providers, school nurses assess and develop a care plan for students with diabetes. School nurses work closely with the family to maintain confidentiality and at the same time ensure that the school is a safe environment for the child. A multidisciplinary team approach is needed, with family, school, and physician collaboration. Training for teachers and fellow classmates is also important. Teachers are often called upon to assist students with their insulin or food management. Younger children with type 1 diabetes, especially those who use insulin pumps, may need careful monitoring—something that is not always possible for the school nurse, who may not be present where and when problems arise. If the child has an insulin reaction, fellow students should be taught to quickly get a member of the school personnel (NASN, 2012b; National Institute of Diabetes and Digestive and Kidney Diseases, 2012). A current position of the American Diabetes Association (ADA) is that a *diabetes medical management plan* should be in place and that the "school nurse should be the primary coordinator and provider of care and should coordinate the training of an adequate number of school personnel" to assist in the care of children with diabetes (ADA, 2012, p. s78). However, many school nurses do not feel comfortable delegating tasks such as administration of insulin or glucagon. See Chapter 13 for more on this issue.

Testing blood sugar and taking insulin at school can be frustrating and can cause children to feel singled out or different from their peers. One study found that adolescents with type 1 diabetes have significantly higher rates of depression than those without diabetes (Fritsch, Overton, & Robbins, 2011). Also, some schools do not permit blood sugar testing and insulin administration in classrooms, so that school health offices are often a place of refuge for diabetic students (Winsch, 2011). It is important for school nurses to understand each child's concerns and to alert teachers and school personnel to the signs and symptoms (as well as the treatment) of hypoglycemia. In addition to the obvious emergency health-related concerns for diabetic children, it can cause long-term health problems for children, though not generally for adults (National Institute for Health and Care Excellence, 2015). Pertinent to the school setting, a classic study showed that diabetes-related severe hypoglycemia does affect memory tasks (Hershey, Bhargava, Sadler, White, & Craft, 1999). Over time, memory deficits can affect learning and progress in school.

Type 2 diabetes cases have been rising, and school nurses can be instrumental in

prevention measures and early identification. It is often found more frequently in Native American and Hispanic populations and less frequently among non-Hispanic Whites. Also, obesity is an independent risk factor, with close to a quarter of children and youth being obese. Visceral fat is associated with insulin resistance and impaired glucose tolerance, a pathology linked to type 2 diabetes. Culturally sensitive interventions that include increased physical activity and education on good nutrition, as well as behavior modification and ongoing methods of support (e.g., group meetings, phone/email reminders) were shown to be effective in a systematic review (Brackney & Cutshall, 2015). Individually tailored counseling for overweight children and families is thought to be more effective than general information about nutrition and exercise (Magnusson, Kjellgren, & Winkvist, 2012). School nurses should assess their school population and promote interventions that benefit at-risk students, as well as the general school population.

SEIZURE DISORDERS. Seizure disorders are not uncommon in the school-age population. Epilepsy is a disorder of the brain in which neurons sometimes give abnormal signals. A person who suffers from epilepsy may have comorbidities including autism, depression, and anxiety (Brooks-Kayal et al., 2013). For the majority of those diagnosed, seizures can usually be controlled with medication (e.g., antiepileptic drugs specific to the pediatric population), surgical treatment, or a special (e.g., ketogenic) diet (Epilepsy Foundation, 2014; National Institute of Neurological Disorders and Stroke, 2015).

It is important for school nurses to develop care plans to address seizure concerns during school hours. Care plans include monitoring medication compliance and teaching school staff about first aid measures for seizure victims. Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying. They may exhibit signs of school avoidance. Nurses need to work with these children and to teach all students about the disease process and the need for empathy and understanding. Similar to issues related to insulin administration for diabetic students, children with seizure disorders may have an emergency medication ordered by their physician (e.g., Diastat, midazolam, lorazepam, clonazepam). Prescribing providers and school nurses should be aware of the laws regarding the administration of seizure rescue medications, particularly as they pertain to unlicensed assistive personnel (Hartman, Devore, & Section on Neurology, Council on School Health, 2016). The Epilepsy Foundation (n.d.) has advocated for its use in schools, and school nurses are often caught between the rights of students and their parents and their state's nursing practice act.

FOOD ALLERGIES AND ANAPHYLAXIS. Another leading chronic condition found in school settings is severe food allergies that can lead to anaphylactic shock. Such severe allergies result in approximately 200,000 ER visits each year (Food Allergy Research & Education, 2016). Food allergies cause 30% to 50% of all anaphylaxis cases (Cianferoni & Muraro, 2012). Eight common foods account for 90% of severe food allergies. They are fish, shellfish, soy, milk, egg, wheat, peanuts, and tree nuts (e.g., cashews, walnuts). Many common foods and school supplies (e.g., play dough) can contain hidden allergens, and care must be taken to prevent exposure. School nurses coordinate and work with students

and their families, along with school personnel, to raise awareness and enlist caution. They also work with families, and health care providers, to ensure that epinephrine via an autoinjector (EpiPen) is available for the child in case of emergencies. Epinephrine reverses the body's allergic reaction to the allergen, and timely intramuscular administration is the treatment of choice for anaphylaxis (Tiyyagura, Arnold, Cone, & Langhan, 2014). It is also used for beesting and other allergies, in addition to food allergies. Students are often allowed to carry an EpiPen on their person because reactions can occur very quickly (Elementary Teachers Federation of Ontario, 2015). School nurses should coordinate with teachers and lunchroom personnel to ensure that proper protocol is followed for allergic reactions. School personnel should be made aware of the food allergy, understand an anaphylactic reaction, and be able to verbalize or demonstrate how to use the EpiPen or other needed medication (NASN, 2012a). Chicago Public Schools has instituted a policy of stocking schools with EpiPens and authorizing school nurses to administer them if it is determined that the child is having an initial anaphylactic reaction. Citing a frightening statistics—that 25% of initial anaphylactic reactions in children occur during school hours—the Student Health and Wellness staff sought a remedy. Problems with implementation, however, include not having daily school nurse coverage in all schools due to budget issues; this is a common problem in school health (Zadikoff, Whyte, DeSantiago-Cardenas, Harvey-Gintoft, & Gupta, 2014).

BEHAVIORAL PROBLEMS AND LEARNING DISABILITIES. Other chronic childhood health problems are those of emotional, behavioral, and intellectual development. These are not always easy to detect and measure, and they can be debilitating. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished. The National Institute of Mental Health (NIMH) reports that emotional and behavioral disorders affect 10% to 15% of children globally (Kid's Mental Health Portal, 2016). Problems such as oppositional defiant disorder, bipolar disorder, and early schizophrenia can affect the school-age population and is a concern to school nurses and staff (Pryjmachuk, Graham, Haddad, & Tylee, 2011; Riley, Ahmed, & Locke, 2016). The causes of emotional behavioral problems and learning disabilities appear to have genetic, environmental, and cultural influences. The number of children with learning disabilities in the lowest economic group is twice that in the highest group (Sondick et al., 2011). Children who were characterized as being in fair or poor health were almost five times as likely to have a learning disability and more than twice as likely to have attention deficit hyperactivity disorder (ADHD) as children with excellent, very good, or good health status (Sondick et al., 2011). High-risk children often come from families with a high incidence of child abuse (physical and sexual) and neglect. The number of children affected by parental drug use has surpassed that of children with disabilities caused by lead poisoning, another major contributor to developmental problems in children.

ADHD is a cluster of problems related to hyperactivity, impulsivity, and inattention. Approximately 6.4 million school-age children have been diagnosed with ADHD (National

Center for Learning Disabilities, 2014). School nurses must be aware of the signs and symptoms and serve as an advocate for these children and their families. At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school may often have difficulty and conflict with peers, as well as problems organizing tasks. They may be more accident prone and may have more school-related problems, such as grade retention and suspension or expulsion. They often have problems with grooming and with handwriting, and they exhibit difficulty sleeping. ADHD is sometimes found with associated disorders, such as communication or language disorders and learning disabilities. It is estimated that as many as one third of children with learning disabilities also have ADHD (National Center for Learning Disabilities, 2014). Counseling and behavior therapy are often used with these children with a 70% to 80% success rate demonstrated by improved behavior (Substance Abuse Mental Health Services Agency, 2015).

Behavioral and emotional problems of school-age children can stem from many causes. School nurses can be alert to early symptoms and refer families for counseling. Collaboration is needed between the child's family, the school, and the child's health care provider to diagnose ADHD and effectively plan appropriate interventions and educational accommodations. Teacher confirmation of ADHD-related behaviors is very important. Numerous checklists and assessment tools are available, and school psychologists typically serve as a source for additional information and resources. School nurses can assist parents in recognizing the symptoms of ADHD and obtaining appropriate treatment and follow-up. A multimodal treatment approach may include stimulant medication, usually methylphenidate (Ritalin or Concerta), dextroamphetamine (Dexedrine), and amphetamine (Adderall), or antidepressants (such as Wellbutrin). Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this method of treatment. Not all children and adolescents respond to medication, and medication dosage must be carefully monitored and titrated. Research suggests that adopting a strengths-based assessment and treatment plan for students with ADHD has potential to provide a healthier educational experience that can reduce the risks of comorbid conditions associated with ADHD. Rather than focus on identifying and treating the deficits associated with ADHD, the strengths-based approach focuses on interventions that reinforce well-being and resilience (Climie & Mastoras, 2015). School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens.

Collaboration is needed between the child's family, the school, and the child's health care provider to diagnose ADHD and effectively plan appropriate interventions and educational accommodations. Teacher confirmation of ADHD-related behaviors is very important. Numerous checklists and assessment tools are available, and school nurses typically serve as a resource for additional information. School nurses in partnership with behavioral health providers can assist parents in recognizing the symptoms of ADHD and

obtaining appropriate treatment and follow-up. A multimodal treatment approach may include stimulant medication, or antidepressants. School accommodations for learning problems and social skills training for the child with ADHD may be indicated. Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this method of treatment. Not all children and adolescents respond to medication, and medication dosage must be carefully monitored and titrated. School nurses can assist parents in this task. The main goal of medication for school-age children is academic improvement. If this does not occur, medication may need to be changed or discontinued. School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens (Chan, Fogler, & Hammerness, 2016).

MEDICATION ADMINISTRATION. Medication administration for a variety of conditions has historically been an important responsibility for school nurses (NASN, 2012c). In schools where a nurse is present every day, the nurse can personally oversee medication administration. Unfortunately, many nurses cover more than one school and so other school personnel (e.g., secretaries, health aides) may be tasked with overseeing medication administration. The majority of states have laws allowing teachers or health aides to administer medication. In these situations, school nurses should provide training and audit records to ensure that proper guidelines are followed. Multiple studies show that medication errors increase when school nurses cover multiple schools and unlicensed personnel assist in medication administration (Richmond, 2011). Problems commonly occur with omission of doses because students fail to come to the office for medication administration. This is especially problematic with students taking insulin or antidiabetic drugs, antibiotics, and medication for ADHD.

Another issue surrounding medication administration in the school setting is regarding delegation. Each state's individual nurse practice act provides rules on delegation of nursing tasks. School nurses must understand their own state's act and the legal implications regarding their decisions. School districts are responsible for including medication administration guidelines in their policies, and school nurses must comply with established guidelines. Recently, much discussion has occurred regarding the administration of Diastat gel in the school setting (ANA & NASN, 2011). Diastat gel is often administered rectally to stop the onset of cluster seizures. However, Diastat can decrease respirations as well. School nurses have the skills and experience to properly assess such occurrences, where lay personnel, even if trained in proper administration of the medication, do not. ANA & NASN (2011) supports only school nurses administering this medication, but parents and others have pushed the administration of Diastat by lay people (Kahn & Grasska, 2014).

In the case of insulin administration in schools, the American Nurses Association filed a lawsuit on behalf of California school nurses to prevent insulin administration by unlicensed personnel. There argument centered on the state's Nurse Practice Act and the need for licensed nurses to administer this medication (with dosage often checked by two

nurses in hospital settings). However, the American Diabetes Association and others argued that not all schools have adequate school nurse coverage, and over one quarter of schools do not employ a licensed nurse. Two courts ruled on the side of the school nurses, but the California Supreme Court ultimately overturned those decisions, making it possible for unlicensed personnel to give medications, including insulin, with parental and medical permission (Balestra, 2012; Walsh & Lambert, 2013). The concept of "in loco parentis" instructs nurses, teachers, and school staff to provide care for the student in the parent's place and with their consent (Health & Welfare Committee, 2012, p. 13).

Health Services to Prevent Illness and Injury

School nurses emphasize prevention and focus many of their efforts on prevention of communicable disease (via immunizations) and of injuries.

School nurses assist with immunization clinics.

IMMUNIZATIONS. Among schoolchildren, the incidence rates of measles (rubeola), rubella (German measles), pertussis (whooping cough), infectious parotitis (mumps), and varicella (chickenpox) have dropped considerably over the last several decades because of widespread immunization efforts, although these communicable diseases do still occur and sometimes with serious complications such as birth defects from rubella and nerve deafness from mumps. Although the number of reported cases of hepatitis A, measles, and meningococcal disease decreased from 2008 to 2009, cases of pertussis and mumps

increased (Maternal and Child Health Bureau, 2013).

Low immunization levels in many areas, particularly among poor populations, and increased disease rates signal the need for constant surveillance, outreach programs, and educational efforts. School nurses are deeply involved in each of these preventive activities. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws for school entrance, which vary among states, have enabled public health personnel to carry out these preventive services. All states require children to be vaccinated against certain communicable diseases as a condition for school attendance (CDC, 2015b). Statewide immunization information systems can be beneficial for schools, school nurses, and children and their families. School nurses, like public health nurses, may have access to not only viewing immunization records but also the ability to update them. This provides ready access for children and parents, as well as school nurses, to check immunization records, track those children whose immunizations are incomplete, and provide critical information during times of disease outbreaks. These systems also make it easier for school nurses to complete district and state immunization reports and work with public health agencies in providing necessary vaccines in a timely manner (Bobo, Etkind, Martin, Chi, & Coyle, 2013).

School nurses often oversee and ensure that children are in compliance with school entrance laws regarding immunizations. They may call parents directly when they note that the student is out of compliance. They may also arrange to help the student get immunized by facilitating appointments or, in some school districts, by directly providing the immunizations. Kaufman et al. (2013) studied randomized control trials to evaluate the effects of face-to-face interventions delivered to individual parents or groups of parents in order to provide information or education about early childhood vaccination. The data collected revealed that these strategies do not consistently improve either immunization rates or parent knowledge and understanding of vaccination. The Centers for Disease Control and Prevention provides information for National Immunization Awareness Month and provides a toolkit for school nurses and others to follow when developing successful immunization outreach programs in schools (CDC, 2016). School nurses can be effective advocates in helping parents make decisions about vaccines (e.g., HPV for adolescents), especially when they have sufficient knowledge and recognize their role as an opinion leader (Rosen, Ashwood, & Richardson, 2016).

Many school districts require TB skin testing upon school entry, but not all states have policies regarding this. Some areas with a high proportion of school entries who have recently immigrated from high-TB countries and areas do require TB skin testing upon admission to school or when transferring in to a district from another area and may use interferon gamma release assay (IGRA) testing as well as skin testing (Flood, 2013). It is important for school nurses to work with their school districts in developing policies for TB screening and monitoring, as TB outbreaks in schools can affect large numbers of students (Galemore, 2016). School nurses work with public health agencies to identify and test contacts and refer them for treatment if necessary. Laboratories can also provide genotypic

testing to determine in-school or out-of-school transmission (Williams et al., 2016). See Chapters 8 and 22 for more on TB testing, parental resistance to vaccines, and current immunization schedules for school-age children and adolescents.

SAFETY. School nurses are also involved in ensuring that injury prevention efforts are encouraged. Emphasis on a healthful physical environment includes proper selection, design, organization, operation, and maintenance of the school building and playground equipment. The Centers for Disease Control and Prevention estimate that there are more than 200,000 children treated in the emergency department every year for playground-related injuries (CDC, 2012).

About 67% of playground injuries involve falls or equipment failure, and the most common injuries are fractures (36%), abrasions/contusions (20%), and lacerations (17%), but concussions and other serious injuries can occur (National Program for Playground Safety, 2016). Custodial personnel assist in the maintenance of school grounds, but school nurses must be aware of conditions and make recommendations to remedy unsafe situations. As school nurses provide first aid treatment for playground injuries, they may observe trends (e.g., a high number of injuries where faulty playground equipment or other factors influence higher injury rates) and request action. When injury trends are noted, school nurses work with maintenance departments and administration to advocate change and prevent future injury. School nurses also assist with physical adaptations for students with special needs (e.g., ramps, electric doors); they work to ensure safety in and around schools, and they are mindful of visual, thermal, and acoustic factors in school buildings, as well as aesthetic values. Additionally, they promote sanitation and the safety of the school bus system, as well as food services.

Another area of growing concern is student safety after natural disasters or emergency situations. Recent earthquakes and potential bioterrorism events may impact schools or not permit children to return home at the end of a school day. School nurses are ideal persons to assist in disaster/emergency relief. Students do spend much of their time in school, and local schools are often designated as shelters in times of disasters (NASN, 2016). School nurses can assist in the development of emergency plans, as well as provide care and comfort to children and their families in times of emergencies.

Health Education and Health Promotion

Another main function of school nursing practice involves education and health promotion. This includes planned and incidental teaching of health concepts and health curriculum development. In some states, school nurses even teach the regular health classes. Education may be one-on-one to help a child obtain better control over asthma or to explain to a newly diagnosed diabetic student what is occurring in his body. As an educator, the school nurse may also teach an entire class regarding a student's severe food allergy or the need for proper hand hygiene. The school nurse explains in simple terms what allergies are and helps students understand that allergies are not contagious, what to do in the case

of an allergic reaction, and the importance of not sharing foods that may contain potential allergens (NASN, 2016). The application of research is important in school nursing. See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE FOR SCHOOL NURSING

A review of the literature identified seven studies that investigated the impact of school-located influenza vaccination (SLIV) program on rates of absenteeism. Six of the articles compared schools that participated in SLIV programs with control schools. Results from all the studies indicated children who were vaccinated had fewer days of being absent.

Although school nurses often work with individual children, they also look at the school community as a whole and should conduct interventions that will benefit the school population. School nurses must also collect data and determine the effectiveness of their treatments. Finally, school nurses must also remember the goals of the institution in which they work (i.e., education) and strive to meet these goals (i.e., increased attendance) while at the same time protecting the public's health.

Hull, H. F., & Ambrose, C. S. (2011). The impact of school-located influenza vaccination programs on student absenteeism: A review of the U.S. literature. Journal of School Nursing, 27(1), 34–42.

Another example of evidence-based practice in school nursing involves a coordinated school health program intervention to increase physical activity and decrease BMI among minority children. The nurse researchers used a parallel group, randomized control design, and employed a community-based participatory research approach between the University of California, Los Angeles, and five underserved elementary schools. Randomization of schools occurred—to either a control group with general education, or Kids N Fitness intervention. Nurses, community health workers, and physical education specialists conducted the weekly 90-minute sessions over a 6-week period that included nutrition and behavior modification, family involvement, and physical activity. All activities were culturally appropriate, and children's exercises included Salsa and Hip Hop dancing, soccer, and jumping rope. Parents were given information on problems that result from obesity in a support group atmosphere. Children and parents were then instructed on healthy food choices, portion control,

and food labels and shopping tips. Baseline measurements (height, weight, BMI, waist circumference, resting BP) were gathered, following physical exam clearance by NPs, and were collected again at the end of the class sessions (4 months) and 12 months after the intervention. Questionnaires on nutrition and physical activity were also used over the same time intervals.

Significant results were found for participants (n = 251) between the two groups and over the time period for the study among those participating in the intervention. For boys, there was a decrease in TV viewing, and for girls, there were higher reports of daily physical activity, PE class attendance, and decreases in BMI at 12 months.

Impact of a nurse-directed, coordinated school health program to enhance physical activity behaviors and reduce body mass index among minority children: A parallel-group, randomized control trial. International Journal of Nursing Studies, 50(6), 727–737.

How could you use information from these studies to improve school nursing practice and the health of school-age children?

Because students trust school nurses, students often listen to them. Educational subjects are limitless, but should always apply to the specific needs of the children in the school. The nurse must use creativity and autonomy to identify and prioritize needs. A school nurse may also teach about basic first aid, nutrition, physical exercise, and seat belt safety, or provide information about careers in the health care professions.

In addition to lecture or verbal teaching, education may also be in the form of posters, e-newsletters, or in-service presentations for educators and parents (Islam et al., 2016). These activities integrate health information with students' daily living experiences to build positive attitudes toward health and to establish sound health practices that will carry forward into adulthood (Avery et al., 2013).

Screenings: Opportunities for Teaching

Most local school districts provide some type of health screening services, usually through the school nurse or local health care providers. Although the goal of all screening is to promote early intervention, screening also provides the school nurse many opportunities to teach students and staff. Referral information resulting from screening results is usually given to parents, and school nurses may contact parents to encourage follow-through (CDC, 2015k; Krause-Parello & Samms, 2011). Children who are not present for school screenings may not receive the benefits of these screenings (e.g., homeschooled and private school students). School nurses often help to coordinate screening resources and benefits, and they often carry out additional screenings for students who were absent when mass

screenings were held.

VISION. The 2014 SHPPS noted that 82.3% of reporting school districts offered vision screening (CDC, 2015). School nurses often oversee routine vision screenings at periodic intervals so that vision problems that can interfere with learning may be detected and treated early (e.g., nearsightedness, farsightedness, strabismus, amblyopia). School nurses also are involved in follow-up and referral. They often send emails or letters to parents, make phone follow-ups, and provide referrals and resources to ensure that corrective eyewear is obtained. Local Lions Clubs may be involved in paying for area optometrists to assist with and/or direct screenings, as well as to provide follow-up care (Mattey, Zein, O'Malley, & Haron, 2013).

HEARING. Hearing screenings were reported by 77.2% of districts, down from earlier surveys (CDC, 2015). These mass screenings are done to detect any serious hearing deficits that may be related to recurrent ear infections or noise-induced hearing loss (NIHL), often resulting from loud music, video games, or excessive exposure to noise. About 20% of school-aged children, aged 6 to 19, have some type of irreversible, permanent hearing damage (Hendershot, Pakulski, Thompson, Dowling, & Price, 2011). Some have a type of *sensorineural hearing loss*—or one that involves the inner ear or the nerves leading from the inner ear. It is permanent and cannot be surgically or medically corrected (American Speech-Language-Hearing Association, 2016). One national survey of school nurses indicated that about half of them saw a lack of educational programs addressing NIHL and noted the need to recommend programs and policies to address all types of hearing loss (Hendershot et al., 2011). Similar to vision screening, school nurses screen and refer students with suspected hearing problems to medical specialists (e.g., audiologists, physicians). School nurses can use the opportunity afforded by vision and hearing screenings to provide education to students and their parents about preventing problems such as noise-induced hearing loss.

OTHER HEALTH SCREENINGS. Height, weight, and sometimes blood pressure and cholesterol screenings are done on a regular basis to monitor normal growth and development and allow for early intervention with populations who are especially susceptible to hypertension and heart disease. In some areas, scoliosis screening is also done, frequently during middle school years or in fifth grade, to permit early detection and referral for medical intervention (e.g., bracing, surgery). One multistate survey found that almost 60% of school nurses reported conducting scoliosis screenings (Krause-Parello & Samms, 2011). Scoliosis may be congenital, but is often idiopathic, and the efficacy of school screening programs has been questioned; some evidence-based recommendations suggest that scoliosis screening should be discontinued (Jakubowski & Alexy, 2014). Literature reviews have not shown sufficient evidence to support screenings, but one population-based cohort study, conducted over a 10-year period, found "sustained clinical effectiveness in identifying patients with adolescent idiopathic scoliosis" that needed continued clinical observation, and the researchers advocated for routine screenings (Deurloo & Verkerk, 2015; Fong et al., 2015, p. 825).

In Texas, and some other areas of the country, *acanthosis nigricans* (hyperpigmentation from various causes, but sometimes a symptom of diabetes) screenings are being done to look for early markers of type 2 diabetes, especially in high-risk populations (Texas Department of Health Services, 2016).

Pediculosis (or head lice) in school-age children is a continual problem for school nurses. Between 6 and 12 million children aged 3 to 11 each year are estimated to be infected with head lice, and school nurses are often called upon to do "head checks" for pediculosis. Pediculicides (e.g., permethrin, pyrethrins, dimethicone) are helpful in killing lice, and school nurses often provide families with education on prevention and eradication methods (Ihde, Boscamp, Loh, & Rosen, 2015; Pontius, 2014). See Chapter 22 for a more in-depth discussion on head lice and treatment.

ORAL AND DENTAL HEALTH: TEACHING AND REFERRAL. Dental caries affect more than half of school-age children and are the most common chronic disease for that age group. In 2010, about 7% of children aged 2 to 17 years had unmet dental needs because the families could not afford dental care (Sondick et al., 2011). Approximately a quarter of U.S. children do not have dental insurance, either private or public (CDC, 2014). The percentage of children and adolescents aged 5 to 19 years with untreated tooth decay is twice as high for those from low-income families (25%) compared with children from higher-income households (11%) (Dye et al., 2012). School nurses can address dental health issues in a variety of ways. At a community level, they can educate the public about the benefits of dental fluoride treatments. They can advocate for fluoridation of drinking water, school-provided fluoride rinses or gels, and dental sealant programs. These are all cost-effective, proven methods of reducing dental caries in school-age children. At the classroom level, school nurses can provide dental education and provide toothbrushes, toothpaste, and floss to ensure that students are able to practice good dental hygiene habits. Local organizations and businesses often will donate such supplies. Many programs from the American Dental Association, the CDC, and other organizations provide resource materials. At an individual level, school nurses can assist in finding resources for those with no dental health insurance. Finally, school nurses can successfully educate parents, especially those who are immigrants or have different cultural beliefs, regarding the importance of oral and dental health (Hassmiller, 2016; Smith, Brach, & Horowitz, 2015; Swan, Barker, & Hoeft, 2010).

Dental screenings or clinics may be conducted to determine the incidence of dental caries, especially in elementary school children, and to encourage follow-up with local dentists for necessary restorations. At the time of the most recent national survey of schools, only 30.3% of districts reported performing some type of oral health screening (CDC, 2015). See Chapter 22.

Promotion of a Healthful School Environment

A third function of school nursing practice includes maintaining and promoting a healthful

school environment. Promotion of healthful school living emphasizes planning a daily schedule for monitoring healthy classroom experiences, extracurricular activities, school breakfasts and lunches, emotional climate, discipline programs, and teaching methods. It also includes screening, observing, and assessing students to identify needs early and to report illegal drug use, bullying, suspected child abuse, and violations of environmental health standards (Patestos, Patterson, & Fitzsimons, 2014). Cyberbullying is another area where school nurses can provide education to students, parents, teachers, and school staff, as well as response to warning signs among school-age children and youth (Van Ouytsel, Walrave, & Vandebosch, 2015). Health promotion also involves the nurse in supporting the physical, mental, and emotional health of school personnel by being an accessible resource to teachers and staff regarding their own health and safety.

PROPER NUTRITION AND EXERCISE. Many factors can affect the school environment—heating, cooling, lighting, safe playgrounds, and policies and practices to limit bullying and social aggression or other forms of school violence. The school cafeteria and physical education activities can promote health or contribute to obesity and sedentary lifestyles.

OBESITY. Obesity rates have steadily increased for all children since the 1980s; the rates have doubled for children between ages 2 to 5 and adolescents (ages 12 to 19). Rates have tripled for those between ages 6 and 11 years. Approximately 17% (or 12.7 million) of children and adolescents aged 2 to 19 years are obese (CDC, 2015c). Obesity often begins in childhood and becomes a risk factor for cardiovascular disease and diabetes later in life. With the increase in child obesity rates, the number of children diagnosed with type 2 diabetes continues to rise, especially among youth of minority race/ethnicity. It is estimated that there are 13,600 newly diagnosed youth under the age of 20 diagnosed with type 2 diabetes annually (National Diabetes Education Program, 2011). In 2011–2012, the CDC (2015c) reported that the prevalence among children and adolescents was higher among Hispanics (22.4%) and non-Hispanic Blacks (20.2%) than among non-Hispanic Whites (14.1%).

As children become older, families have less impact on food choices, and peers begin to have more influence. Results of the 2013 YRBS indicate that very few high school students eat enough fruits and vegetables—of those surveyed only 22% had consumed more than three servings of fruit, and 16% had eaten a sufficient number of vegetables in the 7 days prior to being surveyed (CDC, 2013b).

School nurses should play an integral role in the prevention of overweight and obesity, as well as in addressing the health needs of overweight and obese students (NASN, 2013). Approximately 32% of youth are overweight or obese. Many factors contribute to this health issue: diet, lack of physical activity, genetics, family and social factors, culture, socioeconomic status, and media marketing (NASN, 2013). School nurses can provide education to students and families about healthy food and lifestyle choices and help families connect to resources in the community that will support the adoption of healthier lifestyles. A national survey found that 52.2% of school nurses reported screening for obesity, even

though they noted that childhood obesity was a significant problem. Fewer than half of school nurses reported calculating and recording BMI measurements (Krause-Parello & Samms, 2011). Steele et al. (2011) studied school nurses' perceived barriers to counseling student and parents about weight problems. They found barriers related to the school nurse's knowledge and self-perceived competency, personal weight problems/role model, lack of time and support from school administration, prior negative experiences with families regarding school-based weight management programs, and the student's lack of motivation as well as ineffective interventions to address weight problems for all students. These barriers should be addressed and sound evidence-based interventions sought.

HOMELESSNESS AND HUNGER. Poor nutrition and obesity are not uncommon among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. Homelessness and hunger can also have serious consequences, one being an impact on the academic performance of children. Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition. Infection and illness (e.g., ear infections, asthma, bronchitis, gastroenteritis) that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics. Dental caries are frequent. Poor nutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful malnutrition. Homelessness and food insecurity can lead to overreliance on fast food and convenience stores, and lack of stable housing triggers stress and anxiety, which can lead to obesity. About 43% of homeless children in Baltimore were obese or overweight (Hindman & Mincemoyer, 2014). Dental caries are also much more common among homeless children than other low-income housed children (Chiu, DiMarco, & Prokop, 2013). See Chapters 22 and 28.

School nurses can help coordinate services for homeless children and advocate for better nutritional choices in the lunchroom and vending machines. This may include working for policy changes to limit soft drink sales in public schools. They can also teach all grade levels regarding proper nutrition, and they can educate students and parents alike about nutritious snacks in contrast to snacks with little food value, as well as provide information on community resources (e.g., food banks, health clinics, shelters). School nurses may also work with staff to provide nutrition and exercise programs, support groups, and collaborative efforts to assist families dealing with hunger and homelessness.

EATING DISORDERS. Eating disorders are another area of concern. Issues with body image and control are at the heart of *anorexia nervosa* and *bulimia nervosa*, common problems for adolescent girls. These diseases have emotional causes that pose complex challenges to treatment. School nurses must be aware of the signs and symptoms of eating disorders and be proactive in identifying students at risk, working collaboratively with other members of the mental health treatment service team to advocate for the child. Scoliosis screenings are an optimal time to also observe for eating disorders, as examination of the spine allows for visualization of the body core. School nurses can work with students to

develop a healthier self-concept and identify outside treatment resources (National Eating Disorders Association, 2015).

LEVELS OF PREVENTION PYRAMID

HEALTH ISSUE: Obesity in a school setting

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Work closely with the child, family, physician, and teacher to decrease body mass index (BMI)	• Continue to promote healthy lifestyle choices and daily physical activity	

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Conduct yearly screening of students' heights and weights to calculate BMI • Complete health histories on at-risk children	• Initiate referrals for health care provider follow-up in collaboration with parents of students at risk for obesity

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Limit passive activities and increase sports and physical activity • Teach children how to make better food choices at fast food restaurants • Educate children and teachers to promote good nutrition and a physically active lifestyle • Promote a change of policy to take junk food out of vending machines	

ADOLESCENT HIGH-RISK BEHAVIORS. Mortality and morbidity rates for adolescents are low overall and demonstrate considerable improvement since the early 1900s. There are six categories of high-risk behaviors that are directly related to morbidity and mortality in youth and young adults: behaviors that lead to unintentional injury and violence, tobacco use, alcohol and drug use, sexual behaviors that lead to pregnancies and sexually transmitted infections, unhealthy dietary behaviors, and lack of physical activity (Kann et al., 2012). Many of the health problems faced by adolescents are a result of their own choices and high-risk activity (CDC, 2015i). For example, sexual activity, substance abuse, injury, and violence are all high-risk behaviors in which adolescents can choose to participate or not. The effects of such choices may not be discovered for many years. Suicide is a leading cause of death of adolescents, with boys more likely to die from suicide than girls (Kaslow, 2014). Within the last decade, a good number of states developed

policies to address alcohol and drug use (increasing from 22% to 42%), STD prevention (up from 17.6% to 32%), suicide prevention (from 16% to 28%), and tobacco use (rising from 19.6% to 40%), in an effort to address these behaviors (CDC, 2015d). See Chapter 22.

Sexual Activity: Teen Pregnancy and STDs. Sexual activity is a sensitive issue. However, the 2013 YRBS indicates that 46.8% of students surveyed reported they had had sexual intercourse, and 15.0% had had sexual intercourse with four or more partners in their lifetime (Kann et al., 2012). Each year, about half of new STD cases in the United States occur among those between the ages of 15 and 24 (CDC, 2015). The overall rates of syphilis, gonorrhea, chlamydia, human papillomavirus (HPV), and herpes simplex virus are climbing.

Providing STD services and HIV/AIDS education can be a daunting task. Young people with STDs are often afraid or embarrassed to seek help. Those who have been exposed to the HIV virus may not know that they are infected. Although in some communities the school-based clinic dispenses condoms, in other areas, school nurses may be restricted in what safer-sex products they can provide. However, nurses *can* provide teens with education and with information about resources that are available outside of school property. School nurses can promote, at the local and state level, the HPV vaccine that guards against cervical cancer. They can promote abstinence or delaying sexual initiation, as well as fostering safer-sex messages that promote the use of condoms. Sex education is effective at both delaying the onset of sexual activity and decreasing sexual activity in adolescents who are already sexually active. Comprehensive risk reduction is effective at reducing adolescent pregnancy, HIV, and STIs. It is also effective in increasing safer-sex practices, knowledge of the efficacy of birth control methods, and overall sexual knowledge (CDC, 2015h; Chin et al., 2012). See Chapters 21 and 22.

School nurses are sometimes restricted by state and/or district policies from addressing the issues of sex education and STD (including HIV) prevention. However, they can inform students and others in the community about the existence of youth development and family planning programs, which are often stationed strategically in inner cities, near schools, or in school-based clinics. These agencies are empowered to provide birth control information and counseling to young people.

Substance Abuse. Substance abuse among young people was almost unknown before 1950 and rare before 1960. Now, adolescent drug experimentation and use poses serious physical and psychological threats. During the 30 days before being surveyed, adolescent participants in the 2013 Youth Risk Behavior Survey reported that 23.4% tried marijuana, 15.7% had smoked tobacco, 8.8% had used smokeless tobacco, and 34.9% had consumed alcohol (Kann et al., 2012).

School nurses can assist in programs targeting all substance abuse. Successful programs focus on protective factors, instead of just high-risk behaviors. The programs focus more on the root causes, or why youth choose high-risk activities. When school nurses focus on

developing and advocating for protective factors that assist youth to feel part of their community (Pbert et al., 2011), they can help teens avoid the onset of substance abuse. However, a national study of public secondary schools in the United States revealed that only 43% of high schools implement robust drug-prevention curricula (Catalano et al., 2012). See Chapters 22 and 27.

School nurses can also provide resources for smoking cessation and substance abuse programs. Pbert et al. (2011) found that school nurses are successful members of school smoking cessation programs. In addition to school-based education, programs of peer leadership and parental education/involvement and community-wide task forces have been developed to lobby for local legislation and strengthen community–school ties. School nurses can be advocates at a community level by lobbying the city council for tougher ordinances controlling advertising content and zoning (especially near schools). School nurses often work in conjunction with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay tobacco use. Other groups, such as 4-H clubs, religious congregations, the Catholic Youth Organization, and Boy Scouts, use peer counseling to influence young people to assume responsibility for healthy lifestyles, with the goal of developing decision-making skills that lead to healthy lifestyle choices in adolescence and through adulthood. The school nurse participates in and supports existing programs in addition to counseling and referring young people who need help.

Mental Health Issues and Suicide. Depression, schizophrenia, and eating disorders may first appear during adolescence. It is estimated that one in five children have a mental health problem (NASN, 2013). Many adolescents are reluctant to seek help for emotional problems, or help may not be readily available to them. It is estimated that only 40% of those who need treatment actually receives it (NASN, 2013). Common mental health disorders in adolescence include anxiety, depression, ADHD, eating disorders, bipolar disorder, and schizophrenia (NIMH, n.d.a). Suicide is the third leading cause of death for young people between ages 15 and 24; it is the sixth leading cause of death in children between ages 5 and 14 (American Academy of Child & Adolescent Psychiatry, 2014). Girls attempt suicide more frequently than boys, but the actual suicide rate (those who successfully kill themselves) is higher among boys (American Academy of Child & Adolescent Psychiatry, 2014). School nurses must be aware of the signs and symptoms of mental illness and suicidal intentions. They can work with school psychologists, social workers, and other mental health workers to address the needs of the students. They can also provide grief counseling to peers after a student commits suicide. Recent suicides by youth have been attributed to the students being bullied. School nurses also need to be aware of the increased issues related to bullying in the schools and in cyberspace. The YRBSS states that 20.1% of children had reported being bullied while at school, and 16.2% had experienced cyberbullying (NASN, 2013). School nurses must watch for signs and symptoms, as well as provide interventions, to make people aware of and stop bullying (McNeeley & Blanchard, n.d.). Chapters 22 and 27 have more information on adolescent

and behavioral health issues.

ABUSE AND MALTREATMENT. In 2013, an estimated 679,000 children were victims of abuse and neglect. Of these children, 80% suffered neglect, 18% suffered physical abuse, 9% were sexually abused, and 1,520 died (National Children's Alliance, 2014). Girls tended to be maltreated more often than boys. Black, non-Hispanic youth were also at greater risk. In 2014, the victim rate was reported to be 9.4 per 1,000 children with neglect and physical abuse being the most common (Agency for Children and Families, Children's Bureau, 2016). Child abuse prevention education programs can be found in many school districts as a primary preventive intervention. School nurses are required by law to report suspected or confirmed cases of abuse. In addition, school nurses can educate teachers and other school personnel regarding the signs and symptoms of abuse. Abuse can also include issues related to bullying and school violence (King, 2014). Early identification of abuse and intervention is critical for the safety of the child. The number of adverse childhood experiences related to child abuse is directly correlated with long-term health issues. Eisbach and Driessnack (2010) completed a small qualitative study of school nurses and pediatric/mental health practitioners that highlighted the difficulty nurses have in dealing with this issue and their frustration with reporting abuse that often leads to subsequent inaction by authorities. It is important to be well versed in subtle signs and symptoms of maltreatment and develop strong collaborative relationships with social service professionals. Signs that a child might be maltreated include reports of abuse, a sudden change in behavior, lack of medical treatment follow-through, learning problems of unknown etiology, child responses that are consistently guarded or compliant, and an avoidance of home or certain individuals (NASN, 2014b). For more information on health problems and issues concerning children and adolescents, see Chapter 22.

School-Based Health Clinics

Because of the complex and intertwined emotional, physical, and educational needs of school-age children and adolescents, a more comprehensive interdisciplinary approach to services is needed than the piecemeal approaches attempted previously. School nurses are able to do much to influence schoolchildren's health. However, often they need to refer the children to a health care provider. Yet, more parents are working and less available to take care of their children's health care needs during the day. School-based health centers (SBHCs) provide ready access to health care for large numbers of children and adolescents during school hours, reducing absences from school due to health care appointments. SBHCs provide a variety of services in a user-friendly manner at a convenient location.

In 2013–2014, there were 2,315 SBHCs in the United States; this figure is up 20% from the 2010–2011 *Census of SBHCs* (School-Based Health Alliance, 2014). These clinics are distributed in high schools (23.4%), middle schools (8.8%), and elementary schools (15.3%) and are generally established on school grounds (School-Based Health Alliance, 2014). Some clinics provide services only to schoolchildren, whereas others extend services to their families and to other neighborhood families with preschool-age children. Most

centers are open full-time. Many SBHCs in middle schools and high schools offer abstinence counseling, pregnancy testing, sexually transmitted infection diagnosis and testing, and pap tests (School-Based Health Alliance, 2014).

SBHCs are staffed by interdisciplinary teams of helping professionals, paraprofessionals, and other staff and can include nurses, nurse practitioners, and social workers. Many hospitals, HMOs, and health departments are sponsors of these school clinics, because it is a cost-effective way to decrease visits to the emergency department and promote health, especially to underserved groups such as adolescents. They help meet the need for patient-centered medical homes, as outlined in the Affordable Care Act. Third-party billing, especially to access Medicaid funding, is increasingly more common among SBHCs, and private foundations have also been instrumental in providing financial and technical support. School nurses support the clinics by referring students who need additional attention. In some areas, school-linked health centers are utilized. These clinics are not on school property, but may be nearby or easily accessible through mass transit. Schools refer students to these centers and have established collaborative, working relationships that promote information sharing and support (Larson & Chapman, 2013).

Evaluation research has demonstrated that SBHCs are effective in increasing student access to health care. This is especially true for adolescents, who often are difficult to reach and do not willingly access health care. Onsite SBHC services are more appealing for adolescents, who have been shown to utilize substance abuse and mental health counseling services, as well as STD and family planning services (School-Based Health Alliance, n.d.). SBHCs also have been found to increase the use of contraception in sexually active teenage girls (Ethier et al., 2011).

School Nursing Careers

School nurses must be able to work autonomously. They need excellent communication skills and the ability to prioritize and collaborate with many others (professional and nonprofessional). The pay for school nurses depends on location and employer (health department or school district). In some places, the wage may be lower than acute care nurses, but the health insurance and benefits package are usually quite extensive (NASN, 2014f). School nurses are sometimes frustrated working in an educational setting, in which health may be a secondary priority, but their expertise is generally highly valued. Baisch et al. (2011) examined the value placed on school nursing services by school staff and found that school nurses were "considered vital to eliminating barriers to student learning and improving overall school health" (p. 74). School nurses save time for teachers and administrators, permitting them to focus on their job of educating students. They also found that school nurses positively influence management of student health concerns, student record accuracy, and student immunization rates. In addition, school nurses may become involved with other issues in the school, such as violence prevention, that extend beyond the traditional role of the nurse (King, 2014; Khubchandani, Telljohann, Price, Dake, & Kendershot, 2013).

Some schools of nursing find that their students can be helpful "school nurse extenders" in permitting school nurses to complete more screenings, referrals, and follow-ups for students (Rossman, Dood, & Squires, 2012, p. 734). Many nursing schools are utilizing schools as clinical sites, with school nurses as preceptors, in an effort to bring more new nurses into this specialty area. There are many positive reasons to work as a school nurse: school nurses generally do not work on weekends, many have contracts that give them the summer off, and the daily work schedule and holidays often coincide with those of the nurse's own school-age children, thus allowing a parent to be home with children during off-school hours (NASN, 2014e). Finally, for most of those employed as school nurses, it is a wonderful and rewarding experience to work with children whose eagerness and innocence can often refresh the soul. It is an opportunity to protect and heal our future leaders, who may become the ones who will eventually protect and heal the world. See Perspectives: School Nurse.

PERSPECTIVES SCHOOL NURSE

A great aspect of being a school nurse is being able to work with many different people. I like being able to work with people who aren't necessarily sick but can benefit from my help. Additionally, school nurses must become familiar with resources and people in the community and surrounding areas. By making friends and connections in multiple facilities, occupations, and the like, school nurses can involve local resources as well as specific individuals in improving the population. That is an essential aspect to recognize: nurses shouldn't be alone in working with the community; they should involve as many people as possible, because community members should be active in improving their own area. Unfortunately, working as a school nurse takes a lot of effort and is time consuming. Even with the work that has been done at the school, it makes me wonder just how long our interventions will last. Unlike working in a hospital, where results come in just a few days, school nurses must work tirelessly for long periods of time to see the fruits of their labors. Resources aren't as readily available as they are for other types of nursing. Being a school nurse requires learning how to get funding for projects. School nurses often don't have models to work from, as each situation may be unique. They must be innovative, resourceful, and dedicated in order to stick with a project long enough for it to be beneficial to the population.

My overall opinion on working as a community nurse has changed over the past few weeks. Being a school nurse has been hard, but rewarding. I know several students in my semester who don't really consider community nursing to be truly nursing practice. I would beg to differ; school nursing is probably the epitome of what nursing was meant to

be. It is focused on service and improving the health and well-being of the populace. Although nursing in the early days mainly dealt with fixing problems and injuries after they happened, everyone knows that an ounce of prevention is worth a pound of cure. Therefore, school nurses are doing the work that should benefit people the most. However, because their focus is on prevention, they seem to get little recognition for their work, because they are saving lives before they are endangered, they are saving teeth before they fall out, and they are saving families before they are lost. I believe their work is pivotal to the improvement of society.

Neil P., School Nurse

CORRECTIONAL NURSING

Nurses who work within the criminal justice system—correctional facilities, prisons, jails, detention centers, and substance abuse treatment programs—work with clients spanning a range of ages from juvenile to elderly, both male and female (ANA, 2013a). The facilities in which they work can hold just a few inmates or may house over 30,000 at one time. The United States has 25% of the world's prisoner population, but only 5% of the world's total population (Aufderheide, 2014). In 2010, there were 1,605,127 state and federal prisoners (rate: 497 per 100,000 U.S. residents), a decrease of 9,228 prisoners in 2009 (Guerino, Harrison, & Sabol, 2011). In 2014, about 1 in 36 adults was supervised through adult correctional systems, including probation and parole—the lowest rate since 1996 (Glaze, Kaeble, Minton, Tsoutis, & BJS Statisticians, 2015). The U.S. per capita rate of incarceration is the highest in the world, and approximately 15 million individuals are processed by the correctional system annually (Reznick, Comfort, McCartney, & Neilands, 2011). Tracking the number of nurses who work in correctional facilities is difficult. The last attempt, made in 2000, estimated the number to be 18,033 registered nurses working in corrections (Knox, 2013).

History of Nursing in the Correctional Setting

Correctional nurse taking an inmate's blood pressure.

Although the correctional system of prisons and jails has been around for a very long time, it historically provided minimal, if any, health care to inmates. Early nurses involved with prisoner and mentally ill populations included Dorothea Dix, who visited prisons around the country in the 19th century and found prisoners in chains, without proper sanitation, living conditions, nutrition, or clothing (ANA, 2013a). In the 1970s, Rena Murtha described the nurse at a large prison as the physician's slave, having little personal connection to patient/prisoners (ANA, 2013a). Prison was viewed as a punishment, and the inmates were seen as not deserving of care that was being paid from public dollars. The situation did not change until 1976, when the U.S. Supreme Court issued its decision regarding *Estelle v. Gamble*. The Supreme Court ruled that not providing medical services inflicted pain and denied inmates their Eighth Amendment rights. This decision led to major reforms in the correctional health system. Medical providers were hired and inmates' rights were established (Aufderheide, 2014; Schoenly, 2015). These rights included (American Bar Association, 2016):

- The right to access care and prompt medical treatment
- The right to professional judgment

- The right to care that is ordered
- The right to informed consent
- The right to refuse treatment
- The right to medical confidentiality

The American Correctional Health Services Association (n.d., para. 3) lists the following principles for correctional nurses and other health professionals:

- The inmate should be assessed as a client/patient at every "healthcare encounter."
- Treatment and procedures should only be administered after informed consent and medical diagnosis.
- Inmates have the right to refuse care, and involuntary care is only given when an immediate threat of danger to the inmate or others is present, or in cases of "grave disability."
- Privacy should be protected when possible (always for sound and when possible for sight).
- Health care should be provided to all inmates, without consideration of custody status.
- Providers should correctly identify themselves, as well as their professional certification or license and accompanying duties.
- Providers should not be a part of death penalty execution.
- Maintenance of the confidentiality for health care information and health records at all times (even during transport) should be ensured.
- Participation in research studies on prisoners should only be done after appropriate human subjects criteria have been met.

Although the right to access care or refuse it, the right to informed consent, and the right to confidentiality are considered basic, these are not always easily granted in correctional facilities. Courts have ruled that prisoners who refuse care may "create confusion and discord in the prison" and have permitted administrative decisions to overrule prisoner wishes (Dubler, 2014, p. 18). Confidentiality is tenuous, as correctional officers regularly observe prisoners and general population prisoners can often view inmates visiting some clinics (e.g., HIV/AIDS), leaving little doubt about their diagnosis. Strip/cavity searches and being present during forced takedowns, among other activities unique to this setting, provide new ethical dilemmas for health care professionals (Dubler, 2014).

Although the correctional health system is relatively new, it is under intense pressure from the courts to ensure that adequate and humane care is provided. Several lawsuits have occurred, and unsolved issues in the correctional health care setting continue to be highlighted. Some main issues regard the provision of ethically appropriate and timely patient care for inmates and provide adequate mental health treatment, prevent prisoner-on-prisoner violence, maintain sanitary and safe conditions, and stop inmate neglect and

abuse. Ensuring that inmates' health needs are met—along with the growing number of inmates and the increasing intensity of their health concerns—has imposed a huge financial burden on systems that are already overtaxed. Funding for correctional health care derives from public tax dollars. Some have wondered if such care and expense should be given to incarcerated persons (Cohen, 2013). This is an ethical dilemma nurses working in correctional facilities must face every day. Keeping equipment up-to-date and avoiding shortcuts can also be challenging. In an attempt to decrease costs and save money, most states utilize managed care organizations to provide some services for inmates. Correctional Medical Services (2011) is the largest provider of prison health care in the nation. Some states are increasingly relying on private prison health care providers, or HMOs (Kutscher, 2013).

Many institutions have a house clinic, medical unit, or infirmary. However, these clinics do not have the capability to provide all the services inmates may need. For example, if imaging procedures, such as magnetic resonance imaging (MRI) or computed tomography (CT) scans, are needed or specialty consultations required, inmates must go to other sources outside of the prison or jail. In these instances, most corrections' facilities use managed health care systems. Correctional nurses work in on-site medical units housed in criminal justice facilities. These facilities can be local jails or may be at state and federal prison. The staff members in these units focus on the individual, immediate, and ambulatory care needs of the patients. They also attend to emergency needs and may help manage chronic conditions. They often provide screenings and preventive services. Larger facilities offer ambulatory and emergency care, mental health services, and subacute care units for short-term therapies (e.g., IV medications). As prisoners age, long-term care and end-of-life care must also be provided (Schoenly, 2015). Correctional nurses have the potential to assist inmates to obtain optimal health and thus save taxpayer dollars (International Association of Forensic Nurses, 2015).

The challenge of correctional nursing is to maintain the fundamental nature of nursing in a challenging environment that is not primarily focused on health care and to remain nonjudgmental toward clients (ANA, 2013a). Correctional nurses may face many ethical dilemmas surrounding ensuring patient basic privacy, but also maintaining personal safety. Today, correctional nurses work with a variety of clients, some of them potentially dangerous. Correctional nurses have for many years identified that there is a conflict between health care in prison and the aims of the prison administration (Powell, Harris, Condon, & Kemple, 2010). They may be instructed to avoid unnecessary touching of inmates, empathizing, engaging in conversations beyond medical care, and developing personal relationships with inmates; as well as referring to inmates by first name.

An estimated 6,851,000 persons (or 1 in 36 adults; 2.8% of the population) were under U.S. adult correctional system supervision during 2014; that represents a drop of over 52,000 from the previous year. The correctional population is comprised of both incarcerated adults and those in community supervision (parole or probation), and females represent about 22% of the total population but only 7% of the total prison population.

The peak population was reached in 2007, with 7,399,600 adults in the U.S. adult correctional system. Texas, California, and Georgia have the highest total populations (Carson, 2015; Kaeble, Glaze, Tsoutis, & Minton, 2016). Demographically, inmates differ from the general population. First, inmates have all committed some type of crime, and 97% of those in state and federal prisons are serving more than 1 year, and over half (53.2%) are serving time for violent crimes. Thirteen percent of males and eleven percent of females in state prisons have been convicted of murder. Half of federal prison inmates are serving time for drug offenses. National statistics indicate a larger portion of Black (37%) and White (32%) than Hispanic (22%) male inmates in state and federal prisons. For female prisoners, Whites more than double the total number of Black prisoners and almost triple the number of Hispanic prisoners. The imprisonment rate for males is 890 per 100,000 U.S. residents, but for females, it is only 65. Many prison facilities are overcrowded, and some states have resorted to using private prisons to accommodate overcrowded conditions (Carson, 2015). In addition, the inmate population is drawn disproportionately from lower socioeconomic backgrounds when compared with the general public. This increases their chances of having a long trajectory of poorer access to health care and treatment. Statistics show a greater disproportion of inmates who are chronically ill and have infectious diseases than the nonincarcerated population (Carson, 2015).

Education and Skills Needed

The preferred educational level for correctional nurses is a bachelor's degree. The level of skill, judgment, and autonomy needed by nurses who work in corrections is supported and developed within baccalaureate education. Some institutions may require additional coursework in criminal justice, decision-making, assessment, and administrative skills. Master's level nurses (specifically NPs) also are working in corrections, providing primary health care to inmates. National certification, through the National Commission on Correctional Health Care as a certified correctional health professional (CCHP) or the American Correctional Association (ACA) as a certified correctional nurse (CCN), is available (ANA, 2013a; National Commission on Correctional Health Care, 2015).

Functions of Correctional Nurses

The prime responsibility of the correctional nurse is to restore and maintain the health of inmates by providing nursing care within correctional settings (ANA, 2013a). The work location does set correctional nurses apart as being the only nurses who enter their workplaces through metal detectors and grill gates and into a locked-down unit. Yet, the knowledge and skill set of a correctional nurse overlaps the knowledge and skill sets of many other nursing specialties.

Correctional nurses use public, community, and school health nursing skills, along with skills acquired from the ER, occupational health, mental health, orthopedics, and ambulatory care specialties. Like public, community, and school health nurses, correctional nurses are autonomous and must make decisions on their own. They track and screen for communicable diseases. They assist in setting up resources so that inmates who are released can continue getting medical treatment. They also educate inmates and promote healthful lifestyles among them. They collaborate with other health care professionals (e.g., physicians, dieticians, counselors) to provide appropriate services (Schoenly, 2015).

Correctional nurses often work in clinic settings, assisting the health care provider in assessing medical situations. They review sick call requests to determine what and if any action needs to be taken and by whom (nurse or physician). They may also oversee the medical unit beds that house patients who suffer from a variety of conditions (e.g., neurological trauma) requiring critical care or kidney disease requiring dialysis. They provide nursing care for inmates with uncontrolled diabetes, those with pneumonia needing IV antibiotics, inmates with mental health issues, or those undergoing withdrawal ("detox") from years of substance abuse (International Association of Forensic Nurses, 2015; Schoenly, 2015). They participate in administering medications, as many inmates receive a variety of medications. In addition, by law, inmates in most facilities must have a physical assessment within 14 days of admittance. Correctional nurses often perform these assessments. Correctional nurses also provide assessment and assistance in occupational safety issues and prenatal care with female inmates (Schoenly, 2015; Schoenly & Knox, 2013).

Finally, correctional nurses are called upon to assist in medical emergencies, anywhere in the facility, such as helping with an accident in a woodshop or evaluating an inmate too sick to leave his cell. If inmates need to go to a hospital or appointment outside the correctional facility, a correctional officer generally accompanies them, not the nurse. With so many responsibilities and the uncertainty of new issues, it is imperative for correctional nurses to prioritize their day (see Display 30–5). Because correctional facilities operate 24 hours a day, every day of the year, it is also vital that they also address emergency preparedness and disaster planning. *Continuity of operations plans* (COOP) are the operational guides used during disaster management in correctional facilities, and most also include Incident Command System (ICS) guidelines as outlined by the FEMA. The

National Institute of Corrections publishes a guide for jail emergencies to assist correctional nurses in emergency preparedness. Taylor and Crianza (2011) provide vivid examples of natural disasters affecting a large jail system (over 10,000 inmates) and the need to plan for power, water, and telephone outages, as well as housing and moving prisoners under emergency conditions. In these situations, nursing and other staff are often asked to remain on-site for extended periods of time and while making arrangements for their own families.

DISPLAY 30.5 A DAY IN THE LIFE OF A CORRECTIONAL NURSE

A day in my life depends on whether or not I am working at the infirmary or on the forensic unit. I will begin with the prison's infirmary.

Today, I worked in the infirmary. These are 12-hour day shifts, so I begin at 6 AM and end at 6:30 PM.

6:00 AM I take report from the night shift charge registered nurse (RN). Within our infirmary, we have both a medical side and a psychiatric side where report is given. Following report, I decide with the other nurses whether or not I am going to be responsible for the medical or psychiatric patients, or the walk-ins (acute/emergency care patients).

7:00 AM I take the medical side for the day, and set up the medications and then wait for the other nurse to set up his or her medications for the psychiatric in-patients. We usually do what we call "pill line" together. Following pill line, I return to the nursing station and do my charting.

8:30 AM Currently, we have a quadriplegic and paraplegic on our medical side who require a lot of personal care. We also have several patients with MRSA (methicillin-resistant *Staphylococcus aureus*) requiring fairly extensive dressing/packing changes along with IV antibiotics. I will have officers escort the MRSA patients out to a trauma bed in order for me to perform the dressing change and/or administration of IV antibiotics (usually vancomycin) that take 1 to 2 hours to complete. Following care, these inmates return to their medical cells, and I do my usual charting.

11:00 AM The quadriplegic and paraplegic inmates have call lights, so I have to attend to their needs when called. This may consist of feedings, diaper changes, and repositioning. Depending on the day, I will administer showers or bed baths for them. We also currently have an inmate with Parkinson's disease and comorbid

psychiatric disorder and neuropathy, who also requires a great deal of care. We are not staffed for this type of care and try to get compassionate releases so that they can be sent to nursing homes. Luckily, we all help each other, so I get some assistance from the psychiatric staff.

12:45 PM Lunch when I can get it!

2:00 PM Even though I am responsible for the medical in-patients, I still might take a walk-in or two and do some of the "q30-minute checks" on the psychiatric side.

4:00 PM I attend to call lights and help other staff with their patients.

6:30 PM At the end of the day, I make sure that all my charting is done and then go on my way.

When I work on the forensic unit, my day is a bit different.

6:00 AM I take report from the night RN. On this unit I, along with our one LPN, am responsible for passing all the medications and performing all the blood sugars and insulin administrations for the diabetics in the morning, noon, and afternoon.

10:00 AM Charting, and doing some blood draws, along with giving some shots for those inmates on forced medications. I consider this unit more of a nursing management unit rather than a hands-on patient care unit. Begin mental health notes on B-section bottom tier inmates.

12:00 PM Passing medications, performing blood sugars, and administering insulin for diabetics. More charting and blood draws. I usually make sure that all the medications are current and check for any expired critical medications that might need reordering.

1:00 PM Lunch with staff.

2:00 PM I have to perform an extensive mental health note on all the inmates in the maximum-security unit of this building, which consists of 10 to 12 inmates on average. I then have to finish less extensive mental health notes on all the inmates in our B-section bottom tier, which consists of approximately 20 to 24 inmates. Following all my charting, I enter in all the diabetic care and scan all the medications passed on our electronic MAR (medication administration record).

5:00 PM Passing medications, performing blood sugars, and administering insulin for diabetics. More charting and blood draws. Continue with any mental health notes needing completion, entering the diabetic care, and scan all passed meds into MAR.

6:30 PM End of the day. Finish up any charting and head home.

Travis H., Correctional Nurse

Common Issues in Correctional Nursing

Correctional nurses address several common health problems among their population of interest. These concerns include mental health, drug abuse, and communicable diseases. As the inmate population grows, an increase in elderly and female inmates creates additional health concerns for correctional nurses. The following sections briefly describe some of these concerns, along with examples of what correctional nurses may do to address the issues facing them. See What Do You Think?

What do *you* think?

During sick call today, your correctional nurse colleague notices that four to five inmates from the same housing unit have similar complaints—blurred vision, feeling sick, and some difficulty breathing. It is flu season—could that be the cause? You know that homemade alcohol is not uncommon in prisons and that it can be easily made from fermented fruit or other food waste. Prisoners call it moonshine, pruno, hooch, brew, raisin jack, and other names. You remember reading about a recent CDC report regarding several outbreaks of botulism in California, Utah, and Arizona prisons. Prisoners there had used potato peels, and the closed containers used to produce alcohol permitted the toxin to grow during fermentation. With no heat used to kill it, the bacteria grew and affected everyone who drank the brew. With botulism, it is most important to act quickly, as the toxin leads to nerve paralysis, and when it reaches the respiratory muscles, it can cause death. You talk with your colleague and decide to talk with the housing correctional officers and the patients for further information. I think it is better to be safe than sorry! What do you think?

Adapted from: Schoenly, L. (2016). Botulism and prison brew. Retrieved from http://correctionalnurse.net/?s=botulism

Mental Health Issues

States began to deinstitutionalize mentally ill, as they closed mental health hospitals during the 1960s and 1970s. The goal was to have them live more independent lives, but community treatment programs did not meet expectations, and some believe that many of these individuals ended up incarcerated—or just changing their institutionalization from mental health to prisons (Aufderheide, 2014; Swanson, 2015).

Mental health continues to be a major concern in correctional facilities (NIMH, n.d.b). Around 20% of prisoners have a serious mental illness, and 30% to 60% have a substance abuse disorder. Between 13.1% and 18.6% of state prison inmates have major depressive disorder, and between 2.1% and 4.3% have bipolar disorder, and about the same proportion have schizophrenia or another psychotic disorder (Aufderheide, 2014). In a 2011–2012 study of U.S. prisoners, 15% of state and federal inmates and 26% of local jail inmates reported serious psychological distress in the past 30 days (Beck, Berkofsky, Caspar, & Krebs, 2013). All but six states have more individuals with serious mental illness in at least one jail or prison than in the their largest state psychiatric facility, leading some to seriously question our society's ability to provide appropriate treatment for the mentally ill population (Swanson, 2015). One meta-analysis found a prevalence rate for traumatic brain injury (TBI) among the adult offender population to be 60%, whereas the general population's rate is only 8.5% (Shiroma, Ferguson, & Pickelsimer, 2012). See Figure 30–4 for a graph of inmates with mental health problems.

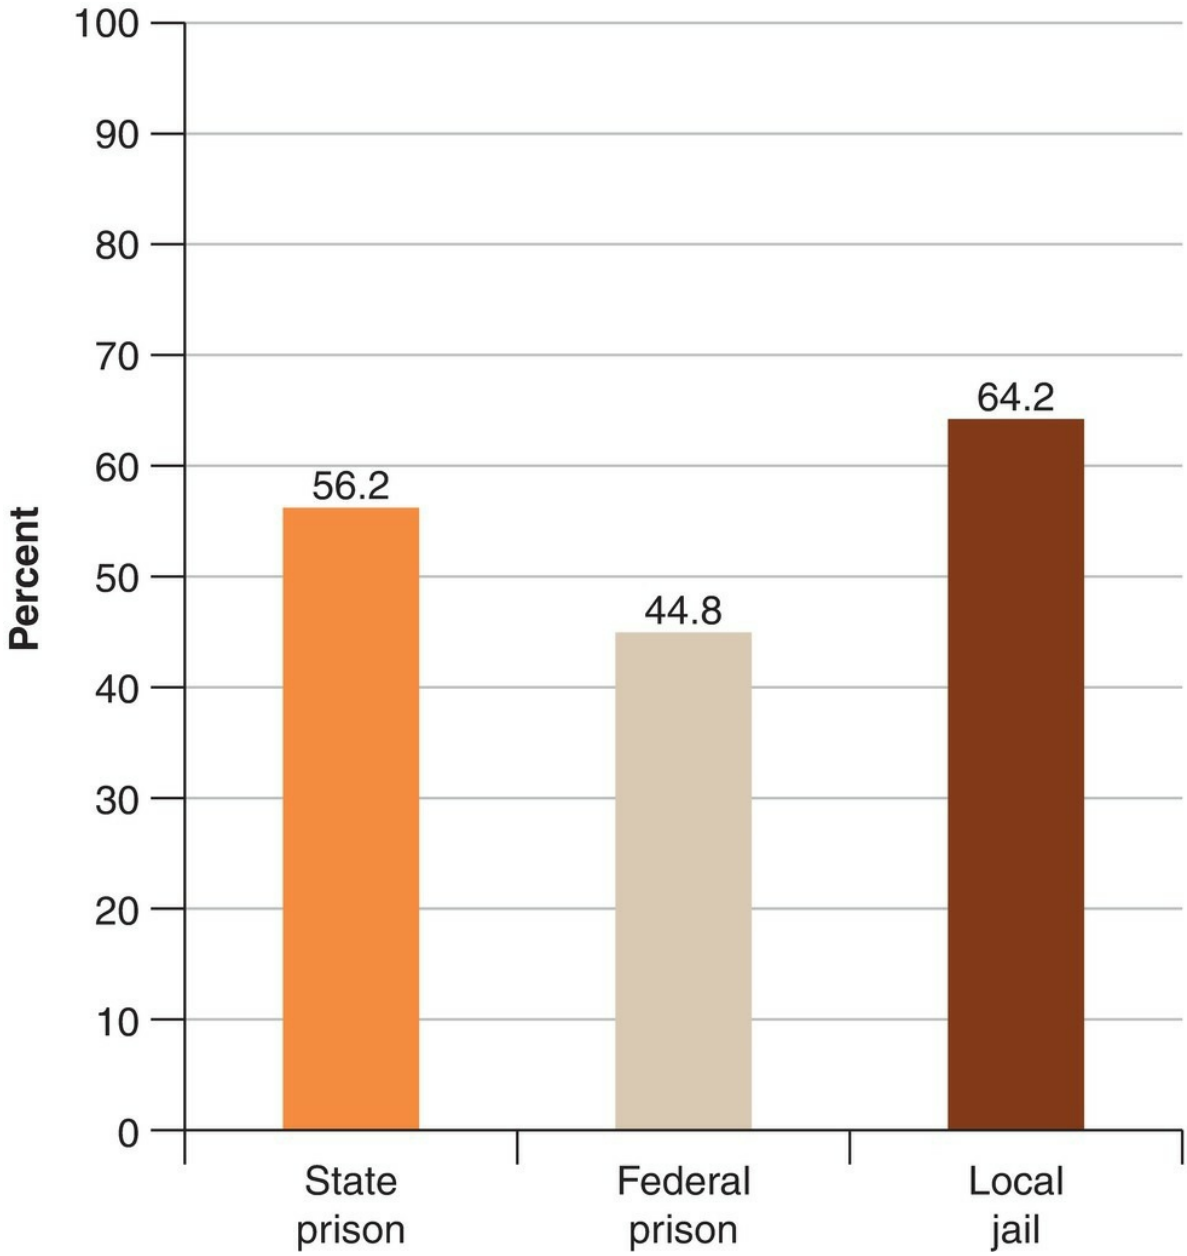

FIGURE 30–4 Inmates with 12-month mental health problems. From National Institute of Mental Health. (n.d.b). Inmate mental health. Retrieved from http://www.nimh.nih.gov/health/statistics/prevalence/inmate-mental-health.shtml

Reported incidents of sexual victimization are 4% for state and federal inmates and 3.2% for jail inmates during 2011–2012 (Beck et al., 2013). Perpetrators of sexual victimization are other inmates (2%) or facility staff (2.4%) or both (.4%) in state or federal institutions. For jail inmates, the proportions are 1.6%, 1.8%, and 0.2%, respectively. For inmate sexual abuse, rates are higher among female inmates, Whites versus Blacks, and those with college educations versus those not finishing high school. In instances of staff sexual victimization of inmates, rates were higher among male inmates, Blacks versus Whites, and for inmates aged 20 to 24 years (Beck et al., 2013). Over 6% of state and federal prison inmates with mental illness or psychological distress report sexual

victimization, and those who report gay, lesbian, or bisexual orientation had the highest rates; 12.2% of prisoners were victimized by other inmates, and 5.4% were victimized by staff (Beck et al., 2013). For inmates who had reported ever having mental health counseling, rates of inmate sexual abuse were three to four times higher than those who had not received counseling.

Mental illness also impacts suicide rates. Since 2000, suicide has been the leading cause of death in jails. In 2013, 334% of jail inmate deaths were due to suicide; this represents an increase of 14% over the previous year. The age of suicide victims was between 25 and 44 in 60% of jail suicides from 2000 to 2013, and the suicide mortality rate was 1.5 times higher for males than female inmates and higher for Whites than other racial/ethnic groups (Noonan, Rohloff, & Ginder, 2015). The rates for suicide are higher in local jails than in state or federal prisons: 40 for jails versus 16 for prisons per 100,000 people in 2012, compared to 13 per 100,000 for the total U.S. population (Kaste, 2015). Often, those incarcerated in local jails have not been in serious trouble with the legal system before this and suffer from "the shock of confinement" (Kaste, 2015, para. 2). For more on behavioral health, see Chapter 27.

Correctional nurses provide a good deal of mental health nursing care and assist in identifying undiagnosed conditions (Hoke, 2015). A postarrest diversion program, in which detainees are evaluated for mental health or substance abuse conditions, is highly effective as long as the resources are not diverted away from these programs (Mental Health America, Positions Statement 52, n.d.). The prearrest diversion programs train police officers to identify persons with mental illness have been successful in assisting with treatment and avoiding arrest.

Correctional nurses assist in multiple medication administrations per day to ensure that inmates receive the medications needed for their mental illnesses. They can also provide counseling regarding medication usage and assist inmates in understanding the side effects of their medication, which for some are many. Correctional nurses advocate for medication changes when they note severe side effects or a change in the mental status of inmates. Nurses can facilitate setting up medication support groups to allow inmates an opportunity to discuss concerns regarding their medications. They also can assist inmates in understanding the importance of taking their medication. As inmates prepare to leave the institution, correctional nurses assist in finding outpatient mental health clinics and other resources that will provide support and further treatment for the inmate. Finally, correctional nurses can provide education and training to other correctional workers regarding signs and symptoms of mental illness and the impact mental health has on decision making and the general health of a person (Schoenly, 2015). See Perspectives: Correctional Nurse.

PERSPECTIVES CORRECTIONAL NURSE

The prison is, in my opinion, a very good place to work. I believe that every student should experience nursing within corrections. I have worked floor nursing before, and working at the prison is much better. Although it can get crazy and chaotic from time to time, the atmosphere is much more laid back. Nurses at the prison seem to have a lot more autonomy than do nurses at other facilities or companies. The prison offers nurses a chance to experience many different skills. You might not gain absolute proficiency in any one skill, but you will gain many skills, and you will become very good at many of them. The nice thing is that nurses come from many different backgrounds, and so they can and will certainly help you and teach you what they know to help with your own skill base. I guarantee that if you work at the prison, you will get to see and experience things that people in normal society will never get the opportunity to see. Come to the prison, and you will get to be a medical nurse, a psych nurse, a triage nurse, an orthopedic nurse, and you can get to do the medical/psychiatric intake screenings for all the new or parole violation inmates who come to the prison on a daily basis. There is probably more, but certainly keep your minds and options open for a great and secure career.

Travis H., Correctional Nurse

Drug Abuse

Drug abuse by inmates is very high. Over 80% of local jail and state prison inmates have used an illegal drug; 55% did so within 30 days prior to their arrest. Cocaine, crack, methamphetamine, and heroin were the most commonly cited drugs of choice. About one third of state prison inmates were under the influence of illegal substances during their offense, and 16.5% admitted committing a crime in order to buy drugs. Substance use is also linked to recidivism rates, with 68% of drug offenders being rearrested within 3 years of leaving prison (Belenko, Hiller, & Hamilton, 2013).

Drug Treatment Alternative to Prison (DTAP) program diverts drug offenders into long-term residential treatment rather than incarceration. If offenders successfully complete treatment, their sentence can be vacated, and program has garnered a 1-year retention rate of 76% and rearrests dropped 42% (Belenko et al., 2013). Other community-based supervision and treatment programs have demonstrated success, as have drug courts.

In jail or prison settings, drug education and counseling programs are offered to inmates and have shown good results, but longer, more intensive counseling is more

effective than brief or intermittent efforts. Innovative programs like Jail In-Reach Intervention demonstrated significantly lower drug and alcohol use 12 months after program completion for female jail inmates. Other interventions, using journaling, community-based drug treatment follow-up, have also shown promise. In prison populations, with higher rates of personality disorders and psychological problems, poor impulse control, greater propensity for risk taking, higher cognitive deficits, and criminal thought patterns, it is critical to utilize evidence-based interventions targeted to the needs of this vulnerable population (Belenko et al., 2013). See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

What Are the Research Priorities in Correctional Nursing?

Because correctional nursing research is sparse and only more recently being conducted, a three-round Delphi technique was used to poll expert correctional nurses, educators, administrators, and researchers to determine research priorities in that specialty field of nursing. The top five research priorities included:

- How to help correctional nurses develop critical thinking skills and determine which skills provide improved correctional nursing performance and patient outcomes.
- Determine correctional nursing's core competencies.
- Define excellent clinical judgment among correctional nurses.
- Which patient outcomes are most affected by correctional nursing care?
- Complete replication studies related to nurse education level in the correctional setting.

How can these priorities advance the profession of nursing in the correctional setting? What other research priorities should be considered?

How has research that has examined education level of nurses and patient outcomes in acute care settings demonstrated the benefits of the BSN? Do you feel that this might be replicated in the correctional setting?

Schoenly, L. (2015). Research priorities in correctional nursing practice: Results of a three-round Delphi study. Journal of Correctional Health Care, 2(4), 400–407.

Of the drug users in prison, 40% of state and 49% of federal inmates had participated in treatment programs, in the latest national sample of U.S. prisoners (Mumola & Karberg, 2007). Correctional nurses can help with referrals and also provide nursing care as patients

withdraw from substances while in prison. Withdrawal can cause life-threatening symptoms that need immediate medical attention. In addition, correctional nurses can organize and provide support groups to assist inmates in staying sober and drug-free. They can advocate for the inclusion of Alcoholics Anonymous, Narcotic Anonymous, and Al-Anon services in the correctional facility. Counseling can be offered to assist inmates as they leave the facility, so that they do not return to prior bad habits if and when they return to areas where drug and alcohol use is rampant (Hoke, 2015; Schoenly, 2015). Returning to this environment increases their chances of returning to substance abuse, and inmates leaving prisons or jails need to be connected to outside resources.

LEVELS OF PREVENTION PYRAMID

HEALTH ISSUE: Sexually transmitted disease (STD) in correctional facilities

TERTIARY PREVENTION

Rehabilitation	Primary Prevention	
	Health Promotion and Education	*Health Protection*
• Work closely with inmates and physician to decrease side effects of STD (i.e., cervical cancer)	• Continue to promote responsible sexual behavior	

SECONDARY PREVENTION

Early Diagnosis	Prompt Treatment
• Provide STD screening upon entering facility • Provide regular, routine STD screenings	• Provide treatment for inmates diagnosed with STDs • Promote facility policies that allow for STD screenings and early treatment

PRIMARY PREVENTION

Health Promotion and Education	Health Protection
• Teach inmates how STDs are transmitted and what can be done to stop transmission (condoms, other preventive measures) • Teach signs and symptoms of commonly occurring STDs • Teach that gonorrhea and chlamydia are often asymptomatic, and so routine screening is important for individuals at risk	

Communicable Disease

In correctional facilities, communicable diseases can spread quickly. A large study of state and federal prisons noted that during the 2009–2010 influenza season, 79% of respondents reported some level of activity, whereas 53% reported an "outbreak" of H1N1 flu and

seven deaths also occurred. Although 90% of those responding stated that they had developed some type of general disaster or influenza emergency plan before flu season, it was noted that "the lack of a consistent system of disease surveillance across prison facilities" (inmates and staff) made it difficult to determine a true baseline and quickly contain or prevent an outbreak (Potter, Schwartz, Blackmore, & May, 2011, p. 73). Many communicable diseases are of great concern in the correctional community such as TB, hepatitis C, and STDs including HIV/AIDS. The concern of communicable disease is not only for the health of the inmate with the disease, but the susceptibility of all inmates and ultimately the general public (if the inmate is released while still infected). Increased rates of these diseases are due to high-risk behaviors and increased rates of abusive behaviors, including rape, both before and during incarceration. Of special note is the fact that most U.S. prisons prohibit distribution of condoms or sterile injection equipment (Reznick et al., 2011).

A hallmark study, conducted by the RAND Corporation (2011), indicated that inmates were four times as likely to have active TB, nine to ten times as likely to have hepatitis C, and five times as likely to be infected with HIV as the general population. Maruschak, Berzofsky, and Unangst (2015) noted that in a 2011–2012 study of U.S. inmates, 21% of prisoners and 14% of jail inmates had hepatitis B or C, TB, or an STD (excluding HIV/AIDS). Testing for tuberculosis was done for 94% of prisoners, and 71% had HIV testing done since being incarcerated. For jail inmates, 54% had TB testing and 11% had HIV testing done. Six percent of prison inmates reported ever having TB, whereas only 0.5% of the general population reported this. The rate for local jail inmates is lower at 2.5% Total hepatitis was reported at 10.9% for prisoners and 0.1% for the general public. HIV/AIDS was reported by 1.3% of prisoners, and by only 0.1% of the general population (Maruschak et al., 2015). In 2012, data reported that the number of inmates living with HIV/AIDS was 20,449 in federal and 1,538 in state correctional facilities (CDC, 2012).

Inmates are at risk for hepatitis C because of the heavy IV drug use among prisoners. Tattooing is also problematic, as is the incidence of piercing and physical violence (Treloar, McCreedie, & Lloyd, 2015). Ten percent of prisoners reported having hepatitis C, and it was the most highly reported communicable disease in a recent survey (Maruschak et al., 2015). Internationally, it can be as high as 38%, and IV drug use is the greatest risk factor. Screening of high-risk populations can help reduce the spread of this virus, but is not always feasible (Zampino, Coppola, Sagnelli, DiCaprio, & Sagnelli, 2015).

TB is widespread among prisoners, and rates are much higher than in the general population. According to the World Health Organization, TB rates of inmates were 23 times higher than the general public for a variety of reasons (Baussano et al., 2010). Some have reported it as high as 50 times greater than national averages and noted that prisons are increasingly reservoirs of drug-resistant TB (O'Grady et al., 2011). Because many inmates are homeless and abuse alcohol and/or drugs, they are more susceptible to TB; to compound the problem, the closeness of living conditions in jails and prisons facilitates the

quick spread of TB (Baussano et al., 2010). Prisoners are at a high risk of moving from latent TB infection to actual tuberculosis, and medication compliance is often low after inmates are discharged. A study in San Francisco found that the stream of TB-infected individuals released from incarceration changes, but there are high numbers of foreign-born individuals who may need to have interferon-gamma release assay testing in order to detect true infections because of the large proportion having received bacillus Calmette-Guérin (BCG) vaccination in their countries of origin (White, Nelson, Kawamura, Grinsdale, & Goldenson, 2012).

Correctional nurses must track rates of communicable diseases and provide education regarding the spread and treatment of those diseases. They must provide data on the number of cases of reportable diseases to the state health department. Correctional nurses can provide preventative care by offering immunizations to inmates. In addition, they can provide the necessary treatment for TB, STDs, and other diseases and can assist in advocating for measures to decrease the spread of disease within correctional facilities. Correctional nurses can assist institutions by providing initial screenings upon arrival of inmates and periodic screening for certain diseases and surveillance of potential communicable diseases during sick call (National Commission on Correctional Health Care, 2016). The CDC (2015j, 2009) recommends routine opt-out screenings for HIV and other communicable screenings if at risk. However, screening based solely on risk may miss many inmates, and so routine screening and treatment of inmates for various communicable diseases may be beneficial and cost-effective.

For chronic communicable diseases, such as HIV/AIDS, correctional nurses can facilitate and organize peer educator groups. These have been found to be successful in educating inmates on HIV/AIDS, substance abuse, and low self-esteem. Others have demonstrated increased HIV testing in inmates and their female partners, along with better communication about HIV-related topics (Reznick et al., 2011). Successful programs also exist to assist inmates as they prepare for release. Correctional nurses can facilitate programs that empower inmates not to return to behaviors that increase their chance of contracting HIV and can also identify resources for inmates suffering from TB, so that they can continue their medication and treatment upon their release.

Future Trends

Because of advances in health care, longer prison terms, and more restrictive policies, inmates are older, sicker, and remain in prison longer than they did even 20 years ago. And historically, inmates have not taken good care of themselves. Hence, a 50-year-old inmate may have the health of a typical 65-year-old in the general public (ANA, 2013a; Schoenly, 2015). This surge in the inmate population is creating a lack of resources and beds for the aging inmate population.

Correctional nurses can increase efforts to empower inmates to take control of their health and can provide them with resources for health care access outside the prison, so that inmates will continue their care upon release. Correctional nurses can also be advocates and lobby state and federal legislatures to allocate funding for the additional resources needed within the prison system (Hoke, 2015).

The female inmate population is also increasing. In addition to women's reproductive health issues, females tend to have higher rates of diabetes, HIV, STDs, mental illness, drug abuse, and emotional issues (ANA, 2013a; Schoenly, 2015). Researchers have found that women in jail have a high risk of cervical cancer and increased rates of abnormal Papanicolaou (Pap) test results (Binswanger, Mueller, Clark, & Cropsey, 2011). Correctional nurses can begin providing routine cervical and breast cancer screenings for female inmates. They can also provide counseling and emotional support. Researchers have suggested that women in prison need trauma-informed, gender-responsive treatment because of past trauma histories (Hayes, 2015; White, 2012). There has been a movement to provide trauma-informed care and gender-responsive programs (GRPs) to women in prison. However, a recent online national survey conducted by the National Institute of Corrections to assess the extent of such programmatic and policy develop concluded that despite widely expressed support for developing gender-responsive, trauma-informed correctional policies, "The degree to which policies adapted for women offenders are aligned with evidence-based literature and theories is unknown" (King & Foley, 2014 p. 3). Women in prison can experience retraumatization through prison practices such as strip searches, pat-downs, and the use of segregation (King & Foley, 2014), as well as sexual and other types of assaults by other inmates or correctional staff (Blackburn, Mullings, & Marquart, 2008). Although trauma-informed, gender-responsive treatment has become a new practice in the correctional setting, it has not been uniformly applied to correctional nursing. As Harner and Burgess (2011) stated,

> …clinicians in correctional facilities have an opportunity to help ensure that incarcerated women leave jails and prisons in better physical and mental health than when they arrived. To that end, the provision of evidence-based, gender-responsive, and trauma-informed care in correctional settings must be our goal (p. 474).

Chronic disease, such as diabetes, cancer, heart disease, arthritis, cirrhosis of the liver, and asthma, is also increasing in the incarcerated population. About 40% of the 2011–2012 population of state/federal prisoners and jail inmates reported having a current

chronic condition; hypertension was the highest reported chronic conditions at 30% of prisoners and 26% of inmates, with arthritis and asthma being the second and third most common chronic conditions. Females, rather than males, were more likely to report a chronic health condition, and older prisoners and inmates over age 50 were about twice to as likely to report a chronic condition as those aged 18 to 24 years. About one quarter of all prisoners and inmates reported multiple chronic conditions (Maruschak et al., 2015). Correctional nurses can facilitate chronic disease clinics to educate and empower inmates to better control their chronic conditions. To this end, correctional nurses need to conduct thorough family health histories, as many health conditions tend to have a genetic component and employ screenings to identify conditions as soon as possible, so that early intervention can decrease complications and stop disease progression. They can follow up by promoting better nutrition and exercise habits and medication management.

Ethical and legal issues in correctional nursing often center on the patient (most often someone convicted of a crime, possibly involving violence). Caring for the patient is vital, but custody must also be maintained and safety is essential. Nurses must demonstrate nonjudgmental attitudes while at the same time ensuring protection from assault. Also, correctional workers (including nurses) may be subject to lawsuits brought by inmates for *deliberate indifference*, or perceived retaliation leading to an adverse action. For instance, this may include withholding health care that could lead to increased health problems in retaliation for the inmate filing grievances or formal complaints against the worker (Pont, Stöver, & Wolff, 2012). Incarceration may present as counterproductive to the health and well-being of the affected population. However, it does create a public health opportunity for providing screening, diagnosis, treatment, and postrelease linkage to care for members of a vulnerable population who may not seek or have access to services otherwise. Correctional nurses have an opportunity, to help reduce the burden of disease for communities by providing trilevel preventive health care pre-, intra-, and postincarceration (Macmadu & Rich, 2015).

CORRECTIONAL NURSING CAREERS

Correctional nurses must have good mental health and assessment skills. They must be able to communicate well and be strong nursing advocates and strong advocates for their clients. They work in an intense environment where their safety could be threatened, and they must deal with clients who may be noncompliant, combative, and manipulative. Correctional nurses must also be very flexible and knowledgeable about a variety of nursing specialties (Minority Nurse, 2016). Correctional nurses are also increasingly becoming Certified Correctional Health Care Professionals (National Commission on Correctional Health Care, 2015).

Salaries depend upon the state, although they tend to be generally higher than in other nursing fields. Moreover, correctional nurses usually receive extensive employee benefits and insurance packages as government employees. Correctional nurses have the ability to see recoveries from illnesses and injuries because they work with the same patients for a longer time than hospital-based nurses. Correctional nursing provides an opportunity to work with a vulnerable population and practice the true art and science of nursing. You use every nursing skill you have learned and advocate for a population that is in need. It can be a challenging, rewarding career. See Perspectives about the hiring process for new correctional nurses.

PERSPECTIVES SUPERVISOR AND A DIRECTOR OF CORRECTIONAL NURSING ON HIRING NEW NURSES

Do you think you might like a job at a prison facility? A Director of Nursing and a Supervisor of Correctional Nursing provide some information on the interview process:

Before we hire new correctional nurses, we ask them to review the correctionalnurse.net blog (Schoenly, 2016) and the Correctional Nurse Manifesto (Schoenly, 2014). As part of the interview process, at the second interview, the nurse candidates have a facility-wide tour with a correctional supervisor and then another interview with the nursing team members. These represent the people with whom they will work; applicants ask questions and be questioned in order to make certain that they are suitable for the unique position of correctional nurse. The nurses who are hired receive civilian training and are assigned a preceptor. The process is designed to educate the candidate to the realities and complexities of correctional nursing. As the director notes,

"No one dreams of going into correctional nursing, but once you are in, you are hooked because you realize the difference you can make."

The interview process follows the guidelines set forth by the ANA Correctional Nursing: Scope and Standards of Practice (2013) and the textbook Essentials of Correctional Nursing (Shoenly & Knox, 2013). This textbook provides crucial information such as the ethical, legal, and safety considerations of correctional nursing; common inmate-patient health care concerns and diseases; nursing care processes; and professional role and responsibilities. Also, unlike the nurses hired in the past, newer correctional nurses do provide health care education and health care clinics for chronic diseases on a regular basis. Because of the lack of an inpatient facility, 24-hour nursing care is not provided in some correctional facilities. When 24-hour nursing care is necessary, the inmates are transferred to a correctional facility where such coverage is available or to an acute care facility if more extensive care is required. In addition, the correctional officers are trained to follow procedure and call 911 during an emergency. There is a policy regarding distribution of medications in the prison setting. For example, red medications, such as psychiatric medications, insulin, and cardiac medications, are administered by the nurses; yellow medications, such as cholesterol medications and antibiotics, can be administered by correctional officers (at the supervisor's particular prison no medications are administered by officers, however); and green medications, such as Tylenol, ibuprofen, and some cardiac medications, are self-administered by the inmates.

Challenges to correctional nursing include the philosophy in the prison setting that "safety comes first," which could result in an inmate missing a sick call. Should this occur, however, their medical needs are taken care of as soon as it is safe and without compromise to their condition, according to both the supervisor and the director of nursing. Transportation for medical issues requiring care outside of the prison can be problematic as there may not be correctional staff available to provide the necessary transportation. Fortunately, this does not happen during emergencies, in which case 911 is called and correctional officers are not involved in the transportation. One emergency that correctional nurses are occasionally faced with is suicide attempts; a situation that is always "scary" even if you have seen it happen before. This situation leads to a lock-down so that all resources can be focused on the suicidal inmate, who sometimes is found hanging and needs to be cut down and resuscitated.

The ability of correctional nurses to deliver medically appropriate care is hindered by the lack of access to preexisting medical records and history. Nurses must often rely on inmate self-reporting rather than a comprehensive medical history. Self-reporting is a far less reliable means for determining an inmate's risk factors and overall wellness. This may be one of the reasons that civil litigation by inmates, alleging medical negligence, is a weighty problem for all correctional agencies.

Aside from the organizational impediments that correctional nurses encounter that may contribute to inmate litigation over medical care is the additional challenge of

finding nurses who hold bachelor or other advanced degrees in nursing to apply for vacant positions. Diploma or Associate degree programs fail to provide the level of training in community and public health, as well as psychiatric nursing that correctional nursing requires. Incarcerated populations present unique health needs that are generally not as pervasively distributed in general medical settings. A CNA HealthPro and Nurses Services Organization (2011) 5-year study on nurses' professional liability exposure reports higher claims indemnity payments for respondents who had only completed a nursing diploma program in comparison to those with a bachelor's or associate's degree. That is why the director of nursing is focusing on hiring BSN-prepared nurses.

The director of nursing also said, "Our goal is for them [inmates] to leave healthier. We have an incredible opportunity to improve the health of our population by returning our patients to the community healthier than when they came to us." She also commented "We are not here to be punitive. We are here to care." The Correctional Nurse Manifesto (Schoenly, 2014, p. 2) mandates that correctional nurses:

- *Treat inmates with the dignity and respect deserving of any patient.*
- *Work within my scope of practice at all times.*
- *Not become cynical to the health requests of my patient population.*
- *Hold myself and my peers to the professional boundaries of practice.*
- *Continually guard my own and other's physical and mental safety.*
- *Speak up when I see ill treatment of my patient population.*
- *Be a force for good in the community in which I work.*

SUMMARY

Nurses who work in publicly funded settings are critical to the health and well-being of their communities. Public health nursing interventions are essential in keeping our nation healthy. They may not be as visible as hospital nurses, who interact with individual patients in the hospital, because PHNs often work from behind the scenes. Those who come in contact with them directly know of their worth, but much of the general population remains unaware of the role and the need for PHNs. PHNs deal with a number of issues including communicable diseases, chronic diseases, injuries, STDs, maternal child health, immunizations, and substance abuse. They work with all ages, ethnicities, socioeconomic groups, and populations. Their emphasis is on health prevention and promotion. Some PHNs work in the uniformed public health service and in other branches of the military.

School nurses work with school populations including students, their families, and the school staff. They provide individual care and are the bridge between medical providers and schools. School nurses provide health care services, such as direct nursing care, first aid, and specialized health care for children with special needs. They also provide population health services and health protection measures such as immunizations and environmental assessments. Finally, school nurses provide health promotion activities including education, health screenings and referrals, immunizations, and staff wellness programs. School-based clinics are another means of providing care for the school population. Children and adolescents are important population groups for community health nurses because their physical and emotional health is vital to the future of our country and because they require guidance and direction.

Correctional nurses work with inmates in federal, state, or local facilities, including drug treatment and juvenile detention centers. They provide individual care in facility clinics and infirmaries while also identifying and developing programs to address major population health concerns of inmates, including mental illness, drug and alcohol abuse, and communicable diseases. The inmate population is growing older, staying longer, and suffering more from chronic disease. This, along with an increase in female inmates, brings additional challenges for correctional nurses.

All three nursing specialty areas impact the health of our communities. Because of the high level of nursing knowledge, communication skills, autonomy, and leadership needed for these nursing specialties, entry level should be at least a baccalaureate degree. Community nurses who work in public settings provide a valuable service needed to keep our nation healthy.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a correctional nurse, you deal with people from a variety of backgrounds, social classes, and past crimes. How can your values and attitudes toward criminal activity impact your treatment of inmates? Does social class, race, age, or gender make any difference in how you feel about them and interact with them as your clients?
2. One of the concerns expressed by correctional facility nurses is the antisocial and manipulative behavior of inmates, along with potential violence. How can a nurse working in a state prison effectively determine the health care needs of inmates?
3. Discuss possible methods of doing nutritional assessments in school-age children. What programs could be instituted to encourage healthier diets and increased exercise? What other factors might need to be considered? How could you, as a school nurse, work with schools and parents to increase physical activity and improve nutrition for school-age children and adolescents?
4. Go to this Web site (https://www.nhlbi.nih.gov/files/docs/public/lung/asthma_actplan.pdf) and print out a copy of the *Asthma Action Plan*. Discuss this with the parent of a school-age child or adolescent who has asthma. Has a school nurse or public health nurse ever gone over a plan with them? Have they ever been shown how to use a peak flow meter or correctly use an asthma inhaler? What methods have they used to control asthma triggers?
5. Describe potential areas of employment as a member of the U.S. Public Health Service. What types of care are rendered? In what areas of the country? What are benefits of this type of nursing career?
6. Most schools require that children entering school show proof of being fully immunized for a variety of communicable diseases. With a partner, discuss what would happen if schools no longer had this requirement. How else can immunizations be reinforced in the public?
7. Many prisoners suffer from mental illness. List types of programs and/or support groups that the nurse could provide for these inmates. What about inmates not formally diagnosed with a mental illness?
8. What do you think are the most significant ethical and legal issues involving correctional nursing? If possible, interview a correctional nurse and discuss this. Also, discuss what they most enjoy about their job, as well as their most significant concerns.
9. Debate the problems of mental illness and substance abuse in prisons. Are prisons and jails appropriate facilities for meeting the needs of these populations? Why or why not? If not, what other alternatives may be more effective?

31 CHAPTER

Private Settings for Community Health Nursing

"To insure good health: eat lightly, breathe deeply, live moderately, cultivate cheerfulness, and maintain an interest in life."

—William Londen

KEY TERMS

Community collaboration
Comprehensive Primary Care Center
Education Resource Center (ERC)
Entrepreneurial nurse
Faith community nurse (FCN)
Federally Qualified Health Center (FQHC)
Nurse-led health centers/clinics (NLHCs)
Occupational and environmental health nurses
Occupational Safety and Health Administration (OSHA)
Request for proposal (RFP)
Safety-net health care provider
Sustainability
wellness centers

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the historical roots of nurse-led health centers.
- Identify the distinctiveness of various nurse-led health center models.
- Describe interventions that support *Healthy People 2020* goals.
- Describe funding sources for nurse-led health centers.
- Articulate the importance of sustainability for nurse-led health centers.
- Describe the evolution of faith community nursing.
- Describe and differentiate among the roles of the faith community nurse.
- Identify the steps for establishing a practice as a faith community nurse.
- Explain the role of the occupational and environmental health nurse and other members of the occupational health team in protecting and promoting workers' health and safety.
- Identify educational preparation for occupational and environmental health nurses.
- Recognize at least three adverse working conditions that impact health status.
- Discuss the opportunities for nurse entrepreneurship in community/public health practice.

Healthy People 2020: Improving the Health of Americans (U.S. Department of Health

and Human Services [USDHHS], Centers for Medicare and Medicaid Services [CMS], 2016a) provides goals and clear objectives for promoting health and preventing disease for the next decade. The next 10 years will see unprecedented changes and challenges in the nation's health. As we ponder what those changes will be, the Healthy People initiative will continue to encourage collaborations across communities and sectors, empower individuals toward making informed health decisions, and measure the impact of prevention activities. Building on the Healthy People goals for the nation's health, there will be ever-increasing opportunities for community/public health nurses to make a difference in their communities. This chapter examines four distinct areas of practice in the community as potential options for your own professional road ahead. Each of these roles contributes in very tangible ways to improving the health of individuals, families, and the communities in which they live. National health care reform and global influences on community/public health nursing are included.

Chapter 30 discussed a wide variety of practice opportunities in the public sector. This chapter examines four unique private sector roles and practice environments available in the United States and in many other countries: nurse-led health centers (NLHCs), faith community nursing, occupational and environmental health nursing, and nurse entrepreneurship. Nurse-led (or nurse-managed) health centers offer the opportunity for more autonomous practice and present excellent learning venues for nursing students. Many such centers are connected to academic nursing programs. Faith community nursing, begun in the mid-1980s, has gained increasing attention in many religious communities. Although volunteers often hold faith-based positions, there are increasing opportunities for paid employment. Occupational and environmental health is a specialty health practice that focuses on the health and well-being of the working population, including both paid and unpaid positions, and therefore covers most of the country's working adults. This role provides the vital link between nursing and sound business practices. The nurse entrepreneur role offers new venues for meeting the health care needs in communities while providing challenging and autonomous practice. Each of these areas of practice offers community health nurses an avenue to address health disparities in their communities, increase years of healthy life, and provide holistic, client-centered care to meet the current and emerging health needs in their communities, as indicated in *Healthy People 2020*.

NURSE-LED HEALTH CENTERS

Nurse-led health centers/clinics (NLHCs), or nursing centers (sometimes referred to as nurse-managed health centers), are organizations that give vulnerable and/or underserved clients access to professional nursing services. Located in or near health professional shortage areas (HPSA) and medically underserved areas (MUA) in both urban and rural communities, NLHCs are found in convenient sites where people live, work, learn, and worship. A nurse executive with an advanced degree provides oversight. Traditionally, targets of service have been those who are least likely to be engaged in ongoing health care services for themselves and their family members. Currently, NLHCs serve population groups of all ages that are both uninsured and underinsured.

Historically, the most frequently cited definition of *nursing centers* is the one developed in the mid-1980s by the American Nurses Association Nursing Centers Task Force. Display 31–1 presents a modified version of this definition. However, with an amendment to Title III of the Public Health Service Act (42 U.S.C. 241 et seq.), the Nurse-Managed Health Clinic Investment Act of 2009 of the 111th Congress provides a more present-day definition of NMHCs. Display 31–2 presents this definition.

DISPLAY 31.1 DEFINITION OF NURSING CENTER

Nursing centers—sometimes referred to as community nursing organizations, nurse-managed centers, nursing clinics, and community nurse–managed health centers—are organizations that give clients and communities direct access to professional nursing services. Professional nurses in these centers diagnose and treat human responses to actual and potential health problems and promote health and optimal functioning among target populations and communities. The services provided in these centers are holistic, client centered, and affordable. Overall accountability and responsibility remain with the nurse executive/director. Nurse-managed health centers are not limited to any particular organizational configuration. Nurse-managed health centers can be freestanding businesses or may be affiliated with universities or other service institutions like home health agencies and hospitals. The primary characteristic of the organization is responsiveness to the health needs of populations. The nurse is responsible for all patient care and operations (Hansen-Turton, Sherman, & King, 2015).

Hansen-Turton, T., Sherman, S., & King, E. (2015). Nurse-led health clinics: Operations, policy and opportunities. New York, NY: Springer.

DISPLAY 31.2 DEFINITION OF NURSE-MANAGED HEALTH CLINIC

The term "nurse-managed health clinic" or "NMHC" means a nurse practice arrangement, managed by advanced practice nurses, that provides primary care or wellness services to underserved or vulnerable populations and is associated with a school, college, university, or department of nursing; federally qualified health center; or an independent nonprofit health or social services agency (Nurse-Managed Health Clinic Investment Act, 2009).

Nurse-Managed Health Clinic Investment Act of 2009, S.B. 1104/H.R. 2754, 111th Congress (2009).

Although all NLHCs share the core elements of these definitions, they vary in their practice models. Services offered at NLHCs range from health promotion and wellness to conventional primary care (Hansen-Turton, 2012; Hansen-Turton, Miller, & Greiner, 2009). In this chapter, the terms NLHC, nurse-led health clinic, and nursing center are used interchangeably to describe this model of contemporary health care.

NLHCs represent a rising movement of health centers that have emerged as vital safety-net health care providers in America's health care delivery system (Hansen-Turton, Sherman, & King, 2015; Pohl, Tanner, Pilon, & Benkert, 2011). A safety-net health care provider is defined as a provider that by mandate or mission organizes and delivers a significant level of health care and other health-related services to the uninsured, Medicaid, and other vulnerable populations (Health Resources and Services Administration, 2013; Institute of Medicine [IOM], 2000).

NLHCs differ from other public health agencies and tertiary medical care facilities. Although some services overlap, the distinctiveness of NLHCs is found in the community orientation of the nurse-managed centers. This model is depicted by *Lundeen's Comprehensive Community-Based Primary Healthcare Model* (Lundeen, 2005) where NLHCs are referred to as community nursing centers and are the central figure in this model of health care utilized at the University of Milwaukee, Wisconsin (see Fig. 31–1).

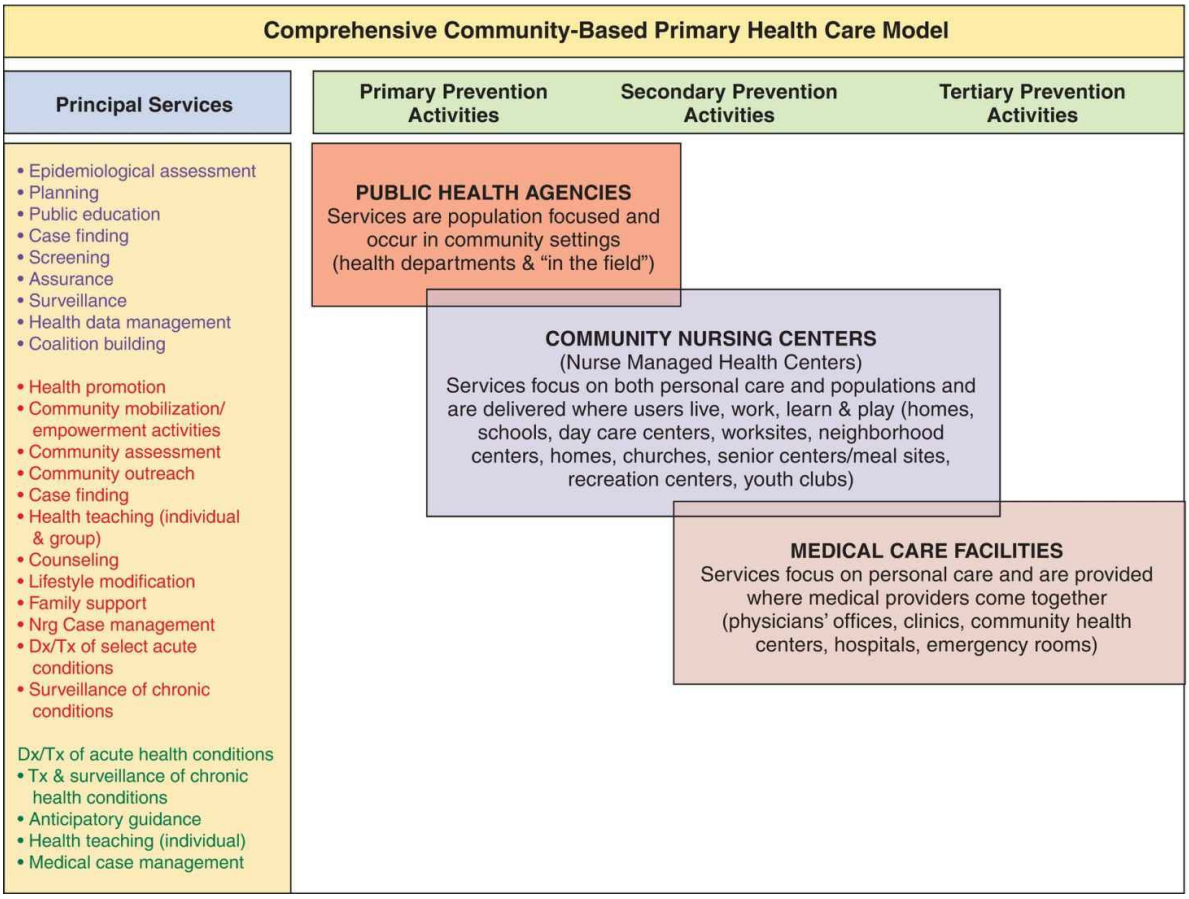

FIGURE 31–1 Comprehensive community-based primary health care model. (From Lundeen, S. (1993, 2005). Lundeen's comprehensive community-based primary health care model. Milwaukee, WI: University of Wisconsin–Milwaukee College of Nursing, with permission.)

Healthy People 2020

The groundbreaking publication of *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* (U.S. Department of Health, Education and Welfare, 1979) focused attention on the nation's health promotion and disease prevention activities. Three decades later, *Healthy People 2020* goals and objectives expand upon this health promotion and disease prevention initiative. The four main goals of *Healthy People 2020* are to attain high-quality, longer lives free of preventable disease, disability, injury, and premature death; achieve health equity, eliminate disparities, and improve the health of all groups; create social and physical environments that promote good health for all; and promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, Office of Disease Prevention and Health Promotion, 2016a). Achieving *Healthy People 2020* goals requires a long-term commitment to community collaboration and partnerships among many diverse people and groups (Kinsey & Miller, 2016). NMHCs are an excellent venue to address identified Key Health Indicators to meet the goals of *Healthy People 2020*. Display 31–3 contains exemplars of *Healthy People 2020* Key Health Indicators that are applicable to NMHCs.

DISPLAY 31.3 *HEALTHY PEOPLE 2020* SELECTED KEY HEALTH INDICATORS EXEMPLARS FOR NMHCS

The Leading Health Indicators are organized under 12 topics. The *Healthy People 2020* Leading Health Indicators are

Access to Health Services

- Persons with medical insurance
    - Persons with a usual primary care provider

Clinical Preventive Services

- Adults who receive a colorectal cancer screening based on the most recent guidelines
- Adults with hypertension whose blood pressure is under control
- Adult diabetic population with an A1c value >9%
    - Children aged 19 to 35 months who receive the recommended doses of

DTaP, polio, MMR, Hib, hepatitis B, varicella, and PCV vaccines

Environmental Quality

Injury and Violence

Maternal, Infant, and Child Health

Mental Health

Nutrition, Physical Activity, and Obesity

Oral Health

Reproductive and Sexual Health

Social Determinants

Substance Abuse

Tobacco

History of the Nurse-Led Model

Although today's NLHCs trace their roots to changes in national health care laws begun in the mid-1960s, the nursing model of holistic care that focuses on vulnerable populations and integrates primary care and public health dates back to the 19th century. Florence Nightingale's passion for at-risk populations, as well as her success related to health reform, provides a model for NLHCs today. Visionaries such as Lillian Wald, who founded the Henry Street Settlement, and Margaret Sanger, who initiated the first family planning clinic, are two examples of nurses providing holistic care to vulnerable populations (see Chapter 2). These nurse activists sought to resolve 20th century problems caused by immigration, urbanization, and industrialization in the United States (Judd & Sitzman, 2014; Wilson, Whitaker, & Whitford, 2012).

Since the late 1970s, in conjunction with the development of educational programs for nurse practitioners, faculties in schools of nursing have established NLHCs. Linkages have provided clinical sites for educating nurses at all levels and settings, as well as for faculty practice opportunities (Resick, Miller, & Leonardo, 2015). For example, one urban academic nursing center at Duquesne University School of Nursing in Pittsburgh, Pennsylvania, involves students and faculty in primary and secondary prevention services to the community. "Brown bag" medication review days, chair exercises, health fairs, safety assessments, nutrition education, computer classes, and health screenings are examples of services and special programs that undergraduate and graduate students have been engaged in for almost two decades. Currently, there are many nursing clinic sites across the city of Pittsburgh that work with older adults and vulnerable populations, providing both nursing and health science students with opportunities for community-based experiences (Duquesne University School of Nursing, 2015; Hansen-Turton et al., 2009). Another academic nursing center at Florida Atlantic University began by providing diabetes care in 2012, but has expanded to a comprehensive health center with six nurse practitioners, three mental health providers, and two diabetes educators (Wood, 2015). Both undergraduate nursing and nurse practitioner students work at the center, and case management, chronic disease management, preventive health, and nutritional counseling are provided to a diverse population. The center has federal, state, and private foundation grant funding. Today, NLHCs meet the traditional role of nurses who have historically provided compassionate health care focusing on the special needs of societies most vulnerable: the poor, the aged, those experiencing social injustice, and those living in geographic areas with limited or no access to adequate health care facilities (National Nursing Centers Consortium [NNCC], 2014). Unlike traditional health care venues that provide primary care and public health services, NLHCs include community participation in program development, implementation, and evaluation (NNCC, 2014). See From the Case Files I.

From the Case Files I

The RICHY Program: Interprofessional Primary Care and Wellness in the Community

In 2014, two local universities, the region's largest health network, and two community nonprofit organizations in Lehigh Valley Pennsylvania spearheaded what would become the Regional Integrated Collaborative for Healthy Youth (RICHY) program. The RICHY program provides an access point to primary care and wellness services for an at-risk population that is difficult to engage. This novel pilot program is believed to be the first of its kind in the country.

This collaboration resulted in the development and implementation of a unique interprofessional initiative targeting homeless, at risk for homelessness, or runaway teens, designed to meet three overarching goals: (1) to support these vulnerable pregnant and parenting women with health services for themselves and their babies, (2) to empower these women to become more active managers of their own care and that of their child, and (3) to educate them on how to best utilize the health care system, thereby reducing costs.

Using an integrated behavioral health model, family nurse practitioner students, graduate social work students, and undergraduate senior nursing students work at a residential housing complex with at-risk adolescent girls and young mothers and their babies. Graduate students working with the program are supervised by both university faculty and clinicians from the health network. Family nurse practitioner students provide primary care and preventive medical services on site. Graduate social work students provide ongoing behavioral health and social work support to the youth between visits as needed, increasing trust and follow-through with recommendations. Senior undergraduate nursing students in a clinical practicum that promotes the nurse-led wellness model provide primary prevention via education. The undergraduate nursing students anecdotally report that the RICHY project broadened their vision of how health care can be delivered in nontraditional settings.

During the first 6 months of the 12-month pilot program, data related to patient health literacy, patient activation, and utilization of the health care system reveal the following:

- Residents attended 41 visits to the Nurse Practitioner–Behavioral Health team during the first 6 months of the program; 78% of the visits focused on health management, which is a primary goal of the program.
- Use of the emergency department (ED) was minimal during the first 6 months. Adolescents went to the ED only one time; three ED visits occurred for young children of the residents; five ED visits were avoided by having

access to the services provided through this initiative.

- Eight of the residents have become patients at the collaborating health network's family medicine community clinic, connecting them to a family medicine primary care practice. These eight individuals have engaged in 15 visits at the FHC across 5 months. All but one resident now has a designated primary care provider, either at FHC or elsewhere.
- Undergraduate nursing students conducted group education primary prevention sessions. All of the residents who attended these sessions reported positive feedback, noting that they learned new information about self-esteem and self-image, when to go to the ED or seek health care, signs of illness in young children, and healthy relationships.

The 12-month data report will help determine if this unique model can become self-sustaining once grant funds supporting it have ended. It will attempt to determine what the value of the program was to the mothers and the organizations involved, if better outcomes were realized for the patients, if decreased health care costs were seen, and how it might be possible to fund such a model in other communities.

Family & Youth Services Bureau. (2015, November 4). An onsite clinic builds healthy connections for homeless youth and their kids. Retrieved from http://ncfy.acf.hhs.gov/news/2015/11/onsite-clinic-builds-healthy-connections-homeless-youth-and-their-kids

Nurse-Led Health Center Models

There are several types of nursing centers; each has an individuality of its own that reflects the community in which it is located and the particular services it offers (Hansen-Turton, Valdez, Ware, & King, 2015; Kinsey & Miller, 2016). Academic-based nursing centers, which are located within schools of nursing, are a common organizational structure. There are also hospital-based and freestanding community-based NLHCs that offer a mixture of primary care, health promotion, wellness, and disease prevention services (Hansen-Turton, Valdez, et al., 2015; Kinsey & Miller, 2016).

NLHCs meet requirements for Federally Qualified Health Center (FQHC) designation as defined in Section 330 of the Public Health Service Act. FQHCs are safety-net providers whereby the main purpose is to enhance primary care services in underserved rural and urban communities (USDHHS, Centers for Medicare and Medicaid Services [CMS], 2011). Hansen-Turton (2012) states that NLHCs meet all of the requirements for FQHC designation, and funding to support them is vital to their existence. Health care reform legislation has helped with this funding. This is an especially important designation, as it enables NLHCs to qualify for many funding sources vital to service provision that would not be available without this designation. The specific requirements are that they:

- be located in an MUA or serve a medically underserved population
- have a nonprofit, tax exempt, or public status
- have a board of directors, a majority of whom must be consumers of the center's health services
- provide culturally competent, comprehensive primary care services to all age groups
- offer a sliding scale fee and provide services regardless of ability to pay

The variety of nursing center models currently being used and their organizational structures demonstrates the diversity of contemporary NLHCs. Display 31–4 describes the major types of centers (wellness centers, specialty nursing centers, and Comprehensive Primary Care Centers) along with the various organizational structures that influence their delivery models.

DISPLAY 31.4 NURSE-MANAGED HEALTH CENTER MODELS

Center Types

- Wellness Center: provides public health as well as health promotion and disease prevention programs, focus on primary and secondary prevention strategies
- Special Care Centers: provide programs that target specific health conditions such as HIV or diabetes
- Comprehensive Primary Care Center: provides traditional primary care and public health programs

Organizational Structure

- Academic Nursing Center: located within a School of Nursing
- Freestanding Center: independent center with its own governing board
- Subsidiary: part of a larger health care system, such as home health agencies, community centers, schools, and other venues
- Affiliated Center: legal partnership with a health care or human services organization

Adapted from Kinsey, K., & Miller, M. E. (2016). The nursing center: A model for nursing practice in the community. In M. Stanhope & J. Lancaster (Eds.), Public Health Nursing: Population-centered health care in the community (9th ed., pp. 455–475). St. Louis, MO: Elsevier.

Funding for Nurse-Led Health Centers

As NLHCs vary in their models, so too are their methods of cost reimbursement, including the following: fee for service, sliding fees, contracts, grant support, third-party payments, and cost-based reimbursement (Hansen-Turton, 2012; Pilon & Hansen-Turton, 2015). Most nursing centers' operational and salary budgets entail a combination of these funding sources.

In Comprehensive Primary Care Centers, advanced practice nurses provide primary care services. Such services are usually reimbursable under Medicaid and managed care medical insurance plans. In wellness centers, public health nurses and other interdisciplinary team members provide a range of primary and secondary prevention strategies. These services are usually not reimbursed by insurance plans but are often covered by grants and contracts (Hansen-Turton, 2012; Resick et al., 2015). Additionally, foundation support and private donations from community organizations and members provide fiscal support for NMHC initiatives (see From the Case Files II).

From the Case Files II

Ms. Jones is a 22-year-old mother of three small children who recently moved to an urban area. She brings her oldest child, age 6, to a local comprehensive primary care nurse-managed health clinic (NMHC) for school immunizations. During the course of the history and physical examination, the nurse practitioner becomes aware that this mother also has two younger children, aged two and three, at home. The family rents a small apartment in housing that was built in the mid-1950s. Ms. Jones reports that her mother (the children's grandmother) also resides with them. The grandmother is the childcare provider while Ms. Jones works as a local hair salon. The grandmother smokes 1.5 to 2 packages of cigarettes daily; Ms. Jones reports that she is a nonsmoker. Upon further questioning, the nurse practitioner learns that the 3-year-old child has a chronic cough and occasional wheezing. Ms. Jones also confides to the nurse practitioner that she recently missed two menstrual periods and is sexually active.

1. What are some possible health care needs of Ms. Jones? Her mother?
2. What screenings should be performed on Ms. Jones? Her mother?
3. What screenings should be performed on Ms. Jones' children?
4. What other interdisciplinary team members should be involved in this family's health care?
5. What are some possible referrals that would benefit this family?

It is important to distinguish between grants and contracts as funding sources for NLHCs. Funding organizations usually release guidelines regarding what initiatives they will fund. Grant guidelines are frequently termed request for proposal (or RFP). Grants can be a source of initial start-up funding as well as a support for ongoing activities (Kinsey & Miller, 2016). A proposal submitted by the NLHC to the funding organization describes how the center would meet the goals and objectives set by the funding organization. Outcomes, or the end results at a specific point in time, are increasingly becoming more important to funders. NLHCs must include measures to collect outcome data and project what outcomes will occur in their submitted proposals. Additionally, funders tend to view initiatives that include interagency collaboration in a more favorable manner. Partnering with one or more NLHCs or other community-based organizations is a strategy that provides additional strength to the proposal when it is under review by the funding organization.

Contracts are another source of funding for NLHCs. Contracts are awards for a legal procurement relationship between a funder and a recipient obligating the contractor to furnish a product or service defined in detail by the funder (National Institutes of Health, Office of Extramural Research, 2013). A contract has specific goals, objectives, and activities, as well as a time frame for which the activities are to be implemented and evaluated. Contracts are awarded on a noncompetitive basis and oftentimes are renewable when goals and objectives are met.

Managing the various funding streams that feed the personnel and operations budgets of an NLHC is an arduous task. To ensure that budgetary dollars are spent in the manner specified by the funding organization, meticulous record keeping and itemization of spending is another undertaking that the nurse executive or an operations coordinator of an NLHC must carry out. It is imperative that key personnel from the NLHC maintain precise records and submit accurate quarterly, semiannual, or annual reports as specified in the grant or contract award.

Sustainability of Nurse-Managed Health Clinics

Sustainability, or the ability to carry on services and health promotion activities when funding is no longer available, is one of the main challenges of NLHCs. The challenge of "sustainability" is a common dilemma that funders and grantees both face at the end of an initiative's funding period (Ely, 2015).

NLHCs have much to offer toward resolving the national health care crisis facing vulnerable populations who are uninsured or underinsured. However, without the ability to maintain fiscal sustainability, NLHCs may fail to reach their full potential for positively influencing the future of health care (Ely, 2015; Hansen-Turton, 2012). Financial sustainability in NLHCs is challenging. Administrative personnel from NLHCs must continually scan local, state, and federal avenues for grant opportunities to maintain, or expand, services (Pilon & Hansen-Turton, 2015).

In the past, funders were often confronted with the task to help organizations find and secure other resources, or extend their own financial support, to ensure the continuity of services. More recently, both public and private funders are stipulating that organizations describe detailed plans for sustainability after the award period ceases in their application submitted for funding. A seminal document by Cutler (2002, p. 23) proposes "critical sustainability questions" that can be used as a preliminary avenue of consideration for organizations such as NMHCs when completing a grant application for funding (see Display 31–5).

DISPLAY 31-5 Critical Sustainability Questions

When applying to a funding organization, applicants should consider the following questions:

1. Assuming acceptable results and assuming that the task will not be fully completed at the end of the grant period, is it expected that this initiative will continue beyond the period for which funding is available?
2. If so, what level of financial and other resources will be needed to continue?
3. What capacity-building measures are needed to make the initiative sustainable? How will these measures be implemented?
4. What is it about this initiative that is likely to attract interest and elicit support?
5. Who are the most likely future funders? (Be specific. If government, what level

of government, what agency, what funding stream? If private, which foundation or other source?)

6. Is there a history of this entity supporting efforts (a) of this sort and (b) of this size?
7. Would success in this effort obviate the need to spend resources on something else, and could that money be diverted to this effort? How?
8. Who within the anticipated funding organization would have to decide to fund, through what processes?

Source: Cutler, I. (2002). End games: The challenge of sustainability. Baltimore, MD: Annie E. Casey Foundation Publisher.

National Organization: The National Nursing Centers Consortium

In 1996, because of interest from several nursing center directors, staff, and community members to address all aspects of operations and to provide ongoing collaboration and continuing education, the Regional Nursing Centers Consortium (RNCC) of Pennsylvania, New Jersey, and Delaware was established. In the short span of 5 years, nursing centers nationwide were contacting the RNCC with inquiries related to all aspects of operations, funding, and sustainability. It became rapidly evident that the RNCC needed to expand its service area to meet the needs of NLHCs around the nation. In 2001, The National Nursing Centers Consortium (NNCC) was formed to represent NLHCs nationwide. Headquartered in Philadelphia, Pennsylvania, with a second office in Washington, DC, the NNCC expanded in 2005 to include an international focus with the addition of an NMHC in Auckland, New Zealand. The vision, mission, and goals of the NNCC are found in Display 31–6.

DISPLAY 31-6 National Nursing Centers Consortium

Mission

To advance nurse-led health care through policy, consultation, programs, and applied research to reduce health disparities and meet people's primary care and wellness needs (para. 2).

Our Mission is Accomplished by

1. Providing national leadership in identifying, tracking, and advising health care policy development
2. Positioning nurse-managed health clinics as a recognized mainstream health care model
3. Fostering partnerships with people and groups who share common goals (para. 3)

Source: National Nursing Centers Consortium. (2014). Who we are. Retrieved from http://www.nncc.us/about-nncc/who-we-are

Best Practices of Nurse-Led Health Centers

In contemporary health care, evidence-based practice is the process of making clinical decisions based upon the best available research evidence, clinical expertise, and client preferences in the context of available resources (Melnyk & Fineout-Overholt, 2014). NLHCs implement evidence-based practice via best guidelines, or the application of the best available evidence to improve practice and systematic reviews have found that they provide effective services (IOM, 2011; Jakimowicz, Stirling, & Duddle, 2015; Schadewaldt & Schultz, 2011). Chapter 4 provides an extensive overview of evidence-based practice.

Biennially, the NNCC conducts a *Best Practice Conference* at varied national locations. This professional conference brings together nurses, staff members, funders, and political leaders to share best practices and participate in networking opportunities. Continuing education credits are available for attendance at scientific sessions. This is one example of how NLHCs set standards for quality improvement and promote professional growth among members.

Nursing Research and NLHCs

NLHCs provide research opportunities, for both primary prevention and wellness initiatives. Descriptive data have been collected about client demographics, types of service provided, funding methods, and sustainability efforts. The first national collection of quality measures for NLHCs compared with national ambulatory care benchmarks is now published (Barkauskas, Pohl, Tanner, Onifade, & Pilon, 2011). The quality measures in this report were for breast cancer screening, cervical cancer screening, diabetes care, hypertension management, and smoking cessation. These authors found that quality measure findings compared favorably with national benchmarks, with high quality demonstrated for chronic disease care management. They also reported that their experience with national data collection proved to be feasible. Additional studies with multisite NLHCs designed to measure variables such as psychosocial needs, accessibility and affordability of services, and quality of life indicators are warranted.

Role of Students in Nurse-Led Health Centers

Undergraduate and graduate students from many disciplines play a vital part in the activities of NLHCs. These disciplines include, but are not limited to, nursing, social work, mental health, dental, nutrition, speech– language–hearing science, and public health. When students engage in NLHC activities for their clinical experience, they become aware of the distinctiveness of nurse-managed centers from other health care delivery systems, the variety of models and organizational structures that exist, and are active participants in vital nursing center activities. Most often, students are engaged in primary and secondary prevention strategies via health education, outreach, immunization, and screening programs. Roles that students fulfill are similar to the roles of their staff mentors, such as advocate, case manager, change agent, educator, and referral agent. Faculty roles in NLHC academic models involve clinical supervision and mentorship of undergraduate and graduate students assigned to the nursing center for their clinical experience (see From the Case Files III).

From the Case Files III

Public health nurses from an academic wellness NLHC and undergraduate student nurses are conducting blood pressure and glucose screenings at a church-sponsored health fair. This event is conducted on Sunday from 10 AM to 2 PM, before, during, and after church services. Approximately 50% of adults screened have hypertension and/or hyperglycemia. One African American male participant, who was asymptomatic, had severe hypertension (220/154) and was immediately transported to the nearest hospital for evaluation.

1. What are some feasible referrals that may have been made for those with abnormal screening results?
2. What types of primary prevention strategies may benefit those attendees who had normal screening results?
3. What is the rationale for conducting the health fair on a Sunday?
4. Why is it important for student nurses to be knowledge about the most current blood pressure guidelines?
5. In what ways do student nurses benefit from participating at a health fair?

Community Service Learning in Nurse-Led Health Centers

Additionally, schools of nursing and NLHCs are an excellent venue to conduct community service learning (CSL) projects with both undergraduate and graduate students. Using a "wall-less" concept of a nursing wellness center, undergraduate and graduate nursing students can participate in CSL activities in a variety of community settings. CSL activities provide opportunities for students to partner with key community agencies to help meet the needs of underserved and vulnerable populations (Resick et al., 2015). Benefits for students include academic growth, life skill development, civic engagement, and partnership with the larger community (Resick et al., 2015). Within NLHCs, broader implications of service learning include interpersonal, social, and moral development, as well as increased awareness of community, national, and global health problems (Sabo et al., 2015). One exemplar of a CSL project conducted at urban and rural schools is the "Safety Town" initiative. This CSL project entails educating preschool and early elementary school–aged children on indoor and outdoor safety for trauma prevention (Miller & Mest, n.d.). Qualitative feedback from nursing students reveals personal and professional growth regarding primary prevention in pediatric trauma in nontraditional clinical settings within the community.

Future Directions for NLHCs

In 2008, the IOM appointed a committee on the Robert Wood Johnson Foundation (RWJF) Initiative on the Future of Nursing. The purpose of this committee was to produce a report making recommendations for the future of nursing. This committee developed four key messages regarding the future of nursing: (1) nurses should practice to the full extent of their education and training; (2) nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression; (3) nurses should be full partners, with physicians and other health care professionals, in redesigning health care in the United States; and (4) effective workforce planning and policy making requires better data collection and information infrastructure (IOM, 2011). NLHCs play a vital role in the transformation of the national health care system. The passage of the Affordable Care Act (ACA) in 2010 (see Chapters 1 and 13) and implementation strategies that were put into action in 2014, are relevant to activities conducted in NLHC models. Main areas of focus for health care reform are prevention and improving the quality of care. In NLHCs, advanced practice nurses lead interprofessional teams as critical safety-net providers in America's health care delivery system. Nurses in NLHCs are vital change agents as they partner with the community, interprofessional team members, and students to improve access to care and health outcomes (Jakimowicz et al., 2015). Continued expansion of the NLHC model in the next decade and beyond will meet key recommendations from the IOM report on nursing's future and the goals of the ACA (Wilson et al., 2012). See Perspectives for an example of an NLHC that meets the needs of the population served, provides continuity of care, and reduces the use of overcrowded and expensive ED services for routine health care.

PERSPECTIVES DENTON COMMUNITY HEALTH CLINIC: A NURSE-LED COMMUNITY CLINIC

In the fall of 2011, I realized that many of the low income or homeless had difficulty accessing health services. Other health organizations in our community, a city of 120,000 in northeast Texas, were promoting that the low-income or homeless population were "noncompliant" and did not care about their health. I had learned through volunteering that access to existing community health care resources presented many barriers. These barriers were minimal payment amounts that were too high, service hours that were not convenient to the low-income population, and pre-enrollment criteria that many could

not meet. Most existing health care organizations required proof of income, proof of residency, and so on. The low-income population often has day jobs and income that may be high 1 week and nonexistent the next week. Many share a residence with others so that it is more affordable and so do not have a proof of residence. Hence, the low-income and/or homeless populations tend to use the hospital EDs for care.

Consequently, equipped with evidence-based knowledge about the low-income and homeless populations, with community health models such a Pender's Health Promotion Model (Pender, Murdaugh, & Parsons, 2011), and population health care frameworks (Bisognano & Kenney, 2012), I embarked in setting up a health clinic that didn't have those unrealistic requirements. Individuals needing health services simply have to fill out an income self-declaration, and if they have no proof, that is fine. There are two reasons for the declaration. First, it helps the staff determine what the person could afford based on their income, and second, it is a screening tool to identify people who may need to be hooked up to community resources. The low-income and homeless populations are very mistrusting of community health and social services. They live day by day. They have to focus on the here and now: Where will my next meal come from? Where will I shower? Where will I launder my clothes? Where will I sleep? Guided by the understanding that the low-income population has its own culture and very specific needs, the clinic was set up as a caring, compassionate, and supportive environment for this population. Research has shown that individuals are more likely to adopt health-promoting behaviors if they are able to develop relationships with role models (Calvert, Isaac, & Johnson, 2012; Cook-Craig, Ely, Flaherty, Dignan, & White, 2012). The staff at the clinic is trained to treat everyone in a nonjudgmental manner. When a patient does not show up for an appointment, the staff calls the individual within a couple of hours of the missed appointment—not to scold the patient, but rather to check and see if the patient is all right. At that time, the staff ascertains the reason for the missed appointment and encourages the individual to reschedule. The staff also educates the person to call the next time so that we know he or she is fine. Consequently, the clinic has a very low rate of patients not showing up for appointments. Patients of the clinic state that they feel "listened to," even though the length of appointments is still only 20 minutes.

Based on the knowledge that this population has difficulty getting time off from work and has problems with lack of transportation in our community and that they work different schedules, the clinic set up its hours to offer early morning hours, lunch time hours, and evening hours. The clinic does not close for lunch, so that if someone can only call at lunch, the call will be answered. Another strategy to improve access is that the clinic provides not only medical care but also behavioral care, by providing medical follow-up for mental health illnesses as well as counseling and social services. The decision to implement these services within the clinic was made because individuals tend to open up more when a relationship is built over time. Hence, treatment for patients' depression, anxiety, and other behavioral health issues are better managed with the help of the counselors and social worker.

The clinic is the patient-centered medical home for this population. Because the providers and staff build a relationship with the patient and family, the clinic staff is able to coordinate care, offer support services, and help individuals strengthen their coping and problem-solving skills.

The outcomes of the clinic interventions in helping individuals learn to manage their chronic illnesses are that individuals are able to keep working, be productive members of society, and learn to seek health services at the clinic rather than use the more expensive hospital ED. Individuals who previously had uncontrolled diabetes are now better controlled and are able to articulate what they need to do to control their blood sugars. Individuals with uncontrolled blood pressure now monitor their own blood pressure and call when the blood pressure goes beyond a certain level. As a nurse, I find myself constantly advocating for patients, ensuring that their needs are being systematically assessed and that the proper interventions are put in place to ensure maximal health at a lower cost. It is a rewarding experience!

FAITH COMMUNITY NURSING

Historical Background of Faith-Based Nursing

Faith community nursing is one of the newest nursing specialties and one of the oldest means of health care delivery. For hundreds of years, deaconesses, sisters, and lay members of religious communities have been involved in ministering to the sick. This tradition was revitalized through the efforts of Reverend Dr. Granger Westberg. As a hospital chaplain and Lutheran minister, Westberg (1990) observed a great need for preventive and holistic health services, especially among the underserved. He estimated that one third of the illnesses his patients experienced could have been prevented, or the severity reduced, by education and health promotion. To address these needs, he launched several church-based holistic health clinics in the 1970s, each staffed by a physician, nurse, and chaplain. These clinics provided health services to the underserved in the community for several years. The clinics eventually closed, but the experience led Reverend Westberg to recognize the unique ability of nurses to bridge the disciplines of medicine and religion and assist the client in understanding the physical and spiritual influences on health (Hickman, 2011).

Spurred by the positive impact of the church-based health clinics, Westberg initiated a pilot project in 1984 in which nurses provided holistic, preventive health care for six Christian congregations in the Chicago area. These nurses were called *parish nurses*. The surrounding communities recognized the beneficial influence of the parish nurses on the six congregations. Gradually, more and more churches sought to incorporate a parish nurse into their staff. The parish nursing movement soon spread outside of Christian religious institutions and beyond the borders of the United States to 22 other countries. The International Parish Nurse Resource Center (IPNRC, n.d.), formed in 1986, provides educational programs and resources for nurses who seek to practice as a parish nurse and for educators wishing to conduct training programs for parish nursing.

The Health Ministries Association (HMA), formed in 1989, was instrumental in developing the first *Scope and Standards of Parish Nursing Practice* (HMA, 2010). In the original standards, the term parish nurse was defined as "a registered professional nurse who serves as a member of the ministry staff of a faith community to promote health and wholeness of the faith community …" (American Nurses Association [ANA]/Health Ministries Association [HMA], 1998, p. 1). The term faith community was defined as an "organization of families and individuals who share common values, beliefs, religious doctrine and faith practices … such as a church, synagogue, or mosque …" (ANA/HMA, 1998, p. 6). These definitions were carried over to the revised scope and standards, published in 2005, and the title of parish nurse was changed to faith community nurse (FCN), while the name of the specialty was changed to faith community nursing (ANA/HMA, 2005). Today, nurses who practice in a faith community may be referred to as FCNs, parish nurses, health ministry nurses, congregational nurses, or church nurses

depending upon preference and the traditions of the faith community. No matter what title is used, a nurse who practices in a faith community should adhere to the *Faith Community Nursing: Scope and Standards of Practice, 2nd ed.* (ANA/HMA, 2012); the current definition of FCN is "a specialized practice of professional nursing that focuses on the intentional care of the spirit as part of the process of promoting holistic health and preventing or minimizing illness in a faith community" (p. 1).

What Do Faith Community Nurses Do?

Activities and interventions used by FCNs are as diverse as their faith communities. Authors have described key aspects of this specialty, which include meeting the emotional and spiritual support needs of the dying and serving as an advocate for individuals who are hospitalized, living at home, or in long-term care facilities (Evans, 2011; Hickman, 2011; Van Dover & Pfeiffer, 2012; Ziebarth, 2014). FCNs are also well positioned to address health conditions associated with stigma or embarrassment such as sexually transmitted infections and HIV (Archibald & Newman, 2015; Stewart, Thompson, & Rogers, 2015) and mental health issues (Caplan & Cordero, 2015; Singh et al., 2015). An FCN seeks to understand how religious beliefs and life transitions (e.g., marriage, divorce, birth, death, illness) impact on spiritual and mental health care (Anaebere & DeLilly, 2012). The ongoing and long-term nature of the FCN's relationship with the faith community is helpful for addressing highly personal and/or stigmatizing subjects as well as increasing awareness and promoting health through education.

FCNs have been instrumental in meeting the educational and health promotion needs of underserved and older adult populations. For example, faith-based approaches were based on scripture and included an exercise program called "Walk by Faith" and cancer screening programs "Ribbons of Faith" (Baltic et al., 2015). Other programs on healthy eating education are known as "Bread of Life" and "The Body is a Holy Temple." Many faith-based interventions address overweight and obesity among vulnerable populations: Elijo Salud is one example of an intervention to address poor eating habits among Hispanic youth (Oakley & Hoebeke, 2014), and Project TEACH (Transforming, Empowering, and Affecting Congregation Health) is another program working with obese Black women to improve their nutrition and exercise behaviors (Cooper, King, & Sarpong, 2015). Seton Health developed a program called "Defy Diabetes!" to identify adults at risk for diabetes, provide education to decrease risk, and improve the management of patients with diabetes. The FCN taught the courses and each session began and ended with prayer. Education was provided on nutrition, exercise, and the role prayer plays in stress relief. Observation and surveys concluded that participants developed awareness of their disease and adopted a healthier lifestyle (Sheehan et al., 2013). A randomized community trial of "Fit Body and Soul," a faith-based lifestyle intervention program to prevent diabetes among an African American population, showed a significant overall decline in fasting plasma glucose (almost 11 mg/dL) for those program participants identified as prediabetic versus an increase (4.22 mg/dL) for those receiving only health education over a 12-week period (Sattin et al., 2016). Participants also had significantly greater weight loss.

A review of parish nursing (FCN) literature from 2008 to 2012 found that FCNs from diverse geographic areas and faith traditions performed consistent interventions to address health concerns that were often aligned with national health priorities (Dandridge, 2014). In addition, many of the interventions, such as education, advocacy, and referral, were comparable to those used in traditional nursing practice. However, FCNs tended to engage

in more health promotion interventions and to integrate spiritual and religious practices into their approaches. FCN services are growing and can provide cost-effective services to a range of populations, including those who may be more difficult to reach through more traditional health care venues (Yeaworth & Sailors, 2014). Holistic support offered by FCNs include actions that address physical, social, emotional, mental, and spiritual needs such as health education, counseling, referral to community agencies, advocacy on the client's behalf to meet needs and reduce complications, and coordinating care by mobilizing other members of the faith community to provide support such as prayer, visitation, meals, and transportation (Dandridge, 2014; Pappas-Rogich & King, 2014). Although the interventions used by FCNs may not emphasize providing direct physical care, such as medication administration, or other prescribed treatments, all registered professional nurses including FCNs share the use of the nursing process (ANA/HMA, 2012). For the FCN, implementation of a plan of care incorporates actions that fall within one or more of the seven roles of the FCN (see Display 31–7).

DISPLAY 31.7 ASSURING CONGREGATIONAL HEALTH AND WHOLENESS

Roles of the Faith Community Nurse

1. Health educator
2. Health counselor
3. Advocate
4. Referral agent
5. Developer of support groups
6. Coordinator of volunteers
7. Integrator of faith and health

Accountability

1. ANA scope and standards of nursing practice
2. ANA scope and standards of faith community nursing
3. Congregational standards
4. Institutional standards
5. ANA social policy statement

6. ANA code of ethics for nurses with interpretive statements
7. State nurse practice act
8. Patients rights

FCNs develop and implement a variety of health programs that address the health needs of their congregants. Many programs have been implemented that address the leading health indicators of *Healthy People 2020* such as physical activity, tobacco use, responsible sexual behavior, injury and violence, immunization, overweight and obesity, substance abuse, mental health, environmental quality, and access to health care (USDHHS, Office of Disease Prevention and Health Promotion, 2016a). Pappas-Rogich and King (2014) studied the role of FCNs and their support of *Healthy People 2020* objectives. A convenience sample of 247 FCNs completed an online survey linked to the International Parish Nurse Resource Center (IPNRC) Web site. Results indicate that most had an average of 15 years experience and were between age 51 and 71, and the majority (95%) was White. More of them were volunteers (68%), and 58% worked part time for 10 hours or less weekly. The parishioners they served were largely White (79%) and 79% of them were over the age of 65. They reported most often doing weekly health counseling and integrating health/faith. The most frequent monthly roles were health educator, making referrals, advocacy, and coordination of volunteers. Almost 40% stated that they never led support groups. The *Healthy People 2020* objectives that were most often implemented included the following:

- Promotion of physical activity (weekly; 33.5%)
- Promotion of good nutrition (monthly; 33.2%)
- Promotion of emotional health/well-being (monthly; 30.1%)
- Reduction/elimination of tobacco use (yearly; 29.8%)
- Reduction of violence through education/counseling (yearly; 30.1%) (p. 232)

The roles of the FCN (see Display 31–7) are well suited to support the development, implementation, and evaluation of these and other faith-based health programs.

Roles of the Faith Community Nurse

The goal of the FCN is "protection, promotion and optimization of health and abilities; prevention of illness and injury" and to respond "to suffering within the context of the values, beliefs, and practices of the faith community" (ANA/HMA, 2012, p. 3). Health promotion outcomes may be primary, directed at prevention of disease, illness, or injury; secondary, focused on early detection and appropriate intervention; or tertiary, concerned with promoting a sense of well-being when preventing or curing a condition may not occur. To achieve the goal of faith community nursing, seven diverse nursing roles are central to incorporate into practice (Dandridge, 2014).

Health Educator

A primary role of the FCN is as a health educator. Anaebere and DeLilly (2012) listed health education as the most common intervention in their study of parish nursing. Increasing awareness of health issues through health education is the foundation for health promotion and lifestyle changes. The FCN uses assessment skills to determine the health issues that may be present in the faith community and assesses the educational needs related to these issues. In the role of health educator, the FCN may provide individual and group education strategies such as providing health education materials, leading health education classes, or providing health screenings. The FCN may also develop educational displays or flyers, or write educational articles for the faith community newsletter or Web site.

Health Counselor

When education alone is not sufficient for empowering the individual to initiate a change or seek assistance, health counseling may be indicated. In the health counselor role, the nurse seeks to understand the individual's perceptions, fears, and barriers that prevent the person from taking action. The FCN may use a five-step health counseling process described as the five A's: ask, advise, assess, assist, and arrange (Agency for Healthcare Research and Quality, n.d.). Using this process, the FCN asks about the person's perceptions related to a specific health concern, advises the person about the health concern and the benefits of taking health-promoting actions, assesses the person's readiness to take action, offers assistance and guidance in planning ways to address the health concern, and arranges follow-up support. FCNs collaborated with a local hospital and pharmacists to promote better medication self-care in older adults (Shillam, Orton, Waring, & Madsen, 2013). They organized medication reviews during brown bag lunches and provided personal health counseling. Three months later, statistically significant results indicated that the older adult participants had decreased their total number of medications.

Advocate

The third role of an FCN is that of an advocate, helping individuals obtain needed services

or care whether in the hospital, a long-term care facility, or at home. In the advocate role, the FCN uses knowledge of the health care system and awareness of safe and effective care practices to facilitate appropriate, timely intervention. Advocacy is indicated when dealing with vulnerable populations, such as older adults, children, or the homeless, who may not have the ability to speak for themselves or may lack the knowledge or awareness of what constitutes safe, effective care. FCNs have actively advocated for those with mental health problems, finding treatment sources and providing referrals and support (Anaebere & DeLilly, 2012).

Referral Agent

The role of referral agent involves several related aspects. First, the nurse needs to develop knowledge of community resources and contacts. Knowledge of what is available, how the service is accessed, eligibility criteria, and limitations of the service is essential. Next, the nurse networks with and develops collaborative relationships with community leaders and agencies that provide the services. Through networking with community agencies, the FCN becomes aware of and able to easily access a variety of community resources to support the client's physical, social, financial, emotional, or spiritual needs. The nurse is able to draw upon the relationships established with agency personnel to facilitate the eventual use of these resources, when needed. The final aspect of referral involves matching the needs of the individual or group to the services available. Thoughtful referral will assist and guide the client through the health care system and connect them with needed community resources. For instance, FCNs can be instrumental in ensuring improved vaccination rates for elderly and those with young children in their congregations and may seek collaborative arrangements with public health agencies (Pappas-Rogich, 2012), and a group of FCNs collaborated with public health staff to develop a toolkit for emergency preparedness and infection control (Reilly et al., 2011).

Developer of Support Groups

Receiving emotional support from persons who share similar experiences can provide strength, comfort, knowledge, and a sense of empowerment. When the FCN discovers a need for a support group that is not currently available in the community at large, the FCN may fulfill the role of developer of support groups. The FCN develops groups tailored to the faith community needs such as coping with loss and grief, cancer, caregiver stress, chronic illness, single parenting, addiction recovery, and more. The FCN may lead or facilitate the support groups or may train others to fulfill those positions. In one congregation, small groups were organized for workshops on sexuality (Cockroft, 2012). In another instance, telephone support groups were organized for homebound elderly members of a congregation; this effort seemed to help them with their movement and speech (Hayman, 2012).

Coordinator of Volunteers

The health ministry mission of a faith community typically includes a variety of services and activities to provide holistic support of the physical, social, emotional, mental, and spiritual needs of its members. Such a diverse array of services cannot be provided by the FCN alone. In the role of coordinator of volunteers, the FCN recruits, trains, and coordinates other members of the faith community. Volunteers provide or assist with a variety of services such as home, hospital, or long-term care visitations; respite care; assisting with transportation needs of homebound individuals; calling or sending cards to ill or injured members; and assisting with health screenings. Health ministry volunteers may include nurses, counselors, physical therapists, pharmacists, and other health care providers, as well as those with no health care background. Lay volunteers have been trained by FCNs to lead exercise groups or provide health education (Ellis & Morzinski, 2013; Reilly et al., 2011; Whisenant et al., 2013).

Integrator of Faith and Health

A distinctly unique role of the FCN is as integrator of faith and health. This role emphasizes the holistic relationship between physical, social, emotional, mental, and spiritual dimensions of the person. The FCN helps the person to improve health or enhance wellness by appreciating how the dimensions of the person are interconnected and by helping the person strengthen or support the weaker aspects, as needed. The FCN assesses community's strengths and health needs and incorporates an understanding of the connection between faith and health (Dandridge, 2014). Using opportunities to enhance the awareness of the interaction between faith and health is central to this role. Patients reported a renewal of their spiritual identity after receiving spiritual care from their FCN in a grounded-theory study by Van Dover and Pfeiffer (2012).

Faith Community Nursing Practice

Models of faith community nursing practice are diverse and may be categorized according to volunteer versus salaried positions with institutional versus faith-based sponsorship. The type of practice model adopted depends upon variables such as the number of faith community members served, the existing health ministry services in place, the faith community's governance structure and financial resources, and existing health care systems in the community at large. Early in the development of faith community nursing, FCNs were typically part-time volunteers who were members of the faith community they served. This voluntary, part-time status, coupled with the newness of faith community nursing practice, has resulted in limited research on faith community nursing. Nonetheless, studies that have been conducted have validated the effectiveness of FCNs and the programs they have implemented:

- Parent–child communication interventions on sex behaviors and cognitive outcomes for Black and Hispanic youth (Sutton, Lasswell, Lanier, & Miller, 2014)
- Faith-based lifestyle intervention to prevent diabetes among African Americans (Sattin et al., 2016)
- Faith-based healthy eating and physical activity intervention (Walk by Faith) to reduce weight and cancer risk among overweight and obese Appalachian adults (Baltic et al., 2015)
- HIV prevention in an Afro Caribbean faith-based community (Archibald & Newman, 2015)
- African American church-based HIV testing and linkage to care (Stewart et al., 2015)

There are growing trends in the types of FCN delivery models used today. In larger faith communities, one trend is to include the FCN as a salaried full- or part-time staff position. Smaller faith communities may join forces and pool resources to hire a full- or part-time FCN to serve multiple congregations. Another trend is the formation of partnerships with organizations such as universities or hospitals that agree to provide nursing services to the faith community. Partnerships with universities may involve individual faculty and student groups. For nursing faculty, faith community nursing can provide a flexible venue for part-time nursing practice that utilizes their skills in teaching and health promotion. The American Hospital Association (2012) reports on the success of a partnership between Methodist Le Bonheur Healthcare and the Congregational Health Network that has improved care transitions. In the 473 patients studied, their mortality rate was about half that of matched patients who were not enrolled in this collaborative service. Nursing students can be involved in providing service to faith communities by participating in service learning projects. The philosophy underlying service learning is that both parties benefit from the partnership; students learn and acquire needed skills, and faith communities obtain needed health education or health screenings (Sabo et al., 2015). A South African study examined the benefits to nursing students engaged in service learning

within a faith community (du Plessis, Koen, & Bester, 2013). Students became more aware of cultural and religious factors with mental health patients they served, and the perception of their role and feelings of competence emerged over the time they participated in home visits. Families expressed feelings of growth and having experienced caring from the students.

Alegent Creighton Health of Omaha, Nebraska, recognized the financial benefits of a program that incorporated faith-based approaches. Data were collected on the cost savings accrued by the health system utilizing an FCN to transition patients from hospital to home and to care for them within their homes. The study indicated cost savings of $1,910,630 from 2005 to 2012 (Yeaworth & Sailors, 2014). Regardless of the model of practice utilized, integrating the FCN position into the faith community's organizational structure is recommended (Hickman, 2011). One way this integration can be provided is through the formation of a *health cabinet* or health and wellness committee within the faith community. The health cabinet was originally described by Reverend Westberg (1990) as a way to provide health ministry for a faith community that is interested in adding an FCN to its staff. The health cabinet includes members from the faith community who are interested in promoting and sponsoring health-related activities and programs for the faith community. Members may be nurses, other health care professionals, or persons with no health care background. The FCN functions as a member of the health cabinet and receives guidance and support from the cabinet in developing, promoting, and delivering programs and services to members of the faith community.

Becoming a Faith Community Nurse

The FCN practices community nursing with a high degree of independence and autonomy. Often, the FCN deals with clients experiencing complex health care situations who may have limited resources and extensive health-related needs. Recommended educational preparation for an FCN includes a bachelor's degree in nursing with community nursing experience as part of the program (ANA/HMA, 2012) and completion of additional education such as the 36-hour *Foundations of Faith Community Nursing* course offered through the IPNRC (IPNRC, n.d.). This course addresses the roles of the FCN and provides information on establishing, promoting, and maintaining an FCN practice. Participants gain experience in resolving complex client situations using scenarios and case studies.

Establishing a Faith Community Nursing Practice

Several steps are involved in creating an FCN position within a faith community. One of the first things to do is assess the community the nurse plans to serve, identifying the health needs of the faith community and the roles of the FCN that meet those needs. For example, a nurse might assess the demographics of the community and determine the most common health concerns and what education or health counseling needs the faith community may have. A needs assessment survey of the membership about health concerns, or topics of interest, may be conducted. Questions to explore include the following: Does the faith community need support groups for members who are experiencing the stress of illness, injury, or loss and grief? Do the members of the faith community need more information or assistance to access existing community resources? And, is there a need for health screening, respite care, or visitation for the sick or injured in their home, hospital, or long-term care facility?

Once the nurse has assessed the needs of the faith community, the next step is to identify how an FCN could help to meet those needs. The FCN uses this information to seek the support of the faith community members and staff, usually through visits with key members of the faith community, including the minister, past and present board members, and long-standing members. The nurse describes to these key members the roles of an FCN and how specific health needs of the faith community could be addressed by the services of an FCN and then solicits input from the staff and spiritual leaders of the faith community.

After key members and leaders of the faith community have verbalized support for adding an FCN to the organization's health ministry, the nurse seeks formal approval from the organization's governing body. The scope of services to be offered, time commitment expected, process of referral to the FCN, means of contacting the FCN, and other administrative aspects of the position should be negotiated before approval is finalized. The organization's bylaws, governing body, committee structure, and spiritual leader will play a part in the formal approval process and in determining where the FCN will fit in the

organizational structure. The approval process may require a formal presentation of the nurse's proposal to the board members or to the faith community as a whole.

Launching an FCN practice should begin after the nurse has received educational preparation as an FCN and has received formal approval from the faith community's governing body. As a subspecialty in community health nursing, it is recommended that the FCN have educational preparation at the bachelor's level and have specific educational preparation as an FCN. A bachelor's degree in nursing provides community health nursing experience, and the foundation course mentioned earlier provides knowledge of the seven roles of the FCN as well as guidance in establishing and maintaining an FCN practice. The FCN must also have an active license. Prior to initiating services, the nurse and the faith community's administrator should assure that proper liability insurance is in effect. The FCN should carry individual professional liability insurance, and the administrator of the faith community should determine if the activities and services that will be provided are covered by the organization's insurance carrier.

If the faith community is not familiar with FCNs, the nurse will want to educate members about the roles of the FCN. The FCN can give presentations about faith community nursing to groups within the faith community, such as prayer circles, adult Sunday school, teen groups, pulpit talks, and existing support groups. During the presentations, the FCN can discuss specific activities that will be actively pursued, such as home or hospital visitations, formation of support groups, teaching health classes, and providing health screening, health counseling, spiritual support, and referral to community resources. These presentations will provide multiple benefits for both the FCN and the members of the faith community by allowing the nurse to establish relationships with members of the faith community and by allowing members to become familiar with the FCN and the services offered (Hickman, 2011).

In addition to providing presentations about faith community nursing to groups within the faith community, the nurse should consider other ways to inform members of the services provided. If the faith community publishes a newsletter or has a Web site, including a brief introduction to faith community nursing and providing some personal background and professional experience, information will be useful. The FCN may develop flyers and brochures that describe what an FCN does and the services offered. These materials may be distributed initially to new members and may be continually displayed on the community bulletin board. Business cards that provide the FCNs name, contact information, and outline FCN services may be distributed. The FCN may also write a monthly feature for the newsletter to provide health education and to keep the congregation informed of the services offered. These strategies and others will provide mechanisms for initial and ongoing marketing of the FCNs services to the faith community and can be useful tools for health promotion (Elwell, 2015).

Another aspect of preparation involves establishing community contacts and compiling information about community resources. The FCN should visit local health-related agencies, clinics, and hospitals and discuss services they provide and determine how these

services may be accessed by FCN referral of faith community members. Information from community organizations, such as the March of Dimes, American Cancer Society, American Heart Association, and others, can provide health information and online resources for health promotion activities.

And finally, the FCN will need to decide on a method of documentation and record keeping. Documentation of the FCN activities and outcomes will provide ongoing evidence of the effectiveness of programs and interventions, which can be used to justify continuation of programs and services. The IPNRC (n.d.) offers resources regarding an electronic documentation system. Miller and Carson (2010) developed a system for documentation in faith community nursing that includes a daily activity log, a monthly activities report (developed from the daily logs), and individual interaction forms (when more in-depth interventions are needed or visits occur over several weeks/months). They note that a system of documentation must be "concise, require minimal time, and be formatted to facilitate tracking activity" so that both the congregation and community partners can quickly discern the FCN role and activities (p. 122) (see Display 31–8). Whatever method of documentation is used, the FCN will need to assure consistent documentation, confidentiality, and proper storage of the records.

DISPLAY 31.8 NORTHERN CALIFORNIA FAITH COMMUNITY NURSE EDUCATION NETWORK DOCUMENTATION

Daily Activities Log

Can be a checklist that includes date, time spent, mileage, and specific activities or patient names (e.g., education programs, meetings, home visits, individual/group contacts, screenings, referrals) and assessment, interventions, and outcomes. Demographic categories are needed (e.g., age, ethnicity, gender), and NANDA, NIC, and NOC categories may be used to group the data for less complicated retrieval.

Monthly Activities Report

These are composed of aggregated data from daily activities logs and provide a summary of care provided by the FCN. Key categories such as individual or group contacts, specific problems, referrals made, programs given, meetings attended, work

with volunteers, and program planning activities are grouped together, again using NANDA, NIC, and NOC classifications.

Individual Interaction Form

This is similar to other patient forms that request a health history, current status of health, contact information, and space for (or a checklist for common) NANDA, NIC and NOC information.

OCCUPATIONAL AND ENVIRONMENTAL HEALTH NURSING

Business and industry provide another group of settings for community health nursing practice. Occupational and environmental health nurses work with employers to cultivate creative and business-appropriate health and safety programs. Program development must take into account the business' unique type of work, workforce demographics, and the work/community environments. The practice of occupational health nursing utilizes an interdisciplinary approach to advocate for the employee's right to have cost-effective, prevention-oriented health and safety programs.

Organizations are expected to provide a safe and healthy work environment in addition to offering insurance for health care. Businesses often choose to hire occupational health nurses (OHNs), because occupational health programs help maximize employee efficiency and decrease costs by effectively reducing work-related injuries, disability claims, absenteeism, and improve employee health and safety. Present-day OHNs observe and assess workers' health status considering the workers job tasks and hazards. Using their specialized training, education, and experience, they use the nursing process to prevent occupational illness and injury. An additional and equally important responsibility is to help organizations maintain compliance with federal, state, and local laws, regulations, and guidelines for workplace health and safety (American Board for Occupational Health

Nurses [ABOHN], 2012).

History of the Occupational and Environmental Health Nurse

Community health nurses have a long history of involvement in occupational health. Betty Moulder provided care for coal miners and families in Pennsylvania beginning in 1888 (American Association of Occupational Health Nurses [AAOHN], 2012). In 1895, the Vermont Marble Company hired Ada Mayo Stewart, said to be the first *industrial nurse* in the United States. Stewart provided care for employees and their families focusing on health promotion and disease prevention (Thompson, 2012). Early on, the profession primarily focused on providing infant and child health education to the employee families as well as the whole community. World War II showed a marked increase in employment of OHNs. In keeping with the changing times, the OHN's practice broadened to include comprehensive health and safety programs designed to prevent illness and injury for the U.S. workforce.

Although occupational and environmental health nursing has been in existence since the late 1800s, the Occupational Safety and Health Act of 1970 led to the proliferation of occupational health nursing employment in the United States. This important legislation established the Occupational Safety and Health Administration (OSHA) in the Department of Labor, to ensure a safe working environment for workers in the United States. In an effort to ensure business and industries meet OSHA standards, OHNs monitor the health status of individual workers, workforce populations, and community groups. OHNs are able to implement evidence-based interventions to prevent or mitigate negative health effects of the work environment by gathering health and hazard data, evaluating the effects of workplace exposures, and developing workplace prevention programs (AAOHN, 2012).

Roles of Occupational and Environmental Health Nurses

Occupational health nursing practice can be divided into three main categories: compliance, care, and health promotion. There is a wide range of legislation that guides occupational and environmental health nursing practice. Some of the prominent guidelines come from Occupational Safety and Health Administration (OSHA) U.S. statutes, Genetic Information Nondiscrimination Act (GINA), Family Medical Leave Act (FMLA), Americans with Disabilities Act (ADA), Health Insurance Portability and Accountability Act (HIPAA), Department of Transportation, and U.S. Environmental Protection Agency (EPA). The following are a few examples of how regulatory guidance can influence an OHN's nursing practice:OSHA standards require training and hearing tests for employees who are exposed to loud noise at the workplace (29 CFR 1910.95).The Department of Transportation (n.d.) requires commercial drivers to pass a physical exam before they are allowed to drive and periodically throughout their driving career (49 CFR 391).The Americans with Disabilities Act (ADA) requires employers with 15 or more employees to make reasonable accommodations for persons with disabilities (ADA, 2000), and nurses are often part of the reasonable accommodation decision-making team.In health care settings, employee health nurses are instrumental in ensuring the institution's compliance with requirements for immunizations and tuberculosis testing (AAOHN, 2012).

The OHN is typically the first person to evaluate an injury that occurs in the workplace. In addition to providing first aid, larger occupational health clinics are moving toward a model that provides not only occupational health services but also case management and primary care (Mattaliano, 2013; Merrill et al., 2013). According to Workforce Management Data Bank, the primary reason employers establish an on-site clinic are to decrease health care costs, improve workers' quality, and improve the company's cost-effectiveness (Graeve, McGovern, Nachreiner, & Ayers, 2014; Moore & Moore, 2014). Comprehensive occupational worksite programs offer both health protection and health promotion services. After employees are injured or become ill at work, OHNs work to ensure a speedy and functional recovery, frequently helping employees work through the workers' compensation or insurance bureaucracy. Although some companies outsource case management for work-related injuries, many OHNs manage cases to ensure the employee's optimum recovery while helping to control costs.

It is in the best interest of both the injured/ill workers and employers to have employees return to the workplace as soon as possible. The National Safety Council estimates that more than 80 million lost work days are due to occupational injuries or illness (Presmanes, 2015). Additionally, the annual costs associated with employee injury or illness, including medical care and the decrease in productivity, come to $183.7 billion (National Safety Council, 2013). Occupational health and environmental nursing activities can assist employers to reduce the amount of time employees remain out of work because of illness and injury. See Display 31–9 Occupational and Environmental Health Nursing Care Plan.

DISPLAY 31.9 OCCUPATIONAL AND ENVIRONMENTAL HEALTH NURSING CARE PLAN

Evelyn Robbins has been the occupational and environmental health nurse at ABC Metals for 4 years. She works with management, the company physician (who works at ABC Metals 2 days a week), union representatives, unit foremen, individual employees, and representatives from the community businesses and neighborhoods surrounding the plant. The company employs 400 workers—380 in manufacturing, primarily an assembly line making telephone electrical boxes, and 20 management and administrative staff.

Recently, 12 employees came to the worksite clinic complaining of hand injuries that had not occurred before. Mr. Robbins treated the wounds, reported the occurrences to the foremen involved, and reported the incidents to management. In addition, she wanted to explore the cause of these injuries so that they could be interrupted. She used the nursing process in her exploration.

Assessment

- Tour the areas where the incidents occurred.
- Inquire among the foremen to determine whether there was a change in routine, equipment, employee assignment, or product being manufactured.
- Ask injured employees what they were doing when the injury occurred.
- Reassess wounds for likenesses and differences, for example, was it the right or left hand and was it on the same part of the hand in each case?

Diagnoses

- Wounds occurred in factory areas where a new piece of equipment had been installed.
- Injured employees did not receive orientation to the equipment.

Plan

- Plan to work with foremen to provide an orientation for all employees who work with the new equipment.
- Plan an orientation program (with foremen, union representatives, and one

employee from each unit in the factory) for all employees before working with new equipment in the future, to prevent further injuries.

Implementation

- Implement the orientation for employees who work with the new equipment.
- Initiate the orientation program as new equipment is introduced into the factory.

Evaluation

- Have there been any new equipment-related injuries in the factory?
- Has there been any change in general safety in the factory related to the increased focus on safety with new equipment?

In addition to addressing the health needs of the employees, it is important for the OHN to recognize the impact of the workplace on their own personal health. For instance, there are various causes of job stress for the occupational and environmental health nurse, and there may be related personal, professional, and employer factors. The nurse may experience role ambiguity because of a lack of professional preparation or inadequate orientation and continuing education. The corporate culture and leadership may foster work overload, not be supportive, and there may be limited career opportunities for the nurse. Like nurses working in acute care and other settings, occupational and environmental health nurses need to apply strategies to reduce job stress and potential job strain by modeling health-affirming choices, networking with other nurses and professional organizations in the community, and setting appropriate occupational health standards (Kamau, Medisauskaite, & Lopes, 2015).

Health Promotion Opportunities

OHNs play a vital role advocating health promotion and wellness programs for the workforce they serve. OHNs are in an ideal position to provide guidance, counseling, education, and coaching for employees who want to improve their health. Faced with high health care costs, many employers are turning to worksite health programs to help employees adopt healthier lifestyles and lower their risk of developing costly chronic diseases while improving worker productivity (AAOHN, 2012).

There is a link between healthy lifestyle and lower health care costs. Workplace wellness programs provide primary, secondary, and tertiary prevention services. Primary prevention examples include immunizations to protect employees against vaccine-preventable illness, safe lifting demonstrations, and postoffer assessments of preexisting limitations so that reasonable accommodations (per the ADA) can be made to prevent work-related injuries (Moore & Moore, 2014). Postoffer employment testing is a way to screen newly hired job

candidates for their ability to complete all essential functions of their new job and to also screen for any preexisting conditions or injuries that may need to be accommodated before they are formally hired. It often includes physical demands analysis. Secondary prevention in the workplace setting often takes place as part of the medical surveillance process. OHNs do many screenings to gather data about the effects of workplace exposures and use the data to prevent occupational illnesses and injuries. Screenings can be based on OSHA standards, the U.S. Preventive Services Task Force (2014) recommendations, and/or other regulatory organizations. The Department of Transportation (DOT), the Mine Safety and Health Administration, and the Nuclear Regulatory Commission are some examples. Tertiary prevention aims to lessen the impact of a chronic illness or injury that has long-term effects. A worker may need to transition to a new job or do his or her existing job in a new or different way, and the OHN serves as a facilitator, advocate, or case manager to limit adverse health effects of the work environment.

Total Worker Health (TWH) is a national initiative designed to provide holistic approaches to employee wellness. TWH is defined as a strategy that integrates occupational safety and protection of health along with health promotion to prevent worker injury and illness and to improve worker well-being and health (National Institute for Occupational Safety and Health [NIOSH], 2015b). American workers spend a large part of their day at work. The workplace is now considered a social determinant of health; job-related factors include salary, the work environment, time spent at work, physical and psychological stress, employee/employer dynamics, and work–life balance. Activities that take place at the workplace, businesses, and industries all can affect the health and well-being of individual workers, families, and communities, and OHNs are often asked to organize workplace health promotion programs (Dombrowski, Snelling, & Kalicki, 2014). Figure 31–2 describes issues the nurse should consider when planning occupational health programs.

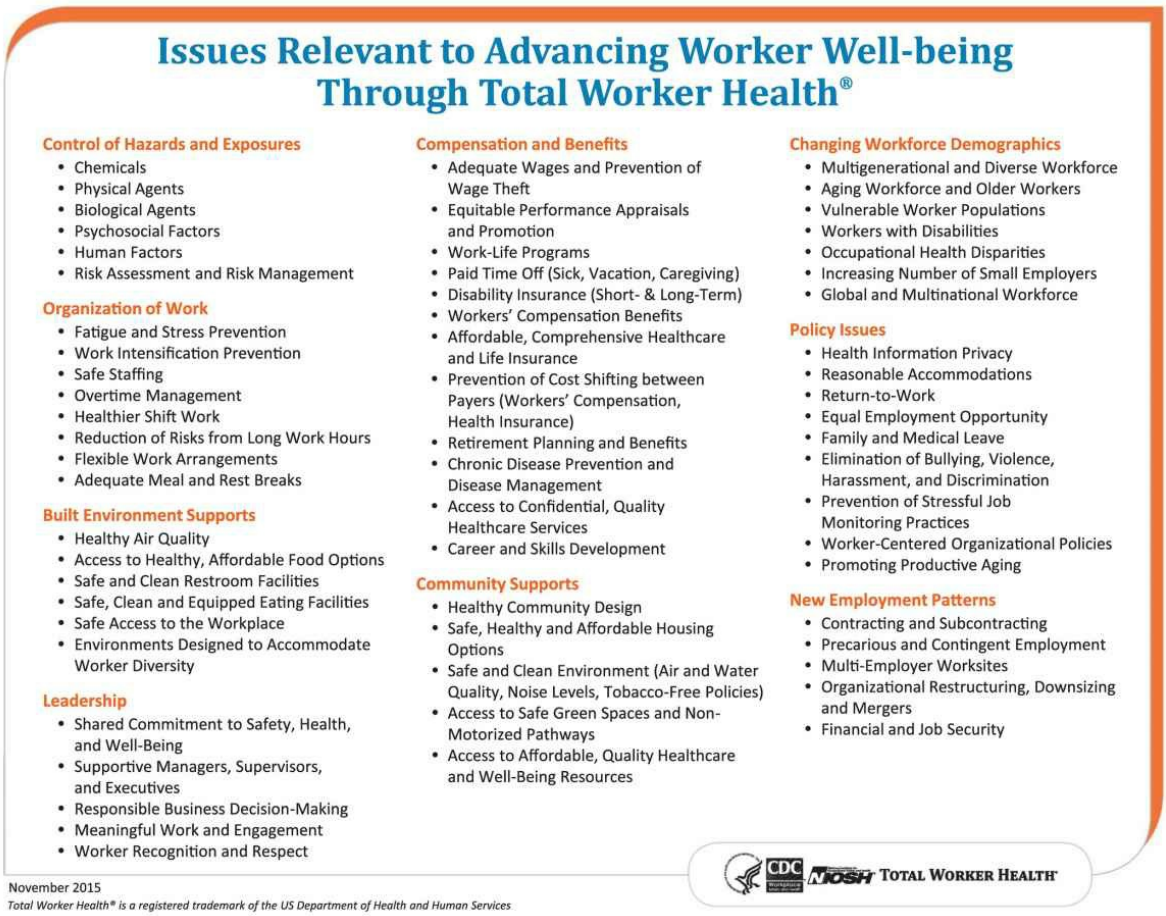

FIGURE 31–2 Relevant issues in Total Worker Health®.

Although OHNs had been advocating healthy lifestyles for several decades, executives of American companies only recently began to recognize the value of having healthy workers. Research supports the link between healthy lifestyle and lower health care costs indicating that healthy employees are less likely to be absent from work and more likely to be more productive when they are at work (Kowlessar, Goetzel, Carls, Tabrizi, & Guindon, 2011; Mattaliano, 2013; Merrill et al., 2013). Integrated approaches that address both physical and mental health have been found to be more effective; integrated approaches that deal with injury prevention, company cost saving, and occupational health and safety have shown less consistent results (Cooklin, Joss, Husser, & Oldenburg, in press). However, getting Americans to embrace a healthy lifestyle of physical activity, good nutrition, and sufficient rest is a challenge.

Because workers spend so much of their life at work (in both hours and years), it is important to develop a culture of health at the workplace. At every encounter with an employee, whether for an occupational health exam or an injury, the nurse has an opportunity to encourage healthy choices. OHNs are learning to become health coaches in an effort to assist individual employees improve their health. Health coaches use a variety of strategies and techniques to motivate individuals to set and attain goals for lifestyle improvements. OHNs partner with communications professionals to craft compelling

messages that encourage healthy choices, and they may provide consultation to upper management in order to help ensure that benefits packages reflect the company's desire for healthful personal practices. Additionally, the OHN is in a position to influence the type of food that is offered in the company's cafeteria as well as the selection of products available in vending machines (Miller, 2011).

The Occupational Health Team

OHNs work in a team environment with a variety of other professionals. Depending on the size of the company, the occupational health team may include a safety specialist, industrial hygienist, ergonomist, industrial or organizational psychologist, toxicologist, physical or occupational therapist, physician, lawyer, and employee assistance counselor. Human resources, management, security, and emergency response personnel are also part of the team. The employee is central to the team and is the reason for the team's existence.

Team collaboration is essential to the success of the occupational and environmental health program, and the OHN has a key role in ensuring adequate and appropriate communication among the members of the team. Establishing working relationships is paramount in the success of a functional and effective team (Draper, Ladou, & Tennenhouse, 2011; Thompson, 2012). Strong interpersonal relationship skills are extremely valuable in a team environment.

Finally, the occupational health team is not complete without the workers themselves. Employees can help identify problems and needs while contributing to decision-making about health programs. Their cooperation in implementing and evaluating programs is essential for an effective health protection and promotion effort.

Settings for Occupational and Environmental Health Nursing

Occupational and environmental health nursing may be one of the most challenging and rewarding nursing specialties, affording nurses the opportunity to establish long-term relationships with their clients and address issues across the wellness–illness continuum. Unlike nursing in acute care settings and public health departments, the employer's primary mission is not typically related to health or illness. Companies exist to make a profit; occupational health and safety professionals are employed to keep workers productive and to ensure compliance with state and federal health and safety requirements (AAOHN, 2012).

Some nurses select occupational health nursing because they are looking for a career change away from acute care nursing. Others find that rotating shifts and working weekends and holidays are not conducive to their desired lifestyle. Still others seek fulfillment through the establishment of more long-term relationships with their clients. On occasion, nurses can move straight into occupational health when they graduate from a BSN program. Nurses who move into occupational and environmental health from an acute care setting should expect a significant learning curve to feel comfortable in this nontraditional setting. Nurses who select the field of occupational health and safety encounter experiences that differ significantly from those found in an acute care setting. To make the adjustment, the nurse should be aware of the factors that make occupational health unique. Unlike hospitals or ambulatory care centers, the workplace is a non–health care institution in which production or service (not health care) is the primary goal. The occupational and environmental health nurse participates in the organization's goals through activities that contribute to the productivity of the workforce. In addition to learning the role of the occupational and environmental health nurse, the nurse needs to understand the parent company and become familiar with the employees' work environment and work tasks (AAOHN, 2012).

In many work settings, the occupational and environmental health nurse is the only health professional. In these situations, the nurse must have excellent assessment skills, not only for individuals but also for the working population served. Independent decision-making is critical. Nurses in occupational settings must also have strong communication skills, including listening, speaking, and writing. Models of practice differ depending on the philosophy and size of the company. Nurse-managed clinics are managed by registered nurses (or advance practice nurses) who employ or contract with other health professionals as needed (Thompson & Wachs, 2012). Nurse-managed clinics may utilize OHNs, a nurse practitioner or physician assistant, a physical therapist, a health educator, and a part-time occupational physician. A single-nurse unit is a common model of practice in many smaller companies. In a single-nurse unit, OHNs typically build strong networks of colleagues with whom they can discuss professional practice issues. Some companies use a medical model of practice, in that a physician determines clinic staffing and the department's approach to clinical practice. During the early 21st century, many companies in the United States began

implementing primary care clinics as a method of controlling the cost of health care. Services in primary care clinics may be extended to dependents and retirees, and they typically offer urgent care services; they may also provide routine health examinations in addition to the usual occupational health services needed by an employer (Guidotti et al., 2013). One cost–benefit analysis of an on-site health clinic at a self-insured university found that it was more cost-effective than were off-site services for upper respiratory infections in full-time employees (McCaskill, Schwartz, Derouin, & Pegram, 2014).

Community-Based Occupational Health Nursing

OHNs work in a variety of settings. The manufacturing sector has a strong tradition of employing OHNs, but utility companies, mines, retail store chains (e.g., grocery, department, home improvement), hospitals, theme parks, banks, school systems, and government also employ OHNs. Because professional nurses have a variety of skill sets, they can care for injuries, manage disabilities, counsel employees who are troubled, help workers control their chronic diseases, and encourage high-level wellness (Burgel & Childre, 2012). Entrepreneurial nurses may set up an occupational health clinic in areas where many small businesses are located (e.g., industrial parks) and provide professional nursing services for employers that may not need a dedicated, full-time nurse (Harber, Alongi, & Su, 2014).

Agencies external to business and industry also provide occupational and environmental health nursing services. Historically, public health nurses from visiting nurse associations made home visits to sick employees and their families. In subsequent years, public health agencies provided part-time nursing services to small companies. These services included supervising the work environment, conducting health examinations, keeping records, disability management, emergency preparedness, teaching about and counseling on health issues, providing first aid, giving immunizations, and referring workers to community resources. More recently, occupational health nursing services have offered health screening and health promotion programs, and one study examining activity logs of a national sample of OHNs found that both management and clinical skills are routinely used and indirect client care is also common (Harber et al., 2014). The majority of the nurse participants were paid directly by their employers. Furthermore, occupational and environmental health nurse consultants based in state departments of health provide consultation and continuing education programs to nurses employed in occupational health settings.

Hospital-based occupational health programs, large medical–industrial health clinics, and insurance companies also provide occupational and environmental health nursing services. These services may be in the form of direct care (e.g., rehabilitation of an injured worker) or indirect care (e.g., consultation on implementing regulations regarding record keeping or compiling health statistics).

A continuing unmet need is attending to the health of workers in smaller companies. These companies tend to have more hazards because equipment and controls are often inadequate. They seldom, if ever, have a health professional on site. Attempts have been made by some communities to provide needed health protection services, but no sustained efforts exist. Community health nurses are in a position to accept this challenge and develop a system that will ensure ongoing service to this high-risk population.

Evidence-Based Practice and Educational Preparation

During the last two decades, a number of nursing education programs (primarily on the graduate level) have developed a specialty focus in occupational and environmental health. In addition, many continuing education programs provide occupational and environmental health nurses with updated information and skill training for identifying and assisting in the management of the physical, chemical, biologic, ergonomic, and psychosocial factors in the work environment that can affect worker health and safety. OHNs are the largest group of health professionals working in occupational health, and quality continuing education and more widespread graduate level educational programs are needed (McCullagh, 2012).

The National Institutes for Occupational Safety and Health (NIOSH), part of the Centers for Disease Control and Prevention (CDC), is an agency established by the Occupational Safety and Health Act of 1970 (Public Law 91-596). NIOSH is responsible for conducting research related to worker health and safety and for educating health and safety professionals to prepare them for evidence-based careers in occupational and environmental health and safety. NIOSH has established 18 university-based Education Resource Centers (ERCs) to fulfill that responsibility (NIOSH, 2015a). Many ERCs provide online courses, and scholarships are available.

Additionally, OHNs may become certified in this specialty field. The American Board for Occupational Health Nurses (ABOHN) is an independent nursing specialty certification board. Founded in 1972, ABOHN is an independent not-for-profit organization that sets professional standards and conducts occupational health nursing specialty certification. ABOHN is the sole certifying body for OHNs in the United States (ABOHN, 2014). This independent nursing specialty board has the stated purposes of (1) establishing standards and examinations for professional nurses in occupational health, (2) elevating and maintaining the quality of occupational health nursing services, (3) stimulating the development of improved educational standards and programs in the field of occupational health nursing, and (4) encouraging OHNs to continue their professional education (ABOHN, 2014).

The Effect of Work on Health

Workers in the United States generally spend more time at work than on any other activity except sleep. Thus, the work environment can have a significant impact on workers' health. Work can contribute to the well-being of employees, provided that they have good, supportive supervision (Modini et al., in press). However, the type of work that people engage in dictates the hazards they encounter. For instance, think about the work of hospital-based nurses. They encounter physical hazards, such as lifting patients in bed without mechanical lifting devices. There are biological hazards associated with blood and body fluids, as well as infectious diseases. Some nurses are at risk for chemical exposures, such as those associated with operating room gases or chemotherapy. Radiation hazards may exist when working with patients undergoing radiation therapy.

Hazardous substances can get into a person's body through inhalation, ingestion, or absorption or percutaneously. Although personal protective equipment (PPE) is available to workers, some may not use PPE consistently, or the equipment may not be entirely effective. Workers exposed to chemicals may not wash their hands sufficiently before eating or smoking, thus providing an opportunity for chemicals to get into their system through ingestion or inhalation.

Employees who work in awkward positions or who do repetitive tasks that use the same muscle groups are at risk for musculoskeletal disorders (MSDs). Stressing muscles and joints repeatedly can result in inflammation and pain and can lead to serious conditions that require physical therapy and/or surgery. Carpel tunnel syndrome is often associated with repetitive movements, like typing at a computer keyboard. Hegmann et al. (2016) conducted a large prospective cohort study to look at the relationship between carpel tunnel syndrome (or abnormal nerve conduction) prevalence and cardiovascular disease risk factors. They found that there was a strong significant relationship with odds ratios between 4.16 and 7.35 (for carpel tunnel and abnormal nerve conduction, respectively). It may be important to examine cardiovascular disease risk factors more closely among those employees with signs of nerve conduction problems.

Employees who compound a workplace exposure with off-work activities that use the same muscle groups in similar actions will accelerate or aggravate a problem. For instance, a mechanic may work on his own car in the evenings and on the weekend, so the muscles that are used every day never really get a chance to rest and recover. A research study examining the prevalence of musculoskeletal disorders (MSDs) among office workers found the highest number of MSDs noted in lower back (almost 50%) and neck (49%) areas (Piranveyseh et al., 2016). Researchers also looked at organizational factors, along with psychosocial and individual factors, and found that they were significantly associated with prevalence of MSDs.

Repeated exposure to loud noise can result in a high-frequency hearing loss (Council for Accreditation in Occupational Hearing Conservation, 2012; Kirchner et al., 2012). Such hearing losses are gradual; employees may not heed advice to wear hearing protection devices, which they may consider uncomfortable or annoying. High-frequency hearing loss diminishes an individual's ability to understand what others are saying, especially in a noisy environment such as a restaurant. Research shows that hearing losses can result in social isolation with resulting depression among the elderly (Ciorba, Bianchini, Pelucchi, & Pastore, 2012; Dawes et al., 2015; Mick, Kawachi, & Lin, 2014). A systematic review of research has demonstrated that repeated occupational exposure to loud noise is associated with increased levels of hypertension, and a smaller effect for noise and cardiovascular disease mortality was also noted (Skogstad et al., 2016).

Shift work, particularly rotating shift work, negatively impacts sleep and rest cycles (Takahashi, 2012). Insufficient sleep is associated with obesity and diabetes (Nakanishi-Minami, Kishida, Funahashi, & Shimomura, 2012). Low-paying jobs may drive workers to get a second or even a third job to make ends meet. Personal stressors or balancing work

and family demands, plus employer expectations at work, can have an adverse effect on worker health (see from the Case Files IV). A systematic review of research on workplace mental health interventions found moderate evidence for effectiveness of these programs and their outcomes. Programs that included both physical and mental health interventions and multicomponent interventions had greater evidence of support (Wagner et al., 2016). Also, education to reduce the stigma associated with mental illness has also been shown to be effective in improving worker knowledge and promoting more supportive behavior toward peers with mental health issues (Hanisch et al., 2016).

From the Case Files IV

The human resources director approaches the occupational health nurse regarding a situation he learned about from a manager in building 2. The manager reported that an employee has been acting out during the last 2 weeks, shouting at other employees. Additionally, the employee's work product has not met quality standards on several occasions during the same time period. Another employee told the manager that she heard the employee say that he was "fed up with everyone" and was going to "put an end to it."

1. What should the occupational health nurse do?
2. Who on the team should be involved with this situation?
3. What preventive measures could be put into place as part of the team's structure to be prepared to respond to situations like this?
4. What could you suggest as a primary intervention for these types of concerns?

Healthy People 2020

Occupational safety and health objectives are included in *Healthy People 2020*. The goal is to promote the health and safety of the U.S. workforce through prevention and early intervention. The intent of the 10 main objectives and eight sub-objectives is to prevent diseases, injuries, and deaths because of working conditions (USDHHS, Office of Disease Prevention and Health Promotion, 2016b). The occupational and environmental health nurse plays a crucial role in assisting businesses and employees to meet *Healthy People 2020* occupational safety and health objectives. See Display 31–10 *Healthy People 2020* Occupational Health and Safety Objectives.

DISPLAY 31.10 *HEALTHY PEOPLE 2020* OCCUPATIONAL HEALTH AND SAFETY OBJECTIVES

OSH-1	Reduce deaths from work-related injuries.
OSH-1.1	Reduce deaths from work-related injuries in all industries.
OSH-1.2	Reduce deaths from work-related injuries in mining.
OSH-1.3	Reduce deaths from work-related injuries in construction.
OSH-1.4	Reduce deaths from work-related injuries in transportation/warehousing.
OSH-1.5	Reduce deaths from work-related injuries in agriculture, forestry, and fishing.
OSH-2	Reduce nonfatal work-related injuries.
OSH-2.1	Reduce work-related injuries in private sector industries resulting in medical treatment, lost time from work, or restricted work activity, as reported by employers.
OSH-2.2	Reduce work-related injuries treated in emergency departments (EDs).
OSH-2.3	Reduce work-related injuries among adolescent workers (15–19 yrs.).
OSH-3	Reduce the rate of injury and illness cases involving days away from work due to overexertion or repetitive motion.
OSH-4	Reduce pneumoconiosis deaths.
OSH-5	Reduce deaths from work-related homicides.
OSH-6	Reduce work-related assaults.
OSH-7	Reduce the proportion of persons who have elevated blood lead concentrations from work exposures.
OSH-8	Reduce occupational-related skin diseases/disorders among FT workers.
OSH-9	Increase the proportion of employees who have access to workplace programs that prevent or reduce employee stress.
OSH-10	Reduce new cases of work-related, noise-induced hearing loss.

Future Trends

The broad goal for occupational health professionals is to promote and maintain the highest level of physical, social, and emotional health for all workers. Occupational health and environmental nurses play a crucial role in making positive strides toward this goal by embracing evidence-based research and best practices. Presently, there is room for improvement toward fully realizing this goal. Productive working communities can be attained by the work of collaborative public health partnerships, private industry, occupational health professionals, government, establishments of higher learning, and the workforce joining together. Changes in U.S. businesses practices and the economic challenges experienced by workers over the last decade have required occupational and environmental health nursing practice to evolve. Downward economic trends, America's increasingly complex health care system, and health care reform will shape the future of occupational health nursing. *The Future of Nursing: Leading Change, Advancing Health* provides a comprehensive report focusing on future nursing practice and health care needs in the United States (IOM, 2011). The report notes three significant factors that will likely impact the future practice of OHNs:

1. Health care reform will significantly influence health care needs.
2. Meeting the increasing health care demand will require that nurses are allowed to practice to the full extent of their scope of practice.
3. Well-prepared nurses will need additional education and training to meet the demand for complexity and increasing volume.

Current occupational and environmental health nurse practice will continue to evolve to meet future needs. The focus is shifting from one-on-one health services to involving broader environmental, business, and research skills. The ACA has a focus on preventive care, and typically, a large portion of wellness activities are provided by RNs. Increases are projected in outpatient-focused care, and emerging models of care, such as the Primary Care Medical Home, are anticipated to influence the delivery of occupational health services. Occupational and environmental health nursing professionals will need extensive education in the areas of community health, social and psychological services, and general management in order to be successful (Spetz, 2014).

Educational training of OHNs has progressed in recent years. The need for nurses with advanced degrees will continue to grow to meet future demands (McCullagh, 2012). New strategies to expand funding, continuing education, certification, and educational opportunities to prepare the next generation of occupational health and environmental nurses remain a top priority. There are a wide range of skills and knowledge required to effectively provide comprehensive workplace wellness programs.

Standard OHN activities include the following:

1. Supervising care for emergencies and minor illnesses
2. Counseling employees about health risks
3. Following up with employees' workers' compensation claims
4. Performing periodic health assessments
5. Evaluating the health status of employees returning to work

EMERGING OCCUPATIONAL HEALTH NURSE ACTIVITIES INCLUDE THE FOLLOWING:

1. Analyzing trends (health promotion, risk reduction, and health expenditures)
2. Developing programs suited to corporate needs
3. Recommending more efficient and cost-effective in-house health services
4. Determining cost-effective alternatives to health programs and services
5. Collaborating with others to identify problems and propose solutions

As we move further into the 21st century, occupational and environmental health nurses and management will share the goal of developing a healthy, productive, and profitable workplace. A healthy workplace consists of healthy and productive employees, and healthy employees mean lower health care costs. Lower costs result in an increased competitive edge and higher profits. Higher profits can make more resources available to support more programs and to improve employee health.

The occupational and environmental health nurse will particularly need skills in effective communication, leadership, change management, research, business acumen, and assertiveness. These tools will be crucial for effectively interpreting the OHN's role and promoting ideas. Success of programs developed by the OHN depends on establishment of positive working relationships with the other team members. Nurses involved in occupational health have a unique opportunity to help shape the health profile of the working population. An example of this type of effort was described in an article by Demko and Martin (2014), discussing the impact of mental health issues in the workplace. The OHN plays a significant role partnering with the employer and advocating on behalf of the employee. Early identification, coordinating treatment, possible absence from the workplace, and case management can all impact the employee's successful return to work. Occupational and environmental health nursing demands a great deal from the nurse. Individual needs in the workplace always compete for the nurse's time and take attention away from aggregate needs, often to the detriment of the latter. To maintain a proper focus on aggregate needs requires discipline and commitment—commitment based on a different mind-set and the realization that the health and productivity of workers are interrelated with the health of the community. The degree of the occupational nurse's influence depends on how the nurse defines the occupational and environmental health nurse role. Also, the nurse must be able to overcome the many obstacles found in the occupational setting, including restrictive company policies, misunderstanding of the nurse's role, and lack of time for innovative program development. The nurse's role in occupational health, therefore, varies considerably. It ranges from providing only emergency care for on-the-job injuries or illness to establishing comprehensive policies and programs covering health

promotion, accident and disease prevention, and innovative care for disease and disability (Guzik, 2013).

NURSE ENTREPRENEUR IN COMMUNITY/PUBLIC HEALTH NURSING

As you have discovered throughout this chapter, the roles and responsibilities of nurses in the community often require skill with grant writing, agency and personnel management, collaboration both inter- and intraprofessionally, fiscal management, and agency promotion. The community/public health nurse often works within an agency or organization to address unmet needs in the community with the ultimate goal of enhancing service delivery. This is true for an FCN, a nurse in an NLHC, or an OHN. These positions are often nonexistent until the nurse is able to identify a need and take the necessary steps to start a stand-alone service or to develop a role within an existing agency. There is, however, a growing trend in nursing to seek a more independent practice in health care delivery and services through entrepreneurship. In 1986, Susan Hartley of the ANA posted a letter to the editor in the *American Journal of Public Health* requesting information on nurse entrepreneurs with the stated goal of "developing a list of nurse entrepreneurs as part of a continuing effort to describe the delivery of nursing services" and to "gather data and resource people to support lobbying efforts to achieve payment systems for nursing" (p. 1034). This brief request punctuates the growing recognition of the varied roles that nurses have and the impact of reimbursement on service delivery. As you think about your own career, can you envision yourself running a health care business, seeking a small business loan to start a venture, or having the courage to explore other professional options? Independent practice is not for everyone, and nurses are often socialized to view their role as working within a larger organization, a health department, a community clinic, and most often a hospital. At some point in your career, you may find yourself working with a nurse entrepreneur or becoming one yourself. The following discussion will give you a glimpse at the challenges and rewards of this journey.

Merriam-Webster (2015) defines an entrepreneur as "one who organizes, manages, and assumes the risks of a business or enterprise" (para. 1). By extension, an entrepreneurial nurse is one who is willing to take on that role within a health care or social context. Common examples of nurse entrepreneurs include legal consultants, forensic nurses, home health care agency owners, authors, and nurse consultants in a variety of areas. The National Nurses in Business Association (n.d.) offers membership and resources for those entrepreneurial nurses who are self-employed or small business owners. For the community/public health nurse, these and many other options offer the independence to provide services in perhaps a new and innovative way. For health care to continue to respond to the changing environment, the innovators are often the ones who have the courage to test those new methods. They may fail or fall short in those efforts, but they learn from both the success and challenges and are better positioned for a successful outcome.

Steps to Becoming a Nurse Entrepreneur

One of the first steps to becoming a nurse entrepreneur is to have an idea. It doesn't have to be a new idea or even a "big" idea, but it must address an unmet need within a community. Community/public health nurses are often the first to identify the challenges and needs within a community and to explore solutions. Very often, participation in professional organizations helps to identify health care issues that can be addressed by nurses. The common refrain—"why doesn't someone just (invent, build, provide, etc.)?"—can often be answered by a nurse. Nurses are problem solvers, and using the nursing process, they assess the situation, identify the problem, determine a course of action, and evaluate the results. This nursing skill can be leveraged for entrepreneurship (e.g., to start a new business venture, to develop a nonprofit agency, or to create educational tools for use by other health care professionals or the general public). Whatever the health care need, nurses can and do find the solutions. This was highlighted in a structured ethnographic study of nurse entrepreneurs in Canada (Wall, 2014). The study took place during a time of significant change and restructuring in Canada's health care system to reduce costs, and the participants chose to leave the system rather than remain in a "dysfunctional, demeaning, abusive, excessively demanding" situation (p. 516). Even though the nurses were engaged in a wide variety of activities (e.g., diabetic outreach business, alternative health care specialist, laser hair removal, occupational health nursing, corporate wellness consultant, project management, wound care specialist, health counseling), they had similar characteristics in common. They were different from other nurses in their quest for challenging experiences and need for change, as well as their tolerance for risk. They often thought "outside the box" and questioned routine hospital practices and procedures. The common strategies they used to effect their transformation into entrepreneurs included the following:

- Capitalizing on the enterprise culture (taking advantage of the instability of the system and increased market focus of Canadians)
- Used self-employment to re-establish services (some of their new businesses filled gaps in service caused by restructuring and reform, like diabetic foot care)
- Using entrepreneurship to broad the meaning of health care (they focused on caring and had a vision that extended beyond the hospital, like a corporate wellness business)
- Expanding professional jurisdiction (being self-employed nurses in Canada requires significant paperwork and oversight and many had to defend their scope of practice and jurisdiction)
- Preparing themselves for a preferred future (they used formal and informal methods to expand their education and training in preparation for their nontraditional roles)
- Reclaiming health services for nursing (project managers offered both business and nursing skills as opposed to solely nonnursing business degrees in administrative roles; diabetic foot care by RNs rather than currently employed lower paid, less

skilled workers)

- Expanding the territory of nursing (laser hair removal was often done by dermatologists or estheticians; foot care could be provided by podiatrists)
- Building on the familiar (even though they were breaking new ground, they all relied on their nursing knowledge base and referred to professional standards and guidelines)
- Applying transferable nursing knowledge to new work (they used the nursing process to guide them in their various endeavors, such as holistic care plans, developing consulting guidelines; they used nursing's "people skills" like active listening and motivational interviewing in work with clients)
- Attending to professional standards (they used professional standards as a basis for developing policies and procedures in their new areas of nursing practice; they practiced within the guidelines of nursing's ethical principles; they sought out evidence-based research to guide their practices) (Wall, 2014, p. 517–521)

Even though they were excited with their new opportunities, they noted consequences (e.g., resistance from the public/other health care providers, regulatory issues/oversight). Some of them still consulted with large hospital systems and health care organizations, and hoped to influence change within those systems. Others found "a niche in the system" and responded to the needs of their consumers (p. 525). All of them sought to move beyond "profit-motivated and opportunistic" viewpoints of entrepreneurship and incorporate professionalism into their independent ventures (p. 526).

A past president of the NNBA, Patricia Bemis, offers a number of suggestions in the development of a business plan (2006). This plan is essential to starting a business, growing a business, and obtaining financial support. At the very minimum, the business plan should include the description of the business; marketing strategies; competitive analysis, design, and development plan; operations and management plan; and financial factors. Bemis also emphasizes the need for choosing a name and marketing format for promotional materials. She cautions that the "name of your business is not about creativity but is an integral component of your marketing strategy" (p. 1). The name should be easily spelled and pronounced, elicit a positive emotional response from the customer, and be short and to the point (see Display 31–11).

DISPLAY 31.11 QUESTIONS TO CONSIDER: NURSE ENTREPRENEURSHIP

1. What are your goals (personal, business)? Do you have the determination and drive to succeed in business? Do you have the means to finance a business? Did you know that the average cost to start up a business is about $30,000 (Beesley, 2015)? What are your assets and potential monthly expenses, as well as your capital expenditures (e.g., property, vehicles, equipment)?
2. What are you interested in doing? Is there a market for this? Who is your target population? What industry trends may influence your success or failure? Who are your competitors?
3. Do you know someone with a successful business that can mentor you in this endeavor? Do you have friends and family who may be able to assist you at low or no cost (e.g., Web site design, business card design, accountant, attorney, business experts)?
4. Have you investigated the benefits of your local Chamber of Commerce, information/loan availability from the federal Small Business Administration (SBA), and any state or foundation grants/loans that may be available?
5. Do you know how to develop a business plan? Have you considered the type of business structure you may need (e.g., sole proprietorship, corporation)?
6. Have you thought of a name for your business? How will you design your logo? What type of Web site design will you need? How will you decide on your business card and letterhead design? What types of brochures will you need?
7. How will you reach your target population (e.g., e-mails, Facebook, local advertising)?

Opportunities

As the health care needs of the population demand newer, better, and less expensive solutions, nurse entrepreneurs are well positioned to address those needs. While there are many examples in your own communities of nurse entrepreneurship, the role of the community/public health nurse can serve as a strong base for meeting the health care challenges locally, nationally, and internationally. One example of a nurse entrepreneur is Nancy Dirubbo, a family nurse practitioner who first opened a New Hampshire women's health center in 1985. She offered patient-centered care and a patient-friendly environment that was designed with feedback from her patients. Always interested in new things, Dirubbo began investigating travel health and obtained certification in this specialty from the International Society of Travel Medicine. She also completed a DNP and decided to transition from the clinic to a new direct pay practice for those clients needing travel health services. Government programs and most private insurance companies do not cover travel health immunizations and visits. She began offering part-time services in the same building as her clinic, and developed clientele through word of mouth. She is actively engaged in CDC and WHO LISTSERVS and has not needed to advertise widely. She has a Web site (http://travelhealthnh.com), and is certified as a yellow fever center by the CDC. She planned for 3 to 5 years as a start-up period for her new business, and she offers comprehensive visits with patients, along with evidence-based education and immunizations. She discusses food safety and potential areas for risk and gives patients a take-home booklet with detailed information about their destination and the education/immunizations she provided during their visit (Clayton, 2015). See Perspectives: Nurse Entrepreneur.

PERSPECTIVES NURSE ENTREPRENEUR

As a newly graduated nurse practitioner, I was excited to step into the role in a small family practice clinic. I worked alongside a family physician who owned the clinic. The two of us worked together to establish office policies and procedures and to provide the best care for our patients. We took pride in the product we delivered because we made decisions that directly impacted patient care.

A few years later, a corporation bought out that small family practice clinic. This corporation had previously been a specialty clinic, but was expanding to include family practice clinics. Upon the sale of the clinic, the administrative decisions were made by

people not only unfamiliar with our patients but unfamiliar with family medicine. They determined how many patients I should see, how long I should spend with each patient, and the services I should or should not provide. Nameless faces on the other end of phone trees addressed my patients' concerns, as the corporation centralized the call centers under the direction of corporate management.

I became frustrated with the dictates of others and the negative impact it had on my patients. This frustration led to my desire to make a change. I could not change the entire system, nor could I change medical staff, administrators, or the corporation. But, I could change my reality and sphere of influence and in turn help the individual patient. In seeking change, I looked to fill a need. I looked to find my niche.

My first entrepreneurial experience came when an owner of a manufacturing plant approached me about creating and running an on-site clinic for his employees. Together, the company owner and I talked about our vision of the clinic. I created a model where I could run the clinic by myself, with one medical assistant. Care was free to employees, and insurance companies were not involved. The owner of the manufacturing plant paid the overhead. This was a model unlike any other on-site medical clinic in the area.

A few years after starting the on-site clinic, I saw the lack of access my patients had to mental health care in my state. Again, I could not fix the entire problem or the broken system, but I could change my sphere of influence. There was a serious shortage of psychiatrists to manage psych meds, so I started a mental health clinic to provide better access to those in my community. This clinic, run by family practice nurse practitioners, provides medication management and psychotherapy to those without access to psychiatry. I rent space to psychologists who provide counseling, and I work with two other experienced NPs to manage medications and make referrals.

Both clinics I own and run are not traditional health care models. I became a nurse practitioner to help others and make a difference in the world. In order to truly make a difference, I assessed the needs in my community and did what I could to fill the gaps.

Kelly Wosnik, DNP, NP-C

Can you think of something that may frustrate you and see where you might provide a much-needed service, like this nurse entrepreneur?

Although the previous example seems unique, we are reminded that early nurses were often self-employed entrepreneurs. Whelan (2012) examined the history of private duty nursing in the United States and noted that most nurses in the early part of the 20th century were independent contractors serving private pay patients in their homes. At that time, hospital-based schools of nursing were most common, and hospitals took advantage of the free labor provided by student nurses who spent most of their time at the hospital. They rarely hired new graduates from these programs, so these new graduates had to find other means of making a living. They sought out patients in need of nursing services and provided this in patients' homes. At this time, most people wanted to be cared for at home and very few used hospitals. Private duty nurses lived in patient homes, working 24/7 until the illness was resolved or the patient died. In order to simplify this process, some enterprising nurses organized an infrastructure of private duty registries. Nurses and patients/families or physicians would contact the agencies (like an employment service), and connections were made for nursing services. The nurses paid a fee to the agency, and the family paid the nurse directly. In some instances, registries were able to place nurses in hospitals to care for patients or to fill an open position there. A few of them also offered sick room supplies and provided special diets. Most registries were nurse-run and nurse-owned, but some were affiliated with hospitals and professional nursing organizations. In 1915, an ANA committee located 40 central registries; in 1924, 75 registries were located (Whelan, 2012). New York City and Chicago had very large central registries. The New York registry closed during the Depression, and the Chicago registry, with innovative leadership and programs, remained open until 1980. By 1949, private duty nurses constituted only about 20% of the total U.S. nurse population. However, even today, hospitals rely on short-term, traveling nurses from various agencies, much like the per diem nurses during the middle decades of the 20th century to fill critical vacancies in acute care settings.

Gilliss (2011) notes that social entrepreneurship works toward good health outcomes for all, without necessarily a profit motive, and that it brings us back to our nursing roots (e.g., Lillian Wald, Florence Nightingale). With health care reform, social entrepreneurship, as well as opportunities to implement innovative programs within public health and other agencies—"intrapreneurship"—can also flourish (Wilson et al., 2012). What is needed are nurses who enjoy a challenge and are willing to take risks in order to provide needed services and improve patient outcomes.

The opportunities are limitless for nurse entrepreneurship; the only missing piece is the nurse willing to take that leap, come up with an idea, explore the options, create a business plan, garner funding, and make a difference. Community/public health nurses are uniquely qualified to address the ever-growing challenges in our communities. As opportunities in one area of nursing practice recede, other avenues open up; the trick is to recognize those opportunities when they present.

SUMMARY

Healthy People 2020 document guides both public and private sector nursing practice well into the next decade. Community health nurses have a number of options available to them as they seek to address the myriad health issues facing our communities. For many, opportunities may present to assume roles in a variety of nontraditional settings, including NLHCs, faith community nursing, occupational and environmental health nursing, and nurse entrepreneurship. All four roles offer the community health nurse the opportunity to address health disparities in their communities, promote healthy lifestyles, and improve the overall health and well-being of their respective populations.

NLHCs represent a growing movement of health centers that have emerged as vital safety-net providers in America's contemporary health care delivery system. Various nursing center models exist and are located in MUA in urban and rural communities. Interdisciplinary teams of advanced practice nurses, social workers, substance abuse counselors, community health outreach workers, and students from varied disciplines provide services that generally focus on primary and secondary prevention strategies. Lundeen's Comprehensive Community-Based Primary Health Care Model demonstrates how NLHCs are distinct from public health agencies and medical care facilities. Funding sources for NLHCs include reimbursement from various organizations, sliding scale fees, grants, contracts, foundation support, and private support via gifts. Sustainability is an ongoing challenge in all NLHC models. An international organization to strengthen the capacity, growth, and development of NLHCs is the NNCC. NLHCs identify, develop, and share best practices. Nurse leaders and staff from NLHCs engage in sociopolitical activities to raise awareness of the outcomes generated by the nursing center model. These activities are implemented to raise awareness of the role of NLHCs in the health care system and to promote sustainability of the centers. Undergraduate and graduate students from various disciplines engage in all aspects of NLHC activities and augment the interdisciplinary team.

FCNs practice community nursing within a unique setting—a faith community. An FCN may provide services to a single faith community or may coordinate services for multiple communities. The FCN addresses the physical, social, emotional, mental, and spiritual needs of the faith community through the roles of health educator, health counselor, referral agent, advocate, developer of support groups, coordinator of volunteers, and integrator of faith and health.

Occupational and environmental health nursing applies the philosophy and skills of nursing, community, and environmental health to protect and promote the health of people in their workplaces. The occupational and environmental health nurse's role is evolving as business becomes more competitive and health care reform has been implemented. That expanded role will include analyzing current trends, recommending more cost-effective and innovative in-house health services, and collaborating with other

members of the multidisciplinary occupational health team, including management, to develop appropriate programs. Occupational and environmental health nurses help companies remain competitive by promoting health and well-being in worker populations.

The nurse entrepreneur is not a new concept. Nurses have traditionally worked in private duty, as well as within existing agencies (hospitals, clinics, or health departments), yet many have sought the autonomy of providing health-related services independently, by starting a new business venture. As community/public health nurses gain experience and confidence in starting and developing health care programs, those same skills can be utilized to identify unmet community needs, develop a business plan, seek funding sources, and start an independent business. The FCN may market his services to a number of small faith communities, an NLHC may, in addition to providing grant-based services, begin marketing services to employees of local businesses, the OHN may recognize a growing need for health education materials that could be purchased by other industries, or the nurse may leverage their specially area skills to publish educational materials or start a nonprofit agency to meet community needs. The opportunities for nurse entrepreneurship are a growing and much needed area for community/public health nurses to explore.

Each of these professional practice areas provides a unique opportunity for community health nursing practice. Escalating health care costs, increasing numbers of uninsured and underinsured, and the many gaps in services experienced by so many in our communities present an unprecedented opportunity for community health nurses. The many unmet needs in our communities can be addressed but only if there are nurses willing to take the "road less traveled" as did Lillian Wald and the other pioneers of nursing. As you ponder your options for practice, consider the challenges and the many benefits of these and the many other practice areas in your community. Perhaps you cannot envision yourself in this type of service at this point in your career. A time may come, however, when you are afforded the chance to participate in your own faith community health education efforts—or refer a client to a NLHC—or possibly collaborate with an occupational and environmental health nurse to address an emerging health issue in your community. You may even find that starting your own business or nonprofit agency affords you the independence and challenge you seek in your career.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. You are practicing as a newly hired nurse in an NLHC. What assessments would you conduct to determine the needs for the local community that surrounds the clinic? What sources of data (qualitative and quantitative) would be useful to you during your assessment?
2. Based upon your findings in the previous question, what public policy issues are apparent in this community? How could you, as a nurse working in this NLHC, impact public policy in the future? What key legislators would you contact? How would you accomplish this?
3. Locate an NLHC in your community. Interview a public health nurse or a nurse practitioner employed there. Ask the nurse to describe the type of NLHC model he/she works in. Ask the nurse about *Best Practices* performed in his/her role. If you cannot locate an NLHC in your local community, search online via the National Nursing Centers Consortium's Web site, and e-mail the nurse listed as the contact person and ask him/her the questions found above. Alternately, you may want to search for an FQHC.
4. This chapter covers the role of the parish or faith community nurse (FCN). Search for information about this area of community health nursing in your community. Do you know an FCN? If so, plan to observe his or her practice for a few hours and explore what the role entails in this faith community.
5. Contact an FCN in your area and arrange to interview or shadow the nurse. Explore the services offered by FCNs in your area. Identify the knowledge and skills needed to function effectively in the role. Discuss the process the nurse used to establish his or her FCN practice. Determine if there is a local or regional professional association for FCNs in your area.
6. Conduct a literature search to discover health programs that have been developed and used by faith communities to address the leading health indicators identified in *Healthy People 2020*. What leading indicators have the most evidence of effective health programs? Which indicators have the least evidence of effective health programs? Evaluate which health program could be adapted for use in your community.
7. This chapter covers the role of the occupational and environmental health nurse. Search for information about this specialty area of nursing in your community. Do you know an occupational health nurse? If so, plan to observe his or her practice for a few hours and explore what the role entails in this organization.
8. Think about workers whom you see every day (grocery store checkers, hairdressers, firefighters, landscapers, utility linemen, etc.). What hazards are they exposed to? What are the potential health problems that they may have due to their work? What

primary prevention efforts would be suitable for those workers?

9. Select an employer close to where you live or go to school. The employer may be a municipal government, a school system, or a for-profit company. If you were to provide occupational health nursing services to the workers of that employer, what information would be important to obtain before providing services? How would you obtain that information? How would you identify risks to that population? What other health care or other professionals would you include in your team approach to health care at this site?
10. Think about your clinical experiences in community/public health nursing. Are their unmet needs in the community that could be addressed through a nurse-led business? What elements would you include in a business plan? Write a one-paragraph statement that you could present in obtaining a small business loan. Locate a nurse entrepreneur and discuss the challenges they met in starting their business; how were those addressed?

32 CHAPTER

Clients Receiving Home Health and Hospice Care

"People from all walks of life agree that someone who is sick deserves, in principle, compassion and care."
—*Paul Farmer*, American anthropologist and physician

KEY TERMS

Centers for Medicare and Medicaid Services (CMS)
Community-based long-term care
Compassion fatigue
Home health care
Homebound
Hospice
Medicaid
Medicare home health benefit
Medicare hospice benefit
Medicare prospective payment system
OASIS (Outcome and Assessment Information Set)
Palliative interventions
Potentially inappropriate medications
Visiting Nurse Associations

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Summarize the history and contemporary circumstances of home health and hospice care.
- Describe Medicare standards for home health and hospice programs.
- Explain family caregiver burdens of providing home care.
- Explain how Medicare reimburses home health and hospice care.
- Describe essential characteristics of home health and hospice nursing practice.
- Identify unique challenges of infection control, medication management, fall prevention, use of technology, and nurse safety during home visits.
- Contrast the goals of home health care and hospice.
- Explain the gaps in home health care and hospice and the need for a coherent community-based long-term care program in the United States.

A home health nurse sits in an upscale condominium with a frail, elderly gentleman tethered to his home oxygen unit and suffering air hunger as he struggles to speak of the "good old days" when he was young, full of vigor, and taking on the world.

During her next visit to a trailer park, she inspects an infected pressure sore that has become smaller and cleaner with each home visit, as the client's wife carefully follows through with wound care teaching. Next, she monitors the pulmonary and cardiac status of a patient newly discharged to his aging bungalow, detecting early signs of cardiac decompensation and treating them at home in close collaboration with his physician. At that same time, her hospice nurse colleague walks into family chaos with a mother in pain and vomiting at the end of her life and then leaves with everyone calm and the patient comfortable. These are the kinds of experiences that make up the daily lives of nurses who work with home care and hospice clients. Indeed, home health and hospice programs allow nurses to practice what some see as the very heart of compassionate and highly skilled nursing care. Home health care and hospice programs are expanding and are the work settings for more and more nurses. Almost 4% of RNs work in home health care settings (National Center for Nursing Workforce Analysis, 2013).

Home health care is discussed in the first section of this chapter, followed by an overview of hospice care. The reader is also referred to the discussions in Chapter 19 on working with families, Chapter 20 on violence in families, Chapter 24 on care of the older adult, and Chapter 26 on chronic illness.

OVERVIEW OF HOME HEALTH CARE

Historically, patients have been cared for in their homes by family members. In the first part of the 19th century, home care was preferred over hospital care. During the later part of the 19th century, private duty nursing was common, and Visiting Nurse Associations were established in many American cities (Buhler-Wilkerson, 2016). The need for health care at home continues to accelerate. Drastic changes in financing and more people living with complex illness have contributed to this trend. For example, early hospital discharges resulting from third-party payers' efforts toward cost containment have forced clients to return home quickly to recuperate from surgeries and severe illnesses. Likewise, a growing population survives and yet suffers from complex chronic and life-threatening illness that they struggle to manage at home. Advanced technologies such as telehealth monitoring, point of care devices, intravenous (IV) antibiotics, chemotherapy, total parenteral nutrition (TPN), dialysis, and mechanical ventilation are routinely provided and maintained in the client's home. As the population ages, and particularly now that the baby boomer generation is entering their elder years, home health nursing is challenged to respond. Professional home health care agencies seek to maximize the client's level of independence and to minimize the effects of existing disabilities through noninstitutional services. Professional home health services aim to decrease rehospitalization rates and prevent or delay institutionalization (National Association for Home Care and Hospice [NAHC], 2010). The NAHC Web site provides a variety of direct services to members, including the publication *Caring* and monthly newsletters.

This section explores the evolution of home health care in the United States; describes home health agencies, clients, and personnel; and examines Medicare criteria and documentation. Finally, the unique characteristics of home health nursing are explored.

HISTORY AND POLITICS OF HOME HEALTH

Throughout human history, family members have provided health care at home. In the United States, the earliest known organized effort to care for the sick poor at home was made by the Ladies Benevolent Society in Charleston, South Carolina, in 1813 (Buhler-Wilkerson, 2007). Later in the 19th century, it became possible for women to become nurses trained in the manner of Florence Nightingale, and wealthy women began to hire them as visiting nurses and to sponsor visiting nurse services. In 1893, Lillian Wald began home visiting in New York City and is famed for professionalizing visiting nursing. One of her most famous collaborations was with insurance companies for payment of home care services. When she retired in 1933, the staff of 265 visiting nurses saw more than 100,000 clients and made over 550,000 home visits (Visiting Nurse Service of New York, 2016). Between 1909 and 1952, 100 million home visits were made to the policyholders of Metropolitan Life Insurance Company. Then, as now, the need for cost containment and therefore quick discharge were in diametric opposition to nursing goals of providing needed care at the patient's side as long as needed (Buhler-Wilkerson, 2016).

In the 20th century, insurance companies began to see the benefit of providing care in homes, rather than hospitals. When Medicare went into effect in the 1960s, less expensive alternatives to hospital care were sought. Private home health agencies evolved from the demand to provide care for the chronically ill client in their home. In the later half of the 20th century, as hospitals became increasingly effective in providing acute care, more people survived to live with debilitating chronic illness and disability, and referral to home care was used to discharge those nonacute patients from the hospital. Payment for home health care visits via Medicare and health insurances has allowed the individuals to rehabilitate at home, and that has proven to increase patient satisfaction and therefore promote positive outcomes while being cost-effective (Buhler-Wilkerson, 2016).

The Medicare home health benefit was established with certain goals in mind. It was designed to provide intermittent home visits, in which nurses and therapists would provide services and instruct clients and families in self-care. Home health nursing was clearly differentiated from longer nursing shifts in which nurses stayed in the home for several hours at a time. The period of visiting was to be brief and provide direct skilled care just temporarily until patients and families could care for themselves. Neither health promotion nor long-term care was valued or reimbursed. Families were expected to manage long-term care alone. Whereas nurses had previously controlled their own practice, services under the new benefit were seen as extensions of medical care, with physicians certifying needed services for short-term treatment of sickness.

The number of Medicare-certified home care agencies grew rapidly until enactment of the Balanced Budget Act (BBA) of 1997, which sought explicitly to reduce federal payments for home health care. To achieve this, payment to providers was changed from reimbursement for each visit to the Medicare prospective payment system that

determined Medicare payment rates based on patient characteristics and need for services. Most private pay insurance agencies followed suit and adopted the standards of the Medicare prospective payment system (PPS). It was felt that compliance with established standards of care would increase positive outcomes in a cost-effective manner. However, the adoption of the standards resulted in a closure of many of the nation's Medicare-certified home health agencies (over 3,000 immediately after the 1997 legislation). Because of standardized reimbursement rates, many Medicare-qualified patients, requiring intensive skilled and personal services, needed to become independent in providing their health care needs at home. As a result, the amount of patient rehospitalizations increased and positive health care outcomes decreased. This has necessitated the focus of the home health nurse to change from provision of care to education and training. The home health nurse is charged with the responsibility of educating the patient and family on specific techniques to address the health need. Visits to the patient home are primarily evaluative of the patient's progress (Buhler-Wilkerson, 2016). In 2012, there were 12,200 home health agencies (Centers for Disease Control and Prevention [CDC], 2015).

With enactment of the Patient Protection and Affordable Care Act, many provisions are currently and will likely continue over the next decade to impact the provision of home health care. Although many of the Medicare policies for home care are unchanged, the act includes a number of new programs that if well implemented, will have a positive impact on home care. For instance, supplemental payments for rural home care providers have been reinstated for 2010–2015. This was done to address the lower ratio of home care professionals in rural areas throughout the United States as compared to more urban areas (Centers for Medicare and Medicaid Services [CMS], 2015f). New innovations included in the act are two programs that directly impact the provision of care in the home (CMS, 2012d):

- *Community First-Choice Option* allows states to offer home- and community-based services to disabled people through Medicaid rather than institutional care in nursing homes.
- *Community Care Transitions Program* helps high-risk Medicare beneficiaries who are hospitalized avoid unnecessary readmissions by coordinating care and connecting patients to services in their communities.

Although the new provisions can enhance the capacity of agencies to provide care, as with any change, the new rules and regulations will undoubtedly be a challenge. One concerning aspect for home health care providers is the 2012 ruling by the U.S. Supreme Court (National Federation of Independent Business et al. vs. Sebelius, Secretary of Health and Human Services) that allows for states to opt out of the provision in the act to expand Medicaid services (Kliff, 2012). Medicaid services are provided primarily to low-income populations. With a growing percentage of payments for home health coming from Medicaid, this is obviously of concern to care providers and consumers of care. Home health care expenditures from Medicaid are expected to exceed Medicare payments in the

coming years. How this shift in payment source and the limitation that many states may impose on Medicaid coverage is unknown at this time. The Centers for Medicare and Medicaid Services (CMS) oversee expenditures and policy implementation.

CMS and other government Web sites provide a wealth of information for the providers of care, as well as consumers (CMS.gov; healthcare.gov). Despite the challenges, the recognition of improved outcomes and cost savings associated with home care as opposed to hospitalization and skilled nursing facility (SNF) stays is encouraging. Stolee, Lim, Wilson, and Glenny (2011) conducted a systematic review to compare rehabilitation measures between home-based and inpatient rehabilitation for musculoskeletal disorders. Their findings supported home-based care with equal or improved outcomes in function, cognition, quality of life, and satisfaction with the intervention. The cost-effectiveness of home-based rehabilitation for older patients can be inferred by these findings. Home health care has been shown to be effective in decreasing long-term care and mortality, as well as reestablishing functional abilities in patients. Those agencies with positive work environments demonstrated lower rates of hospitalizations and higher rates of patient discharges to community settings when compared to those with inferior work environments (Jarrin, Flynn, Lake, & Aiken, 2014). The American Association for Homecare (2015) cites numerous studies comparing costs between the skills and equipment provided in homes versus institutions.

It is important to be aware that a distinct difference exists between professional and nonprofessional home care services provided to clients. Specialists with licenses, certifications, or specific qualifications provide professional home care. These professionals typically work for home care agencies with internal and external standards that guide the provision of their services. Nurses, social workers, physical therapists, occupational therapists, and home health aides are examples of professional home care practitioners. In contrast, there are home care organizations that provide nonprofessional home care and those who sell equipment for home care.

The National Association for Home Care and Hospice (NAHC) developed a code of ethics that serves as a guideline for agencies in assuring that patients and families are treated with a high standard of care and in an ethical manner. The code of ethics for home health agencies addresses:

- Patient Rights and Responsibilities
- Relationships to other Provider Agencies
- Responsibility to the National Association
- Fiscal Responsibilities
- Marketing and Public Relations
- Personnel
- Legislation
- Appeal process

(NAHC, 2016, para. 7)

HOME HEALTH AGENCIES

The mix of Medicare-certified home health care agencies includes voluntary nonprofits, hospital-based agencies, proprietary for-profit agencies, governmental agencies, or agencies not federally certified to provide care.

Voluntary nonprofit agencies traditionally have a charitable mission and are exempt from paying taxes. They are financed with nontax funds such as donations, endowments, United Way contributions, and third-party provider payments. If nonprofit agencies make any money, they reinvest it back into the agency. An unpaid board of directors frequently oversees voluntary agencies. They are considered community based because they provide services within a well-defined geographic location. Whereas in the past these agencies were assured of receiving almost all of the home care referrals in their community, the proliferation of other agencies has eroded their traditional base and put them in a competitive mode. The number of nonprofit home health agencies is diminishing across the country.

Hospital-based agencies comprise about 13% of Medicare-certified agencies (NAHC, 2010). A hospital may operate a separate department as a home health agency. It may be nonprofit or generate revenue for the hospital. The hospital's board of directors or trustees serves as the governing body for hospital-based agencies. The referrals to such hospital-based agencies usually come from the hospital staff, and the missions of the agency and the sponsoring hospital are similar. The same is true for rehabilitation and skilled-nursing facilities with home health departments.

For-profit proprietary agencies may be owned by individuals, but many are part of large, regional, or national chains that are administered through corporate headquarters. Proprietary agencies are expected to turn a profit on the services they provide, either for the individual owners or for their stockholders. They are required to pay taxes on profits generated. Although some participate in the Medicare program, others rely solely on "private-pay" clients (NAHC, 2010). In 2012, over 78% of home health care agencies were for-profit (CDC, 2015).

Some city and county government agencies also provide home care services. They are created and empowered through statutes enacted by legislation. Services are frequently provided by the nursing divisions of state or local health departments and may or may not combine care of the sick with traditional public health nursing services, including health promotion, illness prevention, communicable disease investigation, environmental health services, and maternal–child care.

Many agencies providing services in the home remain outside the federal Medicare system that reimburses skilled nursing. These *noncertified* agencies are usually private and derive their funding from direct payment by the client or from private insurers. They may be governed by individual owners or by corporations. For instance, some agencies offer

private duty shifts of registered nurses, licensed practical nurses, various therapists, or home health aides who are usually paid for out of pocket rather than reimbursed by insurance or Medicare. Other services include unskilled assistance in the home with homemaking or housekeeping. Some of these agencies provide live-in personal care. Other organizations provide *durable medical equipment* (DME), such as wheelchairs, commodes, beds, or oxygen. Additional services include high-technology pharmacy.

CLIENTS AND THEIR FAMILIES

The client in home health care is not only the individual patient but also the family and any significant others. The nurse must consider how the environmental, political, economic, cultural, and religious dimensions impact the client's illness and ability to meet the goals outlined in the plan of care.

Home care recipients are predominantly elderly patients with acute and chronic health needs. The medical diagnoses coincide with the morbidity rates of the region. Many have chronic conditions, which complicate acute conditions. In 2013, it was reported that approximately 12 million people in the United States require home care with the majority of them being women. The most common conditions were diabetes, heart failure, chronic skin ulcers, osteoarthritis, and hypertension (Harris-Kojetin, Sengupta, Park-Lee, & Valverde, 2013).

Individuals recovering from severe illness or living with debilitating chronic illness rely on family members or other sources of unpaid assistance. Almost 30% of the U.S. population provides informal caregiving for an adult family member or friend (National Alliance for Caregiving [NAC], 2012). Two thirds of these providers are women with an average age of 47, although people can become caregivers at any age. Frail elderly caregivers are especially vulnerable to deterioration of their own health because of their caregiving burden. Family caregiving tasks range from personal care such as bathing and feeding to sophisticated skilled care, including managing tracheostomies or IV lines. Primary caregivers are those who assume the daily tasks of care, whereas secondary caregivers assume intermittent responsibilities such as shopping or transportation. Formal caregivers are either volunteers or paid workers, whereas informal caregivers are either family members or those friends and neighbors with substantial relationships to the patient (NAC, 2014).

These informal caregivers assume a considerable physical, psychological, and economic burden in the care of their loved one at home. When layered on top of existing responsibilities, caregiver tasks compete for time, energy, and attention. As a result, caregivers often describe themselves as emotionally and physically drained and may very much need information about resources to assist them. Likewise, the economic cost of providing home care places a significant burden on informal caregivers. Out-of-pocket expenditures include medications, transportation, home medical equipment, supplies, and respite services. These costs may be nonreimbursable and are often invisible, but they are very real to families struggling to provide care on a fixed income. Although family members compassionately assume their responsibilities, their collective burden in our society as a whole is mounting. Home health nurses must continually assess the strain on caregivers as they seek to develop realistic plans of care.

HOME HEALTH CARE PERSONNEL

Nurses and home care aides are the largest number of home care employees (NAHC, 2010). Registered nurses and licensed practical nurses represent just under half of full time equivalent (FTE) positions in Medicare-certified agencies. Home care aides, physical therapy staff, occupational therapists, social workers, and administrative personnel comprise the rest of the home health team. The business and office personnel of a home health agency are critical to the agency's ability to deliver services to clients. Home health nurses must acquire an understanding of the financial aspects of their clients' care and provide this information to the agency staff, so that appropriate and full reimbursement can be obtained for the services provided.

REIMBURSEMENT FOR HOME HEALTH CARE

Both corporate and governmental third-party payers, as well as by individual clients and their families, reimburse home health services. Corporate payers include insurance companies, health maintenance organizations (HMOs), preferred provider organizations (PPOs), and case-management programs. Government payers include Medicare, Medicaid, the military health system (TRICARE), and the Veterans Administration system. These governmental programs have specific conditions for coverage of services, which are often less flexible than those of corporate payers. For a general description of these reimbursement systems, see Chapter 6. The Medicare policies for home health programs set the precedent for all other reimbursement sources and are discussed below.

Medicare Criteria and Reimbursement

Medicare is the largest single payer for home care services in the United States and has set the standard in establishing reimbursement criteria for other payers. Therefore, it is essential that home care nurses seek to understand the complex Medicare home health requirements and rules for determining eligibility for home care services. It is important to acknowledge that a person may be in dire need of care at home, yet not meet eligibility standards for home health care under Medicare. There are five criteria that must all be met to be eligible for reimbursement by Medicare (Display 32–1). Consider the implications of these requirements. Documentation must justify that the plan of care is medically "reasonable and necessary." The person must be under the care of a physician. He or she must be "homebound" and in need of services that Medicare narrowly defines as "skilled." A person who is "homebound" must be confined to home except for visits to the physician, outpatient dialysis, adult day center, or outpatient chemotherapy and radiation therapy. "Skilled" services are restrictively defined and include selected aspects of nursing, physical therapy, or speech therapy. Home visits must be *intermittent* and time limited. Extensive documentation is required according to Medicare specifications (CMS, 2015c). All of these requirements are subject to contradictory interpretations, which can put an agency's reimbursement at risk.

DISPLAY 32.1 MEDICARE HOME HEALTH ELIGIBILITY

1. The type of services and frequency provided must be reasonable and necessary. To determine whether this criterion is met, the client's current health status, medical record, and plan of care are evaluated. If a care plan has been ineffective with a client over a long period of time, continuation of that care plan would not be considered reasonable. Therefore, comprehensive documentation is essential to validate that the provided care was both reasonable and necessary.
2. The client must be homebound. This means that the client leaves the home with difficulty and only for medical appointments or adult day care related to the client's medical care.
3. The plan of care must be entered onto specific Medicare forms. The forms require very specific information regarding the client's diagnosis, prognosis, functional limitations, medications, and types of services needed. The home

health nurse often has the primary responsibility for ensuring that the forms are completed appropriately.

4. The client must be in need of a skilled service. In the home setting, skilled services are provided only by a nurse, physical therapist, or speech therapist. *Skilled nursing services* include skilled observation and assessment, teaching, and performing selected procedures requiring nursing judgment.
5. Services must be intermittent and part-time.

The Medicare PPS pays an agency for a 60-day "episode of care." All services and many medical supplies must be provided under the payment amount adjusted to geographic location and determined by the patient's clinical and functional status at the start of care, as well as the projected need for services over the anticipated 60-day period (CMS, 2012b). When the patient is admitted, the patient is comprehensively assessed using a lengthy tool called the *O*utcome and *A*ssessment *I*nformation *S*et (OASIS). Clinical, functional, psychological, and service scores are calculated from selected OASIS items. The stated purpose of OASIS is to "represent core items of a comprehensive assessment for an adult home care patient; and form the basis for measuring patient outcomes for purposes of outcome-based quality improvement" (CMS, 2012, para. 1). The updated version of this assessment tool is OASIS-C1, and it examines process as well as outcomes (CMS, 2015e). In the ongoing campaign to hold down the federal budget by diminishing health costs, home health care faces the ongoing threat of freezes or cuts in payment. These proposals overlooked the reality that home health care is a cost-effective alternative to hospital and nursing home care. As home health care is restricted to save money and reduce fraud, greater amounts will need to be spent for inpatient care when people cannot cope in the absence of health care assistance at home (see Perspectives: Voices From the Community).

PERSPECTIVES VOICES FROM THE COMMUNITY

It is vital to develop an expanded vision about the health care needs of frail elders and the kinds of services that are needed in the community. Sometimes, after nurses have been working in Medicare home health for a while, they may begin to identify more with the Medicare guidelines than with their patients. Too often, I have heard experienced home health nurses say about a patient living with severe chronic illness, "She doesn't deserve services. She doesn't have skilled needs." In contrast, I would hope knowledgeable nurses would say to families and decision makers, "She needs and deserves services, but the Medicare home health benefit will not pay for them. Our agency cannot continue to provide care because of the limits imposed on us. We'll do everything possible to find help

for her, but resources are limited." This kind of insight leads to patient advocacy, development of community networks, and becoming outspoken about needed changes in health policy. Visiting nurses witness the struggles of chronically ill people living at home; we must not abandon them.

—Beth L., Nursing Instructor

It is a Medicare requirement that patients receiving home health care must be recertified every 60 days. This recertification includes a detailed assessment (OASIS) that validates the need for skilled care within the home and the fact the patient cannot easily receive care from other sources. A face-to-face visit made with a comparison of progress from the initial assessment to the present must be made, and this can be done by the patient's physician, a nurse practitioner, a clinical nurse specialist, or a certified nurse midwife or physician assistants who work under the supervision of a physician. A determination of continued visits is then made based upon the objective data obtained (CMS, 2015b).

Medicare Documentation

Initially, every patient must be assessed using the OASIS tool, which determines reimbursement, is integral to agency surveys and certification, and collects information used to measure quality. OASIS assessment combines objective data gathered by the nurse combined with subjective data gathered from the patient and family to determine optimal functional outcomes for the patient. Selected quality outcomes are measured, and data are released on the CMS Web site (CMS, 2015a), which is accessed as "Home Health Compare" (http://www.medicare.gov/). Display 32–2 identifies selected quality measures. Note that the expectation is that of improving function, not simply stabilizing function, and consider the implications of this standard for very disabled patients.

DISPLAY 32.2 COMPARE HOME HEALTH CARE PROVIDERS

The Medicare.gov Web site offers information for consumers about the quality of home health care agencies. It includes data on how frequently best practices are used in patient care and if patients improved in relation to certain aspects of care. It also includes patient feedback about recent home health agency experiences.

You and/or your clients can go to: https://www.medicare.gov/homehealthcompare/search.html and enter your ZIP Code (or city, state), and you can see a list of all agencies and the services provided by each (that meet certain criteria). You may select agencies for comparison, and general information is provided, along with the quality patient care information and results of patient surveys. For quality patient care, star ratings are used to denote summaries of 9 out of 29 quality measures, with 4 or 5 stars indicating better performance than other agencies. Star rankings of one or two indicate below-average performance. Most agencies nationwide fall within 3 or 3.5 stars. Survey results include percentages related to how often care was given in a professional manner, how well the team communicated with clients, if they discussed pain, medications, and home safety with clients, how the client rates their overall care from this agency, and would they recommend the agency to family/friends. Overall percentages can be graphed for comparison with state and national averages.

The nurse also completes the Medicare plan of care at admission, and the physician must sign this. It is then used to assess agency compliance with Medicare and state

requirements. Obviously, great pains must be taken to assure accuracy. All follow-up services must match the plan of care. Likewise, OASIS identified needs and plan of care services must match (CMS, 2015b).

HOME HEALTH NURSING PRACTICE

The practice of home health nursing has roots in community/public health nursing (see Chapters 2 and 3). The nurse provides home health nursing care to acute, chronic, and terminally ill clients of all ages in their homes while integrating public health nursing principles that focus on the environmental, psychosocial, economic, cultural, and personal health factors affecting a client's and family's health status and well-being. Home health is a unique field of nursing practice that requires a synthesis of public health nursing principles with the theory and practice of medical/surgical, geriatric, mental health, and other nursing specialties. The official journal of the Home Healthcare Nurses Association (HHNA, 2012), *Home Healthcare Nurse*, is the primary source of up-to-date nursing knowledge in this rapidly changing field of practice.

The effective home health nurse must

- Deliberately build trust
- Sense "where people are" and suspend judgment
- Develop a connection at the first visit
- Develop "giant antennae" to detect cues in the home
- Keep the focus on patient care, despite persistent distractions during home visits
- Help people solve their own problems
- Keep priorities fluid
- Determine how to keep the unstable client safe until the next visit
- Thoughtfully maintain boundaries between personal and professional life
- "Make do" with limited supplies
- Face immense challenges with time management and paperwork demands
- Be vigilant about personal safety in neighborhoods and homes
- Continue the development of skills in clinical assessment and care coordination
- Provide effective teaching for patients and families

According to the American Nurses Association (ANA) *Scope and Standards of Practice for Home Health* Nursing (2014), home health nursing goes beyond providing skilled nursing care in the home; it requires the ability of the nurse to coordinate a broad variety of services and professional caregivers in order to manage patients' complex health problems. See Display 32–3 for an abbreviated look at the standards of practice.

DISPLAY 32.3 EXAMPLES OF

STANDARDS OF PRACTICE FOR HOME HEALTH NURSING

Clinical roles of the home health nurse include patient educator, clinical care/case manager, and patient advocate. Standards of practice in this specialty area of nursing encompass:

- Assessment (including family dynamics, knowledge of caregivers, patient values/goals/health beliefs)
- Diagnosis (including validation of diagnosis with patient/family, actual and potential risks, health barriers)
- Outcomes identification (including collaboration with patient/family to identify goals, consideration of cultural, ethical, and personal beliefs and values)
- Planning (including collaborating with patient/family on an individualized plan of care, strategies to address health promotion and restoration, prevention of injury/illness, pain relief/palliative care, interprofessional collaboration regarding care, planning for transitions to and from home health care)
- Implementation (including collaboration on implementing plan of care, engaging patients in disease management, use of evidence-based practice interventions, providing holistic care, utilizing health care technologies and community resources, integrating complementary practices with traditional approaches, promoting problem solving behaviors in patients/families)
- Coordination of care (including collaborating with team members, helping patients/families recognize alternative care options when plan of care no longer meets patient needs, works closely with patients/families during care transitions)
- Health Teaching & Health Promotion (including developmentally and culturally sensitive health promotion/teaching that promotes patient engagement with self-care, utilizes information and health care technologies as appropriate)
- Consultation (including synthesizing evidence, clinical data and theory, involves patients/families in determining role responsibilities and in making decisions, offers education to the team of health care workers)
- Evaluation (including ongoing and systematic outcomes evaluation, engages the team and the patient/family to participate in evaluation process, evaluates patient progress toward short-term goals/objectives, uses evaluation to redesign plan of care, provides results of evaluation to patient/family and health care team members)
- Ethics (including practicing within the ANA [2015] *Code of Ethics for Nurses with Interpretive Statements*)
- Education (including continuing professional education)

- Evidence-Based Practice & Research (including use of current findings to guide clinical nursing practice, sharing research findings with health care team members/peers)
- Quality of Practice (including documentation, participation in quality improvement initiatives, collecting quality-related data, updating guidelines/procedures to improve quality of nursing practice and patient care outcomes)
- Communication (including assessment of patient preferences/literacy/language skills, communicating effectively with interprofessional team members)
- Leadership (including development of conflict resolution and communication skills, serving as a preceptor for new colleagues, participation on agency committees)
- Collaboration (including partnering with others to promote change, helps build consensus, applying negotiation skills and group process techniques with patients/families/health care team, builds teamwork)
- Professional practice evaluation (including evaluation of own practice and identification of strengths/areas needing professional growth, offers feedback to peers on performance)
- Resource utilization (including resources available to patient/family in implementing plan of care, delegates to team members when appropriate, advocates for enhancement of nursing practice through use of technology and additional resources, helps patient/family find services needed for care and cost/benefits/risks of decisions)
- Environmental health (including understanding of risks related to management of supplies (e.g., syringes, needles, medications, waste), assessment of home and neighborhood for unsafe/unsanitary conditions, works to reduce environmental risks that affect health of patient/family, promotes health communities)

Nursing Practice During the Home Visit

The practice competencies of home health nurses can be illustrated with the Home Health Nursing Caregiving Wheel (Fig. 32–1).

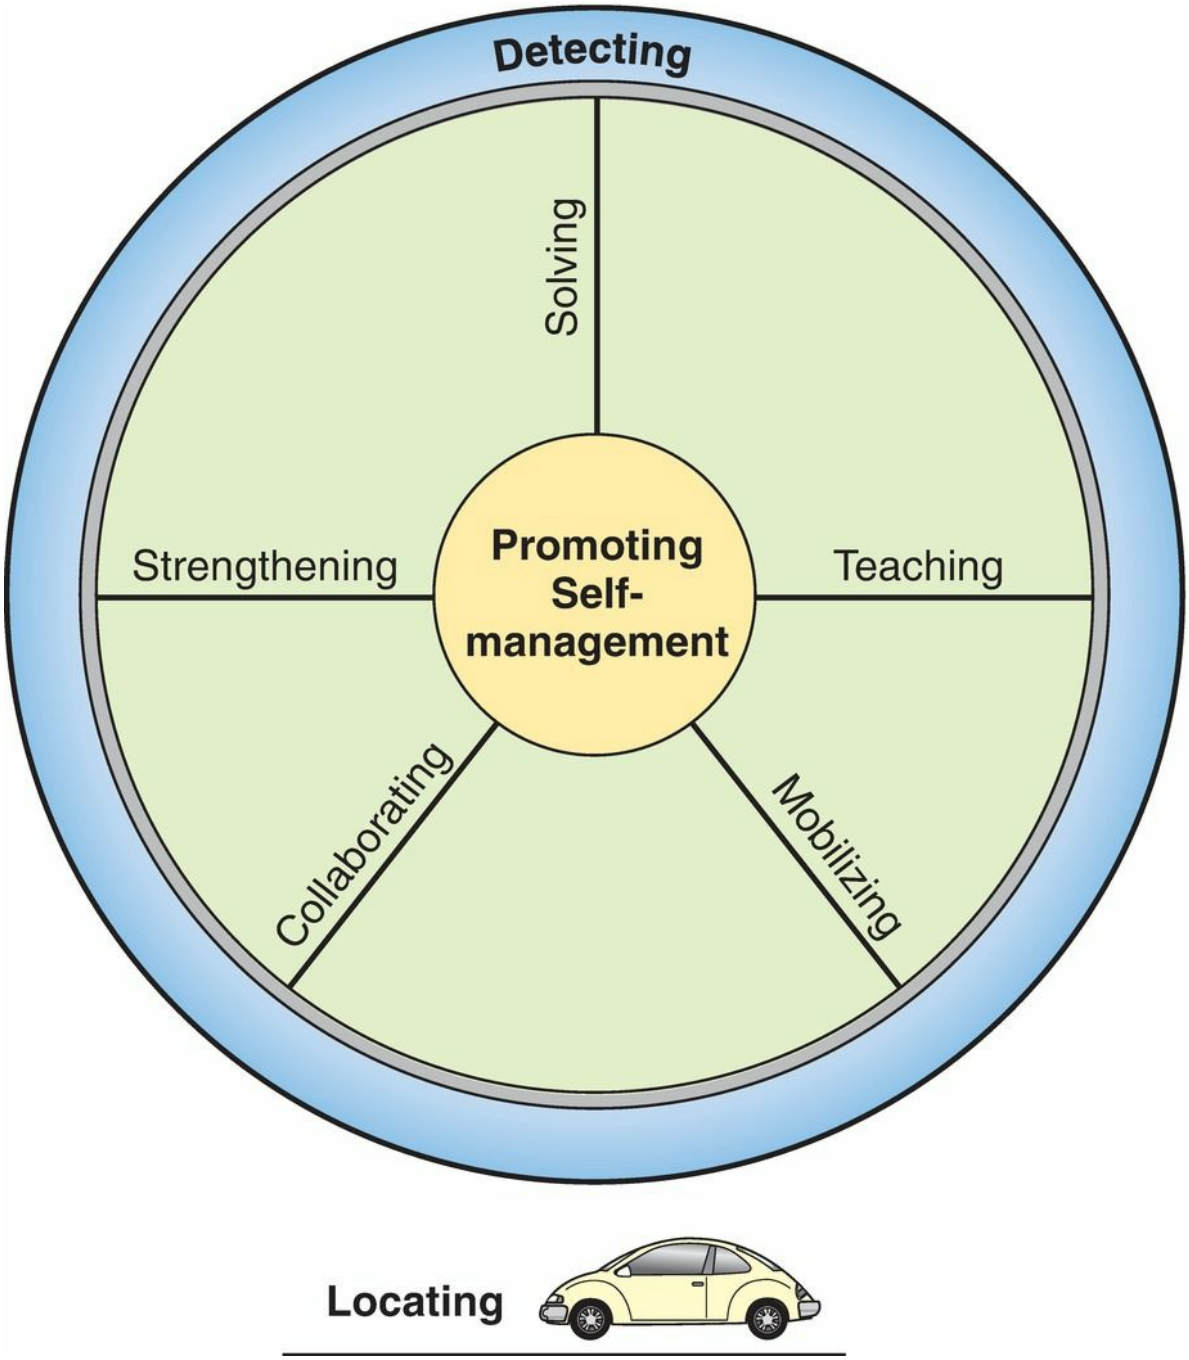

FIGURE 32–1 Home health nursing caregiving wheel.

Locating the Client and Getting Through the Door

The first step in making a home visit is finding where the person lives, which might involve telephone instructions, or a global positioning system (GPS) unit. For most home health nurses, locating clients involves driving their own cars to the home. Sometimes, nurses drive agency cars, and occasionally transportation may involve a bus, subway, boat, or airplane. Directions and household identification can be unclear. In rural areas, tracking down clients can involve vague instructions involving barns, bridges, trees, and other colorful local landmarks (see From the Case Files for an example). When families are

unstable, clients may not be staying in households designated on the nurse's paperwork. They may have moved in with relatives or friends or be back home alone despite major care needs. Locating is especially challenging when neighbors or even family members are not cooperative, for whatever reason.

Even when the wheels stop at the correct household, there is the challenge of getting through the closed door and making the connection. *Always remember that you are a guest in the home*. Respect and attentive listening are the foundation for establishment of trust between the client and nurse. Agendas must be laid aside initially as the nurse focuses on the concerns and realities of both client and family. Assumptions and stereotypes are overturned in the process of discovering how clients live, what they believe, and who comprises their family and community. The nurse must take into account the spiritual, cultural, and developmental, as well as environmental, realms of the client in order to be able to develop individualized plans of care to promote health.

The home health nurse is aware that the client is the driver of the plan of care. To have effective outcomes, the nurse must develop a therapeutic relationship in which the client identifies the desired outcomes. This approach provides increased cooperation between the nurse and client in establishing interventions to reach the desired outcome. The nurse must emphasize positives to the extent possible, rather than telling people what they are doing wrong and need to change. Autonomy should be respected, and the family should be empowered by actions recognizing that they are in charge of their lives. At the same time, the nurse must be up front and truthful regarding the medical and nursing problems that need resolution. For example, a nurse might say, "You might lose your foot if we cannot work together to figure out a plan of care that you can live with. Let's think together about what we can do to prevent it." The nurse, the patient, and family must work together to establish mutually agreed-upon goals. (See Chapters 10 and 25 for more information on communication, collaboration, contracting, and effective approaches for developing effective nurse–client partnerships.)

From the Case Files

Locating the Client's Home

"You can't miss our place," Diane had reassured me on the phone. I slowed in front of the decrepit Sunrise Motel, its roof partially collapsed, and reviewed my notes. I was supposed to turn right on the unmarked gravel road just after the abandoned motel and continue until the road ended. I proceeded slowly through an evergreen tunnel past an old blue truck body, resting belly up. A little girl, perhaps 5 years old, came from around the truck and joined two grade-school-aged boys playing Frisbee

in a clearing. I asked them where Diane Quimby lived, and they pointed around a curve in the road. In a moment, I came to a stop near a large wooded area and a metal shed with smoke coming out of a crooked metal pipe in the roof. I knocked. No answer. I heard dialogue from "General Hospital" coming from inside. I knocked again and shouted, "Hello! It's the nurse." "Come on in!" a loud voice responded.

I pushed open the door. There was no knob. Illuminated by one weak lamp, I could just make out a round face with wire rim glasses and a long gray-blond braid. Here was Diane, sitting on a sagging sofa facing a TV tray and watching television. I could see a wooden table in the corner, three mismatched dining chairs, and a couple of cots against the wall. The air was hazy with the smell of wood smoke.

Diane invited me to pull up a chair. "How are you doing? I am here to see how I can assist you". I began. Diane had unstable, insulin-dependent diabetes and high blood pressure. In June, surgeons had removed her gangrenous left foot with an amputation that ended just below the left knee. Now, there was an infection in the wound that had not healed despite extended use of antibiotics.

During the course of the visit, I learned that Diane had no tub or shower for bathing. She also had no money for dressings and no supplies. Because Diane's vision was impaired, her 9-year-old grandson was doing the dressing changes. Until the latest surgery, Diane worked as a cook in a local board and care home for frail elders. She was 68 years old and had Medicare coverage. I learned that Diane was the legal guardian for two grandchildren, ages 5 and 9.

Apply the nursing process to comprehensively identify and prioritize nursing diagnoses and propose interventions. Use the Home Health Nursing Caregiving Wheel to guide your care planning.

Hub of the Family Caregiving Wheel: Promoting Self-Management

Home health nursing involves home visits to promote independence rather than dependence on the home health team. Lasting health improvement is only possible when the home health nurse works with the client/family to make decisions that are truly their own. Although financial incentives push home health nurses to minimize the number of visits and duration of service, pressuring a client or family to adopt the agency agenda denies any sense of partnership and can backfire, resulting in nonadherence to the therapeutic regimen. This can place a client in a no-win situation.

Every effort is made to develop capacity for independent self-care, so that the home team can safely withdraw. Obviously, this is quite appropriate for those recovering from an episode of acute illness. The challenge to the home health nurse is often assisting the severely chronically ill client be able to adapt in the community to be safe and functional. Coordination with other professionals must often be instituted to provide comprehensive

quality care. This may include social workers, clergy, physical therapists occupational therapists, as well as mental health professionals. Because regulations require that the client make progress toward the outcomes, the nurse must often limit or terminate visits when measurable progress is not being made. This may lead to rehospitalization or the inability to provide self-care. Currently, no governmental program assures long-term care for those people unable to care for themselves. The home health nurse must utilize interprofessional collaboration to agency social workers to mobilize resources to care after the agency leaves.

Rim of the Home Health Caregiving Wheel: Detecting

Nurses in the home are challenged by an extraordinarily complex environment with much to investigate and frequently many distractions to ignore. Detecting is an all-encompassing, continuing assessment process as the nurse seeks to understand the client's health in the context of home. The nurse keeps her ears and eyes "wide open." Who lives in the home? How do they interact? Who are the caregivers, and how do they care? What is the relevance of culture and religion in the life of the household? How does the physical environment impact patient safety and security? Can the bathroom tub be used? The questions are endless. The OASIS format provides the baselines for the first visit, and then the nursing assessment broadens with each visit as the nurse continually widens his or her lens to take it all in. Home visits reveal discoveries that can never be imagined in clinic or hospital settings. Take for example the client whose refrigerator no longer chills and whose impaired vision prevents awareness of the expanding family of roaches in the kitchen. Upon each visit the nurse is assessing:

- Client safety: Is the client in a safe environment where the outcome can be reached? Are there safety devices available for client safety? Are essential services (food, power, water, housing, security) available and sufficient for the client to function safely independently in the home?
- Supportive, knowledgeable caregivers: Are the caregivers attentive, knowledgeable, and willing to provide care to the client in the absence of the nurse? Is the caregiver competent in providing care?
- Material resources: Does the client have the necessary material resources to support the interventions? Are the medications, dressings, and supplies accessible? Does the patient have the financial support to obtain the equipment?

Spokes of the Home Health Caregiving Wheel: Collaborating, Mobilizing, Strengthening, Teaching, Solving Problems

Home health nursing competencies that radiate from the hub and contribute to promotion of self-care and family care include *collaborating* with multiple team members and *mobilizing resources* in the community that can sustain the client after discharge. The home health care nurse usually is the coordinator of all other home health team members. Working with the social worker, the nurse proposes needed connections with community

services. Likewise, *strengthening* involves development of self-management or family caregiving ability. People learn that they can give injections, manage IV lines, safely take complex drug regimens, provide rehabilitation for loved ones after stroke, and perform countless other skills that they do not believe possible until a nurse shows them and they discover that they can do it themselves.

The home health nurse is constantly *teaching* clients and/or family caregivers through concrete explanation, discussion, and modeling behavior. Teaching facts is no assurance of behavior change and improved management of a health problem. Underlying factors influencing health behavior must be diagnosed and addressed. Health coaching, also called *motivational interviewing, is useful. The* principles of adult learning highlight that adults must be involved and see some self-benefit in order to learn. Instead of telling people what to do, this involves asking people how they would like to change—for instance, "What worries you the most?" Those concerns and relevant feelings must be validated, and the nurse leads the person to consider options for change. The solution develops through a mutual, participatory process. Ultimately, people are responsible for their own health decisions (see Chapter 11).

Finally, home health nursing competency requires flexibility and creativity in *solving* health care problems and the challenges of everyday living. All outcomes of care can be achieved only by adapting to the skills and resources available in the home. Although people of all socioeconomic backgrounds present with severe health problems requiring home health nursing, many families live on the margins. The home health nurse must often be creative in obtaining supplies and adjusting to conditions in the home. For example, how do patients and families with no running water wash their hands before providing care, such as dressing changes? This may lead the home health nurse to contact social agencies in order to provide services or teach the patient and family the use of alcohol-based gels to clean their hands. The home health nurse must be nonjudgmental, but work with the patient and family to help them understand the need to keep areas clean.

Home Health Nursing Case Management

The home health nurse is the case manager for each client and responsible for coordination of the other professionals and paraprofessionals involved in the client's care.

The nurse plans the frequency and duration of visits. Will home visits be made twice weekly, once weekly, or every day? For how long will visits continue? As the care is provided and the client's condition improves, the home health nurse determines whether the frequency of visits should be reduced or whether the client can be discharged.

The home care nurse is the primary contact with the client's physician, collaborating on the initial plan of care, reporting changes in the client's condition, and securing changes in the plan of care. The nurse conducts case conferences among team members to share information, discuss problems, and plan actions to affect the best possible outcomes for the client. Medicare mandates such case conferences every 60 days in home care. The nurse case manager also supervises the paraprofessionals, such as home health aides, who also serve the homebound client. The definition of homebound involves two considerations: (1) it takes extraordinary effort for the client to leave their home and receive care and (2) that they need physical assistance or the use of medical equipment (e.g., walkers, wheelchairs, crutches) in order to leave their home (Medicare Interactive, n.d.).

The home health nurse must know who is going to pay for services from the first visit to the time of discharge from the agency. If the client does not have a source of payment for the care that is needed, the agency must determine whether the client will receive the care free of charge or at a reduced rate. Many agencies have a sliding fee scale, which means that the charge for the services is based on the client's ability to pay.

Selected Nursing Challenges in the Home

Working in the home immerses the nurse in challenges unlike anything encountered in controlled institutional environments. Some of these include infection control, medication safety, fall risk, technology at home, and nurse safety.

Infection Control

Home health nurses frequently need to work with the family to prevent infection in clients who are debilitated and may be immunocompromised; in addition, many are now dwelling at home with invasive medical devices that make them especially vulnerable to infection. Likewise, nurses are challenged to consider how to protect the home health care team, family, and community from a client with contagious disease. In such cases, all people living in the home will need instruction. Some households have inadequate facilities to control disease transmission. There may be no access to running water, no heating unit to boil equipment, or inadequate facilities to dispose of contaminated equipment. These conditions necessitate the development of creative solutions to control infection.

Complexities of the home environment require the nurse to carefully consider exactly how microorganisms are likely to exit the body, how might they be transmitted, and how are they likely to enter the body of another individual. Households cannot be organized like hospital units with isolation rooms. The nurse must decide when gloves are absolutely essential, when protecting clothing with a gown is needed, when a mask should be worn, and what environmental surfaces are likely to be contaminated and must be scrupulously cleaned. How should soiled tissues or dressings, dishes, and laundry be handled? What is realistic and can actually be carried out by client and family? As in the hospital environment, hands are the main method of transmission of contagion, and hand hygiene is the main intervention that must be emphasized. In a study of 423 home health nurses, almost 6% reported having been diagnosed with a multiple-drug-resistant organism acquired on their jobs, and almost 80% of nurses report that their agency does not have an infection control specialist on staff (Kenneley, 2012).

To guide the nurse, home health agencies have adapted infection control policies and procedures based on the Centers for Disease Control and Prevention's (CDCs) isolation precautions for health care settings each agency setting up their own specific policy and procedure based upon the standard (Siegel, Rhinehart, Jackson, Chiarello, & Healthcare Infection Control Practices Advisory Committee, 2011).

Medication Safety

Home health nurses assume major responsibility for medication safety. The home health client taking multiple medications is at particular risk of multiple errors in self-administration, including incorrect medication, dose, time, interval, or route. Often, doses are missed or doubled. Clients may discontinue a drug or not complete the full course.

Sometimes, the drug or drugs ordered are inappropriate considering the patient's condition at home.

The home presents risks of medication errors that are different from those found in hospital or nursing home. Every visiting nurse has stories of finding drawers and cupboards filled with multiple prescriptions from various physicians, some current and some outdated for many years. Polypharmacy becomes very obvious in the home setting. Clients often have received prescriptions from multiple sources for similar drugs. Also, well-meaning friends often share their prescriptions with the attitude that it "helped them." Clients taking at least one potentially inappropriate medication were found to be at greater risk when they received Medicare or Medicaid-provided services (Bao, Shao, Bishop, Schackman, & Bruce, 2011). Using data from the 2007 National Home and Hospice Care Survey, 38% of elderly home health clients were taking one or more potentially inappropriate medications, and the risk for polypharmacy showed a correlated increase (Bao et al., 2011). Potentially inappropriate medications (PIM) are those that senior citizens should avoid due to either their ineffectiveness or because the potential adverse effects overshadow the proposed benefits; they also should be avoided if other, safer drugs are available (Bao et al., 2011). Additional findings from the Bao et al. study included an increased risk of exposure to potentially inappropriate medications when clients were admitted to home health care from a nursing home or other subacute facility, rather than community admission. This not only supports the need for home care but improvements to discharge planning from skilled nursing facilities.

Even if the client is well organized and taking every drug prescribed, those prescriptions may have originated from several providers over time and may have contradictory side effects. Sometimes, medication errors at home include failure to clearly reconcile hospital or nursing home orders with home discharge orders. Although weekly medication organizers can helpfully put medications in order, they can also confuse new or impaired users. Distraction, visual impairment, forgetfulness, depression, and cognitive impairment are common causes of unintentional medication noncompliance. The home health nurse investigates how the medication is taken by reviewing and reconciling the current list of medications and having the patient explain and demonstrate the process he goes through. Intervention requires clear and repeated instruction, updating the medication list, charting or diagramming the schedule for medication taking, and assuring that the client or caregiver knows how to use the medication box. See Chapter 24 for more on medication issues with older adults.

Some of the reasons for intentional noncompliance are knowledge deficit, unacceptable side effects, no immediately obvious consequence when the drug is stopped, resistance to authority, perception of personal weakness if needing medication, and prohibitive cost (Gottlieb, 2016). Health insurance plans with restrictive formularies, high copayments, and limited incomes have been associated with lower levels of medication compliance (Iuga & McGuire, 2014). The home health nurse seeks to nonjudgmentally elicit reasons and mutually work out solutions that help clients manage medications at home and prevent

intensive medical interventions.

Risk of Falling

Falls are a serious issue especially for the elderly. Estimates are that one in three adults 65 years and older will fall each year, and 250,000 are hospitalized for hip fractures (CDC, 2015). Physiological risk factors include orthostatic hypotension and cardiac dysrhythmias, dizziness, neurologic and musculoskeletal effects on gait and balance, urinary urgency, impaired hearing or vision, alcohol or drug abuse, and medication effects impairing alertness, balance, urinary frequency, and blood pressure. Clients should be observed as they move through their home and carry out activities of daily living. It is important to investigate factors that obstruct movement or threaten balance. The nurse in the home should inspect sidewalks, stairs, and surfaces outside the home; floor, rugs, electrical cords, stairs, lighting, and clutter inside the home; kitchen safety; and bathroom features including grab bars and a raised seat for the toilet and safety modifications for the bathtub. Common home modifications, such as eliminating throw rugs and loose mats and the use of nonslip bath mats, have a significant protective effect. Display 32–4 lists teaching guidelines to prevent falls. See Chapter 24 for more on fall prevention in the home.

DISPLAY 32.4 TEACHING TO PREVENT FALLS

- Encourage the client to
  Get exercise to strengthen leg muscles and improve balanceBe aware of effects and side effects of medicationsHave vision checked regularlyEliminate hazards at home

Steps for home safety

Remove things that you can trip over (books, papers shoes, throw rugs).

Install handrails and lights on all staircases.

If using throw rugs, secure them with double-sided tape to prevent slipping.

Put grab bars inside and next to the tub or shower as well as the toilet.

Use nonslip mats in the bathtub and on shower floors.

Improve the lighting in the home.

Wear shoes both inside and outside the home.

Technology at Home

Home health nurses teach patients and their family to manage a wide array of complex technologies. Home regimens often require mini-intensive care units. In the past, the average home had a limited capacity for technology; medication was swallowed, and food and fluid were consumed with the aid of fork and spoon. Now, the IV needle has evolved into venous access devices, and plastic IV fluid bags can be stacked in the refrigerator and hung from the arm of a lamp. The household becomes home to dialysis, ventilators, isolation suites, enteric and IV nutrition, and vasopressors—the list goes on. Nurses teach clients and families to manage it all; we become the guardians and advocates of complex regimens that require multiple nursing visits. Paradoxically, our primary mission is to be protectors and advocates for the well-being of client and family. Consider the human impact when the machines and the sickbed become the center of household activities (Munck, Sandgren, Fridlund, & Martensson, 2012). Also, medical devices have caused injuries and deaths, so careful instructions on use in the home and oversight are needed (Swayze & Rich, 2012). Home health nurses have the unique position of being able to assess the client in their own environment and determine the impact of their health

condition on their desired lifestyle. Sometimes, we can foster dialogue with clients and families to consider the benefits and burdens of continuing technologies. Consider four reasons why technology may be inappropriate: (1) the technology is not achieving a therapeutic purpose, (2) the therapeutic purpose can be met more simply, (3) complications of the intervention outweigh benefits, and (4) the resulting quality of life does not justify the technology. See Perspectives: Home Health Nursing.

PERSPECTIVES HOME HEALTH NURSING

I have worked in home health for about 15 years. I started in the hospital on a pediatrics unit and later moved to home health. Recently, I have been working with medically fragile children who are discharged home but who still need more intensive care than can be provided by the families (e.g., premature infants; children with either cardiac, neurological, or respiratory problems; those on ventilators or with feeding tubes). The child or infant may need daily treatments and careful monitoring, and their physician requests medically necessary services from the home health agency. As a pediatric home health nurse, I provide skilled nursing care for set periods of time (up to 24 hours/day). A nurse is always available on call, and we develop close relationships with our families. We often check in with them by phone between visits and help parents adjust to the "tubes and wires" or other technology needed by their infant or child. Sometimes, parents send us a note with their preemie's "first day of school" photo. It is uplifting to see these fragile newborns looking like any other kindergartener. I really love my job!

Ava, Pediatric Home Health Nurse

Adapted from Hand to Hand. (2016). What does a pediatric home health provider do? Skilled nursing care at home. Retrieved from http://handtohold.org/resources/meet-the-provider/what-does-a-pediatric-home-health-provider-do-skilled-nursing-care-at-home/

Recent information technologies being adopted by home health care agencies significantly improve quality of client care. These include medical records available instantly on the nurse's laptop or tablet and daily telemedicine monitoring of electrocardiogram, blood pressure, oxygen saturation, and other vital measures. This is known as telehealth because objective measurements of the patient's current health status can be transmitted electronically to a home health agency or physician office. These assessments can be monitored, and the patient plan of care may be altered based on the analysis. Determination of face-to-face visits from the home health nurse or the physician is often based on the change in the plan of care. For example, a patient with the medical

diagnosis of congestive heart failure is showing an increase in blood pressure and weight; this may warrant an immediate visit so that medications may be adjusted and a subsequent hospital visit may be avoided. As the results of one study cautioned (Shea & Chamoff, 2012), health care providers may overestimate the value of telemedicine in self-care for chronic conditions. The findings of the study support using explicit goals and intensions with clients and to individualize instructions provided. Essentially, frequency of contact did not mean quality communication. See Chapter 10 for more on technology in the community.

Nurse Safety

Nurses and other health care workers experience higher rates of workplace violence when compared with other types of work (Gross, Peek-Asa, Nocera, & Casteel, 2013). Home health nurses face risks not only dealing with driving to their client's homes but also because of environmental hazards: the nurses must be constantly aware of personal safety and surroundings. Client homes are uncontrolled environments, unlike acute care hospital settings, and nurses may face instances of family violence, illegal drug activity, or weapons may be present. The surrounding neighborhood also may pose risks of violence, car theft, vandalism, and robbery. Many home health organizations and their nurses work closely with local law enforcement agencies to identify the wisest process for visiting dangerous neighborhoods and isolated rural areas. Every home health care agency should have a carefully developed program to assure the safety of personnel traveling to homes, and training on how to predict aggressive behaviors, diffuse threatening circumstances, along with methods of self-protection if threats escalate. One study of California home health and hospice agencies found that only 55% of the 40 participants reported formal workplace violence prevention programs in place, even though state guidelines for this were recommended 20 years earlier (Gross et al., 2013). For those having programs, more emphasis was placed on pet dangers than on potential dangers of patient history of violence or mental illness, guns, and substance abuse. Surrounding community threat assessment was generally not included. Only 15% of participating agencies provided employee training on prediction of aggression and violence. Very few gave trainings on diffusion of threats or methods for self-protection. Nurses making home visits were seldom members of the safety committees that oversaw these programs and policies. If the personal safety of the nurse is in jeopardy, then the client may be discharged from the agency's care if other arrangements cannot be made. Display 32–5 lists practices for safe home visiting.

DISPLAY 32.5 SAFE HOME

VISITS

- Carry a cell phone.
- Be sure the agency knows your itinerary.
- Clarify directions before travel. Use GPS and client directions to the home.
- Make joint visits or request security escort if safety is threatened. Discuss plan for discontinuance of visits with supervisor when there is strong evidence of personal danger.
- Call to schedule the visit, and do not go into the home without invitation.
- Dress simply without expensive jewelry. Do not carry large amounts of cash. Keep wallet or purse locked in the trunk of your car during the visit.
- Wear an agency badge.
- Follow family directions about how to get by in their neighborhood and when to come in or leave their home. Patients and families usually have a desire to protect their nurse.

THE FUTURE OF CARE IN THE HOME

In conclusion, it can be seen that present-day Medicare home health care intervenes during brief episodes of acute medical trouble, relies on family at home as caregivers, and is expected to get in and out of the home as inexpensively as possible. Consider instead the true needs of the frail elderly or severely disabled who require prolonged psychosocial support, personal care, housekeeping, promotion of health, prevention of deterioration, and early detection of medical problems. In other words, they need case management that extends over months and years. For this to happen, the United States must continue to develop a community-based long-term care system. Home health nurses will play a pivotal role in that system. The primary role of the home health nurse will be education and advocacy for the client. Some baby boomers will be able to afford these services by paying out of their own pockets for a network of elder management services. Most baby boomers will need the development of a national community-based long-term care benefit. The Affordable Care Act is one step in that direction, but two programs provided in the act, the Community First Choice Option and the Community Care Transitions Program, do not provide for the long-term care so often required (CMS, 2015f). They are, however, a step in the right direction. *Healthy People 2020* provides a number of objectives *scattered throughout the document* that support the health and well-being of home health clients and their caregivers (USDHHS, 2016).

OVERVIEW OF THE HOSPICE MOVEMENT

Although science and technology have advanced in the world of health care, death is ultimately inevitable for all of us. The contemporary circumstances of death in America are often dehumanizing; most people die in hospitals and long-term care institutions, surrounded by strangers. Uncertainty and denial often prevail during the final stage of life because prognoses are uncertain, and many serious illnesses are now treated aggressively until the last breath. The battle against the "evil" of death seems to be the primary emphasis, with patient, family, and professionals wanting to believe that it is possible to win the final struggle. In the twenty-first century, fatal conditions have been turned into expensive chronic illnesses. Too often, discomfort is not relieved, and treatment causes further suffering. And as the period of disability extends and the body deteriorates, social isolation develops. The modern preoccupation with action, productivity, and beauty has little interest in the process of dying. In dramatic contrast to the dehumanization of death, the hospice movement has developed to humanize the end-of-life experience and provide palliative care. Palliative interventions relieve suffering without curing underlying disease. The hospice movement has emphasized four major changes in end-of-life care: (1) care should encompass body, mind, and spirit; (2) death should be discussed and not considered off-limits; (3) medical technology should be used only when absolutely necessary; and (4) clients should be actively involved in discussions about treatment decisions. Table 32–1 contrasts home health with hospice. This section explores the evolution of hospice care in the United States, describes hospice agencies, and examines Medicare criteria for hospice reimbursement. It concludes with an exploration of the unique characteristics of hospice nursing practice.

Table 32–1 Contrasts Between Home Health and Hospice

Hospice	Home Health
Emphasis is on quality of life and comfort.	Emphasis is on rehabilitation, physiological stabilization, and adaptation.
Focus is on health of whole family.	Focus is on health of client.
Plan of care is guided by client choice.	Plan of care is determined by medical need and client choice.
Nurse is case manager until death.	Nurse is case manager until home health discharge.
Client chooses how to live last days.	Priority is given to correcting physiologic imbalances.
Intermittent visits increase in frequency as death becomes imminent.	Intermittent visits decrease in frequency as client stabilizes.
Nurses are expert in symptom control.	Symptom control is domain of physician with some nurses having expertise.
Sedatives and opioids are expertly adjusted to eliminate suffering.	Sedatives and opioids are used hesitantly to reduce suffering.
End-of-life disease course is managed to avoid crises.	End-of-life problems tend to be seen as medical crises.
Goal is for symptoms at end of life to be managed at home if possible.	Client is brought to hospital for unmanaged symptoms.
Spiritual care is focus of whole team.	Spiritual needs are met by own clergy.
Survivors have bereavement support.	No bereavement support is provided.

EVOLUTION OF HOSPICE CARE

In medieval Europe, hospices were refuges for the sick and dying. The contemporary hospice movement originated in England, where a physician, Dame Cicely Saunders, founded St. Christopher's Hospice in 1967. Dr. Saunders was credentialed as a nurse, social worker, and physician, and she developed a unique program based both on compassion and skillful relief of physical discomfort through around-the-clock analgesics administered by mouth. It had been previously assumed that only injections, administered sparingly, could be used for terminal pain control. In 1974, the first hospice in the United States was established in Branford, Connecticut. Florence Wald, who was then Dean of the Yale School of Nursing, led this movement. Because even in the 1970s, there was concern about saving money by keeping less critical patients out of the hospital and shortening hospital stays, and hospices in the United States came to focus on providing care in the home. To that end, Congress established the permanent Medicare hospice benefit in 1986, with the intention of keeping people at home, yet receiving comprehensive services that are less expensive than hospitalization (National Hospice and Palliative Care Organization, 2015).

Hospice characteristics have changed over time. Initially, nearly all clients suffered from terminal cancer; presently, people with a variety of end-stage diseases are served. Heart and pulmonary diseases, AIDS, Alzheimer's, renal failure, amyotrophic lateral sclerosis (ALS) and other neurological conditions, along with serious strokes, are all potential diagnoses for hospice care (Cummings, 2013). Many diseases that were once quick death sentences have now become chronic, life-limiting diseases. Palliative care, to ease pain and suffering and improve quality of life, can be offered in earlier stages of illness, along with continuing medical treatments. With prognoses difficult to predict and denial of death by the patient and family a continuing issue, some hospice referrals are now made very late in the disease process. Brief hospice stays make it difficult to significantly help families and clients prepare for death. With highly reliable Medicare payment, for-profit hospices have expanded and are competing in many communities for the hospice market share. They grew by 128% between 2001 and 2008; nonprofit hospices only grew by 1% during that time. Many have used aggressive marketing campaigns, and there is a consensus that most serve a higher percentage of patients that require less expensive care, leading to better profit margins (Bouchard, 2011). There is concern that the original purpose of hospice may be lost when profit motives abound. And, a study of hospice expansion found the mean length of hospice stay increased from 72.1 to 92.6 days during roughly the same time period that for-profit hospice growth occurred. Larger Medicare spending was noted, not offset by reduced hospital spending. Explanations for this included poor prognostication in patients, for instance, with Alzheimer's leading to longer hospice experiences and fewer end-of-life hospital expenses (Gozalo, Plotzke, Mor, Miller, & Teno, 2015).

HOSPICE SERVICES AND REIMBURSEMENT

As in home health care, Medicare has determined the way services are provided. The Medicare hospice benefit requires that a client who has a prognosis of 6 months or less must sign up for the comfort-focused hospice benefit and waive regular Medicare health services, except for conditions unrelated to their terminal illness. This mandates that the client acknowledges a terminal prognosis and chooses comfort care instead of life-extending care from a Medicare-approved hospice. When this choice is made, the hospice coordinates care in all settings, functioning both as clinical and financial case manager. The government pays a flat rate to the hospice for each day the patient receives care. There are four payment levels: (1) routine home care with intermittent visits, (2) continuous home care when the patient's condition is acute and death is near, (3) inpatient hospital care for symptom relief, and (4) respite care in a nursing home to relieve family members (CMS, 2015d).

Hospices coordinate home care and direct inpatient care if needed. The emphasis is on palliation, with a focus on physical, psychosocial, and spiritual comfort. A strong emphasis is placed on caring for the entire family. The hospice team includes nurses, physicians, home health aides, physical and occupational therapists, social workers, volunteers, palliative medication and medical equipment specialists, and bereavement counselors. Staff members meet regularly to explore together the challenges of assuring comfort at the end of life. A nurse or physician is available on-call 24 hours a day/7 days a week (CMS, 2015d).

Trained volunteers fill an important need in hospice care. They act as companions to the client when the family must be somewhere else or is away for short respite. They run errands for family members, shop, organize hot meals prepared by friends and neighbors, provide childcare, and perform other services as needed.

HOSPICE AND PALLIATIVE CARE NURSING PRACTICE

The nurse's role is central in the hospice interdisciplinary team. The hospice/palliative care nurse functions as case manager and visits the client more frequently than other members of the team. Nurses work in close collaboration with physicians in the development of a plan of care to assure management of symptoms. This plan of care changes rapidly as the end of life nears. In addition to home visits focusing on palliation and interdisciplinary planning, hospice nurses rotate through 24-hour call 7 days a week to assure continuous availability by telephone and visits for emergent problems reported by client or family. Hospice nursing competencies and challenges are similar to those described for home health nurses, with the added expertise needed to relieve physical and emotional suffering of terminally ill clients and their families. The American Nurses Association (ANA) and the Hospice and Palliative Nurses Association (HPNA) (2014) have established standards of practice for hospice and palliative nursing. Certification of hospice and palliative nursing is available. Palliative care nursing addresses the continuum of patient illness and provides both effective pain management and support, as the patient either prepares for continued life-prolonging treatments or a peaceful and dignified death. It is centered on patients and families, generally begins with life-threatening illness, and ends with family bereavement care. An overview of palliative care nursing standards encompasses the same general standards as home health nursing standards, with specific competencies

delineated (e.g., comfort care, suffering and symptom palliation, support of patient/family throughout illness course, reaffirmation of goals with families during regularly scheduled family meetings, care coordination with interdisciplinary team members).

Hospice caregiving can be illustrated as a tree, strongly rooted in the process of nurses deliberately practicing self-care for themselves (Fig. 32–2). This tree has been drawn to explain the expert competencies of hospice nurses who were interviewed to capture the essence of their practice, as described by Zerwekh (1995, 2006). Each of the hospice nursing practices visualized by the tree diagram is briefly summarized below.

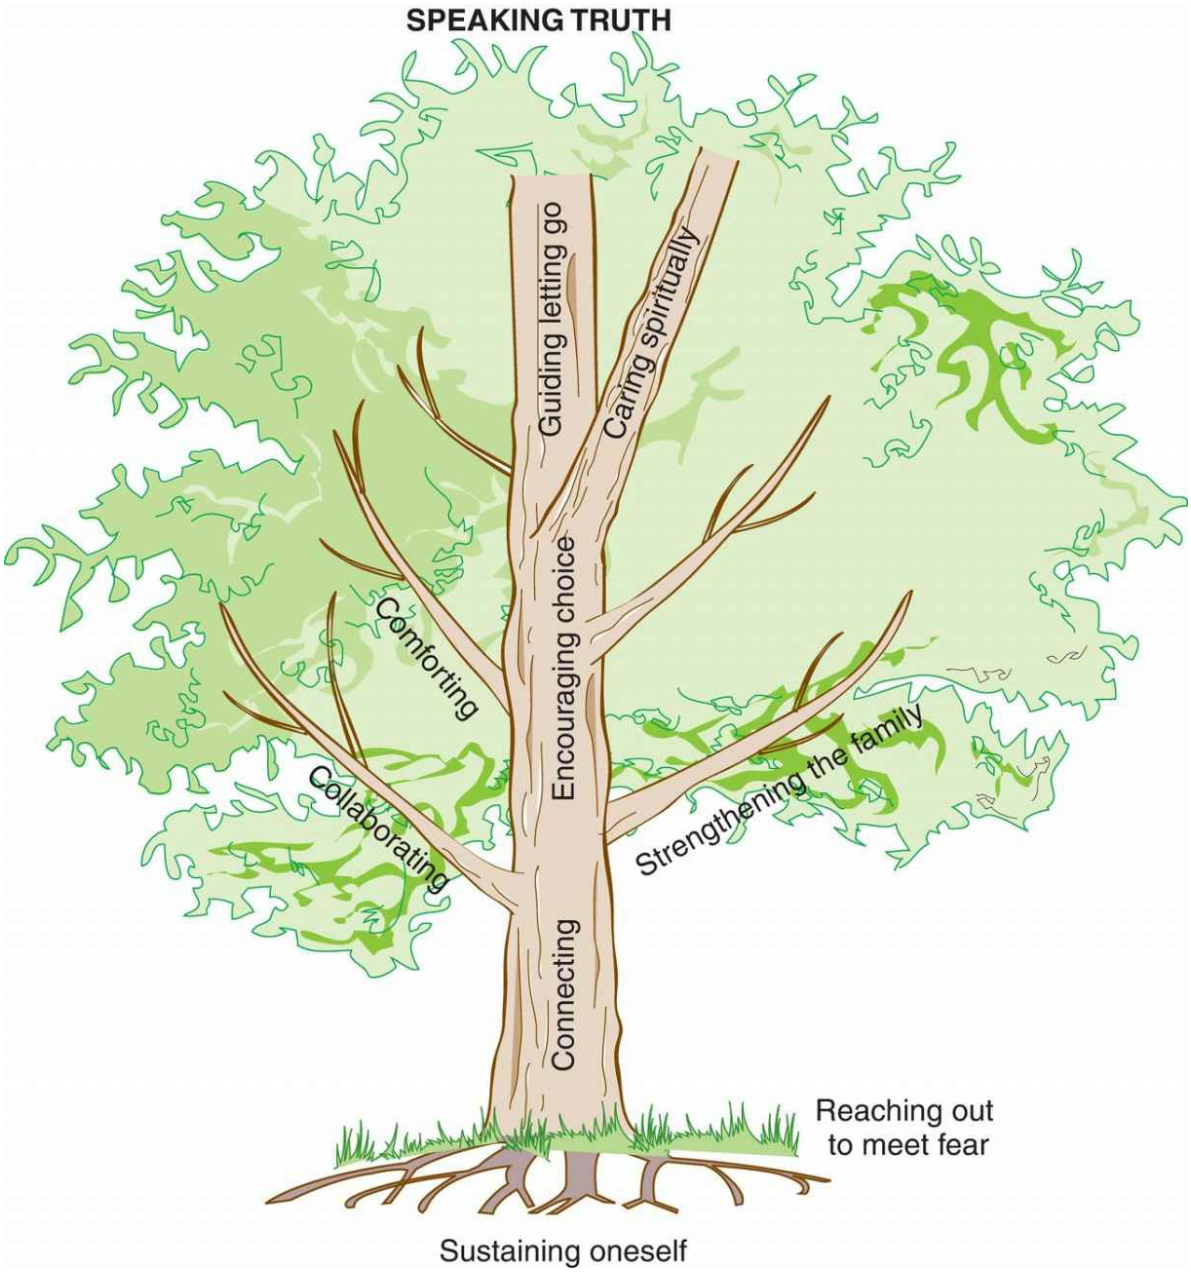

FIGURE 32–2 The hospice caregiving tree.

Roots of Hospice Nursing: Sustaining Oneself

Effective hospice nurses understand that to care for others, they must care for themselves. Without strong healthy roots, the tree will not thrive. *Sustaining oneself* requires deliberate effort to maintain one's own physical, emotional, and spiritual well-being. Knowing oneself, identifying sources of stress, and learning how to care for self are important. Expert hospice nurses keep themselves healthy by maintaining a balance between giving and receiving, letting go of predetermined agendas and idealistic hopes to achieve more than is humanly possible, being emotionally open and clear, and deliberately replenishing themselves to restore their energy. Hospice nurses are constantly giving of themselves and embracing the suffering of their clients. This makes them particularly vulnerable to "compassion fatigue" and burnout (Harris & Griffin, 2015; Slocum-Gori, Hemsworth, Chan, Carson, & Kazanjian, 2011; Wentzel & Bryziewicz, 2014).

The Trunk Reaching Upward: Connecting, Speaking Truth, and Encouraging Choice

Rooted in self-care, hospice nurses practice *connecting*, which refers to the centrality of relationships in providing hospice care. The hospice nurse seeks to understand the emotional and spiritual distress common to the end of life, particularly the progressive experience of loss after loss. Guided by that understanding, hospice nurses emphasize attentive listening to understand each individual's unique story. This requires quieting your own thoughts to truly hear what is being expressed. Sometimes, listening involves simply being present in the moment, paying attention. Having heard the client's story, it is important for hospice nurses to speak honestly when other professionals and family feel obliged to keep being cheerful and positive. Hospice nurses openly seek to speak truthfully about many issues that can be painful to discuss. *Speaking truth* is visualized as encircling the entire top of the caregiving tree. Hospice nurses bring up difficult subjects, so that the client is freed to speak about his greatest fears and concerns. Sometimes, it leads to joint problem solving and *encouraging choice* through informed decision-making (Monsen, Radosevich, Kerr, & Fulkerson, 2011). After truth has been discussed and the client has made a decision, the hospice nurse often advocates for client wishes against the resistance of various authorities. Remember that these are the final decisions in a dying person's life.

Collaborating

Interdisciplinary teamwork is an essential branch on the tree. Hospice team members communicate around the table and are constantly consulting each other, as well as family caregivers (Wittenberg-Lyles et al., 2013). The hospice interdisciplinary team members share information and work interdependently. The hospice nurse coordinates the plan of care and day-to-day efforts to provide physical and psychosocial comfort. The hospice nurse supervises licensed and unlicensed health care personnel to provide symptom control and management of activities of daily living for the terminally ill patient (Kilpatrick, Lavoie-Tremblay, Ritchie, & Lamothe, 2011). The physician is responsible for medical care and serves as liaison with the client's primary care physicians. Social workers, spiritual counselors, physical therapists, pharmacists, and volunteers are integral members of the hospice team as they provide environmental, developmental, and spiritual interventions to aid the patient with psychological peace. The hospice interdisciplinary team is constantly challenged to work creatively together to find solutions for complex end-of-life suffering with emotional, spiritual, and physical components.

Strengthening the Family

The death of a family member causes great disruption for all involved. When family members are in a caregiving role in the home, they experience significant personal suffering. They are vulnerable to physical and emotional illness themselves. The process of taking care involves managing the illness and all practical assistance, seeking information and resources, and preparing for death itself. Family members often are caught up with family issues and struggles with the health care system. An extremely important role in hospice nursing involves strengthening family members' abilities as caregivers. Teaching caregiving requires creative teaching methods and flexibility. Often, the hospice nurse is able to help family members communicate with each other, gather them together, and act as an intermediary if necessary (Mandel & Savoy, 2011).

FEATURE-EVIDENCE-BASED PRACTICE

Nurses and Compassion Fatigue

Do you wonder how hospice nurses sustain compassionate practice as they work day in and day out with suffering patients who always die? Expert hospice nurses embrace the suffering of the client and family and become susceptible to compassion fatigue. Compassion fatigue is often viewed as secondary stress. It is the stress felt by the caregiver from exposure to a traumatization. Nurses often describe this as overload. Although signs of compassion fatigue are individualized, they often include exhaustion and a reduced ability to express empathy for the client. This may result in withdrawal by the nurse emotionally from the client and family, as well as the role of nurse. One study, conducted at a nonprofit hospice in Texas, found that the exposure to "chronic bereavement" experienced by hospice nurses often led to sleep problems and symptoms of depression (Carter, Dyer, & Mikan, 2013, p. e368). Others have noted the spiritual, physical, and mental exhaustion that is part of the cost of caring and the need to set boundaries, take care of themselves through exercise, hobbies, and reflection or sharing stories (Melvin, 2012; Slocum-Gori, Hemsworth, Chan, Carson, & Kazanjian, 2011).

Staying healthy as a hospice nurse requires a high level of self-awareness. The nurse must be aware of the signs and symptoms that they may have a tendency to exhibit. Symptoms are individualized based on how the nurse adapted to stress in the

past. Often they are subject to developmental, spiritual, cultural, and environmental influences. Recognition of the symptoms allows the hospice nurse to institute stress-relieving activities early in the process. According to the Compassion Fatigue Awareness Project (2013), some symptoms that a nurse may experience include

- Isolating oneself; poor self-care (appearance, hygiene)
- Repressed emotions; apathy; mentally/physically exhausted
- Always finding blame with others; many complaints about job/administration
- Substance abuse; compulsive behaviors (e.g., eating, spending, gambling)
- In debt; legal problems; recurrent flashbacks/nightmares; chronic health problems
- Problems concentrating; feeling preoccupied; denies problems

Compassion fatigue can affect an agency, if enough nurses suffer from the problem and nothing is done to assist them. It can cause problems between nurses and administrators, lead to high turnover and absenteeism, and lead to self-perpetuation. Organizations may exhibit these symptoms:

- Poor teamwork; high absentee rates; continually changing coworker relationships
- Challenging/breaking agency rules; aggression among staff members
- Poor task/assignment completion; unable to meet deadlines; lack of flexibility
- Negative feelings toward management; reluctance toward change
- Poor vision of future; not able to believe that improvements can be made

(Compassion Fatigue Awareness Project, 2013)

Compassion fatigue is not isolated to hospice nurses. A review of the literature will show that nurses score higher for compassion fatigue and burnout than many other professions. Those nurses who are both professional and family caregivers (e.g., RN daughter caring for failing mother) are at special risk for compassion fatigue (Ward-Griffin, St-Amant, & Brown, 2011). Often it is noted that caregivers experiencing compassion fatigue are unable to identify it in themselves. What ways can you identify compassion fatigue in others? What recommendations can you make to reduce compassion fatigue for yourself?

Comforting

Hospice nurses develop extensive expertise in pain and symptom management. Contemporary medical/surgical nursing textbooks discuss the essentials in this field, and advanced knowledge is developed through experience, continued education, and reading. Display 32–6 lists fundamental palliative principles, and Display 32–7 identifies four important components of pain relief.

DISPLAY 32.6 FUNDAMENTALS OF PALLIATIVE CARE

- Make no assumptions about what is wrong.
- Believe the patient's report of symptoms.
- Relieve discomfort to the extent that the patient chooses and finds acceptable.
- Investigate the biologic, psychosocial, and spiritual dimensions of discomfort.
- Anticipate symptoms, and relieve them before they occur again.
- Use nursing and complementary (integrative) interventions.
- Become an expert in the use of palliative medication.
- Continually evaluate the effectiveness of interventions.
- Choose the least complex and most manageable interventions that patients and families can manage themselves at home.
- Never give up. Persist in trying different palliative strategies.

DISPLAY 32.7 ESSENTIAL COMPONENTS OF PAIN RELIEF

1. Continually assess the extent of pain and the relief afforded by interventions.
2. Schedule analgesics around the clock to maintain continuous blood levels and prevent the return of pain.
3. Use the least invasive route for analgesic administration, with oral as first

choice.

4. Follow the World Health Organization (2016) three-step ladder:

Step 1 for mild pain: Nonopioid (acetaminophen or NSAID) plus adjuvant such as corticosteroid, antidepressant, anxiolytic, or anticonvulsant

Step 2 for persisting pain: Opioid and nonopioid and/or adjuvant

Step 3 for moderate to severe pain: Strong opioid and nonopioid and/or adjuvant

Source: World Health Organization. (2016). WHO's cancer pain ladder for adults. Retrieved from www.who.int/cancer/palliative/painladder/en

Note: WHO also offers guidelines for persisting pain in children: www.who.int/medicines/areas.quality_safety.guide_perspainchild/en/

Spiritual Practice and Letting Go

As death draws near, spiritual needs intensify, with the final search for meaning, reconciliation, hope, and transcendence beyond the limits of human lived experience (Dillon, Roscoe, & Jenkins, 2012). This is a developmental milestone as well as a spiritual and physical journey. The effect of the journey on the client is also impacted by the environmental and cultural habits and customs the client has experienced through their lifetime. Spirituality is in essence learned behavior and is individually defined by the client (Richardson, 2014). In a multisite study of quality of life for advanced cancer patients being treated with palliative radiation, researchers found that those who used religious and spiritual coping reported improved quality of life on all outcome measures. They also noted that the majority of patients (85%) wanted nurses to attend to their spiritual concerns (Vallurupalli et al., 2012). Hospice nurses recognize spiritual distress and practice spiritual caring interventions that include respect for beliefs and spiritual practices and fostering reconciliation if there is a problem with estrangement from family, friends, and faith tradition. The nurse must remain objective, free from personal beliefs and customs, while they attentively listen to the client and promote life review. Although this is a developmental milestone in the client's life is often perceived to be stressful for the client, and the act of listening often gives them psychological peace. In a qualitative metaethnography, Dillon et al. (2012) uncovered the expressed need of African Americans for hospice care that integrates and emphasizes spiritual support, not merely acceptance or tolerance. Both research studies cited above challenge the hospice nurse to support that spiritual journey so needed by the dying and their family members.

Guiding letting go is a truly unique nursing practice that involves helping the client to let go of former activities and hopes, including life itself. This involves listening to intense emotions and helping the person and family find resolution (Raingruber & Wolf, 2015). Sometimes, it involves participating in a vigil at the bedside of the dying person and encouraging loved ones to say their final words of farewell. It is this action that often is that one thing that gives the client peace. See Perspectives: Hospice/Palliative Care Nursing.

PERSPECTIVES
HOSPICE/PALLIATIVE CARE NURSING

When I graduated from nursing school, I went directly into the intensive care unit. I loved it! I enjoyed the challenge of working intensely with one or two patients, as well as the supportive work environment with my close-knit group of colleagues. With marriage and

children (my first pregnancy resulted in twins), the 12-hour shifts and full-time schedules were more difficult to balance with family life. At first, I dropped down to working one weekend a month. But, with our growing family, it seemed that I would not be able to remain in the ICU. I talked to a friend and learned about our hospital's hospice agency; she enjoyed working there, and I thought I would give it a try. It was a perfect fit for me and for our four boys. People always think of hospice/palliative care as depressing, but I find it to be very fulfilling. I think about it as "joining with a family" at their most vulnerable time. The patients let you in, sharing very personal things about their life with you, and they are grateful for your assistance at this time of transition. It can be a very spiritual experience, and I consider it a privilege to be able to share this time with my patients and their families. The only difficult cases for me are the children; our agency doesn't have a large pediatric hospice, but it is beginning to expand. It is difficult for parents to lose a child, as one would expect. I remember coming home after a long night with a family whose young child lost his long battle with cancer and hosting my 2-year-old's birthday party with family and friends. I couldn't help but think about the contrast —my happy, healthy toddler and the loss of a young boy to cancer. But, I know that I made a difference for that family and child; I am honored to be a hospice/palliative care nurse.

Jessica, Hospice RN

ETHICAL CHALLENGES IN HOSPICE NURSING

The hospice nurse confronts striking ethical challenges at the end of life. As an advocate for the client, the hospice nurse must integrate their own knowledge of the pathophysiology of the disease process with the physiological needs of the dying client while accounting for the psychological and cultural needs of the client and family (Storch, 2015). As client advocates, we, as nurses, must be aware of the ethical challenges surrounding the dying experience. Wide-ranging issues include respect or disregard for client autonomy, relief or disregard for client suffering, and avoidance of killing at the very end of life (Fernandes, 2015). The hospice nurse needs to develop their own knowledge of nursing and medical ethics in order to question the ethical implications of interventions and to advocate for client and family. An example of this is the widely held belief in hospice care that dehydration enhances client comfort. Cohen, Torres-Vigil, Burbach, de la Rosa, & Bruera (2012) conducted a phenomenological study with 84 caregivers and 85 clients regarding the issue of hydration of advanced-cancer patients receiving hospice care. Their findings revealed that patients and their families viewed fluids as enhancing comfort, dignity, and quality of life. Physiologically, as nurses, it is understood that often this is not the case. These findings support the need to tailor individual care based on specific patient needs and family preferences (Cohen et al., 2012). They challenge the hospice nurse to embrace ongoing professional development in order to keep abreast of best practice modalities.

Ethical unrest in the client, family, as well as the nurse is best addressed through the institutional ethics board. This board consists of various disciplines specializing in health care, ethics, legal, and spiritual care. When the nurse is unsure of the ethical ramifications of decisions by the client or family, it is their obligation to bring the case before the board following the procedures of the institution. See Chapter 4 for more on ethics.

THE FUTURE OF HOME HEALTH AND HOSPICE

Given a rapidly expanding population of elders living longer with challenging chronic illnesses, home health and hospice care in the home will soon need to transform into a community-based long-term care system that doesn't discharge after an acute episode or admit only at the very end of life. In response to out-of-control medical inflation, federal and state governments have sought to hold down expenses in all areas, including restrictions on home health and hospice care. However, costs keep rising in step with technologic and pharmacologic innovation and marketing. Containing costs will eventually force a shift in services from expensive institutional and high technology interventions to community-based home services.

The entire model for service provision in the home must change to a health care delivery system that continuously serves those living with disabling and terminal illness to maximize well-being at home, anticipate and prevent crises, and minimize emergent and inpatient interventions. Hospice care is focused on symptom management, not curative interventions. Care revolves around maintenance of quality of life, not necessarily quantity. Clients in hospice care, under Medicare regulations, receive care for symptom management. If care is needed for other health conditions not related to the terminal diagnosis, care is received under their original Medicare benefit. Hospice services should be based on client choice and the reality of a terminal diagnosis. The physician must sign a declaration stating that the terminal diagnosis, if it follows the normal course of the disease process, will cause death in a finite period of time (6 months or less). A sustainable, affordable approach to care in the home requires ongoing case management to coordinate and manage resources with incentives that control cost while assuring quality of life and comfort. The hospice nurse becomes a coordinator of an interprofessional team of health care, spiritual, and community resources. Team members often include volunteers, who, after training, become involved with respite care for the family. Determination of the team members is defined in collaboration with the client and family to allow them independence and minimize the disruption to their individual lifestyle. Although inpatient hospices do exist, the goal of the hospice nurse is to keep the client in their home environment for as long as possible. There is evidence that palliative care may prolong life, and there is a call to make services more available in all settings (e.g., nursing homes, hospitals, homes) in order to provide equitable care for all and to augment the palliative care workforce (Meier, 2011). Nurses, nurse practitioners, and home visiting physicians will need to have the diagnostic and therapeutic resources to monitor physiologic status and intervene in the home. Telehealth and home monitoring will be essential. The focus must change from doing everything possible to prolong physiologic survival to promoting meaningful and comfortable lives. Nurses will have an active role in this process.

The Institute of Medicine (2015) report, *Dying in America: Improving Quality and*

Honoring Individual Preferences Near the End of Life, gives direction for needed changes that put the requirements of patients and families first. The report encourages policy changes and serves as a charge for all of us to advocate for improved social, spiritual, and psychological support and care for those of us nearing the end of our lives. As health care providers, we need to strive to provide compassionate, quality-centered, evidence-based care that is consistent with the wishes of our patients and their families.

FEATURE-POPULATION-FOCUS HOSPICE CARE FOR CHILDREN

Although it may be difficult for a family to accept hospice care for their terminally ill child, there is increasing evidence showing that a pediatric palliative care program reduces stress and worry for caregivers. Also, because medical care is received in a stress-free setting, the quality of life as well as length of life may be increased (Gans et al., 2015). Hospice plays an important role in supporting the child and family in the areas of medical, social, spiritual, and psychological support. The value of this service and underutilization justify research in this area. The National Hospice and Palliative Care Organization is committed to care of the child and family who can benefit from hospice care. They provide professional resources and education, as well as patient education information.

Children with life-threatening illnesses are hospitalized more often and spend more days in the hospital than those whose diseases are not life threatening. Communication between the health care team and education of health care workers can often eliminate these hospitalizations (Nageswaran, Radulovic, & Anania, 2014).

Sanchez Varela et al. (2012) also explored the barriers to the use of hospice by children. In this North Carolina study of hospice organizations, the researchers used quantitative methods to determine the factors contributing to underutilization of hospice services. Factors included lack of trained pediatric nurses, pediatric pharmacy, pediatrician consultation, coordination of care, as well as inconsistent communication between care providers. Other factors of importance were limited referrals and the wishes of the family to continue with curative therapy, which could preclude qualification for hospice services.

Although the studies were conducted in separate countries, similar needs emerged from both studies. Most important to nursing practice is the limited access to ongoing education and the lack of consistent professional experiences with these children and their families. Both of these factors were seen as contributing to

underutilization of services. What can be inferred from these findings is that efforts to maintain a trained hospice workforce with specialized skill in working with children, ongoing opportunities to develop and maintain skills, and wider use of hospice in this population are needed. The identified value of hospice services and the findings of these studies support ongoing research into methods to increase use of these services and the infrastructure to create and maintain a trained workforce.

Do you think most nurses working in hospitals are aware of hospice and palliative care services for children? What could you do to help communicate the availability and effectiveness of hospice services for children with life-threatening illnesses?

SUMMARY

Community/public health nurses have an important role in working with clients who receive home care or hospice services. As the population continues to age, the need for nurses to work with older adults where they live, as they are discharged from acute care settings earlier and earlier and, if they are terminally ill, during their final months and days, will only increase. Services are also needed for clients across the lifespan.

Many types of home care agencies exist: voluntary, proprietary, hospital based, official, homemaker, and hospice. Both formal and informal caregivers provide service. Professional staff members, such as nurses, social workers, therapists, and certified nursing assistants, work in collaboration with family members and, in some situations, with friends and neighbors.

Hospice is a newer concept in the United States, but has a longer history in England. Medicare covers hospice care without the restrictions experienced by nonhospice home care clients. Hospice and palliative care programs provide holistic care to clients during the last months of life. Many programs are home based, and they may be offered by a home health agency. In addition to in-home hospices, inpatient hospices exist; these can be located in a freestanding building, in an area of a SNF, or in a section of an acute care facility. The focus of hospice care is not historically aimed at cure, and it employs holistic caregiving practices that involve family members, professionals, and volunteers.

The nurse provides direct physical nursing care both in home health care and with hospice clients. In addition, the nurse teaches clients, family members, and volunteers; supervises; collaborates with team members; and case manages. Nurse assessment of clients to determine health status and eligibility for additional services as well as service as a client advocate occur with both groups of clients. Determining the frequency and duration of services occurs in home care. With both home care and hospice clients, the nurse must become familiar with the requirements of documentation to promote continuity of care and ensure reimbursement.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Search the Internet for home health and hospice agencies in your city or town. Select two agencies and compare the employment opportunities of each (one nonprofit and one for-profit). How do these job descriptions and the published pay ranges compare to hospitals in your area? What are the benefits of working in home health and hospice? Will the agency hire new graduates, or do they require prior acute care experience?
2. John S., age 58 years, was recently diagnosed with liver cancer following years of heavy alcohol consumption. At the urging of his physician, his wife contacted the local hospice agency for assistance. You have been assigned this case. When you arrive at John's house, his wife tells you that he refuses to see you and is continuing to drink alcohol. She is very distressed and begins to cry. How would you handle this situation? What are some of the issues inherent in this case?
3. Review your personal health insurance policy or that of a family member. What coverage, if any, is provided for home health or hospice care? What restrictions are stated in the coverage—total reimbursement, source of care, or length of service? Do you think this will be adequate to meet your or your family member's needs when these services may be needed? What other options might be available to help defray the cost of this type of care?
4. Interview a home health nurse to find out the most rewarding part of their job. What things are problematic? Ask about a typical case and home visit. How does this compare to your experiences in your community health nursing clinical course? Do you feel that home health nursing might be something you will consider in the future?
5. Interview a nurse working in hospice and palliative care. Have them describe their most memorable cases. Ask if they have noticed signs of compassion fatigue among colleagues. Discuss the signs and symptoms listed in this chapter, and compare with those your interviewee mentions. What do they feel is most rewarding about their work? Consider if this specialty might be a good fit for you.
6. Compare and contrast the roles and functions of home health nurses and those working in hospice/palliative care with acute care (hospital) nursing. What are the main similarities? What differences do you notice?
