To my husband, my children, and my grandchildren—they make it all worthwhile!
This book is dedicated to them and to my parents and my sisters who always encouraged me to keep learning, growing, and believing.

—Cherie Rector

ACKNOWLEDGMENTS

It saddened me that I was unable to continue to work with my dear friend and colleague Dr. Cherie Rector on the ninth edition of this textbook. Her unwavering devotion to public health nursing practice, research, and nursing education has been an inspiration to me over the past decade. Cherie and her team of contributors reflect the best that our specialty practice has to offer. I join her in encouraging all of you to consider practicing in the community at some point in your career. There is no better way to make real and lasting changes to the health and welfare of the public, whether it is locally, nationally, or in the international arena. I would also like to express my gratitude to Dr. Judy Allender. It was she who first gave me the opportunity to join her as a contributor in the sixth edition and to team with Cherie as a coauthor for the seventh and eighth editions. Her mentorship in public health nursing education provided the opportunity for me to share with so many students my passion for this specialty and my belief that there is not a finer career than serving as a PHN.

Kristine D. Warner, PhD, MPH, RN
Assistant Dean and Managing DirectorMEPN Program
University of California, San FranciscoSan Francisco, California

Despite this being the ninth edition of this textbook, it remains a work in progress. Feedback from nursing students and faculty, as well as from working public health nurses, continues to be reflected in this edition of the book. It is hoped that this textbook meets the needs of students and faculty, and continuing comment and reaction is always welcome.

The contributors, both continuing and new to this edition, have worked diligently, and gratitude is owed for sharing their expertise and knowledge. It is also important to acknowledge the work of past contributors whose words may still be found in some form in this ninth edition. I am especially grateful to have worked with Dr. Kristine Warner on the last two editions of this book and appreciate the thought and insight she has always brought to this project. I would also like to acknowledge the work of Dr. Judy Allender, who first gave me the opportunity to contribute to the fifth and sixth editions of this textbook, and then to work with Kris Warner as coauthors on the past two editions.

Editors Shana Murph, Jennifer Forestieri and Christina Burns, as well as the administrative staff at Wolters Kluwer, have worked tirelessly, and their efforts are greatly appreciated. Natalie Silver, who helped with photos/permissions and APA references, was a

valuable member of the team on this edition. I thank her for her efforts and her quick turnarounds.

It would have been impossible to complete this edition without the love and support (not to mention patience) of family, friends, and close colleagues. It is my hope that this textbook may spark an interest in nursing students to explore public health nursing and join us in this great specialty area of nursing!

Cherie Rector, PhD, RN, PHN
Professor Emeritus
Department of Nursing
California State University, Bakersfield
Bakersfield, California

ABOUT THE AUTHOR

Dr. Cherie Rector is a native Californian and an Emeritus Professor in the Department of Nursing at California State University, Bakersfield. While there she served as lead faculty in community health nursing, Director of the School Nurse Credential Program and the RN to BSN Program, helping to develop and revise curriculum in those areas. She also served in an administrative position as Director of Allied Health and the Disabled Students Program at College of the Sequoias. She has also been the Coordinator of the School Nurse Credential Program and the RN to BSN Program at California State University, Fresno, overseeing curriculum development in those areas. Undergraduate teaching areas have included community health nursing, foundations/health assessment, health teaching, and leadership; graduate courses have consisted of community health nursing, research, vulnerable populations, family theories, interprofessional development, and school nursing. She has served as a consultant to school districts and hospitals in the areas of child health, research and evidence-based practice, and has served on various state, local, and national boards and in leadership roles in professional nursing organizations. Over the course of her career, Dr. Rector has practiced in community health and school nursing settings and in acute care neonatal nursing. Her grants, research, publications, and presentations have focused largely on child and adolescent health, school nursing, public health nursing, nursing education, and disadvantaged students. She earned an associate degree in nursing from College of the Sequoias and a bachelor of science in nursing degree from the Consortium of the California State Universities, Long Beach. She completed a master's degree in nursing (Clinical Nurse Specialist, Community Health) and a school nurse credential from California State University, Fresno. Her PhD in educational psychology is from the University of Southern California. She is an active member of the American Public Health Association, the Western Institute of Nursing, and the Association of Community Health Nursing Educators. Dr. Rector and her husband have three grown sons, eight grandsons, and three granddaughters.

PREFACE

Barbara Spradley began the first edition of this book in 1981, and the ninth edition of *Community and Public Health Nursing: Promoting the Public's Health* continues to provide undergraduate nursing students with an introduction to public health and population-focused nursing in the community. Nursing in community settings may include sites such as public health departments, schools, correctional facilities, community-based organizations, churches and parishes, as well as industrial or business settings. Although most newly graduated nurses plan to work in hospital and acute care settings, especially since the bulk of their education has been focused toward that end, it is still important to provide a solid grounding in public and community health nursing. That content is what distinguished university-prepared nurses from hospital or diploma nurses early on, and it remains an important area of practice. Knowledge of public health nursing provides new nurses with a broader focus of patient care (e.g., families, aggregates, communities, populations, and not just individual patients). Even though a new graduate may choose to work in a hospital setting, it is still important for the nurse discharging the patient to have an understanding of the patient's unique circumstances and how to best join with the patient and their family in working to prevent further illness and promote better health. To help students better understand the "whole" patient, throughout this book, students are provided with examples and information that will broaden their knowledge of patients and enable them to provide more effective nursing care—wherever they may choose to be employed. Population-focused tools and interventions are needed in acute care, as infection rates continue to rise and nurse-sensitive outcome indicators are closely monitored. Nonpayment for medical errors or early hospital readmissions is becoming the norm, and nurses are involved in quality improvement and patient safety at all levels of practice and in all practice settings.

In the process of learning about public health nursing, it is hoped that a spark may be lit in those nursing students interested in this nursing specialty and its rich history. Public health nurses often work in a more autonomous practice setting and can have a real impact on the general health status of their communities through large-scale interventions and political advocacy. Nurses working in the community are important role models for social justice and are on the front line of communicable disease prevention and control.

The purpose of this book is to give undergraduate students a solid, basic grounding in public health nursing practice and to introduce them to key populations with whom they may work in the community setting, as well as important public health principles. Entry-level public health nurses may also find it a helpful resource as they begin to familiarize themselves with their unique practice settings and target populations. The nexus of public health nursing lies in the application of public health principles along with nursing science

and practice skills in order to promote health, prevent disease, and protect at-risk populations. Throughout this book, the term *community health nurse* is used interchangeably with *public health nurse* as a description of the practitioner who does not simply "work in the community" (i.e., is physically located outside the hospital setting, in the community), but rather one who has a focus on nursing and public health science that informs their community-based, population-focused nursing practice.

NEW TO THIS EDITION

This edition reflects a continuing effort to try to keep this textbook user-friendly for nursing students, who are entering the world of public health nursing for the first time. The goal is to write in an accessible style with little use of jargon or long passages of dry narrative. Also, a more conversational quality is sought, and the use of examples or features that highlight student, client, practitioner, and instructor perspectives on common issues and problems is used to make this new area more familiar to students. Pertinent examples and case studies are used throughout the book to convey real-life situations and interventions in order to aid students in applying the concepts and principles of public health nursing practice. Storytelling has been shown to be very effective in nursing education, as Patricia Benner and others have noted. These client stories (case studies) can greatly influence learning, especially as the student strives to grasp the art and skill of working with clients in a community setting. The goal of this book is also to provide the most accurate, pertinent, and current information for students and nursing faculty. Experts in various fields and specialty areas of public health nursing, including Homeland Security and the military, as well as veteran's health, have contributed to this edition, in an effort to provide a balanced and complete product. With the addition of over 35 contributors from across the country and countless reviewers, the content reflects a broad spectrum of views and expertise. However, it has been carefully edited to make this a cohesive textbook with a shared commentary.

New Content

- QSEN: Focus on Quality—feature highlights quality and safety concepts in applicable chapters. These include QSEN (Quality and Safety Education for Nurses) concepts related to environmental health and disasters, patient-centered care (family/community; empowerment), teamwork/collaboration (communication; system barriers), EBP/QI/ethics, and data (i.e., tracking the homeless).
- Population-Focus—this feature helps refocus student attention to chapter concepts from a population-focused viewpoint. Although chapter content often contains population-based information, in some chapters, an additional focus on population is needed. Current case studies or examples of effective population-based interventions help make the concept of population-based health more evident and understandable to students.
- LGBT content has been incorporated throughout the text and in some features in an effort to help nursing students to better comprehend and address the needs of this population.
- Veterans Health content has also been the focus of some features (e.g., Case Files, Perspectives), critical thinking activities, and has been added to chapter content in order to better explore this population and the PHN role in serving them.

New Organization

For the ninth edition, population-focused public health nursing and *Healthy People 2020* goals and objectives have been emphasized throughout the text, and additional case studies, perspectives, and examples of evidence-based practice have been added. More visual interest, with photos and new graphics highlighting written content, is incorporated into this edition. Chapter and unit organization is similar, but additional content has been added where needed and some content moved to *thePoint*.

Unit I, Foundations of Community Health Nursing, covers fundamental principles and background about public health nursing. Chapter 1 discusses basic public health concepts of health, illness, wellness, community, aggregate, population, interprofessional collaboration, and levels of prevention. Leading Health Indicators are introduced in this chapter, along with *Healthy People 2020* goals and objectives. In Chapter 2, public health nursing's rich and meaningful history is explored, along with social influences that have shaped our current practice. New features, highlighting PHN examples during different historical phases have been added, along with new photos. Educational preparation and the roles and functions of public health nursing are discussed in both Chapters 2 and 3. Core Public Health Functions are described in Chapter 3, and common settings for public health nursing are introduced, along with the roles of community health nurses, and QUAD Council PHN Competencies. Chapter 4 considers values, ethical principles, and decision making unique to this nursing specialty. Quality and safety are also introduced. Evidence-based practice and research principles relating to community health nursing are discussed, along with the nurse's role in utilizing current research. Community-based participatory research is highlighted. Cultural principles are defined, and the importance of cultural diversity and sensitivity in public health nursing are explained in Chapter 5, as well as cultural assessment and folk remedies. Several cultural groups are highlighted.

Unit II, Public Health Essentials for Community Health Nursing, covers the structure of public health within the health system infrastructure and introduces the basic public health tools of epidemiology, communicable disease control, and environmental health. Chapter 6 examines the economics of health care and compares U.S. outcomes with those of other countries, while also discussing the implications of the Affordable Care Act and the impact of health care reform on community health nursing. It also examines official health agencies and their organizational structures, as well as types of health insurance, and landmark legislation and policies related to public health. Different methods of epidemiologic investigation and research are explored in Chapter 7, along with the PHN's role in epidemiology. Population-focused communicable disease control, immunization programs, and communicable disease investigation are covered in Chapter 8. Important environmental health concepts and assessments are included in Chapter 9, along with public health nursing's role in researching and intervening to promote a healthier environment for all. Prevention is emphasized and an ecological approach is used to address issues of environmental health and safety.

Unit III, Community Health Nursing Toolbox, includes common tools used by the public health nurse to ensure effective practice. Chapter 10 covers communication, collaboration, working with groups, contracting with clients, and the use of informatics and health technology in community health nursing. Big Data, EHRs, mobile health, and GIS, among other technologies, are examined, and examples of technology applications are provided. Health promotion is the focus of Chapter 11, with an emphasis on helping clients and aggregates achieve behavioral change through the application of the levels of prevention, as well as educational and theoretical models. In Chapter 12, the focus is on planning and developing community health programs including the contribution of the QSEN project to community/public health nursing practice. Designing interventions and evaluating outcomes, along with social marketing approaches and grant funding, are examined. Chapter 13 concludes this unit with an explanation of the public health nurse's role in political advocacy and policy making, highlighting examples of PHN and community involvement in addressing policy issues.

Unit IV, The Community as Client, further expands the focus of the public health nurse. Chapter 14 examines common theories and models used in public health nursing practice, with examples of application to practice. Chapter 15 applies the nursing process to communities as clients (contrasted to individual patient focus in acute care). Different types of assessments are discussed, along with sources of data, community diagnoses, and community development. Global health and international nursing are considered in Chapter 16. International agencies, NGOs, and various foundations, along with global health problems/practices, are discussed and are highlighted by real-life case examples and perspectives. Preparedness is examined in Chapter 17, with a closer look at disasters, terrorism, and war. The public health nurse's role in emergency preparedness, disaster management, preventive measures against terrorism, and *Healthy People 2020* objectives are also included in this chapter, along with triage and QSEN considerations during mass casualty incidents and disasters.

Unit V, The Family as Client, introduces the family as an aggregate, and Chapter 18 provides theoretical frameworks to promote healthy families and help nurses to better understand and work with families experiencing dysfunction. Applying the nursing process to families, completing family health assessments, and making home visits are covered in Chapter 19. Helpful tools are provided, and case studies help to emphasize concepts. In Chapter 20, family violence, including child, spousal/intimate partner, and elder abuse, is examined. Other violence affecting families, such as rape, homicide, suicide, and community violence, is also included, along with effective prevention strategies, assessments, interventions, and resources.

Unit VI, Promoting and Protecting the Health of Aggregates with Developmental Needs, provides information about client groups as often aggregated by public health departments. Chapter 21 covers common issues, concerns, and interventions for maternal child clients and their infants (e.g., adolescent pregnancy, risk factors, health services for mothers and infants through preschool). Health problems affecting children and

adolescents (e.g., diabetes, asthma, injuries, communicable disease, substance abuse, preventive programs) are examined in Chapter 22, and the prevention and health promotion concerns of adult women and men are highlighted in Chapter 23, along with the PHN's role. Unique issues facing the older client can be found in Chapter 24 (e.g., common myths, preventive measures, health services, end-of-life care). These chapters build upon the content presented in Unit V, and describe public health nursing efforts with these select population groups.

Unit VII, Promoting and Protecting the Health of Vulnerable Populations, deals with how to best address the needs of the most vulnerable among us. In Chapter 25, the concept of vulnerability is addressed along with theoretical frameworks and effective methods of working with vulnerable clients and populations. In Chapter 26, clients with chronic illnesses and disabilities are discussed, along with the role of the community health nurse working with these clients. Federal legislation and national organizations serving those with disabilities and chronic illnesses are also highlighted. Chapter 27 covers clients and populations with behavioral health problems, such as mental health issues and substance abuse, and provides screening, intervention, and referral resources for PHNs. The homeless population is addressed in Chapter 28, along with factors contributing to homelessness and the role of the community health nurse. Chapter 29 addresses the unique challenges of rural, migrant, and urban populations. It also explores issues of social justice, medically underserved populations, and frontier nursing.

Unit VIII, Settings for Community Health Nursing, examines public and private settings in more depth. Practice options in government-sponsored agencies, such as state and local public health departments, public schools, correctional facilities, and the U.S. Public Health Service are described in Chapter 30. Nurse-led health centers, faith-based nursing, occupational health, and entrepreneurship are included in Chapter 31, which focuses on private agency opportunities for PHNs. These chapters provide overviews of a number of practice options available to both new and experienced nurses. Finally, the important roles of home health and hospice/palliative care nursing, especially given our aging population, are discussed in Chapter 32.

Features of the Text

The ninth edition of *Community and Public Health Nursing: Promoting the Public's Health* includes key features from previous editions as well as new features.

Features continued from previous editions include the following:

- Evidence-Based Practice—this feature incorporates current research examples and how they can be applied to public/community health nursing practice to achieve optimal client, aggregate, and population outcomes.
- From the Case Files—presentation of a scenario/case study, often with student-centered, application-based questions. Emphasizing nursing process, students are challenged to reflect on assessment and intervention in typical, yet challenging, examples of public health nursing practice.
- Levels of Prevention Pyramid boxes enhance understanding of the levels of prevention concepts, basic to community health nursing. Each box addresses a chapter topic, describes nursing actions at each of the three levels of prevention, and is unique to this text in its complexity and comprehensiveness.
- *Healthy People 2020*—highlights pertinent goals and objectives to promote health and is applied to specific populations or problems noted in each of the chapters. Where appropriate, mid-term or 2010 evaluations are included in the text.
- Voices From the Community/Student Voices/Perspectives—this feature is included in most chapters and provides stories (viewpoints) from a variety of sources. The perspective may be from a nursing student, a novice or experienced public health nurse, a faculty member, a policy maker, or a client. These short features are designed to promote critical thinking, help students reflect on commonly held misconceptions about public/community health nursing, and recognize the link between skills learned in this specialty practice and other practice settings, especially acute care hospitals.
- What Do YOU Think?—brief features, scattered throughout the text, used to provoke thought or stir discussion on subject matter that is often unique to public health. Much like an instructor would stop and ask a thought question during lecture, these features encourage the reader to pause and more deeply consider an issue.
- Learning Objectives and Key Terms sharpen the reader's focus and provide a quick guide for mastering the chapter content.
- Summary—includes highlights at the end of each chapter, providing an overview of material covered and serving as a review for study.
- References at the end of each chapter provide classic sources, current research, and a broad base of authoritative information for furthering knowledge on each chapter's subject matter.
- Activities to Promote Critical Thinking—this feature is provided at the close of

each chapter and is designed to challenge students, promote critical thinking and application of chapter content, as well as active involvement in solving community health problems. Internet activities, small group work, and interviews with clients or key community informants or experts are often included.

- Additional Assessment Tools are provided throughout the chapters. They are added to enhance assessment skills with individuals, families, or aggregates/populations.

Community and Public Health Nursing: Promoting the Public's Health, ninth edition, has ancillary resources designed with both students and instructors in mind, available on Web site: thePoint®

- Guided Lecture Notes and PowerPoint Presentations
- Student Quiz Bank
- Journal Articles
- Assignments, Discussion Topics, Case Studies, and Pre-Lecture Quizzes
- Test Generator
- Learning Objectives
- Image Bank

COMPREHENSIVE, INTEGRATED DIGITAL LEARNING SOLUTIONS

We are delighted to introduce an expanded suite of digital solutions to support instructors and students using *Community and Public Health Nursing: Promoting the Public's Health*, ninth edition. Now for the first time, our textbook is embedded into two integrated digital learning solutions—one specific for prelicensure programs and the other for postlicensure—that build on the features of the text with proven instructional design strategies. To learn more about these solutions, visit http://www.nursingeducationsuccess.com/ or contact your local Wolters Kluwer representative.

Lippincott
CoursePoint

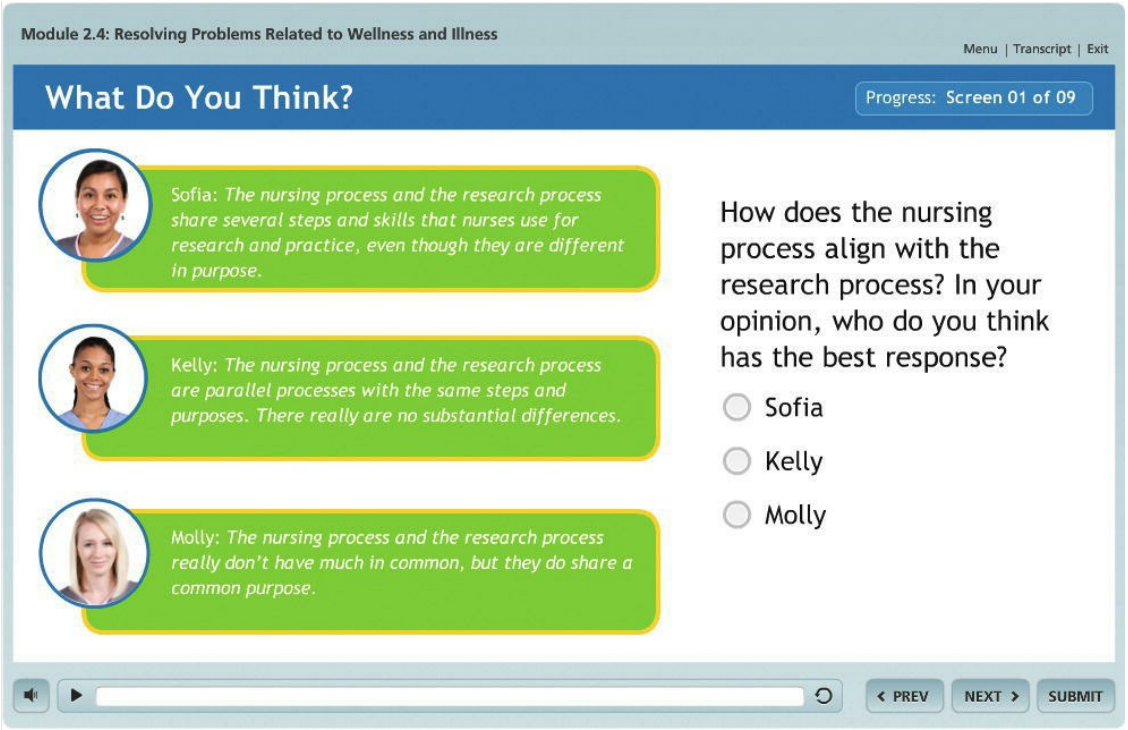
Our prelicensure solution, Lippincott CoursePoint, is a rich learning environment that drives course and curriculum success to prepare students for practice. Lippincott CoursePoint is designed for the way students learn. The solution connects learning to real-life application by integrating content from *Community and Public Health Nursing* with video cases, interactive modules, and evidence-based journal articles. Ideal for active, case-based learning, this powerful solution helps students develop higher-level cognitive skills and asks them to make decisions related to simple-to-complex scenarios.

Lippincott CoursePoint for Community and Public Health Nursing features:

- Leading content in context: Digital content from *Community and Public Health Nursing: Promoting the Public's Health*, ninth edition, is embedded in our Powerful Tools, engaging students and encouraging interaction and learning on a deeper level.
- The complete interactive eBook features annual content updates with the latest evidence-based practices and provides students with anytime, anywhere access on multiple devices.
- Full online access to Stedman's Medical Dictionary for the Health Professions and Nursing ensures students work with the best medical dictionary available.
- Powerful tools to maximize class performance: Additional course-specific tools provide case-based learning for every student:
- Video Cases help students anticipate what to expect as a nurse, with detailed scenarios that capture their attention and integrate clinical knowledge with community and public health concepts that are critical to real-world nursing practice. By watching the videos and completing related activities, students will flex their problem-solving, prioritizing, analyzing, and application skills to aid both in NCLEX preparation and preparation for practice.

- Interactive Modules help students quickly identify what they do and do not understand, so they can study smartly. With exceptional instructional design that prompts students to discover, reflect, synthesize, and apply, students actively learn. Remediation links to the digital textbook are integrated throughout.
- Curated collections of journal articles are provided via Lippincott NursingCenter, Wolters Kluwer's premier destination for peer-reviewed nursing journals. Through integration of CoursePoint and NursingCenter, students will engage in how nursing research influences practice.
- Data to measure students' progress: Student performance data provided in an intuitive display lets instructors quickly assess whether students have viewed interactive modules and video cases outside of class, as well as see students' performance on related NCLEX style quizzes, ensuring students are coming to the classroom ready and prepared to learn.

To learn more about Lippincott CoursePoint, please visit www.nursingeducationsuccess.com/coursepoint



Lippincott
RN to BSN
Online

Lippincott RN to BSN Online: Nursing Research is a postlicensure solution for online and hybrid courses, marrying experiential learning with the trusted content in *Community and Public Health Nursing*, ninth edition.

Built around learning objectives that are aligned to the BSN Essentials and QSEN

nursing curriculum standards, every aspect of Lippincott RN to BSN Online is designed to engage, challenge, and cultivate postlicensure students.

- Self-paced interactive modules employ key instructional design strategies—including storytelling, modeling, case-based and problem-based scenarios—to actively involve students in learning new material and focus students' learning outcomes on real-life application.

- Pre- and postmodule assessments activate students' existing knowledge prior to engaging with the module and then assess their competency after completing the module.
- Discussion board questions create an ongoing dialogue to foster social learning.
- Writing and group work assignments hone students' competence in writing and communication, instilling the skills needed to advance their nursing careers.
- Collated journal articles acquaint students to the body of nursing research ongoing in recent literature.
- Case study assignments, including unfolding cases that evolve from cases in the interactive modules, aid students in applying theory to real-life situations.
- Best Practices in Scholarly Writing Guide covers APA formatting and style guidelines.

Used alone or in conjunction with other instructor-created resources, Lippincott RN to BSN Online adds interactivity to courses. It also saves instructors time by keeping both textbook and course resources current and accurate through regular updates to the content.

CONTENTS

Unit 1 Foundations of Community Health Nursing

CHAPTER 1
The Journey Begins: Introduction to Community Health Nursing

Cherie Rector

Community Health ■ The Concept of Community ■ The Concept of Health ■ Components of Community Health Practice ■ Characteristics of Community Health Nursing

CHAPTER 2
History and Evolution of Community Health Nursing

Cherie Rector and Kristine D. Warner

Historical Development of Community Health Nursing ■ Societal Influences on the Development of Community Health Nursing ■ Preparation for Community Health Nursing

CHAPTER 3
Setting the Stage for Community Health Nursing

Dana Todd

Core Public Health Functions ■ Standards of Practice ■ Roles of Community Health Nurses ■ Settings for Community Health Nursing Practice

CHAPTER 4
Evidence-Based Practice and Ethics in Community Health Nursing

Anne Bongiorno and Cherie Rector

Evidence-Based Practice ■ Steps of the EBP Process ■ Cultivating a Spirit of Inquiry ■ Asking the Question ■ Differences Between EBP Implementation, Quality Improvement, and Research ■ Quantitative and Qualitative Research ■ Understanding Research Basics to Promote EBP ■ Impact of Research on Community Health and Nursing Practice ■ The Community Health Nurse's Role in Research ■ Values and Ethics in Community Health Nursing ■ Values ■ Standards for Behavior ■ Qualities of Values ■ Value Systems ■ Values Clarification ■ Ethics

CHAPTER 5
Transcultural Nursing in the Community
Sheila Adams-Leander
The Meaning of Culture ■ Characteristics of Culture ■ Ethnocultural Health Care Practices ■ Selected Cultural Communities ■ Transcultural Community Health Nursing Principles

Unit 2 Public Health Essentials for Community Health Nursing

CHAPTER 6
Structure and Economics of Community Health Services
Lisabeth M. Searing
Historical Influences on Health Care ■ Public Health Care System Development in the United States ■ Health Organizations in the United States ■ International Health Organizations ■ Significant Legislation ■ The Economics of Health Care ■ Sources of Health Care Financing: Public and Private ■ Trends and Issues Influencing Health Care Economics ■ Health Care Reform ■ Effects of Health Economics on Community Health Practice ■ Implications for Community Health Nursing

CHAPTER 7
Epidemiology in Community Health Care
Betty C. Jung
Historical Roots of Epidemiology ■ Concepts Basic to Epidemiology ■ Sources of Information for Epidemiologic Study ■ Methods in the Epidemiologic Investigative Process ■ Conducting Epidemiologic Research

CHAPTER 8
Communicable Disease Control
Karin L. Lightfoot
Basic Concepts Regarding Communicable Diseases ■ Major Communicable Diseases in the United States ■ Primary Prevention ■ Secondary Prevention ■ Tertiary Prevention ■ Using the Nursing Process for Communicable Disease Control ■ Legal and Ethical Issues in Communicable Disease Control

CHAPTER 9
Environmental Health and Safety

Jeanne M. Leffers

Environmental Health and Nursing ■ Concepts and Frameworks for Environmental Health ■ Core Functions of Public Health

Unit 3 Community Health Nursing Toolbox

CHAPTER 10

Communication and Collaboration in the 21st Century: Informatics and Health Technology in Community Health Nursing

Annmarie Donahue Samar and Colleen Marzilli

Communication in Community Health Nursing ■ Contracting in Community Health Nursing ■ Communicating with Groups ■ Collaboration and Partnerships in Community Health Nursing ■ Health Technology

CHAPTER 11

Health Promotion: Achieving Change Through Education

Dana Todd

Health Promotion through Change ■ Social Determinants of Health ■ Change through Health Education ■ Domains of Learning ■ Learning Theories ■ Characteristics of Effective Instructors ■ Health Teaching Models ■ Teaching at Three Levels of Prevention ■ Effective Teaching ■ Discussion

CHAPTER 12

Planning and Developing Community Programs and Services

Debra J. Millar

Program Planning: The Basics ■ Identifying Group or Community Health Problems ■ Evaluation of Outcomes ■ Models Useful in Program Evaluation ■ Social Marketing ■ Grants

CHAPTER 13

Policy Making and Community Health Advocacy

Susan M. Swider

Health in These United States: How Healthy Are We? ■ Health Policy Analysis ■ Perspectives: Policy Impacts at Local, State, and National Levels ■ Legislative Process at the National Level ■ Policy Analysis for the Public Health Nurse ■ Political Action and Advocacy for PHNs ■ Current U.S. Health Policy Options ■ Power and Empowerment

Unit 4 The Community as Client

CHAPTER 14

Theoretical Basis of Community/Public Health Nursing

Karin L. Lightfoot

When the Client Is a Community: Characteristics of Community/Public Health Nursing Practice ■ Theories and Models for Community/Public Health Nursing Practice ■ Public Health Practice Models ■ Principles of Community/Public Health Nursing ■ Societal Influences on Community-Oriented, Population-Focused Nursing

CHAPTER 15

Community as Client: Applying the Nursing Process

MAJ Lakisha N. Flagg

What is a Healthy Community? ■ Dimensions of the Community as Client ■ The Nursing Process Applied to the Community as Client ■ Community Assessment Methods ■ Sources of Community Data ■ Planning to Meet the Health Needs of the Community ■ Implementing Health Promotion Plans for the Community ■ Evaluating Implemented Community Health Improvement Plan

CHAPTER 16

Global Public Health Nursing: Population Health Around the Globe

Debra J. Millar

A Framework for Global Public Health Nursing ■ The Context ■ The Population ■ Providers of Health Care ■ The Procedures/Interventions ■ Community Health Nursing Opportunities

CHAPTER 17

Being Prepared: Impact of Disaster, Terrorism, and War

Beverly A Dandridge

Disasters ■ Terrorism and Wars

Unit 5 The Family as Client

CHAPTER 18

Theoretical Basis for Promoting Family Health

Mary Ann Drake

Family Health ■ What is Family Health Nursing? ■ Definitions of Family ■ Universal Characteristics of Families ■ Social Class ■ Traditional Families ■ Contemporary

Families ■ Implications for Community Health Nurses

CHAPTER 19
Working with Families: Applying the Nursing Process

Ezra C. Holston

Nursing Process with Families as Clients ■ Planning the Home Visits to Meet the Family Health Needs ■ Using the Nursing Process ■ Family Health Assessment ■ The Family Diagnosis Process ■ Planning and Implementing Education and Health Promotion ■ Evaluating Implemented Family Health Plans ■ Effects of Family Health on Family Members ■ Characteristics of Healthy Families ■ Public Health Nursing Practice Guidelines

CHAPTER 20
Violence Affecting Families

Barbara Joyce

Dynamics and Characteristics of a Crisis ■ History of Family Violence ■ Family Violence Against Children ■ Partner/Spousal Abuse ■ Mistreatment of Elders ■ Other Forms of Family Violence ■ Levels of Prevention: Crisis Intervention and Family Violence ■ Families Facing Violence from Outside the Family ■ Methods of Crisis Intervention ■ Role of the Community Health Nurse in Caring for Families in Crisis

Unit 6 Promoting and Protecting the Health of Aggregates with Developmental Needs

CHAPTER 21
Maternal–Child Health: Working with Perinatal, Infant, Toddler, and Preschool Clients

Katherine Laux Kaiser and Dana Todd

Health Status and Needs of Pregnant Women and Infants ■ Infants, Toddlers, and Preschoolers ■ Health Services for Infants, Toddlers, and Preschoolers ■ Role of the Public and Community Health Nurse

CHAPTER 22
School-Age Children and Adolescents

Peggy H. Anderson

School–Child's Work ■ Health Problems of School-Age Children ■ Adolescent Health ■ Health Services for School-Age Children and Adolescents

CHAPTER 23
Adult Women and Men

Barbara Blake and Gloria Ann Jones Taylor

Demographics of Adult Women and Men ■ Life Expectancy ■ Health Disparities ■ Health Literacy ■ Major Health Problems of Adults ■ Women's Health ■ Men's Health ■ Role of the Community Health Nurse

CHAPTER 24
Older Adults: Aging in Place

Bonnie Callen

Geriatrics and Gerontology ■ Health Status of Older Adults ■ Dispelling Ageism ■ Meeting the Health Needs of Older Adults ■ Levels of Prevention ■ Health Costs for Older Adults: Medicare and Medicaid ■ Elder Abuse ■ Approaches to Older Adult Care ■ Health Services for Older Adult Populations ■ End of Life: Advance Directives, Hospice, and Palliative Care ■ Care for the Caregiver ■ The Community Health Nurse in an Aging America

Unit 7 Promoting and Protecting the Health of Vulnerable Populations

CHAPTER 25
Working with Vulnerable People

Naomi Ervin

The Concept of Vulnerable Populations ■ Vulnerability and Inequality in Health Care ■ Working with Vulnerable Populations

CHAPTER 26
Clients with Disabilities and Chronic Illnesses

Janna L. Dieckmann and Colleen Marzilli

Perspectives on Disability, Chronic Illness, and Health ■ Health Promotion and Prevention Needs of the Disabled and Chronically Ill ■ Civil Rights Legislation ■ Families With a Disabled or Chronically Ill Member ■ Organizations Serving the Needs of the Disabled and Chronically Ill ■ The Role of the Community/Public Health Nurse

CHAPTER 27
Behavioral Health in the Community

Deborah S. Finnell

Defragmenting Health Care ■ Incidence and Prevalence of Mental Disorders, Substance Use, and Substance Use Disorders ■ Mental Health Disorders: Screening, Intervention, and Referral to Treatment ■ Alcohol Use Screening, Intervention, and Referral to Treatment ■ Screening for Drug Use Including Prescription Medication for Nonmedical Reasons ■ Tobacco Screening, Intervention, and Referral to Treatment ■ Community- and Population-Based Interventions ■ Role of the Community Mental Health Nurse

CHAPTER 28
Working with the Homeless

Mary Lashley

Scope of the Problem ■ Health Care and the Homeless ■ Resources to Combat Homelessness ■ Role of the Community Health Nurse

CHAPTER 29
Issues with Rural, Migrant, and Urban Health Care

Cherie Rector, Judith M. Paré and Robin M. White

Definitions and Demographics ■ Population Characteristics ■ Rural Health Issues ■ Migrant Health ■ The Role of Community Health Nurses in Caring for a Mobile Workforce ■ Community Health Nursing in Rural Areas ■ Urban Health ■ Social Justice and Public Health Nursing

Unit 8 Settings for Community Health Nursing

CHAPTER 30
Public Settings for Community Health Nursing

Beverly A Dandridge, Rebecca Doughty and Margaret Oot-Hayes

Public Health Nursing ■ Public Health Funding and Governmental Structures ■ Nursing Roles in Local, State, and Federal Public Health Positions ■ Public Health Nursing Careers ■ Correctional Nursing ■ Correctional Nursing Careers

CHAPTER 31
Private Settings for Community Health Nursing

Mary Ellen Miller, Angelique Lawyer and Carol Pochron

Nurse-Led Health Centers ■ Faith Community Nursing ■ Occupational and Environmental Health Nursing ■ Nurse Entrepreneur in Community/Public Health Nursing

CHAPTER 32

Clients Receiving Home Health and Hospice Care

Elizabeth Wright

Overview of Home Health Care ■ History and Politics of Home Health ■ Home Health Agencies ■ Clients and Their Families ■ Home Health Care Personnel ■ Reimbursement for Home Health Care ■ Home Health Nursing Practice ■ The Future of Care in the Home ■ Overview of the Hospice Movement ■ Evolution of Hospice Care ■ Hospice Services and Reimbursement ■ Hospice and Palliative Care Nursing Practice ■ Ethical Challenges in Hospice Nursing ■ The Future of Home Health and Hospice

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Define community health and distinguish it from public health.
- Explain the concept of community.
- Diagram the health continuum.
- Name 3 of the 10 leading health indicators.
- Discuss ways that public health nursing (PHN) practice is linked to acute care nursing practice.
- Discuss the two main components of community health practice (health promotion and disease prevention).
- Differentiate among the three levels of prevention.
- Describe the eight characteristics of community health nursing.

Opportunities and challenges in nursing are boundless and rapidly changing. You have spent a lot of time and effort learning how to care for individual patients in medical–surgical and other acute care–oriented nursing specialties. Now you are entering a unique and exciting area of nursing—community/public health.

As one of the oldest specialty nursing practices, public health nursing offers unique challenges and opportunities. A nurse entering this field will encounter the complex challenge of working with populations rather than just individual clients and the opportunity to carry on the heritage of early public health nursing efforts with the benefit of modern sensibilities. There is the challenge of expanding nursing's focus from the individual and family to encompass communities and the opportunity to affect the health status of populations. There also is the challenge of determining the needs of populations at risk and the opportunity to design interventions to specifically address their needs. There is the challenge of learning the complexities of a constantly changing health care system and the opportunity to help shape service delivery. Public health nursing is community based and, most importantly, it is population focused. Operating within an environment of rapid change and increasingly complex challenges, this nursing specialty holds the potential to shape the quality of community health services and improve the health of the general public.

You have provided nursing care in familiar acute care settings for the very ill, both young and old, but always with other professionals at your side. You have worked as part of a team, in close proximity, to welcome a new life, reestablish a client's health, or comfort someone toward a peaceful death. Now, you are being asked to leave that familiar acute care setting and go out into the community— into homes, schools, recreational facilities, work settings, parishes, and even street corners that are commonplace to your clients and unfamiliar to you. Here, you will find few or no monitoring devices, charts full of laboratory data, or professional and allied health workers at your side to assist you. You will be asked to use the nontangible skills of listening, assessing, planning, teaching, coordinating, evaluating, and referring. You will also draw on the skills you have learned throughout your acute care setting experiences (e.g., behavioral health nursing, women's, children's, adult health nursing) and begin to "think on your feet" in new and exciting situations. Often, your practice will be solo, and you will need to combine creativity, ingenuity, intuition, and resourcefulness along with these skills. You will be providing care not only to individuals but also to families and other groups in a variety of settings within

the community. Talk about boundless opportunities and challenges! (See Perspectives: Student Voice.)

PERSPECTIVES STUDENT VOICE

I was really terrified when I got to my community health rotation and found that I had to go to people's homes and knock on their doors! I was going to graduate in a few months, and I felt really comfortable in the hospital…. I knew the routines and the machines well. Now, I had to actually find houses and apartments in an area of the city I would normally never venture into! And it wasn't clear to me what I was supposed to do! I didn't have much equipment—a baby scale, a blood pressure cuff, a stethoscope, a thermometer, and a paper tape measure—that was all! I was told to go visit this 16-year-old mother who had a 4-month-old baby and to monitor the baby's progress. I don't even have children! What can I tell her? And, besides, she is a teenager who "knows it all." My clinical instructor told me to "build a relationship with her" and to "gain trust and rapport." That is hard to do when you are scared to death! I was afraid of her responses, of being out in that part of the city alone, and of trying to answer questions without anyone there to turn to. But I wanted to get through nursing school, so I drove over there and knocked on her door. I was shocked to see the condition of the apartment building in which she lived—peeling paint, loud music, trash everywhere, and strange characters at every turn. When she answered the door, she seemed uninterested—or maybe a little defensive. I told her who I was and why I was there, and she motioned me inside and pointed toward the baby, propped up on the tattered couch. I spent the next 15 weeks visiting Anna and her baby: weighing and measuring the baby, doing a Denver II and sharing the results with Anna, helping her schedule appointments for immunizations, listening to Anna's story of abuse and abandonment, and realizing that what I was doing was actually exciting and rewarding. By the end of my rotation, I was truly going to miss Anna and little José! He always smiled at me, and I enjoyed "playing" with him as I instructed her about baby-proofing her apartment, finding resources for food and clothing, and getting birth control. We even talked about how she could finish high school. I thought about Anna and José occasionally,

when young mothers would bring their babies into the emergency department, where I worked after graduation. I learned from my community health nursing rotation that I needed to look beyond the bravado of a teenage mother and try to "connect" with her in order to assure that she would follow through with the antibiotics and antipyretics we were prescribing for her baby's dangerously high fever and serious infection. A year and a half after I graduated, one day when it had been particularly hectic but was now calming down, I glanced up to see Anna and José. She looked so relieved to see me! She was frantic with worry about the serious burn José had on his right hand. The other nurses were mumbling about "child abuse" and how "irresponsible teen mothers always were." I learned that Anna had left José with a neighbor for an hour while she visited a nearby high school to see about getting her GED. The older neighbor was not used to dealing with a busy toddler, and she had left the handle of a pan of refried beans where José could reach it. The team treated José's burn, and I gave Anna instructions for follow-up care. The bond we had developed was still there. She trusted me, and I knew that she would follow through with the instructions. I also knew that the other nurses who were making comments about her did not know Anna's circumstances. I feel that I am a more effective ER nurse because of the things I learned in community health. Someday, when I get tired of the hospital, I may try working as a public health nurse. You never know!

Courtney, Age 25

You may feel that this is too demanding. You may be anxious about how you will perform in this new setting. But perhaps, just perhaps, you might find that this new area is a rewarding kind of nursing—one that constantly challenges you, interests you, and allows you to work holistically with clients of all ages, at all stages of illness and wellness, one that absolutely demands the use of your critical thinking skills. And you may decide, when you finish your public health nursing course, that you have found your career choice. Even if you are not drawn away from acute care nursing, your community health nursing experience will give you a deeper understanding of the people for whom you provide care—where and how they live, the family and cultural dynamics at play, and the problems they will face when discharged from your care. You will also discover myriad community agencies and resources to better assist you in providing a continuum of care for your clients. Finding out begins with understanding the concepts of community and health.

This chapter provides an overview of the basic concepts of community and health, the components of public health practice, and the salient characteristics of contemporary public health nursing practice, so that you can enter this specialty area of nursing in concert with its intentions. The opportunities and challenges of community health nursing will become even more apparent as the chapter progresses. The discussion of the concepts and theories that make public health nursing an important specialty within nursing begins with the broader field of community health, which provides the context for public health nursing

practice.

COMMUNITY HEALTH

Human beings are social creatures. All of us, with rare exception, live out our lives in the company of other people. An Eskimo lives in a small, tightly knit community of close relatives; a rural Mexican may live in a small village with hardly more than 200 members. In contrast, someone from New York City might be a member of many overlapping communities, such as professional societies, a political party, a religious group, a cultural society, a neighborhood, and the city itself. Even those who try to escape community membership always begin their lives in some type of group, and they usually continue to depend on groups for material and emotional support. Communities are an essential and permanent feature of the human experience.

The communities in which we live and work have a profound influence on our collective health and well-being (Muth, 2015). How can community green spaces influence obesity rates in children? A research example may provide some clues. In a population-based study of schoolchildren, researchers in Spain found 11% to 19% lower levels of obesity and overweight, as well as less excessive screen time (TV and gaming), in residential areas that had surrounding green spaces (Dadvand et al., 2014). From the beginning, people have attempted to create healthier communities. Here are three recent examples:

- Before the historic Surgeon General's Report on Smoking and Health, it was common to see people smoking on television, at work, in restaurants, and even in physician offices (CDC, 2011; Kanarek et al., 2011). Since that report linked tobacco to disease and death more than 40 years ago, much has changed in our living spaces. In most states, it is now uncommon to see smoking in public places, and smokers are often relegated to outdoor smoking areas. With the assistance of the Master Settlement Agreement negotiated by state attorneys general and the tobacco industry in 1999, $206 billion has been given to states to promote smoking cessation; create smoke-free environments in the workplace, restaurants, and bars; and develop antismoking public information campaigns; however, during times of budget deficit, some funds were used to balance state budgets (Clark, Sparks, McDonald, & Dickerson, 2011). Along with policy changes and settlements, public awareness has been raised about the harmful effects of secondhand smoke (Kroon, Corelli, Roth, & Hudmon, 2013). However, smoking still causes around 443,000 deaths annually in the United States, and by 2030, it is expected that 10 million people around the world will die annually because of smoking (Clark et al., 2011). Smokers tend to suffer diseases of old age on average 12 years earlier than do nonsmokers, and they also appear physically older (McEwen & Grothier, 2014). Although total U.S. consumption of tobacco products has dropped from 20.9% in 2005 to 17.8% in 2013, and many states have been successful in implementing strategies suggested by the Centers for Disease Control and Prevention (CDC) (e.g., raising prices of tobacco products, enacting laws for smoke-free public spaces, limiting tobacco

advertising while utilizing antismoking campaigns, limiting access to tobacco vending machines or sales to minors, smoking cessation programs and hotlines), more needs to be done in order to reach the *Healthy People 2020* goal of adult cigarette smokers at or below 12% (Jamal et al., 2014). The Surgeon General has recommended further strategies (e.g., lowering nicotine content to nonaddictive levels, placing even greater restrictions on sales of products, and banning some categories of tobacco products completely) (Jamal et al., 2014). Even though 56% of Americans now report that they would like to make smoking in public places illegal, 19% generally oppose an outright ban on smoking, leaving a toehold for tobacco companies to promote the individual's right to choose smoking over the public's right to the health benefits of banning tobacco (Gallup, 2014). Vaping or using e-cigarettes is now being similarly banned in some areas (Moore, Chang, & Larson, 2014).

- More than 26 million American children and adults live with asthma. Evidence of a connection between asthma attacks and community environments has been demonstrated both in the United States and abroad (Iqbal, Oraka, Chew, & Flanders, 2014). Inner-city children have been shown to demonstrate higher rates of asthma, and research has shown strong allergic reactions, especially to rat and cat allergens (Rao et al., 2015). Public health officials note chronic environmental factors as a possible cause for increased asthma cases: pollution from high-traffic areas, secondhand smoke in homes, as well as poor living conditions characterized by dust mites, mold, industrial air pollution, mouse and cockroach droppings, and animal dander. However, research completed at Johns Hopkins University in 2015 counters that claim. Researchers examined records for 23,065 children living in 5,853 census tracts and found asthma prevalence of 12.9% for inner-city children and 10.6% for those living outside of inner cities. When they statistically adjusted for age, gender, region, and race/ethnicity, there was no statistical difference found. They noted that poverty increased the risk of asthma for children (Keet et al., 2015). For 2015, the city named "asthma capital" of the United States was Memphis, Tennessee (Asthma and Allergy Foundation of America [AAFA], 2015). Many of the asthma capitals were in the South, largely owing to the lack of smoke-free legislation in many tobacco-producing states, along with poor air quality and high pollen counts. To further make the case for a connection between environment and asthma, the 1996 Olympics in Atlanta brought an unexpected benefit: a 42% reduction in asthma-related emergency room visits. With the Olympic congestion downtown, Atlanta restricted traffic and thus improved air quality. The same outcomes were experienced with the Beijing Olympics. Internationally, Singapore also noticed a reduction in emergency room visits for asthma after it restricted automobile traffic in its central business district (Li, Wang, Zhang, Lin, & Yang, 2011).
- In a local effort to address the problem of childhood obesity, Santa Clara County—where one in four children are obese or overweight—passed an ordinance that sets standards for toys included with children's restaurant meals. It simply requires that the meals that include the toys meet basic nutritional standards. It does not ban toys.

However, the fast food industry has opposed this effort, as they spend over $360 million on toys that encourage kids and parents to purchase 1.2 billion kids' meals annually. Second only to television advertising targeted to children, the toys given away with kids' meals are a substantial expenditure by the fast food industry. And interestingly, 10 of 12 meals with the highest calorie levels were found to include toys —indicating that these toys are used to market meals to children that may promote obesity (Public Health Institute, 2010). So, lawmakers counter that toys should only be used as an incentive for kids to purchase meals with lower sugar, sodium, fat, and calories; a model ordinance is now available on the Web for other communities to access (Change Lab Solutions, 2015). The community of Santa Clara, and later San Francisco, California, took a stand to improve their environment in order to address a serious health problem that is affecting their population.

Systems theory, advanced by biologist Ludwig von Bertalanffy in the 1940s and modified by Ross Ashby in the 1950s, proposes that systems are open that there is interaction between systems and their environment (European Meeting on Cybernetics and Systems Research [EMCSR], 2012). As systems theory reminds us that a whole is greater than the sum of its parts, the health of a community is more than the sum of the health of its individual citizens. A community that achieves a high level of wellness is composed of healthy citizens, functioning in an environment that protects and promotes health. Public health, as a specialty of nursing practice, seeks to provide organizational structure, a broad set of resources, and the collaborative activities needed to accomplish the goal of an optimally healthy community.

When you work in hospitals or other acute care settings, your primary focus is the individual patient. Patients' families are often viewed as ancillary. Public health, however, broadens the view to focus on families, aggregates, communities, and populations. The community becomes the recipient of service, and health becomes the product. Viewed from another perspective, public health is concerned with the interchange between population groups and their total environment and with the impact of that interchange on collective health. The narrow view of the solitary patient, so common in acute care nursing, is expanded to encompass a much wider vista.

Although many believe that health and illness are individual issues, evidence indicates that they are also community issues and that the world is a community. The spread of the human immunodeficiency virus (HIV) pandemic (nationally and internationally) is a dramatic and tragic case in point, having spread across the globe with 35 million people in 2013 living with HIV/AIDS and an additional 2.1 million new infections annually (AIDS.gov, 2014). Sadly, approximately 19 million do not know that they are infected with the virus. Other community, national, and global concerns include the rising incidence and prevalence of tuberculosis, second in infectious deaths only to HIV/AIDS (World Health Organization [WHO], 2015a), the serious international public health problem of cardiovascular disease (American Heart Association, 2015), the rise in antibiotic

resistance that has led to calls for global treaties to combat resistant strains (Hoffman et al., 2015), terrorism, and pollution-driven environmental hazards. Whereas the United States and other developed nations continue to fight rising rates of obesity, many countries in Africa battle malnutrition and starvation. Communities can influence the spread of disease, provide barriers to protect members from health hazards, organize ways to combat outbreaks of infectious disease, and promote practices that contribute to individual and collective health (American Nurses Association [ANA], 2013; County Health Rankings, 2015; Institute of Medicine [IOM], 2002).

Many different professionals work in community health to form a complex team. The city planner designing an urban renewal project necessarily becomes involved in community health. The social worker providing counseling about child abuse or working with adolescent substance abusers is involved in public or community health. A physician treating clients affected by a sudden outbreak of hepatitis and assisting public health epidemiologists and PHNs to find the source is engaged in public health practice. Prenatal clinics, meals for the elderly, genetic counseling centers, and educational programs for the early detection of cancer all are part of the public health effort.

The professional nurse is an integral member of this team, a linchpin and a liaison between physicians, social workers, government officials, and law enforcement officers. Public health nurses work in every conceivable kind of community agency, from a state public health department to a community-based advocacy group. Their duties range from examining infants in a well-baby clinic to teaching elderly stroke victims in their homes to planning community and population-focused interventions (e.g., marketing campaigns to reduce tobacco use) to carrying out epidemiologic research or engaging in health policy analysis and decision-making. Despite its breadth, however, public health nursing is a specialized practice. It combines all of the basic elements of professional clinical nursing with public health and community practice. Together, we will examine the unique contribution made by community health nursing to our health care system.

Community health and public health share many features. Both are organized community efforts aimed at the promotion, protection, and preservation of the public's health. Historically, as a practice specialty, public health has been associated primarily with the efforts of official or government entities—for example, federal, state, or local tax-supported health agencies that target a wide range of health issues. In contrast, private health efforts or nongovernmental organizations (NGOs), such as those of the American Lung Association or the American Cancer Society, work toward solving selected health problems. The latter augments the former. Currently, community health practice encompasses both approaches and works collaboratively with all health agencies and efforts, public or private, which are concerned with the public's health. In this text, community health practice refers to a focus on specific, designated communities. It is a part of the larger public health effort and recognizes the fundamental concepts and principles of public health as its birthright and foundation for practice.

In the IOM's landmark publication, *The Future of the Public's Health* (1998), the

mission of public health is defined simply as "fulfilling society's interest in assuring conditions in which people can be healthy" (p. 7). (See Perspectives: Public Health Nursing Instructor.) Winslow's classic 1920 definition of public health still holds true and forms the basis for our understanding of community health in this text:

> Public health… is the science and art of preventing disease, prolonging life, and promoting health and efficiency through organized community efforts for the sanitation of the environment, the control of communicable infections, the education of the individual in personal hygiene, the organization of medical and nursing services for the early diagnosis and preventive treatment of disease, and the development of the social machinery to insure everyone a standard of living adequate for the maintenance of health (Clinton County Health Department, n.d., para. 1).

PERSPECTIVES PUBLIC HEALTH NURSING INSTRUCTOR

When I first introduce the topic of public health, I ask students "Why do people end up in the hospital?" Many of them give the usual answers—"They need surgery," "They get in accidents," and the like. Then, I tell them the *Story of Jason*:

"Why is Jason in the hospital? (Because he has a bad infection in his leg.)

But why does he have an infection? (Because he has a cut on his leg and it got infected.) But why does he have a cut on his leg? (Because he was playing in the junkyard next to his apartment building and there was some sharp, jagged steel there that he fell on.)

But why was he playing in a junkyard? (Because his neighborhood is kind of run-down. A lot of kids play there, and there is no one to supervise them.)

But why does he live in that neighborhood? (Because his parents can't afford a nicer place to live.)

But why can't his parents afford a nicer place to live? (Because his Dad is unemployed and his Mom is sick.)

But why was his Dad unemployed? (Because he doesn't have much education and he can't find a job.) But why…?"

And they suddenly become more aware of the complex social and economic issues that affect health (Public Health Agency of Canada, 1999. *Toward a Healthy Future: Second Report on the Health of Canadians*, p. vii.).

More recent and concise definitions of public health include "an effort organized by society to protect, promote, and restore the people's health" (Last, 2014, p. 1) and "the health of the population as a whole rather than medical health care, which focuses on treatment of the individual ailment" (LMAS District Health Department, n.d., para. 1). A Web site sponsored by the Association of Schools of Public Health with support from Pfizer Public Health, *What Is Public Health?* (ASPH, 2015), provides some interesting videos and information about this topic and also proffers this definition:

> Public health protects and improves the health of individuals, families, communities, and populations locally and globally (para. 1).
> The public health field confronts global health issues, such as improving access to health care, controlling infectious disease, and reducing environmental hazards, violence, substance abuse, and injury (para. 3).
> Public health professionals focus on preventing disease and injury by promoting healthy lifestyles. (para. 2).

The core public health functions have been delineated as assessment, policy development, and assurance. These are discussed in more detail in Chapter 3.

Given this basic understanding of public health, the concept of community health can be defined. Community health is the identification of needs, along with the protection and improvement of collective health, within a geographically defined area.

One of the challenges public health practice faces is to remain responsive to the community's health needs. As a result, its structure is complex; numerous health services and programs are currently available or will be developed. Examples include health education, family planning, accident prevention, environmental protection, immunization, nutrition, early periodic screening and developmental testing, school programs, mental health services, occupational health programs, and the care of vulnerable populations. The Department of Homeland Security, for example, is a community health and safety agency developed in the aftermath of the terrorist attacks on New York City and Washington, DC, on September 11, 2001.

Community health practice, a part of public health, is sometimes misunderstood. Even many health professionals think of community health practice in limiting terms such as sanitation programs, health clinics in poverty areas, or massive public awareness campaigns to prevent communicable disease. Although these are a part of its ever-broadening focus, community health practice is much more. To understand the nature and significance of this field, it is necessary to more closely examine the concept of community and the concept of health.

THE CONCEPT OF COMMUNITY

The concepts of community and health together provide the foundation for understanding community health. Broadly defined, a community is a collection of people who share some important feature of their lives. In this text, the term community refers to a collection of people who interact with one another and whose common interests or characteristics form the basis for a sense of unity or belonging. It can be a society of people holding common rights and privileges (e.g., citizens of a town), sharing common interests (e.g., a community of farmers), or living under the same laws and regulations (e.g., a prison community). The function of any community includes its members' collective sense of belonging and their shared identity, values, norms, communication, and common interests and concerns (Anderson & McFarlane, 2015). Some communities—for example, a tiny village in Appalachia—are composed of people who share almost everything. They live in the same location, work at a limited type and number of jobs, attend the same churches, and make use of the sole health clinic with its visiting physician and nurse. Other communities, such as members of Mothers Against Drunk Driving (MADD) or the community of professional nursing organizations, are large, scattered, and composed of individuals who share only a common interest and involvement in a certain goal. Although most communities of people share many aspects of their experience, it is useful to identify three types of communities that have relevance to community health practice: geographic, common interest, and health problem or solution. Unit 4 contains more in-depth information about the community as client.

Geographic Community

A community often is defined by its geographic boundaries and thus is called a geographic community. A city, town, or neighborhood is a geographic community. Consider the community of Hayward, Wisconsin. Located in northwestern Wisconsin, it is set in the north woods environment, far removed from any urban center and in a climatic zone characterized by extremely harsh winters. With a population of approximately 2,300, it is considered a rural community. The population has certain identifiable characteristics, such as age and sex ratios, and its size fluctuates with the seasons: summers bring hundreds of tourists and seasonal residents. Hayward is a social system as well as a geographic location. The families, schools, hospital, churches, stores, and government institutions are linked in a complex network. This community, like others, has an informal power structure. It has a communication system that includes gossip, the newspaper, the "co-op" store bulletin board, and the radio stations. In one sense, then, a community consists of a collection of people located in a specific place and is made up of institutions organized into a social system.

Local communities such as Hayward vary in size. A few miles south of Hayward lay several other communities, including Northwoods Beach and Round Lake; these three, along with other towns and isolated farms, form a larger community called Sawyer County. If a nurse worked for a health agency serving only Hayward, that community would be of primary concern; however, if the nurse worked for the Sawyer County Health Department, this larger community would be the focus. A public health nurse employed by the State Health Department in Madison, Wisconsin, would have an interest in Sawyer County and Hayward, but only as part of the larger community of Wisconsin.

Frequently, a single part of a city can be treated as a community. Cities are often broken down into *census tracts*, or neighborhoods. In Seattle, for example, the district near the waterfront forms a community of many transient and homeless people. In New York City, the neighborhood called Harlem is a community, as is the Haight-Ashbury district of San Francisco.

In community health, it is useful to identify a geographic area as a community. A community demarcated by geographic boundaries, such as a city or county, becomes a clear target for the analysis of health needs. Available data, such as morbidity and mortality figures, can augment assessment studies to form the basis for planning health programs. Media campaigns and other health education efforts can readily reach intended audiences. Examples include distributing educational information on safe sex, self-protection, the dangers of substance abuse, or where to seek shelter from abuse and violence. A geographic community is easily mobilized for action. Groups can be formed to carry out intervention and prevention efforts that address needs specific to that community. Such efforts might include more stringent policies on day care, shelters for battered women, work site safety programs in local hazardous industries, or improved sexuality education in the schools.

Furthermore, health actions can be enhanced through the support of politically powerful individuals and resources present in a geographic community.

On a larger scale, the world can be considered as a global community. Indeed, it is very important to view the world this way. Borders of countries change with political upheaval. Communicable diseases are not aware of arbitrary political boundaries. A person can travel around the world in <24 hours, and so can diseases. Children starving in Africa affect persons living in the United States. Political uprisings in the Middle East have an impact on people in Western countries. Floods or tsunamis in Southeast Asia or volcano eruptions in Iceland have meaning for other national economies. The world is one large community that needs to work together in order to ensure a healthy today and a healthier and safer tomorrow. Global health has become a dominant phrase in international public health circles. Globalization raises an expectation of health for all, for if good health is possible in one part of the world, the forces of globalization should allow it elsewhere and everyone then enjoys the benefits (InterAction, 2013). Governments need to work together to develop a broader base for international relations and collaborative strategies that will place greater emphasis on global health security. We learn more about global health issues and the global community in Chapter 16.

Common-Interest Community

A community also can be identified by a common interest or goal. A collection of people, even if they are widely scattered geographically, can have an interest or goal that binds the members together. This is known as a *common-interest community*. The members of a church in a large metropolitan area, the members of an international nursing professional organization, and families who have lost members to suicide are all common-interest communities. Sometimes, within a certain geographic area, a group of people may develop a sense of community by promoting their common interest. Disabled individuals scattered throughout a large city may emerge as a community through a common interest in promoting adherence to federal guidelines for wheelchair access, parking spaces, toilet facilities, elevators, or other services for the disabled. The residents of an industrial community may develop a common interest in air or water pollution issues, whereas others who work but do not live in the area may not share that interest. Communities form to protect the rights of children, stop violence against women, clean up the environment, promote the arts, preserve historical sites, protect endangered species, develop a smoke-free environment, or provide support after a crisis. The kinds of shared interests that lead to the formation of communities vary widely.

Common-interest communities whose focus is a health-related issue can join with community health agencies to promote their agendas. A group's single-minded commitment is a mobilizing force for action. Many successful prevention and health promotion efforts, including improved services and increased community awareness of specific problems, have resulted from the work of common-interest communities. MADD is one example. In 1980, after a repeat drunk-driving offender killed her 13-year-old daughter Cari, Candace Lightner gathered with a group of outraged mothers at a restaurant in Sacramento, California. Across the country, another mother was soon touched by a similar tragedy. Cindi Lamb's five-and-a-half-month-old infant daughter became a quadriplegic at the hands of a repeat drunk driver. Within a short time, the two women joined forces to form MADD, and 2 years later, President Ronald Reagan organized a Presidential Task Force on drunk driving and invited MADD to participate. With media attention and perseverance, MADD quickly grew to over 100 chapters across the United States and Canada and worked to establish a federal legal minimum drinking age and standard blood alcohol levels of 0.08%, as well as to defend sobriety checkpoints before the Supreme Court. The National Highway Transportation and Safety Administration credited MADD when they released the 1994 figures showing a 30-year low in alcohol-related traffic deaths. Even though our U.S. numbers have dropped considerably, still, in 2013, over 10,000 people were killed and almost 300,000 injured by drunk drivers. MADD now claims more than 3 million members worldwide and is one of the largest and most successful common-interest organizations (MADD, 2015). Similar dangers exist with texting and driving, but the common-interest community has not yet solidified behind this cause as with MADD. About one third of drivers between 18 and 64 admit to texting while

driving, and 341,000 accidents in 2013 resulted from texting while driving. Forty-six states ban texting while driving, but much still needs to be done (Schumaker, 2015).

Community of Solution

A type of community encountered frequently in community health practice is a group of people who come together to solve a problem that affects all of them. The shape of this community varies with the nature of the problem, the size of the geographic area affected, and the number of resources needed to address the problem. Such a community has been called a *community of solution*. For example, a water pollution problem may involve several counties whose agencies and personnel must work together to control upstream water supply, industrial waste disposal, and city water treatment. This group of counties forms a community of solution focusing on a health problem. In another instance, several schools may collaborate with law enforcement and health agencies, as well as legislators and policy makers, to study patterns of substance abuse among students and design possible preventive approaches. The boundaries of this community of solution form around the schools, agencies, and political figures involved. Figure 1–1 depicts some communities of solution related to a single city.

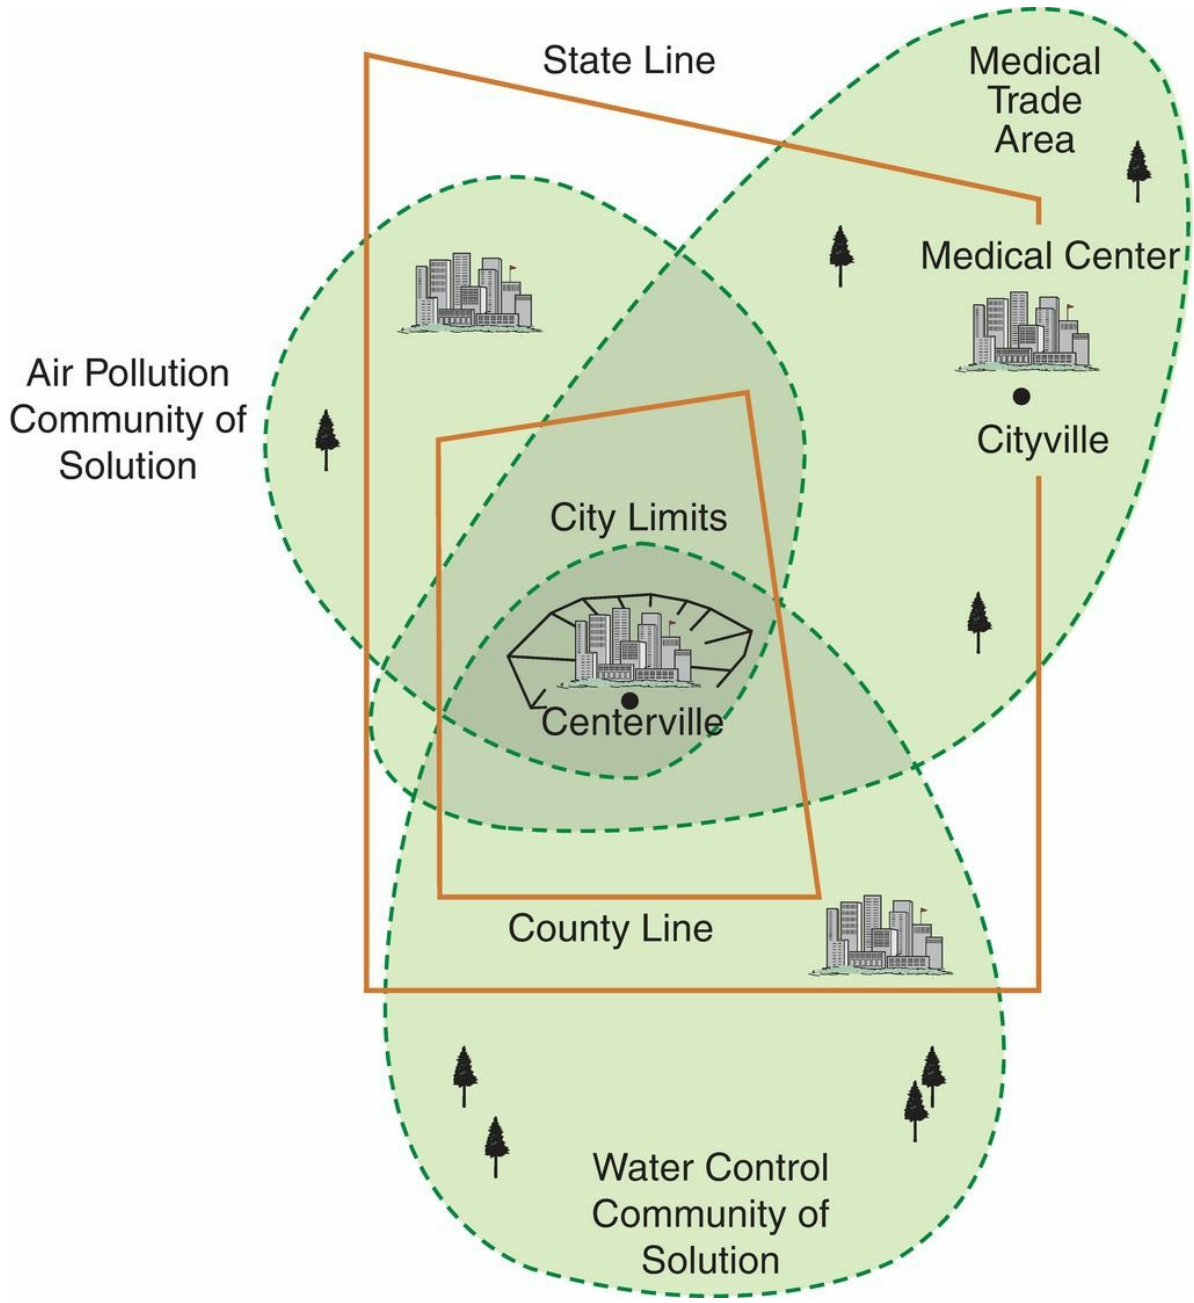

FIGURE 1–1 A city's communities of solution. State, county, and city boundaries (*solid lines*) may have little or no bearing on health solution boundaries (*dashed lines*).

In recent years, communities of solution have formed in many cities to attack the spread of HIV/AIDS and have worked with community members to assess public safety and security and create plans to make the community a safer place in which to live. Public health agencies, social service groups, schools, and media personnel have banded together to create public awareness of dangers that are present and to promote preventive behaviors (e.g., childhood obesity). The 1967 Folsom Report recognized that community problem solving is often hampered by the very administrative and political entities and structures that should be helping. Instead, they often create "barriers to communication and compromise," and thus communities of solution must step in (Griswold, Lesko, & Westfall, for the Folsom Group, 2013, p. 232). More integration of health services (e.g., acute care, ambulatory, community care) to create better value and streamlined services, creation of larger networks, opportunities for partnerships, recognition of existing barriers and environmental hazards, better coordination between community partners and governmental authorities, and sharing of technology and knowledge are all critical components in communities of solution. One example is HeartBeat Connections, a community of solution in a rural area, that acknowledged the most common barriers for clinical cardiovascular disease prevention (e.g., lack of follow-up, lack of time) and organized an interprofessional team using telephone outreach to manage medications and provide counseling and education. They also integrated medical care and public health by connecting clients to farmers' markets, fitness facilities, weight management classes, and other community resources. Another program examined social determinants of health in an inner-city area of Milwaukee to create a chronic disease management program located in food pantries. Nurse-led teams of community health workers and faith-based volunteers

focused on clients with high cholesterol, hypertension, and diabetes (Griswold et al., 2013). A community of solution is an important conduit for change in community health.

Populations and Aggregates

The three types of communities just discussed underscore the meaning of the concept of community: in each instance, a collection of people chose to interact with one another because of common interests, characteristics, or goals. The concept of population has a different meaning. In this text, the term population refers to all of the people occupying an area or to all of those who share one or more characteristics. In contrast to a community, a *population* is made up of people who do not necessarily interact with one another and do not necessarily share a sense of belonging to that group. A population may be defined geographically, such as the population of the United States or a city's population. This designation of a population is useful in community health for epidemiologic study and for collecting demographic data for purposes such as health planning. A population also may be defined by common qualities or characteristics, such as the elderly population, the homeless population, or a particular racial or ethnic group. In community health, this meaning becomes useful when a specific group of people (e.g., homeless individuals) is targeted for intervention; the population's common characteristics (e.g., the health-related problems of homelessness) become a major focus of the intervention.

In this text, the term *aggregate* refers to a mass or grouping of distinct individuals who are considered as a whole and who are loosely associated with one another. It is a broader term that encompasses many different-sized groups. Both communities and populations are types of aggregates. The aggregate focus, or a concern for groupings of people in contrast to individual health care, becomes a distinguishing feature of community health practice. Community health nurses may work with aggregates such as pregnant and parenting teens, elderly adults with diabetes, or gay men with HIV/AIDS. Unit 6 discusses public health nursing with aggregates and Unit 7 discusses vulnerable populations.

Most registered nurses (RNs) in the United States work in hospitals (56% in 2013), revealing a similar percentage in 2004. These nurses most often work with individuals, not aggregates or communities. However, over 14% of RNs work in public or community health and home health settings and have a greater focus on families and communities (Budden, Zhong, Moulton, & Cimiotti, 2013). With health care reform legislation, the nursing workforce in public health, home visitation programs, and nurse-managed health centers is being expanded, and grant funding for nursing faculty and advanced practice nurses is more readily available (American Nurses Association [ANA], 2014). Dr. David Satcher, former U.S. Surgeon General, has remarked:

> Nurses have always been ahead of their time in their focus on prevention and health promotion. As we move toward a more balanced health system with more focus and support for health promotion and disease prevention, the role of nurses will be more significant than ever before. (Delack, 2010)

Because of public health nursing's focus on communities, aggregates, and families, new nursing and health care delivery systems may be developed that are more gainful and effective in preventing health problems that require expensive hospitalizations.

Community health workers, including community health nurses, need to define the community targeted for study and intervention: Who are the people who comprise the community? Where are they located, and what are their characteristics? A clear delineation of the community or population must be established before the nurse can assess needs and design interventions. The complex nature of communities also must be understood. What are the characteristics of the people in terms of age, gender, race, socioeconomic level, and health status? How does the community interact with other communities? What is its history? What are its resources? Is the community undergoing rapid change, and, if so, what are the changes? These questions, as well as the tools needed to assess a community for health purposes, are discussed in detail in Chapter 15.

THE CONCEPT OF HEALTH

Health, in the abstract, refers to a person's physical, mental, and spiritual state; it can be positive (as being in good health) or negative (as being in poor health). Optimal health is defined in a seminal article by a well-known health care consultant as "a dynamic balance of physical, emotional, social, spiritual, and intellectual health" (O'Donnell, 2009, p. iv). In a classic article from 1997, Sarrachi describes health as a "basic and universal human right" (p. 1409). The World Health Organization (WHO) offers a positive explanation of health as "a state of complete physical, mental, and social wellbeing and not merely the absence of disease or infirmity" (WHO, 2015b, para. 1). Our understanding of the concept of health builds on this classic definition. Health, in this text, refers to a holistic state of well-being, which includes soundness of mind, body, and spirit. Community health practitioners place a strong emphasis on wellness, which includes this definition of health, but also incorporate the capacity to develop a person's potential to lead a fulfilling and productive life—one that can be measured in terms of *quality of life*. Today, our health is greatly affected by the lifestyles we lead, the preventive measure we take, and the risk behaviors in which we engage (Chong, Tsunaka, Tsang, Chan, & Cheung, 2011). An individual's behavioral risk factors, such as smoking, physical inactivity, or substance abuse, can be assessed through the use of various interview techniques and questionnaires or surveys (Anderson et al., 2014; Humeniuk et al., 2011). The Behavioral Risk Factor Surveillance Survey, the Youth Risk Behavior Survey, Jackson's Smoking Susceptibility Scale, and the Physical Activity and Nutrition Behaviors Monitoring Form are some examples.

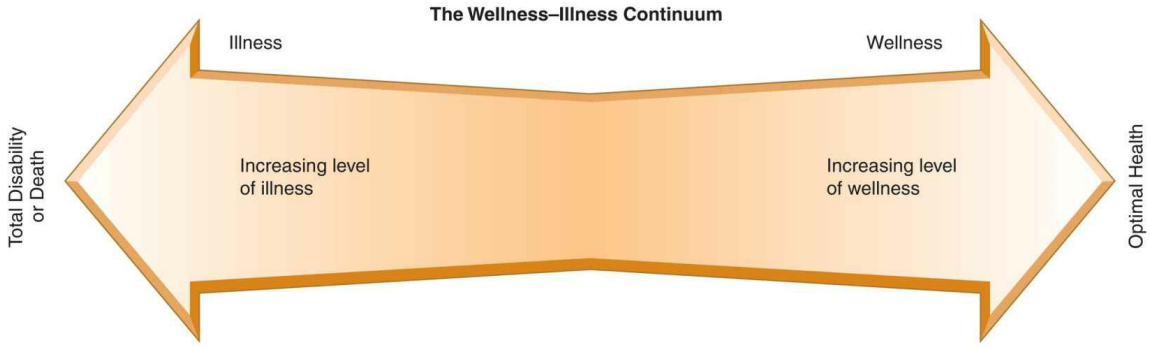
There is an increasing awareness of the strong relationship of health to environment. This is not a new concept. Almost 150 years ago, Florence Nightingale explored the health and illness connection with the environment. She believed that a person's health was greatly influenced by ventilation, noise, light, cleanliness, diet, and a restful bed (Leffers, McDermott-Levy, Smith, & Sattler, 2014). She laid down simple rules about maintaining and obtaining "health," which were written for laywomen caring for family members to "put the constitution in such a state as that it will have no disease" (Nightingale, 1859/1992, preface). The "built environment" is a concept under study by public health and other professionals, as it is well documented that the man-made structures and surroundings in a community (e.g., highways and bike paths, parks and open spaces, public buildings, and housing developments) have an impact on the health of individuals and populations (CDC, 2016a; Hystad et al., 2014; Trowbridge & Schmid, 2013). Environment's relationship to health is discussed in more detail in Chapter 9.

In some cultures, health is viewed differently. Some see it as the freedom from and absence of evil. Illness may be seen as punishment for being bad or doing evil (Galanti, 2013). Many individuals come from families in which beliefs regarding health and illness are heavily influenced by religion, superstition, folk beliefs, or "old wives' tales." This is not unusual, and encountering such beliefs when working with various groups in the

community is common. Chapter 5 explores these beliefs more thoroughly for a better understanding of how health beliefs influence every aspect of a person's life, as well as principles of transcultural nursing in the community.

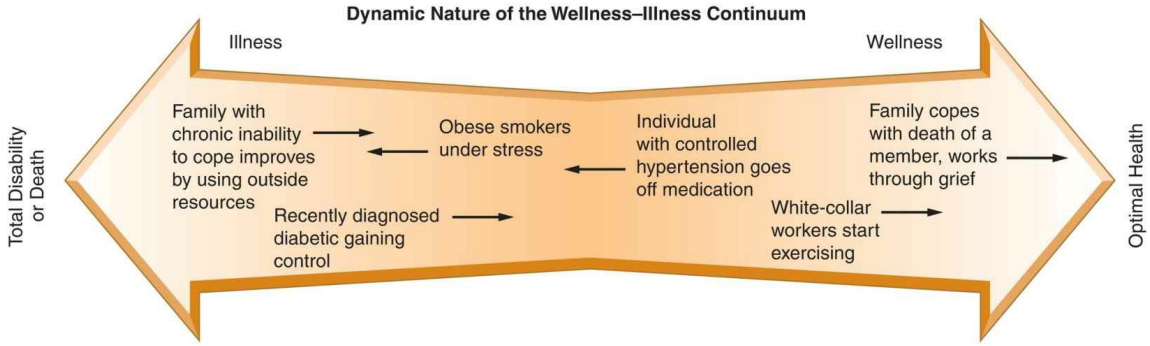
Prerequisites for health were outlined in the WHO (2015b) as "peace, shelter, education, food, income, a stable eco-system, sustainable resources, social justice, and equity" (para. 4). Although health is widely accepted as desirable, the nature of health is often ambiguous. Consumers and providers often define health and wellness in different ways. To clarify the concept for nurses who are considering community health practice, the distinguishing features of health are briefly characterized here; the implications of this concept for professionals in the field can then be examined more fully.

The Health Continuum: Wellness–Illness



Society suggests a polarized or "either/or" way of thinking about health: either people are well or they are ill. Yet, wellness is a relative concept, not an absolute, and illness is a state of being *relatively* unhealthy. The study of factors affecting health and illness is known as epidemiology, and it is discussed in Chapter 7. There are many levels and degrees of wellness and illness, from a robust 75-year-old woman who is fully active and functioning at an optimal level of wellness to a 75-year-old man with end-stage renal disease whose health is characterized as frail. Someone recovering from pneumonia may be mildly ill, whereas a teenaged boy with functional limitations because of episodic depression may be described as mildly well.

The continuum, however, can change. The Human Genome Project, begun in 1990 and completed in 2003, ushered in the genomic era of health care. This project has the potential to move the health continuum toward greater health. *Genomics*, the identification and plotting of human genes and the study of the interaction of genes with each other and the environment, is beginning to alter how we view and treat disease. Intervention services can be individually designed based on genetic findings, and client lifestyle modifications may be recommended from birth—a very powerful type of preventive health care. In the last 10 years, specific genes for about 3,000 mendelian (monogenic) diseases have been discovered, and genetic links between over 900 gene locations and complex traits (multigenic) diseases have been established (Green, Guyer, & National Human Genome Research Institute, 2011). Pharmacogenomics can now, in limited fashion, permit the design of drugs tailored to a person's genetic makeup or to a targeted disease. For example, we now have "rapid genomic analysis" of tumors in a relatively quick period of time (days, not months) and are able to determine the "molecular taxonomy" of the disease along with which treatment is most effective in fighting specific breast cancers (Green et al., 2011, p. 209). This has also shown promise with brain tumors (Carey, 2015). Currently, those with a family history of breast and ovarian cancer are encouraged to look into genetic counseling and testing for BRCA 1/2 mutations, and individuals diagnosed with colon cancer have genetic counseling and testing options to determine if their cancer is an hereditary form called Lynch syndrome. These innovations are already credited with saving lives (U.S. Department of Health and Human Services [USDHHS], 2016b). We may soon be able to identify individuals who may have adverse reactions to medications, based upon their genetic susceptibility, and could create "epigenetic test panels for obesity" (Cordero, Li, & Oben, 2015, p. 361; Green et al., 2011). Already, hundreds of biotech products are in clinical trials, some involving the connection between genetics, microbes, and disease (Furusawa, Horinouchi, Hirasawa, & Shimizu, 2013). The capacity for this new age of health care will be a reality over the next decade, and we must guard against limiting access to this type of care and permitting further disenfranchisement of vulnerable populations while safeguarding information, protecting human subjects, and assuring ethical oversight (Green et al., 2011). Ethical issues such as this will be discussed in more detail in Chapter



4.

Other innovations in epigenetics, the study of human gene activity changes not involving alterations in DNA that can be passed from one generation to the next, may be even more astounding. Epigenetic marks can turn genes off and on and help explain why "environmental factors like diet, stress, and prenatal nutrition can make an imprint on genes… passed from one generation to the next" (Cloud, 2010, para. 8); there is some evidence that a substantial component of risk for metabolic disease (e.g., adult obesity) has a basis in prenatal development (Godfrey et al., 2011). Lifestyle choices like overeating, smoking, and drug use may influence genes that affect obesity and longevity, for instance, to be more strongly or weakly expressed. Drugs have already been developed for some epigenetic marks (e.g., blood malignancies, tumors), and this area of science holds promise in discovering why, for instance, autism is more frequently found in boys or why one twin develops asthma when the other does not. The Human Epigenome Project has begun but will take much more time and technological advances in order to achieve success than the Human Genome Project did. Leaders in the field of epigenetics estimate that it will be another decade before we will be able to determine "how one person's epigenome differs from another" (Powledge, 2015, para. 11).

Because health involves a range of degrees from optimal health at one end to total disability or death at the other (Fig. 1–2), it often is described as a continuum. This health continuum applies not only to individuals but also to families and communities. A nurse might speak of a *dysfunctional family*, meaning one that is experiencing a relative degree of illness or altered functioning; or a healthy family might be described as one that exhibits many wellness characteristics, such as effective communication and conflict resolution, as well as the ability to effectively work together and use resources appropriately. More information on families is included in Unit 5.

The level (degree) of illness increases as one moves toward total disability or death; the level of wellness increases as one moves toward optimal health. This continuum shows the relative nature of health. At any given time a person can be placed at some point along the continuum.

A person's relative health is usually in a state of flux, either improving or deteriorating. This diagram of the wellness-illness continuum shows several examples of people in changing states of health.

FIGURE 1–2 The health continuum.

Likewise, a community, as a collection of people, may be described in terms of degrees of wellness or illness. The health of an individual, family, group, or community moves back and forth along this continuum throughout the lifespan. Healthy people make healthy communities and a healthy society. The Declaration of Alma Ata, which took place in 1978, noted that health is a "fundamental human right" and that the level of health must be raised for all countries in order for any society to improve their health (WHO, 2015c, para. 2).

By thinking of health relatively, as a matter of degree, the scope of nursing practice can be broadened to focus on preventing illness or disability as well as promoting wellness. Traditionally, most health care has focused on treatment of acute and chronic conditions at the illness end of the continuum. Gradually, the emphasis is shifting to focus on the wellness end of the continuum, as outlined in the government document, *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2016a). This effort aims to improve the health of American citizens by establishing objectives and benchmarks that can be monitored over time. There have been Healthy People objectives for 2000, 2010, and now for 2020. The four overarching goals of *Healthy People 2020* are to:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death
- Achieve health equity, eliminate disparities, and improve the health of all groups

- Create social and physical environments that promote good health for all
- Promote quality of life, healthy development, and healthy behaviors across all life stages (para. 5)

These goals overarch the 42 topics and objectives (see Display 1–1). The objectives are stated in measurable terms that specify targeted incidence and prevalence changes and address age, gender, and culturally vulnerable groups along with improvement in public health systems. Progress toward the *Healthy People 2010* objectives has been mixed, with the final report noting that out of 969 original objectives, only 733 had reliable sources of data tracking. Of those final 733 objectives, 23% met or exceeded targets, 48% moved toward the target, 5% showed no change, and 24% actually moved away from the target (CDC, 2013). Whereas our life expectancy has improved and childhood immunization rates have risen, with some advancement toward reducing racial and ethnic disparities, our rates of obesity and diabetes have risen well beyond baseline levels from the previous decade (CDC, 2013). The leading health indicators for *Healthy People 2020*, an outcomes metric for measuring progress toward national public health goals, are found in Display 1–2.

DISPLAY 1.1 ISSUES IN COMMUNITY HEALTH NURSING

The mission of *Healthy People 2020* strives to:

Identify nationwide health improvement priorities.

Increase public awareness and understanding of the determinants of health, disease, and disability and the opportunities for progress.

Provide measurable objectives and goals that are applicable at the national, state, and local levels.

Engage multiple sectors to take actions to strengthen policies and improve practices that are driven by the best available evidence and knowledge

Identify critical research, evaluation, and data collection needs.

Healthy People 2020 Topic Areas

- Access to Health Services
- Adolescent Health

- Arthritis, Osteoporosis, and Chronic Back Conditions
- Blood Disorders and Blood Safety
- Cancer
- Chronic Kidney Disease
- Dementia, including Alzheimer's Disease
- Diabetes
- Disability and Health
- Early and Middle Childhood
- Educational and Community-Based Programs
- Environmental Health
- Family Planning
- Food Safety
- Genomics
- Global Health
- Health Communication and Health Information Technology
- Health-Related Quality of Life and Well-Being
- Health Care–Associated Infections
- Hearing and Other Sensory or Communication Disorders
- Heart Disease and Stroke
- HIV
- Immunization and Infectious Diseases
- Injury and Violence Prevention
- Lesbian, Gay, Bisexual, and Transgender Health
- Maternal, Infant, and Child Health
- Medical Product Safety
- Mental Health and Mental Disorders
- Nutrition and Weight Status
- Occupational Safety and Health
- Older Adults
- Oral Health
- Physical Activity
- Preparedness
- Public Health Infrastructure
- Respiratory Diseases
- Sexually Transmitted Diseases
- Sleep Health
- Social Determinants of Health
- Substance Abuse
- Tobacco Use
- Vision

DISPLAY 1.2 LEADING HEALTH INDICATORS

The leading health indicators are used to measure the health of the nation. There are 26 indicators arranged under 12 general topics. Each of the leading health indicators has one or more objectives from *Healthy People 2010* associated with it. As a group, the leading health indicators reflect the major health concerns in the United States, and progress toward the goals derived from these will be assessed during the 2010–2020 time period. The leading health indicators were selected on the basis of their ability to motivate action, the availability of data to measure progress, and their importance as public health issues. The federal consumer health information Web site, www.healthfinder.gov, is a good starting point for more information on these topics. The Progress Update is available for download at www.healthypeople.gov.

Access to Health Services

- Increase the proportions of persons with health insurance (AHS-1.1).
- Increase the proportion of persons who have a usual primary provider (AHS-3).

Clinical Preventive Services

- Increase the proportion of adults who receive a colorectal cancer screening based on the most recent guidelines (C-16).
- Increase the proportion of adults with hypertension whose blood pressure is under control (HDS-12).
- Reduce the proportion of the diabetic population with an A1c value >9% (D-5.1).
- Increase the proportion of children aged 19 to 35 months who receive the recommended doses of DTaP, polio, MMR, Hib, hepatitis B, varicella, and PCV vaccines (IID-8).

Environmental Quality

- Reduce the number of days the Air Quality Index (AQI) exceeds 100 (EH-1).
- Reduce the proportion of children exposed to secondhand smoke (TU-11.1).

Injury and Violence

- Reduce fatal injuries (IVP-1.1).
- Reduce homicides (IVP-29).

Maternal, Infant, and Child Health

- Reduce all infant deaths (MICH-1.3).
- Reduce total preterm births (MICH-9).

Mental Health

- Reduce the suicide rate (MHMD-1).
- Reduce the proportion of adolescents who experience major depressive episodes (MDEs) (MHMD-41).

Nutrition, Physical Activity, and Obesity

- Increase the proportion of adults who meet current federal physical activity guidelines for aerobic physical activity and muscle strengthening activity (PA-2.4).
- Reduce the proportion of adults who are obese (NWS-9).
- Reduce the proportion of children and adolescents who are considered obese (NWS-10.4).
- Increase total vegetable intake for persons aged 2 years and older (NWS-15.1).

Oral Health

- Increase the proportion of children, adolescents, and adults who visited the dentist in the past year (OH-7).

Reproductive and Sexual Health

- Increase the proportion of sexually active females aged 15 to 44 years who received reproductive health services in the past 12 months (FP-7.1).
- Increase the knowledge of serostatus among HIV-positive persons (HIV-13).

Social Determinants

- Increase the proportion of students who graduate with a regular diploma 4 years after starting ninth grade (AH-5.1).

Substance Abuse

- Reduce the proportion of adolescents using alcohol or any illicit drugs during the past 30 days (SA-13.1).
- Reduce the proportion of adults engaging in binge drinking during the past 30 days (SA-14.3).

Tobacco

- Reduce the number of adults who are current cigarette smokers (TU-1.1).
- Reduce the number of adolescents who smoked cigarettes in the past 30 days (TU-2.2).

What do *you* think?

Life expectancy has risen 40 years since 1900, yet only 7 years of this growth can be attributed to disease care improvements. The remainder of the gain is the result of improvements in prevention and environmental health (e.g., clean water, improved sanitation). Do you think there is a direct link between your health and your environment?

Community health practice ranges across the entire health continuum; it always works to improve the degree of health in individuals, families, groups, and communities. In particular, community health practice emphasizes the promotion and preservation of wellness and the prevention of illness or disability. *Healthy People 2010* and *Healthy People 2020* emphasize that the health of an individual is linked to the health of the larger community and that this larger community's health is related to the health of the corresponding state and ultimately our nation (Barile et al., 2013).

Community characteristics of health have been described by the Centers for Disease Control as health-related quality of life indicators. Early descriptions included such things as rates of poverty and unemployment, levels of high school education and severe work disability, mortality rates, and the proportion of adolescent births (Kanarek et al., 2000). However, even what most people would consider lifestyle choices (e.g., dietary patterns leading to obesity, reduced levels of physical activity, smoking, alcohol consumption) can be strongly influenced by environmental factors. Canada has examined such factors as income distribution, life stress, body mass index (BMI) and dietary practices, smoking and alcohol use, unemployment rate, leisure time physical activity, number of health professionals, as well as the total health expenditures in their list of health indicators (Public Health Agency, 2013). The *Community Health Status Indicators Project* provides county-

level reports related to such things as infectious and chronic diseases, health-related quality of life, behavioral risk factors, vulnerable populations, causes of death, births, and summary measures of health and health disparities (Kanarek, Tsai, & Stanley, 2011). How does the United States compare to other developed countries on population health indicators? (See Chapter 6 for details.) *Partnerships to Improve Community Health* and *Racial and Ethnic Approaches to Community Health (REACH)* are programs designed to focus on population-based interventions and participatory approaches to improve the health of local communities (CDC, 2016b). They provide resources and support for local communities to address the preventable risk factors related to chronic disease, such as poor diet, tobacco use, excessive use of alcohol, and physical inactivity (Largo-Wight, 2011). A healthy community environment is defined as one that "encompasses aspects of human health, disease, and injury that are determined or influenced by factors in the overall environment"; it is important to note the interplay between health and the environment, not just "how health is affected by the direct pathological impacts of various chemical, physical, and biological agents, but also by factors in the broad physical environments" (e.g., urban development, housing, transportation, agriculture, industry) (CDC, 2014, para. 4).

Another description of a healthy community, first described by Cottrell (1976) as a *competent community*, is one in which the various organizations, groups, and aggregates of people making up the community do at least four things:

1. They collaborate effectively in identifying the problems and needs of the community.
2. They achieve a working consensus on goals and priorities.
3. They agree on ways and means to implement the agreed-on goals.
4. They collaborate effectively in the required actions.

Healthy communities and healthy cities impact the health of their populations and vice versa. In the 1980s, the WHO initiated the *Healthy Cities* movement to improve the health status of urban populations. A healthy city is defined as "one that is continually creating and improving those physical and social environments and expanding those community resources that enable people to mutually support each other in performing all functions of life and in developing their maximum potential" (WHO, 2015e, para. 1). The 10 key components of a healthy city are listed in Display 1–3. How many of these are found in your city or community?

DISPLAY 1.3 QUALITIES OF A HEALTHY COMMUNITY

- Equity (lack of disparities)
- A strong economy and employment opportunities (lack of poverty)
- Education
- Health care and preventive health services
- A stable, sustainable ecosystem and environment
- Inclusive, equitable, and broad community participation
- Employ environmental strategies
- Engage multisector participation
- The capacity to assess and address their own health concerns
- Collaboration between partners
- Housing/Shelter
- Civic engagement
- Healthy public policy
- Access to healthy food
- Safety
- Opportunities for active living
- Transportation
- Empowered population
- Healthy child development
- Use data to guide and measure efforts

From Health Resources in Action. (2013, July 25). Defining healthy communities. Boston, MA: Author. Retrieved from http://www.hria.org/uploads/catalogerfiles/defining-healthy-communities/defining_healthy_communities_1113_final_report.pdf

Health as a State of Being

Health refers to a state of being, including many different qualities and characteristics. An individual might be described in terms such as energetic, outgoing, enthusiastic, beautiful, caring, loving, and intense. Together, these qualities become the essence of a person's existence; they describe a state of being. Similarly, a specific geographic community, such as a neighborhood, has many characteristics. It might be characterized by the terms congested, deteriorating, unattractive, dirty, and disorganized. These characteristics suggest diminishing degrees of vitality. A third example might be a population, such as workers involved in a massive layoff, who band together to provide support and share resources to effectively seek new employment. This community shows signs of healthy adaptation and positive coping.

Health involves the total person or community. All of the dimensions of life affecting everyday functioning determine an individual's or a community's health, including physical, psychological, spiritual, economic, and sociocultural experiences. All of these factors must be considered when dealing with the health of an individual or community. The approach should be holistic. A client's placement on the health continuum can be known only if the nurse considers all facets of the client's life, including not only physical and emotional status but also the status of home, family, and work.

When considering an aggregate or group of people in terms of health, it becomes useful for intervention purposes to speak of the "health of a community." With aggregates as well as individuals, health as a state of being does not merely involve that group's physical state but also includes psychological, spiritual, and socioeconomic factors. As an example, the health of the Gulf Coast region is yet to be fully determined after a massive oil-drilling spill in the Gulf of Mexico that has caused losses in fishing, tourism, and wetlands storm protection as a result of the worst oil spill in U.S. history. In 2015, 5 years after the spill, an $18.7 billion settlement was reached (Naylor, 2015). The true impact—including long-term health effects—is hotly contested and will not be known for years. It is another serious blow to this region affecting population health. This oil spill comes 5 years after hurricane Katrina made landfall on the Gulf Coast in August 2005. Widespread damage occurred after the deadliest hurricane since the 1920s with over 80% of the city underwater, and then, only 26 days later, hurricane Rita (the fourth most intense Atlantic hurricane on record) hit near the Texas–Louisiana border causing over $150 billion in damages (Plyer, 2015). The Centers for Disease Control (CDC) estimated that more than 200,000 people converged on evacuation centers, and the country watched in anguish as the Federal Emergency Management Agency (FEMA) struggled to meet the emergency needs of the survivors. Over one million people were displaced and over a million housing units were damaged across the Gulf Coast (Plyer, 2015). At the same time, over 1,800 deaths were attributed to Katrina, and the survivors were left with many physical, emotional, and social difficulties. There were hundreds of chemical and petroleum spills in the Katrina aftermath, and health problems related to contact with polluted water (e.g., rashes, asthma, nausea).

Mold exposure was another environmental hazard, and the temporary housing trailers provided to survivors were found to have high levels of formaldehyde (three times the average household exposure) causing residents to have nosebleeds, respiratory problems, skin rashes, and headaches (Anthamattan & Hazen, 2011). We examine disaster and bioterrorism as it relates to community health nursing in Chapter 17.

Subjective and Objective Dimensions of Health

Health involves both *subjective* and *objective* dimensions; that is, it involves both how people feel (subjective) and how well they can function in their environment (objective). Subjectively, a healthy person is one who feels well and who experiences the sensation of a vital, positive state. Healthy people are full of life and vigor, capable of physical and mental productivity. They feel minimal discomfort and displeasure with the world around them. Again, people experience varying degrees of vitality and well-being. The state of feeling well fluctuates. Some mornings we wake up feeling more energetic and enthusiastic than we do on other mornings. How people feel varies day by day, even hour by hour; nonetheless, how they feel overall is a strong indicator of their overall state of health.

Health also involves the objective dimension of ability to function. A healthy individual or community carries out necessary activities and achieves enriching goals. Unhealthy people not only feel ill but they are limited, to some degree, in their ability to carry out daily activities. Indeed, levels of illness or wellness are measured largely in terms of ability to function (Junehag, Asplund, & Svedlund, 2014). A person confined to bed is labeled sicker than an ill person managing self-care. A family that meets its members' needs is healthier than one that has poor communication patterns and is unable to provide adequate physical and emotional resources. A community actively engaged in crime prevention or in policing of industrial wastes shows signs of healthy functioning. The degree of functioning is directly related to the state of health (see Perspectives: Voices From the Community).

PERSPECTIVES VOICES FROM THE COMMUNITY

I never thought much about being healthy or not, now that you ask. I keep busy, I cook like I'm expecting company, I have a good appetite. I really think all these so-called healthy things people suggest are fads, just so someone can get rich—like tofu and low fat this and that. Don't give me margarine, only butter, … and skim milk, it's like drinking water! I work in my garden, I read, and I eat fresh foods, and don't talk

to me about my smoking, it's the one pleasure I have left.

—Bettie, age 81

The ability to function can be observed. A man dresses and feeds himself and goes to work. Despite financial exigencies, a family nourishes its members through a supportive emotional climate. A community provides adequate resources and services for its members. These performances, to some degree, can be regarded as indicators of health status.

The actions of an individual, family, or community are motivated by their values. Some activities, such as walking and taking care of personal needs, are functions valued by most people. Other actions, such as bird watching, volunteering to help a charity, or running, have more limited appeal. In assessing the health of individuals and communities, the community health nurse can observe people's ability to function but also must know their values, which may contrast sharply with those of the professional. The influence of values on health is examined more closely in Chapter 4.

The subjective dimension (feeling well or ill) and the objective dimension (functioning) together provide a clearer picture of people's health. When they feel well and demonstrate functional ability, they are close to the wellness end of the health continuum. Even those with a disease, such as arthritis or diabetes, may feel well and perform well within their capacity. These people can be considered healthy or closer to the wellness end of the continuum. Figure 1–3 depicts the relationships between the subjective and objective views of health.

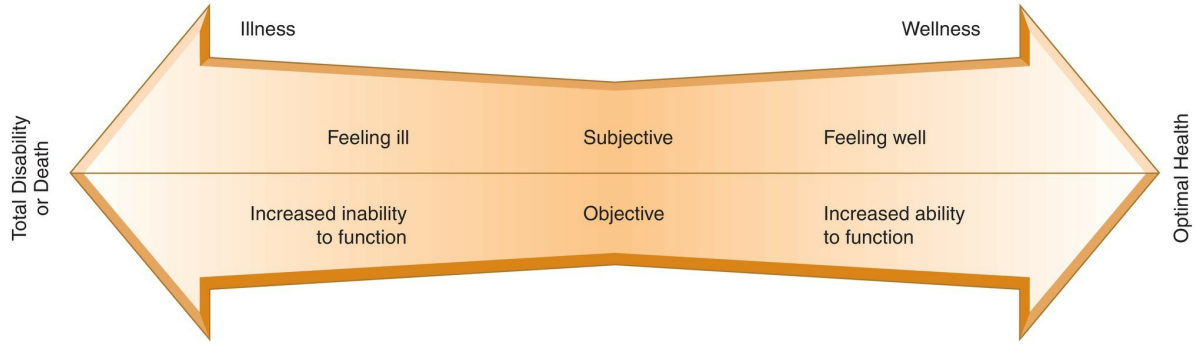

FIGURE 1–3 Subjective and objective views of the wellness–illness continuum.

Continuous and Episodic Health Care Needs

Community health practice encompasses populations in all age groups with birth to death developmental health care needs. These continuous needs may include, for example, assistance with providing a toddler-proof home or establishing positive toilet-training techniques, help in effectively dealing with the progressive emancipation of preteens and teenagers, anticipatory guidance for reducing and managing the stress associated with retirement, or help coping with the death of an aged parent. These are developmental events experienced by most people, and they represent typical life occurrences. The community health nurse has the skills to work at the individual, family, and group level to meet these needs. On an individual and family level, a home visit may be the appropriate place for intervention. If the nurse sees that the community has many young and growing families, and several families have similar developmental issues, a class for mothers and babies, parents and teenagers, or preretirement adults may be formed to meet weekly at the library or health clinic waiting room. In these instances, the nurse works with groups ranging from small to large.

In addition, populations may have a one-time, specific, negative health event, such as an illness or injury that is not an expected part of life. These episodic needs might derive from the birth of an infant with Down's syndrome, a head injury incurred from an automobile crash, or a diagnosis of HIV/AIDS, tuberculosis, or another communicable disease. For instance, in 2014, the CDC raised its response level for the Ebola outbreak in West Africa to its highest alert status. Two Americans who were working with patients there had contracted Ebola and were treated in the United States with an experimental medication (Mundell, 2014). Months later, a nurse in Texas contracted Ebola from her patient who had traveled to West Africa. The patient died, but the nurse survived (McLaughlin & Yan, 2015). See more on communicable diseases in Chapter 8.

In a given day, the community health nurse may interact with clients having either continuous or episodic health care needs, or both. For example, when can parents expect a child with Down's syndrome to begin toilet training? How do middle-aged adults, planning their retirement and preparing for the death of an aged parent, deal with their adult child's AIDS diagnosis? Complex situations such as these may be positively influenced by the interaction with and services of the community health nurse.

COMPONENTS OF COMMUNITY HEALTH PRACTICE

Community health practice can best be understood by examining two basic components—promotion of health and prevention of health problems. The levels of prevention are a key to community health practice.

Promotion of Health

Promotion of health is recognized as one of the most important components of public health and community health practice. Health promotion includes all efforts that seek to move people closer to optimal well-being or higher levels of wellness. Nursing, in particular, has a social mandate for engaging in health promotion (Pender, Murdaugh, & Parsons, 2014). Health promotion programs and activities include many forms of health education—for example, teaching the dangers of drug use, demonstrating healthful practices such as regular exercise, and providing more health-promoting options such as heart-healthy menu selections. Community health promotion, then, encompasses the development and management of preventive health care services that are responsive to community health needs. Wellness programs in schools and industry are examples. Demonstration of such healthful practices as eating nutritious foods and exercising more regularly often is performed and promoted by individual health workers. In addition, groups and health agencies that support a smoke-free environment, encourage physical fitness programs for all ages, or demand that food products be properly labeled underscore the importance of these practices and create public awareness.

The goal of health promotion is to raise levels of wellness for individuals, families, populations, and communities (WHO, 2015d). Community health efforts accomplish this goal through a three-pronged effort to:

1. Increase the span of healthy life for all citizens
2. Reduce health disparities among population groups
3. Achieve access to preventive services for everyone

Specifically, in the 1980s, the U.S. Public Health Service published the Surgeon General's Report, *Healthy People*, and continued with *Promoting Health, Preventing Disease: 1990 Health Objectives for the Nation* and *Healthy People 2000*. The third set of health objectives for the nation, *Healthy People 2010* (CDC, 2015), built on the previous two decades of success in Healthy People initiatives. These documents provide guidance for promoting health as a nation. *Healthy People 2020* carries on this tradition.

The Surgeon General's Report provided vision and an agenda for significantly reducing preventable death and disability nationwide, enhancing quality of life, and greatly reducing disparities in the health status of populations. It emphasized the need for individuals to assume personal responsibility for controlling and improving their own health destiny. It challenged society to find ways to make good health available to vulnerable populations whose disadvantaged state placed them at greater risk for health problems. Finally, it called for an intensified shift in focus from treating preventable illness and functional impairment to concentrating resources and targeting efforts that promote health and prevent disease and disability. The Institute of Medicine's 2001 report, *The Future of the Public's Health in the 21st Century*, notes that the majority of health care spending, "as much as 95%," focuses

on “medical care and biomedical research,” whereas evidence suggests that “behavior and environment are responsible for over 70% of avoidable mortality” and that health care is only one of many “determinants of health” (p. 2).

The implications of this national agenda for health have far-reaching consequences for persons engaged in health care. For centuries, health care has focused on the illness end of the health continuum, but health professionals can no longer justify concentrating most of their efforts exclusively on treating the sick and injured. We now live in an age when it is not only possible to promote health and prevent disease and disability, but it is our mandate and responsibility to do so. (For more on health promotion, see Chapter 11.)

Prevention of Health Problems

Prevention of health problems constitutes a major part of community health practice. Prevention means anticipating and averting problems or discovering them as early as possible in order to minimize potential disability and impairment. It is practiced on three levels in community health: primary prevention, secondary prevention, and tertiary prevention (Pacala, 2015). These concepts recur throughout the chapters of this text, in narrative format and in the Levels of Prevention Pyramids, because they are basic to community health nursing. Once the differences among the levels of prevention are recognized, a sound foundation on which to build additional community health principles can be developed.

Primary prevention obviates the occurrence of a health problem; it includes measures taken to keep illness or injuries from occurring. It is applied to a generally healthy population and precedes disease or dysfunction. Examples of primary prevention activities by a public health nurse include providing childhood vaccinations; encouraging elderly people to install and use safety devices (e.g., grab bars by bathtubs, hand rails on steps) to prevent injuries from falls; teaching young adults healthy lifestyle behaviors, so that they can make them habitual behaviors for themselves and their children; or working through a local health department in consultation with a school district to help control and prevent communicable diseases such as rubeola, poliomyelitis, or varicella by providing regular immunization programs and vaccine oversight.

Primary prevention involves anticipatory planning and action on the part of community health professionals, who must project themselves into the future, envision potential needs and problems, and then design programs to counteract them so that they never occur. A community health nurse who instructs a group of overweight individuals on how to follow a well-balanced diet while losing weight is preventing the possibility of nutritional deficiency (see Levels of Prevention Pyramid). Educational programs that teach safe sex practices or the dangers of smoking and substance abuse are other examples of primary prevention. In addition, when the community health nurse serves on a fact-finding committee exploring the effects of a proposed toxic waste dump on the outskirts of town, the nurse is concerned about primary prevention. The concepts of primary prevention and planning for the future are foreign to many social groups, who may resist on the basis of conflicting values. The Parable of the Dangerous Cliff (Display 1–4) illustrates such a value conflict. How often does our nation put an ambulance at the bottom of the cliff? How cost-effective is that approach?

LEVELS OF PREVENTION PYRAMID

SITUATION: Poor nutritional habits and inactivity are leading to obesity among children and adults and greater incidence of type 2 diabetes.

GOAL: Using the three levels of prevention, negative health conditions are avoided, or promptly diagnosed and treated, and population health is improved.

TERTIARY PREVENTION

	Health Promotion and Education	*Health Protection*
• If diabetic, encourage weight, blood pressure, and cholesterol maintenance, along with good glucose control to prevent complications of diabetes. • Reassess data to determine effectiveness of interventions.	• Teach children and families the importance of maintaining a healthy weight through proper diet and exercise. Promote awareness of dangers of obesity and diabetes through use of PSAs and billboards.	• Provide weight loss support. • Provide access to periodic health care to check A_1C levels and foot and eye exams.

SECONDARY PREVENTION

• Encourage weight loss in obese populations to prevent development of type 2 diabetes. Provide screening programs for high-risk groups. • Refer clients with high glucose or other problems (e.g., hypertension, high cholesterol) to primary care provider or diabetes clinics.	• Initiate educational and incentive programs to improve dietary practices. • Teach clients (individuals or families) on a one-to-one basis to modify dietary practices and activity levels.

PRIMARY PREVENTION

• Provide nutrition educational programs to promote awareness at schools, work sites, etc. • Encourage restaurants and schools to offer healthy menu items. • Recommend nutrition classes offered at neighborhood centers or health care facilities	• Promote physical fitness, nutritional, and wellness activities. • Work with local entities to reduce easy access to sodas, tax high-calorie foods, and provide easier access to fresh fruits and vegetables, as well as provide bike paths and walking clubs.

DISPLAY 1.4 PARABLE OF THE DANGEROUS CLIFF

Twas a dangerous cliff, as they freely confessed,

Though to walk near its crest was so pleasant;
But over its terrible edge there has slipped
A duke, and full many a peasant.
The people said something would have to be done
But their projects did not at all tally.
Some said, “Put a fence around the edge of the cliff”;
Some, “an ambulance down in the valley.”
The lament of the crowd was profound and was loud,
As their hearts overflowed with their pity;
But the cry of the ambulance carried the day
As it spread through the neighboring city.
A collection was made to accumulate aid
And the dwellers in highway and alley
Gave dollars or cents not to furnish a fence
But “an ambulance down in the valley.”
“For the cliff is all right if you’re careful,” they said.
“And if folks ever slip and are dropping,
It isn’t the slipping that hurts them so much
As the shock down below when they’re stopping.”

So for years (we have heard), as these mishaps occurred,
Quick forth the rescuers sally,
To pick up the victims who fell from the cliff,
With the ambulance down in the valley.
Said one in his plea, "It's a marvel to me
That you'd give so much greater attention
To repairing results than to curing the cause;
You had much better aim at prevention.
For the mischief, of course, should be stopped at its source,
Come neighbors and friends, let us rally.
It is far better sense to rely on a fence
Than an ambulance down in the valley."
"He is wrong in his head," the majority said;
"He would end all our earnest endeavor.
He's a man who would shirk this responsible work,
But we will support it forever.
Aren't we picking up all, just as fast as they fall, and giving them care liberally?
A superfluous fence is of no consequence,
If the ambulance works in the valley."
The story looks queer as we've written it here,
But things oft occur that are stranger.
More humane, we assert, than to care for the hurt,
Is a plan for removing the danger.
The very best plan is to safeguard the man,
And attend to the thing rationally;
To build up the fence and try to dispense
With the ambulance down in the valley.
Better still! Cut down the hill!

Adapted from Malins, J. (1896). Fence or ambulance? Journal of Education, 76(11), 291.

Secondary prevention involves efforts to detect and treat existing health problems at the earliest possible stage, when disease or impairment is already present. Hypertension and cholesterol screening programs in many communities help to identify high-risk individuals

and encourage early treatment to prevent heart attacks or stroke. Other examples are encouraging breast and testicular self-examination, regular mammograms, and Pap smears for early detection of possible cancers and providing skin testing for tuberculosis (in infants at 1 year of age and periodically throughout life, with increasing frequency for high-risk groups). Secondary prevention attempts to discover a health problem at a point when intervention may lead to its control or eradication. This is the goal behind testing of water and soil samples for contaminants and hazardous chemicals in the field of community environmental health. It also prompts community health nurses to watch for early signs of child abuse in a family, emotional disturbances among widows, or alcohol and drug abuse among adolescents.

Tertiary prevention attempts to reduce the extent and severity of a health problem to its lowest possible level, so as to minimize disability and restore or preserve function. Examples include treatment and rehabilitation of persons after a stroke to reduce impairment, postmastectomy exercise programs to restore functioning, and early treatment and management of diabetes to reduce problems or slow their progress. The individuals involved have an existing illness or disability whose impact on their lives is lessened through tertiary prevention. In community health, the need to reduce disability and restore function applies equally to families, groups, communities, and individuals. Many groups form for rehabilitation and offer support and guidance for those recuperating from some physical or mental disability. Examples include Alcoholics Anonymous, halfway houses for psychiatric patients discharged from acute care settings, ostomy clubs, and drug rehabilitation programs. In broader community health practice, tertiary prevention is used to minimize the effects of an existing unhealthy community condition. Examples of such prevention are insisting that businesses provide wheelchair access, warning urban residents about the dangers of a chemical spill, and recalling a contaminated food or drug product. When a community experiences a disaster such as an earthquake, a fire, a hurricane, or even a terrorist attack, preventing injuries among the survivors and volunteers during rescue is another example of tertiary prevention—eliminating additional injury to those already experiencing a tragedy.

Health assessment of individuals, families, and communities is an important part of all three levels of preventive practice. Health status must be determined to anticipate problems and select appropriate preventive measures. Community health nurses working with young parents who themselves have been victims of child abuse can institute early treatment for the parents to prevent abuse and foster adequate parenting of their children. If the assessment of a community reveals inadequate facilities and activities to meet the future needs of its growing senior population, agencies and groups can collaborate to develop the needed resources.

Health problems are most effectively prevented by maintenance of healthy lifestyles and healthy environments. To these ends, community health practice directs many of its efforts to providing safe and satisfying living and working conditions, nutritious food, and clean air and water. This area of practice includes the field of preventive medicine, which is a

population-focused, or community-oriented, branch of medical practice that incorporates public health sciences and principles (American Board of Medical Specialties, n.d.).

CHARACTERISTICS OF COMMUNITY HEALTH NURSING

As a specialty field of nursing, community health nursing adds public health knowledge and skills that address the needs and problems of communities and aggregates and focuses care on communities and vulnerable populations. Public health nursing is grounded in both public health science and nursing science, which makes its philosophical orientation and the nature of its practice unique. It has been recognized as a subspecialty of both fields. Recognition of this specialty field continues with a greater awareness of the important contributions made by community health nursing to improve the health of the public.

Knowledge of the following elements of public health is essential to community health nursing (ANA, 2013; Swider, Krothe, Reyes, & Cravetz, 2013):

- Priority of preventive, protective, and health-promoting strategies over curative strategies (see Chapters 11 and 12)
- Means for measurement and analysis of community health problems, including epidemiologic concepts and biostatistics (see Chapter 7)
- Influence of environmental factors on aggregate health (see Chapter 9)
- Principles underlying management and organization for community health, because the goal of public health is accomplished through organized community efforts (see Chapter 15)
- Public policy analysis and development, along with health advocacy and an understanding of the political process (see Chapter 13)

Confusion over the meaning of "community health nursing" arises when it is defined only in terms of where it is practiced. Because health care services have shifted from the hospital to the community, many nurses in other specialties now practice in the community. Examples of these practices include home health care, community mental health, geriatric nursing, long-term care, and occupational health. Although community health nurses today practice in the same or similar settings, the difference lies in applying the public health principles to large groups and communities of people—or having a population focus (Fig. 1–4). For nurses moving into this field of nursing, it requires a shift in focus—from individuals to a broader focus on aggregates and populations. Nursing and other theories undergird its practice (see Chapter 14), and the nursing process (incorporated in Chapters 15 and 19) is one of its basic tools (see the levels of prevention discussed earlier).

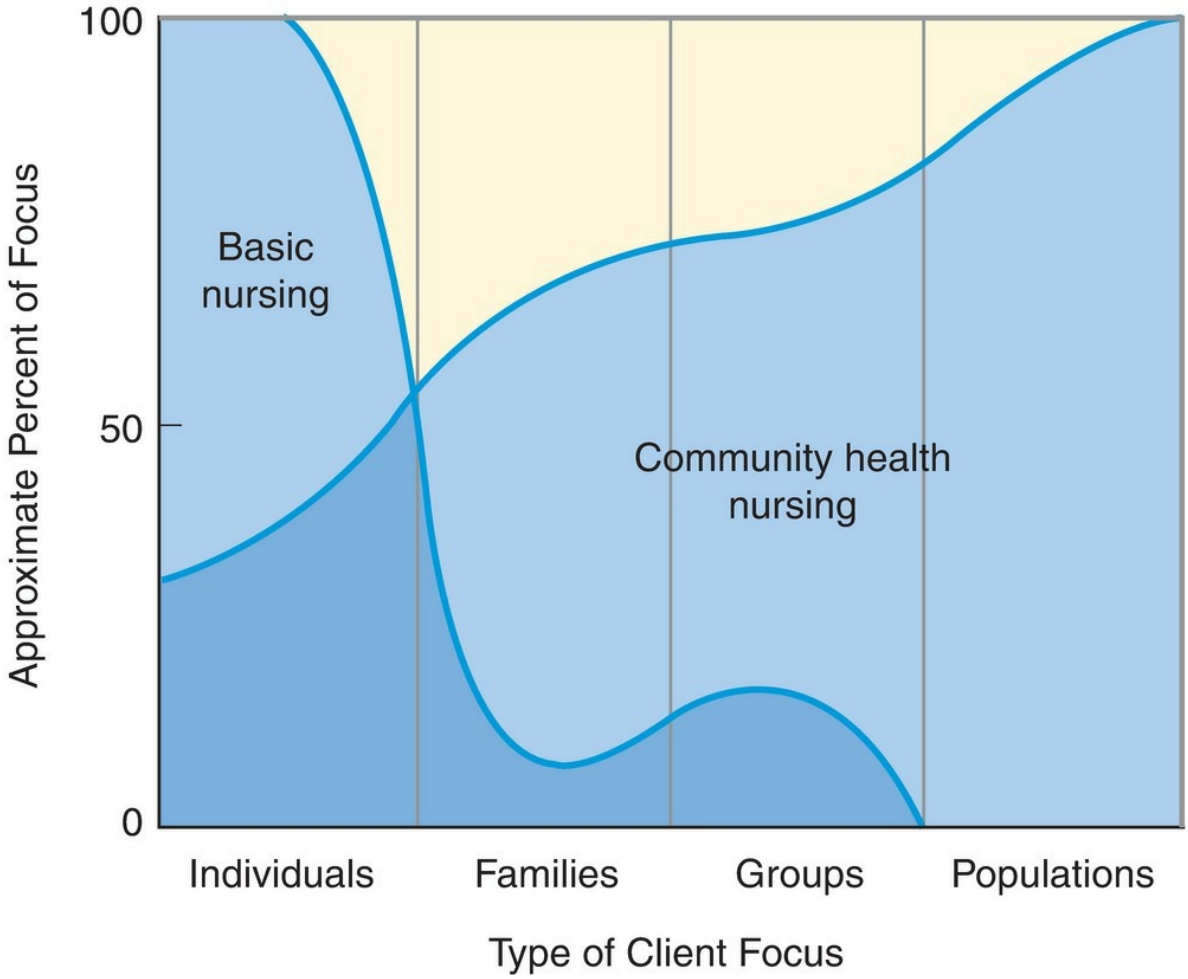

FIGURE 1–4 Difference in client focus between basic nursing and community health nursing.

Community health nursing, then, as a specialty of nursing, combines nursing science with public health science to formulate a community-based and population-focused practice (Anderson & McFarlane, 2015). "Public health nursing practice focuses on population health through continuous surveillance and assessment of the multiple determinants of health with the intent to promote health and wellness; prevent disease, disability, and premature death; and improve neighborhood quality of life" (ANA, 2013, p. 2) (see Display 1–5). For instance, community health nurses are nursing when their concern for homeless individuals sleeping in a park leads to development of a program providing food and shelter for this population. Community health nurses are nursing when they collaborate to institute an HIV/AIDS education curriculum in the local school system. When they assess the needs of elderly people in retirement homes to ensure necessary services and provide health instruction and support, they are, again, nursing. They utilize primary, secondary, and tertiary interventions that are evidence-based and develop programs and services that help achieve health for all.

DISPLAY 1.5 THE DEFINITION AND PRACTICE OF PUBLIC HEALTH NURSES

Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences (para. 2).

Key characteristics of practice include (1) a focus on the health needs of an entire population, including inequities and the unique needs of subpopulations; (2) assessment of population health using a comprehensive, systematic approach; (3) attention to multiple determinants of health; (4) an emphasis on primary prevention; and (5) application of interventions at all levels—individuals, families, communities, and the systems that impact their health (para. 4).

The baccalaureate degree in nursing (BSN) is recommended for entry-level public health nurses (para. 12).

From American Public Health Association (APHA) Public Health Nursing Section. (2013). The definition and practice of public health nursing. Washington, DC: APHA.

During the first 70 years of the 20th century, community health nursing was known as public health nursing. The PHN section of the American Public Health Association's (2013) definition of a public health nurse is someone who promotes and protects the health of populations and who is prepared at the baccalaureate level. The later title of community health nursing was adopted to better describe where the nurse practices. For the purposes of this text, the terms are used interchangeably.

Eight characteristics of public health nursing are particularly salient to the practice of this specialty (ANA, 2013, pp. 8–9):

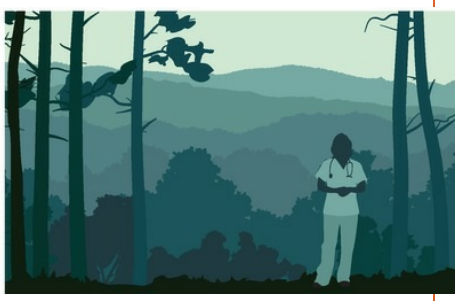
1. The client or "unit of care" is the population.
2. The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.
3. Public health nurses collaborate with the client as an equal partner.
4. Primary prevention is the priority in selecting appropriate activities.
5. Public health nursing focuses on selecting strategies that create healthy environmental, social, and economic conditions in which populations may thrive.
6. A public health nurse is obligated to actively identify and reach out to all who might benefit from a specific activity or service.
7. Optimal use of available resources and creation of new evidence-based strategies are necessary to assure the best overall improvement in the health of the population.
8. Collaboration with other professions, populations, organizations, and stakeholder groups is the most effective way to promote and protect the health of people.

Population Focused

The central mission of public health practice is to improve the health of population groups. Community health nursing shares this essential feature: it is population focused, meaning that it is concerned for the health status of population groups and their environment. A population may consist of the elderly living throughout the community or of Middle Eastern refugees clustered in one section of a city. It may be a scattered group with common characteristics, such as people at high risk of developing heart disease or battered women living throughout a county. It may include all people living in a neighborhood, district, census tract, city, state, or province. Community health nursing's specialty practice serves populations and aggregates of people.

Working with individuals and families as aggregates has been common for community health nursing; however, such work must expand to incorporate a population-oriented focus, a feature that distinguishes it from other nursing specialties. Basic nursing focuses on individuals, and community health nursing focuses on aggregates, but the many variations in community needs and nursing roles inevitably cause some overlap.

A population-oriented focus requires the assessment of relationships. When working with groups and communities, the nurse does not consider them separately but rather in context—that is, in relationship to the rest of the community. When an outbreak of hepatitis occurs, for example, the community health nurse does more than just work with others to treat it. The nurse tries to stop the spread of the infection, locate possible sources, and prevent its recurrence in the community. As a result of their population-oriented focus, community health nurses seek to discover possible groups with a common health need, such as expectant mothers or groups at high risk for development of a common health problem (e.g., obese children at risk for type 2 diabetes, victims of child abuse). Community health nurses continually look for problems in the environment that influence community health and seek ways to increase environmental quality. They work to prevent health problems, such as promoting school-based education about nutrition and physical activity or exercise programs for groups of seniors.



The Greatest Good for the Greatest Number of People

A population-oriented focus involves a new outlook and set of attitudes. Individualized care is important, but prevention of aggregate problems in community health nursing practice reflects more accurately its philosophy and benefits more people. The community or population at risk is the client (see Display 1–6). Furthermore, because community health nurses are concerned about several aggregates at the same time, service will, of necessity, be provided to multiple and overlapping groups. The ethical theory of *utilitarianism* promotes the greatest good for the greatest number. Further discussion of ethical principles in community health nursing can be found in Chapter 4.

DISPLAY 1.6 PARABLE OF THE TREES: POPULATION-FOCUSED PRACTICE

There were once two sisters who inherited a large tract of heavily forested land from their grandmother. In her will, the grandmother stipulated that they must preserve the health of the trees. One sister studied tree surgery and became an expert in recognizing and treating diseased trees. She also was able to spot conditions that might lead to problems and prevent them. Her work was invaluable in keeping single or small clusters of trees healthy. The other sister became a forest ranger. In addition to learning how to care for individual trees, she studied the environmental conditions that affected the well-being of the forest. She learned the importance of proper ecologic balance between flora and fauna and the impact of climate, geography, soil conditions, and weather. Her work was to oversee the health and growth of the whole forest. Although she spent time walking through the forest assessing conditions, her aerial view from their small plane was equally important for spotting fires, signs of disease, or other potential problems. Together, the sisters preserved a

healthy forest.

Nursing also has tree surgeons and forest rangers. Various nursing specialties, like the tree surgeons, serve the health needs of individuals and families. Community health nurses, like the forest rangers, study and address the needs of populations. Both are needed and must work together to ensure healthy communities.

Clients as Equal Partners

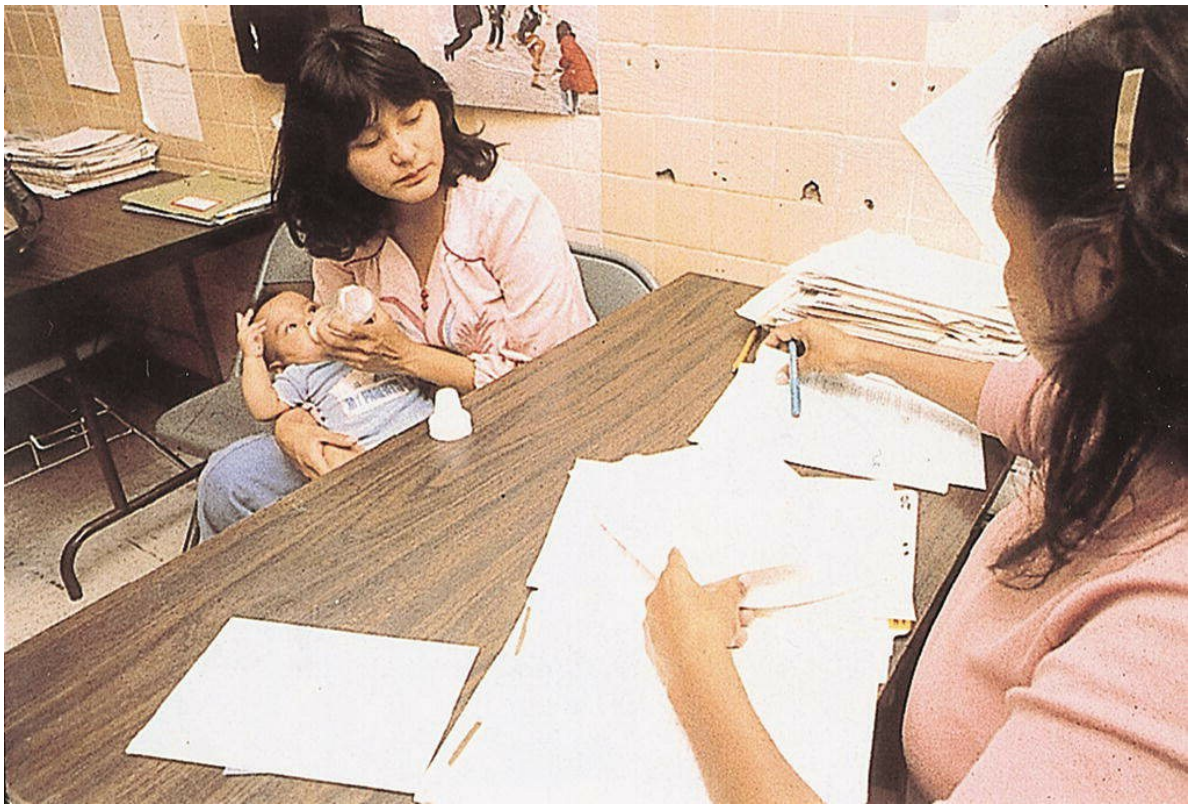
The goal of public health, "to increase quality and years of healthy life and eliminate health disparities" (CDC, 2013, para. 1), requires a partnership effort. Just as learning cannot take place in schools without student participation, the goals of public health cannot be realized without consumer participation. Community health nursing's efforts toward health improvement go only so far. Clients' health status and health behavior will not change unless people accept and apply the proposals (developed in collaboration with clients) presented by the community health nurse.

Public health nurses can encourage individuals' participation by promoting their autonomy rather than permitting a dependency. For example, elderly persons attending a series of nutrition or fitness classes can be encouraged to take the initiative and develop health or social programs on their own. Independence and feelings of self-worth are closely related. By treating people as independent adults, with trust and respect, community health nurses help promote self-reliance and the ability to function independently. Autonomy is an important objective of public health, as is equality (Owens & Cribb, 2013).

Frequently, consumers are intimidated by health professionals and are uninformed about health and health care. They do not know what information to seek and are hesitant to act assertively. For example, a migrant worker brought her 2-year-old son, who had symptoms resembling those of scurvy, to a clinic. Recognizing a vitamin C deficiency, the physician told her to feed the boy large quantities of orange juice but gave no further explanation. Several weeks later, she returned to the clinic, but the child was much worse. After questioning her, the nurse discovered that the mother had been feeding the child large amounts of an orange soft drink, not knowing the difference between that beverage and orange juice. Obviously, the quality of care is affected when the consumer does not understand and cannot participate in the health care process. Health literacy, or the ability to "obtain, process, and understand basic health information and services needed to make appropriate health decisions," is an important concept that is discussed more fully in Chapter 10 (Eberle, 2014, para. 1).

When people believe that their health, and that of the community, is their own responsibility, not just that of health professionals, they will take a more active interest in promoting it. The process of taking responsibility for developing one's own health potential is called self-care. As people maintain their own lives, health, and well-being, they are engaging in self-care. Some examples of self-care activities at the aggregate level include building safe playgrounds, developing teen employment opportunities, and providing senior exercise programs.

When people's ability to continue self-care activities drops below their need, they experience a self-care deficit. At this point, nursing may appropriately intervene. However, nursing's goal is to assist clients to return to or reach a level of functioning at which they can attain optimal health and assume responsibility for maintaining it (Alligood, 2014;



Berbiglia, 2011; Breiddal, 2012). To this end, community health nurses foster their clients' sense of responsibility by treating them as adults capable of managing their own affairs. Nurses can encourage people to negotiate health care goals and practices, develop their own programs, contact their own resources (e.g., support groups, transportation services), identify and implement lifestyle changes that promote wellness, and learn ways to monitor their own health.

When planning for the health of communities, for example, partnerships must be established and the values and priorities of the community incorporated into program planning, data collection and interpretation, and policymaking. More information on program planning is given in Chapter 12.

Prioritizing Primary Prevention

In community health nursing, the promotion of health and prevention of illness are a first-order priority. Less emphasis is placed on curative care. Some corrective actions always are needed, such as cleanup of a toxic waste dump site, stricter enforcement of day care standards, or home care of the disabled; however, community health best serves its constituents through preventive and health-promoting actions (Anderson & McFarlane, 2015; USDHHS, 2016a). These include services to mothers and infants, prevention of environmental pollution, school health programs, senior citizens' fitness classes, and "workers' right-to-know" legislation that warns against hazards in the workplace.

Another distinguishing characteristic of community health nursing is its emphasis on positive health, or wellness (Anderson & McFarlane, 2015). Medicine and acute care nursing have dealt primarily with the illness end of the health continuum. With the potentials of genomics and epigenetics becoming reality, the wellness end of the continuum will come into greater focus. In contrast, community health nursing always has had a primary charge to prevent health problems from occurring and to promote a higher level of health. For example, although a community health nurse may assist a population of new mothers in the community with postpartum fatigue and depression, the nurse also works to prevent such problems among women of childbearing age by developing health education programs, establishing prenatal classes, and encouraging proper rest and nutrition, adequate help, and stress reduction.

Community health nurses concentrate on the wellness end of the health continuum in a variety of ways. They teach proper nutrition or family planning, promote immunizations among preschool children, encourage regular physical and dental checkups, assist with starting exercise classes or physical fitness programs, and promote healthy interpersonal relationships. Their goal is to help the community reach its optimal level of wellness.

This emphasis on wellness changes the role of community health nursing from a reactive to a proactive stance. It places a greater responsibility on community health nurses to find opportunities for intervention. In clinical nursing and medicine, individual patients seek out professional assistance because they have health problems. They present their problems to the health care practitioner for diagnosis and treatment. Public health nurses, in contrast, seek out potential health problems in the community. They identify high-risk groups and institute preventive programs. They watch for early signs of child neglect or abuse and intervene when any occur, often long before a request for help is made. They look for possible environmental hazards in the community, such as smoking in public places or lead-based paint in older housing units, and work with appropriate authorities to correct them. A wellness emphasis requires taking initiative and making sound judgments, which are characteristics of effective community health nursing.

Selecting Strategies That Create Healthy Conditions in Which Populations May Thrive

With our population focus, it is prudent for public health nurses to design interventions for the whole community, not limiting it to only those individuals seeking service, or only the poor and vulnerable, but promoting the health of entire populations and working to prevent "disease, injury and premature death" (ANA, 2013, p. 3). Advocacy for our clients (individuals, families, aggregates, communities, or populations) is an essential function of public health nursing. We want to create healthy environments for our clients so that they can thrive and not simply survive, and we do this by having a proactive stance toward trends in health care and society, ever changing public concerns, and work with policy and legislative activities (ANA, 2013). More information about health advocacy and policymaking is provided in Chapter 13.

Actively Reaching Out

We know that some clients are more prone to develop disability or disease because of their vulnerable status (e.g., poverty, no access to health care, homeless). Outreach efforts are needed to promote the health of these clients and to prevent disease. In acute care and primary health care settings, like emergency rooms or physician offices, clients come to you for service. However, in community health, nurses must focus on the whole population—not just those who come to us for services—and seek out clients wherever they may be (ANA, 2013). Like Lillian Wald and her Henry Street Settlement, community health nurses must learn about the populations they serve and be willing to search out those most at risk. You can learn more about the rich history of community/public health nursing in Chapter 2. Chapters 25 through 29 cover vulnerable populations.

Optimal Use of Available Resources

It is our duty to wisely use the resources we are given. For most public health agencies, budgets are critically stressed. Tertiary health care uses up the greatest percentage of our health care dollar, leaving decreased funds for primary and secondary services (IOM, 2002; McClellan & Rivlin, 2014), and challenging economic times lead to deep budget cuts at state and local levels. The use of documented evidence as a basis for community health nursing practice promotes more efficient and cost-effective strategies in health promotion (ANA, 2013). It is vital that community health nurses ground their practice in research (see Chapter 4) and use that information to educate policy makers about best practices (see Chapter 13). Utilizing personnel and resources effectively and prudently will pay off in the long run.

Interprofessional Collaboration

Community health nurses must work in cooperation with other team members, coordinating services and addressing the needs of population groups. This interprofessional collaboration among health care workers, other professionals and organizations, and clients is essential for establishing effective services and programs. Individualized efforts and specialized programs, when planned in isolation, can lead to fragmentation and gaps in health services. For example, without collaboration, a well-child clinic may be started in a community that already has a strong Early and Periodic Screening and Developmental Testing (EPSDT) program, yet community prenatal services may be nonexistent. Interprofessional collaboration is important in individualized practice, because nurses need to plan with the client, family, physician, social worker, physical therapist, teacher, or counselor and must keep them informed of the client's health status; however, it is an even greater necessity when working with population groups, especially those from vulnerable or at-risk segments.

Effective collaboration requires team members who are strong individuals, with various areas of expertise, and who can make a commitment to team goals. Community health nurses who think and act interdependently make a great contribution to the team effort. In appropriate situations, community health nurses also function autonomously, making independent judgments. Collaboration involves working with members of other professions on community advisory boards and health planning committees to develop needs assessment surveys and to contribute toward policy development efforts. In addition to partnering with the population, other groups the public health nurse collaborates with include:

- Academic and research institutions
- Businesses and industries
- Community organizations, coalitions, and advocacy groups
- Community service agencies such as schools, law enforcement, urban planning, and emergency response
- Faith-based organizations
- Health care providers and facilities
- Legislative, regulatory, and policy-making bodies
- Local, state, and federal public health organizations
- Members of the public health team, such as epidemiologists, social workers, health promotion specialists, nutritionists, environmental health workers, and health educators (ANA, 2013, p. 15).

Interprofessional collaboration requires clarification of each team member's role, a primary reason for community health nurses to fully understand the nature of their practice. When planning a city-wide immunization program with a community group, for example, community health nurses need to explain the ways in which they might

contribute to the program's objectives. They can offer to contact key community leaders, with whom they have established relationships, to build community acceptance of the program. They can share their knowledge of the public's preference about times and locations for the program. They can meet with various local agencies and organizations (e.g., health insurance companies, local hospitals) to gain financial support. They can help to organize and give immunizations, and they can influence planning for follow-up programs. Another component includes development of policies to promote and protect the health of clients. Meeting with local legislators and providing testimony to local, state, and national bodies are common methods of ensuring enactment of effective health policies. Public health nurses can join with others to promote legislation to mandate helmets for cyclists, ban sugar-laden beverages in school vending machines, or provide funding for specific community-based programs. Collaboration is discussed further in Chapter 10.

Client participation is promoted when people serve as partners on the health care team. An aim of community health nursing is to collaborate *with* people rather than do things *for* them. As consumers of health services are treated with respect and trust, confidence and skill in self-care are gained. Thus, promoting their own health and that of their community as their contribution to health programs becomes increasingly valuable. The consumer perspective in planning and delivering health services makes those services relevant to consumer needs. Community health nurses encourage the involvement of health care consumers by soliciting their ideas and opinions, by inviting them to participate on health boards and committees, and by finding ways to promote their participation in decisions affecting their collective health. By assessing the needs of community, based partly upon the population's perceptions, the public health nurse can discover the most pressing health needs and work toward more effective interventions. Community assessment and intervention are explored in depth in Chapter 15.

SUMMARY

Community health nursing has opportunities and challenges to keep the nurse interested and involved in a community-focused career for a lifetime. Community health is more than environmental programs and large-scale efforts to control communicable disease. It is defined as the identification of needs and the protection and improvement of collective health within a geographically defined area. To comprehend the nature and significance of community health and to clarify its meaning for the specialty practice of community health nursing, it is important to understand the concepts of community and of health.

A *community*, broadly defined, is a collection of people who share some common interest or goal. Three types of communities were discussed in this chapter: geographic, common-interest, and health problem-solving communities. Sometimes, a community such as a neighborhood, city, or county is formed by geographic boundaries. At other times, a community may be identified by its common interest; examples are a religious community, a group of migrant workers, or citizens concerned about air pollution. A community also is defined by a pooling of efforts by people and agencies toward solving a health-related problem.

Health is an abstract concept that can be understood more clearly by examining its distinguishing features. First, people are neither sick nor well in an absolute sense but have levels of illness or wellness. These levels may be plotted along a continuum ranging from optimal health to total disability or death. This is known as the *health continuum*. A person's state of health is dynamic, varying from day to day and even hour to hour.

Second, health is a state of being that includes all of the many characteristics of a person, family, or community, whether physical, psychological, social, or spiritual. These characteristics often indicate the degree of wellness or illness of an individual or community and suggest the presence or absence of vitality and well-being.

Third, health has both subjective and objective dimensions: the subjective involves how well people feel; the objective refers to how well they are able to function. Most often, functional performance diminishes dramatically toward the illness end of the health continuum.

Fourth, health care needs can be either continuing, as in developmental concerns that occur over a person's lifetime, or episodic, occurring unexpectedly once or twice in a lifetime. Community health nursing deals with continuing needs, whereas episodic needs are more often managed in acute care settings.

Community health practice incorporates the elements of promotion of health and prevention of health problems.

The eight important characteristics of community health practice are the client is the population; the primary obligation is to achieve the greatest good for the greatest number of people; working with clients as equal partners; primary prevention is the priority; focus

on strategies that create healthy environmental, social, and economic conditions; actively identify and reach out to all who might benefit; make optimal use of available resources and create new evidence-based strategies; and collaborate with a variety of professions, populations, organizations, and other stakeholders to promote and protect the health of populations (ANA, 2013).

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify a community of people about whom you have some knowledge. What makes it a community? What characteristics do this group of people share? Work on this activity in a group of peers or family members. Do they think as you do? Is there a difference between the views of family members and those of nursing student peers?
2. Select three populations for whom you have some concern, and place each group on the health continuum. What factors influenced your decision?
3. Describe three preventive actions (one primary, one secondary, and one tertiary) that might be taken to move each of your selected populations closer to optimal wellness.
4. Select a current health problem and identify the three levels of prevention and corresponding activities in which you as a community health nurse would engage at each level.
5. Discuss how you might implement one health promotion effort with each of your selected populations.
6. Browse the Internet for community health nursing research articles that focus on levels of prevention. Find one focusing on each level. For those involved in the articles focusing on secondary and tertiary prevention, what could you as a community health nurse have done to keep the clients at the primary level of prevention?
7. Place yourself on the health continuum. What factors influenced your decision?
8. Using the eight characteristics of community health nursing outlined in this chapter, give examples of how a community health nurse might demonstrate meeting each characteristic.

2 CHAPTER

History and Evolution of Community Health Nursing

"Our basic idea was that the nurse's peculiar introduction to the patient and her organic relationship with the neighborhood should constitute the starting point for a universal service to the region. We considered ourselves best described by the term 'public health nurses.'"

—*Lillian Wald* (1867–1940), Pioneer of Public Health Nursing

KEY TERMS

Causal thinking
Community-based nursing
Consumption
District nursing
Frontier nursing service
Henry street settlement
Industrial nursing
Nightingale model
Tenement
Visiting nurse association

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Describe the four stages of community health nursing's development.
- Recognize the contributions of selected nursing leaders throughout history to the advancement of community health nursing.
- Analyze the impact of societal influences on the development and practice of community health nursing.
- Explore the academic and advanced professional preparation of community health nurses.

You just left the home of a client who is concerned about a new family that just moved into the building where she lives. This family of six lives in an apartment with barely enough room for two. After years in this neighborhood, you are well aware of the high rents charged for apartments with peeling paint, rodents, and garbage all around the buildings. Your client is concerned that the young mother looks "worn out" and coughs all the time. She said she tried to help, but the family doesn't speak much English. She describes four young children all under the age of about 5. She's never seen the husband, but you know that most of the men in this neighborhood

leave early in the morning to try to get some day work, so you are not surprised. You thank her for the information and assure your client that you will do what you can to help her new neighbors. You start thinking about how you will prepare for the visit to the family who doesn't even expect you. At the top of your planning list is trying to find someone who speaks their language; you only know a few words. You suspect without even seeing the mother what the cough means, although you hope you are wrong. Then you think about the four young children living so close together and creating so much work for a woman who isn't well. The husband may want to help his wife more, but if he doesn't work, they don't have money to pay rent and buy food. You wonder if he has the cough too.

As you read this scenario, what picture comes to mind? What language did this family speak? What disease did this young mother most likely have? Now, think about when this event might have occurred. If you thought this was a current scenario, it certainly could be, but this scenario was actually set in the early 1900s. This family emigrated from Greece and had not yet mastered the English language. The mother likely had consumption (the common name for tuberculosis at that time). Because birth control information was not available to most women, the mother was unable to effectively space out her pregnancies. The filthy and overcrowded housing, termed tenements, was typical of the time. The husband found work as a laborer where he could. Few social services were available—if there was no work, there was no food for the family, and no money to pay the rent. The family came to America with the hope of a new start, but what they found was in many ways worse than what they had left. At least at home in Greece, they had family and friends to count on; here, they were alone. There were others from Greece who lived in the neighborhood, but it wasn't the same support system as every person was struggling to survive. Life was hard, and they worried most about their children, wondering what the future could hold for them.

Public health nurses in the early 20th century had to deal with many of the same issues we face today. We thought that tuberculosis was a disease of the past; now clients with multidrug-resistant strains are becoming alarmingly more common. Poverty, communicable diseases, poor housing, lack of social services, and limited access to family planning information remain as challenges to improving the health of our populations. As a community health nurse, you will be facing similar challenges to those faced by nurses of the past. As Abrams and Hays (2013) remind us, public health nursing practice is dynamic and "the problems of public health emerge and recycle in both new and familiar ways" (p. 475). History may not seem to be exciting, but without it, we often fail to see patterns and learn from the past mistakes. The occasionally misquoted saying by George Santayana (1863–1952), "Those who cannot remember the past are condemned to repeat it," serves to caution us not to "forget" our heritage (Wikiquote, 2016, para. 3). As you read through this chapter, think about how public health nursing practice today has been shaped by the hard work of those nurses who went before.

This chapter examines the international roots of community health nursing as a

specialty, exploring the historical and philosophical foundations that undergird the dynamic nature of its practice. The chapter traces community health nursing's rich historical development, highlighting the contributions of several nursing leaders and examining the global societal influences that shaped early and evolving community health nursing practice. The final section of the chapter describes the academic and advanced professional preparation required of public health nurses today. Nursing's past influences its present, and both guide its future in the 21st century.

HISTORICAL DEVELOPMENT OF COMMUNITY HEALTH NURSING

Before the nature of public health nursing can be fully grasped or its practice defined, it is necessary to understand its roots and the factors that shaped its growth over time. Public health nursing is the product of centuries of growth and adaptation. Its practice has adapted to accommodate the needs of a changing society, yet it has always maintained its initial goal of improved population health. Community health nursing's development, which has been influenced by changes in nursing, public health, and society, can be traced through several stages. This section examines these stages.

The history of public health nursing, since its recognized inception in Europe and more recently in America, encompasses continuing change and adaptation (Donahue, 2011). The historical record reveals a professional nursing specialty that has been on the cutting edge of innovations in public health practice and has provided leadership to public health efforts. A summary of public health nursing made in the early 1900s still holds true:

> It is precisely in the field of the application of knowledge that the public health nurse has found her great opportunity and her greatest usefulness. In the nationwide campaigns for the early detection of cancer and mental disorders, for the elimination of venereal disease, for the training of new mothers, and the teaching of the principles of hygiene to young and old; in short, in all measures for the prevention of disease and the raising of health standards, no agency is more valuable than the public health nurse (Central Hanover Bank and Trust Company, Department of Philanthropic Information, 1938, p. 8)

In tracing the development of public health nursing and, later, community health nursing, the leadership role has been clearly evident throughout its history. Nurses in this specialty have provided leadership in planning and developing programs, in shaping policy, in administration, and in the application of research to community health.

Four general stages mark the development of public/community health nursing: (1) the early home care nursing stage, (2) the district nursing stage, (3) the public health nursing stage, and (4) the community health nursing stage. See Chapter 1 for a more complete discussion of the interchangeable terms *public health nurse* and *community health nurse*. In the course of the historical evolution of this specialty, there was a definite shift in thinking about the focus of practice, resulting in the broader use of the term *community health nurse*. However, the discussion that follows is about the practice emphasis, not the title. There are nurses in practice who use the title public health nurse, in addition to those called community health nurses; the term community/public health nurse has been widely accepted as depicting the generalist practice in this specialty (Callen et al., 2010). The title public health nurse is used, not just for those working in public health agencies but also those working in many diverse community settings where population-focused nursing occurs (Kulbok, Thatcher, Park, & Meszaros, 2012). Whether by custom, preference, or established employment title, nurses call themselves by many professional titles. It is

important to recognize that the work of the nurse is, as it always has been, to improve the health of the community.

Early Home Care Nursing (Before Mid-1800s)

The prototype of community-based nursing can be seen within the historical development of home care nursing. For many centuries, female family members and friends tended the sick at home. In fact, in 1837, Farrar reminded women, "You may be called upon at any moment to attend upon your parents, your brothers, your sisters, or your companions" (p. 57). The focus of this care was to reduce suffering and promote healing.

The Origins of Early Nursing

The early roots of home care nursing began with religious and charitable groups; even emergency care was provided. In 1244, a group of monks in Florence, Italy, known as the Misericordia, provided first aid care for accident victims on a 24-hour basis. Another example is the Knights Hospitallers, who were warrior monks in Western Europe. They protected and cared for pilgrims on their way to Jerusalem (Pugh, 2001). During the 1500s, the Spanish nurse Bernardino de Obregon and his congregation provided both care of the ill and specialized nursing training at "houses of approval" (Jesús & Martínez, 2010, p. 27). These and other men's contributions to the early practice of nursing have been long overlooked. Further, the lack of attention to these early works "perpetuates the notion of men nurses as anomalies" (Evans, 2004, p. 321).

Medieval times saw the development of various institutions devoted to the sick, including hospitals and nursing orders. In England, the Elizabethan Poor Law, written in 1601, provided medical and nursing care to the poor and disabled. St. Frances De Sales organized the Friendly Visitor Volunteers in the early 1600s in France. This association was directed by Madame de Chantel and assisted by wealthy women who cared for the sick poor in their homes (Dolan, 1978). In 1617, St. Vincent de Paul started the Sisters of Charity in Paris, France. This organization was composed of nuns and lay women dedicated to serving the poor and needy. The ladies and sisters, under the supervision of Mademoiselle Le Gras in 1634, promoted the goal of teaching people to help themselves as they visited the sick in their homes. In their emphasis on preparing nurses and supervising nursing care, as well as determining causes and solutions for clients' problems, the Sisters of Charity laid a foundation for modern community health nursing (Bullough & Bullough, 1978).

Unfortunately, the years that followed these accomplishments marked a serious setback in the status of nursing and care of the sick. From the late 1600s to the mid-1800s, the social upheaval after the Reformation caused a decline in the number of religious orders, with subsequent curtailing of nursing care for the sick poor. Babies continued to be delivered at home by self-declared midwives, who generally had little or no training. Most midwives in the 14th to the 17th century were women "of a mature age, married or widowed with grown-up children," and they learned the skill of midwifery from experience or apprenticeship working with a veteran midwife (Kontoyannis & Katsetos, 2011, p. 32).

Concern over high maternal mortality rates prompted efforts to better prepare midwives and medical students. One midwifery program began in Paris in 1720, and, in 1741, Dr. William Smellie organized a midwifery program in London (Bullough & Bullough, 1978). Licenses were available, but fees were often high. When long labors resulted in fetal death, midwives called in barber-surgeons who used "hooks, knives, or crockets" to remove the dead fetus (Kontoyannis & Katsetos, 2011, p. 33). A 17th century birth was "women's business," and when the midwife arrived, the husband left the room, which was described as "dark and warm." The midwife performed an internal exam to determine the degree of cervical dilation, after applying "fresh butter or other oils" to her hand; she then worked to "stretch the opening" and applied "various sweet oils or lubricants …to the perineal area… to encourage softening and relaxation of the tissues" (Kontoyannis & Katsetos, 2011, p. 33). How does that compare to current practice?

The Industrial Revolution created additional problems; among them were epidemics, high infant mortality, occupational diseases and injuries, and increasing mental illness in both Europe and America. Hospitals were built in larger cities, and dispensaries were developed to provide greater access to physicians. However, disease was rampant; mortality rates were high; and institutional conditions, especially in prisons, hospitals, and "asylums" for the insane, were deplorable. The sick and afflicted were kept in filthy rooms without adequate food, water, cover, or care for their physical and emotional needs (Bullough & Bullough, 1978). Reformers such as John Howard, an Englishman who investigated the spread of disease in hospitals in 1789, revealed serious needs that would not be addressed until much later (Bullough & Bullough, 1978; Kalisch & Kalisch, 2004). It would take another 64 years and the seminal work of John Snow with the London cholera epidemic of 1853 to link a water pump with the transmission of the disease (Ramsey, 2006). The germ theory proposed by Louis Pasteur in 1862 dispelled many myths of the time, including the miasmic theory of disease (Fealy, McNamara, & Geraghty, 2010). The term miasma referred to "bad air" and was attributed as the cause of illness not "germs." The work of these early scientists would bring attention to the need for changes in the care of the sick as well as the prevention of illness.

During this same period, Dorothea Dix brought attention to the plight of the mentally ill from abuse and neglect in U.S. jails and almshouses. In what was arguably one of the first social research efforts in the United States, she presented her firsthand accounts of the terrible situations she found to the legislatures of Massachusetts, New York, New Jersey, and Pennsylvania (Reddi, 2005). Through her efforts, there was an almost 10-fold increase in the number of mental institutions, and the overall care of the mentally ill improved. Although not trained as a nurse, Dix would in later years oversee the Union Army female nurses prior to resuming her efforts with the mentally ill.

Although few in number, both Catholic and Anglican religious nursing orders continued the work of caring for the sick poor in their homes. For example, in 1812, the Sisters of Mercy organized in Dublin to provide care for the sick at home. With the status of women at an all-time low, often only the least respectable women pursued nursing. In

1844, in his novel *Martin Chuzzlewit*, Charles Dickens (1910) portrayed the nurse Sairey Gamp (Fig. 2–1) as an unschooled and slovenly drunkard, reflecting society's view of nursing at the time (Dolan, Fitzpatrick, & Herrmann, 1983). It was in the midst of these deplorable conditions and in response to them that Florence Nightingale began her work.

FIGURE 2–1 Sairey Gamp.

The Early Nightingale Years

Much of the foundation for modern community health nursing practice was laid through Florence Nightingale's remarkable accomplishments (Fig. 2–2). She has been referred to as a reformer, a reactionary, and a researcher who developed the "secular profession of nursing in the 19th century" (Abrams & Hays, 2013, p. 475; Palmer, 2001). Born in 1820 into a wealthy English family, her extensive travel, excellent education—including training at the first school for nurses in Kaiserswerth, Germany—and determination to serve the needy resulted in major reforms and improved status for nursing. Her work during the Crimean War (1854–1856) with the wounded in Scutari is well documented (Florence Nightingale Museum Trust, 1997; Lee, Clark, & Thompson, 2013; Woodham-Smith, 1951). Conditions in the military hospitals during the war were unspeakable. Thousands of sick and wounded men lay in filth, without beds, clean coverings, food, water, or laundry facilities. Florence Nightingale organized competent nursing care and established kitchens and laundries that resulted in hundreds of lives saved. Her work further demonstrated that capable, holistic nursing intervention could prevent illness and improve the health of a population at risk—precursors to modern community health nursing practice (Hogan, 2015). Nightingale's subsequent work reforming health in the military was supported by implementation of another public health strategy: the use of biostatistics. Through meticulously gathered data and statistical comparisons, Miss Nightingale demonstrated that military mortality rates, even in peacetime, were double those of the civilian population because of the terrible living conditions in the barracks. She promoted five essential components to optimal health and healing—pure air and water, efficient drainage, cleanliness, and adequate lighting. This work led to important military reforms and prioritization of hygiene (Lee et al., 2013). Even during World War II, British nurses were still fighting disease and unsanitary conditions as they worked with civilian victims of typhus epidemics—once again bringing Nightingale's work to the forefront (Brooks, 2013).

FIGURE 2–2 Florence Nightingale's concern for populations at risk, as well as her vision and successful efforts at health reform, provided a model for community health nursing today.

Miss Nightingale's concern for populations at risk included a continuing interest in the population of the sick at home. Her book, *Notes on Nursing: What It Is, and What It Is Not*, published in England in 1859, was written to improve nursing care in the home. It was also during this period that Nightingale clarified nursing as a woman's occupation (Evans, 2004). This gender distinction in nursing was due more to the culture of the times than as a direct exclusion of men from the practice; it was consistent with social norms of that period. Florence Nightingale also became a skillful lobbyist for health care reform. Her exemplary influence on English politics and policy improved the quality of existing health care and set standards for future practice. Furthermore, she demonstrated how population-focused nursing works (Lee et al., 2013).

In her work to help establish the first nonreligious school for nurses in 1860 at St. Thomas Hospital in London, she promoted a standard for proper education and supervision of nurses in practice, known as the Nightingale Model. Principles she wrote about in *Notes on Nursing* relate directly to her early education and the notions held by Hippocrates in ancient Greece, which she had studied for years. Specifically, her concern

with the environment of patients, the need for keen observation, the focus on the whole patient rather than the disease, and the importance of assisting nature to bring about a cure all reflect Hippocrates' teachings (Nightingale, 1859/1969; Palmer, 2001).

Another great nurse and healer in her own right was Mary Seacole (1805–1881), who has been called the "Black Nightingale." She was the daughter of a Scottish soldier and a well-respected "doctress" who practiced Creole or Afro-Caribbean medicine in Jamaica and began helping her mother at an early age. Married only briefly to Edwin Seacole, her husband died in 1844. Spending many years developing her skills, she helped populations who experienced tropical diseases, especially cholera, in Central America, Panama, and the Caribbean. She attempted, through many formal channels, to join Florence Nightingale in Scutari, but was rejected again and again. Undaunted, she went to the Crimea on her own to open a hotel for sick and convalescing soldiers, where she met Miss Nightingale and many of the troops she had cared for in Jamaica. Many of the military commanders sought her out for her knowledge of healing, and she was affectionately known by the troops as "Mother Seacole." After the war and into her old age, she continued to provide nursing care in London and when visiting Jamaica. She focused her caregiving among high-risk clients of the day and did so in an innovative, entrepreneurial manner unique for women, especially for women of color in the 1800s (National Geographic Education Staff, 2013). Her autobiography *Wonderful Adventures of Mrs. Seacole in Many Lands* was published in 1857 and became a best seller, providing much needed financial support for Mary Seacole (National Geographic Education Staff, 2013; Stanley, 2007). W.H. Russell Esq. wrote in the introduction "…I trust that England will not forget one who nursed her sick, who sought out her wounded to aid and succour them, and who performed the last offices for some of her illustrious dead" (Seacole, 1857). United Kingdom (UK) and Jamaican stamps were issued in her honor, and her portrait hangs in the National Portrait Gallery (UK) (National Geographic Education Staff, 2013) (see Display 2–1).

DISPLAY 2–1 TWENTY YEARS IN HISTORY: 1845 TO 1865

1845	Dorothea Dix addresses the New Jersey and Pennsylvania legislatures regarding abuse and neglect of the mentally ill.
1848	The first women's rights convention in the United States is held in Seneca Falls, New York.
1849	Harriet Tubman escapes from slavery and will lead many slaves to freedom through the Underground Railroad.
1850	Florence Nightingale begins nursing training at the Institute of St. Vincent de Paul in Alexandria, Egypt.
1854	Florence Nightingale cares for the injured in the Crimean War.
1855	Mary Seacole establishes a boarding house to care for sick and injured soldiers in the Crimea.
1857	Ellen Ranyard pioneers the first "district nursing" program in England.
1860	Florence Nightingale's *Notes on Nursing: What It Is, and What It Is Not* is published.
1861	Civil War embroils the country until 1865. Harriet Tubman serves as an unpaid nurse to wounded civilians and soldiers. Dorothea Dix is placed in charge of all female nurses in Union military hospitals.
1865	Sojourner Truth serves as a nurse for the Freedman's Relief Association during Reconstruction in Washington, DC.

District Nursing (Mid-1800s to 1900)

Nightingale's Continued Influence

The next stage in the development of community health nursing was the formal organization of visiting nursing or district nursing. In 1859, William Rathbone, an English philanthropist, became convinced of the value of home nursing as a result of private care given to his wife. He employed Mary Robinson, the nurse who had cared for his wife, to visit the sick poor in their homes and teach them proper hygiene to prevent illness. The need was so great that it soon became evident that more nurses were needed. In 1861, with Florence Nightingale's help and advice, Rathbone opened a training school for nurses connected with the Royal Liverpool Infirmary and established a visiting nurse service for the sick poor in Liverpool. Florence Lees, a graduate of the Nightingale School, was appointed first Superintendent-General of the District Nursing System (Hughes, 1902; Mowbray, 1997). As the service grew, visiting nurses were assigned to districts in the city—hence the name, district nursing. The names of these nurses were entered into a central roll, and they were known as "Queen's Nurses," as Queen Victoria recognized the benefits of this program for her people and was a supporter (Hughes, 1902, p. 344). Subsequently, other British cities also developed district nursing training and services. An example is the Nurse Training Institution for district nurses, founded in Manchester in 1864 and the work done by Ellen Ranyard and others in London (Prochaska, 1980/2003). Privately financed, the nurses were trained and then "dispensed food and medicine" to the sick poor in their homes; they were "closely supervised by various middle and upper class women who collected the necessary supplies" (Bullough & Bullough, 1978, p. 143).

Although Florence Nightingale is best remembered for her professionalization of nursing, she had a full understanding of the need for community health nursing. This was documented in her writings and recorded conversations:

- Hospitals are but an intermediate stage of civilization. At present, hospitals are the only place where the sick poor can be nursed, or, indeed often the sick rich. But the ultimate object is to nurse all sick at home (Nightingale, 1876).
- The aim of the district nurse is to give first-rate nursing to the sick poor at home (Nightingale, 1876 [cited in (Mowbray, 1997, p. 24)]).
- The health visitor must create a new profession for women (conversation with Frederick Verney, 1891 [cited in (Mowbray, 1997, p. 25)]).

For years, Miss Nightingale studied the social and economic conditions of India (Nightingale, 1864). The plight of the poor and ill in India led her to become involved with Frederick Verney in a pioneering "health at home" project in England in 1892. She wrote a series of papers on the need for "home missioners" and "health visitors," endorsing the view that prevention was better than cure, and set up training courses in 1980 for "sanitary visitors," later known as "health visitors" who taught families about cleanliness in

the home, food preparation, and hygiene (Mowbray, 1997; Wright, 2011, p. 304).

Home Visiting Takes Root

In the United States, the first community health nurse, Frances Root, hired by the Women's Branch of the New York Mission in 1877, pioneered home visits to the poor in New York City. District nursing associations were founded in Buffalo in 1885 and in Boston and Philadelphia in 1886 (Display 2–2). These district associations served the sick poor exclusively, because patients with enough money had private home nursing care. However, the English model with its standards for visiting nurses' education and practice, established in 1889 under Queen Victoria, was not followed in the United States. Instead, visiting nursing organizations sprang up in many cities without common standards or administration. Twenty-one such services existed in the United States in 1890 (Bullough & Bullough, 1978; Kalisch & Kalisch, 2004).

DISPLAY 2–2 TWENTY YEARS IN HISTORY: 1873 TO 1893

1873	First Nightingale model nursing school established in the United States at Bellevue Hospital.
1877	Francis Root—First Public Health Nurse hired by the Women's Branch of the New York Mission.
1878	Woman Suffrage Amendment is introduced in the U.S. Congress.
1879	Mary Eliza Mahoney becomes the first African American to graduate from an American nursing school.
1881	American Red Cross established by Clara Barton and associates becoming its first president.
1885	Visiting Nurse Association established in Buffalo, New York.
1886	Visiting Nurse Associations established in Philadelphia and Boston.
1893	Lillian Wald and Mary Brewster organized a visiting nurses service for the poor in New York, which would be named the Henry Street Settlement in 1906. *American Society of Superintendents of Training Schools for Nursing* founded by Isabel Adams Hampton Robb (later renamed the National League for Nursing).

Although district nurses primarily cared for the sick, they also taught cleanliness and wholesome living to their patients, even during that early period. For example, the Boston program, founded by the Women's Educational Association, "emphasized the teaching of hygiene and cleanliness, giving impetus to what was called instructive district nursing" (Bullough & Bullough, 1978, p. 144). This early emphasis on prevention and "health nursing" became one of the distinguishing features of district nursing and, later, of public health nursing as a specialty.

The work of district nurses in the United States focused mostly on the care of individuals. District nurses recorded temperatures and pulse rates and gave simple

treatments to the sick poor under the immediate direction of a physician. They also instructed family members in personal hygiene, diet and healthful living habits, and the care of the sick. The problems of early home care patients in the United States were numerous and complex. Thousands of European and eastern European immigrants filled tenement housing in the poorest and most crowded slums of the large coastal cities during the late 1800s. Inadequate sanitation, unsafe and unhealthy working conditions, and language and cultural barriers added to poverty and disease. Nursing educational programs at that time did not prepare district nurses to cope with their patients' multiple health and social problems.

The sponsorship of district nursing changed over time. Early district nursing services in both England and the United States were founded by religious organizations. Later, sponsorship shifted to private philanthropy. Funding came from contributions and, in a few instances, from fees charged to patients on an ability-to-pay basis. Finally, visiting nursing began to be supported by public money. An early example occurred in Los Angeles where, in 1898, a nurse was hired as a city employee, making Los Angeles the first city in the United States to establish "municipal nursing" (Brainard, 1922). Although one form of funding dominated, all three types of financing continued to exist, as they still do. Although the government was beginning to assume more responsibility for the public's health, most district nursing services during this time remained private.

In England, the establishment of "health visitors" in poor areas of London began early in the 19th century. These health care providers enhanced the English model of health visitor/district nurse/midwife as the backbone of the primary health care system in the second half of the 1800s. "The impact of early health visiting was clearly shown by the halving of infant mortality in the areas within two years" (Beine, 1996, p. 59). The main focus of the health visitor's work was giving advice to poor mothers and teaching hygiene to prevent infant diarrhea (Beine, 1996).

Public Health Nursing (1900 to 1970)

By the beginning of the 20th century, district nursing had broadened its focus to include the health and welfare of the general public, not just the poor. This new emphasis was part of a broader consciousness about public health. Robert Koch's demonstration that tuberculosis was communicable led the Johns Hopkins Hospital to hire a nurse, Reba Thelin, in 1903, to visit the homes of tuberculosis patients. Her job was to ensure that patients followed prescribed regimens of rest, fresh air, and proper diet and to prevent possible infection (Sachs, 1908). A growing sense of urgency about the interrelatedness of health conditions and the need to improve the health of all people led to an increased number of private health agencies. These agencies supplemented the often-limited work of government health departments. By 1910, new federal laws made states and communities accountable for the health of their citizens.

Nurses Making a Difference

Around 1900, Jessie Sleet was hired by the Charity Organization Society's (COS) tuberculosis committee as a temporary district nurse in New York City (Mosley, 2007). Her position called for her to visit the city's Black community, which was ravaged by the disease. Jessie Sleet had been trained at the Provident Hospital in Chicago (a hospital for Black patients), which had a nurse's training program for Black women. Credited as the first Black public health nurse, Ms. Sleet was not eagerly accepted by the COS membership, but they agreed in the hope that the Black community would eventually accept her. She was so successful in her efforts that, 1 year later, the society hired her as a permanent employee (Mosley, 2007). Jessie Sleet was a pioneer in early community health nursing practice and forged the way for many others. Display 2–3 outlines other historical events during those intervening years.

DISPLAY 2–3 TWENTY YEARS IN HISTORY: 1894 TO 1914

1894	Mary Adelaide Nutting appointed Superintendent of the Johns Hopkins School of Nursing—under her leadership, the curriculum was expanded from 2 to 3 years and limited the number of hours students could work.
1895	Vermont Marble Company forms the Industrial Nursing Service to care for sick employees and their families.
1897	First meeting of the *Nurses Associated Alumnae of the United States and Canada* that in 1911 would be renamed the American Nurses Association.
1898	Spanish American War leads to outbreak of Yellow Fever among solders.
1900	Jessie Sleet Scales becomes the first African American public health nurse in United States.
1902	New York City Board of Education hires Lina Rogers Struthers as a school nurse and begins the first public school nurse program in the county.
1905	American Red Cross receives Congressional Charter.
1906	Pure Food and Drug Act (prohibits misbranding and adulteration of drugs).
1909	Metropolitan Life Insurance Company provides first insurance reimbursement for visiting nursing care.
1910	Public Health Nursing program instituted at Teacher's College, Columbia University.
1912	National Organization for Public Health Nursing formed, with Lillian Wald as the first President.
1914	Margaret Sanger publishes the monthly newsletter *The Woman Rebel* to promote contraception and is charged with distributing illegal "birth control" information.

As specialized programs such as infant welfare, tuberculosis clinics, and venereal disease control were developed, there was an increased demand for nurses to work in these areas (Fig. 2–3). As Bullough and Bullough (1978, p. 143) commented, "Although the hospital nursing school movement emphasized the care of the sick, a small but growing number of nurses were finding employment in preventive health care." In 1900, there were an estimated 200 public health nurses. By 1912, that number had grown to 3,000 (Gardner, 1936). This was an important development: "it brought health care and health teaching to the public, gave nurses an opportunity for more independent work, and helped to improve nursing education" (Bullough & Bullough, 1978, p. 143).

FIGURE 2–3 This photo depicts an early public health nurse, carrying her bag of equipment and supplies, at a regular home visit in the late 1800s. Physical and psychological care, as well as health lessons, were provided to families.

The role of the district nurse expanded during this stage. Lillian D. Wald (1867–1940), a leading figure in this expansion, first used the term *public health nursing* to describe this specialty (Ruel, 2014). District nurses, while caring for the sick, had pioneered in health teaching, disease prevention, and promotion of good health practices. Now, with a growing recognition of familial and environmental influences on health, public health nurses broadened their practice even more. Nurses working outside of the hospital increased their knowledge and skills in specialized areas such as tuberculosis, maternal and child health, school health, and mental disorders (Fig. 2–4).

FIGURE 2–4 Well baby clinic in Framingham, Massachusetts (1920).

Lillian Wald's contributions to public health nursing were enormous. A graduate of the New York Hospital Training School, she started teaching home nursing but quickly changed to a career of social reform and nursing activism (Christy, 1970). Appalled by the conditions of an immigrant neighborhood in New York's Lower East Side, she and a nurse-friend, Mary Brewster, started the Henry Street Settlement in 1893 to provide nursing and welfare services. The Lower East Side was home to many poor Irish, Italian, Jewish, and Chinese immigrants, and the Henry Street Visiting Nurse Service visited many sick children and families in their homes. One of the worst periods of depression occurred during this time, and the nurses supplied individuals and families with ice for keeping food fresh and also meals, medicine, and sterilized milk. They also made referrals to hospitals and clinics, as needed, and "emphasized the human dignity of even the poorest" tenement families (Fee & Bu, 2010, p. 1206). Wald's books, *The House on Henry Street* (1915) and *Windows of Henry Street* (1934), portray her work and views on public health nursing. Nurses supervised visits conducted through her organization; this was in contrast to earlier models, in which lay boards administered nursing services, and actual care was supervised by laypersons. It was during these early years that Wald asked Jessie Sleet to recommend another Black nurse for service at the settlement (Mosley, 2007). Miss Sleet recommended her schoolmate Miss Elizabeth Tyler, a graduate of the Freedmen's Hospital Training

School for Nurses (Washington, DC). In 1906, Miss Tyler became the first Black nurse hired at the Henry Street Settlement; she would not be the last, as the number steadily grew (Fee & Bu, 2010). This was no small event in the progress of public health nursing and was a clear demonstration of Lillian Wald's commitment to social change.

Wald's Growing Influence

The work done at the Henry Street Settlement showed clearly that nursing could reduce illness-caused employee absenteeism. She demonstrated this in her early work with the city of New York. She would use this success to address the issue of childhood illness and school absenteeism (Bullough & Bullough, 1978; Hawkins & Watson, 2010). In the early 1900s, medical inspectors sent home approximately 15 to 20 children per day from each school in New York City for health-related reasons. However, no one followed up with them to make sure that they were properly treated and returned to school. Wald suggested that placing nurses in the schools would allow for follow-up on recurring cases and home visits during the periods of exclusion. She argued that the nurses could supplement the work done by local physicians, who occasionally examined the children. Offering the services of one nurse for 1 month, Wald hoped to demonstrate how effective a school nurse could be. The work done by this first school nurse, Lina Rogers Struthers, was a resounding success (Kalisch & Kalisch, 2004). One year after this initial experiment, the number of children sent home from the New York City schools had dropped dramatically. By September 1903, only 1,000 children needed to be excluded (compared with 10,000 one year earlier); this was a nearly 10-fold reduction. As a result, the New York Board of Health hired dozens of nurses to work at the schools becoming the first school nursing program in the country; by 1905, 44 nurses covered 181 public schools (Hawkins & Watson, 2010; Vessey & McGowen, 2006). In 1917, Lina Rogers Struthers would go on to author the first textbook for school nurses *The School Nurse: A Survey of the Duties and Responsibilities of the Nurse in the Maintenance of Health and Physical Perfection and the Prevention of Disease Among School Children*. See Chapter 30 for current information about school nursing. See Perspectives for an early school nurse's experience (Figs. 2–5 and 2–6).

PERSPECTIVES LILLIAN "TOMMY" FULLER

Lillian Fuller was born in 1902, the only girl in a family of seven children living in rural Minnesota. Thus, she was nicknamed "Tommy." She grew up in Mountain Iron, a boomtown for iron mining and lumber companies for several decades. The town was owned by the mining company and surrounded by large ore pits; her family lived in a tar-papered house near saloons, bordellos, and the local jail. As a senior in high school, she decided that she wanted to be a nurse, but remembering the Dickens' character, Sairey Gamp, her family sent her to a college in St. Paul. She later prevailed and attended a hospital nursing school in Chicago, where she spent some time with the Chicago Visiting Nurse Association (VNA), under Edna L. Foley (a colleague of Lillian Wald). She worked

with "crippled children" in four schools in the Hull-House district, where she met Jane Addams (the founder of social work). She arranged social services and physiotherapy for children in the Infantile Paralysis Aftercare program until she graduated from nursing school in 1925. She continued to work for the VNA until 1933, when she returned to Mountain Iron and took a nursing position with the Works Progress Administration (WPA)—a depression-era program to help unemployed individuals find jobs. She did a health census of her community for the WPA for a fee of $100. The next year, she worked as a half-time school nurse at the Mountain Iron School for $65 a month. She utilized the public health model of school nursing, as she was taught, and did the usual eye testing, first aid, checking for head lice, and taking care of rashes, stomachaches, colds, and accidents. She had medications on hand (even morphine), as the nearest hospital was five miles away, and she was thought of as the local health care authority as there was often no physician available. Because she was so well known in the community, she was able to initiate sex education programs in the schools and began a Future Nurses Club. In the summers, she worked as a camp nurse; the first year, there was a polio epidemic that cost the life of one of the counselors and sickened two of the campers. After many years of diligent service "Tommy" finally retired from school nursing in 1967, about the time that the first public health nurse practitioners were graduating from a new program in Colorado. She continued to provide service to the community, visiting sick elderly and lobbying for removal of an abandoned iron "tipple" or waste dump. A senior housing unit was eventually built on the site. Her practice spanned an important period in nursing: from early VNA service, working with colleagues of Lillian Wald, to a school nursing practice on the Iron Range of Minnesota where she often practiced independently and was an advocate for her children, families, and community. We can learn much from her life and service.

From Hawkins, J. W., & Watson, J. C. (2010). School nursing on the Iron Range in a public health nursing model. Public Health Nursing, 27(6), 571–578.

Just 6 years after her efforts with the New York City schools, Wald embarked on another visionary path. In 1909, she convinced the Metropolitan Life Insurance Company that nurse intervention could reduce death rates (Hamilton, 2007; Hawkins & Watson, 2003). In collaboration with the Henry Street Settlement, the company organized the Visiting Nurse Department and provided services to policyholders in a section of Manhattan (see Display 2–3). The success of this program resulted in expansion to other parts of the city and to 12 other eastern cities within 1 year. By 1912, the company had organized 589 Metropolitan nursing centers and, when possible, contracted with local Visiting Nurses Associations, although they also hired their own nurses (Kalisch & Kalisch, 2004; Ruel, 2014).

The legendary accomplishments of Lillian Wald reflect her driving commitment to serve needy populations. Through her efforts, the New York City Bureau of Child Hygiene was formed in 1908 and the Children's Bureau at the federal level in 1912. Wald's

emphasis on illness prevention and health promotion through health teaching and nursing intervention, as well as her use of epidemiologic methodology, established these actions as hallmarks of public health nursing practice. She promoted rural nursing and family-focused nursing and encouraged improved coursework at the Teachers College of Columbia University (New York) to prepare public health nurses for practice. Through her work and influence with the legislature to establish health and social policies, improvements were made in child labor and pure food laws, tenement housing, parks, city recreation centers, immigrant handling, and teaching of mentally handicapped children. In 1912, she helped to found and was first president of the National Organization for Public Health Nursing (NOPHN), an organization that set standards and guided public health nursing's further development and impact on public health (Christy, 1970; Feld, 2008). Her exemplary accomplishments truly reflect a concern for populations at risk. They further demonstrate how nursing leadership, involvement in policy formation, and use of epidemiology led to improved health for the public.

Another Nurse—Another Problem

During the same period that Lillian Wald and her contemporaries were working to alleviate the suffering caused by disease and poverty, another nurse, Margaret Sanger, began a different battle. Sanger, who was born in 1879, had seen her own mother die at the age of 48 after a long struggle with tuberculosis. Her 18 pregnancies undoubtedly contributed to her both contracting the disease and eventually succumbing to it. After her mother's death, she was accepted at White Plains Hospital as a nursing probationer (Ruffing-Rahal, 1986). Later, as a visiting nurse, Sanger was prevented by the Comstock Act of 1873 from providing any information on contraception to the women she cared for (Baker, 2011; Draper, 2006). She knew, as did many others, that the affluent and educated in American society were the only ones to have reliable contraception. Even discussing the topic was prohibited, placing increased pressure on the poor and uneducated women who were most in need of this basic information. In 1912, Sanger watched helplessly as a 28-year-old mother of three died from abortion-induced septicemia. "A few months earlier, during a similar crisis, this woman had begged Sanger for the "secret" of preventing future pregnancy" (Ruffing-Rahal, 1986, pp. 247–248). In 1916, Sanger openly offered birth control information in the Brownsville section of Brooklyn. Ten days after opening the first birth control clinic in America, Sanger was arrested, and the clinic was closed. But, later attempts were more successful (Baker, 2011). This was not the first, nor would it be her last encounter with the legal system (see Display 2–4). Her open defiance of a law that she saw as unjust eventually resulted in the formation of the International Planned Parenthood Federation (Fig. 2–7).

FIGURE 2–7 Margaret Sanger, thought to be standing in front of her birth control clinic.

DISPLAY 2–4 TWENTY YEARS IN HISTORY: 1917 TO 1937

1917	United States entry into World War I.
	The 18th Amendment is passed by Congress (ushering in Prohibition).
1918	U.S. Public Health Service establishes Division of Public Health Nursing to aid the war effort.
	World War I Armistice.
	Worldwide influenza epidemic begins.
	Frances Reed Elliott becomes the first African American nurse accepted into the American Red Cross Nursing Service.
1919	19th Amendment passed by Congress.
1920	Women vote for the first time in a presidential election.
1921	Margaret Sanger founds the American Birth Control League to distribute contraception information.
1925	Frontier Nursing Service established.
1929	Stock Market crash (beginning of the Great Depression).
1933	18th Amendment repealed (Prohibition ends).
1935	Passage of the Social Security Act.
1937	Birth control information now legal in all but two states (Massachusetts and Connecticut).

Call the Midwife

In Great Britain, midwifery continued to be in demand. This was especially true among the working class during the post–war period of the 1950s and 1960s. With London's East End as the backdrop, the popular PBS/BBC series, *Call the Midwife*, depicts the work of midwives during that time period (Stevens, 2013). At that time, there were over 10,000 midwives and district nurses in England, many traveling to home visits on bicycles, who provided education on nutrition, food safety, and care of infants and children, as well as home health care for injured workers and their usual duties of delivering babies.

During this period of public health nursing, as a result of the influence of Lillian Wald and other nursing leaders, the family began to emerge as a unit of service (Fig. 2–8). The multiple problems faced by many families impelled a trend toward nursing care generalized enough to meet diverse needs and provide holistic services. There was also a call for specialization in some densely populated areas where tuberculosis, infant care, and school children were a primary concern (Brainard, 2012; King, 2011; Ruel, 2014). Public health nurses gradually gained more autonomy in such areas as home care and instruction of good health practices to families and community groups. Some examples include population work with children and families affected by polio and the subsequent mass immunization clinics after a vaccine was developed, as well as a single PHN's experience providing care to those living in an isolated outpost on Kodiak Island, Alaska, during an outbreak of tuberculosis-related pneumonia (Carter, 2001; Curtis, 2008). Their collaborative relationships with other community health providers grew as the need to avoid gaps and

duplication of services became apparent. One example of an innovative program was the East Harlem Nursing and Health Service that operated between 1928 and 1941. It's territory was 87 city blocks that housed 112,000 mostly Italian immigrants and Italian Americans; most of the men were factory workers, tradesmen, and laborers, and the families, especially the infants, had higher mortality rates than those for New York City overall (D'Antonio, 2013). They offered "integrated family services," with interdisciplinary and independent public health nurses practicing in tandem with other professionals who specialized in nutrition, mental health, social work, and education. A goal was to directly affect the "process of family building" and address the social determinants of health that devastated families during the Great Depression. With federal funding available, Mayor LaGuardia promoted public health nursing, along with hospital construction and neighborhood health centers. A shift from home births to hospital deliveries was dramatic —from 85% in 1927 having babies at home with midwives to 65% in 1934 having babies delivered by physicians in hospitals. This, along with the failure to attain financial sustainability as required by their major funder, the Rockefeller Foundation, led to the demise of this innovative public health program (D'Antonio, 2013). Out of necessity, public health nurses began keeping better records of their services and continued home visiting for those in need. They also responded to population health needs, as more individual care was now available at hospitals and health centers. See From the Case Files: New York City PHNs and the 1918 Influenza Pandemic.

From the Case Files I

New York City PHNs and the 1918 Influenza Pandemic

The 1918 influenza pandemic caused over 40 million deaths worldwide and 675,000 U.S. deaths. The country was at war (World War I), and the American Red Cross, the U.S. Public Health Service, and health care workers were stretched thin. The epidemic began in New York City with three cases during mid-September, 1918. It spread quickly and crossed social class and income boundaries; within a few days, there were 31 new cases reported (Keeling, 2009). Cities across the Eastern seaboard requested assistance, and a coordinated plan for a decentralized response was set in place. Lillian Wald, who directed the Henry Street visiting nurses, had weathered epidemics on the Lower East Side of New York City before and quickly responded to this new, even more virulent threat. When making home visits, nurses found "whole

families were ill…without anyone to give them the simplest nursing care" (Keeling, 2009, p. 2735). One person described "People, desperate in their need watched from windows and doorways for the nurse. They surrounded her on the street, imploring her to go in six directions at once" (Geister, 1957, October, pp. 583–584). Wald noted almost 500 calls for nursing services to patients with influenza and pneumonia in the "first four days of October" and that nurses were instructed to wear masks but "31 out of….170 had succumbed to influenza" (Keeling, 2009, p. 2736). The Nurses' Emergency Council was organized for a citywide response, led by Lillian Wald who requested that all who employed nurses allow them to work in caring for those afflicted by the epidemic. With this central structure, duplication of services was avoided, and quicker services could be provided. Wald requested automobiles for the visiting nurses to help them travel more quickly and carry "linens, pneumonia jackets, and quarts of soup"; the nurses started work early every morning and went out again at 4 PM to check on cases reported later each day (Keeling, 2009, p. 2737). They finished rounds around midnight, only to start again early the next morning. In Harlem, a nurse reported on a family of seven—the mother has influenza, "the father has lobar pneumonia, two children have measles and bronchopneumonia, and one child is only four weeks old," noting that they had no care until their case was reported to the VNA. This was a common situation across the city. As the epidemic began to subside, the Nurses' Emergency Council discontinued central services on the 6th of November, and the Henry Street nurses opened postinfluenza clinics to address the follow-up needs of families. There were almost 11,000 deaths from influenza and almost 10,000 deaths from pneumonia reported in New York City over the 2-month period of the epidemic. All that the nurses could provide was comfort care—clean linens, bed baths, fluids, and monitoring. There was little help from the federal level of government, and private, philanthropic, and religious organizations worked together with local government and nursing agencies to combat the deadly epidemic.

How do you think your city or county would respond to a new pandemic threat similar to the one in 1918? How would PHNs be involved?

From Keeling, A. W. (2009). "When the city is a great field hospital": The influenza pandemic of 1918 and the New York City nursing response. Journal of Clinical Nursing, 18, 2732–2738.

Geister, J. (1957, October). The flu epidemic of 1918. Nursing Outlook, 5, 582–584.

Another form of public health nursing, industrial nursing, also expanded during the early 1900s. J. & J. Colmans of Norwich, England, hired Philippa Flowerday Reid, the first known industrial nurse, in 1878. Her job was to assist the company physician and to visit sick employees and their families in their homes. In the United States, the Vermont Marble Company was first to begin a nursing service in 1895, and other companies followed soon after. By 1910, 66 firms in the United States employed nurses. During World War I, the number of industrial nurses greatly increased with the recognition that nursing service

reduced worker absenteeism (Bullough & Bullough, 1978). Early industrial nursing was the forerunner of modern occupational and environmental health nursing. See Chapter 31 (Fig. 2–9).

FIGURE 2–9 A PHN, wearing an overcoat, hat, and carrying a nurses' bag, stands in front of a pile of trash as she makes her way through a neighborhood.

During this stage, the institutional base for much of public health nursing shifted to the government. By 1955, 72% of the counties in the continental United States had local health departments. Public health nursing constituted the major portion of these local health services and emphasized health promotion, as well as care for the ill at home (Scutchfield & Keck, 2009). Some of the district nursing services, known as *visiting nurse associations* (VNAs), remained privately funded and administered, offering their own home nursing care. In some places, city or county health departments joined administratively and financially with VNAs to provide a combination of services, such as home care of the sick and health promotion to families. The Red Cross offered public health nursing services from 1912 to 1951. The first incarnation was the Rural Nursing Services headed by Fannie Clement, and the Town and Country Nursing Service was organized and provided both rural areas and cities with nursing services. Jane A. Delano was the director of the Red Cross during this time. The final incarnation was the Red Cross Public Health Nursing Service, and the earliest service of Philadelphia Red Cross Society nurses was to Johnstown flood victims. The Red Cross provided public health nursing services to families of soldiers during both World Wars (Ramsay, 2012).

Rural public health nursing, which had already been organized around 1900 in Great Britain, Germany, and Canada, also expanded in the United States (see Chapter 29). Initially, starting in 1912, rural nursing was privately financed and largely administered through the Red Cross and the Metropolitan Life Insurance Company, but responsibility had shifted to the government by the 1940s (Bullough & Bullough, 1978). An innovative example of rural nursing was the Frontier Nursing Service, which was started by Mary Breckenridge (1881–1965) in 1925, to serve mountain families in Kentucky. From six outposts, nurses on horseback visited remote families to deliver babies and provide food and nursing services. The work was hard, but rewarding; it combined general public health nursing and midwifery (January, 2009). Over the years, the service has expanded to provide medical, dental, and nursing care. The Frontier Nursing Service continues today, with its remarkable accomplishments of reducing mortality rates and promoting health among this disadvantaged population, as the parent holding company for the Frontier School of Midwifery and Family Nursing. It is the largest nurse–midwifery program in the United States. In addition, Mary Breckinridge Healthcare, Inc. consists of a home health agency, two outpost clinics, one primary care clinic, and the Kate Ireland Women's Healthcare Clinic (Simpson, 2000). For more on rural nursing and the Frontier Nursing Service, see Chapter 29. See Perspectives: Roaming Through the Hills with the PHN.

PERSPECTIVES ROAMING THROUGH THE HILLS WITH THE PHN

As a state nursing supervisor, I visit PHNs during a typical week providing services in rural Virginia. The first PHN's territory consisted of a mountainous area, with winding, often muddy roads. Our first visit was made on horseback: "The road straight up the mountain was winding and lovely and way below in a gorge ran a stream" on our way to Star-Chapel School (Webb, 2011, p. 291). After traveling by horseback all day, we crossed a final stream to reach a house that backed up to the mountain; "the stream dashing over the rocks at the front door" where we were invited to spend the night (p. 292). The family was eager to help the nurse who had cared for others during the 1918 flu epidemic. At the school, we checked the children, and the PHN talked to them about how to prevent disease and the importance of personal hygiene. We visited two more schools on the way back home. In the southwest corner of the state, I visited another PHN, and we traveled 30 miles by logging train, which seemed to be "balanced on the peak of a mountain top" to visit a small, isolated town that desperately wants a nurse to visit schoolchildren and families (p. 292). In another county, the PHN visits with a girl who is recovering from meningitis, and her mother brags that she wants a clean glass and washes

her hands now before she eats every meal. We then travel to a log cabin where mothers and children meet every week, and the PHN weighs babies and provides health pamphlets and talks about "babies, screening houses, homemade ice boxes," and other topics of interest (p. 293). The women cook gingerbread and make hot cocoa in an old stone fireplace there. We later visited a rundown camp and saw many women "each with three to eight children hanging on their skirts," and a 14-year-old who stopped dipping snuff, as the nurse advised (p. 293). The nurse had promised her a prize, and she proudly claimed it. The PHN talked with a 12-year-old girl who refused to go to school and found that the reason was that she couldn't see, and her eyes were hurting. The mother agreed that she needed to see a specialist, but the girl would not agree to this unless her father made her go. The PHN was disappointed to see a 4-year-old, who had agreed to stop chewing tobacco, come by to visit her with a cigarette in his mouth! Our state needs many more PHNs, and we are budgeting the money for services, but we don't have enough nurses who are willing to do this type of rural pioneer nursing. It can be very rewarding.

From Webb, B. (2011). Roaming through Virginia with the public health nurse. Public Health Nursing, 28(3), 291–293. Reprint of 1920 article.

This public health nursing stage was characterized by service to the public, with the family targeted as a primary unit of care. Official health agencies, which placed greater emphasis on disease prevention and health promotion, provided the chief institutional base (Fig. 2–10).

FIGURE 2–10 Preschool child is weighed by African American nurse at an improvised baby station and child health clinic set up in a church.

Nurses in Military Service

Since Florence Nightingale's service to the British soldiers during the Crimean War, nurses have continued to provide service during wartime. Women served in many capacities (nurses, cooks, seamstresses) during the Revolutionary war. Clara Barton, famous for founding the American Red Cross, volunteered her services during the Civil War, as did about 20,000 women of different races and classes (D'Antonio, 2010). Some nursing graduates were contracted to serve during the Philippine American War and in the Spanish American War at the turn of the 20th century.

In 1901, the Army Nurse Corps was established, and in 1908, the Navy Nurse Corps was added (Lineberry, 2013). During World War I, many new graduates responded to the pleas of the Red Cross for nurses to care for the sick and wounded and entered the Army Nurse Corps. At the start of World War II, the Red Cross called for 50,000 nurses to join the armed services (Lineberry, 2013). In 1945, President Franklin D. Roosevelt "desegregated nursing in the U.S. Armed Forces" (D'Antonio, 2010, p. 132). Earlier, in 1942, the Cadet Nurse Corps was created to feed the demand for nurses during World War II, but military nurses didn't receive permanent commissioned officer status until 1947 (Robinson, 2009). About 74,000 nurses served during the second world war, and some ended up behind enemy lines, in combat, and as Japanese prisoners of war (Lineberry,

2013). Using educational benefits of the G.I. Bill, military nurses returning from World War II were sometimes limited because of enforced freshman quotas for women, as male veterans were given preference until 1952 (Barnum, 2011). However, schools of public health reported increased enrollment by returning military nurses in programs preparing them for public health nursing. This specialty practice provided them with more autonomy and a more independent practice than hospital nursing (Barnum, 2011).

In 2011, 18% of the over 2.2 million active military personnel were females (National Public Radio, 2011). Not all female military personnel are nurses and not all military nurses are females. See more on publicly-funded settings for nurses, including the U.S. Public Health Service, in Chapter 30.

The Profession Evolves

By the 1920s, public health nursing was acquiring a more professional stature, in contrast to its earlier association with charity. Nursing as a whole was gaining professional status as a science, in addition to being an art. National nursing organizations began to form during this stage and contributed to nursing's professional growth. The first of these emphasized establishing educational standards for nursing. Called the American Society of Superintendents of Training Schools for Nurses in the United States and Canada, it was started by Isabel Hampton Robb in 1893, and later became known as the National League of Nursing Education in 1912. This was the forerunner of the National League for Nursing (NLN), which was established in 1952 (Ellis & Hartley, 2012). In 1890, a meeting of nursing leaders at the World's Fair in Chicago initiated an alumnae organization of 10 schools of nursing to form the National Associated Alumnae of the United States and Canada in 1896, which was created to promote nursing education and practice standards. In 1899, the group was renamed the Nurses' Associated Alumnae of the United States and Canada. Canada was excluded from the title in 1901, because New York, where the organization was incorporated, did not allow representation from two countries. In 1911, the organization went through a final name change to the American Nurses' Association (ANA), while Canadian nurses formed their own nursing organization (Ellis & Hartley, 2012). As mentioned previously, NOPHN, founded by Lillian Wald and Mary Gardner, brought together nurses who worked in the community setting to promote the public's health. Their 1929 definition of public health nursing stated that nurses working in "organized community services" provided care to the "individual, family, and community" in order to correct "defects," prevent disease, and promote health and that duties also "may include skilled care of the sick in their homes" (Abrams, 2004, p. 507). In 1931, NOPHN developed "general and specialized objectives" regarding work with individuals, families, and communities (Abrams, 2004, p. 507). In 1949, the organization outlined 12 functions of skilled public health nurses working in the community setting:

> Maternity, infancy, preschool, school, and adult health services; morbidity, communicable diseases, tuberculosis, syphilis and gonorrhea; orthopedic; industrial; and mental hygiene (Abrams, 2004, p. 508).

The organization also began adopting the term community health nursing as a less "restrictive" view that incorporated a greater focus on scientific advances in health care that involved changing the behavior of individuals, compared to public health nursing that focused primarily on population health and environmental control of communicable diseases and sanitation (Abrams, 2004, p. 508). In 1952, NOPHN merged with the NLN. These three organizations, in particular, strengthened ties between nursing groups and improved nursing education and practice (Figs. 2–11 and 2–12).

FIGURE 2–11 Ethel May Jones, an African American public health nurse who was employed as a midwife/teacher by a State Board of Health, is shown dressed in her uniform and carrying her bag.

FIGURE 2–12 An African American public health nurse walks pass a rural wooden house.

As nursing education became increasingly rigorous, collegiate programs began to include public health as essential content in basic nursing curricula. The first collegiate program with public health content to be accredited by the NLN began in 1944 (National Organization for Public Health Nursing, 1944; Display 2–5). Previously, only postgraduate courses in public health nursing had been offered for nurses choosing this specialty. Adelaide Nutting had developed the first such course in 1912, at Teachers College in New York, in affiliation with the Henry Street Settlement. A group of agencies met in 1946 to establish guidelines for public health nursing, and by 1963, public health content was required for NLN accreditation in all baccalaureate degree level nursing programs (Kulbok & Glick, 2014). The nurse practitioner (NP) movement, starting in 1965 at the University of Colorado, was initially a part of public health nursing and emphasized primary health care to rural and underserved populations. The number of educational programs to prepare NPs increased, with some NPs continuing in public health and others moving into different clinical areas (Hawkins & Watson, 2010).

DISPLAY 2–5 TWENTY YEARS IN HISTORY: 1941 TO 1961

1941	United States enters into World War II.
1943	Cadet Nursing Corps Program established, providing federal funding for academic nursing education in exchange for work in "essential nursing services."
1944	First basic program in nursing accredited as including sufficient public health content. Public Health Service Act authorizes qualified nurses to be commissioned in the U.S. Public Health Service.
1945	World War II ends. United Nations votes to establish the World Health Organization.
1946	Hill-Burton Act approved—shift to hospital-based care with federal funding of hospitals and medical centers. Communicable Disease Center established (forerunner of the Centers for Disease Control and Prevention).
1949	Lucile Petry Leone becomes the Chief Nurse Officer of the Public Health Service, the first nurse, and the first woman to achieve flag rank in the Public Health Service or military.
1950	United States involved in Korean Conflict (this ends in 1953).
1954	Brown vs. Board of Education—Landmark Supreme Court decision prohibits racial segregation in public schools.
1955	Introduction of the Salk Polio vaccine.
1956	Health Amendments Act provided funds to support public health nurse advanced training.
1961	The Peace Corps is founded. United States enters into the Vietnam War.

Community Health Nursing (1970 to the Present)

The emergence of the term *community health nursing* heralded a new era. By the late 1960s and early 1970s, while public health nurses continued their work, many other nurses who were not necessarily practicing public health were based in the community. Their practice settings included community-based clinics, doctors' offices, worksites, and schools. To provide a label that encompassed all nurses in the community, the ANA and others called them community health nurses. Display 2–6 provides examples of significant events in mid-1960s to early 1980s.

DISPLAY 2–6 TWENTY YEARS IN HISTORY: 1965 TO 1985

1965	Medicare and Medicaid are established.
1969	National Environmental Policy Act provides first coordinated oversight effort.
1972	Social Security Administration allows Medicare coverage for those <65 years with long-term chronic disease and end-stage renal disease.
1973	U.S. military troops leave South Vietnam. Roe vs. Wade—Landmark Supreme Court decision legalizes abortion.
1977	Global smallpox eradication achieved.
1978	Drug-resistant TB reported in Mississippi.
1979	*Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* released.
1985	Red Cross Blood Services begin testing for HIV antibody.

This term was not universally accepted, however, and many people—including nurses and the general public—had difficulty distinguishing community health nursing from public health nursing. For example, nursing education, recognizing the importance of

public health content, required course work in public health for all baccalaureate students. This meant that graduates were expected to incorporate public health principles such as health promotion and disease prevention into nursing practice, regardless of their sphere of service. Consequently, some questioned whether public health nursing retained any unique content. Although leaders such as Carolyn Williams clearly stated that community health nursing's specialized contribution lay in its focus on populations (Williams, 1977), this concept did not appear to be widely understood or practiced.

Confusion also arose regarding the question of whether community health nursing was a generalized or a specialized practice. Graduates from baccalaureate nursing programs were inadequately prepared to practice in public health; their education had emphasized individualized and direct clinical care and provided little understanding of applications to populations and communities. By the mid-1970s, various community health nursing leaders had identified knowledge and skills needed for more effective community health nursing practice (Roberts & Freeman, 1973). These leaders valued promoting the health of the community, but both education and practice continued to emphasize direct clinical care to individuals, families, and groups in the community (de Tornyay, 1980). Reflecting this view, the ANA's Division of Community Health Nursing developed *A Conceptual Model of Community Health Nursing* in 1980. This document distinguished generalized community health nursing preparation at the baccalaureate level and specialized community health nursing preparation at the masters or postgraduate level. The generalist was described as one who provides nursing service to individuals and groups of clients while keeping "the community perspective in mind" (American Nurses Association, Community Health Nursing Division, 1980, p. 9).

To distinguish the domains of community and public health nursing, in 1984, the U.S. Department of Health and Human Services, Bureau of Health Professionals, Division of Nursing, convened a Consensus Conference on the Essentials of Public Health Nursing Practice and Education in Washington, DC (U.S. Department of Health and Human Services [USDHHS], Division of Nursing, 1984). This group concluded that *community health nursing* was the broader term, referring to all nurses practicing in the community, regardless of their educational preparation. *Public health nursing*, viewed as a part of community health nursing, was described as a generalist practice for nurses prepared with basic public health content at the baccalaureate level and a specialized practice for nurses prepared in public health at the master's level or beyond. For a public health nursing viewpoint, see Perspectives: Nursing Instructor and the Public Health Nursing Bag (Fig. 2–13).

FIGURE 2–13 A PHN on a home visit. The nurse is removing something from her bag in preparation for an examination as a little girl watches.

PERSPECTIVES NURSING INSTRUCTOR AND THE PUBLIC HEALTH NURSING BAG

When I was a nursing student, I shadowed a public health nurse on her visits for a day. She carried the standard PHN bag, a rectangular flat-topped black leather bag with long handles on both sides; she seemed to be a magician, as she continued to pull things out of her bag during the home visit to a very poor migrant family living in a small rural farm labor camp. She had a folded newspaper in the back pocket of her bag, and she carefully unfolded it and placed her bag on top of it. She pulled out a small bottle of liquid soap and a few paper towels, and washed her hands at the kitchen sink as she asked the mother about her concerns and questions. She weighed and measured the newborn (scale carried in the trunk of her car; disposable paper tape and paper barrier for scale from her bag) and performed a brief exam (stethoscope and supplies from her bag). She gave the mother a card with information on birth control and the location/hours of the health department clinic. The mother was worried about the 2-year-old being fussy and not wanting to eat and asked the nurse to check her for a sore throat. The nurse pulled out a tongue depressor and an otoscope to check the child's ears and throat. Ear tips were cleaned with alcohol swabs from her bag, and trash was properly disposed of. She reported to the mom that the little girl had no current signs of an infection, but to watch for her and go to the clinic if she felt that things got worse. The mother also expressed concern about her 4-year-old, thinking that he may not be "ready for school" in the fall, so the nurse pulled Denver testing supplies out of her bag and assessed the child. She talked to the mother about developmentally appropriate activities for the child and pulled a sticker from her bag to reward the 4-year-old for "playing games" with her and the 2-year-old for complying with the brief exam. When the visit was over, the PHN had cleaned and put everything (but the baby scale) carefully back into place in her bag (e.g., stethoscope, otoscope, supplies); she picked it up and folded the newspaper with the "dirty" side inward, and she was ready for the next visit.

You may or may not be using the PHN bag in your nursing program today. Only about one third of nursing schools responding to a 2009 survey reported that they used the traditional PHN bag in their clinical courses (Aaltonen et al., 2009). But, the bag is still very functional, and it has a rich history. You can see early photos of Lillian Wald carrying a PHN bag over the tenement rooftops in New York City. Zarbock (1996) noted that PHNs for many decades have provided care in the home from the depths of the small, black public health nursing bag. Abrams (2009) noted that the bag was needed for carrying "supplies that were required in a home but

which would not have been available" (p. 106). Common supplies in the 1930s included bottled green soap, Vaseline, alcohol, shaving cream, oral and rectal thermometers (glass), tongue depressors, safety pins, applicators, hand lotion, and various glass supplies (e.g., medicine droppers, connectors, tips). Rubber supplies included catheters and rectal tubes. Dressings, towels, and other linens, along with an apron, masks, and cord ties, were also included. A folder for health forms, notes, pamphlets, maps, pencils, pens, and a notebook were also carried. If the local medical society approved, the nurse might also include a stethoscope and sphygmomanometer. Sometimes, newspapers and a cap and gown were needed in cases where contamination was an issue (NOPHN, 1939). Aseptic technique was used, with the inside of the bag considered clean, and all bottles either washed in hot water or sterilized before being returned to the bag after use. For decades, bag technique was taught in nursing schools. If possible, the bag was placed on a chair rather than the floor, and newspapers were used as a barrier if needed. A waste bag could be made out of folded newspapers, and the PHN had to wash her hands before reaching into the bag for supplies (NOPHN, 1939). Abrams (2009) notes that the bag was a "symbol of authority and respect" and that it often served as "a teaching tool" as the nurse demonstrated good hygiene when working with families. Many families and communities became familiar with the "public health nurse carrying her black bag"—which became both a symbol and a tool (p. 109).

I am proud to carry the little black bag that embodies such a rich history.

Holly, Public Health Nursing Instructor

Abrams, S. E. (2009). The public health nursing bag as tool and symbol. Public Health Nursing, *26*(1), 106–109.

Finally, confusion also arose regarding the changing roles and functions of community health nurses. Accelerated changes in health care organization and financing, technology, and social issues made increasing demands on community health nurses to adapt to new patterns of practice. Many new kinds of community health services appeared. Hospital-based programs reached into the community. Private agencies proliferated, offering home care and other community-based services. Other community health professionals assumed responsibilities that traditionally had been the domain of public health nursing. For example, some school counselors in Oregon began coordinating home visits previously done by school nurses, and health educators (who were part of a more recently developed discipline) took over large segments of client education. Social workers, too, provided services that overlapped with community health nursing roles. Health educators, counselors, social workers, epidemiologists, and nutritionists working in community health came prepared with different backgrounds and emphases in their practice. Their contributions were and still are important. Their presence, however, forced community

health nurses to reexamine their own contribution to the public's health and incorporate stronger interdisciplinary and collaborative approaches into their practice (see "Levels of Prevention Pyramid").

LEVELS OF PREVENTION PYRAMID

GOAL: Clarify and enhance the community health nurse's role to promote impact

TERTIARY PREVENTION

- Promote increasing influence of the nurse through an expanded role in service delivery
- Minimize the impact of community misunderstandings of the nurse's role through education

SECONDARY PREVENTION

- Promote aggregate-level interventions
- Foster nurse involvement on community boards and other political groups

PRIMARY PREVENTION

- Participate in policy formation
- Be politically active
- Assist in acquiring funding for community health programs
- Conduct research on health and nursing outcomes to enhance evidence-based practice
- Collaborate with the news media to publicize current public health issues

The debate over these areas of confusion continued through the 1980s, and some issues remain unresolved. Still, the direction in which public health and community health nursing must move remains clear: to care *for*, not simply *in*, the community. Public health nursing continues to mean the synthesis of nursing and the public health sciences applied to promoting and protecting the health of populations. Community health nursing, for some, refers more broadly to nursing in the community. In this text, the term *community*

health nursing is used synonymously with *public health nursing* and refers to specialized, population-focused nursing practice, which applies public health science and nursing science. A possible distinction between the two terms might be to view community health nursing as a beginning level of specialization and public health nursing as an advanced level. A position paper sponsored by the Association of Community Health Nursing Educators (ACHNE) emphasized the use of the title, public health nurse, as the "unique ecological focus on population health" and the "synergy of the nursing, social, and public health sciences" (Levin et al., 2008, p. 179). Clarification and consensus on the meaning of these terms may help to avoid misconceptions and misuse and are explored more fully in Chapter 3. Whichever term is used to describe this specialty, the fundamental issues and defining criteria remain the same:

- Are populations and communities the target of practice?
- Are the nurses prepared in public health and engaging in public health practice?

As public/community health nursing continues to evolve, many signs of positive growth are evident. Community health nurses are carving out new roles for themselves in primary health care. Collaboration and interdisciplinary teamwork are recognized as crucial to effective community nursing. Practitioners work through many kinds of agencies and institutions, such as senior citizen centers, ambulatory services, mental health clinics, and family planning programs. Community needs assessment, documentation of nursing outcomes, program evaluation, quality improvement, public policy formulation, and community nursing research are high priorities. This field of nursing is assuming responsibility as a full professional partner in community health.

Internationally, community health nursing services are well established in England, Scandinavia, the Netherlands, and Australia. Services, however, are relatively underdeveloped in France and Ireland. Furthermore, relatively few professional nurses are working in the community in central and Eastern Europe and in Russia. Ivanov and Paganpegara (2003) note that changes have occurred in nursing education subsequent to the collapse of the Soviet Union, but they have not included content in public health nursing. Moreover, the concepts of health promotion and health education are not well understood, with the vast majority of health care provided at the tertiary level. It is concerning that modernization in many countries has not included expansion of public health services in general and community health nursing more specifically. A study in Turkey found that public health nursing education needed to be strengthened and updated (Kadioglu, Albayrak, & Esin, 2013).

For countries in the European Union, new public health nursing competencies form the basis of revised core educational modules that are focused on upgrading public health nursing and promoting better health for individuals and populations (Danielson, Krogerus-Therman, Sivertsen, & Sourtzi, 2005). A comparative study of public health nursing preparation in Canada and European Union countries found that varied practice environments and educational practices led to inconsistencies in preparation as well as

involvement in policy making and leadership in PHN practice (Hemingway, Aarts, Koskinen, Campbell, & Chassé, 2012). In the United Kingdom, dual programs for nursing and health visitors (public health nursing) are encouraged and have been shown to increase the number of nurses who go into health visiting or public health nursing (Drennan, Porter, & Grant, 2013).

In many of the most populated regions of the world—such as China, Africa, and India—volunteers, lay providers, and paraprofessionals often provide the bulk of community health services. In Thailand, nursing has moved from hospital-based training to university-based education, with an increased professionalization of nursing (Thaweeboon, Peachpansri, Pochanapan, Senachack, & Pinyopasakul, 2011). In Taiwan, a call was issued for high school graduation as a minimum requirement for college nursing program entrance, along with revised curriculum content that bases teaching approaches on the public health needs of an increasingly older and chronically ill population (Yeh, Chao, & Chao, 2012). Ayandiran, Irinoye, Olayiwola, and Mtshali (2013) chronicled the "long and tortuous journey" of nursing education reforms in Nigeria to improve nursing practice by promoting evidence-based practice and critical thinking (p. 7). They call for meaningful use of distance learning technologies to provide access to all nurses. A survey of 150 Nigerian nurses found that most nurses valued continuing professional education, but wanted online courses and a means for utilizing this as a way to move up the career ladder. However, currently, no monitoring or evaluation methods are in place to fully determine the impact of continuing education on nursing competence or outcomes for patients (Nsemo, John, Etifit, Mgbekem, & Oyira, 2013). As they continue to make progress toward improved nursing practice and outcomes, a survey noted that Nigerian public health nurses found that the use of standardized nursing languages in charting improved documentation (Odutayo, Olaogun, Oluwatosin, & Ogunfowokan, 2013).

In 1978, a joint World Health Organization and the United Nations Children's Fund International Conference in Alma-Ata, in the Soviet Union, adopted a declaration on primary health care as the key to attaining the goal of health for all by the year 2000. At this conference, delegations from 134 governments agreed to incorporate the concepts and principles of primary health care in their health care systems to reach this goal (World Health Organization, 1978; 2016). This was adopted by the World Health Assembly and endorsed by the United Nations General Assembly in 1981. On paper, at least, everyone acknowledged the crucial need for nurses to be involved in reaching this goal. In practice, support has not been forthcoming in many countries. Policy makers and the public still need to be educated to realize that nursing's most effective contributions to the overall health of the population are based in the community.

Table 2–1 summarizes the most important changes that have occurred during community health nursing's four stages of development. It shows these changes in terms of focus, nursing orientation, service emphasis, and institutional base.

Table 2–1 Development of Community Health Nursing

Stages	Focus	Nursing Orientation	Service Emphasis	Institutional Base (Agencies)
Early home care (before mid-1800s)	Sick poor	Individuals	Curative	Lay and religious orders
District nursing (1860–1900)	Sick poor	Individuals; preventive	Curative; beginning of	Voluntary; some government
Public health nursing (1900–1970)	Needy public	Families	Curative; preventive	Government; some voluntary
Emergence of community health nursing (1970–present)	Total community	Populations; illness prevention	Health promotion; practice	Many kinds; some independent

SOCIETAL INFLUENCES ON THE DEVELOPMENT OF COMMUNITY HEALTH NURSING

Many factors have influenced the growth of community health nursing. To better understand the nature of this field, the forces that began and continue to shape its development must be recognized. Six are particularly significant: advanced technology, progress in causal thinking, changes in education, demographic changes and the role of women, the consumer movement, and economic factors.

Advanced Technology

Advanced technology has contributed in many ways to shaping the practice of community health nursing. For example, technologic innovation has greatly improved health care, nutrition, and lifestyle and has resulted in an increase in life expectancy. Consequently, community health nurses direct an increasing share of their effort toward meeting the needs of the elderly population and addressing chronic conditions. The advances in technology in the home can be life altering, as we now have advances in genetics and genomics, less invasive surgical and diagnostic techniques, electronic health records, and 3-D printing of human tissues and organs (Huston, 2013). For example, the use of social media can enable the community health nurse to reach an even broader audience. Duggan and Smith (2014) found that 73% of U.S. adults use social media and about half are active on several networking sites. PatientsLikeMe is an example of consumer Web sites that permits individuals to "monitor their disease, treatments, and self-reported experiences" (Jackson, Fraser, & Ash, 2014, para. 7). They can also choose to share information with researchers and other patients with similar symptoms or diseases.

Despite the benefits, with any type of information sharing, there is always the risk of inaccurate information being disseminated. Online access to health information can provide a critical link to information for all individuals, especially isolated elderly persons, but it is important to recognize that not all Web sites are reputable. It is critical for the community health nurse to carefully check any Web sites that are recommended for clients. And, it is important for clients to access only reputable sites and participate in discussion groups that utilize a facilitator or moderator. Technology is also helpful in monitoring health, such as smartphone apps or devices that track diet, exercise, and sleep. Public health nurses can use technology to promote social media campaigns for disease prevention and foster healthy habits. Social media can have a downside, as cyber bullying and a potential for invasion of privacy exist (Jackson et al., 2014).

Advanced technology has been a strong force behind industrialization and urbanization. Population density leads to many health-related problems, particularly the spread of disease and increased stress. As people travel and relocate, they are separated from families and traditional support systems; technology such as Skype and social media such as Facebook help keep them connected.

Finally, innovations in communications and computer technology have shifted America from an industrial society to more of an "information economy." Our economy is built on information—the production and marketing of knowledge—making it global and active around-the-clock. Community health nurses now are in the business of information distribution, and they use computer technologies to enhance the efficiency and effectiveness of their services. Geographic information systems (GIS) is an example of emerging computer technology that the community health nurse can use to design and evaluate population-focused programs (Callen et al., 2010). GIS technology can be a valuable tool

for many purposes, including examining health disparities and outbreaks of disease and for determining health priorities within a community (Rababah, Curtis, & Drew, 2014). This spatial software permits nursing research and epidemiologic studies examining the association between stressful environmental exposures and preterm birthrates for African American mothers (Bloch, 2011). GIS is also helpful in public health nursing as a tool for program planning and determining accessibility of community services (Carlson, York, & Primomo, 2011).

Telenursing, telehealth, and nursing informatics are part of our professional activities as community health nurses. We communicate by e-mail, use computer-based applications to enhance education among peers and with clients, and utilize electronic health records and billing programs. We have the ability to remotely visit our clients, and we regularly videoconference on smartphones, tablets, and laptops. We can even take a "bird's-eye" view of the distribution of service providers and chronic disease clusters in a community through the use of GIS technology. Access to information is increasing, and the use of the information is limitless. The emerging difficulty is how to manage the sheer volume of information and still meet the needs of our communities. See Chapter 10.

Community health nurses, as well as nurses in all areas of the profession, are developing skills with informatics and various forms of technology. The Technologies Informatics Guiding Education Reform (TIGER) encourages this integration of technology into nursing practice (Jackson et al., 2014).

Progress in Causal Thought

Relating disease or illness to its cause is known as causal thinking in the health sciences. Progress in the study of causality, particularly in epidemiology, has significantly affected the nature of community health nursing (Fos & Fine, 2000; Thomas & Weber, 2001). The *germ theory* of disease causation, established in the late 1800s, was the first real breakthrough in control of communicable disease. At that time, it was established that disease could be spread or transmitted from patient to patient or from nurse to patient by contaminated hands or equipment. Nurses incorporated the teaching of cleanliness and personal hygiene into basic nursing care.

A second advance in causal thinking was initiated by the tripartite view that called attention to the interactions among a causative agent, a susceptible host, and the environment. This information offered PHNs new ways to control and prevent health disorders (Galea, Riddle, & Kaplan, 2010). For example, nurses could decrease the vulnerability of individuals (hosts) by teaching them healthier lifestyles. They could instigate measles vaccination programs as a means of preventing the organism (agent) from infecting children. They could promote proper disinfection of a neighborhood swimming pool (environment) to prevent disease.

Further progress in causal thinking led to the recognition that not just one single agent but many factors—a multiple causation approach—contribute to a disease or health disorder, as well as health inequalities (Raphael, 2012). A food poisoning outbreak that is associated with a restaurant might be caused not only by the *Salmonella* organism but also by improper food handling and storage, lack of adherence to minimum food preparation standards, and lack of adequate health department supervision and enforcement (see Chapter 7). A chronic condition such as coronary heart disease can be related to other kinds of multicausal factors such as heredity, diet, lack of exercise, smoking, and personal and work stress.

Community health nurses can control health problems by examining all possible causes and then attacking strategic causal points. Efforts to prevent human immunodeficiency virus (HIV)/AIDS provide a dramatic case in point. Contact reporting, condom use, protection of health workers serving patients infected with the HIV, screening for HIV infection, and public education about HIV/AIDS were most helpful at the start of the epidemic as an example of a multifaceted approach. Once antiretroviral medications became available, public health nurses visited vulnerable HIV/AIDS clients and provided much needed social support and monitoring of medication compliance, as well as additional education (Kelly, Hartman, Graham, Kallen, & Giordano, 2014). Daily or monthly nursing visits and nurse observation of prophylactic HIV medication among high-risk injection drug users in Thailand improved medication adherence and lowered HIV infection risk (Martin et al., 2015).

Current causal thinking has led to a broader awareness of unhealthy conditions; in

addition to disease, problems such as accidents and environmental pollution are major targets of concern. Work-related stress, environmental hazards, chemical food additives, and alcohol and nicotine consumption during pregnancy are all examples of concerns in community health nursing practice.

Nursing's contribution to public health adds a further application to causal thinking. That is, nursing seeks to identify and implement the causes, or contributing factors, of wellness. Community health nurses do more than prevent illness; they seek to promote health. By conducting research and applying evidence-based practice findings, community health nurses promote health-enhancing behaviors. Nurses promote healthier lifestyle practices such as eating healthy diets, exercising, and maintaining social support systems; promote healthy conditions in schools and worksites; and designing meaningful activities for children, adolescents, adults, and the elderly (Kulbok et al., 2012).

Changes in Education

Changes in education, especially those in nursing education, have had an important influence on community health nursing practice. Education, once an opportunity for a privileged few, has become widely available; it is now considered a basic right and a necessity for a vital society. When people's understanding of their environment grows, an increased understanding of health usually is involved. For the community health nurse, health teaching has steadily assumed greater importance in practice. For the learner, education has led to more responsibility. As a result, people believe that they have a right to know and question the reasons behind the care they receive. Community health nurses have shifted from planning for clients to collaborating with clients.

Education has had other effects. Scientific inquiry, considered basic to progress, has created a dramatic increase in knowledge. The wealth of information relevant to community health nursing practice means that nursing students have more content to assimilate, and practicing community health nurses have to make greater efforts to keep abreast of knowledge in their field. In contrast to earlier times, when nurses were trained to work as apprentices in hospitals or health agencies and to follow orders perfunctorily, today's educational programs, including continuing education, prepare nurses to think for themselves in the application of theory to practice. Evidence-based practice is emphasized, and students implement projects based upon best evidence and community values (Kulbok et al., 2012; Milbrath & DeGuzman, 2015). Environmental health issues have come to the forefront. Leffers, McDermott-Levy, Smith, and Sattler (2014) examined the response of nursing education to the 1995 Institute of Medicine report on *Nursing, Health, and the Environment*. They noted that the Alliance of Nurses for Healthy Environments, a group of public health nurses and others committed to promoting environmental health issues, was instrumental in making progress in this area of nursing education. The Henry Street Consortium (Schaffer et al., 2010), the Quad Council (Swider, Krothe, Reyes, & Cravetz, 2013), and the American Nurses Association (2013) have all updated public health nursing competencies and standards of practice, and others have sought to clarify competencies in family planning public health nursing (Hewitt, Roye, & Gebbie, 2014). Olson Keller, Strohschein, and Schaffer (2011) have described the synthesis of public health and nursing beliefs, values, and practice in their document, "Cornerstones of Public Health Nursing." Rush University evaluated and revised their graduate curriculum for advanced practice clinical nurse specialist in public/community health nursing to match outcome competencies of the Quad Council competencies for second-tier manager/specialist roles (Swider et al., 2006); others have provided teaching and learning strategies for baccalaureate degree programs that offer entry-level public health nursing courses (Callen et al., 2013).

Public health professionals, including public health nurses, are often members of interdisciplinary teams, highlighting the need for more interprofessional educational opportunities for all helping profession students (Uden-Holman, Curry, Benz, & Aquilino,

2015). Population-level simulations regarding poverty and other issues help to bring serious problems to life for nursing students (Yang, Woomer, Agbemenu, & Williams, 2014). But, due to diminishing public health budgets, finding appropriate clinical placements for public health nursing students can be challenging, and innovative solutions for clinical placements are often required (Young, Acord, Schuler, & Hansen, 2014). Poor utilization of public health nursing credentialing exams, often due to a perceived lack of value/reward or recognition in the workplace or a lack of knowledge about the exams, has caused issues with availability of these exams (American Nurses Credentialing Center [ANCC], 2016; Bekemeier, 2009; Doutrich & Dotson, 2012; Little, Vandenhouten, & DeVance-Wilson, 2013).

While baccalaureate nursing degree programs provide public health nursing coursework, graduate-level programs in community/public health nursing have been on the decline since the 1996 release of the AACN document, *Essentials of Master's Education for Advanced Practice Nursing*, defining advanced practice nursing as only those specialties that require graduate coursework in advanced physical assessment, pathophysiology, and pharmacology and focusing on provision of care to individuals. In 2006, the Doctorate of Nursing Practice degree was approved. Some instruction in population health is required; however, the curriculum does not easily match the needs of advanced public health nurses (Canales & Drevdahl, 2014; Swider et al., 2009; Swider, Levin, & Kulbok, 2015). While Duffy, McCullagh, and Lee's (2015) assessment of the need for advanced practice public health nurses in Michigan showed promising results, this may not be true in other areas.

In 2014, 55% of RNs had a bachelor's degree or higher; this is short of the 80% recommended by 2020 in the Institute of Medicine (IOM) report, *The Future of Nursing: Leading Change, Advancing Health* (American Nurses Association, 2014; IOM, 2011). More advanced degrees were also promoted in this report and the need for barriers to be removed so that nurses could "practice to the full extent of their education and training" (IOM, 2011, p. 4). Working "as full partners" with many other professionals, nurses should be involved in "redesigning health care" and implementing evidence-based practice to improve patient outcomes and nursing practice (p. 4). With health care reform, a paradigm shift from illness care to wellness and health promotion is taking place. Disease prevention and promotion of wellness and health are important areas of focus for public health nurses, and a population focus is an important component of health care reform. Care coordinators, who can help individuals better manage their chronic illnesses and promote more effective use of health care resources, are also part of health care reform (Kunic & Jackson, 2013). All of these changes have an impact on nursing education. In this new health care system, there is a strong need to focus on learning to work effectively as team members, systems approaches to care, and understanding of new payment structures that reward innovation, efficiency, safety, and quality, rather than waste and inefficiency (Buerhaus et al., 2012; Chard, 2013).

Community health nursing has always required a fair measure of independent thinking and self-reliance; now, community health nurses need skills in such areas as population

assessment, policy making, political advocacy, research, management, collaborative functioning, global health, human diversity, as well as information and health care technology (Callen et al., 2010, 2013; Kulbok et al., 2012). As the result of expanding education, public health nurses have had to reexamine their practice, sharpen their knowledge and skills, and clarify their roles.

Demographic Changes and the Role of Women

The changing demographics in the United States and the changing role of women have profoundly affected community health nursing. In the 20th century, the Women's Rights movement made considerable progress; women achieved the right to vote and gained greater economic independence by moving into the labor force (see Displays 2–2 and 2–4). In 2014, over 140 million people were employed in nonfarm positions in the United States, marking a recovery from the 2007–2009 Great Recession with average weekly hours and wages both increasing (U.S. Department of Labor, Bureau of Labor Statistics, 2015). Our current labor force is "older, more racially and ethnically diverse, and composed of more women" (Toosi, 2012, p. 43). The total labor force is projected to grow more slowly (e.g., 1% over the 2010 to 2020 time period), with 53% males and 47% females by 2020.

Nursing has historically been a predominantly female profession. In 2012, there were 2.9 million active registered nurses and over 3.8 million expected by 2025 (USDHHS, 2014). Nationally, the average age of the RN workforce is 50, with 53% of RNs over the age of 50; between 2010 and 2013, 11% of licenses issues were to males. Although most nursing schools remain full and many have a waiting list, the number of nurses staying active in their profession is dwindling. Those remaining in the profession are "graying" and retiring. Added to this is the aging population of nursing faculty, which raises concern over meeting the increased demand for nurses in the coming decade.

Salaries for nurses compare favorably with those for other workers who have 4 years of education in fields other than health care, such as education, human services (e.g., social work), and business. When compared with other workers in the health care field, however, nurses generally do not fare as well. For example, among the 2,655,020 practicing RNs in the United States in 2015, the median salary was $67,490. In comparison, the median salary for physical therapists was $84,020; for dental hygienists, it was $72.330; and for occupational therapists, it was $80,150 (U.S. Department of Labor, Bureau of Labor Statistics, 2016).

Changing demographics, such as shifting patterns in immigration, varying numbers of births and deaths, and a rapidly increasing population of elderly persons, affect community health nursing planning and programming efforts. Monitoring these changes is essential for relevant and effective nursing services. Equally important is a diverse and representative workforce in nursing. The 2013 findings of the National Sample Survey of Registered Nurses indicated that the vast majority of nurses (83%) specifying a racial background selected White (non-Hispanic). Approximately 6% identified as Asian and 6% as Black/African American; Hispanic/Latino comprised 3%, and only 2% of nurses declared Native American/Alaskan Native, or Native Hawaiian/Other Pacific Islander (1% respectively). An additional one percent stated "Other" (Budden, Zhong, Moulton, & Cimiotti, 2013). Currently, about 15% of nurses work in public health or community settings (e.g., corrections, school nursing, occupational nursing, home health, public/

community health agencies). Increased racial and ethnic representation in community health nursing is essential and remains one of the major challenges facing the profession in the coming years.

Although the diversity of career options and employment opportunities for women has been a positive social factor, these gains have impacted the number of women entering nursing. As a profession, nursing's contributions and status have improved, but its ability to compete with careers offering higher pay and status remains problematic. Changes resulting from the women's movement continue. Nurses still struggle for equality—equality of recognition, respect, and autonomy, as well as job selection, equal pay for equal work, and equal opportunity for advancement in the health field. If community health nurses are to influence the field of community health, they need status and authority equal to that of their colleagues. This step requires nurses to demonstrate their competence and learn to be assertive in assuming roles as full professional partners. The women's movement has contributed to community health nursing's gains in assuming leadership roles, but a need for greater influence and involvement remains for all nurses.

The Consumer Movement

The consumer movement has also affected the nature of community health nursing. Consumers have become more aggressive in demanding quality services and goods; they assert their right to be informed about goods and services and to participate in decisions that affect them regardless of sex, race, or socioeconomic level. This movement has stimulated some basic changes in the philosophy of community health nursing. Health care consumers are viewed as active members of the health team rather than as passive recipients of care. They may contract with the community health nurse for family care or group services, represent the community on the local health board, or act as ombudsmen by serving as representatives or advocates for their community constituents (e.g., to investigate complaints and report findings to protect the quality of care in a local nursing home). This assumption of consumers' responsibility for their own health means that the community health nurse often supplements clients' services, rather than primarily supervising them (Hagel, Keith, Brown, Samoylova, & Hoversten, 2015).

The consumer movement has also contributed to increased concern for the quality of health services, including a demand for more humane, personalized health care. Dissatisfied with fragmented services offered by an array of health workers, consumers seek more comprehensive, coordinated care (Marjoua & Bozic, 2012). For example, senior citizens in a high-rise apartment building need more than a series of social workers, nutritionists, recreational therapists, nurses, and other callers ascertaining a variety of specific needs and starting a variety of separate programs. Community health nurses seek to provide holistic care by collaborating with others to offer more coordinated, comprehensive, and personalized services—a case management approach. The 2015 Gallup Poll is an example of the current attention given to the opinions of consumers and is discussed in Display 2–7. In this poll, nursing is the most highly rated profession with respect to honesty and ethics; not a bad position to be in.

DISPLAY 2–7 NURSES RANK HIGHEST IN HONESTY AND ETHICAL STANDARDS

Nurses are again at the top of the list, according to a Gallup Poll taken in 2015. When asked how they would rate the honesty and ethical standards of members of various professions, Americans rated nurses highest. Each year, a random sample of American rates select professions on a five-point scale ranging from "very high" to

"very low." Since being added to the list in 1999, nurses have been at the top of the list each year except 2001, when firefighters took the No. 1 spot. The four lowest professions in 2015 were car salespeople, telemarketers, and members of Congress at 8%, and lobbyists at 7%. Here are the results for the top ten scoring professions:

Nurses	85%
Pharmacists	68%
Medical doctors	67%
High school teachers	60%
Police officers	56%
Clergy	45%
Funeral directors	44%
Accountants	39%
Journalists	27%
Bankers	25%

Economic Forces

Myriad economic forces have affected the practice of public health nursing. Unemployment and the rising cost of living, combined with mounting health care costs, resulted in greater numbers of people carrying little or no health insurance. With limited or no access to needed health services, these populations are especially vulnerable to health problems and further economic stress. Health care reform, or the Affordable Care Act, was enacted to address this problem, but it is not a panacea (see Chapter 6). Other economic forces affecting public health nursing are changing health care financing patterns; decreased federal, state, and local subsidies of public health programs; and pressures for health care cost containment (see Chapter 6; Display 2–8). The 2012 Institute of Medicine report, *For the Public's Health: Investing in a Healthier Future*, notes that a large amount of this nation's disease burden is preventable and that health care reforms to access, quality, and payment systems are not sufficient to improve our health and level of health care expenditures. Population-based health interventions are needed, along with universal coverage and addressing system inefficiencies and waste. Changes in how funding is allocated to local and state public health departments, along with a "dedicated, stable, and long-term financing structure" for communities and an infrastructure for federal research to promote prevention strategies, implement programs, and determine comparative effectiveness of interventions (p. 11).

DISPLAY 2–8 TWENTY YEARS IN HISTORY: 1986 TO 2006

1986	*Standards of Community Health Nursing Practice* published by ANA.
	National Center for Nursing Research created at the National Institutes of Health.
1990	*Healthy People 2000: National Health Promotion and Disease Prevention Objectives*.
1991	Elizabeth Dole becomes the first woman president of the American Red Cross since Clara Barton.
1993	National Center for Nursing Research becomes the National Institute of Nursing Research.
1996	*Health Insurance Portability and Accountability Act* (HIPPA) signed into law.
	Food and Drug Administration issues restrictive regulations for cigarettes and smokeless tobacco.
1997	Oregon legalizes Death With Dignity, allowing terminally ill patients to end their lives with self-administered lethal injection.
1999	*Scope and Standards of Public Health Nursing Practice* published by ANA.
	Targeted drug therapies for some cancers introduced (Herceptin, TyKerb).
2000	*Healthy People 2010: Understanding and Improving Health*.
	Draft sequencing of human genome completed and released to public.
2001	September 11 attacks result in over 3,000 deaths in New York City, Washington, and Pennsylvania.
2002	Hormone replacement therapy linked to increased risk of heart attack, blood clots, stroke, and breast cancer.
2003	War in Iraq begins.
	Worldwide epidemic of Severe Acute Respiratory Syndrome (SARS).
2006	Medicare Part D Prescription Drug benefit implemented.
	Public Health Nursing: Scope and Standards of Practice published by ANA.
	HIV-cocktail drug, Atripla, and HPV vaccine, Gardasil, approved by FDA.

Global economic forces also influence community health nursing practice. As the United States experiences increasing interdependence with foreign countries for trade, investment, and production of goods, the population has experienced a growing mobility and increased immigration, particularly among Hispanic and Asian groups. Refugees from wars and uprisings are also seeking asylum. Under these conditions, the spread of communicable diseases poses a serious threat, as do problems associated with unemployment and poverty. Furthermore, the fastest-growing sector of the job market is in technical fields, which require new or retrained workers, and these jobs frequently are accompanied by health problems related to the stresses of ever-changing technology and financial and competitive pressures to produce.

Community health nursing has responded to these economic forces in several ways. One is by assuming new roles, such as health educators in industry or case managers for government and privately sponsored programs for the elderly. Another is by directly competing with other community health service providers, particularly in such areas as ambulatory care or home care. Still another is by developing new programs and service emphases. Elder daycare, respite care, drug prevention projects, mentoring programs for pregnant/parenting adolescents, programs for the homeless, lifestyle intervention clinics, and working with social workers to meet the health needs of foster children are a few examples of the response by public health nursing to the changing community needs created by demographic and economic forces (Nymberg & Drenvenhorn, 2015; Schaffer & Mbibi, 2014; Schneiderman, 2008). Yet another PHN response has been to develop new revenue-generating services, such as workplace wellness or health-screening programs, to augment depleted budgets. Economic factors continue to play a significant role in shaping community health nursing practice. Yet, public health nurses continue to be resourceful in finding ways to foster the community's optimal health while adapting to changing economic conditions (Fig. 2–14).

FIGURE 2–14 Community Health Nurse weighing a baby.

PREPARATION FOR COMMUNITY HEALTH NURSING

The demands of community health nursing practice are significant, as described in Chapter 1, and are elaborated elsewhere in this textbook. The daily routine of the public health nurse may include organizing a flu clinic for seniors in the community, making home visits, giving a presentation on playground safety at a parent–teacher meeting, participating in a team meeting about a population-focused grant, answering telephone calls, and charting. All of the skills learned in a basic bachelor's degree nursing program are needed. Furthermore, larger public health nurse roles also include service on community advisory boards, grant writing for new programs, or participation in or presentation of in-service programs. Academic preparation for this role is necessary, as is continuous professional development, and this training must meet the requirements of both employers and, in many instances, state regulations. While associate degree nursing programs do not specifically entail public health nursing coursework, RN to BSN completion programs are available and provide the coursework needed for PHN certification in most states. Continuing education is encouraged and may be required in your state. To move up into supervisory or leadership roles, or as advanced practice nurses (e.g., nurse practitioners working in women's health or well-child clinics), graduate-level education is needed (Display 2–9).

DISPLAY 2–9 TWENTY YEARS IN HISTORY: 2008 AND BEYOND

2008	Barack Obama elected President; first African American to hold this position.
2009	*Essentials of Baccalaureate Nursing Education for Entry Level Community/Public Health Nursing* published by the Association of Community Health Nursing Educators, Education Committee. H1N1 swine outbreak declared a national emergency with over 22 million American's contracting the disease and 4,000 deaths.
2010	*Patient Protection and Affordable Care Act* signed and includes federal funding for nurse–family home visitation programs such as the Nurse Family Partnership to improve maternal/child health. Grant funding approved for existing school-based clinics as well as new construction. Institute of Medicine publishes the *Future of Nursing: Leading Change, Advancing Health*.
2011	*The Future of Nursing: Leading Change, Advancing Health*, an Institute of Medicine report was released. *Healthy People 2020* released. Medicare reimbursement to Certified Nurse-Midwives increased from 65% to 100% of the Physician Fee Schedule. National Health Service Corps (NHSC) hires over 10,000 additional nurses and other health care professionals.
2012	*Patient-Centered Outcomes Research Institute (PCORI)* established, with two recognized nurse leaders/researchers serving on the Board of Governors and Methodology Committee. Institute of Medicine publishes *For the Public's Health: Investing in a Healthier Future*.
2013	Under *Affordable Care Act*, grants and scholarships expanded for nursing and other health professionals. ANA publishes second edition of *Public Health Nursing: Scope and Standards of Practice*.
2014	*Advanced Nursing Education Grant* program funded to expand the number of nurses in advanced nursing education and practice. *Nursing Education and Loan Repayment Program* expanded to include up to 85% of loan forgiveness for registered nurses, advanced practice nurses, and faculty members working a minimum of 2 years in either critical shortage areas or accredited schools of nursing.
2015	Right-to-Die legislation for terminally ill patients enacted in California.

SUMMARY

The specialty of community health nursing developed historically through four stages. The early home care stage (before the mid-1800s) emphasized care to the sick poor in their homes by various lay and religious orders. The district nursing stage (mid-1800s) included voluntary home nursing care for the poor by specialists or "health nurses" who treated the sick and taught wholesome living to patients. The public health nursing stage (1900–1970) was characterized by an increased concern for the health of the general public. The community health nursing stage (1970 to the present) includes increased recognition of community health nursing as a specialty field, with focus on communities and populations.

Six major societal influences have shaped the development of community health nursing. They are advanced technology, progress in causal thinking, changes in education, the changing demographics and role of women, the consumer movement, and economic factors such as health care costs, access, limited funds for public health, and increased competition among health service providers.

Academic preparation for community health nursing begins at the baccalaureate level. However, students beginning at the diploma or associate degree level can advance to a BSN completion program and are then prepared to enter this challenging specialty in nursing. Once students achieve an undergraduate degree, completion of additional educational programs is required to keep current and, in most states, to maintain licensure, advance in practice opportunities, or branch out into administration, teaching, or research.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Select one societal influence on the development of community health nursing and explore its continuing impact. What other events are occurring today that shape community health nursing practice? Support your arguments with documentation. Use the Internet to find your documentation.
2. Search the Web for information about a historical public health nursing leader. Using this information, determine how this practitioner might deal with current population-based issues such as HIV/AIDS, sexually transmitted diseases, obesity, or child neglect and abuse.
3. Read a historical article about early public health nursing experiences (e.g., January, 2009 article or Curtis, 2008 article listed in the References). Compare these experiences with your public health clinical experiences today. What are the most striking similarities and differences?
4. Assume that you have been asked to make a home visit to a 75-year-old man, living alone, whose wife recently died. Besides assessing his individual needs, what additional factors should you consider for assessment and intervention that would indicate an aggregate or population-focused approach? What self-care practices might you promote? How would you provide health education to your client?
5. Interview a public health nursing director or supervisor to determine what population-based programs are offered in your locality. Explore nursing's role in the assessment, development, implementation, and evaluation of these programs. Discuss with the director how community health nurses might expand their population-focused interventions.
6. Find information about advanced nursing degrees that may be available locally or online. Compare your findings with other classmates' findings. Which specialty areas are of interest to you?

Assessment
Assurance
Case management
Clinician
Collaborator
Educator
Leader
Manager
Policy development
Triple Aim

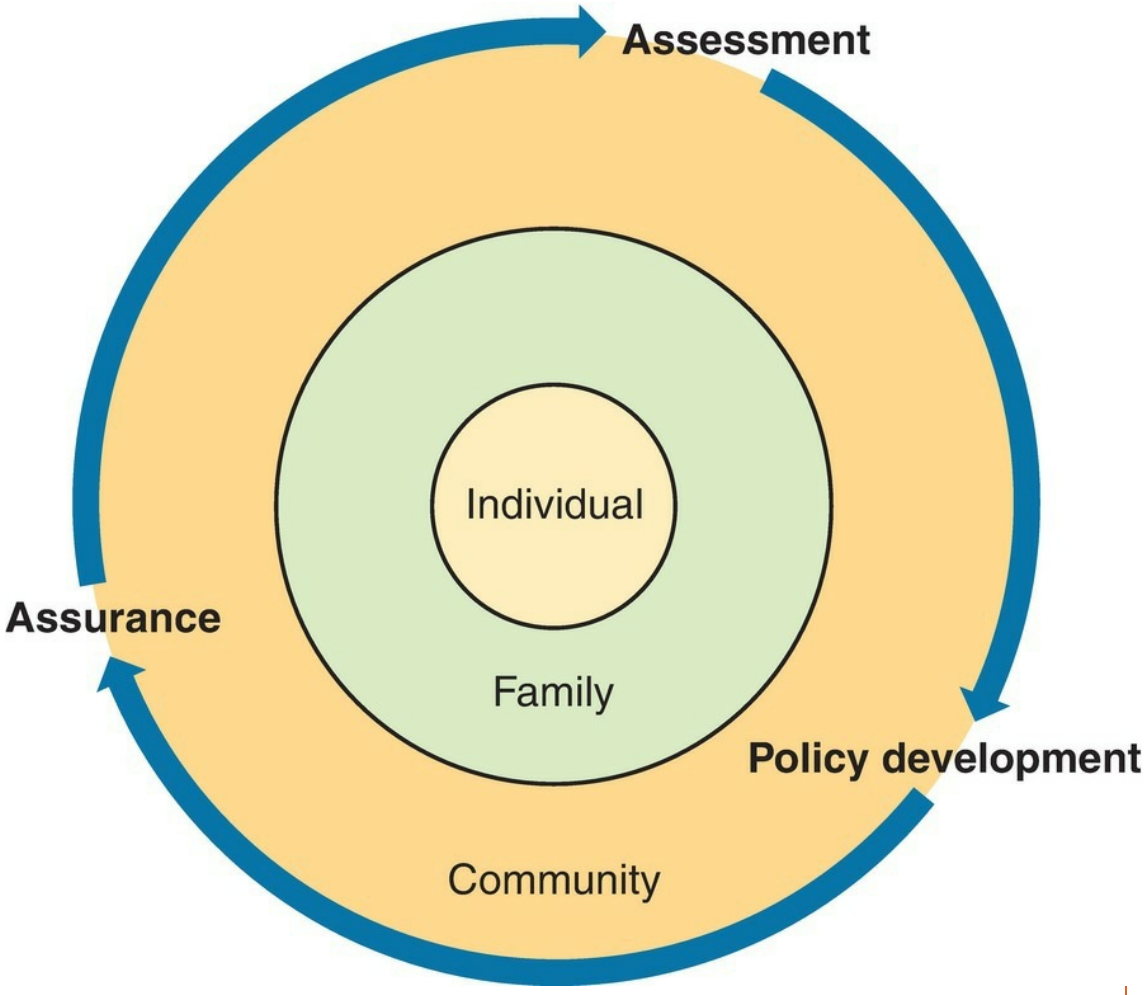
LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify the three core public health functions basic to community health nursing.
- Describe and differentiate among seven different roles of the community health nurse.
- Discuss the seven roles within the framework of public health nursing functions.
- Explain the importance of each role for influencing people's health.
- Identify and discuss factors that affect a nurse's selection and practice of each role.
- Describe seven settings in which community health nurses practice.
- Discuss the nature of community health nursing, and the common threads basic to its practice, woven throughout all roles and settings.
- Identify principles of effective nursing practice in the community.

Historically, community health nurses have engaged in many professional roles. Nurses in this professional specialty have provided care to the sick, taught positive health habits and self-care, advocated on behalf of needy populations, developed and managed health programs, provided leadership, and collaborated with other professionals and consumers to implement changes in health services. Although the practice settings may have differed, the essential goal of the community health nurse has always been a healthier community. The home certainly has been one site for

practice, but so too have public health clinics, schools, factories, and other community-based locations. Today, the roles and settings of community health nursing practice have expanded even further, offering a wide range of professional opportunities. This chapter examines how the conceptual foundations and core functions of community health practice are integrated into the various roles and settings of community health nursing. It provides an opportunity to gain greater understanding about how and where community health nursing is practiced. Moreover, it will expand awareness of the many existing and future possibilities for community health nurses to improve the public's health. As you read through this chapter, think about client populations that you may have encountered in the acute care setting and consider your role with these same populations in a community setting. Perhaps you may discover a community health nursing specialty area that you never even considered.



CORE PUBLIC HEALTH FUNCTIONS

Community health nurses work as partners within a team of professionals (in public health and other disciplines), nonprofessionals, and consumers to improve the health of populations. The various roles and settings for practice hinge on three primary functions of public health: assessment, policy development, and assurance (Institute of Medicine, 1988). These functions are foundational to all roles assumed by the community health nurse and are applied at three levels of service: to individuals, to families, and to communities (see Display 3–1). Regardless of the role or setting of choice, these three essential responsibilities direct the work of all community health nurses.

DISPLAY 3.1 PUBLIC HEALTH NURSING WITHIN THE CORE PUBLIC HEALTH FUNCTIONS MODEL

The model includes assessment, policy development, and assurance surrounding the individual, family, and community. *Assessment* is the systematic collection, assembly, analysis, and dissemination of information about the health of a community. *Policy development* uses the scientific information gathered during assessment to create comprehensive public health policies. *Assurance* is the pledge to constituents that services necessary to achieve agreed-upon goals are provided by encouraging actions of others (private or public), requiring action through regulation, or providing service directly.

From Institute of Medicine. (1988). The future of public health. Retrieved from http://www.cdc.gov/nphpsp/essentialservices.html

Assessment

An essential first function in public health, assessment, means that the community health nurse must gather and analyze information that will affect the health of the people to be served. As described in Display 3–1, assessment is *the systematic collection, assembly, analysis, and dissemination of information about the health of a community*. The nurse and others on the health team need to determine health needs, health risks, environmental conditions, political agendas, and financial and other resources, depending on the individuals, community, or population targeted for intervention. Data may be gathered in many ways; typical methods include interviewing people in the community, conducting surveys, gathering information from public records (many of which are available online), and using research findings.

The community health nurse is typically both trusted and valued by clients, agencies, and private providers. Trust placed in the community health nurse can often be attributed to consistency, honesty, dependability, and an ongoing presence in the community. Although securing and maintaining the trust of others is pivotal to all nursing practice, it is even more critical when working in the community. Trust can afford a nurse access to client populations that are difficult to engage, to agencies, and to health care providers. In the capacity of trusted professional, community health nurses gather relevant client data that enable them to identify strengths, weaknesses, and needs. It is important to recognize that as difficult as it may be for the nurse to gain the trust and respect of the community, if ever lost, these attributes can be difficult if not impossible to regain.

At the community level, assessment is done both formally and informally as nurses identify and interact with key community leaders. With families, the nurse can evaluate family strengths and areas of concern in the immediate living environment and in the neighborhood. At the individual level, people are identified within the family who are in need of services, and the nurse evaluates the functional capacity of these individuals through the use of specific assessment measures and a variety of tools. Assessment of communities and families as the initial step in the nursing process is discussed more fully in Chapters 15 and 19.

Policy Development

Policy development (defined in Display 3–1) is enhanced by the synthesis and analysis of information obtained during assessment. At the community level, the nurse provides leadership in convening and facilitating community groups to evaluate health concerns and develop a plan to address those concerns. Typically, the nurse recommends specific training and programs to meet identified health needs of target populations. This is accompanied by raising the awareness of key policy makers about factors such as health regulations and budget decisions that negatively affect the health of the community (see Chapter 13). With families, the nurse recommends new programs or increased services based on identified needs. Additional data may be needed to identify trends in groups or clusters of families, so that effective intervention strategies can be used with these families. At the individual level, the nurse assists in the development of standards for individual client care, recommends or adopts risk classification systems to assist with prioritizing individual client care, and participates in establishing criteria for opening, closing, or referring individual cases.

Assurance

Assurance activities—activities that make certain that services are provided—often consume most of the community health nurse's time. Community health nurses perform the assurance function at the community level when they provide services to target populations, improve quality assurance activities, maintain safe levels of communicable disease surveillance and outbreak control, and collaborate with community leaders in the preparation of a community emergency preparedness plan. In addition, they participate in outcome research, provide expert consultation, promote evidence-based practice, and provide services within the community based on standards of care.

Essential Services

To more clearly articulate the services that are linked to the core functions of assessment, policy development, and assurance, a list of 10 essential services was developed in 1994 by the Public Health Functions Steering Committee (U.S. Department of Health and Human Services [USDHHS], 1997) (see Display 3–2). This initial effort to define the service components of the core functions provided an organized service delivery plan for public health providers across the country. A model depicting the relationships between the core functions and the essential services was eventually developed (USDHHS, Office of Disease Prevention and Health Promotion, 1999). The model (Fig. 3–1) shows the types of services necessary to achieve the core functions of assessment, policy development, and assurance. It also emphasizes the circular or ongoing nature of the process. The placement of research at the center of the model is a clear indication of the high priority placed on providing scientific evidence in all areas of service delivery. Research is essential to evidence-based practice and is vital to achieving healthy communities. As you review this model, think about what types of services might be provided in each category, depending on whether you are focusing on an individual, a family, or a community. It is not necessary that the community health nurse provide each of the listed services. Working in collaboration with an interdisciplinary team, the community nurse can support the efforts of others to achieve improved health in the community. What is important is that the team members all recognize their respective roles and are working toward the same goal.

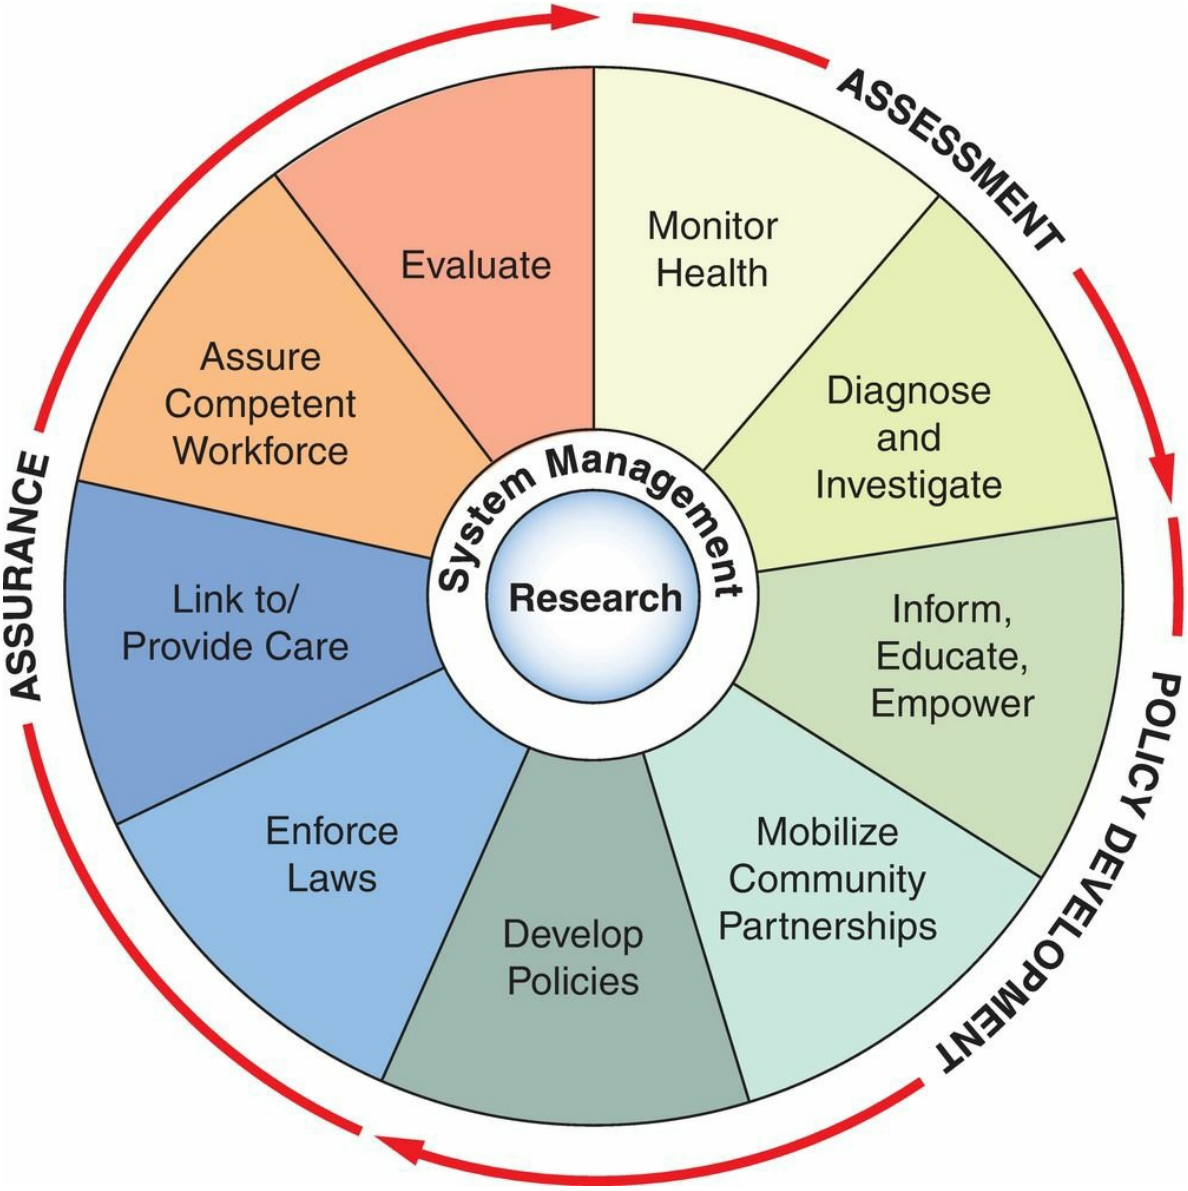


FIGURE 3–1 The core functions and 10 essential services of public health. (From Centers for Disease Control and Prevention. (2015). Retrieved from http://www.health.gov/phfunctions/public.htm)

DISPLAY 3.2 TEN ESSENTIAL SERVICES OF PUBLIC HEALTH

1. *Monitor* health status to identify and solve community health problems.
2. *Diagnose and investigate* health problems and health hazards in the community.

3. *Inform*, *educate*, and *empower* people about health issues.
4. *Mobilize* community partnerships and action to identify and solve health problems.
5. *Develop policies and plans* that support individual and community health efforts.
6. *Enforce* laws and regulations that protect health and ensure safety.
7. *Link* people to needed personal health services and assure the provision of health care when otherwise unavailable.
8. *Ensure* competent public and personal health care workforces.
9. *Evaluate* effectiveness, accessibility, and quality of personal and population-based health services.
10. *Research* for new insights and innovative solutions to health problems.

From Centers for Disease Control and Prevention. (2014). National public health performance standards: The 10 essential public health services. Retrieved from http://www.cdc.gov/nphpsp/essentialservices.html

STANDARDS OF PRACTICE

In 2008, the American Association of Colleges of Nursing (AACN) published the revised *The Essentials of Baccalaureate Education for Professional Nursing Practice*. Building on the 1998 version, this document was a major step in providing clear guidelines as to what constitutes professional nursing education. Roles of beginning professional nursing practice were grouped into three broad roles: "provider of care; designer/manager/coordinator of care; and member of a profession" (AACN, 2008, p. 3). Although this document describes educational preparation in all areas of nursing practice, the link to community health nursing is quite evident. The document outlines the knowledge, skills, and attitudes seen as vital to the education of the baccalaureate nurse. Practice-focused outcomes typically associated with community health nursing are emphasized in Essential Seven: Clinical Prevention and Population Health, stressing that "health promotion and disease prevention at the individual and population level are necessary to improve population health and are important components of baccalaureate generalist nursing practice" (AACN, 2008, p. 4). This document clearly articulates the growing need to prepare nurses to assume a variety of roles in the community emphasizing that the baccalaureate nurse "is prepared to practice with patients, including individuals, families, groups, communities, and populations across the lifespan and across the continuum of healthcare environments" (AACN, 2008, p. 4).

Community health nursing practice is further defined by specific standards developed under the auspices of the American Nurses Association (ANA) in collaboration with the Quad Council of Public Health Nursing Organizations (ANA, 2013c). The Quad Council is composed of representatives from the ANA—Council on Nursing Practice and Economics; the American Public Health Association—Public Health Nursing Section; the Association of Community Health Nursing Educators (ACHNE); and the Association of Public Health Nurses (APHN). These four organizations represent academics and professional practitioners, providing a broad spectrum of views regarding professional practice in the field of community health nursing. *Public Health Nursing: Scope and Standards of Practice* (ANA, 2013c) provides guidance as to what constitutes public health nursing and how it can be differentiated from other nursing specialties. Standards of care are consistent with the nursing process and include assessment, population diagnosis and priorities, outcomes identification, planning, implementation, and evaluation. This document is an important reference for all those practicing in the community. It provides the basis for evaluating an individual's performance in this field and is used by many employers to assess job performance.

In addition to their work on the practice standards, the ACHNE published the updated *Essentials of Baccalaureate Nursing Education for Entry-Level Community/Public Health Nursing* in 2010 (Education Committee of ACHNE). This document builds on previous versions and is consistent with both the *Essentials* document (AACN, 2008) and the scope and standards of public health nursing practice (ANA, 2013c). This document

describes core professional values as well as knowledge and basic competencies. Core values of professional behavior emphasize community/population as client, prevention, partnership, healthy environment, and diversity. Building on these common values, 15 essential concepts and their related competencies are delineated including 3 newly defined essentials; communication; social justice; and emergency preparedness, response, and recovery (ACHNE, Education Committee, 2010). It is also important to recognize that an emphasis of *Healthy People 2020* is to create and support a competent public and personal health care workforce including professional competencies required for sound practice (see Display 3–3) (USDHHS, 2016a).

DISPLAY 3.3 *HEALTHY PEOPLE 2020*—PUBLIC HEALTH INFRASTRUCTURE

Workforce Objectives

PHI-1Increase the proportion of federal, tribal, state, and local public health agencies that incorporate core competencies for public health professionals into job descriptions and performance evaluations.PHI-2(Developmental) Increase the proportion of tribal, state, and local public health personnel who receive continuing education consistent with core competencies for public health professionals.PHI-3Increase the proportion of Council on Education for Public Health (CEPH) accredited schools of public health, CEPH-accredited academic programs, and schools of nursing (with a public health or community health component) that integrate core competencies for public health professionals into curricula.PHI-4Increase the proportion of 4-year colleges and universities that offer public health or related majors and/or minors.PHI-5(Developmental) Increase the proportion of 4-year colleges and universities that offer public health or related majors and/or minors that are consistent with the core competencies of undergraduate public health education. PHI-6Increase the proportion of 2-year colleges that offer public health or related associate degrees and/or certificate programs.

PHI, public health infrastructure.

From U.S. Department of Health and Human Services (USDHHS). (2015). Healthy people 2020 topics and objectives: Public health infrastructure. Retrieved from https://www.healthypeople.gov/2020/topics-objectives/topic/public-health-infrastructure/objectives

The community health nurse provides nursing services based on other standards developed by the ANA, such as the *Code of Ethics for Nurses with Interpretive Statements* (2015a), *Nursing's Social Policy Statement* (2010), and *Nursing: Scope and Standards of Practice* (2015b). Each of these documents provides essential information regarding sound general nursing practice. When combined with *Public Health Nursing: Scope and Standards of Practice* (ANA, 2013c), they provide the community health nurse with a clear understanding of accepted practice in this nursing specialty. The Quad Council of Public Health Nursing Organizations is comprised of the Association of Public Health Nurses (APHN), the Association of Community Health Nursing Educators (ACHNE), the Public Health Nursing Section of the American Public Health Association, and the American Nurses Association Council on Nursing Practice and Economics. The Quad Council of Public Health Nursing Organizations updated the Core Competencies for Public Health Nurses (CCPHN) in 2011. The competencies include eight domains consisting of analytic assessment skills, policy development/program planning skills, communication skills, cultural competency skills, community dimensions of practice skills, public health sciences skills, financial planning and management skills, and leadership and systems thinking skills. The competencies consist of three tiers of practice beginning with the public health nurse generalist in tier one followed by the public health nurse specialist in tier two and ending with the public health nurse administrator practice skills in tier three (Swider, Krothe, Reyes, & Cravetz, 2013). The tier one public health nursing competencies are listed in Display 3–4.

DISPLAY 3.4 TIER 1 PUBLIC HEALTH NURSING COMPETENCIES

Domain 1: Analytic and Assessment Skills

1. Identifies the determinants of health and illness of individuals and families, using multiple sources of data
2. Uses epidemiologic data and the ecological perspective to identify health risks for a population. Identifies individual and family assets and needs, values and beliefs, resources and relevant environmental factors
3. Identifies variables that measure health and public health conditions
4. Uses valid and reliable methods and instruments for collecting qualitative and quantitative data from multiple sources. Develops a data collection plan using appropriate technology to collect data to inform the care of individuals, families, and groups

5. Identifies sources of public health data and information. Collects, interprets, and documents data in terms that are understandable to all who were involved in the process, including communities
6. Uses valid and reliable data sources to make comparisons for assessment
7. Identifies gaps and redundancies in data sources in a community assessment through work with individuals, families, and communities
8. Applies ethical, legal, and policy guidelines and principles in the collection, maintenance, use, and dissemination of data and information
9. Describes the public health nursing applications of quantitative and qualitative data
10. Collects quantitative and qualitative data that can be used in the community health assessment process. Assesses data collected as part of the community assessment process to make inferences about individuals, families, and groups
11. Utilizes information technology to collect, analyze, store, and retrieve data related to public health nursing care of individuals, families, and groups
12. Practices evidence-based public health nursing to promote the health of individuals, families, and groups
13. Uses available data and resources related to the social determinants of health when planning care for individuals, families, and groups

Domain 2: Policy Development/Program Planning Skills

1. Identifies policy issues relevant to the health of individuals, families, and groups. Describes the structure of the public health system and its impacts on individuals, families, and groups within a population
2. Identifies the implications of policy options on public health programs and the potential impacts on individuals, families, and groups within population
3. Identifies outcomes of health policy relevant to PHN practice
4. Collects information that will inform policy decisions. Describes the legislative policy development process. Identifies outcomes of current health policy relevant to PHN practice
5. Describes the structure of the public health system. Identifies public health laws and regulations relevant to PHN practice. Provides public health nursing services in a manner consistent with laws and regulations
6. Participates as a team member in developing organizational plans to implement programs and policies
7. Participates in teams to assure compliance with organizational policies
8. Assists in the design of an evaluation plan for an individual-, family-, or community-focused program. Participates as a team member to evaluate programs to individuals, families, and groups for their effectiveness and quality
9. Understands methods and practices used to identify and access public health information for individuals, families, and groups

10. Understands that quality improvement is important to the practice of public health nursing. Participates in quality improvement teams. Describes various approaches used to improve public health processes and systems. Utilizes quality indicators and core measures to identify and address opportunities for improvement in the care of individuals, families, and groups

Domain 3: Communications Skills

1. Assesses the health literacy of the individuals, families, and groups served
2. Communicates effectively in writing, orally, and electronically. Communicates in a culturally responsive and relevant manner. Communications are characterized by critical thinking
3. Solicits input from individuals, families, and groups when planning and delivering health care
4. Utilizes a variety of methods to disseminate public health information to individuals, families, and groups within a population
5. Demonstrates presentation of targeted health information to multiple audiences at a local level, including groups, peer professionals, and agency peers
6. Communicates effectively with individuals, families, and groups and as a member of interprofessional team(s)
7. Articulates the role of public health nursing to internal and external audiences

Domain 4: Cultural Competency Skills

1. Utilizes the social and ecological determinants of health to work effectively with diverse individuals, families, and groups
2. Uses concepts, knowledge, and evidence of the social determinants of health in the delivery of services to individuals, families, and groups. Utilizes information technology to understand the impact of the social determinants of health on individuals, families, and groups
3. Adapts public health nursing care to individuals, families, and groups based on cultural needs and differences
4. Explains factors contributing to cultural diversity
5. Articulates the benefits of a diverse public health workforce
6. Demonstrates culturally appropriate public health nursing practice with individuals, families, groups, and community members. Contributes to promoting culturally responsive work environment

Domain 5: Community Dimensions of Practice Skills

1. Utilizes an ecological perspective in health assessment, planning, and interventions with individuals, families, and groups

2. Identifies research issues at a community level. Functions effectively as a member of a community-based participatory research (CBPR) team
3. Identifies community partners for PHN practice with individuals, families, and groups
4. Collaborates with community partners to promote the health of individuals and families within the population
5. Partners effectively with key stakeholders and groups in care delivery to individuals, families, and groups
6. Participates effectively in activities that facilitate community involvement
7. Describes to individuals, families, and groups the role of government and the private and nonprofit sectors in the delivery of community health services
8. Utilizes community assets and resources to promote health and to deliver care to individuals, families, and groups
9. Seeks input from individuals, families, and groups and incorporates it into plans of care
10. Supports public health policies, programs, and resources. Identifies opportunities for population-focused advocacy for individuals, families, and groups

Domain 6: Public Health Sciences Skills

1. Incorporates public health and nursing science in the delivery of care to individuals, families, and groups
2. Describes the historical foundation of public health and public health nursing
3. Describes how individual-, family-, and group-focused programs contribute to meeting the core public health functions and the 10 essential services
4. Uses basic descriptive epidemiological methods when conducting a health assessment for individuals, families, and groups
5. Interprets research relevant to public health interventions for individuals, families, and groups
6. Accesses public health and other sources of information using informatics and other information technologies
7. Identifies gaps in research evidence to guide public health nursing practice
8. Complies with the requirements of patient confidentiality and human subject protection
9. Participates in research at the community level to build the scientific base of public health nursing

Domain 7: Financial Management and Planning Skills

1. Describes the interrelationships among local, state, tribal, and federal public health and health care systems

2. Describes the structure, function, and jurisdictional authority of the organizational units within federal, state, tribal, and local public health agencies
3. Adheres to the organization's policies and procedures, including emergency preparedness and response
4. Provides data for inclusion in a programmatic budget
5. Describes the impact of budget constraints on the delivery of public health nursing care to individuals, families, and groups
6. Provides input into budget priorities
7. Provides data to evaluate care and services for individuals, families, and groups. Contributes to the evaluation plan for a program targeting individuals, families, and/or groups
8. Adapts the delivery of public health nursing care to individuals, families, and groups based on reported evaluation results
9. Provides input into the fiscal and narrative components of proposals for funding from external sources
10. Applies basic human relations and conflict management skills in interactions with peers and other health care team members
11. Utilizes public health informatics skills relative to the public health nursing care of individuals, families, and groups
12. Provides input into contracts and other agreements for the provision of services
13. Delivers public health nursing care within budgetary guidelines

Domain 8: Leadership and Systems Thinking Skills

1. Incorporates ethical standards of practice as the basis of all interactions with organizations, communities, and individuals. Incorporates ethical standards into all aspects of public health nursing practice
2. Applies systems theory to PHN practice with individuals, families, and groups
3. Participates with stakeholders to identify vision, values, and principles for community action
4. Identifies internal and external factors affecting PHN practice and services
5. Uses individual, team, and organizational learning opportunities for personal and professional development as a public health nurse
6. Acts as a mentor, coach, or peer advisor/reviewer for public health nursing staff. Maintains personal commitment to lifelong learning and professional development
7. Participates in quality initiatives that identify opportunities for improvement. Provides data to measure, report, and improve organizational performance
8. Adapts the delivery of public health nursing care in consideration of changes in the public health system and the larger social, political, and economic environment. Maintains knowledge of current public health laws and policies relevant to public health nursing practice

From Swider, S., Krothe, J., Reyes, D., & Cravetz, M. (2013). The Quad Council practice competencies for public health nursing. Public Health Nursing, 30(6), 519–536, with permission.

With specific standards of practice and clear competencies to achieve, the community health nurse can integrate the core functions of assessment, policy development, and assurance throughout all of the various roles and community settings of practice.

ROLES OF COMMUNITY HEALTH NURSES

Just as the health care system is continually evolving, community health nursing practice evolves to remain effective with the clients it serves. Over time, the role of the community health nurse has broadened. This breadth is reflected in the description of public health nursing from the American Public Health Association, Public Health Nursing Section (2013):

> Public health nursing is a specialty practice within nursing and public health. It focuses on improving the population health by emphasizing prevention, and attending to multiple determinants of health. Often used interchangeably with community health nursing, this nursing practice includes advocacy, policy development, and planning, which addresses issues of social justice. With a multi-level view of health, public health nursing action occurs through community applications of theory, evidence, and a commitment to health equity (para. 3).

Community health nurses wear many hats while conducting day-to-day practice. At any given time, however, one role is primary. This is especially true for specialized roles, such as that of full-time manager. This chapter examines seven major roles: clinician, educator, advocate, manager, collaborator, leader, and researcher. It also describes the factors that influence the selection and performance of those roles.

Clinician Role

The most familiar role of the community health nurse is that of clinician or care provider. The provision of nursing care, however, takes on new meaning in the context of community health practice. The clinician role in community health means that the nurse ensures health services are provided not just to individuals and families, but also to groups and populations. Nursing service is still designed for the special needs of clients; however, when those clients comprise a group or population, clinical practice takes different forms. It requires different skills to assess collective needs and tailor service accordingly. For instance, one community health nurse might visit elderly residents in a seniors' high-rise apartment building. Another might serve as the clinic nurse in a rural prenatal clinic that serves migrant farm workers. These are opportunities to assess the needs of entire aggregates and design appropriate services.

For community health nurses, the clinician role involves certain emphases that are different from those of basic nursing. Three clinician emphases, in particular, are useful to consider here: holism, health promotion, and skill expansion.

Holistic Practice

Most clinical nursing seeks to be broad and holistic. In community health, however, a holistic approach means considering the broad range of interacting needs that affect the collective health of the "client" as a larger system (Dossey & Keegan, 2016). Holistic nursing care encompasses the comprehensive and total care of the client in all areas, such as physical, emotional, social, spiritual, and economic. All are considered and cared for when the client is a large system, just as they should be with individual clients. The client is a composite of people whose relationships and interactions with each other must be considered in totality. Holistic practice must emerge from this systems perspective (Fig. 3–2).

FIGURE 3–2 PHN student visiting an elderly client in her home.

For example, when working with a group of pregnant teenagers living in a juvenile detention center, the nurse would consider the girls' relationships with one another, their parents, the fathers of their unborn children, and the detention center staff. The nurse would evaluate their ages, developmental needs, and peer influences, as well as their knowledge of pregnancy, delivery, and issues related to the choice of keeping or giving up their babies. The girls' reentry into the community and their future plans for school or employment would also be considered. Holistic service would go far beyond the physical condition of pregnancy and childbirth. It would incorporate consideration of pregnant adolescents in this community as a population at risk. What factors contributed to these girls' situations, and what preventive efforts could be instituted to protect other teenagers or these teens from future pregnancies? The clinician role of the community health nurse involves holistic practice from an aggregate perspective.

Focus on Wellness

The clinician role in community health also is characterized by its focus on promoting wellness. As discussed in Chapter 1, the community health nurse provides service along the entire range of the health continuum, but especially emphasizes promotion of health and prevention of illness. Effective services include seeking out clients who are at risk for poor health and offering preventive and health-promoting services, rather than waiting for them to come for help after problems arise. The community health nurse identifies people, programs, and agencies interested in achieving a higher level of health and works with them

to accomplish that goal and to sustain the expected changed behavior (Pender, Murdaugh, & Parsons, 2015). The nurse may help employees of a business learn how to live healthier lives or work with a group of people who want to quit smoking. The community health nurse may hold seminars with a men's group on enhancing fathering skills or assist a corporation with the implementation of a health promotion program. Groups and populations are identified, which may be vulnerable to certain health threats, and preventive and health-promoting programs can be designed in collaboration with the community (Pender et al., 2015). Examples include immunization of preschoolers, family planning programs, cholesterol screening, and prevention of behavioral problems in adolescents. Protecting and promoting the health of vulnerable populations is an important component of the clinician role and is addressed extensively in the chapters in Unit VII on vulnerable aggregates.

Expanded Skills

Many different skills are used in the role of the community health clinician. In the early years of community health nursing, emphasis was placed on physical care skills. With time, skills in observation, listening, communication, and counseling became integral to the clinician role as it grew to encompass psychological and sociocultural factors. Recently, environmental and community-wide considerations—such as problems caused by pollution, violence and crime, drug abuse, unemployment, poverty, homelessness, and limited funding for health programs—have created a need for stronger skills in assessing the needs of groups and populations and intervening at the community level. The clinician role in population-based nursing also requires skills in collaboration with consumers and other professionals, use of epidemiology and biostatistics, community organization and development, research, program evaluation, administration, leadership, and effecting change (ANA, 2013c). These skills are addressed in greater detail in later chapters.

Educator Role

A second important role of the community health nurse is that of educator or health teacher. Health teaching, a widely recognized part of nursing practice, is legislated through nurse practice acts in a number of states and is one of the major functions of the community health nurse (ANA, 2013c).

The educator role is especially useful in promoting the public's health for at least two reasons. First, community clients are usually not acutely ill and can absorb and act on health information. For example, a class of expectant parents, unhampered by significant health problems, can grasp the relationship of diet to fetal development. They understand the value of specific exercises to the childbirth process, are motivated to learn, and are more likely to perform those exercises. Thus, the educator role has the potential for finding greater receptivity and providing higher-yield results.

Second, the educator role in community health nursing is significant because a wider audience can be reached. With an emphasis on populations and aggregates, the educational efforts of community health nursing are appropriately targeted to reach many people. Instead of limiting teaching to one-on-one or small groups, the nurse has the opportunity and mandate to develop educational programs based on community needs that seek a community-wide impact. Community-wide antidrug campaigns, dietary improvement programs, and improved handwashing efforts among children provide useful models for implementation of the educator role at the population level and demonstrate its effectiveness in reaching a wide audience (Bastable, 2014).

One factor that enhances the educator role is the public's higher level of health consciousness. Through plans ranging from the President's Council on Fitness, Sport and Nutrition (2016) to local antismoking campaigns, people are recognizing the value of health and are increasingly motivated to achieve higher levels of wellness. When a middle-aged man, for example, is discharged from the hospital after a heart attack, he is likely to be more interested than before the attack in learning how to prevent another. He can learn how to reduce stress, develop an appropriate and gradual exercise program, and alter his eating habits. Families with young children often are interested in learning about children's growth and development; most parents are committed to raising happy, healthy children. Health education can affect the health status of people of all ages (Pender et al., 2015). Today, in more businesses and industries, nurses promote the health of employees through active wellness education and injury prevention programs. The companies recognize that improving the health of their workers, which includes earning a living wage, means less absenteeism and higher production levels, in addition to other benefits (Kowlessar, Goetzel, Carls, Tabrizi, & Guindon, 2011; Lahiri & Faghri, 2012). Some companies even provide exercise areas and equipment for employees to use and pay for the cost of their participation or allow paid time off for exercise. See Chapter 31 for more information on occupational health nursing.

Whereas nurses in acute care teach patients with a one-on-one focus about issues related to their illness and hospitalization, community health nurses go beyond these topics to educate people in many areas. Community-living clients need and want to know about a wide variety of issues, such as family planning, weight control, smoking cessation, and stress reduction. Aggregate-level concerns also include such topics as environmental safety, sexual discrimination and harassment at school or work, violence, and drugs. What foods and additives are safe to eat? How can people organize the community to work for reduction of violence on television? What are health consumers' rights? Topics taught by community health nurses extend from personal and family health to environmental health and community organization.

As educators, community health nurses seek to facilitate client learning. Information is shared with clients both formally and informally. Nurses serve as consultants to individuals or groups. Formal classes may be held to increase people's understanding of health and health care. Established community groups may be used in the nurse's teaching practice. For example, a nurse may teach parents and teachers at a parent–teacher meeting about signs of mood-modifying drug and alcohol abuse, discuss safety practices with a group of industrial workers, or give a presentation on the importance of early detection of child abuse to a health planning committee considering funding a new program. At times, the community health nurse facilitates client learning through referrals to more knowledgeable sources or through use of experts on special topics. The nurse facilitates client self-education; in keeping with the concept of self-care, clients are encouraged and helped to use appropriate health resources and to seek out health information. The emphasis throughout the health teaching process continues to be placed on illness prevention and health promotion. Health teaching as a tool for community health nursing practice is discussed in detail in Chapter 11.

Advocate Role

The issue of clients' rights is important in health care. Every patient or client has the right to receive just, equal, and humane treatment. The role of the nurse includes client advocacy, which is highlighted in the ANA *Code of Ethics for Nurses with Interpretive Statements* (2015a) and *Nursing's Social Policy Statement* (2010). Our current health care system is often characterized by fragmented and depersonalized services, and many clients —especially the poor, the disadvantaged, those without health insurance, and people with language barriers—frequently are denied their rights. They become frustrated, confused, degraded, and unable to cope with the system on their own. The community health nurse often acts as an advocate for clients, pleading their cause or acting on their behalf. Clients may need someone to explain which services to expect and which services they ought to receive, to make referrals as needed, and to write letters to agencies or health care providers for them. They need someone to guide them through the complexities of the system and assure the satisfaction of their needs. This is particularly true for minorities and disadvantaged groups (Mead et al., 2013; Peek, Ferguson, Bergeron, Maltby, & Chin, 2014) (Fig. 3–3).

FIGURE 3–3 Like nurses working in every type of setting, PHNs are advocates for their clients.

Advocacy Goals

Client advocacy has two underlying goals. One is to help clients gain greater independence or self-determination. Until they can research the needed information and access health and social services for themselves, the community health nurse acts as an advocate for the clients by showing them what services are available, those to which they are entitled, and how to obtain them. A second goal is to make the system more responsive and relevant to the needs of clients (Byers, 2015). By calling attention to inadequate, inaccessible, or unjust care, community health nurses can influence change (see Chapter 13).

Consider the experience of the Merrill family. Gloria Merrill has three small children. Early one Tuesday morning, the baby, Tony, suddenly started to cry. Nothing would comfort him. Gloria went to a neighbor's apartment, called the local clinic, and was told to come in the next day. The clinic did not take appointments and was too busy to see any more patients that day. Gloria's neighbor reassured her that "sometimes babies just cry." For the rest of the day and night, Tony cried almost incessantly. On Wednesday, Gloria and her children made the 45-minute bus ride to the clinic and waited 3 hours in the crowded reception room; the wait was punctuated by interrogations from clinic workers. Gloria's other children were restless, and the baby was crying. Finally, they saw the physician. Tony had an inguinal hernia that could have strangulated and become gangrenous. The doctor admonished Gloria for waiting so long to bring in the baby. Immediate surgery was necessary. Someone at the clinic told Gloria that Medicaid would pay for it. Someone else told her that she was ineligible. At this point, all of her children were crying. Gloria had been up most of the night. She was frantic, confused, and felt that no one cared. This family needed an advocate.

Advocacy Actions

The advocate role incorporates four characteristic actions: being assertive, taking risks, communicating and negotiating well, and identifying resources and obtaining results.

First, advocates must be assertive. Fortunately, in the Merrill's dilemma, the clinic had a working relationship with the City Health Department and contacted Tracy Lee, a community health nurse liaison with the clinic, when Gloria broke down and cried. Tracy took the initiative to identify the Merrill's needs and find appropriate solutions. She contacted the Department of Social Services and helped the Merrill family to establish eligibility for coverage of surgery and hospitalization costs. She helped Gloria to make arrangements for the baby's hospitalization and the other children's care.

Second, advocates must take risks—go "out on a limb" if need be—for the client. The community health nurse was outraged by the kind of treatment received by the Merrill family: the delays in service, the impersonal care, and the surgery that could have been planned as elective rather than as an emergency. She wrote a letter describing the details of the Merrill's experience to the clinic director, the chairman of the clinic board, and the nursing director. This action resulted in better care for the Merrill family and a series of meetings aimed at changing clinic procedures and providing better telephone screening.

Third, advocates must communicate and negotiate well by bargaining thoroughly and convincingly. The community health nurse helping the Merrill family stated the problem clearly and argued for its solution.

Finally, advocates must identify and obtain resources for the client's benefit. By contacting the most influential people in the clinic and appealing to their desire for quality service, the nurse caring for the Merrill family was able to facilitate change.

Advocacy at the population level incorporates the same goals and actions. Whether the population is homeless people, battered women, or migrant workers, the community health nurse in the advocate role speaks and acts on their behalf. The goals remain the same: to promote clients' self-determination and to shape a more responsive system. Advocacy for large aggregates, such many with inadequate health care coverage or access to care, means changing national policies and laws (see Chapter 13). Advocacy may take the form of presenting public health nursing data to ensure that providers deliver quality services. It may mean conducting a needs assessment to demonstrate the necessity for a shelter and multiservice program for the homeless. It may mean testifying before the legislature to create awareness of the problems of battered women and the need for more protective laws. It may mean organizing a lobbying effort to require employers of migrant workers to provide proper housing and working conditions. In each case, the community health nurse works with representatives of the population to gain their understanding of the situation and to ensure their input.

Manager Role

Community health nurses, like all nurses, engage in the role of managing health services. As a manager, the nurse exercises administrative direction toward the accomplishment of specified goals by assessing clients' needs, planning and organizing to meet those needs, directing and leading to achieve results, and controlling and evaluating the progress to ensure that goals are met. The nurse serves as a manager when overseeing client care as a case manager, supervising ancillary staff, managing caseloads, running clinics, or conducting community health needs assessment projects. In each instance, the nurse engages in four basic functions that make up the management process. The management process, like the nursing process, incorporates a series of problem-solving activities or functions: planning, organizing, leading, and controlling and evaluating. These activities are sequential, yet they also occur simultaneously for managing service objectives (Cherry & Jacob, 2014). While performing these functions, community health nurses most often are participative managers; that is, they participate with clients, other professionals, or both to plan and implement services.

Nurse as Planner

The first function in the management process is planning. A planner sets the goals and direction for the organization or project and determines the means to achieve them. Specifically, planning includes defining goals and objectives, determining the strategy for reaching them, and designing a coordinated set of activities for implementing and evaluating them, which tends to include broader, more long-range goals (Cherry & Jacob, 2014; USDHHS, 2016a). Planning may be strategic. An example of *strategic planning* is setting 2-year agency goals to reduce teenage pregnancies in the county by 50%. Planning may be operational, which focuses more on short-term planning needs. An example of *operational planning* is setting 6-month objectives to implement a new computer system for client record keeping.

The community health nurse engages in planning as a part of the manager role when supervising a group of home health aides working with home care clients. Plans of care must be designed to include setting short-term and long-term objectives, describe actions to carry out the objectives, and design a plan for evaluating the care given. With larger groups, such as a program for a homeless population, the planning function is used in collaboration with other professionals to determine appropriate goals for shelter and to strengthen the response to homelessness (Rogers et al., 2012). The concepts of planning with communities and families are discussed further in Chapters 15 and 19, respectively.

Nurse as Organizer

The second function of the manager role is that of organizer. This involves designing a structure within which people and tasks function to reach the desired objectives. A manager

must arrange matters so that the job can be done. People, activities, and relationships have to be assembled to put the plan into effect. Organizing includes deciding on the tasks to be done, which person will do them, how to group the tasks, who reports to whom, and where decisions will be made (Cherry & Jacob, 2014). In the process of organizing, the nurse manager provides a framework for the various aspects of service, so that each runs smoothly and accomplishes its purpose. The framework is a part of service preparation. When a community health nurse manages a well-child clinic, for instance, the organizing function involves making certain that all equipment and supplies are present, required staff are hired and are on duty, and that staff responsibilities are clearly designated. The final responsibility as an organizer is to evaluate the effectiveness of the clinic. Is it providing the needed services? Are the clients satisfied? Do the services remain cost-effective? The organizer must address all of these questions.

Nurse as Leader

In the manager role, the community health nurse also must act as a leader. As a leader, the nurse directs, influences, or persuades others to effect change that will positively impact people's health and move them toward a goal. The leading function includes persuading and motivating people, directing activities, ensuring effective two-way communication, resolving conflicts, and coordinating the plan. Coordination means bringing people and activities together, so that they function in harmony while pursuing desired objectives. Transformational and authentic leadership is characterized by ability of leaders to inspire change and demonstrate empathy and leads to increased job satisfaction and performance (Lievens & Vlerick, 2014; Mortier, Vlerick, & Clays, 2015). Change management strategies are necessary to achieve the Triple Aim of improving population health, reducing healthcare costs, and providing improved patient outcomes (Shirey & White-Williams, 2015).

Community health nurses act as leaders when they direct and coordinate the functioning of a hypertension screening clinic, a weight control group, or a three-county mobile health assessment unit. In each case, the leading function requires motivating the people involved, keeping open clear channels of communication, negotiating conflicts, and directing and coordinating the activities established during planning, so that the desired objectives can be accomplished.

Nurse as Controller and Evaluator

The fourth management function is to control and evaluate projects or programs. A controller monitors the plan and ensures that it stays on course. In this function, the community health nurse must realize that plans may not proceed as intended and may need adjustments or corrections to reach the desired results or goals. Monitoring, comparing, and adjusting make up the controlling part of this function. At the same time, the nurse must compare and judge performance and outcomes against previously set goals and standards—a process that forms the evaluator aspect of this management function (Kulbok,

Thatcher, Park, & Meszaros, 2012).

An example of the controlling and evaluating function is evident in a program started in several preschool day care centers. The goal of the project is to reduce the incidence of illness among the children through intensive physical and emotional preventive health education with staff, parents, and children. The two community health nurses managing the project are pleased with the progress of the classes and monitored the application of the prevention principles in day-to-day care. However, staff became busy after several weeks, and some plans were not being followed carefully. Preventive activities, such as ensuring that the children coughed into their shirtsleeve and washed their hands after using the bathroom and before eating, were not being closely monitored. Several children who were clearly sick had not been kept at home. Staff was often overlooking quiet or reserved children and not ensuring their inclusion in activities. The nurses worked with staff and parents to motivate them and get the project back on course. They held monthly meetings with the staff, observed the classes periodically, and offered one-on-one instruction to staff, parents, and children. One activity was to establish competition between the centers for the best health record, with the promise of a photograph of the winning center's children and an article in the local newspaper. Their efforts were successful.

Management Behaviors

As managers, community health nurses engage in many different types of behaviors. First described in a classic book by Mintzberg (1973), the management roles were grouped into three sets of behaviors: decision-making, transferring of information, and engaging in interpersonal relationships (Management at Work, 2016).

Decision-Making Behaviors

Mintzberg identified four types of decisional roles or behaviors: entrepreneur, disturbance handler, resource allocator, and negotiator. A manager serves in the entrepreneur role when initiating new projects. Starting a nurse-managed center to serve a homeless population is an example. Community health nurses play the disturbance handler role when they manage disturbances and crises—particularly interpersonal conflicts among staff, between staff and clients, or among clients (especially when being served in an agency). The resource allocator role is demonstrated by determining the distribution and use of human, physical, and financial resources. Nurses play the negotiator role when negotiating, perhaps with higher levels of administration or a funding agency, for new health policy or budget increases to support expanded services for clients (Management at Work, 2016). Zori, Nosek, and Musil (2010) found that nursing managers with strong critical thinking skills and open-mindedness created a more positive workplace for staff nurses.

Transfer of Information Behaviors

Mintzberg described three informational roles or behaviors: monitor, information disseminator, and spokesperson. The monitor role requires collecting and processing information, such as gathering ongoing evaluation data to determine whether a program is meeting its goals. In the disseminator role, nurses transmit the collected information to people involved in the project or organization. In the spokesperson role, nurses share information on behalf of the project or agency with outsiders (Management at Work, 2016). One effective means of information sharing is to have open, two-way communication between managers and staff that promotes teamwork (Macphee, Wardrop, Campbell, & Wejr, 2011). See Chapter 10 for more on communication.

Interpersonal Behaviors

While engaging in various interpersonal roles, the community health nurse may function as a figurehead, a leader, and a liaison. In the figurehead role, the nurse acts in a ceremonial or symbolic capacity, such as participating in a ribbon-cutting ceremony to mark the opening of a new clinic or representing the project or agency for news media coverage. In the leader role, the nurse motivates and directs people involved in the project. In the liaison role, a network is maintained with people outside the organization or project for information exchange and project enhancement (MindTools, 2015).

Management Skills

What types of skills and competencies does the community health nurse need in the manager role? Three basic management skills are needed for successful achievement of goals: human, conceptual, and technical. *Human skills* refer to the ability to understand, communicate, motivate, delegate, and work well with people (Cherry & Jacob, 2014). An example is a nursing supervisor's or team leader's ability to gain the trust and respect of staff and promote a productive and satisfying work environment. A manager can accomplish goals only with the cooperation of others. Therefore, human skills are essential to successful performance of the manager role. *Conceptual skills* refer to the mental ability to analyze and interpret abstract ideas for the purpose of understanding and diagnosing situations and formulating solutions (Zori et al., 2010). Examples are analyzing demographic data for program planning and developing a conceptual model to describe and improve organizational function. Finally, *technical skills* refer to the ability to apply special management-related knowledge and expertise to a particular situation or problem. Such skills performed by a community health nurse might include implementing a staff development program or developing a computerized management information system. See Chapter 10 on technology in PHN.

Case Management

Case management has become the standard method of managing health care in the delivery systems in the United States, and managed care organizations have become an integral part

of community-oriented care. Case management is a systematic process by which a nurse assesses clients' needs, plans for and coordinates services, refers to other appropriate providers, and monitors and evaluates progress to ensure that clients' multiple service needs are met in a cost-effective manner. With health care reform, the importance of case management, or care coordination among an interdisciplinary team, is emphasized as a means to control costs and improve client outcomes (Families USA, 2013). As clients leave hospitals earlier, as families struggle with multiple and complex health problems, as more elderly persons need alternatives to nursing home care, as competition and scarce resources contribute to fragmentation of services, and as the cost of health care continues to increase, there is a growing need for someone to oversee and coordinate all facets of needed service (Moreo, Moreo, Urbano, Weeks, & Greene, 2014). Through case management, the nurse addresses this need in the community (Fig. 3–4).

FIGURE 3–4 Community health nurses may serve as case managers for battered women and other aggregates.

The activity of case management often follows discharge planning as a part of continuity of care. When applied to individual clients, it means overseeing their transition from the hospital back into the community and monitoring them to ensure that all of their service needs are met. Case management also applies to aggregates (Joo & Huber, 2014). In this context, it involves overseeing and ensuring that group or population health-related needs are met, particularly for those who are at high risk of illness or injury. For example, the community health nurse may work with battered women who come to a shelter. First,

the nurse must ensure that their immediate needs for safety, security, food, finances, and childcare are met. Then, the nurse must work with other professionals to provide more permanent housing, employment, ongoing counseling, and financial and legal resources for this group of women. Whether applied to families or aggregates, case management, like other applications of the manager role, uses the three sets of management behaviors and engages the community health nurse as planner, organizer, leader, controller, and evaluator.

Collaborator Role

Community health nurses seldom practice in isolation. They must work with many people, including clients, other nurses, physicians, teachers, health educators, social workers, physical therapists, nutritionists, occupational therapists, psychologists, epidemiologists, biostatisticians, attorneys, secretaries, environmentalists, city planners, and legislators. As members of the health team, community health nurses assume the role of collaborator, which means working jointly with others in a common endeavor, cooperating as partners. Successful community health practice depends on this multidisciplinary collegiality and leadership (Stringer et al., 2014). Everyone on the team has an important and unique contribution to make to the health care effort. As on a championship ball team, the better that all members play their individual positions and cooperate with other members, the more likely the health team is to win.

The community health nurse's collaborator role requires skills in communicating, in interpreting the nurse's unique contribution to the team, and in acting assertively as an equal partner. The collaborator role also may involve functioning as a consultant.

The following examples show a community health nurse functioning as collaborator. Three families needed to find good nursing homes for their elderly grandparents. The community health nurse met with the families, including the elderly members; made a list of desired features, such as a shower and access to walking trails; and then worked with a social worker to locate and visit several homes. The grandparents' respective physicians were contacted for medical consultation, and in each case, the elderly member made the final selection. In another situation, the community health nurse collaborated with the city council, police department, neighborhood residents, and the manager of a senior citizens' high-rise apartment building to help a group of elderly people organize and lobby for safer streets. In a third example, a school nurse noticed a rise in the incidence of drug use in her schools. She initiated a counseling program after joint planning with students, parents, teachers, the school psychologist, and a local drug rehabilitation center.

Leadership Role

Community health nurses are becoming increasingly active in the leadership role, separate from leading within the manager role mentioned earlier. The leadership role focuses on effecting change (see Chapter 11); thus, the nurse becomes an agent of change. As leaders, community health nurses seek to initiate changes that positively affect people's health. They also seek to influence people to think and behave differently about their health and the factors contributing to it. The leader recognizes the complex set of factors contributing to health outcomes and works to address those myriad factors in affecting needed change (Kulbok et al., 2012). The role of social determinants of health, such as the availability of health services and how the physical environment affects population health, is discussed in Chapter 11 in relation to health promotion of individuals and communities.

At the community level, the leadership role may involve working with a team of professionals to direct and coordinate such projects as a campaign to eliminate smoking in public areas or to lobby legislators for improved child day care facilities. When nurses guide community health decision-making, stimulate an industry's interest in health promotion, initiate group therapy, direct a preventive program, or influence health policy, they assume the leadership role. For example, a community health nurse started a rehabilitation program that included self-esteem building, career counseling, and job placement to help women in a halfway house who had recently been released from prison.

The community health nurse also exerts influence through health planning. The need for coordinated, accessible, cost-effective health care services creates a challenge and an opportunity for the nurse to become more involved in health planning at all levels: organizational, local, state, national, and international. A community health nurse needs to exercise leadership responsibility and assert the right to share in health decisions (Cherry & Jacob, 2014). One community health nurse determined that there was a need for a behavioral health program in his district. He planned to implement it through the agency for which he worked, but certain individuals on the health board were opposed to adding new programs because of the cost. The nurse's approach was to gather considerable data to demonstrate the need for the program and its cost-effectiveness. He invited individual, key board members to lunch to convince them of the need. He prepared written summaries, graphs, and charts, and at a strategic time, he presented his case at a board meeting. The behavioral health program was approved and implemented.

A broader attribute of the leadership role is that of visionary. A leader with *vision* develops the ability to see what can be and leads people on a path toward that goal. A leader's vision may include long- and short-term goals. In one instance, it began as articulating the need for stronger community nursing services to an underserved population in an inner-city neighborhood served by a community health nurse. In this densely populated, tenant-occupied neighborhood, drugs, crime, and violence were commonplace. One summer, an 8-year-old boy was shot and killed. The enraged immigrant families in the

neighborhood felt helpless and hopeless. The nurse visited several families, and they shared their concerns with him. The nurse felt strongly about this blighted community and offered to work with the community to effect change. He gathered volunteers from neighborhood churches, and together, they began to discuss the community's concerns. Together, they prioritized their needs and began planning to make theirs a healthy community. The nurse organized his workweek to provide health screening and education to families in the basement of a church on one morning each week. Initially, only a few families accessed this new service. In a matter of months, it became recognized as a valuable community service, and it expanded to a full day; the expanding volunteer group soon outgrew the space. The community health nurse worked closely with influential community members and the families being served. They determined that many more services were needed in this neighborhood, and they began to broaden their outreach and think of ways to provide the needed services.

Within a year, the group had written several grants to the city and to a private corporation in an effort to expand the voluntary services. The funding that they obtained allowed them to rent vacant storefront space, hire a part-time nurse practitioner, contract with the health department for additional community health nursing services, and negotiate with the local university to have medical, nursing, and social work students placed on a regular basis. The group, under the visionary leadership of the community health nurse, planned to add a one-on-one reading program for children, a class in English as a second language for immigrant families, a mentoring program for teenagers, and dental services. Even the police department had opened a substation in the neighborhood, making their presence more visible. This community health nurse's vision filled an immediate, critical need in the short term and developed into a comprehensive community center in the long term. Violence and crime diminished, and the neighborhood became a place where children could play safely.

Researcher Role

In the researcher role, community health nurses engage in the systematic investigation, collection, and analysis of data for solving problems and enhancing community health practice. But how can research be combined with practice? Although research technically involves a complex set of activities conducted by persons with highly developed and specialized skills, research also means applying that technical study to real practice situations. Community health nurses base their practice on the evidence found in the literature to enhance and change practice as needed. For example, the work of researchers over two decades supports the value of intensive home visiting to high-risk families (Glover, 2014; Olds et al., 2014). The outcomes of this research are changing practice protocol to high-risk families in many health departments today.

Research is an investigative process in which all community health nurses can become involved in asking questions and looking for solutions. Collaborative practice models between academics and practitioners combine research methodology expertise with practitioners' knowledge of problems to make public health nursing research both valid and relevant. The ongoing need for evidence-based practice is supported by *Healthy People 2020*, which stresses that the "emerging field of public health systems and services research is playing an important role in the development of this evidence base; its role should be supported and expanded over the decade, with a strong focus on translating research into practice" (USDHHS, 2016b, para. 14).

The Research Process

Community health nurses practice the researcher role at several levels. In addition to everyday inquiries, community health nurses often participate in agency and organizational studies to determine such matters as practice activities, priorities, and education of public health nurses (Gifford, Lefebre, & Davies, 2014). Some community health nurses participate in more complex research on their own or in collaboration with other health professionals (Butterfield, Hill, Postma, Butterfield, & Odom-Maryon, 2011; Wieland et al., 2011). The researcher role (at all levels) helps to determine needs, evaluate effectiveness of care, and develop a theoretic basis for community health nursing practice. Chapters 4 and 12 will explain community health research in greater detail.

Research literally means to *search again*—to investigate, discover, and interpret facts. All research in community health, from the simplest inquiry to the most complex epidemiologic study, uses the same fundamental process. Simply put, the research process involves the following steps: (1) identify an area of interest, (2) specify the research question or statement, (3) review the literature, (4) identify a conceptual framework, (5) select a research design, (6) collect and analyze data, (7) interpret the results, and (8) communicate the findings (see Chapter 4).

Investigation builds on the nursing process, that essential dynamic of community

health nursing practice, using it as a problem-solving process (Burns & Grove, 2015). In using the nursing process, the nurse identifies a problem or question, investigates by collecting and analyzing data, suggests and evaluates possible solutions, and either selects a solution or rejects them all and starts the investigative process over again. In a sense, the nurse is gathering data for health planning—investigating health problems to design wellness-promoting and disease-preventing interventions for community populations.

Attributes of the Researcher Role

A questioning attitude is a basic prerequisite for good nursing practice. A nurse may have revisited a patient many times and noticed some change in her condition, such as restlessness or pallor; consequently, the nurse wonders what is causing this change and what can be done about it. In everyday practice, numerous situations challenge the nurse to ask questions. Consider the following examples:

- The local newspaper reports that another group of children has been arrested for using illegal drugs. Is there an increase in the incidence of illegal drug use in the community?
- Children attending a day care center appear to have excessive bruises on their arms and legs. What is the incidence of reported child abuse in this community? What could be done to promote earlier detection and improved reporting?
- Elderly persons are living alone and without assistance in a neighborhood. How prevalent is this situation, and what are this population's needs?
- While driving through a particular neighborhood, the nurse notices not a single playground. Where do the kids play?

Each of these questions places the nurse in the role of investigator. They demonstrate the fundamental attitude of every researcher: a spirit of inquiry. See Chapter 4 for more about research and evidence-based practice in PHN.

A second attribute, careful observation, is also evident in the examples just given. The nurse needs to develop a sharpened ability to notice things as they are, including deviations from the norm and subtle changes suggesting the need for nursing action. Coupled with observation is open-mindedness, another attribute of the researcher role. In the case of the bruises seen on day care children, a community health nurse's observations suggest child abuse as a possible cause. However, open-mindedness requires consideration of other alternatives, and as a good investigator, the nurse explores these possibilities as well.

Analytic skills also are used in this role. In the example of illegal drug use, the nurse already has started to analyze the situation by trying to determine its cause-and-effect relationships. Successful analysis depends on how well the data have been collected. Insufficient information can lead to false interpretations, so it is important to seek out the needed data. Analysis, like a jigsaw puzzle, involves studying the pieces and fitting them together until the meaning of the whole picture can be described.

Finally, the researcher role involves tenacity. The community health nurse persists in an investigation until facts are uncovered and a satisfactory answer is found. Noticing an absence of playgrounds and wondering where the children play are only a beginning. Being concerned about the children's safety and need for recreational outlets, the nurse gathers data about the location and accessibility of play areas, as well as expressed needs of community residents. A fully documented research report may result. If the data support a need for additional play space, the report can be brought before the proper authorities.

SETTINGS FOR COMMUNITY HEALTH NURSING PRACTICE

The previous section examined community health nursing from the perspective of its major roles. The roles can now be placed in context by viewing the settings in which they are practiced. The types of places in which community health nurses practice are increasingly varied and include a growing number of nontraditional settings and partnerships with nonhealth groups. Employers of community health nurses range from state and local health departments and home health agencies to managed care organizations, businesses and industries, and nonprofit organizations. For this discussion, these settings are grouped into seven categories: homes, ambulatory service settings, schools, occupational health settings, residential institutions, faith communities, and the community at large (domestic and international). This section provides a brief overview of the various settings. Chapters 30 and 31 will provide much more detail on specific roles and settings, including both public and private practice settings.

Homes

Since Lillian Wald and the nurses at the Henry Street Settlement first started their practice in 1983, the most frequently used setting for community health nursing practice was the home. In the home, all of the public health nursing roles are performed to varying degrees. Clients who are discharged from acute care institutions, such as hospitals or behavioral health facilities, are regularly referred to community health nurses for continued care and follow-up. Here, the community health nurse can see clients in a family and environmental context, and service can be tailored to the clients' unique needs (Fig. 3–5).

FIGURE 3–5 Public health nurses make home visits to assess and follow up with clients.

For example, Mr. White, 67 years of age, was discharged from the hospital with a colostomy. Doreen Levitz, the public health nurse from the county public health nursing agency, immediately started home visits. She met with Mr. White and his wife to discuss their needs as a family and to plan for Mr. White's care and adjustment to living with a colostomy. Practicing the clinician and educator roles, she reinforced and expanded on the teaching started in the hospital for colostomy care, including bowel training, diet, exercise, and proper use of equipment. As part of a total family care plan, Doreen provided some forms of physical care for Mr. White as well as counseling, teaching, and emotional support for both Mr. White and his wife. In addition to consulting with the physician and social service worker, she arranged and supervised visits from the home health aide, who gave personal care and homemaker services. She thus performed the manager, leader, and

collaborator roles.

The home is also a setting for health promotion. Many community health nursing visits focus on assisting families to understand and practice healthier living behaviors. Nurses may, for example, instruct clients on parenting, infant care, child discipline, diet, exercise, coping with stress, or managing grief and loss.

The character of the home setting is as varied as the clients served by the community health nurse. In one day, the nurse may visit a well-to-do widow in her luxurious home, a middle-income family in their modest bungalow, an elderly transient man in his one-room fifth-story walk-up apartment, and a teen mother and her infant living in a group foster home. In each situation, the nurse can view the clients in perspective and, therefore, better understand their limitations, capitalize on their resources, and tailor health services to meet their needs. In the home, unlike in most other health care settings, clients are on their own "turf." They feel comfortable and secure in familiar surroundings and often are better able to understand and apply health information. Client self-respect can be promoted, because the client is host and the nurse is a guest.

Sometimes, the thought of visiting in clients' homes can cause anxiety for the nurse. This may be the nurse's first experience outside the acute care, long-term care, or clinic setting. Visiting clients in their own environment can make the nurse feel uncomfortable. The nurse may be asked to visit families in unfamiliar neighborhoods, and she must walk through those neighborhoods to locate the clients' homes. Frequently, fear of the unknown is the real fear—a fear that often has been enhanced by stories from previous nurses. This may be the same feeling as that experienced when caring for your first client, first entering the operating room, or first having a client in the intensive care unit. However, in the community, more variables exist, and basic safety measures should be used. General guidelines for safety and making home visits are covered in detail in Chapter 19. Nevertheless, the specific instructions given during the clinical experience should be followed, and everyday, commonsense safety precautions should be used.

Changes in the health care delivery system, along with shifting health economics and service delivery (discussed in Chapter 6), are changing community health nursing's use of the home as a primary setting for practice. Many local health departments are finding it increasingly difficult to provide widespread home visiting by their public health nurses. Instead, many agencies are targeting populations that are most in need of direct intervention. Examples include families of children with elevated blood lead levels, low-birth-weight babies, clients requiring directly observed administration of tuberculosis medications, and families requiring ongoing monitoring because of identified child abuse or neglect. With limited staff and limited financial resources, the highest-priority clients or groups are targeted.

With skills in population-based practice, community health nurses serve the public's health best by focusing on sites where they can have the greatest impact. At the same time, they can collaborate with various types of home care providers, including hospitals, other

nurses, physicians, rehabilitation therapists, and durable medical equipment companies, to ensure continuous and holistic service. The nurse continues to supervise home care services and engage in case management. The increased demand for highly technical acute care in the home requires specialized skills that are best delivered by nurses with this expertise. Chapter 32 further examines the nurse's role in the home health and hospice settings. The ANA documents *Home Health Nursing: Scope and Standards of Practice* (2013b) and *Palliative Nursing: Scope and Standards of Practice* (ANA/Hospice and Palliative Nurses Association, 2014) offer additional insight on these specialty areas.

Ambulatory Service Settings

Ambulatory service settings include a variety of venues for community health nursing practice in which clients come for day or evening services that do not include overnight stays. A community health center is an example of an ambulatory setting. Sometimes, multiple clinics offering comprehensive services are community based or are located in outpatient departments of hospitals or medical centers. They also may be based in comprehensive neighborhood health centers. A single clinic, such as a family planning clinic or a well-child clinic, may be found in a location that is more convenient for clients, perhaps a church basement or empty storefront. Some kinds of day care centers, such as those for the physically disabled or adults with behavioral health issues, use community health nursing services. Additional ambulatory care settings include health departments (city, county, or state) and community health nursing agencies, where clients may come for assessment and referral or counseling. An increasing number of nurse-managed health centers have also been formed over the past decade, often as a community service component of schools of nursing. The mission of these centers varies, but they are typically used to enhance student clinical experiences while providing identified community needs in the areas of primary health care and health promotion (see Chapter 31).

Offices are another type of ambulatory care setting. Some community health nurses provide service in conjunction with a medical practice; for example, a community health nurse associated with a health maintenance organization sees clients in the office and undertakes screening, referrals, counseling, health education, and group work. Others establish independent practices by seeing clients in community nursing centers as well as making home visits.

Another type of ambulatory service setting includes places where services are offered to selected groups. For example, community health nurses practice in migrant camps, on tribal lands, at correctional facilities, in children's day care centers, through faith communities, in coal-mining communities, and in remote frontier areas. In each ambulatory setting, all of the community health nursing roles are used to varying degrees (see Perspectives: Student Voice).

PERSPECTIVES STUDENT VOICE

A GRADUATING STUDENT VIEWPOINT ON POSTGRADUATION EMPLOYMENT

Before entering nursing school, I spent 6 years on active duty as a corpsman in the Navy. I remembered seeing some nurses who visited our hospital wearing what looked like Navy uniforms, but was told that they worked for the federal government and weren't in the Navy. I didn't think much of it until I was looking up information on the U.S. Public Health Service and the Surgeon General. Only then did it dawn on me that those nurses were part of the Commissioned Corps of the Public Health Service. I didn't even know they existed, much less what they did, so I looked around the section of the Web site dealing with nursing. It turns out that they do quite a bit—respond to disasters, provide health services to Native Americans, and even work with the federal prisons. It surprised me to find out that they hire new graduates for many of their positions. I still haven't decided what I want to do after I graduate, but I may seriously consider this option. They even have an extern program available while I'm still in school—who knows, I may be in uniform again.

Matt, Age 24

Schools

Schools of all levels make up a major group of settings for community health nursing practice. Nurses from community health nursing agencies frequently serve private schools at elementary and intermediate levels. Public schools are served by the same agencies or by community health nurses hired through the public school system. The community health nurse may work with groups of students in preschool settings, such as Montessori schools, as well as in vocational or technical schools, junior colleges, and college and university settings. Specialized schools, such as those for the developmentally disabled, are another setting for community health nursing practice (Fig. 3–6).

FIGURE 3–6 School nursing is another community health nursing role.

Community health nurses' roles in school settings are changing. School nurses, whose primary role initially was that of clinician, are widening their practice to include more health education, interprofessional collaboration, and client advocacy. For example, one school had been accustomed to using the nurse as a first-aid provider and record keeper. Her duties were handling minor problems, such as headaches and cuts, and keeping track of such events as immunizations. This nurse sought to expand her practice and, after consultation and preparation, collaborated with a health educator and some of the teachers to offer a series of classes on personal hygiene, diet, and sexuality. She started a drop-in center for health counseling at the school and established a network of professional contacts for consultation and referral.

Community health nurses in school settings also are beginning to assume managerial and leadership roles and to recognize that the researcher role should be an integral part of their practice. The nurse's role with school age and adolescent populations is discussed in detail in Chapters 22 and 30. The ANA and the National Association of School Nursing have published *School Nursing: Scope and Standards of Practice* (2011), a document that provides additional information on this important specialty.

Occupational Health Settings

Business and industry provide another group of settings for community health nursing practice. Employee health has long been recognized as making a vital contribution to individual lives, the productivity of business, and the well-being of the entire nation. Organizations are expected to provide a safe and healthy work environment, in addition to offering insurance for health care. More companies, recognizing the value of healthy employees, are going beyond offering traditional health benefits to supporting health promotional efforts. Some businesses, for example, offer healthy snacks, such as fruit at breaks, and promote jogging during the noon hour. A few larger corporations have built exercise facilities for their employees, provide health education programs, and offer financial incentives for losing weight or staying well.

Community health nurses in occupational health settings practice a variety of roles. The clinician role predominated for many years, as nurses continued to care for sick or injured employees at work. However, recognition of the need to protect employees' safety and, later, to prevent their illness led to the inclusion of health education in the occupational health nurse role. Occupational and environmental health nurses also act as employee advocates, assuring appropriate job assignments for workers and adequate treatment for job-related illness or injury. They collaborate with other health care providers and company management to offer better services to their clients. They act as leaders and managers in developing new health services in the work setting, endorsing programs such as hypertension screening and weight control. Occupational health settings range from industries and factories, such as an automobile assembly plant, to business corporations and even large retail sales systems. The field of occupational health offers a challenging opportunity, particularly in smaller businesses, where nursing coverage usually is not provided. Chapter 31 more fully describes the role of the nurse serving the working adult population. The American Association of Occupational Health Nurses sets the standards for this specialty and is the exclusive publisher of the *Standards of Occupational and Environmental Health Nursing* (2012).

Residential Institutions

Any facility where clients reside can be a setting in which community health nursing is practiced. Residential institutions can include a halfway house in which clients live temporarily while recovering from drug addiction or an inpatient hospice program in which terminally ill clients live. Some residential settings, such as hospitals, exist solely to provide health care; others provide a variety of services and support. Community health nurses based in a community agency maintain continuity of care for their clients by collaborating with hospital personnel, visiting clients in the hospital, and planning care during and after hospitalization. Some community health nurses serve one or more hospitals on a regular basis by providing a liaison with the community, consultation for discharge planning, and periodic in-service programs to keep hospital staff updated on community services for their clients. Other community health nurses with similar functions are based in the hospital and serve the hospital community.

A continuing care center is another example of a residential site providing health care that may use community health nursing services. In this setting, residents usually are elderly; some live quite independently, whereas others become increasingly dependent and have many chronic health problems. The public health nurse functions as advocate and collaborator to improve services. The nurse may, for example, coordinate available resources to meet the needs of residents and their families and help safeguard the maintenance of quality operating standards. Chapter 24 discusses the community health nurse's role with elders aging in place. Chapter 32 discusses nursing services needed by clients after hospitalization through home care services or by families and clients in hospice programs. Sheltered workshops and group homes for mentally ill or developmentally disabled children and adults are other examples of residential institutions that serve clients who share specific needs.

Community health nurses also practice in settings where residents are gathered for purposes other than receiving care, where health care is offered as an adjunct to the primary goals of the institution. For example, many nurses work with camping programs for children and adults offered by religious organizations and other community agencies, such as the Boy Scouts, Girl Scouts, or the YMCA. Other camp nurses work with children and adults who have chronic or terminal illnesses, through disease-related community agencies such as the American Lung Association, American Diabetes Association, and American Cancer Society. Camp nurses practice all available roles, often under interesting and challenging conditions.

Another often-overlooked practice setting is the correctional institution. Inmates may be incarcerated both short and long term and have the same health care needs as the general public. Because of the unique nature of this population, there are typically additional health and social service needs for this population, often stemming from the reason for the incarceration in the first place (drug abuse) and that place them at increased risk for select

health problems (AIDS, tuberculosis, poor nutrition, etc.). The challenge to the nurse in this setting is to provide health care in an unbiased and nonjudgmental manner within the realities of the setting. Chapter 30 discusses the role of the nurse in the correctional setting, and the ANA's *Correctional Nursing: Scope and Standards of Practice* (2013a) offers insight into this practice specialty.

Residential institutions provide unique settings for the community health nurse to practice health promotion. Clients are more accessible, their needs can be readily assessed, and their interests can be stimulated. These settings offer the opportunity to generate an environment of caring and optimal quality health care provided by community health nursing services.

Faith Communities

Faith community nursing finds its beginnings in an ancient tradition. The beginnings of community health nursing can be traced to religious orders (see Chapter 2), and for centuries, religious and spiritual communities were important sources of health care. In faith community nursing today, the practice focal point remains the faith community and the religious belief system provided by the philosophical framework. Faith community nursing may take different names such as church-based health promotion, parish nursing, or primary care parish nursing practice. Whatever the service is called, it involves a large-scale effort by the church community to improve the health of its members through education, screening, referral, treatment, and group support.

In some geopolitical communities, faith community nurses are the most acceptable primary care providers. The role of the nurse can be broad, being defined by the needs of the members and the philosophy of the religious community. However, the goal is to enhance and extend services available in the larger community, not to duplicate them.

The ANA has published standards of care for faith community nursing practice in collaboration with the Health Ministries Association, Inc. (ANA, 2012). The standards act as guidelines for faith communities that plan to offer or are offering faith community nursing services. This specialty area of practice is guided by a variety of standards set up by several groups. Together, these standards provide guidance and direction for caregiving within the faith community.

When community health nurses work as faith community nurses, they enhance accessibility to available health services in the community while meeting the unique needs of the members of that religious community, practicing within the framework of the tenets of that religion. A nurse working within a faith community must be cognizant of the basic principles and practices of the religious group served. In most situations, the nurse is a practitioner of the same religious belief system. Chapter 31 provides more detailed information about this specialty area of practice.

Community at Large

Unlike the six settings already discussed, the seventh setting for community health nursing practice is not confined to a specific philosophy, location, or building. When working with groups, populations, or the total community, the nurse may practice in many different places (Display 3–5). For example, a community health nurse, as clinician and health educator, may work with a parenting group in a church or town hall. Another nurse, as client advocate, leader, and researcher, may study the health needs of a neighborhood's elderly population by collecting data throughout the area and meeting with resource people in many places. Also, a nurse may work with community-based organizations such as an HIV/AIDS organization or a support group for parents experiencing the violent death of a child. Again, the community at large becomes the setting for practice for a nurse who serves on health care planning committees, lobbies for health legislation at the state capital, runs for a school board position, or assists with flood relief in another state or another country (Fig. 3–7).

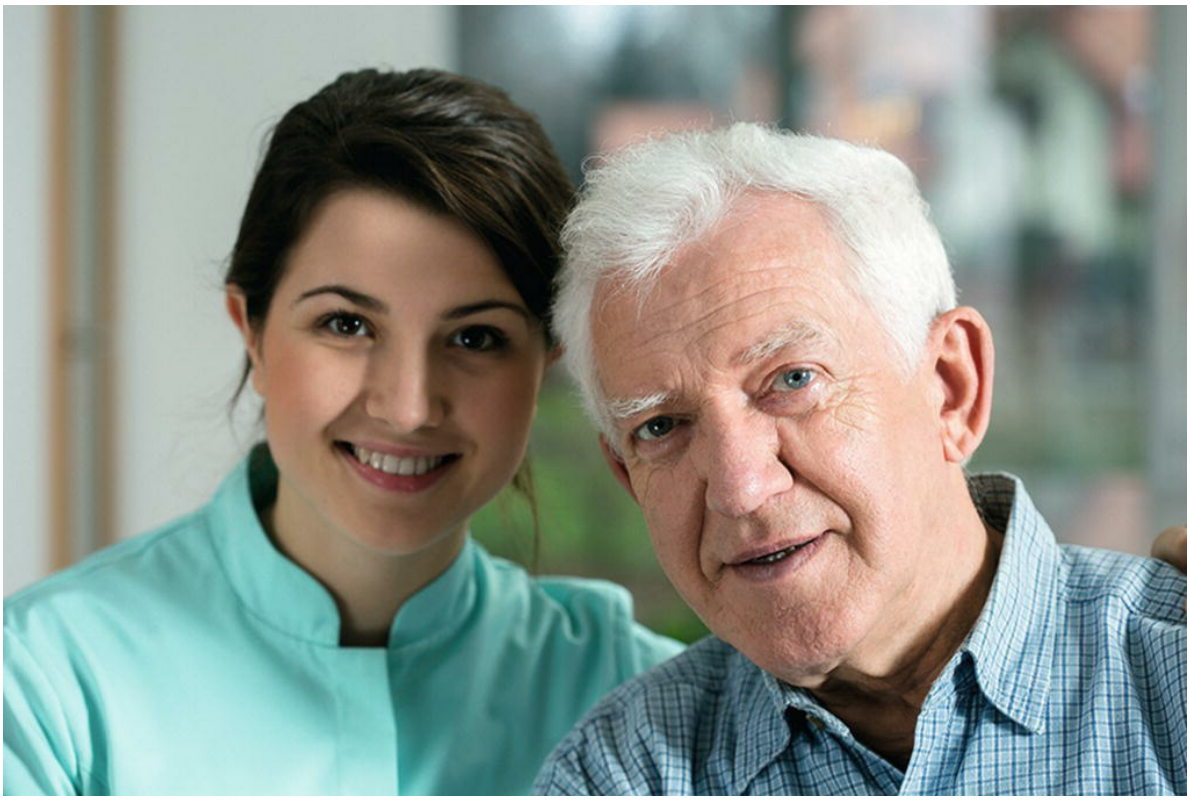

FIGURE 3–7 The community health nurse works with many different groups, including the elderly.

DISPLAY 3.5 INNOVATIVE COMMUNITY HEALTH NURSING PRACTICE

In some community health nursing courses, students do not have access to an established agency such as a health department or community center from which to establish a client base. Student nurses and practicing community health nurses can provide outreach services and do case-finding in innovative settings such as these:

Settings	Clients	Roles of the Community Health Nurse
1. Senior centers when flu shots are given or commodities are distributed	Older adults	Educator, clinician, advocate
2. Outside of grocery stores, department stores, movie theaters, large pharmacies	People of all ages and families	Educator, clinician, advocate
3. At parent–teacher association (PTA) meetings, sporting events, dances, and school registration (in collaboration with school nurses)	Young adults, children, and teenagers	Educator, clinician, advocate
4. Outside of concerts, plays, the circus, etc.	People of all ages	Educator, clinician, advocate
5. Other public gatherings: farmers markets, neighborhood yard sales, etc.	People of all ages	Educator, clinician, advocate
6. Conferences or seminars	People of all ages	Leader, educator, clinician
7. "On the street"	Homeless persons, passersby, transients, low-income urban dwellers	Educator, clinician, advocate
8. Truck stops	Predominantly employed men	Educator, clinician, advocate

Leader's role—initiate, plan, strategize, collaborate, and cooperate with community groups to present programs that are focused on specific population's needs.

Educator's role—teach nutrition, stress management, safety, exercise, prevention of sexually transmitted diseases, and other men and women's health issues, child home/school/play and stranger safety, and child growth and development, and provide anticipatory guidance. Have pamphlets available to support verbal information on health and safety topics, specific diseases, social security, Medicare, and Medicaid.

Clinician's role—perform blood pressure screening, height, weight, blood testing for diabetes and cholesterol, occult blood test, hearing and vision tests, scoliosis measurements, and administration of immunizations.

Advocate's role—provide information regarding community resources as needed, cut "red tape" for those who need it, answer questions, and guide people to

additional resources, such as Web sites and “800” phone numbers.

Although the term “setting” implies a place, remember that community health nursing practice is not limited to a specific site. Community health nursing is a specialty of nursing that is defined by the nature of its practice, not its location, and it can be practiced anywhere. As you read through this chapter, perhaps an area of practice or a particular population captured your attention. If you are interested in tribal health, you might consider working as a U.S. Public Health Service nurse, or if you find that you are more interested in providing comprehensive health promotion programs to rural individuals, a nurse-managed health center may be of interest. Opportunities for community health nursing include the American Red Cross, state and local health departments, the Peace Corps, and various international aid groups. Both private and public health agencies are actively seeking nurses with an interest in improving the health of their communities. Take some time to read over Chapters 30 and 31; perhaps you will find an opportunity that supports your professional goals.

SUMMARY

Community health nurses play many roles, including that of clinician, educator, advocate, manager, collaborator, leader, and researcher. Each role entails special types of skills and expertise. The type and number of roles that are practiced vary with each set of clients and each specific situation, but the nurse should be able to successfully function in each of these roles as the particular situation demands. The role of manager is one that the nurse must play in every situation, because it involves assessing clients' needs, planning and organizing to meet those needs, directing and leading clients to achieve results, and controlling and evaluating the progress to ensure that the goals and clients' needs are met. A type of comprehensive management of clients that has become known as *case management* is an integral part of community health nursing practice.

As a part of the manager role, the nurse must engage in three crucial management behaviors: decision-making, transferring information, and relationship building. Nurses must also use a comprehensive set of management skills: human skills that allow them to understand, communicate, motivate, and work with people; conceptual skills that allow them to interpret abstract ideas and apply them to real situations to formulate solutions; and technical skills that allow them to apply special management-related knowledge and expertise to a particular situation or problem.

There also are many types of settings in which the community health nurse may practice and in which these roles are enacted. "Setting" does not necessarily refer to a specific location or site but rather to a particular situation. These situations can be grouped into seven major categories: homes; ambulatory service settings, where clients come for care but do not stay overnight; schools; occupational health settings, which serve employees in business and industry; residential institutions such as hospitals, continuing care facilities, halfway houses, or other institutions in which people live and sleep; faith communities, where care is based on the philosophy of the religious organization; and the community at large, which encompasses a variety of expected and innovative locations.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Discuss ways for a community health nurse to make service holistic and focused on wellness with

- Preschool-age children in a day care setting
- A group of chemically dependent adolescents
- A group of elders living in a senior high-rise building

2. Select one public health nursing role and describe its application in meeting the needs of your friend or next-door neighbor.
3. Describe a hypothetical or real situation in which you, as a community health nurse, would combine the roles of leader, collaborator, and researcher (investigator). Discuss how each of these roles might be played.
4. If your community health nursing practice setting is the community at large, will your practice roles be any different from those of the nurse whose practice setting is the home? Why? What determines the roles played by the community health nurse?
5. Interview a practicing community health nurse and determine which roles are integral to the nurse's practice over a 1-month period. Describe the ways in which each role is enacted. How many instances of this nurse's practice were aggregate focused? In which of the settings does the nurse mostly practice? If you were a public health consultant, what suggestions might you make to expand this nurse's role into aggregate-level practice?
6. Choose one of the PHN roles or practice areas described in this chapter that may be of interest to you. Compare your choice with one or two other classmates. What drew each of you to your choice? Why?
7. Search the Internet and find two research articles on community health nursing. In what settings did the research take place? Did the nursing authors collaborate with interdisciplinary team members on this research? If so, how do you think this collaboration helped the research? If you were to conduct research in the community, would you conduct it with only nurses on the team, or would your team be interdisciplinary? Why? What would be the benefits or limits of each approach?

4 CHAPTER

Evidence-Based Practice and Ethics in Community Health Nursing

"Research is formalized curiosity. It is poking and prying with a purpose."
—*Zora Neale Hurston* (1891–1960), Novelist

"We must not see any person as an abstraction. Instead, we must see in every person a universe with its own secrets, with its own treasures, with its own sources of anguish, and with some measure of triumph."
—*Elie Wiesel* from The Nazi Doctors and the Nuremberg Code

KEY TERMS

Research/Evidence-Based Practice
Community-based participatory research (CBPR)
Conceptual model
Control group
Descriptive statistics
Evidence-based practice
Experimental design
Experimental group
Generalizability
Health policy evaluation
Inferential statistics
Instrument
Integrative review
Meta-analysis
Mixed methods
Nonexperimental design
Qualitative research
Quantitative research
Quasi-experiment
Randomization
Randomized control trial (RCT)
Reliability
Research
Research utilization
Systematic review
True experiment
Validity
Ethics

Autonomy
Beneficence
Bioethics
Distributive justice
Egalitarian justice
Equity
Ethical decision-making
Ethical dilemma
Ethics
Fidelity
Instrumental values
Justice
Moral
Moral evaluations
Nonmaleficence
Respect
Restorative justice
Self-determination
Self-interest
Social justice
Terminal values
Value
Value systems
Values clarification
Veracity
Well-being

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Discuss the concept of evidence-based practice (EBP).
- List the necessary steps in the process of EBP.
- Explain the difference between quantitative research and qualitative research.
- List the nine steps of the research process.
- Analyze the potential impact of research on community health nursing practice.
- Identify the community health nurse's role in conducting research and using research findings to improve his or her practice.
- Describe the nature of values and value systems and their influence on community health nursing.
- Articulate the impact of key values on professional decision-making.
- Discuss the application of ethical principles to community health nursing decision-making.
- Use a decision-making process with and for community health clients that incorporates values and ethical principles.

As a new student in community health nursing, you may ask, "Can I really do something to make a difference in the lives of my clients?" You may often feel shocked and discouraged by the crushing poverty and overwhelming sense of helplessness experienced by many of your clients and by the continual recurrence of substance

abuse, domestic violence, job failure, and criminal activity. For the first time, you may truly confront the inequalities and injustices of our health care system. You will face many ethical dilemmas in community health nursing. You may ask, "Why should I bother to make home visits to pregnant teens? Why should I offer smoking cessation classes at the local homeless shelter? Why should I teach clients about the importance of taking their antituberculosis medications? Will it really matter?"

Recent community health nursing research validates that nursing care *does* matter and that you really *can* make a difference in the lives of your clients. For example, Nurse–Family Partnership (NFP) programs, based on research conducted by David Olds and his colleagues, are reaping results in many communities across the United States and around the world (Canadian Nurse-Family Partnership Network, 2010; Coalition for Evidence-Based Policy, 2015; Mejdoubi et al., 2013; 2015; Nurse-Family Partnership, 2011a, 2011b, 2011c, 2015; U.S. Department of Health and Human Services [USDHHS], 2011a). In a classic longitudinal study by Olds and his research team (1997), conducted with a primarily white sample in a semirural setting over a 15-year period, regular visits by public health nurses (PHNs) to poor, unmarried women and their first-born children resulted in dramatic differences when compared with similar mothers and children in a control group. Many of the women in the study were younger than 19 years of age, and nurses made an average of 9 prenatal visits and 23 child-related visits (up to age 2 years). The effects of the intervention continued for up to 15 years after the birth of the first child.

Statistically significant differences were noted in the following outcomes:

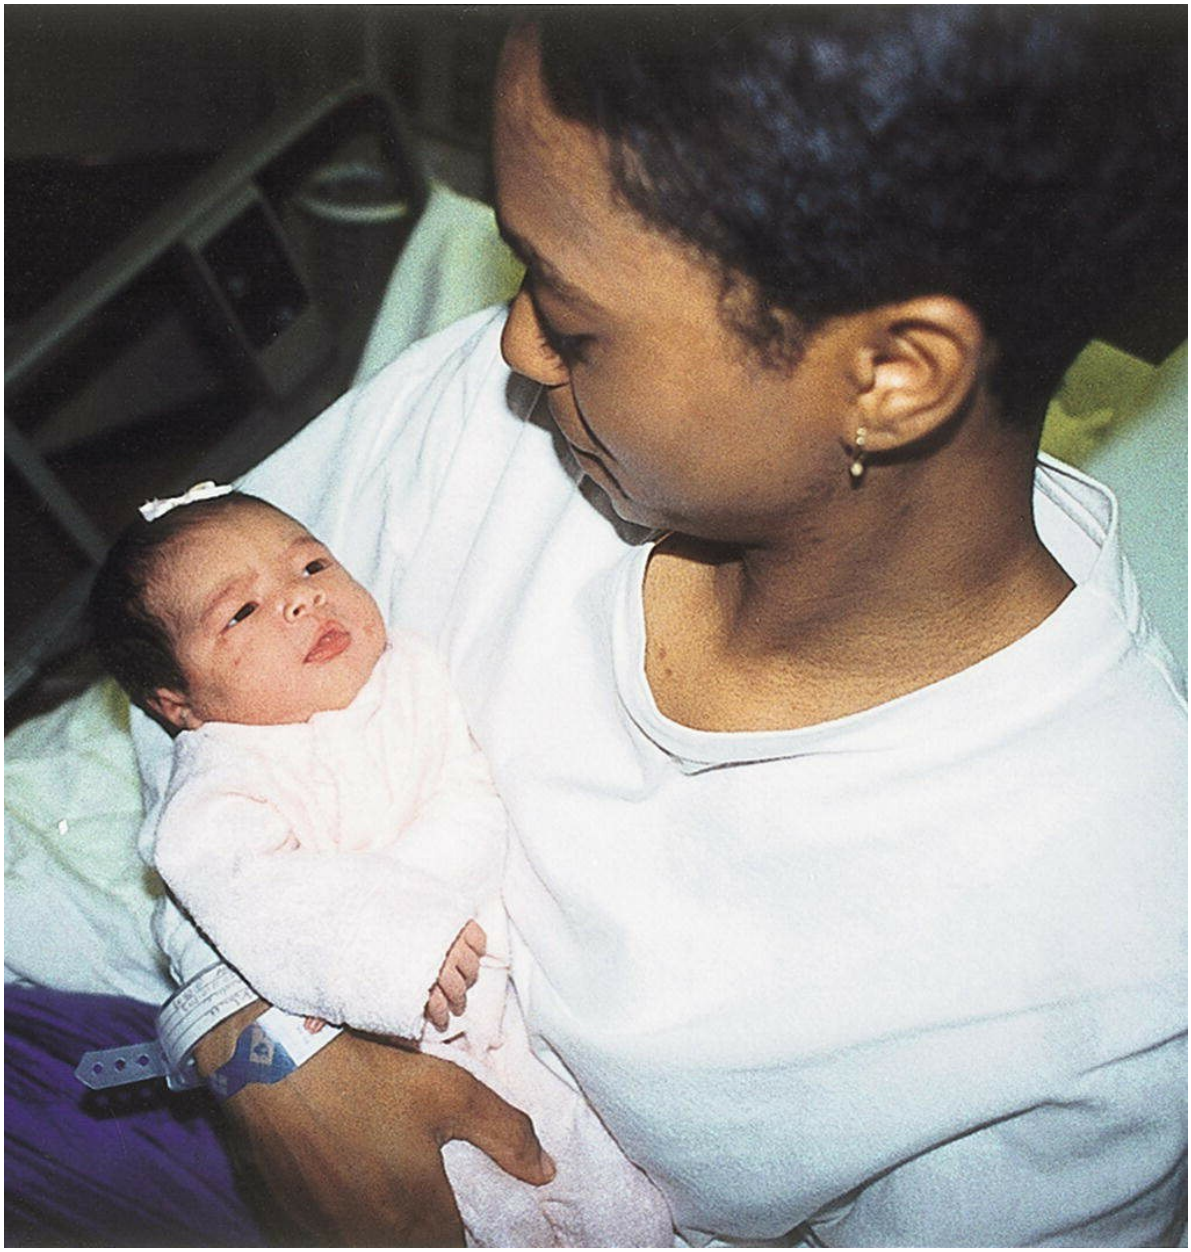
- Fewer subsequent pregnancies and an increased percentage of live births
- Longer intervals of time between first and second births
- Fewer incidences of reported child abuse and neglect
- Fewer months on public assistance and food stamps
- Fewer reported arrests and convictions of mothers
- Less impairment from alcohol or other drug use reported by mothers

In a more recent randomized 12-year follow-up study, Olds and his colleagues (2010) examined mother and child benefits when the first child turned 12. They found "no statistically significant program effects" for intimate partner violence, alcohol/drug use, arrests/incarceration, psychological distress, or placement of children in foster care (p. 419). However, in this largely African American urban sample of almost 600 participants, they did find statistical differences for:

- Longer relationships between mothers and their partners
- Decreased role impairment related to drug and alcohol use
- Greater personal sense of control

They also noted significant findings for cost savings; less government funding was spent

on these participants versus control subjects on Medicaid, welfare, and food stamps (Olds et al., 2010).



A 2014 study examining data from 1,138 women compiled over two decades (1990–2011) looked at outcome measures of maternal mortality and preventable-cause child mortality rates (Olds, Kitzman, Knudtson et al., 2014). Four treatment interventions were examined. The first was simply transportation for prenatal care, the second added developmental screening for infants and toddlers to the transportation, the third included prenatal and postpartum home visiting along with transportation, and the fourth consisted of transportation, screening, pre-/postpregnancy home visiting along with infant/toddler home visiting. Findings revealed the following:

- Maternal mortality rates for both control groups (1, transportation only, and 2, transportation with child developmental screening) were higher than for those in both of the intervention groups (3, prenatal and postpartum home visiting with transportation, and 4, full home visiting with pregnant mother and infant/toddler, along with screenings and transportation). Results comparing the first two versus the last two groups were statistically significant (p = 0.008), indicating that the interventions were worthwhile.
- Child data, only available in groups 2 (child screening with transportation) and 4 (full intervention with transportation), revealed statistical significance for preventable-cause child mortality rate (p = 0.04) for those in the group with all components of the NFP (group 4).

These and other studies are powerful evidence noting the effectiveness of a program of regular community/PHN visits to this vulnerable group (USDHHS, 2011b). A classic study by the Olds research team studying pregnancy outcomes, childhood injuries, and repeated childbearing (Kitzman et al., 1997) was recognized by the National Institute of Nursing Research (National Institutes of Health, n.d.) as one of ten landmark nursing research studies.

The NFP model is based on theory and research. Olds and his colleagues have conducted repeated RCTs with different populations living in a variety of settings and contexts, over varying lengths of time (Eckenrode et al., 2010; Kitzman et al., 2010; Olds et al., 2010, 2014), and have consistently found that the NFP program:

- Improves prenatal health
- Reduces rates of subsequent pregnancies/births
- Increases intervals between births
- Increases in maternal employment
- Improves child school readiness (NFP, 2011, para. 3)

Mother–infant bonding

In a time of tight budgets, number crunchers may ask: do community health nurses really make the difference, or can less expensive health care workers also get results? An early study by Olds et al. (2004) examined differences between nurse and paraprofessional (e.g., home aides) visitation in a large, randomized study of mostly Mexican American low-income first-time mothers. At the beginning of the study, no statistical differences were noted between control and paraprofessional subjects. Two years after the end of the program, participants visited by paraprofessionals had fewer low-birth-weight babies and better results than did control subjects on measures of mastery and mental health, and their home environments were conducive to early learning. On the other hand, mothers visited by nurses showed immediate as well as long-term benefits. They had longer intervals between first and second births, there were fewer incidences of domestic violence, and their

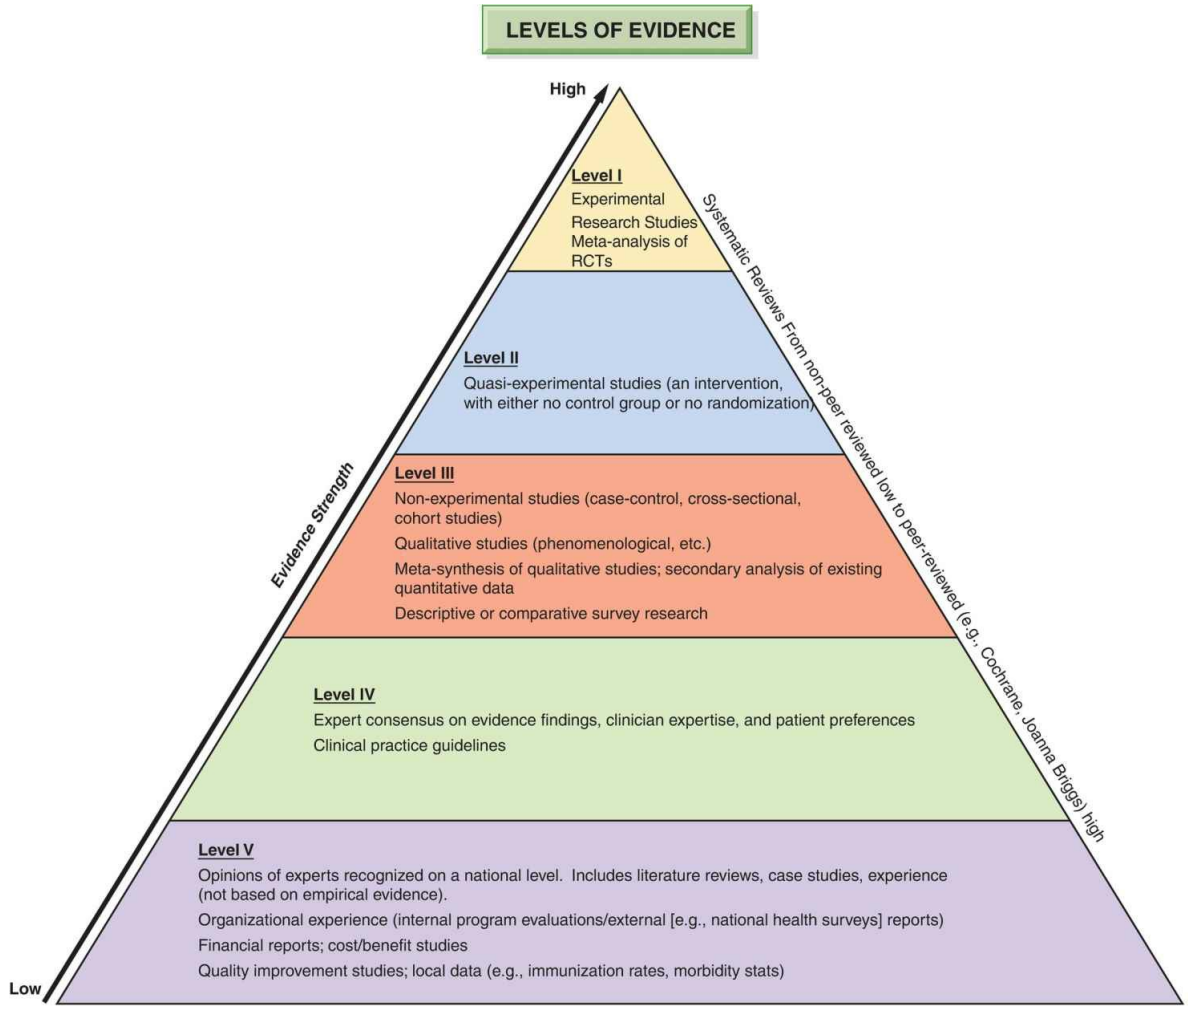
home environments were found to be conducive to early learning. Children of those mothers had better behavioral adaptation during testing, more advanced language scores, and better executive functioning. Others have reported similar findings (Isaacs, 2008).

More current research found "no significant paraprofessional effects on emotional/behavioral problems" among children of mothers with fewer psychological means in a study comparing paraprofessionals to control group counterparts. The only statistically significant effect was on "visual attention/task switching" for 9-year-olds (Olds et al., 2014, p. 114). Those children visited by nurses were found to have

- Fewer emotional and behavioral problems overall at age 6 ($p = 0.08$)
- Fewer internalizing problems at age 9 ($p = 0.08$)
- Less dysfunctional attention at age 9 ($p = 0.07$)

When compared to control-group counterparts, nurse-visited children exhibited better receptive language at the ages of 2, 4, and 6 ($p = 0.01$), and better sustained attention at ages 4, 6, and 9 ($p = 0.006$). Olds and his fellow researchers are convinced that public/community health nurses are the key to success!

In tough budget times, state and local agencies may be hesitant to expand programs. But the costs of community health nurse visits are more than offset by the large savings in both dollars and human suffering (Olds et al., 2010). Over the years, several policy and think tank groups have done cost–benefit analyses of the NFP, all concluding that this program reaps large returns on investment. A study on "costs, outcomes, and return on investment" from NFP was funded by the Pew Center on the States and noted that Medicaid spending for a first-born child could be reduced by 8%; this translates into $12,299 in savings per family (Miller, 2012). If NFP is fully funded by Medicaid, costs are recouped by the time the child reaches age 6, and 1.4 times the cost is returned when the child reaches age 18. Food stamp costs, decrease by 9%, welfare spending by 7%, and savings in Child Protective Services, criminal justice, and special education costs can lead to savings of $18,939 per family (Miller, 2012). An earlier Brookings Institute report recommended, among other things, that the government invest $14 billion for nurse home-visiting programs to promote prenatal care and child development (Isaacs, 2007). Other policy groups have echoed their support for policy changes based upon this carefully crafted and studies intervention (NFP, 2011c). When H.R. 3590 (The Patient Protection and Affordable Care Act—"health care reform") was passed in 2010, early childhood home visitation programs were singled out as effective practices and new grant funding to states was made available to promote these programs (U.S. Congress, 2010). The original 5-year funding of the Maternal, Infant, and Early Childhood Home Visiting (MIECHV) program was due to expire at the end of 2014, but many organizations and individuals let Congress know of their support for this research-based intervention and funding was extended for 2 more years even in the face of a stagnant legislative branch of government (Schmit, Schott, Pavetti, & Matthews, 2015; NFP, 2015). Many communities have sought to institute FNP (Institute of Medicine [IOM], 2014). Dr. Olds and his colleagues (2013) have encouraged



replication, using the established framework undergirding their proven results. The value of this program that provides PHNs to visit at-risk mothers and children in their homes has been validated. So, PHNs really *do* make a difference!

This evidence about the effectiveness of public health nursing visits could be gleaned only by conducting formal nursing research. Research in nursing is not a new phenomenon; Florence Nightingale is considered the earliest nurse researcher. She collected and analyzed data on the soldiers she cared for during the Crimean War (1859). She also employed principles of EBP because she sought to enhance their care by using evidence to improve her nursing practice and patient outcomes. Research is the systematic collection and analysis of data related to a particular problem or phenomenon. Research that is properly conducted and analyzed has the potential to yield valuable information that can affect the health of large groups of people. Indeed, it should guide our practice of community health nursing, and it often serves as the basis for changes in health care policies and programs. The Quad Council PHN Competencies include analytic assessment skills, basic public health science skills, and policy development/program planning skills that include research and EBP (2011). In the current national atmosphere of managed care and obstinately rising health care costs, the importance of valid research on how health care dollars can be spent to benefit the greatest number of people is vitally important.

EVIDENCE-BASED PRACTICE

Across many different settings, from acute to community-based care, implementation of EBP guidelines or practices has been shown to improve nursing practice and client outcomes, as well as reduce costs and standardize care (Doren et al., 2010; Stevens, 2013). But how did this more recent paradigm shift toward EBP occur? Dr. Archie Cochrane, a British epidemiologist, is widely regarded as the force behind evidence-based clinical practice in medicine (The Cochrane Collaboration, 2015). As health care has become more and more complex, we have developed "superspecialists" and increasingly advanced technology, as noted in Gawande's seminal work, *The Checklist Manifesto (*2010, p. 31). Even though we often cling to "the way we've always done it," we certainly have ample evidence of the need for a shift to EBP in health care: the IOM has been studying the issues of health care quality and effectiveness over the 15 years or more and has called for widespread and systematic changes through their reports—*To Err Is Human: Building a Safer Health System* (IOM, 2000), *Crossing the Quality Chasm: A New Health System for the 21st Century* (IOM, 2001), and *Priority Areas for National Action: Transforming Health Care Quality* (IOM, 2003). These landmark reports draw attention to the fact that we spend billions of dollars each year researching new treatments, and more than a trillion dollars are spent annually on health care, but "we repeatedly fail to translate that knowledge and capacity into clinical practice" (IOM, 2003, p. 2). In response, the federal Agency for Healthcare Research and Quality (AHRQ) has established EBP centers across the United States and Canada. Schools of nursing, such as Arizona State University, the University of Texas Health Science Center at San Antonio, Case Western Reserve, and the University of Rochester, also have established centers for EBP.

The Future of Nursing highlights the need for nursing to work with other health professionals in "redesigning health care" by "conducting research" and improving practices through evidence-based means (IOM, 2011, pp. 7, 11). According to Melnyk and Fibneout-Overholt (2014), evidence-based practice in nursing means just that—systematically searching for and critically appraising and synthesizing evidence (or research findings), along with consideration of expert clinical nursing judgment and patients' wishes, in making decisions about how to care for patients or clients (see Display 4–1, Steps of Evidence-Based Practice and Fig. 4–1). Rebar, Gersch, Macnee, and McCabe (2014, p. 6) further clarify it as:

(2007) *Johns Hopkins Nursing Evidence-Based Practice Model & Guidelines.* Indianpolis, IN: Sigma Theta Tau International; Olson keller, L., & Strohschein, S. (2011, June1). *Show me the evidence: Evidence-based public health nursing practice.* Webinar. Handouts retrieved from http://publichealthnurses.org/images/uploads/Webinar_I_Slides_Updated.pdf; Olson Keller, L., & Strohschein, S. (2011, June 15). *Innovations in translating evidence into practice.* Webinar. Handouts retrieved from http://publichealthnurses.org/images/uploads/Web_II_Handout_(1).pdf

Figure 4–1 Levels of evidence.

DISPLAY 4.1 THE STEPS OF EVIDENCE-BASED PRACTICE PROCESS

0. Cultivate a spirit of inquiry.
1. Ask the burning clinical question in PICOT format.*
2. Search for and collect the most relevant best evidence.
3. Critically appraise the evidence (i.e., rapid critical appraisal, evaluation, and synthesis)
4. Integrate the best evidence with one's clinical expertise and patient preferences

and values in making a practice decision or change.
5. Evaluate outcomes of the practice decision or change based on evidence.
6. Disseminate the outcomes of the EBP decision or change.

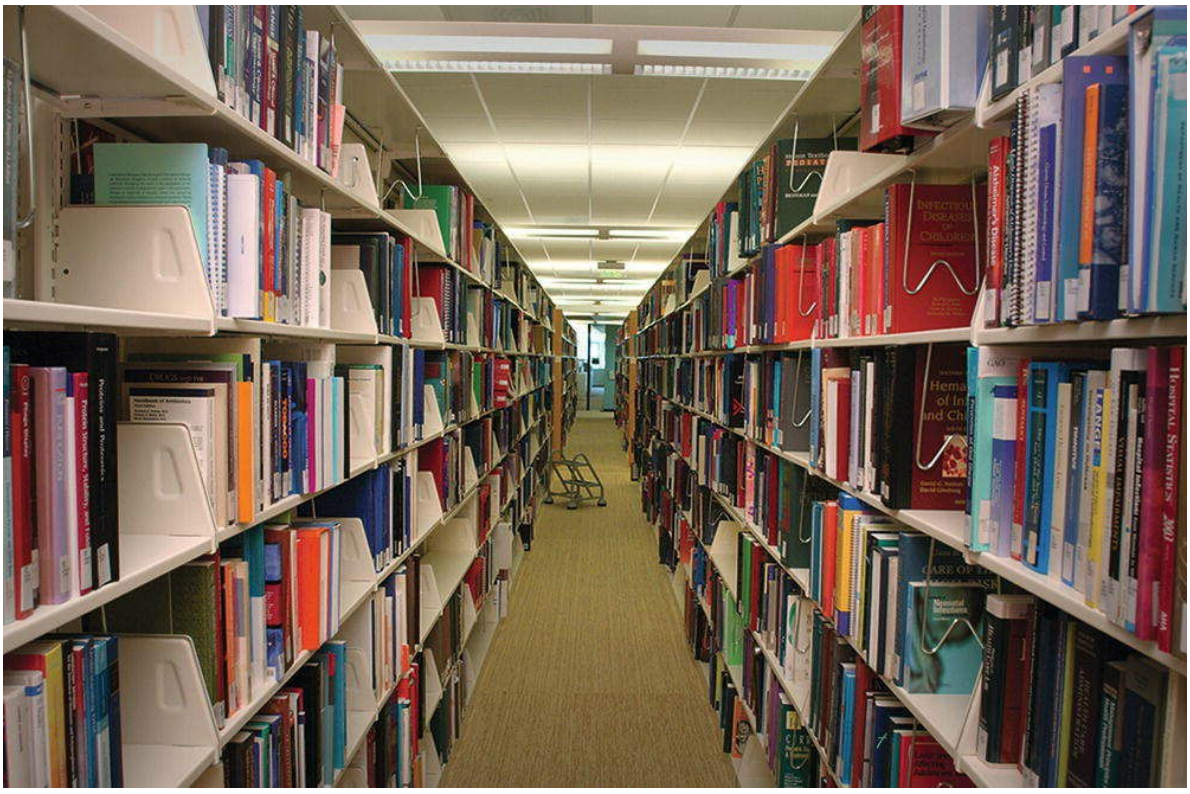
*PICOT stands for Population/Patient Problem, Intervention, Comparison, Outcome, Time.

From Melnyk, B., & Fineout-Overholt, E. (2014). Evidence-based practice in nursing and healthcare: A guide to best practice (3rd ed., p. 15). Philadelphia, PA: Lippincott Williams & Wilkins, with permission.

- Reviewing the best available evidence, most often the results of research
- Using the nurse's clinical expertise
- Determining the values and cultural needs of the individual
- Determining the preferences of the individual, family, and community

Olson Keller and Strohschein (2011, June 1) note that, in public health, the best available evidence includes not only that from clinical research but also from health data (e.g., immunization rates, mortality rates, health status surveys) and practice (e.g., program evaluations, reports from expert panels). Clinical reasoning is an important component in EBP. Practice knowledge of expert clinical nurses is vital to the process and efficacy of results (Lee, Johnson, Newhouse, & Warren, 2013a; Melnyk, Gallagher-Ford, Long, & Fineout-Overholt, 2014). Training programs are necessary for nurses to successfully apply EBP to their practices, in the community as well as in acute care (Black, Balneaves, Garossino, Puyat, & Qian, 2015). For those working in hospitals where quality improvement (QI) is at the forefront, it can be difficult to discern differences between EBP, research, and QI. It is helpful to consider Porter-O'Grady's (2010) view of EBP as the "integration of the best possible research" evidence with clinical knowledge and expertise, along with patient preferences and needs (p. 1). Thinking critically about practice problems is an important component of EBP. Reflecting on why we do things a particular way and critically thinking through a problem in a purposeful, systematic way are vital steps in the process. For instance, Porter-O'Grady (2010) finds commonalities between EBP and critical thinking:

- Explore a problem.
- Address a purpose or goal.
- Make assumptions about the problem derived from an assessment of the problem and its elements.
- Clarify the problem around central concepts or key indicators.
- Access data, evidence, information, and sources to better explain the problem.
- Interpret accumulated evidence about the specific situation or problem.
- Use reasoning, processing, defining, planning, and documenting to guide subsequent actions in addressing the issue.
- Act on the problem, consistent with protocols and parameters, and assess its effect and impact, as well as the process.
- Evaluate, adjust, generalize, and apply to a broader problem set (indicative of a



successful problem-solving process).

STEPS OF THE EBP PROCESS

The effective practitioner utilizes his or her clinical judgment and expertise to reflect on the practice of community health nursing and determine if safe, effective, quality, and cost-efficient care is being delivered. Problems or situations that need clarification can then be identified, and current research can be reviewed to guide needed changes in practice. Although acknowledged barriers exist, they can be overcome utilizing available resources (Grant, Stuhlmacher, & Bonte-Eley, 2012). Melnyk and Fineout-Overholt (2014, pp. 10–16) outline the steps of the EBP process as seen in Display 4–1:

1. Cultivate a spirit of inquiry.
2. Ask the burning clinical question in PICOT format (see below).
3. Search for and collect the most relevant best evidence.
4. Critically appraise the evidence for its validity, reliability, and applicability, and then synthesize that evidence.
5. Integrate the best evidence with one's clinical expertise and patient preferences and values in making a practice decision or change.
6. Evaluate outcomes of the practice decision or change based on evidence.
7. Disseminate the outcomes of the EBP decision or change.

These steps will be explored in more detail, as well as available resources and implications for public health nursing practice.

Finding evidence can be daunting in this era of information overload. (Photo courtesy of CDC Public Health Image Library.)

CULTIVATING A SPIRIT OF INQUIRY

The importance of this initial step cannot be overstated. In order for effective change to occur, current practices must be continually examined, questioned, and challenged. Individuals and organizations must be open to this cultural shift from the status quo, and it should be reflected in the agency's mission and philosophy (Melnyk & Fibneout-Overholt, 2014). There is a need for continual curiosity about how we can best conduct our practice and the evidence needed to guide our clinical decision-making; we also need to be immersed in a supportive culture that sustains this curiosity. Asking questions like "Why are we doing this?" and "Is there evidence to support this practice?" demonstrates this spirit of inquiry. Agencies that provide access to systematic reviews, evidence-based journals, and research consultants also demonstrate a commitment to this step.

ASKING THE QUESTION

What if you or your colleagues doubt the effectiveness of some method in your current nursing practice and want to find out if there is new research or evidence that may convince you to make a change? How do you begin your journey to EBP? Melnyk and others suggest that the first step to solving the problem is "asking the burning clinical question" (2014, p. 10). This question may be about client care or effective interventions, such as:

- What methods are most effective in ensuring client medication compliance with tuberculosis (TB) protocols?
- What is the best information I can give new mothers about preventing sudden infant death syndrome (SIDS)?

It could also be about systems approaches to population health:

- What is the most effective method of immunizing toddlers?
- How can PHNs better collaborate with families, physicians, and hospitals in preventing quick readmission of heart failure patients due to poor understanding and control of symptoms?

The PICOT question (see Display 4–2) is one way to develop an answerable, searchable EBP question. First, the population or problem must be specified. The Association of Women's Health, Obstetric, and Neonatal Nurses (AWHONN) asked a "burning clinical question" when they wanted to find a scientific basis for the development of standards of practice for their members regarding counseling pregnant women on smoking cessation. The project, *Setting Universal Cessation Counseling, Education, and Screening Standards* (SUCCESS), was an attempt to integrate best practices in primary care settings where women of childbearing age receive care. They did extensive searches in the Cumulative Index on Nursing and Allied Health Literature (CINAHL) and MEDLINE for research studies relating to low-birth-weight infants, effects of prenatal smoking on infants, and effects of smoking cessation intervention on premature labor and birth weight with both pregnant women and those seeking care prior to conception (Albrecht, Kelly-Thomas, Osborne, & Ogbagaber, 2011). They critically analyzed articles and found evidence of a higher incidence of many complications, including preterm labor, premature rupture of membranes, lower birth weight and length, spontaneous abortion, and placenta previa or abruption in women using tobacco. Infants and children exposed to secondhand smoke had a higher risk for ear infections, asthma and other respiratory problems, SIDS, and learning disorders. Significant evidence suggested that this was a problem that needed to be addressed. They also concluded that health care providers could provide office-based assessments and utilize client-focused protocols. At each visit, their members are encouraged to ask women to tell them about their current smoking habit, and they implement the five A's intervention model (Ask, Advise, Assess, Assist, Arrange). If there is

an indication that the client is not ready to quit smoking, the practitioner can implement the five R's (Relevance, Risks, Rewards, Roadblocks, and Repetition). This is a powerful example of taking evidence, evaluating it, and applying it to a problem that can be addressed through nursing practice and promoted by a nursing professional organization (Association of Women's Health, Obstetric and Neonatal Nurses [AWHONN], 2014).

DISPLAY 4.2 PICOT: COMPONENTS OF AN ANSWERABLE, SEARCHABLE QUESTION

Term	Definition	Specific Example
Patient population/problem	The patient population or problem of interest, for example: • Age • Gender • Ethnicity • With certain disorder (e.g., hepatitis A)	For example: • Adolescent females, ages 12–20
Intervention	The intervention or range of interventions of interest, for example: • Exposure to disease • Risk behavior (e.g., smoking) • Education	For example: • Sexuality education program
Comparison intervention or issue of interest	What you want to compare the intervention against, for example: • No disease • Absence of risk factor (e.g., smoking) • Placebo or no intervention	For example: • Current practice or no intervention
Outcome	Outcome of interest, for example: • Risk of disease • Rate of occurrence of adverse outcome (e.g., death) • Accuracy of diagnosis	For example: • Unplanned pregnancies
Time	The time involved for the intervention to demonstrate an outcome, for example: • Time it takes for intervention to achieve the outcome • Time interval selected to observe the population or problem/condition	For example: • One school year (to implement curriculum)

Adapted from Melnyk, B., & Fineout-Overholt, E. (2014). Evidence-based practice in nursing and healthcare: A guide to best practice (3rd ed., p. 28–29). Philadelphia, PA: Lippincott Williams & Wilkins, used with permission.

Finding the Evidence

Melnyk and Fibneout-Overholt (2014) stress the importance of systematically searching for all relevant research on a clinical question of interest and critically analyzing the evidence. They argue that this is not merely research utilization, in which new interventions may be tried based on the results of one or two good studies, but true synthesis of pertinent evidence from several studies (e.g., systematic reviews of RCTs) and critical reviews of both quantitative and qualitative studies pertinent to a particular question of interest. While doing this, the nurse must keep in mind the unique needs and wants of the clients served, as well as current practice standards, guidelines, and ethical considerations. National clinical practice guidelines should be reviewed (e.g., National Guideline Clearinghouse at www.guideline.gov), and expert clinicians may be interviewed for their opinions on the problem at hand. Nurses often rely on RN peers, along with guidelines and experience with patients, rather than current evidence, and this can result in poor practice decisions because of inadequate information (O'Leary & Mhaolrunaigh, 2012). A solid understanding of the evidence is needed.

Although expert nurses may be a good starting point in seeking evidence, clinically relevant research that is both medically sound and patient centered must be reviewed. Excellent places to begin are integrative or systematic reviews that compile all recent studies and summarize what is known about the problem or situation. The Cochrane Collaboration (www.cochrane.org) lists systematic reviews on various topics of interest to both physicians and nurses. For instance, a community health nurse working with a group of adults who have diabetes might be interested in the systematic review on the importance of exercise for clients with type 2 diabetes. An early systematic review found that those who participated in aerobic exercise had decreased body fat and triglyceride levels and improved blood sugar control (even for those who did not lose any weight). However, a later systematic review found that both aerobic and resistance exercise helped achieve control of diabetes (Yang, Scott, Mao, Tang, & Farmer, 2013). Although a community health nurse may certainly have a "hunch" that exercise is good for his or her clients, this newer systematic review of current studies provides solid evidence on which to base specific recommendations. Another review on promoting adherence to antiretroviral therapy for human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) clients might be helpful to a PHN supervisor in designing an AIDS case management program utilizing PHNs. A systematic review of 124 studies including a large majority of RCTs done in North America, Africa, and Europe found a "large and overall strong evidence base" for five interventions: (a) cognitive-behavioral therapy (CBT), (b) education, (c) directly observed therapy (DOT), (d) treatment supporters, and (e) active reminder devices (ART) such as text messaging (Chaiyachati, Ogbuoji, Price, Suthar, Negussie, & Barnighausen, 2014, p. s199). From this evidence, a community health nurse case manager may conclude that medication compliance can be effectively ensured through development of a nurse–client relationship, group support, and focused patient education on medication

management skills. Another source of systematic reviews includes the Campbell Collaboration (http://www.campbellcollaboration.org), covering education and social welfare research that may be of interest to PHNs who are examining, for instance, effective group or individual interventions such as parenting programs for teens (Barlow et al., 2011).

The AHRQ EBP centers also provide evidence reports that are easily accessible online (http://www.ahrq.gov/research/findings/evidence-based-reports/overview/index.html). Searching may be done by use of a topical index, clinical area, or health care services (e.g., bioterrorism) and technical areas (e.g., community-based participatory research [CBPR]). Other sources for systematic or integrative reviews include the following:

- Cochrane Nursing Care Field podcasts (http://cncf.cochrane.org/podcasts)
- Cochrane Public Health Group (http://ph.cochrane.org)
- *Worldviews on Evidence-Based Nursing* from Sigma Theta Tau International (www.nursingsociety.org)
- *Evidence-Based Nursing*, a British online journal (www.ebn.bmjjournals.com)
- Joanna Briggs Institute, an Australian nursing research organization (joannabriggs.org)
- The Community Guide, a CDC site for research on population health promotion (http://www.thecommunityguide.org/index.html)
- Health-Evidence Canada, a Canadian website for promoting evidence-based decision-making (http://health-evidence.ca/)
- Research and Development (RAND) Corporation research briefs (www.rand.org)

Critical Appraisal of the Evidence

Collection and critical analysis of the best evidence in the literature, like that done by AWHONN above, constitute the second and third steps in the EBP process. Systematic reviews should be carefully examined to determine validity (Thompson, Tiwari, Fu, Moe, & Buckley, 2012). You can do this by asking these types of questions:

- What was the review question? (Specific population, intervention, etc.)
- Were search strategies explained and are they reasonable?
- What were exclusion criteria/were any important, relevant studies overlooked?
- Were the studies in the review properly designed and executed (were findings valid)?
- Were there similar results found in all studies?
- How reliable are the results (only minimal bias)?
  For instance:
  - Were sample sizes large enough?
  - Were results statistically significant?
  - Were there confounding factors (e.g., outside influences that make you doubt the results; differences between groups in intervention or outcome assessment, high rates of attrition)?

It is also helpful to compare the results with previous research and clinical practice (Melnyk & Fibneout-Overholt, 2014). Qualitative research, discussed later, can also be evaluated by asking questions:

- How were study participants chosen?
- Is the data accurate and complete?
- Are the results plausible? Is it logical, consistent, and relevant?

Grids outlining levels and quality of evidence in public health nursing are available (www.publichealthnurses.org). But what if no systematic reviews are available in your area of interest? Where can you find the necessary evidence needed in order to make good practice decisions? You can look for RCTs, meta-analysis research, program evaluation studies, systematic literature reviews, or practice guidelines (see Fig. 4–1, Levels of Evidence), keeping in mind that several studies (or one or two large-scale, tightly controlled studies) are preferred.

Integrating the Evidence

Fourth, it is important to make a decision, based on your clinical expertise and knowledge of your clients' values and preferences, about incorporating this information into your practice. You can do this by asking:

- How can I apply these results to my community health nursing practice?
- Will it benefit my clients?
- Are my clients similar to the population studied?
- Do I have the necessary resources?
- Does this go against my client's values or preferences?

Evidence has shown that PHNs have been effective with different client populations in ameliorating postpartum depression, promoting awareness, and facilitating improved family functioning in families with neglected and abused children, and the benefits of the NFP for children, mothers, and families have been consistently demonstrated (Glavin, Smith, Sorum, & Ellefsen, 2010; Kobayashi, Fukushima, Kitaoka, Shimizu, & Shimmanouchi, 2014; Mejdoubi et al., 2011; NFP, 2010; Olds, Kitzman, Knudtson et al., 2014; Sierau et al., 2016). Newer research outside of public health nursing may also be applied in the community, depending upon clinical expertise and knowledge of our clients. For instance, a new area of research about treating low levels of vitamin D in the elderly found that it may reduce risk of mortality among institutionalized elderly who are at risk for falls, but it doesn't seem to reduce the rate of fractures (LeBlanc, Zakher, Daeges, & Chou, 2015). Other researchers found that for elderly females with poor renal function who are living in nursing homes, vitamin D supplements alone may not be sufficient (Terabe et al., 2012). Depending upon age group, in general, population screening for vitamin D insufficiency may be more cost-effective than universal supplementation (Lee et al., 2013b). This research might spark an interest for community health nurses to counsel adult clients attending yearly flu clinics to include this supplement in their daily regimen, especially in areas where exposure to sunlight is less prevalent.

New research examines if the elderly may benefit from vitamin D supplementation.

An example of a systematic review of interest to PHNs is from the Cochrane Nursing Care Field and concerns smoking cessation. Young and Skorga (2011) produced a synopsis of a Cochrane review done by Lindson et al. in 2010 that examined 10 clinical trials for differences in success rates and adverse events between participants who abruptly quit smoking and those who utilized a more gradual reduction in smoking. Findings revealed no statistical differences between the two groups for smoking abstinence, despite types of interventions used (e.g., self-help therapy, pharmacotherapy, behavioral support). However, some of the study results were inadequate, making it impossible to conclude if there were

any differences in adverse effects. Because smoking cessation is often advised for community health clients, PHNs could utilize this information to guide them to encourage either method of smoking cessation for their clients. When examining population-based strategies, The Community Guide provides task force recommendations based on systematic reviews, along with additional resources on the topic of interest. For instance, when searching the term "dental caries," community water fluoridation is recommended, as are school-based/school-linked sealant delivery programs. However, state or community sealant promotion programs are not recommended owing to insufficient evidence.

Evaluating Outcomes

The final step of the EBP process is to evaluate any practice change. For instance, if you decide to implement findings from the systematic review on HIV/AIDS medication compliance cited above, a standardized protocol of home visits and patient education by PHNs would need to be established and both baseline and postintervention data collected in order to deduce any potential positive change noted. Results can vary based on specific environment, population, implementation, and other factors. Evidence can lead you to choose a course, but evaluation of your outcomes is necessary to ensure that you have achieved the best results.

The design of an evidence-based research project represents the overall plan for carrying out the study. The overall plan guides the conduct of the study and, depending on its effectiveness, can influence investigators' confidence in their results. A major consideration in selecting a particular design is to try to control as much as possible those factors that are not included in the study but can influence the results. For example, in a classic study by Douglas, Mallonee, and Istre (1999), researchers wanted to discover the percentage of homes with functioning smoke alarms. They initially conducted a telephone survey, a commonly used method of survey research in community health, and found that 71% of households reported functioning smoke alarms. Concerned that this might be an inflated number, they conducted an on-site survey to confirm the results. After face-to-face interviews, they found that only 66% of householders reported having functioning alarms. However, when researchers actually tested the smoke alarms in those homes, only 49% were fully functioning. By having researchers actually test the smoke alarms, this design controlled for inflated results of the more commonly conducted, convenient, and economical telephone survey. Is self-report always unreliable? A classic small study of working middle-aged women revealed that self-reported weekly physical activity was strongly associated with data, indicating in this case self-report yielded reasonably reliable data (Speck & Looney, 2006). This provides evidence that the community health nurse must determine the most efficacious method of obtaining necessary data.

A more recent study examined physical activity during pregnancy and compared normal-weight and obese females (Renault et al., 2012). Baseline assessment of prepregnancy physical activity was done by questionnaire. Assessment during pregnancy was done by the use of pedometers worn for one week during every month of pregnancy. Obese participants had lower activity levels before and during pregnancy compared to normal-weight participants. Interestingly, pregnancy weight gain was higher in normal-weight participants compared to obese women. It was also lower in obese women who were noncompliant than in those who were compliant with pedometer use.

In an example of research with a specific population, researchers sought to control the variables to ensure true results. Sweet, Polivka, Chaudry, and Bouton (2014) designed and implemented an urban home-based intervention program for children with asthma. They

completed pre- and postintervention assessments of asthma outcomes (e.g., symptoms, activity limitations, nighttime awakenings, use of inhalers, emergency department visits, missed days at school), caregiver quality of life (e.g., feeling helpless or frightened, missing work, awakened at night, worried about medications/side effects), asthma trigger–related household activities (e.g., smoking, using fragrance-free cleaning products), and asthma management activities (e.g., having an asthma action plan, using spacer with inhaler). At the beginning of the study, the participating families received home assessments and interventions (e.g., pest control, mold abatement) and a "Healthy Homes Action Plan" binder with a review of verbal education about ways to reduce asthma triggers around the home. This was done in an effort to provide a more consistent baseline for comparison (Sweet et al., 2014).

With another population common to PHNs, researchers knew from their review of the literature and practical experience that pregnant teens are a vulnerable population who often receive no prenatal care. Their inadequate use of resources and risk-taking behaviors often lead to premature delivery and low-birth-weight infants, as well as greater behavioral and cognitive problems of children leading to diminishing educational outcomes (Schaffer, Goodhue, Stennes, & Lanigan, 2012). The goals of the program were to refer and provide services to pregnant and parenting adolescents and children, as well as examine outcome measures of healthy births, delayed subsequent pregnancy, teens remaining in school, and improved maternal–child bonding as well as use of community resources.

Researchers sought to design a comprehensive program that included development of trust between PHN and teen participant, community outreach and coordination with schools and other agencies, utilization of a mental health curriculum, and provision of items needed to care for the infant or child (up to the age of two). Home visiting was an integral component of the program, where education about pregnancy, child development, and available community resources were stressed. Support and advocacy, along with discussion of the mental health curriculum, were also important. An evaluation of this PHN visiting program for pregnant and parenting teen in the Midwest assessed the "changes in program participants" and did not examine if the program "actually caused the changes" (p. 224). With a goal of reaching all pregnant and parenting teens, the evaluation revealed that 77% of eligible teens were referred to this program and 78% of those chose to accept services. Of those receiving 6 or more visits, 96% (vs. 90% of nonparticipants) had babies with healthy weights. For those with 10 or more visits, 76% (vs. 56% of nonparticipants) continued or graduated from school. Fewer participants had subsequent births, and more participants had safer, more supportive homes than did nonparticipants. Also, 95% had up-to-date immunizations and 97% were regularly taking their children in for well-child visits (Schaffer et al., 2012).

Pregnant teens

Once an intervention is developed, further research can evaluate its appropriateness and, ultimately, its effectiveness. Beyond EBP implementation, other lines of clinically based research can also be designed. The choice of research design influences the ability to generalize the results, and the attention given to the details of the study affects the value of the knowledge derived. Research done with larger numbers of participants drawn from a geographically diverse area is more complete than small-scale, exploratory studies done in an isolated area with a small, homogeneous sample. Valid tools or instruments and appropriately applied statistical methods lead to greater confidence in the results of the study.

Disseminating Outcomes

We need to share our results in order to improve the body of knowledge in public health nursing and provide studies that can be used in future systematic reviews. Often, community health nurses are required to report results to stakeholders (e.g., grant-funding agencies, local or county governing bodies). Formal reports are often required, or scorecards may be used that compare local results to state and national data. We can also share outcomes information with our colleagues locally, through informal networking, blogs, or pertinent listserv, etc. However, when EBP outcomes are shared at state and national professional meetings or through publication in peer-reviewed journals, a wider audience is reached and our knowledge based is exponentially increased.

DIFFERENCES BETWEEN EBP IMPLEMENTATION, QUALITY IMPROVEMENT, AND RESEARCH

If you have worked as a student in an acute care hospital, you have been introduced to quality or performance improvement (QI/PI) initiatives. QI/PI became even more important to health care after the IOM reports cited earlier. These approaches involve a systematic analysis of data and processes with the aim of improving the delivery of health care. Over the last decade, the National Quality Forum has endorsed over 600 quality measures, and hospitals are now required to publicly report certain quality data indicators. The Centers for Medicare and Medicaid Services (CMS) began to financially penalize hospitals by not paying for services when certain quality indicators were not met (e.g., pressure ulcers) and is now developing incentives for better quality care, such as nurse-sensitive value-based purchasing (Kavanagh, Cimiotti, Absulem, & Coty, 2012). See Chapter 6. Accrediting bodies for acute care hospitals first mandated quality care initiatives, but these are now spreading to ambulatory areas and other settings (Chassin, Loeb, Schmaltz, & Wachter, 2010). With the push for accreditation in public health agencies, this issue is becoming even more pertinent to PHNs and to public health systems with a focus on population health (Kronstadt, Beitsch, & Kaye, 2015; MacDonald, Newburn-Cook, Allen, & Reutter, 2012; Thomas, Corso, & Monroe, 2015).

The differences between QI/PI, EBP implementation, and clinical research are sometimes unclear (Conner, 2014). Melnyk and Fibneout-Overholt (2014) note that generalizability of findings is often not part of EBP project implementation because representative samples are not used. Rather, convenience samples of inpatients or clients are used to test initiatives for practice improvement. However, that distinction alone does not release nurses from gaining ethical approval (e.g., Institutional Review Board [IRB], Human Subjects Committee [HSC]). This is certainly required when disseminating results through publication or national presentations. Informed consent is another area where clear distinctions are also problematic. If you change your practice to benefit your clients, based on the best evidence and your clinical judgment/knowledge of your clients, it would be cumbersome to ask for written consent from every patient before implementing changes. It is not feasible, and it is expected that professional practice changes will be made over time without consulting clients. However, some clinical management oversight is expected in order to ensure that client rights are not violated.

One example of a QI project (or arguably an EBP implementation project) that was halted because of questions raised by the federal oversight agency for human subjects research protection is a large-scale study (67 intensive care units [ICUs] in Michigan) implementing EBP procedures to reduce catheter infection rates. The outcomes were "stunning," as it was estimated that over 1,500 lives were saved over the 18 months of the

QI initiative (Gawande, 2010). However, the federal agency criticized the hospital that organized the study for dismissing the need for patient consent; it had been waived because their IRB saw it as QI and exempt. Researchers published the phenomenal results, bringing it to the attention of federal overseers. Protection of human subjects remains vitally important, and practical rules, infrastructure, and supervision within organizations can ensure that QI activities are appropriately reviewed and differentiated from clinical research. Some researchers are concerned that important research may be affected if rigid rules of consent are applied to QI studies in the same way they are in research studies (Wilfond, 2013). Stausmire (2014) provides a checklist to help nurses determine if their project falls under the auspices of an IRB (e.g., research or QI). QI is not only important in acute care settings, but public health agencies are increasingly organizing QI teams and implementing studies (Davis et al., 2014).

To effectively practice EBP implementation, community health nurses must know how to correctly compose a clinical question, find an appropriate database to search for systematic reviews or other evidence, critically review the evidence, consult practice guidelines and expert practitioners, and work with their clients to develop an appropriate plan of action. A clear understanding of basic research principles is needed to apply the principles of EBP and integrate the latest research into community health nursing practice. Evidence, in the form of systematic reviews, is most often drawn from quantitative research studies, but some public health nursing researchers also advocate the use of qualitative research in making evidence-based public health practice decisions (Martin, Kewwick, Crayton, & LeVeck, 2012; Sweet, Polivka, Chaudry, & Bouton, 2014; Weekes, Haas, & Gosselin, 2014). See Quality and Safety Education in Nursing (QSEN).

QUANTITATIVE AND QUALITATIVE RESEARCH

Scientific inquiry through research is generally pursued by means of two different approaches: quantitative research and qualitative research. Both can be part of research and EBP. Quantitative research concerns data that can be quantified or measured objectively. This could be as simple as counting the number of children receiving vaccination for varicella in immunization clinics during the past month and noting the number of reported cases of postvaccination complications. Fleming (2011) collected quantitative data from a school nurse database on the number and types of visits students made to school nurses' offices (total visits = 12,797). Data on visits were broken down by ethnicity and poverty level in an attempt to determine if differences existed between racial/ethnic groups and poor/not poor students who used school nursing services. Findings indicated that students who were poor regularly visited the school nurse's office, and these findings were consistent across racial/ethnic groups. Poor, black children accounted for 29% of visits and were the group using services most frequently. Most children visited the nurse for physical problems, but about 33% of poor White and Hispanic children visited the nurse for social–emotional reasons. Only 20% of Black and 10% of Asian children did this. This research gives a snapshot in time, but cannot address students' motivating factors for visits. More variables would need to be included in the study design.

QSEN—Focus on Quality: Patient-Centered Care

Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient preferences, values, and needs.

Knowledge

Integrate understanding of multiple dimensions of patient-centered care:

- Patient/family/community preferences and values
- Coordination and integration of care
- Involvement of family and friends
- Transition and continuity

Describe how diverse cultural, ethnic, and social backgrounds function as sources of patient, family, and community values.

Skills

Provide patient-centered care with sensitivity and respect for the diversity of human experiences.

Attitudes

Value seeing health care situations "through patients' eyes"; value patient's expertise with own health and symptoms; support patient-centered care for individuals and groups whose values differ from our own.

You have all dealt with individual patients in acute care settings. Some of you have also worked closely with patient families. Now, you will be widening your lens to focus on larger groups of patients (e.g., aggregates) and communities (e.g., populations). How do these QSEN competencies apply to aggregates such as mothers addicted to drugs or to population groups such as the elderly in your community?

As health care continues to evolve, nurses are being asked to shift to systems thinking, rather than just focus on an individual patient. This is how we will solve the problems with quality and safety in health care. Dolansky and Moore (2013) state that we must "broaden….problem identification from a focus on personal effort in a single situation to a focus on sequences of events with possible multiple causes for both individuals and populations" (para. 11). For example, we will not effectively address the high rates of early readmission for heart failure patients by simply checking prescriptions before discharge for an individual patient or even giving them reminder magnets to put on their refrigerators in the hope that this will help them remember to take their medications. Because many early readmissions were long ago found to often be preventable and due to inadequate discharge planning and poor follow-up/social support, among other things (Vinson, Rich, Sperry, Shah, & McNamara, 1990), hospitals are no longer being reimbursed and are seeking more innovative methods of addressing this issue.

We need to work with interdisciplinary teams to identify high-risk patients, prepare patients and their families for discharge, and then work with specialized programs that follow patients while they are at home to make sure they are weighing daily, monitoring their symptoms, and taking their medications. Early identification of potential problems and home visits by Advanced Practice Nurses (APNs) or predischarge scheduling of office visits with their medical providers has been shown to reduce 30-day readmission rates (Bradley, Curry, Horwitz, Sipsma et al., 2013). Transitional care interventions proposed by nurses (Naylor, Aiken, & Kurtzman, 2011) have demonstrated effectiveness and are proving their significance to health care reform (Stauffer, Fullerton, Fleming et al., 2011).

What other problems do you see that could benefit from a broader focus on quality and safety?

Larsen and Reif (2011) provide an example of a quantitative study that includes an intervention and a control group. Because the United States is becoming increasingly diverse (see Chapter 5), the researchers wanted to find an effective method of training nursing students to more successfully work with diverse clients. They utilized the common approach of classes on culture, but added a 2- to 3-week immersion experience (living in another country/culture) for those in the intervention group. A control group did not participate in an immersion experience, but both groups were tested at baseline and again after the intervention group returned from their immersion experiences. Those who had both the classes and the immersion experience showed statistically significant posttest scores on transcultural self-efficacy and change, leading them to recommend that all nursing students be encouraged to participate in "immersion experiences to enhance transcultural competence" (p. 1). By adding the variable of immersion experiences, a greater level of transcultural effectiveness was reached.

Quantitative research is helpful in identifying a problem or a relationship between two or more variables, such as type of treatment (e.g., cultural immersion experiences) and an outcome (e.g., greater levels of transcultural self-efficacy). In so doing, quantitative studies tend to examine isolated parts of problems or phenomena and do not generally pay attention to the larger context or overall health of individuals. Quantitative research involves a reductionist tendency (i.e., focusing on the parts rather than the whole) and, if used exclusively, can limit nursing knowledge, because many of the important aspects of client services (e.g., quality of life, grieving, spirituality) cannot be measured objectively.

A more subjective or qualitative approach is needed to study those areas that need a broader focus or those that do not lend themselves to objective measurement.

Qualitative research emphasizing subjectivity asks "how" or "why." An example of this research examined mentorship provided by PHNs working with pregnant and parenting teens (Schaffer & Mbibi, 2014). Rather than just counting visits, like the previous example with school nurse visits, the researchers interviewed both PHNs and teen clients about their perceptions. PHN themes included being nonjudgmental, working from clients' strengths, meeting them where they are, sticking with them, honoring clients as persons, giving information, making referrals, and facilitating decisions. PHNs found success in the relationship with clients if teens delivered healthy babies, stayed in school/found a job, and ensured child's safety and school readiness. For the pregnant and parenting adolescent clients, the identified themes included PHN is extremely trustworthy, is part of my support network, helps me build independence, and helps me with decisions. They envisioned success as finishing school and being able to provide for their child, along with being a good role model. This information is much richer because it is not elicited from a forced-choice questionnaire; it is prompted by open-ended questions and follow-up questions in an effort to discover feelings and beliefs.

It is not uncommon to find research studies in which both quantitative and qualitative approaches are used. When both types of data are collected and analyzed (and inferences are drawn from both), this is known as mixed methods research (Polit & Beck, 2012). A study examining the experiences and perceptions of nurses working with elderly stroke victims at adult daycare facilities (Park & Han, 2010) used both a questionnaire and a focus group to determine the importance of services provided (skilled nursing services, functional recovery, heath counseling, referral, and supporting personal care) and the nurses' work experiences. While the survey questionnaire elicited important information about perceptions of the importance of their work, the focus group allowed nurses to more specifically discuss challenges and concerns that would not have otherwise been revealed. Concerns about policies that promoted standardized, rather than individualized, care, along with role confusion owing to the nurse's work sometimes conflicting with the duties of social workers, and the need for better education for families to provide continuity of care outside the daycare facility were some of the themes noted by researchers. This mixed method study provides a broader picture of the gaps between identified areas of "key services" and the reality of issues that need to be resolved in order to facilitate better nursing

care and client outcomes (p. 267). Mixed methods are also helpful in program evaluation and can provide a more holistic vision (Polit & Beck, 2014).

Another method of analyzing research in community health uses a statistical procedure known as meta-analysis to evaluate the results of many similar quantitative research studies in an attempt to integrate the findings and combine the sample sizes of many small studies to obtain a single-effect measure or a summary statistic (Melnyk & Fibneout-Overholt, 2014). By combining the results of many similar studies, meta-analysis affords greater statistical power and can give the researcher a more complete general perspective, especially when research on a certain issue may seem inconclusive. An example of this type of nursing research can be found in the Cochrane Library. A meta-analysis done by Jianzhong, Ma, and Weihua (2014) sought to answer the review question, "What is the most useful strategy for communicating to consumers the effectiveness of contraceptives in preventing pregnancy?" and reviewed seven randomized controlled trials with over 4,500 female participants (p. 438). Four of the studies were from clinical sites and three from community settings. Outcome measures included knowledge of effectiveness, attitude about contraception, and choice or eventual use of a particular contraceptive method. In order for meta-analysis to be valid, studies chosen for analysis should be similar in design, participants, and methods. However, this was not the case in this study. Two trials gave participants multiple teaching sessions on contraceptives, and five trials only gave participants one session that included information on contraceptives, along with other things such as HIV. The seventh study had a control group and two intervention groups using different ways of analyzing contraceptive effectiveness. Because of the vast differences in methodologies and lack of consistent quality of the research studies, the researchers concluded that they were unable to answer their review question and determine the most useful strategy for teaching clients about contraceptive effectiveness in pregnancy prevention. They encouraged more studies and better reporting of interventions and evaluations.

UNDERSTANDING RESEARCH BASICS TO PROMOTE EBP

In order to fully integrate the principles of EBP, it is important to have a basic understanding of the research process. More in-depth information on this subject is available in nursing research texts (e.g., Polit & Beck, 2014), but a brief synopsis is provided here (see Display 4–3). EBP methods are encouraged over basic research, especially for practicing PHNs. Doctorally prepared nurses and public health professionals, in conjunction with practicing PHNs or health department staff, more often conduct traditional research studies. Problems recently identified and studied within community health nursing include the following:

DISPLAY 4.3 STEPS IN THE RESEARCH PROCESS

All effective research follows a series of predetermined, highly specific steps, building on the previous one and providing the foundation for the eventual discussion of research findings. It is important to understand basic research principles in order to effectively implement EBP.

1. Identify an area of interest.
2. Formulate a research question or statement.
3. Review the literature.
4. Select a conceptual model.
5. Choose a research design.
6. Obtain IRB or HSC approval.
7. Collect and analyze data.
8. Interpret results.
9. Communicate findings.

Identify an Area of Interest

- The problem of interest needs *specificity* (i.e., it must be specific enough to direct the formulation of a research question). For example, concern about child safety is too broad a problem; instead, the focus could be on a narrower subject, such as the use of child restraints and car seat availability and use in a

particular community.

- The problem must also be *feasible*. Feasibility concerns whether the area of interest can be examined, given available resources. For example, a statewide study of the needs of pregnant adolescents might not be practical if time or funding is limited, but a study of the same group in a given school district could be more easily accomplished.
- The *meaning* of the project and its *relevance* to nursing must also be considered, such as exploring the implications for nursing practice in the study of pregnant adolescents. The nurse's specialty influences the selection of a problem for study and also the particular perspective or approaches used. Community health nurses think in terms of the broader community; their research efforts are developed with the needs of the community or specific populations in mind.

Formulate a Research Question or Statement

- Just like the PICOT question in EBP, the research question or statement reflects the kind of information desired and provides a foundation for the remainder of the project. The manner in which the question or statement is phrased suggests the research design for the project. For example, the question "What are nurses' attitudes toward pregnant women who use methamphetamine?" determines that the design will be simple, nonexperimental, and exploratory (see later discussion). In contrast, the question "What is the effect of an educational program on nurses' attitudes toward drug-abusing pregnant women?" suggests an experiment that will evaluate changes in nurses' attitudes toward pregnant women who abuse drugs after receiving an educational intervention. The first research question suggests a broad, open-ended conversation with nurse participants, asking them to discuss their attitudes toward pregnant women who abuse drugs, such as methamphetamine. From the data obtained, general themes and patterns will emerge, leading the researcher to some overall conclusions. The second question examines the effects that an educational program may have on nurses' attitudes about pregnant women who abuse crack cocaine, for instance. This is most likely a quantitative, evaluative study that may involve pretesting to determine the nurses' attitudes, conducting one or more classes, and then posttesting to determine whether any change occurred in attitude or beliefs.
- Good examples of research questions addressed recently by community health nurses include:
    - What are the barriers to mask wearing for Influenza-type illnesses [*variable*] among urban Hispanic households [*population of interest*] (Ferng, Wong-McLoughlin, Barrett, Currie, & Larson, 2011)?
    - Are there intentions to reduce the risk of falling again [*variable*] among

older homebound women [*population of interest*] (Porter, Matsuda, & Lindbloom, 2010)?
    - What are the levels of psychological and physical abuse [*variables*] among pregnant women in a Medicaid-sponsored prenatal program [*population of interest*] (Raffo, Meghea, Zhu, & Roman, 2010)?

Review the Literature

- A traditional review of the literature consists of two phases. The first phase consists of a cursory examination of available publications related to the area of interest. Although several nursing research journals publish studies reflecting all areas of nursing practice, most specialty areas have dedicated journals. *Public Health Nursing, Family and Community Health, Journal of Community Health Nursing, American Journal of Public Health, Journal of School Health, Nursing and Health Sciences*, and *Journal of School Nursing* are some of the journals that publish studies of particular interest to community health nurses. In this phase, the investigator develops knowledge about the area of interest that is somewhat superficial but sufficient to make a decision about the value of pursuing a given topic.
- The second phase of the literature review involves an in-depth, critically evaluated search of all publications relevant to the topic of interest. The goal of this phase is to narrow the focus and increase depth of knowledge. Journal articles describing research conducted on the topic of interest provide the most important kind of information, followed by clinical opinion articles (information on the topic described by experts in the field) and books. Journal articles provide more up-to-date information than do books, and systematic investigations provide a foundation for other studies. Prior research that has already been done on the topic of interest provides a solid foundation for later replication studies.
- Criteria for compiling a good review of the literature include (a) using articles that closely relate to the topic of interest (relevancy); (b) using current articles that provide up-to-date and recent information, usually within the past 5 years (although earlier articles may be included based on their importance to the area of interest); and (c) using both primary and secondary sources. A *primary source* is a publication that appears in its original form. A *secondary source* is an article in which one author writes about another author's work; EBP systematic reviews fall into this category.
- The conclusions from the literature review become the basis for the new study's assumptions and methodology. Rather than making a "leap of knowledge," the hypothesis or research question must be created by basing assumptions on previous research studies.

Select a Conceptual Model

- In relation to research, a conceptual model is a framework of ideas for explaining and studying a phenomenon of interest. A conceptual model conveys a particular perception of the world; it organizes the researcher's thinking and provides structure and direction for research activities. Models are like a framework on which to "hang" concepts or variables, and they should be used to guide the design and methods for collecting research data.
- All fields of study identify their major areas of concerns or boundaries. Nursing, since the early work of Florence Nightingale, is concerned with the interaction between humans and the environment in relation to health (Blais & Hayes, 2015). Betty Neuman's Systems Model (Neuman & Fawcett, 2011) has often been used as an organizing framework for research studies in community health and acute care nursing, as well as curriculum design. Although nurse investigators frequently and successfully use conceptual models developed within other fields, the advantage of using nursing models is that they provide an understanding of the world in terms of nursing's major concerns (see Chapter 14).

Choose a Research Design

Complete descriptions of various research designs and specific methodologies are available in basic nursing research texts. For the purposes of this chapter, a few important considerations underlying design selection are described. First, quantitative approaches use two major categories of research design: experimental and nonexperimental (or descriptive).

- Experimental design requires that the investigators institute an intervention and then measure its consequences. Investigators hypothesize that a change will occur as a result of their intervention, and then they attempt to test whether their hypothesis was accurate. Experimental design requires investigators to randomly assign subjects to an experimental group (those receiving the intervention) and a control group (those not receiving the intervention). This process, called randomization, is the systematic sorting of research subjects, so that each one has an equal probability of selection.
- Another important distinction made within the experimental category of research is between true experiments and quasiexperiments. True experiments are characterized by instituting an intervention or change, assigning subjects to groups in a specific manner (randomization), and comparing the group of subjects who experience the manipulation to the control group (those not receiving the intervention). Randomized control trials (RCTs) are generally considered the gold standard of experimental research—they are commonly

used to determine the safety and efficacy of new medications or to test the effectiveness of one intervention over another, and they are a foundation of EBP (Melnyk & Fibneout-Overholt, 2014).

- Quasi-experiments lack one of these elements, such as the randomization of subjects. Community health nurses conduct quasi-experiments more often than true experiments because it is often difficult (and sometimes impossible) to use randomization. For instance, a nurse may conduct a nutrition education intervention with fifth grade students at a particular school. Although the nurse can have one classroom participate in the intervention and another remain the control group, he or she cannot randomly assign the children to classrooms (i.e., intervention or control). Therefore, this research would be characterized as quasi-experimental in nature.
- Nonexperimental designs (also called *descriptive designs*) are used in research to describe and explain phenomena or examine relationships among phenomena. Examples of this approach include examining the relationship between gender and smoking behaviors among adolescents, describing the emotional needs of families of clients with Alzheimer disease, and determining the attitudes of parents in a given community toward sex education in the schools. In each of these instances, the focus of the research is on the relationships observed or the description of what exists. Such nonexperimental designs are often the precursors of experiments.

Obtain Institutional Review Board Approval *(see p. 16)*

Collect and Analyze Data *(see p. 16)*

Interpret Results

The explanation of the findings of a study flows from the previously formulated research plan. The findings need to be a logical conclusion, based upon the building blocks of the literature review, conceptual framework, research question, and methodology (Polit & Beck, 2014). You can't jump to a conclusion for which you have not laid a foundation. Findings need to make sense, to be reasonable and logical.

Communicate Findings

- The findings of nursing research projects need to be shared with other nurses, regardless of the studies' outcomes. Negative as well as positive findings can make a valuable contribution to nursing knowledge and influence nursing practice. Whether or not the hypothesis was verified is not the most important part of research; it is equally important to know about results that are inconclusive or not statistically significant, because this information is also

necessary to build the science of nursing. For instance, in an early NFP (see beginning of this chapter) study by Eckenrode et al. (2000, 2001), researchers found that participants who received nurse home visitation during pregnancy and through the child's second birthday had significantly fewer child maltreatment reports with the mother as perpetrator or the study child as subject than did participants not receiving nurse home visitation. However, for mothers reporting more than 28 incidents of domestic violence, no significant reductions were noted. This is important information, because ongoing domestic violence may limit the effectiveness of these types of programs. A review of evidence on perinatal home visiting and intimate partner violence (Sharps, Campbell, Baty, Walker, & Bair-Merritt, 2008) concluded that those programs that add "specific intimate partner violence interventions" may be able to demonstrate reductions in violence along with improvements in infant and maternal health (p. 480). In future work, researchers need to elicit more information about domestic violence when trying to evaluate the effectiveness of this type of intervention.

- The research report should include the key elements of the research process. The research problem, methodology used, results of the study, and the investigators' conclusions and recommendations are presented. Whether investigators are presenting their findings verbally or writing for publication, they need to discuss the implications of their findings for nursing practice (Polit & Beck, 2014).

- Young women's reasons to seek sexually transmitted infection screening (Backonja, Royer, & Lauver, 2014)
- Perception of barriers to immunization among parents of Hmong origin (Baker, Dang, Ly, & Diaz, 2010)
- Revealing the voices of PHNs by exploring their lived experiences (Joyce, O'Brien, Belew-LaDue, Dorjee, & Smith, 2015)
- Development of a causal model for elder mistreatment (Pickering & Phillips, 2014)
- Implementation of a diabetes prevention program in public housing communities (Whittemore, Rosenberg, Gilmore, Withey, & Breault, 2014)
- An intervention study of the expectations and self-efficacy of African American parents who discuss sexuality with their adolescent sons (Weekes, Haas, & Gosselin, 2014)
- A rural African American faith community's solutions to depression disparities (Bryant, Haynes, Kim Yeary, Greer-Williams, & Hartwig, 2014)
- Factors associated with increased HPV vaccine use in rural-frontier U.S. states (Lai, Ding, Bodson, Warner, & Kepka, 2016)
- The impact of an urban home-based intervention program on child asthma outcomes (Sweet et al., 2014)

- Policy implications of hospital nurse staffing and public health emergency preparedness (McHugh, 2010)
- Socioeconomic factors affecting infant sleep-related deaths in St. Louis (Hogan, 2014)

Each of these problem areas provides direction for the formulation of related research questions. Clear research questions, thorough review of the literature, human subjects protection, and a sound research design are factors to consider when evaluating the results of studies for incorporation into your practice.

A research question is a starting point for both traditional research and EBP methods. While somewhat similar in purpose (to answer a question), there are fewer steps in the EBP process (see Display 4–1). Formulation of a PICOT question in EBP is a similar process to the research question outlined in the steps of the research process, especially in its specificity (see Display 4–2).

Although the EBP steps outlined by Melnyk and Fineout-Overholt (2014) end with evaluation and dissemination, it is generally recognized that the final steps in the research process also apply to EBP. Most EBP research requires human subjects' approval, and dissemination of findings is very important in order to advance the science of nursing and provide effective outcomes for our clients. These steps will be examined in more detail.

Obtain Institutional Review Board or Human Subjects Committee Approval

Whenever research is to be conducted that involves human subjects, prior approval must be gained from either an IRB or an HSC. This can be true for research studies or when measuring client outcomes elicited from EBP-implemented changes in nursing interventions (unless, perhaps, this is a QI effort that affects all clients equally and involves only one setting). The reason for this approval is to safeguard the rights of prospective study participants. Each health department should have a committee or a gatekeeper, such as the health officer, who understands the federal guidelines for protecting subjects involved in research studies.

The purpose of an IRB is to protect the rights of human subjects and ensure compliance with federal laws.

Sadly, one of the most egregious examples of exploitation of human subjects was a study carried out by the U.S. Public Health Service. The Tuskegee study, begun in 1932 and ended in 1972, sought to learn more about syphilis and to justify treatment services for blacks in Alabama (Centers for Disease Control and Prevention [CDC], 2013). The 399 men with syphilis who participated in the study had agreed to be examined and treated. However, they were misled about the exact purpose of the study and were not given all of the facts; therefore, they were unable to truly give informed consent. Even after penicillin

became the drug of choice for treatment of syphilis in 1947, the researchers failed to offer this treatment to the infected participants. Later, a nurse historian found evidence that research on syphilis was also funded by the Public Health Service and conducted in Guatemala. However, these participants were purposely infected with syphilis, causing even greater outrage and a formal apology from President Barack Obama to Guatemalan President Alvaro Colom (Reverby, 2011). Because of earlier Nazi atrocities, the Nuremberg Code and the Declaration of Helsinki were adopted by the world scientific community and then revised in 1975 as a means of ensuring ethical research practices; the President's Council on Bioethics was established in 2001 after President Clinton apologized on behalf of the nation to the Tuskegee participants and their families in 1997 (Blais & Hayes, 2015; CDC, 2013). See Evidence-Based Practice: Ethics in Action.

EVIDENCE-BASED PRACTICE

Ethics in Action

Today, safeguards are in place to ensure that studies are stopped when either potential harm or insufficient benefit are noted. In April 2011, a drug trial examining daily use of an antiretroviral medication as a means of pre–HIV exposure prophylaxis was found to be ineffective in preventing HIV infection. No difference in rates of infection was noted for women taking the medication and another group taking a placebo, even though an earlier drug study with men showed some promise in HIV prevention (AllAfrica, 2011). In an earlier drug trial, a major international study of a drug-conserving protocol for AIDS medication was stopped because those who were in the on-again, off-again group got sicker than those taking continuous medication therapy (Associated Press, 2006). More than 5,000 HIV patients in 33 countries participated in this study, which was halted by the National Institutes of Health. This large-scale study was initiated after several smaller studies had suggested a possible benefit from the on-and-off medication strategy. It was hoped that this strategy of only taking medications when immune cell levels dropped would not only cut costs, it would decrease medication side effects for patients. What researchers found was that this episodic strategy actually increased side effects related to the heart, liver, and kidney. Researchers say that the results are difficult to explain, but because of patient safety, it was best to stop the clinical trial.

Drug safety was also questioned in a study of Avandia, a drug used by some people with type 2 diabetes. In the summer of 2010, the Food and Drug Administration (FDA) ordered researchers to stop enrolling new participants in a trial of this drug because of heart risks and to notify the more than 1,300 participants already in the study of these risks (Wilson, 2010). In fall of 2010, they significantly restricted access to this drug, and in spring 2011, cardiovascular risk warnings were added to the label and the drug could only now be given to patients enrolled in a special FDA program (FDA, 2011).

What ethical principles are involved? Is there an ethical dilemma? Consider the rights of a few versus the rights of many. Apply Iserson's (1999) three tests (under heading Decision-Making Frameworks).

The following ethical principles are widely viewed as basic protections for research participants (U.S. Department of Health & Human Services [USDHHS], n.d.a). Freedom from harm or exploitation encompasses several aspects. First, no research can be done that may inflict permanent or serious harm. Second, the research study must be stopped if it becomes evident that harm may come to participants. Debriefing, or allowing participants to ask questions of the researcher at the conclusion of the study, as a means of protecting them from any unseen psychological harm, is also a component. There should be some

identified benefits from participation in the research study, and any costs or risks should be clearly outlined, so that participants can more easily determine the cost–benefit ratio (referred to as *full disclosure*). Subjects should also be told that they are able to withdraw from the study at any time without prejudice or penalty (known as *self-determination*). Consent forms should include full disclosure of the nature of the study, the time and commitment required of subjects, the researcher's contact information, and a pledge of confidentiality (or *assurance of privacy*).

Vulnerable subjects, as determined by federal guidelines, include children, mentally or emotionally disabled people, physically disabled people, institutionalized people (e.g., prisoners), pregnant women, and the terminally ill. Special care must be taken to ensure protection of vulnerable subjects. Once approval has been obtained from the proper entities, data collection can begin (USDHHS, n.d.b).

Collect and Analyze Data

The value of the data collected in any research study or EBP project depends largely on the care taken when measuring the concepts of concern, or variables. The specific tool used to measure the variables in a study, often a questionnaire or interview guide, is called an instrument. The accuracy of the instrument used and the appropriateness of the choice of instruments can clearly influence the results. For instance, Spielberger's State-Trait Anxiety Inventory is a well-researched questionnaire used in studying anxiety levels in adults. It has been shown to accurately measure state anxiety and the more stable tendency toward anxious personality—*trait anxiety*. Because of this evidence, one could infer that more accurate measurements of anxiety could be found using this instrument than a researcher-developed questionnaire that has never been tested for validity and reliability.

Validity and Reliability

Two tests are used to evaluate instrument accuracy: validity and reliability. Validity is the assurance that an instrument measures the variables it is supposed to measure. If a written questionnaire is being used in the study, the questions included would be evaluated to make certain that they are appropriate to the subject (content validity) and that the variable of interest is actually being measured (construct validity).

Reliability refers to how consistently an instrument measures a given research variable within a particular population. Test–retest reliability ensures that similar results are obtained using the same instrument with the same population at two separate testing times. If similar results are obtained on two separate occasions, the test can be considered reliable.

Statistical tests and measurements are often used to analyze subjects' responses to questionnaires to evaluate internal consistency. A questionnaire is internally consistent to the extent that all of its subparts measure the same characteristic. Cronbach's alpha (*a*) is often cited as a measure of internal consistency and is reported as a correlation coefficient, so that the closer the value is to +1.0, the greater the degree of internal consistency. Results higher than 0.7 are generally regarded as desirable.

Within the area of community health nursing research, instruments appropriate to the measurement of nursing concepts may not be available. Researchers may use questionnaires that have been designed and tested by other investigators, or they may begin the tedious task of developing their own. Both approaches to measuring the variables of interest are acceptable; however, using available instruments of known reliability and validity saves considerable time (Melnyk & Fibneout-Overholt, 2014).

Methods of Collecting Data

A variety of methods can be used to collect data, including self-report (subjects report their own experience verbally or in written form), observation (investigators observe subjects and document their observations), physiologic assessment (investigators use measures of

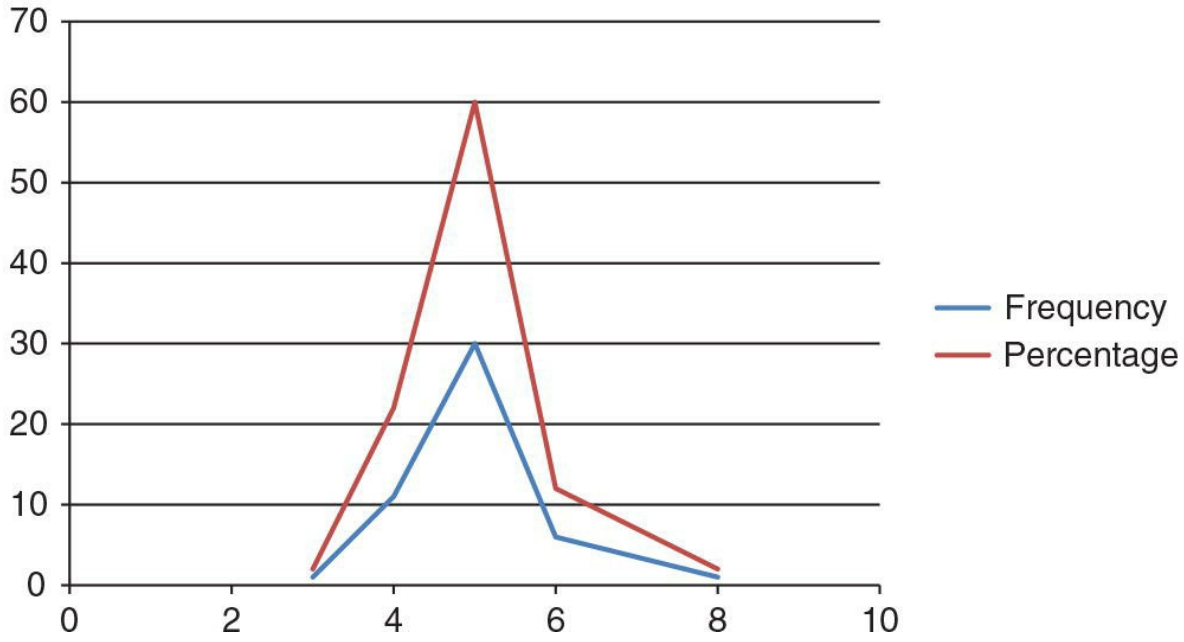
physical evidence, such as blood pressure or impaired mobility), and document analysis (investigators review and analyze written materials, such as health records). For example, using these four methods, investigators examining the stress level of the caregiver when a family member chooses to die at home might do the following:

1. Design or use an existing written questionnaire or interview schedule (self-report).
2. Outline a schema, such as a list of potential stress-induced behaviors, for observing caregivers as they function in the home (observation).
3. Measure various physiologic indicators of stress, such as hypertension, insomnia, or poor diet (physiologic assessment).
4. Ask caregivers to keep a diary of their activities and feelings for 2 weeks, and analyze the diaries for evidence of stress (document analysis).

In most instances, the nature of the data to be collected dictates the best method of collection. One or more methods may be appropriate, given the topic of concern. In the example mentioned, a combination of the first three methods would probably be appropriate, or the diary could be substituted for the questionnaire.

Surveys are common methods of collecting data. (Photo courtesy of CDC Public Health Image Library.)

Methods of Analyzing Data



Once collected, data must be analyzed so that a meaningful interpretation can be made.

Statistical procedures reduce great amounts of information to smaller chunks that can be easily interpreted. When deciding on an appropriate statistical procedure, it is helpful to consider the two major categories of statistical analysis: descriptive and inferential statistics.

Descriptive statistics portray the data collected in quantitative or mathematical terms. Commonly used descriptive statistical methods include calculating the average number (or *mean*) of a particular set of occurrences and calculating *standard deviations* (how much each score on the average deviates from the mean) and percentages. For example, an investigator analyzing data collected from 50 clients with chronic pain might find their mean pain score to be 4.96 (on a scale from 0 [no pain] to 10 [worst pain]), with a standard deviation of 0.83. These descriptive statistics suggest that clients are grouped around the middle of the pain scale and differ very little in the amount of pain they experience. The investigator may also report that more than 95% of the female clients experience pain rated between 4 and 6 on the 10-point pain scale. These descriptive statistics can be reported graphically (using graphs or charts) or in written form as shown in Table 4–1 for an example of both methods.

Table 4–1 Pain Ratings

Value	Frequency	Percent (%)
3.00	1	2.0
4.00	11	22.0
5.00	30	60.0
6.00	6	12.0
7.00	1	2.0
8.00	1	2.0
Mean 4.96	Standard deviation 0.83	

Inferential statistics involve making assumptions about features of a population based on observations of a sample. For example, the Gallup poll, which surveys a sample of the population to determine what opinion they hold on a particular topic (e.g., favorite presidential candidate), uses inferential statistics to estimate the proportion of the total population that favors a particular candidate (McKenzie, Neiger, & Thackeray, 2012). The potential for generalizability, the ability to apply the research results to other similar populations, has great value to health professionals. It allows researchers to test their hypotheses on smaller groups before instituting widespread changes in methods, programs, and even national health policies.

Inferential statistics are also used to test hypotheses in research; they provide information about the likelihood that an observed difference between two or more groups could have happened just by chance or might be the result of some intervention or manipulation. These statistical procedures provide a determination of the extent to which changes or differences between sets of data are attributable to chance fluctuations and estimate the confidence with which one can make generalizations about the data.

It is appropriate to use both descriptive and inferential statistics to analyze the data from a study. For example, in a study designed to examine the effects of prenatal education on the health status of pregnant women, investigators might use inferential statistics to find a significant difference in health status between the group who experienced the educational program (experimental group) and the group who did not (control group). The investigators might also use descriptive statistics to report the percentage of women from the experimental group who attended all classes and the means and standard deviations for the women's health status scores.

Interpret Results

The explanation of the findings of a study flows from the previously formulated research plan. The findings need to be a logical conclusion, based upon the building blocks of the literature review, conceptual framework, research question, and methodology (Polit & Beck, 2014). You can't jump to a conclusion for which you have not laid a foundation. Findings need to make sense, to be reasonable and logical. When findings support the directions developed in the research plan, their interpretation is relatively straightforward. For example, a group of community health nurse investigators might design a study to determine the effect of parenting classes on the self-esteem of single welfare mothers between 21 and 35 years of age. They could use Coopersmith's (1967) ideas on self-esteem as their conceptual model, hypothesize that self-esteem will improve as a result of the classes, and design an experiment to test their idea. If self-esteem does, in fact, increase, their finding flows logically from their framework.

If the findings do not support the hypothesis of the study, investigators question various aspects of the research to develop an explanation. In this instance, a number of questions could be posed. Coopersmith posited that self-esteem would relate to feelings of success in a given endeavor. Can that position be inaccurate? Could the parenting classes have been ineffective? Perhaps they did not enhance feelings of success. Could the intervention have been too weak to show a statistical difference (not enough sessions)? Were there problems with the methodology used? Were there too few subjects or intervening, confounding factors that affected the results? All of these questions and more should be considered in an attempt to explain the results.

If the study is descriptive in nature (i.e., one that was designed to describe particular characteristics of a population), the direction of the findings is not a concern. A detailed, accurate report of the results and their implications alone is appropriate. Given either an experimental or a descriptive design, the importance of accuracy cannot be overemphasized. Leaps of faith when reporting the results of a study are not appropriate unless labeled as such. For example, one could not conclude from the study on parenting classes that these classes develop expert parenting skills, given that parenting skills were not assessed.

A valuable contribution can be made to the advancement of nursing knowledge when investigators use their results to make suggestions for future research. The investigators' knowledge of a particular area and their experience in conducting a specific study give them an excellent background for identifying future research possibilities. As in EBP, results should be disseminated through publication, presentation, or other means.

IMPACT OF RESEARCH ON COMMUNITY HEALTH AND NURSING PRACTICE

Research has the potential to have a significant impact on community health nursing in three ways, by affecting public policy and the community's health, the effectiveness of community health nursing practice, and the status and influence of nursing as a profession. Community health nurses have been involved in research addressing all three of these dimensions.

Public Policy and Community Health

Research, with policy implications for addressing the health needs of aggregates, has been conducted on numerous topics. Many studies done by nurses and others have examined issues related to prevention, lifestyle change, quality of life, and health needs of specific at-risk populations (see Evidence-Based Practice: A Change of Position).

EVIDENCE-BASED PRACTICE

A Change of Position

A good number of mothers today place their infants in a supine position—on their backs—to sleep. However, for most of us writing this textbook, the opposite was true —we were placed as sleeping infants in the prone position, on their stomachs. For generations, mothers were told that babies would be at risk of aspiration if they were

put to sleep on their backs. Why did this change? In the late 1980s, research indicated that prone positioning of infants was related to greater incidences of SIDS, according to a group at the National Institute of Child Health and Human Development (NIH) who conducted an epidemiologic study examining SIDS risk factors (Hoffman, Damus, Hillman, & Krongrad, 1988). In the early 1990s, an expert panel from the same institute and the American Academy of Pediatrics concluded that infant sleeping positioning was an important factor in prevention of SIDS, and a recommendation was made for parents to place their infants on their backs when sleeping. The *Back to Sleep* campaign began in 1994 (National Institutes of Health, 2010). Since then, the incidence of SIDS has continued to drop steadily in the United States—from 130.3 deaths in 1990 to 39.7 deaths per 100,000 live births in 2013. Despite this decrease, there is still an ethnic difference in incidence with American Indians having a rate of 213.3 deaths compared to 53.8 deaths for Hispanics (CDC, 2015). More recent research has focused on an increased risk with parental use of alcohol (Phillips, Brewer, & Wadensweiler, 2010), possible deficits in serotonin and tryptophan hydroxylase causing increased risk for SIDS (Duncan et al., 2010), and an abnormality in the hippocampal area of the brain that helps control body temperature, heart rate, and breathing (Trachtenberg, Haas, & Krous, 2012). Current recommendations from the American Academy of Pediatrics (2011) include continuing the *Back to Sleep* campaign and advising parents to always:

- Place their sleeping infants in a supine position (not on side or stomach)
- Use a firm sleeping surface (no pillows or quilts under the baby)
- Keep soft objects (e.g., stuffed animals) and loose bedding (e.g., extra quilts, positioners/wedges, bumper pads, or loose bedding) out of baby's crib
- Not smoke during pregnancy and avoid baby's exposure to secondhand smoke
- Not share the bed with baby—put baby in a separate crib or bassinet with parents in the same room
- Offer a pacifier at sleep time throughout the 1st year of life (it has been shown to reduce the risk of SIDS)
- Avoid overheating (keep room temperature comfortable for lightly clothed adults—do not overbundle babies or cover their heads)
- Encourage "tummy time" to aid in development and reduce incidence of positional plagiocephaly (uneven, flat head)
- Avoid the use of apnea monitors (not shown to be effective) and other commercial devices marketed as effective in reducing SIDS cases (not sufficient proof of efficacy)

AAP also recommends that infants get all recommended vaccinations and that mothers breast-feed babies. Do your community health clients put their babies to sleep on their backs? If not, how can you convince them that it is beneficial?

Often, both quantitative and qualitative methods are useful when conducting health policy evaluation studies to determine whether existing health services are appropriate and accessible, as well as effective. Researchers at the University of California Los Angeles (UCLA) Center for Health Policy Research found that older adults in rural California had higher rates of obesity/overweight, food insecurity, and lower rates of physical activity than their urban or suburban counterparts (Durazo et al., 2011). Utilizing data from the California Health Interview Survey, they noted that these conditions are risk factors for diabetes, heart disease, and repeated falls. Barriers to transportation and health care access, along with financial constraints and social and physical isolation, make this a complex issue that should be addressed on local, state, and national levels. They recommended policies to improve access to healthy food and adequate numbers of health care providers, as well as access to Internet and transportation, as a means of addressing the disparities. PHNs can use this type of research to advocate for resources, apply for grant funding, and negotiate collaborative agreements.

The results of health policy studies can influence public policy, the quality of services, and, in turn, the public's health: This is the conclusion of a Robert Wood Johnson initiative targeting smoking behaviors (Giovino et al., 2009). Examining the history of this paradigm shift in the United States provides a powerful example of the use of research in changing health policies and promoting population health. This change began in a few states and has spread, to varying degrees, across all 50 states. As an example, several studies conducted by a researcher at the University of Miami led to further policy changes regarding cigarette smoking. One study examined the projected health benefits and cost savings of raising the legal age for smoking in the United States to 21 (Ahmad, 2005a). Using a computer simulation model, the researcher concluded that changing the policy would net total savings of $212 billion in the United States and reduce the prevalence of cigarette smoking substantially. A similar study, looking only at the state of California, found that raising the legal smoking age to 21 would yield an 82% drop in prevalence in teen smoking and would save $24 billion over 50 years' time (Ahmad, 2005b). Taxes are another disincentive for smokers. California raised excise taxes on cigarettes in 1999, but Ahmad (2005c) used another computer simulation to reveal that an additional "20% tax-induced cigarette price increase would reduce smoking prevalence from 17% to 11.6% … and reduce smoking-related medical costs by $188 billion" (p. 276). Raising cigarette taxes again would both decrease the number of smokers and increase the tax revenue that could be used to further reduce smoking in California. However, other effective methods of reducing cigarette smoking exist. Levy et al. (2005) noted that smoking prevalence declined between 1997 and 2003, and, although most of the change could be explained by price increases, researchers also found that clean air laws, widespread media campaigns, and more easily accessible smoking cessation interventions also played a part. They encouraged lawmakers to continue with tax increases and to strengthen clean air laws that ban smoking in public places. In a Minnesota study, smoke-free workplaces were found to be more effective than free nicotine replacement therapy (Ong & Glantz, 2005). Other researchers have found that antismoking advertising focusing on the addictive nature of cigarettes and

the dangers of environmental tobacco smoke to children increased the chances of quitting among adult smokers who have children living in their homes (Netermeyer, Andrews, & Burton, 2005). Consistent and wide-ranging antismoking media campaigns that emphasize social unacceptability and easier access to smoking cessation classes were also emphasized to policy makers (Alamar & Glantz, 2006). A study by nursing researchers found that culturally specific smoking cessation outreach approaches were helpful in motivating rural smokers living in the southeastern United States (Butler et al., 2014).

Another group of nursing researchers examined the use of smokeless tobacco, both alone and in conjunction with cigarette use among blue-collar workers in a national survey of drug use and health (Noonan & Duffy, 2014). Almost 10% of survey respondents currently used smokeless tobacco, and just over 5% of them used it exclusively. The remainder used both forms of tobacco. They examined the factors that were also related to sole use of smokeless tobacco and found that current reported binge drinking, use of marijuana, marital status, age, gender, and race/ethnicity were common, along with type of blue-collar job. For those who used both smokeless tobacco and cigarettes, similar factors were also discovered, but illicit drug use and cigar smoking, rather than use of marijuana, were discovered. Workplace cessation programs were recommended for this population.

Community Health Nursing Practice

A primary purpose for conducting community health research is to gain new knowledge that will improve health services and promote the public's health. Consequently, most nursing research has implications for nursing practice. Many studies focus on a specific health need or at-risk population and then suggest nursing actions to be taken based on study findings. An example is a study examining HIV health education strategies and community outreach to rural Hispanic populations living along the U.S.–Mexico border. Hernandez, Mata, Provencio Vasquez, and Martinez (2014) assessed needs of rural health clinics for linguistically and culturally suitable health education materials. The goal was to integrate education, screening, and referral during routine clinic appointments in order to better address HIV and sexually transmitted infections in this vulnerable and often underserved population. Researchers felt that this addressed health equity and translated local research findings that would improve services and practice. DeGuzman and Kulbok (2012) offer a framework for nurses interested in studying the built population and its impact on vulnerable populations. The framework added to Florence Nightingale's original work on environment and health, and adapted frameworks dealing with social determinants of health and environmental health promotion to better fit with public health nursing research. They encouraged PHNs to conduct research in this area to "gain valuable insight into the pathways linking built environment to health of vulnerable populations" (p. 341), as more evidence is necessary to advocate for policy changes and improve the health of populations. Individual-level measures are not thought to be as effective as population-based approaches in improving the health of a nation (Abbot, 2015). Other issues that can be individual or population-based include obesity, physical activity, vaccinations, and communicable diseases.

Nursing's Professional Status and Influence

The third way in which research has a significant impact on community health nursing is in its potential to enhance nursing's status and influence. As community health nursing research sheds light on the critical health needs of at-risk populations, exposes deficiencies in the health care system, demonstrates more efficient and cost-effective methods for delivering services, and documents the effectiveness of nursing interventions, the profession will gain a stronger voice and have a greater impact on health policy and programs. After all, PHNs have always been advocates for their clients and promoted policies that improved health.

A recent example of CBPR assessed tribal youth physical activity and programming among an American Indian tribe of 1,000 people (Perry & Hoffman, 2010). Community-based participatory research (CBPR) is defined as research done in communities in which those persons affected by the condition or issue of interest and other key community stakeholders have an opportunity to participate fully in each phase of the research study—from conception to design and during execution, analysis, and interpretation, as well as formulation of conclusions and communication of results, they actively and equally share in decision-making power (Kulbok, Thatcher, Park, & Meszaros, 2012; NIH, n.d.; Perry & Hoffman, 2010). These community health nurse researchers recognized the inherent mistrust of university researchers among tribal communities and spent considerable time establishing relationships and discussing ideas with tribal members. Because this research involved children and adolescents, they engaged the Tribal Youth Council, as well as the adult Tribal Council, and established a Community Advisory Board to help them design their study. This board met an average of twice monthly for 8 months. They produced a data-sharing agreement that specified the type of data and how it would be collected, along with how to protect confidentiality of the data and who would have access to the data (Perry & Hoffman, 2010). They also collaborated on development of a questionnaire to collect information on favorite and least favorite exercise, motivators and barriers to exercise, and some demographic questions. They also designed two focus groups (one with 8- to 11-year-olds and another with 15- to 18-year-olds) to determine types and amounts of daily physical activity, as well as preferences and ideas to promote physical activity among the youth. The goal of the research project was to determine tribal youths' current patterns of behavior patterns, beliefs, and preferences related to physical activity. Results showed that youth "differentiated exercise and sports" and had different barriers and motivators for each (p. 111). They saw exercise as "work" that could improve mood and health and stabilize their weight, along with improving strength and conditioning. None of the tribal youth met the national recommendations for physical activity (60 minutes of moderate to vigorous physical activity daily), and they were less active, on average, than youth in national studies. They reported spending 50% of their day in "sedentary activities" (p. 111) and cited motivators for physical activity to be coaches, friends, team, and school. Barriers were deemed to be lack of time, lack of programs, and school and/or work. The

results were presented to the tribe, and much discussion ensued. The tribe began boys' and girls' basketball groups and planned for additional baseball and wrestling teams. They are exploring other alternatives to promote physical activity (e.g., family days to teach traditional games, building walking trails) and felt that they had ownership of this research and their destiny. The researchers respected "tribal knowledge, traditions, and beliefs"—a theme of CBPR and of public health nursing—while helping to provide effective solutions to potential health problems.

Strong documentation supports the effectiveness of community health nursing interventions. Nurses in the community setting must provide empirical proof of their worth as professionals while serving the needs of their clients. This kind of information must be made visible if it is to influence legislators, planners, administrators, and other decision-makers in health care (Hinshaw & Grady, 2011). As visibility increases, nursing's status and influence will increase.

THE COMMUNITY HEALTH NURSE'S ROLE IN RESEARCH

Community health nursing has a focus on health promotion and disease prevention and providing services across the lifespan where people live, work, and learn. PHNs also focus on the development of community capacity building for health, and work with partnerships, coalitions, and policy makers to promote a healthier environment. Community health nurses have two important responsibilities with respect to research in community health: to apply research findings to practice (EBP) and to conduct or participate in nursing research. Because research results provide essential information for improving health policy and the delivery of health services, community health nurses must be knowledgeable consumers of research. That is, they need to be able to critically examine research reports and apply study findings to improve the public's health.

Community health nurses have many opportunities to apply the results of other investigators' research and systematic reviews, but a necessary prerequisite is to be informed about research findings. As an essential part of their role, community health nurses must read the journals focusing on public health and community health nursing. Subscribing to some of these journals enables nurses to make a regular review of research an ongoing part of their professional practice. Nursing agencies and employment sites in community health can encourage nurses to become more knowledgeable about research findings by subscribing to journals and circulating them among staff, by holding seminars to discuss recent research results, and by promoting nurses' application of research findings in their practice.

Although the amount of health nursing research is expanding, and its quality is improving, many more community health nurses need to conduct research and participate in EBP. An increasing number of nurses have developed skill in research through advanced preparation, and they are conducting investigations related to aggregate health needs. Other community health nurses work collaboratively with trained investigators on a variety of research projects affecting community health. Whether initiated by the nurse or involving the nurse as a team member, these projects are an opportunity to influence the types of research questions that are addressed and the ways in which the research is carried out, factors that ultimately affect the community's health (Kulbok et al., 2012).

VALUES AND ETHICS IN COMMUNITY HEALTH NURSING

Whereas the research process leads to EBP and expands nursing theory, there are other ways to develop knowledge in nursing. According to the classic treatise by Carper (1978), there is an art to nursing, which comes from our aesthetic sensibilities. Our personal history and experiences inform our practice, as well as our values and beliefs about what it means to be a good nurse. These values and beliefs support your own decisions about the right course of action to take, how to be just and fair in dealing with others, and what outcomes you deem to be right. Every profession has ethical codes that guide decision-making and provide a framework for thinking about practice issues that have a moral dimension. In this chapter, we consider the philosophical background for nursing ethics and discuss some of the recent issues that you may encounter in your community health nursing experiences that will stimulate your thinking about how you define your own philosophy of nursing.

For well over a decade, nurses have ranked highest in a Gallup poll for perceived honesty and ethical standards, beating out the clergy, physicians, and police officers (Gallup, 2016). Clearly, the public has a favorable impression of nursing as a profession that can be trusted. Nursing has had an ethical code for practice since 1910, when Gettner published "The Nightingale Pledge." This evolved into the current "Code of Ethics for Nurses," as the American Nurses Association (ANA) has updated the code to reflect current issues and ideologies. The latest revision was approved in 2015.

The Code of Ethics for Nurses is based on respect for persons. Respect for the dignity and value of each individual encompasses not only our patients but also our colleagues, our workplaces, and society at large. It also includes a mandate to respect the values and beliefs of each individual nurse. Because our personal experiences, our education, and our cultural and social values shape our beliefs, we have an obligation to think about those values that shape our practice. Having a greater awareness of our personal beliefs is a process called values clarification. This is an essential first step in a discussion of ethics, so that we have established moral beliefs, against which ethical dilemmas can be evaluated. As EBP is the result of the rigorous application of scientific method, our philosophy of nursing is based on clarity about our ethical code of practice, and a logical system for moral reasoning so that we are able to practice with integrity and within the context of social justice (ANA, 2015).

For the nurse in community health, the focus is on providing care for populations within our community of concern. This is a potential source for ethical conflict, when the needs of the individual must be evaluated in light of the needs of the larger group. There are social, political, and economic issues that must be separated out from the ethical concerns (ANA, 2010). Consider the following situations:

- Imagine, for example, that you are providing health care to a population of migrant

farm workers whose housing lacks adequate toilets, bathing facilities, heating, and equipment for cooking and refrigerating food. You recognize that this is a valid health and safety issue. However, when you report the situation to your supervisor, you are told to ignore the conditions because the wineries that employ the workers contribute heavily to a high-profile clinic for all low-income children in your area. What would you do?

- What if you were working in a homeless shelter and were told to evict someone who would not agree to take a tuberculin skin test? You agree that residents should comply with this demand, but would you hesitate to implement the eviction if the resident were elderly or the teenage mother of a newborn?

CODE OF ETHICS FOR NURSES—PROVISIONS, APPROVED AS OF JANUARY 6, 2015

The nurse, in all professional relationships, practices with compassion and respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of their health problems.

1. The nurse respects the unique attributes of every person, practices with compassion and respect for each person's self-worth and dignity.
2. "The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population" (p. v).
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse is responsible and accountable for individual nursing practice and determines actions consistent with the nurse's obligation to provide optimum patient care, with a focus on health promotion.
5. The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to "maintain competence, and to continue personal and professional growth" (p. v).
6. The nurse is a key member of the team in maintaining and improving ethical environments for both patient care and the work of nursing in the provision of safe and quality care.
7. The nurse plays a leadership role in advancement of the profession through contributions to practice, education, administration, and knowledge

development and most importantly the development of health policy and nursing policy.

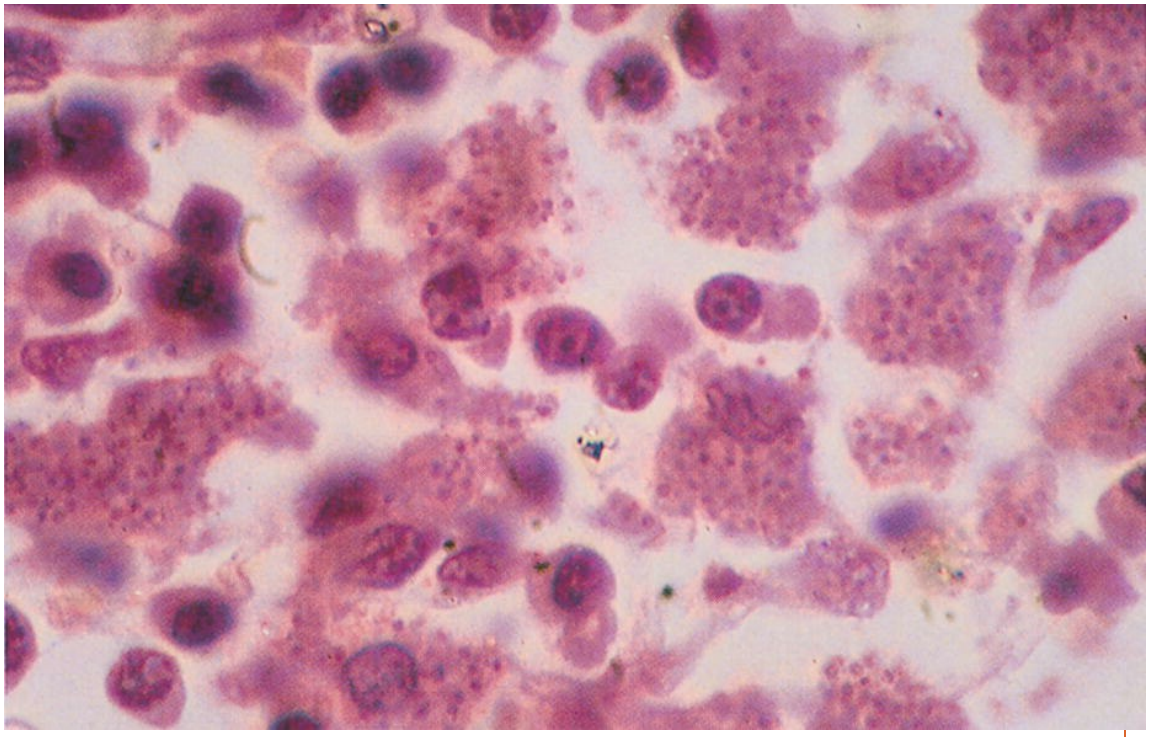
8. The nurse works together with "other health professionals and the public" to protect and promote human rights and diminish health disparity and improve health diplomacy in the community and globally (p. v).
9. The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values, for maintaining the reliability and integrity of the nursing profession and its practice, and for shaping social policy.

Adapted from American Nurses Association (ANA). (2015). Code of ethics for nurses with interpretive statements. Silver Spring, MD: Author.

Within the United States, many marginalized people are failed by the public health care system or may go without any health care at all. At the same time, affluent individuals enjoy a plethora of health care options, including preventive screenings and health promotion classes. For instance, seven surgical operations are the average for an American over their lifetime, and each year, approximately 5 million people will be admitted to an ICU in this country (Gawande, 2010; 2012). Community health nurses often are confronted by this disparity when making ethical decisions about client care. Social justice, human rights, and equality are hallmarks of public health nursing ethics (see more in Chapters 13, 25, and 29).

In addition to these dilemmas, progress in the United States often is linked to the exploitation of people in less-developed countries, and this contributes to widening disparities in health, wealth, and human rights. Distributive justice, or the fair allocation of goods and services, comes into play (discussed later in this chapter and in Chapter 29). Failure to respond to such global challenges only leads to greater poverty and deprivation, continuing conflict, escalating migration, and the spread of infectious disease, all further adding to our ethical dilemmas.

Advances in technology also contribute to ethical dilemmas. For example, electronic health records make client information readily accessible, thus raising issues of confidentiality, clients' rights, issues of empowerment, and informed consent (Vezyridis & Timmons, 2015). Sensitive information is now frequently stored electronically and may be accessed through unethical means (Widup, Bassett, Hylender, Rudis, & Spitler, 2015). Technology also forces nurses to confront the issues of genetic testing and stem cell research, as well as assisted suicide and euthanasia (Katz, 2015). Further ethical questions arise regarding organ, tissue, and limb transplants and the decisions about who is to receive them, as well as what happens to tissues removed during biopsy or surgery (Ertin, Harmanci, Mahmutoglu, & Basagaoglu, 2010). See Display 4–4. Ethical issues in nursing practice have been described as a "moving picture," with challenges, values, and obligations continually being questioned (Izumi, Nagae, Sakurai, & Inamura, 2012).



Underlying every issue and influencing every ethical and professional decision are

values. Ethics and values are inextricably intertwined in professional decision-making, because values are the criteria by which decisions are made.

DISPLAY 4.4 IMMORTAL CELLS, ETHICAL DILEMMA

How would you feel if tissues or cells taken from you during surgery or a routine biopsy were subsequently used in health research without your knowledge or permission (or remuneration)? That happened to Henrietta Lacks, a black woman from Baltimore, whose cells (known as HeLa cells) were the first immortal human cells and used in the development of the field of virology. HeLa cells were tested in the first space missions to determine zero gravity's effects and were vital to the development polio and hepatitis B vaccines, as well as chemotherapy, in vitro fertilization, cloning, and gene mapping (Skloot, 2011). These cells, taken from a biopsy of her cervix a few months before she died of cervical cancer in 1951, were useful in the development of medications for leukemia, herpes, hemophilia, and influenza. They have been used in innumerable studies around the world, to test the effects of massive radiation (e.g., nuclear blasts), hormones, vitamins, steroids, TB, salmonella, and hemorrhagic fever. HeLa cells were also instrumental in many historic scientific discoveries (e.g., cigarettes caused lung cancer, how cancer cells grew differently from normal cells, how HIV infected cells) and continue to be used today in scientific research. Although this happened in the 1950s, today, it is still often considered legal for a researcher to use tissues removed from your body for scientific research without your consent. It has been considered by law to be "abandoned waste" and may be used for gain without the knowledge, consent, or reimbursement to the donor.

From Skloot, R. (2011). The immortal life of Henrietta Lacks. New York, NY: Random House/Broadway Books.

VALUES

What are values? A value is something that is perceived as desirable or a personally held abstract belief about the worth and truth associated with behaviors, thoughts, or objects (Guido, 2013). A value motivates people to behave in certain ways that are personally or socially preferable. Values are usually derived from societal norms, as well as from family and/or religious beliefs. We develop our value system as a result of our experiences with others (e.g., family, peers, schools, churches, jobs). As seen in Chapter 5, a group's culture often is defined by its members' common or shared values.

STANDARDS FOR BEHAVIOR

In general, values function as standards that guide actions and behavior in daily situations or act as a code of conduct for living one's life. Once internalized by an individual, a value, such as honesty, becomes a criterion for that individual's personal conduct. Values may function as criteria for developing and maintaining attitudes toward objects and situations or for justifying a person's own actions and attitudes. Values also may be the standard by which people pass moral judgments on themselves and others (Guido, 2013).

Values have a long-term function in giving expression to human needs. Values motivate people in their work setting, in their personal lives, and in dealing with their health, as well as with the larger society. In addition, values are used as standards to guide presentation of the self to others, to ascertain personal morality and competency, and to persuade and influence others by indicating which beliefs, attitudes, and actions of others are worth trying to reinforce or change. As a practitioner, values act as a compass to direct the nurse when working with clients.

QUALITIES OF VALUES

The nature of values can be described according to five qualities: endurance, hierarchical arrangement, prescriptive–proscriptive belief, reference, and preference.

Endurance

Values remain relatively stable over time, persisting to provide continuity to personal and social existence. Enduring religious beliefs, for example, offer stability to many people. This is not to say that values are completely stable over time; values do change throughout a person's life. Certainly, the values of children are different from adults. Moral development generally follows a prescribed path, according to Lawrence Kohlberg (Colby & Kohlberg, 1987) and Carol Gilligan (1982), researchers studying changes in moral behavior and judgment from childhood to adulthood. Yet social existence in the community requires standards within the individual as well as an agreement about standards among groups of individuals (Pereira, 2015). As Kluckhohn (1951, p. 400) once pointed out, without values, "the functioning of the social system could not continue to achieve group goals; individuals … could not feel within themselves a requisite measure of order and unified purpose." A group's culture provides such a set of enduring values. By adding an element of collective purpose in social life, values most often guarantee endurance and stability in social existence.

Hierarchical System

Isolated values usually are organized into a hierarchical system in which certain values have more weight or importance than others. For instance, in a team sport such as baseball, values regarding individual performance, batting and running records, speed, and throwing and catching all fall into a hierarchy, with the values of team and winning being at the top. As an individual confronts social situations throughout life, isolated values learned in early childhood come into competition with other values, requiring a weighing of one value against another. Concern for others' welfare, for instance, competes with self-interest. Through experience and maturation, the individual integrates values learned in different contexts into systems in which each value is ordered relative to other values (Harris, 2011; Iacobucci, Daly Luindell, & Griffin, 2012).

Prescriptive–Proscriptive Beliefs

Rokeach (1973) described values as a subcategory of beliefs. He argues that some beliefs are *descriptive* or capable of being true or false (e.g., the chair on which I am sitting will hold me up). Other beliefs are *evaluative*, involving judgments of good and bad (e.g., that was an excellent lecture). Still other beliefs are *prescriptive–proscriptive*, determining whether an action is desirable or undesirable (e.g., this music is too loud, those baseball fans shouldn't yell when the pitcher is winding up). Values, Rokeach says, are prescriptive–proscriptive beliefs. They are concerned with desirable behavior or "what ought to be." For example, parents' values about child behavior determine how they choose to discipline their children, using corporal punishment, a time-out, or a laissez-faire attitude where behavior is largely ignored. Some parents believe that their 2-year-old child has the capacity to control his bladder, and when the child wets his pants, he is being "rebellious" and should be punished. Values have cognitive, affective, and behavioral components. According to Rokeach, to have a value, it is important to know the correct way to behave or the correct end state for which to strive (cognitive component); to feel emotional about it—to be affectively for or against it (affective component); and to take action based on it (behavioral component). More recent research has further delineated moral regulation within the framework of avoidance versus approach motivation (Else-Quest, Higgins, Allison, & Morton, 2012; Sheikh & Janoff-Bulman, 2010). For example if you used duty as a basis for action, these would be proscriptive moral emotions. Duty is a consequential emotion, where you would think about concrete negative consequences to an action. For example, what would happen if you did not study well for an exam in nursing school? Prescriptive moral emotions might focus more abstractly and in a positive manner on what ought to be done; these might inspire you to study so that you can be a "crackerjack" nurse at the bedside. Think about which beliefs or values (prescriptive/proscriptive) inspire you to do well in nursing school (Cornwall & Higgins, 2015).

Reference

Values also have a reference quality. That is, they may refer to end states of existence called terminal values, such as spiritual salvation, peace of mind, or world peace, or they may refer to modes of conduct called instrumental values, such as confidentiality, keeping promises, and honesty. The latter can have a moral focus or a nonmoral focus, and these values may conflict (Husted, Scotto, Husted, & Wolf, 2015).

For example, a nurse may experience a conflict between two moral values, such as whether to act honestly (tell a client about a fatal diagnosis) or to act respectfully (honor the family's request not to tell the client). Similarly, the nurse may experience conflict between two nonmoral values, such as whether to plan logically (design a traditional group intervention for mental health clients) or to plan creatively (design an innovative field experience). The nurse also may experience conflict between a nonmoral value and a moral value, such as whether to act efficiently or to act fairly when establishing priorities for funding among community health programs. Ethical reasoning in nursing develops over time, as novice nurses are exposed to various situations. Students and novice nurses struggle to apply ethics, even when exposed to theoretical underpinnings. Although nurses may inherently have great moral courage, its use is limited because of lack of confidence in ethical decision-making in practice (Iacobucci et al., 2012; Laabs, 2012; Murray, 2010).

Adults generally possess only a few—perhaps no more than 20—terminal values, such as peace of mind or achievement. These are influenced by complex physiologic and social factors. The needs for security, love, self-esteem, and self-actualization, proposed by Maslow (1969), are believed to be the greatest influences on terminal values. Although an individual may have only a few terminal values, the same person may possess as many as 50 to 75 instrumental values. Any single instrumental value, or several instrumental values combined, also may help to determine terminal values. For example, the instrumental values of acceptance, taking it easy, living 1 day at a time, and not being concerned about the future can shape the terminal value of peace of mind, whereas the instrumental values of hard work, driving oneself to compete, and not letting anyone get in the way can influence the terminal value of achievement. Figure 4–2 illustrates the influence of instrumental values and human needs on the development of terminal values.

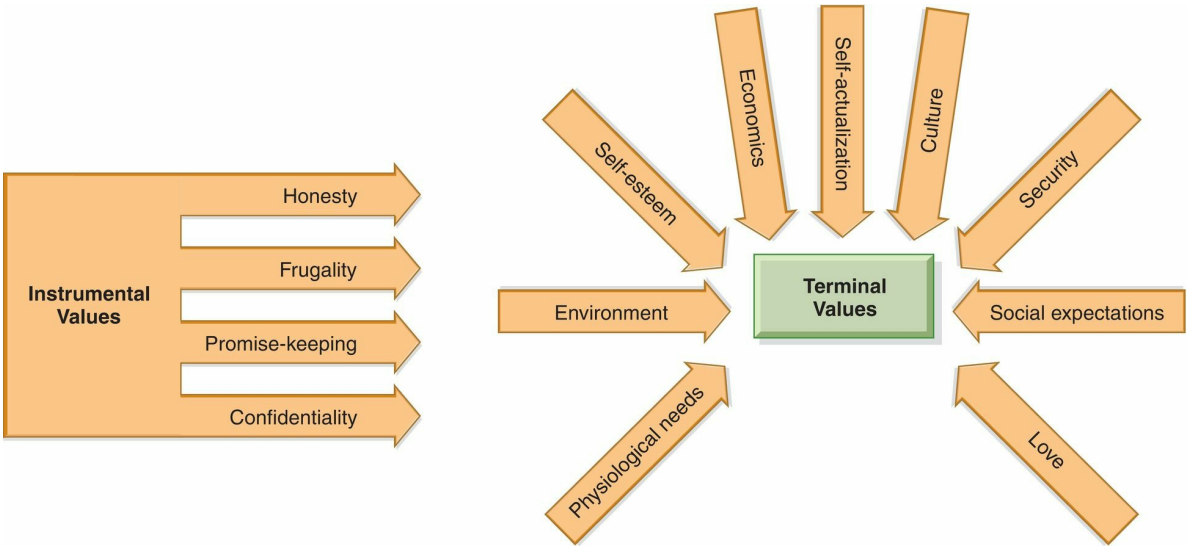


Figure 4–2 Factors influencing terminal values.

Preference

A value may show preference for one mode of behavior over another, such as exercise over inactivity, or it may show a preference for one end state over another, such as physical fitness and leanness over sedentary lifestyle and obesity. The preferred end state, or mode of behavior, is located higher in the personal value hierarchy.

VALUE SYSTEMS

Value systems generally are considered organizations of beliefs that are of relative importance in guiding individual behavior (Harris, 2011; Rokeach, 1973; Weiner, McConnell, Latella, & Ludi, 2013). Instead of being guided by single or isolated values, however, behavior at any point in time (or over a period of time) is influenced by multiple or changing clusters of values. Therefore, it is important to understand how values are integrated into a person's total belief system, how values assume a place in a hierarchy of values, and how this hierarchical system changes over time.

Hierarchical System of Values

Learned values are integrated into an organized system of values, and each value has an ordered priority with respect to other values (Harris, 2011; Rokeach, 1973; Wiener et al., 2013). For example, a person may place a higher value on physical comfort than on exercising. This system of ordered priority is stable enough to reflect the continuity of someone's personality and behavior within culture and society, yet it is sufficiently flexible to allow a reordering of value priorities in response to changes in the environment or social setting (e.g., society's emphasis on physical fitness and youth) or changes based on personal experiences (e.g., diagnosis of type 2 diabetes). Behavioral change would be regarded as the visible response to a reordering of values within an individual's hierarchical value system.

Conflict Between Values in a System

Nurses often enter patient and community situations that activate several values in their system of beliefs. Because not all of the activated values are compatible with one another, conflict between values occurs. This conflict between values is a part of the decision-making process, and resolving these value conflicts is crucial to making good decisions. Community health nurses face such conflicts of values when caring for patients whose determinants of health create a situation where we must decide how to use of scarce resources for care (Blacksher, 2015). This can be a struggle when patients want the freedom to choose how to live their life but don't want to suffer either. One example is how the smoker with COPD wants home health visits but refuses to quit smoking. Even within a single community agency, nurses may find that they prioritize client service or programming values differently.

Some values seem to consistently triumph over others, persisting as stronger directives for individual behavior; an example is the value placed on high achievement in the United States. Providing quality health care for all without sacrificing the basic rights of a few is an ongoing ethical struggle for most people (Sorrell, 2012). Other values lose their positions of importance in a value hierarchy (e.g., resuscitation of all hospital patients vs. Do Not Resuscitate orders) (Fagerlin et al., 2013). It is this changing arrangement of values in a hierarchical system that determines, in part, how conflicts are resolved and how decisions are made. In this way, people's value systems function as a learned organization of principles and rules that help them to choose among alternative courses of action to reach decisions.

VALUES CLARIFICATION

One way to understand the influence and prioritize values in your own behavior, as well as in that of community health clients, is to use various values clarification techniques in decision-making. Values clarification is a process that helps to identify the personal and professional values that guide your actions, by prompting you to examine what you believe about the worth, truth, or beauty of any object, thought, or behavior and where this belief ranks compared with your other values. Because individuals are largely unaware of the motives underlying their choices, values clarification is important for understanding and shaping the kind of decisions people make. Only by understanding your values and their hierarchy can you ascertain whether your choices are the result of rational thinking or of external influences, such as cultural or social conditioning. Values clarification by itself does not yield a set of rules for future decision-making and does not indicate the rightness or wrongness of alternative actions. It does, however, help to guarantee that any course of action chosen by people is consistent and in accordance with their beliefs and values (Abhyankar, Bekker, Summers, & Velikova, 2011).

Process of Valuing

Before values clarification can take place, it must be understood how the process of valuing occurs in individuals. In 1977, Uustal listed the following seven steps, which remain useful today:

1. Choose the value freely and individually.
2. Choose the value from among alternatives.
3. Carefully consider the consequences of the choice.
4. Cherish or prize the value—feel good about the choice.
5. Publicly affirm the chosen value.
6. Incorporate the value into behavior, so that it becomes a standard or a pattern of behavior.
7. Consciously use the value in decision-making.

These steps provide specific actions for the discovery and identification of people's values. They also assist the decision-making process by explicating the process of valuing itself. For example, some people may choose to value honesty in a presidential candidate. They may choose this over other values, such as knowledge of foreign affairs or public speaking ability, because, when considering the consequences, they want a leader who will deliver on promises made and who will continue to be the person represented to the public during the campaign. They prize this value of honesty, affirm it publicly, and consciously use it as a standard when deciding on whom to vote into office or to reject.

Values Clarification Strategies

In 1978, Uustal offered several values clarification strategies that are ultimately useful to the decision-making process in community health nursing practice today. Strategy 1 is a way for nurses to come to know themselves and their values better (Fig. 4–3). Strategy 2 assists in discovering value patterns and the priority of values within personal value systems (Fig. 4–4). Strategy 3 can be used to examine personal responses to selected issues in nursing practice. Each response helps to establish priorities of values by asking the nurse to choose among the alternatives presented or to indicate degree of agreement or disagreement (Fig. 4–5). Other values clarification strategies are included in the critical thinking activities at the end of this chapter to assist in understanding personal ordering of values and when considering directions for change. These strategies also help the nurse to assist community health clients to become clearer about their own values.

Name Tag

Take a piece of paper and write your name in the middle of it. In each of the four corners, write your responses to these four questions:

1. What two things would you like your colleagues to say about you?
2. What single most important thing do you do (or would you like to do) to make your nurse–client relationships positive ones?
3. What do you do on a daily basis that indicates you value your health?
4. What are the three values you believe in most strongly?

In the space around your name, write at least six adjectives that you feel best describe who you are.

Take a closer look at your responses to the questions and to the ways in which you described yourself. What values are reflected in your answers?

Figure 4–3 Values clarification strategy 1.

Patterns

Which of the following words describe you? Draw a circle around the seven words that best describe you as an individual. Underline the seven words that most accurately describe you as a professional person. (You may circle and underline the same word.)

ambitious reserved assertive opinionated
concerned generous independent
easily hurt outgoing reliable indifferent
capable self-controlled fun-loving
suspicious solitary likable dependent
intellectual argumentative dynamic unpredictable
compromising thoughtful affectionate obedient
logical imaginative self-disciplined
moody easily led helpful slow to relate

Reflect on the following questions:

1. What values are reflected in the patterns you have chosen?
2. What is the relationship between these patterns and your personal values?
3. What patterns indicate inconsistencies in attitudes or behavior?
4. What patterns do you think a nurse should cultivate?

Figure 4–4 Values clarification strategy 2.

Forced Choice Ranking

How do you order the following alternatives by priority? (There is no correct set of priorities.) What values emerge in response to each question?

1. With whom on a nursing team would you become most angry? The nurse who
   _____ never completes assignments.
   _____ rarely helps other team members.
   _____ projects his or her feelings on clients.

2. If you had a serious health problem, you would rather
   _____ not be told.
   _____ be told directly.
   _____ find out by accident.

3. You are made happiest in your work when you use
   _____ your technical skills in caring for adults with complex needs.
   _____ your ability to compile data and arrive at a nursing diagnosis.
   _____ your ability to communicate easily and skillfully with clients.

4. It would be most difficult for you to
   _____ listen to and counsel a dying person.
   _____ advise a pregnant adolescent.
   _____ handle a situation of obvious child abuse.

Figure 4–5 Values clarification strategy 3.

All of these strategies can be used to analyze and understand how values are meaningful to people and ultimately influence their choices and behavior. Clarification of a person's values is the first step in the decision-making process, and it affects the ability of people to make ethical decisions. Values clarification also promotes understanding and respect for values held by others, such as community health clients and other health care providers. As pointed out by Uustal (1977, p. 10), "Nurses cannot hope to give optimal, sensitive care to any patient without first understanding their own opinions, attitudes, and values." This values clarification process provides a backdrop for next exploring the role of values in

ethical decision-making. Values clarification has also proven helpful with clients. A recent study in patient choice of anticoagulant showed how this method could assist with clarity in drug choice (Palacio, Kirolos, & Tamariz, 2015). Focused values clarification exercises, as part of a package of decision aids (e.g., pamphlets, videos), for patients making treatment or screening decisions were found to improve knowledge of options/risks/benefits and promote decision-making in choosing the best anticoagulant for the patient's lifestyle and preferences.

ETHICS

Values are central to any consideration of ethics or ethical decision-making. Yet, it is not always obvious at first what constitutes an ethical problem in health care or in the practice of community health nursing. Most nurses easily recognize the moral crisis in some kinds of decisions—for example, whether to let seriously deformed newborn infants die, whether to terminate pregnancies resulting from rape, or whether to provide universal health care coverage. However, other, less obvious moral dilemmas often found in the routine practice of community health nursing are not always considered to be ethical in nature.

What is ethics and what is *ethical*? The *Merriam Webster Online Dictionary (2015)* defines ethics as "the principles of conduct governing a group" (para. 1). Ethics may also be viewed as a set of moral principles or a theory or system of moral values. Ethics are often idealized as "what ought to be." Ethical decision-making, then, means making a choice that is consistent with a moral code or that can be justified from an ethical perspective. Of necessity, the decision-maker must exercise moral judgment. Remember that the term moral refers to conforming to a standard that is right and good. Community health nurses become "moral agents" by making decisions that have direct and indirect consequences for the welfare of themselves and others. Bioethics refers to using ethical principles and methods of decision-making in questions involving biologic, medical, or health care issues all while keeping the centrality of the patient to practice in the face of contemporary systems issues in care (Burkhardt, & Nathaniel, 2014). The next section examines how a PHN makes these moral decisions.

Public Health Ethics

Protection and promotion of health are at the core of public health nursing. Ethical principles are further clarified in this specialty area. Public health ethics is defined as "a systematic process to clarify, prioritize and justify possible courses of public health action based on ethical principles, values and beliefs of stakeholders, and scientific and other information" (CDC, 2016, para. 1). Specific ethical principles apply to public health in general (e.g., advocacy for healthy communities and equitable distribution of limited resources; balance between individual rights and the collective good) and public health nursing specifically (e.g., professional ethics). Preventing disease or harm, respecting individual rights, and encouraging community input are common values, as well as empowerment of the disenfranchised and equal access to resources. Promoting health, protecting confidentiality (except where justified), and collaborating or partnering with other community agencies are viewed as universal practices. Other principles include respecting diverse values/beliefs and working effectively with different cultural groups to enhance the social and physical environment while employing competent public health professionals. Public health is most often concerned distribution of resources and shaping behavior and thoughts, which may include resources such as clean water and constraints, such as quarantine. We need to keep in mind the responsibility of the world to global justice when implementing public health programs and policy (Jennings, 2015). Without care in global justice, there may be an uneasy balance between individual and public interests and rights.

A framework is applied in public health ethics inquiry. Three core functions of this inquiry include

1. Identifying and clarifying the ethical dilemma
2. Analyzing it in terms of alternative courses of action and their consequences
3. Resolving the dilemma by deciding which course of action best incorporates and balances the guiding principles and values (CDC, 2016, para. 5)

Identifying Ethical Situations

Ethics involves making evaluative judgments. To be ethically responsible in the practice of community health nursing, it is important to develop the ability to recognize evaluative judgments as they are made and implemented in nursing practice. Nurses must be able to distinguish between evaluative and nonevaluative judgments. Evaluative statements involve judgments of value, rights, duties, and responsibilities. Examples are "Parents should never strike their children" and "It is the duty of every citizen to vote." Among the words to watch for are verbs such as *want, desire, refer, should,* or *ought* and nouns such as *benefit, harm, duty, responsibility, right,* or *obligation*.

Sometimes, the evaluations are expressed in terms that are not direct expressions of evaluations but clearly are functioning as value judgments. Winland-Brown et al. (2015) provide useful clinical applications of the ANA code of ethics and refer to the obligations or duties of nurses to both patient and self (see "Code of Ethics for Nurses: Provisions"). Another important step is to distinguish between moral and nonmoral evaluations. Moral evaluations refer to judgments that conform to standards of what is right and good. Moral evaluations assess human actions, institutions, or character traits rather than inanimate objects, such as parks or architectural structures. They are prescriptive–proscriptive beliefs having certain characteristics separating them from other evaluations such as aesthetic judgments, personal preferences, or matters of taste. Moral evaluations also have distinctive characteristics (Brambilla & Leach, 2014):

- Morality and sociability impact social judgment. We want to be able to anticipate others' actions that could lead to benefit or harm or their skill and ability.
- Values possess universality or reflect a standpoint that applies to everyone. They are evaluations that everyone in principle ought to be able to make and understand, even if some individuals, in fact, do not.
- Moral evaluations avoid giving a special place to a person's own welfare. They have a focus that keeps others in view, or at least considers one's own welfare on a par with that of others.

Moral evaluations, like "parents should take care of their children," meet these criteria. A nonmoral evaluation, like "Mrs. X has five children," does not evoke a moral judgment of Mrs. X, but only an assessment of her family composition.

Resolving Moral Conflicts and Ethical Dilemmas

When judgments involve moral values, conflicts are inevitable. In clinical practice, the nurse may be faced with moral conflicts, such as the choice between preserving the welfare of one set of clients over that of others. For example, the nurse may have to choose whether to keep a promise of confidentiality to persons who are infected by HIV when these individuals continue to have unprotected sex with unknowing partners. Nurses may have to choose between protecting the interests of colleagues or the interests of the employing institution by reporting a nurse who makes phone visits rather than home visits, so that she can spend more time shopping online from work. They may have to decide whether to serve future clients by striking for better conditions or to serve present clients by refusing to strike. Often, nurses' values are at odds with their employers' values and procedures. The moral values of a nurse may conflict with the policies and practices of a particular bureaucracy, as nurses are taught that their clients (individuals, families, aggregates) are their focus of concern (Wright & Brajtman, 2011). Each decision involves a potential conflict between moral values and is called an ethical dilemma. An ethical dilemma occurs when morals conflict with one another, causing the nurse to face a choice with equally attractive or equally undesirable alternatives (Burkhardt & Nathaniel, 2014). If you are faced with two or more values of equal importance that will lead to different actions, then you are dealing with an ethical dilemma. It can create a decision-making problem, even in ordinary nursing situations.

Decision-Making Frameworks

To resolve ethical dilemmas or the conflict between moral values in community health nursing practice, and to provide morally accountable nursing service, several frameworks for ethical decision-making have been proposed. Among these frameworks, three key steps are considered as fundamental to choosing alternative courses of action that reflect moral reasoning: separate questions of fact from questions of value, identify both clients' and nurse's value systems, and consider ethical principles and concepts (see Fig. 4–6).

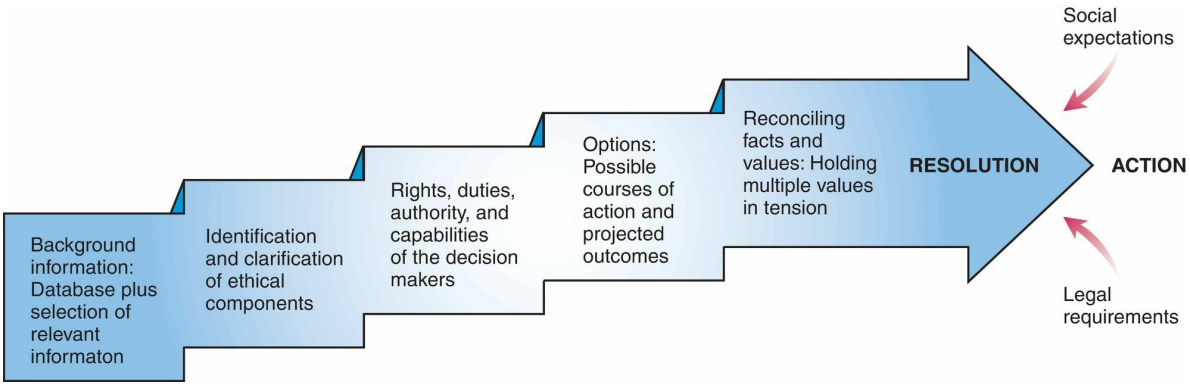

Figure 4–6 An ethical decision-making framework. Although legal requirements or social expectations may sway a decision one way or another, they are extrinsic to the ethical analysis and should not be confused with right and wrong. What is legal and what is expected are not necessarily right and wrong.

The identification of clients' values and those of other persons involved in conflict situations is an important part of ethical decision-making. In the example given in From the Case Files I, what are Mr. Bell's values? What are the values of neighbors who are concerned about him, but feel that they can no longer care for him? What are the nurse's values? What are the values of the nurse's employer? What are society's values?

From the Case FilesI

Mr. Bell

Community health nurses encounter value differences every day, and value differences, in turn, create ethical problems. Consider, for example, the dilemma faced by one nurse in Seattle on her first home visit to an elderly man, Mr. Bell, referred by concerned neighbors. This 82-year-old gentleman was homebound and living alone with severe arthritis under steadily deteriorating conditions. Overgrown shrubs and vines covered the yard and house, making access impossible except through the back door. A wood burning stove in the kitchen was the sole source of heat. The kitchen, along with a corner of the dining room, constituted Mr. Bell's living quarters. The remainder of the once-lovely three-bedroom home, including the bathroom, was layered with dust, unused. His bed was a cot in the dining room; his toilet, a 2-pound coffee can sitting under the cot. Unbathed, unshaven, and existing on food and firewood brought by neighbors, Mr. Bell seemed to be living in deplorable conditions. Yet he prized his independence so highly that he adamantly refused to leave. Mr. Bell had one son living in a neighboring state, but had little contact with him.

The conflict of values between Mr. Bell's choice to live independently and the nurse's value of having him in a safer living situation raises several ethical questions. When do health practitioners or family members have the right or duty to override an individual's preferences? When do neighbors' rights (Mr. Bell's home was an eyesore and his care was a source of anxiety for his neighbors) supersede one homeowner's rights? Should the nurse be responsible when family members can help but won't take action?

In this case, the nurse entering Mr. Bell's home applied her values of respect for the individual and his right to autonomy even at the risk of public safety. Not until he fell and broke a hip did he reluctantly agree to be moved into a nursing home.

An ethical decision-making framework referred to as the DECIDE model is initially useful in determining the problem and reviewing options. What is missing from this model is the patients' preference, a vital component (Park, 2012). For public health, patients'

preference may be replaced with the harm versus benefit argument. The DECIDE model It includes the following steps:

D—*Define the problem (or problems)*. What are the key facts of the situation? Who is involved? What are their rights and duties and your rights and duties?

E—*Ethical review*. What ethical principles have a bearing on the situation, and which principle or principles should be given priority in making a decision?

C—*Consider the options*. What options do you have in the situation? What alternative courses of action exist? What help, means, and methods do you need to use?

I—*Investigate outcomes*. Given each available option, what consequences are likely to follow from each course of action open to you? Which is the most ethical thing to do?

D—*Decide on action*. Having chosen the best available option, determine a specific action plan, set clear objectives, and then act decisively and effectively.

E—*Evaluate results*. Having initiated a course of action, assess how things progress, and when concluded, evaluate carefully whether or not you achieved your goals.

Other frameworks can be used. The framework for ethical decision-making shown in Display 4–5 helps to organize thoughts and acts as a guide through the decision-making process. The steps help to determine a course of action, with heavy responsibility at the evaluation level: here the outcomes need to be judged and decisions repeated or rejected in future situations. Figure 4–6 summarizes several views in the field on ethical decision-making. This framework advocates keeping multiple values in tension before resolution of conflict and action on the part of the nurse. It suggests that value conflict is not capable of resolution until all possible alternative actions have been explored. Three tests may be helpful in your decision-making process (Edwards & Robey, 2010; Iserson, 1999):

DISPLAY 4.5 A FRAMEWORK FOR ETHICAL DECISION-MAKING

Clarify the ethical dilemma: Whose problem is it? Who should make the decision? Who is affected by the decision? What ethical principles are related to the problem?

Gather additional data: Have as much information about the situation as possible. Be up to date on any legal cases related to the ethical question.

Identify options: Brainstorm with others to identify as many alternatives as possible. The more options identified, the more likely it is that an acceptable solution will be found.

Make a decision: Choose from the options identified and determine the most acceptable option, the one more feasible than others.

Act: Carry out the decision. It may be necessary to collaborate with others to implement the decision and identify options.

Evaluate: After acting on a decision, evaluate its impact. Was the best course of action chosen? Would an alternative have been better? Why? What went right and what went wrong? Why?

- Impartiality test—Would you be willing to have this done to you? The "golden rule."
- Universalizability test—If every nurse in similar circumstances did the same as you, would you be comfortable with that "universal rule"?
- Interpersonal justifiability test—Can you state a reason for your choice and justify your actions to your peers, supervisors, and society?

Final resolution of the ethical conflict occurs through a conscious choice of action, even though some values would be overridden by other stronger, presumably moral values. The triumphant values would be those located higher in the decision-maker's hierarchy of values.

Basic Values that Guide Decision-Making

When applying a decision-making framework, certain values influence community health nursing decisions. Three basic human values are considered key to guiding decision-making in the provider–client relationship: self-determination, well-being, and equity.

Self-Determination

The value of self-determination or individual autonomy is a person's exercise of the capacity to shape and pursue personal plans for life. Self-determination is instrumentally valued because self-judgment about a person's goals and choices is conducive to an individual's sense of well-being. Informed consent derives from self-determination. When one respects self-determination, it is based on the belief that better outcomes will result when autonomy is held in high regard. The outcomes that could be maximized by respecting self-determination or autonomy include enhanced self-concept, enhanced health-promoting behaviors, and enhanced quality of care. Self-determination is a major value in the United States, but does not receive the same emphasis in all societies or ethnic groups (Owens & Cribb, 2013; Soenens & Vansteenkiste, 2010).

In health care contexts, the desire for self-determination has been of such high ethical importance in U.S. society that it overrides practitioner determinations in many situations. Client empowerment is an approach that differs from the paternalistic approach to health care in which decisions are made for, rather than with, the client; instead, it enables patients and professionals to work in partnership (Cawley & McNamara, 2011). Many physicians and other health providers, including community health nurses, fail to recognize the high value attributed to self-determination by many consumers or the differences in views of self-determination among ethnic groups. The freedom of our patients must be respected and integrated into the matrix of health care decisions in any encounter or program (Risjord, 2014).

The conflict between provider and consumer may be broader. When self-determination deteriorates into self-interest, it poses a major roadblock to equitable health care. Self-interest is the fulfillment of one's own desires, without regard for the greater good. Consumers mostly have to fend for themselves when they encounter the world of for-profit health care, just as they do in other commercial markets, where "buyers beware" is the standard. This is well discussed in litigation against for-profit nursing homes as it looks at the impact of poor staffing on care, numerous citations, but no action taken in defense of the patients in the home (Harrington, Stockton, & Hooper, 2014).

When providing health care, self-determination and taking personal responsibility for health care decisions should be nurtured. This includes informing clients of options and the reasoning behind all recommendations. Yet self-determination and personal autonomy at times are impermissible or even impossible. For example, society must impose restrictions on unacceptable client choices, such as child abuse and other abusive behaviors, or

situations in which clients are not competent to exercise self-determination, as is true for certain levels of mental illness or dementia. There are two situations in which self-determination should be restricted: when some objectives of individuals are contrary to the public interest or the interests of others in society (e.g., endangering others with a communicable disease) and when a person's decision-making is so defective or mistaken that the decision fails to promote the person's own values or goals. When a person cannot fully comprehend the options, the consequences of actions related to the options, and the true costs and benefits, he may not have adequate capacity for making health care decisions. In these situations, self-determination is justifiably overridden on the basis of the promotion of one's own well-being or the well-being of others—another important value in health care decision-making (Kelly, 2013; Soenens & Vansteenkisrte, 2010).

Well-being

Well-being is a state of positive health. Although all therapeutic interventions by health care professionals are intended to improve clients' health and promote well-being, well-intended interventions sometimes fall short if they are in conflict with clients' preferences and needs. Determining what constitutes health for people and how their well-being can be promoted often requires knowledge of clients' subjective preferences. It is generally recognized that clients may be inclined to pursue different directions in treatment procedures based on individual goals, values, and interests. Community health nurses, who are committed not only to helping clients but also to respecting their wishes and avoiding harming them, must understand each client group's needs and develop reasonable alternatives for service from which clients may choose (see From the Case Files II). In addition, when individuals are not capable of making a choice, the nurse or other surrogate decision-maker is obliged to make health care decisions that promote the value of well-being. This may mean that the alternatives presented by the nurse for choice are only the alternatives that will promote well-being. With shared decision-making, the nurse seeks not only to understand clients' needs and develop reasonable alternatives to meet those needs but also to present the alternatives in a way that enables clients to choose those they prefer. Well-being and self-determination are two values that are intricately related when providing community health nursing services (Jormfeldt, 2014; Rath & Harter, 2010).

From The Case Files II

Andrea Vargas, PHN: A Family Living in Poverty

Contrasting value systems may be seen in many community health practice settings. Andrea Vargas, a community health nurse, experienced such a contrast on her first home visit to a family living in poverty. Referred by a school nurse for the children's recurring problems with head lice and staphylococcal infections, the family was living in a converted outbuilding on the outskirts of town. Although basically clean and orderly, nonetheless the living conditions were cramped, inadequate, and unsafe. Three hammocks were strung, stacked one upon the other, across the far corner of the room to accommodate the three younger children (out of a total of six). The older two children slept on the couch and the floor, while the baby slept with the single mother in the small bed. There was an old gas stove for cooking, and it was currently being used to heat the room, as the wall heater did not work. The mother did not know why it was no longer working. She seemed "stuck"—unable to muster the effort to talk with the landlord about the lack of a working heater. Even though using a gas stove to heat the room was dangerous (because of carbon monoxide), it seemed to her to be the easiest way to deal with the problem. Andrea knew that landlords were sometimes slow to respond to the needs of low-income renters and she saw this as unjust. The mother's main pleasure in life was watching soap operas on television, and Andrea felt that the mother seemed disinterested in trying to improve her circumstances. The nurse interpreted the situation through the framework of her own value system, in which health and safety were priorities, and justice was an instrumental value. Yet the mother, who might have shared those values in the past, appeared to prize pleasurable diversion, perhaps as a way to cope with her situation. In this instance, it is possible that environmental influences reordered the family's value system priorities. Rather than imposing her own values, Andrea chose to determine the priorities of the family, assess their needs, and begin where they were. Will she have a greater chance at success by doing this?

Equity

The third value that is important to decision-making in health care contexts is the value of equity or justice, which means being treated equally or fairly. The principle of equity implies that it is unjust (or inequitable) to treat people the same if they are, in significant respects, unalike. In other words, different people have different needs in health care, but all must be served equally and adequately (Maiese, 2013). Equity generally means that all individuals should have the same access to health care according to benefit or needs (see

Levels of Prevention Pyramid). However, effectively applying this value is often a complex enterprise and fraught with difficulties (McLeod, Blakelu, Kvizhinadze, & Harris, 2014).

LEVELS OF PREVENTION PYRAMID

SITUATION: Provide distributive justice for battered women and children by changing a proposed state law that would eliminate funding for shelters for battered women and children to a law that preserves resources for this population.

GOAL: Using the three levels of prevention, negative health conditions are avoided or promptly diagnosed and treated, and the fullest possible potential is restored.

TERTIARY PREVENTION

	Health Promotion and Education	*Health Protection*
If unable to stop the proposed law: • Seek volunteer services to fill the gaps in funding paid employees. • Seek donations to support existing shelter buildings.	• Educate the public regarding the need for lost/limited services using various forms of media and/or venues.	• Seek private resources or grants to fund shelters. • Propose a new bill to match private funding for shelters at the next legislative session.

SECONDARY PREVENTION

• Recognition that the proposed bill is going to pass	• Advocate for amendments to the proposed bill to preserve limited funding for shelters.

PRIMARY PREVENTION

• Advocacy • Active lobbying against the bill • Garnering community support in favor of the revised bill	• Community understand the impact of the potential loss • Put a "human face" on the problem

The major problem with this definition of equity is, of course, that it assumes that an adequate level of health care can be economically available to all citizens. In times of limited technical, human, and financial resources, however, it may be impossible to fully respect the value of equity (Hussein, 2010; Karadag & Hakan, 2012). Choices must be made and resources allotted, while the value obligations of professional practice create conflicts of

values that seem impossible to resolve. Many of these conflicts are reflected in current health care reform efforts that focus on access to services, quality of services, and ways to control rising costs. We also have many new genomics issues with access to care paramount in equity decisions (Rogowski, Grosse, Schmidtke, & Marckmann, 2014). The following list represents some of the most pressing aggregate health problems related to inequities in the distribution of and access to health and illness care facing patients worldwide.

- *Too many women go without preventive care*. The overall rate of infant mortality (all infant deaths before 1 year of age) is 5.1 per 1,000 in the United States, which is good news, as it is lower than previous rates. Although rates for infant mortality remain high, rates have declined among African Americans over the last few years, from 12.9 to 11.3 per 1,000 in the United States (Kaiser Family Foundation [KFF], 2015a). Native Hawaiian and other Pacific Islanders and Native American infant mortality rates have also declined—but all infant mortality rates among people of color are higher than those for White, non-Hispanic, and Hispanic Americans (5.1). Forty-nine percent of pregnancies in the United States during 2001 were unintended —among White and Hispanic females, 40% and 54%, respectively, were reported as unintended. But among African American females, 69% report unintended pregnancies. Poverty is strongly related to difficulty in accessing family planning services (Snow, Laski, & Mutumba, 2015) as are health care system factors (e.g., access), provider-related factors (e.g., similar culture), and patient preferences (Dehlendorf, Rodrigue, Levy, Borrero, & Steinauer, 2010).
- *Immunization rates for children entering kindergarten are an example of how public health works.* In most states, exemption rates are low, with Idaho having the highest exemption rates (CDC, 2015). Compliance with scheduled vaccines is high. Less than 1% of children between 19 and 35 months are unvaccinated. According to the CDC, "consistent, high coverage rates are needed to provide community immunity (herd immunity) and protect children from disease outbreaks like measles" (CDC, 2015, para. 7). Childhood immunization rate disparities have been dramatically reduced through multiple interventions and a strong infrastructure of vaccine services (Walker, Smith, & Kolasa, 2014). The many interventions and programs implemented during this period, including Vaccines for Children (VFC), have built a successful infrastructure for vaccination services.
- *Vast disparities in immunization rates exist* for adults along racial and ethnic lines, as well as poverty level. Even with a number of health care encounters and socioeconomic factors controlled for in a study comparing non-Hispanic White and non-Hispanic Black influenza vaccination rates, the rate for Blacks was only 70% that of Whites (Liu, 2011).
- *The uninsured are likely to go without physician care*. Differences in access to expensive, discretionary procedures emerge according to health insurance status, race, and ethnicity, as well as other sociodemographic factors. The Affordable Care Act has helped to improve the numbers of previously uninsured in America from a high of 32

million without insurance, to current levels of 9 million people uninsured. Those who remain uninsured are the working poor. Over half of those without health insurance live at 200% below the poverty level White non-Hispanic Americans remain more likely to be insured than people of color (Kaiser Family Foundation, 2015b).

- *Environmental hazards threaten global health*. Global trade, travel, and changing social and cultural patterns make the population vulnerable to diseases that are endemic to other parts of the world, as well as to previously unknown diseases. The Ebola outbreak highlighted the need for better preparation for pandemics (DeMoro, 2014). Pollution of air, water, and soil to support industry contributes to pathogen mutations and threatens public health. Specific geological exposures to pathogens can also affect health, such as long-term arsenic exposure (Wardrop & LeBlond, 2015).
- *Equity is tied to social justice* (see below) and can be a difficult concept to truly grasp because we have difficulty understanding how our own privilege creates equity and, therefore, cannot see how those who lack what we have live in a socially *unjust world.* People are socialized to see the world through the eyes of their own experience. Once we can break that cycle of socialization and "unpack" how race, gender, income, education, age, and sexual identity influence equity and social justice, we then become allies to those who lack privilege. True equity occurs when we first understand our own privilege. Social justice happens when those who are seen as "other" are treated to the same equity as the historically privileged (Adams et al., 2013). See Display 4–6, Society and Individual Responsibility in Health Care.

DISPLAY 4.6 SOCIETY AND INDIVIDUAL RESPONSIBILITY IN HEALTH CARE

To promote the achievement of equity, self-determination, and clients' well-being, certain conclusions drawn from the literature can enhance community health nursing practice (Badzek, Henaghan, & Turner, 2013; Blacksher, 2014; Holt & Convey, 2012). *Society has an ethical obligation to ensure equitable access to health care for all.* This obligation is centered on the special importance of health care and is derived from its role in relieving suffering, preventing premature death, restoring functioning, increasing opportunity, providing information about an individual's condition, and giving evidence of mutual empathy and compassion.

1. *The societal obligation is balanced by individual obligations*. Individuals ought to

pay a fair share of the cost of their own health care and take reasonable steps to provide for such care when they can do so without excessive burdens.

2. *Equitable access to health care requires that all citizens can secure an adequate level of care without excessive burdens*. Equitable access also means that the burdens borne by individuals in obtaining adequate care ought not to be excessive or to fall disproportionately on particular individuals. Communities need to be empowered to address distribution problems.
3. *When equity occurs through the operation of private forces, there is no need for government involvement*. However, the ultimate responsibility for ensuring that society's obligation is met—through a combination of public and private sector arrangements—rests with the federal government.
4. *The cost of achieving equitable access to health care ought to be shared fairly*. The cost of securing health care for those who are unable to pay ought to be spread equitably at the national level and should not fall more heavily on the shoulders of particular practitioners, institutions, or residents of different localities.
5. *Efforts to contain rising health care costs are important but should not focus on limiting the attainment of equitable access for the least-served portion of the public*. Measures designed to contain health care costs that exacerbate existing inequities or impede the achievement of equity are unacceptable from a moral standpoint. Aggregates in the community should be involved in planning and problem solving to increase the distribution of resources where those resources are most needed.

Ethical Decision-Making in Community Health Nursing

The key values of self-determination, well-being, and equity influence nursing practice in many ways. The value of self-determination has implications for how community health nurses regard the following:

- The choices of clients
- Privacy
- Informed consent
- Diminished capacity for self-determination

The value of well-being has implications for how community health nurses seek to:

- Prevent harm and provide benefits to client populations
- Determine effectiveness of nursing services
- Weigh costs of services against real client benefits

The value of equity has implications for community health nursing in terms of its priorities for:

- Distributing health goods (macro allocation issues)
- Deciding which populations will obtain available health goods and services (microallocation issues)

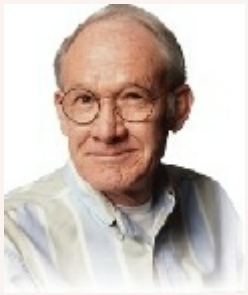
Decisions based on one value means that this value often will conflict with other values. For example, deciding primarily on the basis of client well-being may conflict with deciding on the basis of self-determination or equity. How community health nurses balance these values may even conflict with their own personal values or the professional values of nursing as a whole. In these situations, values clarification techniques used with an ethical decision-making process may assist in producing decisions that promote the greatest well-being for clients without substantially reducing their self-determination or ignoring equity.

Ethical Principles

Based in utilitarianism and deontology, seven fundamental ethical principles provide guidance in making decisions regarding clients' care: respect, autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity (Guido, 2013).

Respect

The principle of respect refers to treating people as unique, equal, and responsible moral agents. This principle emphasizes one's importance as a member of the community and of the health services team. To apply this principle in decision-making is to acknowledge



community clients as valued participants in shaping their own and the community's health outcomes. It includes treating them as equals on the health team and holding them, as well as their views, in high regard (Guido, 2013).

Autonomy

The principle of autonomy means freedom of choice and the exercise of people's rights. Individualism and self-determination are dominant values underlying this principle (William Glasser Institute, 2010). As nurses apply this principle in community health, they promote individuals' and groups' rights to and involvement in decision-making. This is true, however, only so long as those decisions enhance these individuals' and groups' well-being and do not harm the well-being of others. When applying this principle, nurses should make certain that clients are fully informed and that the decisions are made deliberately, with careful consideration of the consequences (see From the Case Files III).

From the Case Files III

Tom Hardy, PHN: An Elderly Client Gives Up

Tom Hardy, PHN, has been assigned to monitor Mr. Jack, an elderly man who was diagnosed with TB (positive skin test, positive sputum and x-ray). Mr. Jack's wife unexpectedly died recently, and he is depressed and wants to "join her." He is not eating or sleeping much. He refuses to take TB medications, or his eight other medications for heart disease, thyroid insufficiency, type 2 diabetes, glaucoma, high cholesterol and triglycerides, and hypertension. He has consistently refused any of Tom's suggestions or assistance. He does not want to see a mental health counselor, and Tom wonders if he should continue to make home visits. He has a busy caseload and needs to focus on the most pressing cases. Mr. Jack's children feel that his depression and refusal of medications are a "temporary condition" in response to his wife's death and have asked for Tom's assistance in keeping their father healthy. Why is this an ethical dilemma? What are the ethical principles involved? What does Mr. Jack value? What are his children's values? What are Tom's values? Prioritize your values. What are the possible actions you could take?

Beneficence

The ethical principle of beneficence means doing good or benefiting others. It is the promotion of good or taking action to ensure positive outcomes on behalf of clients (Burkhardt & Nathaniel, 2014). In community health, the nurse applies the principle of beneficence by making decisions that actively promote community clients' stated interests and their view of well-being (Husted et al., 2015). Examples might encompass the development of a seniors' health program that ensures equal access to all in the community who are in need, and the support of programs to encourage preschool immunizations.

Nonmaleficence

The principle of nonmaleficence means avoiding or preventing harm to others as a consequence of a person's own choices and actions (Burkhardt & Nathaniel, 2014). This involves taking steps to avoid negative consequences. Community health nurses can apply this ethical principle in decision-making by actions such as encouraging physicians to prescribe drugs with the fewest side effects, promoting legislation to protect the environment from pollutants emitted from gasoline even if it raises prices, and lobbying for lower speed limits or gun controls to save lives.

Justice

The principle of justice refers to treating people fairly (Guido, 2013). It means the fair distribution of both benefits and costs among society's members. Examples might include equal access to health care, equitable distribution of services to rural as well as urban populations, not limiting the amount or quality of services because of income level, and fair distribution of resources—all of these draw on the principle of justice.

Within this principle are three different views on allocation, or what constitutes the meaning of "fair" distribution. One, distributive justice, says that benefits should be given first to the disadvantaged or those who need them most (see Levels of Prevention Pyramid). Decisions based on this view particularly help the needy, although it may mean withholding goods from others who may also be deserving, but less in need (e.g., food stamps). The second view, egalitarian justice, promotes decisions based on equal distribution of benefits to everyone, regardless of need (e.g., Medicare). The third, restorative justice, determines that benefits should go primarily to those who have been wronged by prior injustice, such as victims of crime or racial discrimination. Programs are in place to compensate victims for their injury or families for their loss—a beginning step to "restore justice." Another example includes the funds that were set up by several agencies, corporations, and groups to assist the families of the victims of the September 11, 2001, terrorist attacks. The principle of justice seeks to promote equity, a value that was discussed in the previous section.

Social justice refers to the fair and equitable distribution of wealth, economic opportunity, and access to privileges in society and is tied to human rights (Adams et al., 2013). The National Association of Social Workers (2011) describes social justice as the "view that everyone deserves equal economic, political and social rights and responsibilities." See Chapter 25 for more on social justice.

Veracity

The principle of veracity refers to telling the truth. Community clients deserve to be given accurate information in a timely manner. To withhold information or not tell the truth can be self-serving to the nurse or other health care providers and hurtful, as well as disrespectful, to clients. Truth-telling involves treating clients as equals, and it expands the opportunity for greater client involvement, as well as provides needed information for decision-making (Husted et al., 2015).

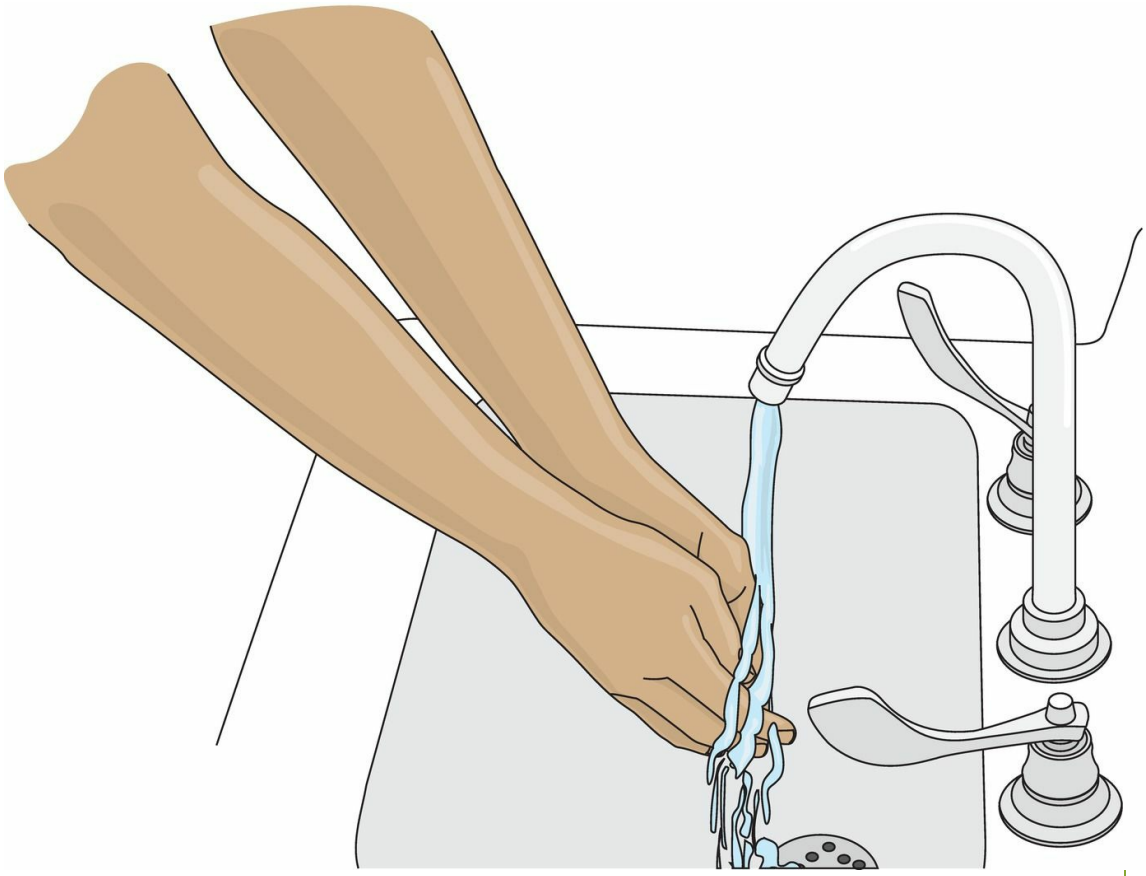
Fidelity

The final ethical principle, fidelity, means keeping promises. People deserve to count on commitments being met. This principle involves the issues of trust and trustworthiness (Brambilla, Rusconi, Sacchi, & Cherubini, 2011; Guido, 2013). Nurses who follow through on what they have said earn their clients' respect and trust. In turn, this influences the quality of the nurse's relationship with clients, who then are more likely to share information, which leads to improved decisions and better health. Conversely, when a promise (e.g., a commitment to institute child care during health classes) is not kept, community members may lose faith and interest in participation.

Ethical Standards and Guidelines

As the number and complexity of ethical decisions in community health increase, so too does the need for ethical standards and guidelines to help nurses make the best choices possible. The ANA's *Code for Nurses with Interpretive Statements* (2015) provides a helpful guide. Some health care organizations and community agencies, using the ANA code or a similar document, have developed their own specific standards and guidelines. For instance, the Public Healthy Leadership Society's veteran text, *Principles of the Ethical Practice of Public Health* (2002), guides both institutions and individual practitioners as they serve the public. More recently, the Association of State and Territorial Directors of Nursing (ASTDN, n.d.), a public health nursing organization, published a text on how to incorporate ethical principles into local health department processes and provide guidelines for the PHN role in eliminating health inequalities.

More health care organizations are using ethics committees or ethics rounds to deal with ethical aspects of client services (Guido, 2013). These committees are common in the acute care setting and in senior and long-term care settings, and they often focus on such issues as caregiving dilemmas involving practitioner negligence or poor client outcomes and the related health care decisions. In long-term care and home care settings, such a committee may consider conflicts in client care issues that involve family members. However, these committees also function in a variety of community health care settings. In public health agencies, cases of clients with complicated communicable disease diagnoses and health care provider concerns are discussed as they relate to policy, protocols, and the health and safety of the broader population.



SUMMARY

Implementation of EBP enables community health nurses to promote health and prevent illness among at-risk populations and to design and evaluate community-based interventions. EBP is essential to ensuring economical and effective interventions for our clients. Systematic reviews can provide direction for those who have developed a "burning clinical question." Finding accurate, complete information and critically appraising it is vital (see Evidence-Based Practice: Hand washing).

EVIDENCE-BASED PRACTICE

Hand washing

As nurses, we are taught the importance of hand washing. In nursing school, we are educated to wash our hands before and after patient care—it is often drilled into us. But, when you work in the community, you do not always have ready access to soap and water. Many PHNs choose to carry small bottles of hand sanitizer as a practical alternative to hand washing. Community-based research has confirmed the effectiveness of waterless alcohol-based hand sanitizers for new mothers living in areas without adequate water supplies and for reducing microbes on the soiled hands of farmworkers harvesting produce in the fields (deAceituno et al., 2015; Pickering, Boehm, Mwanjali, & Davis, 2010). It is also important to educate our patients, both at home and in acute care environments, about the importance of hand washing. Use of waterless wash and traditional hand washing are both effective (Sunni, Kennedy, Davis, Thompson, & Jones, 2014). Where would you go to find a systematic or integrative review of this subject? How would you go about presenting this information at a staff meeting to stimulate changes in policies and procedures?

Research is defined as the systematic collection and analysis of data related to a particular problem or phenomenon. *EBP* is characterized as the use of best evidence, along with the nurse's clinical judgment and knowledge of patient's wishes, in making decisions about nursing practice and client outcomes. It encompasses the steps outlined in Display 4–1.

Systematic reviews are summaries of evidence usually compiled and analyzed by expert panels on a specific problem of interest, using predetermined criteria.

Research has a significant impact on community health and nursing practice in three ways. It provides new knowledge that helps to shape health policy, improve service delivery, and promote the public's health. It contributes to nursing knowledge and the improvement of nursing practice. And it offers the potential to enhance nursing's status and influence through documentation of the effectiveness of nursing interventions and broader recognition of nursing's contributions to health services.

Nurses must become responsible consumers of research, keeping abreast of new knowledge and applying it in practice. Nurses must learn to evaluate evidence critically, assessing the validity and applicability to their own practice. Nurses should search for current evidence and discuss EBP initiatives with colleagues and supervisors. More community health nurses must also conduct EBP implementation studies of their own or collaborate with other community health professionals in doing clinical research. A commitment to the use and conduct of research will move the nursing profession forward and enhance its influence on the health of at-risk populations.

Values and ethical principles strongly influence community health nursing practice and ethical decision-making. *Values* are lasting beliefs that are important to individuals, groups, and cultures. A value system organizes these beliefs into a hierarchy of relative importance that motivates and guides human behavior. Values function as standards for behavior, as criteria for attitudes, and as standards for moral judgments, and they give expression to human needs. The nature of values can be understood by examining their qualities of endurance, their hierarchical arrangement, and their function as prescriptive–proscriptive beliefs and by examining them in terms of reference and preference.

The nurse often is faced with decisions that affect client's values and involve conflicting moral values and ethical dilemmas. Understanding what personal values are and how they affect behavior assists the nurse in making ethical evaluations and addressing ethical conflicts in practice. Various strategies can guide the nurse in making these decisions; one example is values clarification, which clarifies what values are important. Several frameworks for ethical decision-making that include the identification and clarification of values impinging on the making of ethical decisions were discussed in this chapter.

Three key human values influence client health and nurse decision-making: the right to make decisions regarding a person's health (self-determination), the right to health and well-being, and the right to equal access and quality of health care. At times, these values are affected by the value of self-interest on the part of another person or a system. Seven fundamental principles guide community health nurses in making ethical decisions: respect, autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity.

This chapter discusses current research as it relates to and impacts community health nursing practice. The steps of EBP are emphasized. The chapter includes information on constructing a clinical question and incorporating client considerations and clinical

guidelines, as well as helpful resources for finding and analyzing research studies. Ethics and values are also examined, as they relate to both research and community health nursing practice. This chapter explores the nature and function of values and value systems, the role of values and value systems in ethical decision-making, the central values related to health care choices and their potential conflicts, and the implications of values and ethics for community health nursing decision-making and practice.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. As a community health nurse working in a large city, you have a large number of children with lead poisoning due to environmental contamination. You are interested in lead abatement programs. Where can you find evidence on successful programs/outcomes, cost–benefit analysis, and policies that have been implemented in other areas?
2. You want to determine whether a group of sexually active teenagers who are at risk for HIV/AIDS would be receptive to an educational program on HIV/AIDS. Where would you look for a systematic review on this topic?
3. Select a community health nursing systematic review or research article from the references listed in this chapter (or choose one of your own) and analyze its potential impact on health policy and on public health nursing practice.
4. You have just completed an EBP implementation study on the effectiveness of a series of birth control classes in three high schools, and the results show a reduction in the number of pregnancies over the last year. Describe three ways in which you could disseminate this information to your nursing colleagues and other community health professionals.
5. You are alarmed to note that the new area to which you have been assigned has high rates of TB. Searching the Internet and your college library databases to research this topic, determine the most effective forms of treatment and discuss the feasibility of implementing some newer approaches with your specific target population.
6. Take the BBC Morals—Social Responsibility Questionnaire (available at http://www.bbc.co.uk/science/humanbody/mind/surveys/morals) and discuss your results with a trusted classmate. How similar were your responses? Why?
7. Describe where you stand on the following issues. For each statement, decide whether you strongly agree, agree, disagree, strongly disagree, or are undecided:
    a. Clients have the right to participate in all decisions related to their health care.
    b. Nurses need a system designed to credit self-study.
    c. Continuing education should not be mandatory to maintain licensure.
    d. Clients always should be told the truth.
    e. Standards of nursing practice should be enforced by state examining boards.
    f. Nurses should be required to take relicensure examinations every 5 years.
    g. Clients should be allowed to read their health record on request.
    h. Abortion on demand should be an option available to every woman.
    i. Critically ill newborns should be allowed to die.
    j. Laws should guarantee desired health care for each person in this country.
    k. Organ donorship should be automatic unless a waiver to refuse has been signed.
8. In a grid similar to the one shown, write a statement of belief in the space provided

and examine it in relation to the seven steps of the process of valuing. Areas of confusion and conflict in nursing practice that should be examined are peer review, accountability, confidentiality, euthanasia, licensure, clients' rights, organ donation, abortion, informed consent, and terminating treatment. To the right of your statements, check the appropriate boxes to indicate when your beliefs reflect one or more of the seven steps in the valuing process. Is your belief a value according to the valuing process?

9. Rank in order the following 12 potential nursing actions, using "1" to indicate the most important choice in a client–community health nurse relationship and "12" to indicate the least important choice:

Statement	1 Freely chosen	2 Alternatives	3 Consequences	4 Cherished	5 Affirmed	6 Incorporated	7 Employed

___Touching clients
___Empathetically listening to clients
___Disclosing yourself to clients
___Becoming emotionally involved with clients
___Teaching clients
___Being honest in answering clients' questions
___Seeing that clients conform to professionals' advice
___Helping to decrease clients' anxiety
___Making sure that clients are involved in decision-making
___Following legal mandates regarding health practices
___Remaining "professional" with clients
___(Add an alternative of your own)

Examine your ordering of these options. What values can be identified based on your responses in this exercise? How do these values emerge in your behavior?

10. Request to attend one or two sessions of an ethics committee meeting of a community health agency or a local acute care hospital. Observe and make notes on (a) what values are evident in the discussion, (b) what ethical principles are used, (c) what decision-making framework is used, and (d) what you would have liked to

contribute if you had been a member of the committee.

5 CHAPTER

Transcultural Nursing in the Community

"People everywhere share common biological and psychological needs, and the function of all cultures is to fulfill such needs; the nature of the culture is determined by its function."

—*Bronislaw Malinowski* (1884–1942), Cultural Anthropologist

"Looking from far and above, from our high places of safety in the developed civilization, it is easy to see all the crudity and irrelevance of magic. But without its power and guidance early man could not have mastered his practical difficulties as he has done, nor could man have advanced to the higher stages of civilization."

—*Horace Miner* (1912–1993), Anthropologist

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Define and explain the concept of culture.
- Discuss the meaning of cultural diversity and its significance for community health nursing.
- Describe the meaning and effects of ethnocentrism on community health nursing practice.
- Identify five characteristics shared by all cultures.
- Contrast the health-related values, beliefs, and practices of selected culturally diverse populations with those of the dominant U.S. culture.
- Conduct a cultural assessment.
- Apply principles of transcultural nursing in community health nursing practice.

American society values individuality, and we are a country of immigrants. Many different cultural groups and races built this nation. For example, pilgrims came here hundreds of years ago, to seek freedom to practice their religious beliefs. It took a powerful independent resolve to pioneer the West in the 1800s. Partly because of this pioneer spirit, people from all nations have sought to live in America. Some came of their own free will for adventure and opportunity. Others saw this land as a refuge from political, religious, or economic strife. Still others were brought here against their will. Consequently, we have not become the ideal *melting pot* once described, but, rather, an amalgamation of people who have different values, ideals, and behaviors.

Americans have many differences, but we also have much in common. In the Western culture, there is joy in seeing children grow and develop in unique ways. An individual's creative achievements are applauded. There is also respect for one another's personal preferences about food, dress, or personal beliefs. The right to be oneself—and thereby to be different from others—is even protected by state and federal laws.

Although individuality is a cherished American value, there are limits to the range of differences most Americans find acceptable. People whose behavior falls outside the acceptable range may be labeled as misfits. For example, the U.S. culture approves of moderate social drinking, but not alcoholism. The beliefs and sanctions of the dominant or majority culture are called dominant values. In the United States, the majority culture is made up largely of non-Hispanic Whites, whose dominant values include the work ethic, thrift, success, independence, initiative, privacy, cleanliness, youthfulness, attractive appearance, and a focus on the future. However, in some regions and states, non-Hispanic Whites are not the majority. For example, in California, only 40% of the population is non-Hispanic White (California Pan-Ethnic Health Network, 2015). Between 2010 and 2050, the proportion of the population identified as White is projected to continue to fall below other ethnicities (U.S. Census Bureau, n.d.a.).

Dominant values reflect the cultural power differentials that exist in this country in that powerful groups "invoke structure in their own interests while the less powerful are more constrained" (Roscigno, 2012, para. 8). The powerful exert control over political, economic, and social structures that influence all members of society. Many years ago, this country put laws into place prohibiting discrimination on the basis of "race, color, religion, national origin, and sex," as well as qualified disabled persons (U.S. Equal Employment Opportunity Commission, n.d., para. 1). But, Alexander (2012, p. *x*) sees a new "racial caste system alive and well in the age of colorblindness" as evidenced by the high proportion of incarcerations among nondominant groups, especially Blacks. Schrecker and Bambra (2015) argue that political decisions affect the health of populations, specifically those that began with deregulation, private sector growth, and reductions in government spending in this country and others, have led to increased rates in poverty, inequality, obesity, and other health problems tied to the social determinants of health. (See Chapters 13 and 25 for more on social determinants of health.)

Given this awareness, dominant values are important to consider in the practice of community health nursing because they can shape people's thoughts and behaviors. Why are some client behaviors acceptable to health professionals and others not? Why do nurses have such difficulty persuading certain clients to accept new ways of thinking and acting? Explanations can be found by examining the concept of culture, especially its influence on health and on community health nursing practice. For example, an emphasis on the need for milk in the diet may reflect cultural blindness, considering the number of people from diverse ethnic groups who are lactose intolerant, and food allergies appear to go undiagnosed in minority children (Taylor-Black & Wang, 2012). Regardless of their own cultural backgrounds, nurses are socialized throughout the educational process; the biomedical model is frequently the framework, and dominant social values are often involuntarily reinforced.

THE MEANING OF CULTURE

Culture refers to the beliefs, values, and behavior that are shared by members of a society and provide a template or "road map" for living. Culture tells people what is acceptable or unacceptable in a given situation. Culture dictates what to do, say, or believe. Culture is learned. As children grow up, they learn from their parents and others around them how to interpret the world. In turn, these assimilated beliefs and values prescribe desired behavior. We think of this as learned behavior, but can culture actually impact your neurobiology? For more on this see What Do You Think?

What do *you* think?

CAN CULTURE AFFECT YOUR NEUROBIOLOGY?

The neuroscience of culture is an emerging area of research. Studies that link cognitive neuroscience with cultural and social psychology include those examining "emotion, perspective-taking, memory, object perception, attention, language, and the self" (Rule, Freeman, & Ambady, 2013, p. 3). For instance, researchers studied brain activity through the use of functional magnetic resonance imaging (fMRI) while both young and elderly American and East Asian participants were shown a

series of images depicting various objects on different backgrounds. For both cultures, the younger subjects demonstrated similar brain activity. But a marked contrast was noted between the older subjects, with the neural responses of those only from the East Asian culture showing minimal activity to changes of single objects while the Americans' activity in the lateral occipital complex was continually active (Burton, 2007). Americans were more focused on the individual objects as new ones were introduced, but the East Asians maintained focus on the background information and not on new individual objects, according to earlier research. The explanation for this is that Asian culture is "less individual-oriented than Western culture" and more interdependent (p. 6). Even with Westernization, they feel that these differences demonstrate that "culture is sculpting the brain at the level of perception"—evidence that culture can impact us on a biological level (p. 6).

A later study by Ng, Han, Mao, and Lai (2010) used similar methods to examine neural representation of self and significant others among a sample of "Westernized bicultural Chinese" (p. 83). While undergoing fMRI imaging, participants were asked to make trait judgments regarding self, mother, or an unidentified individual. Either Western or Chinese culture priming was used before the testing. Those with Western priming demonstrated an increased differentiation of self from either mother or unidentified individual, but Chinese priming subjects showed less differentiation. The results of a quantitative meta-analysis of 35 fMRI studies "suggest that cultural differences in social and non-social processes are mediated by distinct neural networks" (Han & Ma, 2014, p. 293). The differences between Western and East Asian study participant neural activity emphasized the individual versus other-oriented cultures.

Korn et al. (2014, para. 1) used the board game, *Monopoly*, to test "cultural influences on social conformity, positivity biases, and self-related neural activity" in two groups of participants (one of German and the other of Chinese origin). Each participant played a timed game with three other people from the same cultural background, and all of them were asked to rate the other three players on 40 negative and 40 positive adjectives (using a 4-point Likert scale). The means were shared with each participant before a second timed game began, and participants were tested to determine how much influence this feedback had in their own personality ratings before and after the feedback. Greater conformity to social feedback was found among the Chinese participants and less among the Germans. Also, all participants processed the feedback from others in a way that was biased toward the positive, or changed behavior based on more pleasant feedback, and cultural groups showed no differences. Germans had greater self-related changes in prefrontal activity during the feedback-processing period when compared to Chinese; the researchers noted that this real-life interaction by way of a board game added to the knowledge of cultural diversity.

Functional MRI was used to examine the neurobiological basis of shame and

guilt (Michl et al., 2014). One study examined German participants, and compared results with a previous study using Japanese participants. Both groups demonstrated similar areas of brain activity for both shame and guilt states; however, the similarity did not extend to gender, as there was a difference for women experiencing guilt. Women showed neural activity in the temporal regions, but men had additional activity in the frontal and occipital areas of the brain, as well as the amygdala. Could this be due to culturally different gender roles?

Generally, anthropologists describe culture as systems of beliefs, values, and norms of behavior found in all societies. This is more than simply custom or ritual; it is a way of organizing and thinking about life. It gives people a sense of security about their behavior; without having to consciously think about it, they know how to act. Culture also provides the underlying values and beliefs on which people's behavior is based. For example, culture determines the value placed on achievement, independence, work, and leisure. It forms the basis for the definitions of male and female roles. It influences a person's response to authority figures, dictates religious beliefs and practices, and shapes child-rearing. Giger (2017) describes culture as a patterned response of behavior that develops from the impact of social and religious structures in a community. This develops over time from infancy through old age and can be apparent in a community's intellectual and artistic achievements.

Every community and social or ethnic group has its own culture. Furthermore, all of the individual members believe and act based on what they have learned within that specific culture. As anthropologist Edward Hall (1959) said over a half-century ago, culture controls our lives. Even the smallest elements of everyday living are influenced by culture. For instance, culture determines the proper distance to stand from another person while talking with him or her. A comfortable talking distance for Americans is at least 2.5 feet, whereas Latin Americans prefer a shorter distance for dialogue, often only 18 inches. Culture also influences one's perception of time. In the non-Hispanic White American

culture, when someone makes an appointment, it is expected that the other person will be on time, or not more than a few minutes late; to keep a person waiting (or to be kept waiting) for 45 minutes or more is considered insulting. Yet other cultural groups, including Native Americans and Hispanics, have a much more flexible response to time. Their members feel that time is much more elastic, and if someone is kept waiting, it is not considered a thoughtless act. So, as you can see, culture is the knowledge people use to design their own actions and, in turn, to interpret others' behavior (Spradley, McCurdy, & Shandy, 2015).

Culture influences rules about the appropriateness of public displays of affection.

Cultural Diversity

Race refers to biologically designated groups of people whose distinguishing features, such as skin color, are inherited; examples include Asian, Black, and White, although the term race is more of a social construct because humans are one species. An ethnic group is an assemblage of people who have common origins and a shared culture and identity; they may share a common geographic origin, race, language, religion, traditions, values, and food preferences (Spector, 2013). When a variety of racial or ethnic groups join a common, larger population, cultural diversity becomes more apparent and more easily distinguished. Cultural diversity, also called *cultural plurality*, means that a variety of cultural patterns coexist within a designated geographic area. Cultural diversity occurs not only between countries or continents but also within many countries, including the United States (Spector, 2013). However, the term *culture*, used alone, has no single definition. We have defined it for use in this book at the beginning of this section. Others have described culture as meaning the total, socially inherited characteristics of a group, comprising everything that one generation can tell, convey, or hand down to the next generation.

Cultural diversity in the United States began when Native Americans were challenged by early foreign settlements. Early settlers came primarily from European countries through the 1800s, peaking in numbers just after the turn of the 20th century, with almost 9 million immigrants admitted in the first decade. During much of that time, especially during the late 1600s through the early 1800s, Africans were enslaved and brought to the United States against their will, mostly to southern states, where they were sold to plantation owners as property in order to labor on large plantations and farms. Slavery and cultural oppression has had profound effects for many generations (Klein, 2012). Immigration stayed high during the early 1900s, and then dropped sharply from 1930 to 1950. Immigration from non-European regions, such as Asia and South America, then steadily increased. The total number of immigrants from all countries in the 1990s actually exceeded the number who arrived during the first decade of the 1900s, when immigration was formerly at its peak (Table 5–1).

Table 5–1 Immigrants to the United States, 1901–2013

Decade	Number of Immigrants
1901–1910	8,795,386
1911–1920	5,735,611
1921–1930	4,107,209
1931–1940	528,431
1941–1950	1,035,039
1951–1960	2,515,479
1961–1970	3,322,677
1971–1980	4,493,314
1981–1990	7,338,062
1991–2000	9,095,417
2001–2013	2,052,593

From Baker, B., & Rytina, N. (2014). U.S. lawful permanent residents 2013. Department of Homeland Security Annual Flow Report. Retrieved from https://www.dhs.gov/sites/default/files/publications/ois_lpr_pe_2013_0.pdf

Currently, the foreign-born population is believed to be a difficult group to count, and that increases the likelihood of coverage error for this population. English language ability, literacy skills, understanding of the census, residential attachment, and legal status are all factors that contribute to coverage error in censuses and surveys (Jensen, Bhaskar, & Scopilliti, 2015). More accurate counts come from the immigrants seeking naturalization, becoming United States citizens. As shown in Table 5–2, immigrants come from all regions of the world, in greater numbers from some areas than others (Monger & Yankay, 2014).

Table 5–2 Persons Obtaining Legal Permanent Resident Status by Region of Birth, 2013

Race and Hispanic/Latino Origin	Census 2000, Population	Percent of Population	Census 2010, Population	Percent of Population	Percent Change, 2000–2010
Total Population	**281,421,906**	**100.0%**	**308,745,538**	**100.0%**	**+9.7%**
White	211,460,626	75.1	196,817,552	63.7	–5.7
Black or African American	34,658,190	12.3	37,685,848	12.2	+12.3
American Indian and Alaska Native	2,475,956	0.9	2,247,098	0.7	–18.4
Asian	10,242,998	3.6	14,465,124	4.7	–43.3
Native Hawaiian and other Pacific Islander	398,835	0.1	481,576	0.15	+35.4
Hispanic or Latino	35,305,818	12.5	50,477,594	16.3	+43.0

Although the numbers of legal immigrants have dropped, illegal immigration continues to be a controversial topic in this country, especially after the tragedy of 9/11. Plans to end the flow of illegal immigrants from Mexico included building a 700-mile fence along the border, and legislation that more stiffly penalized employers of undocumented workers. In the late 20th and early years of the 21st century, the numbers of migrants losing their lives while crossing illegally into this country rose dramatically, from 87 in 1999 to 417 in 2009. That number only includes the known deaths, and does not include those who may have died and whose bodies were not found (Sacchetti, 2014). While social justice is an important issue in public health nursing, what is often not considered in the national debate over this issue is the economic desperation that drives people to put themselves in such jeopardy. The issue of social justice is discussed more in Chapters 13 and 29.

Table 5–3 U.S. Population by Race and Hispanic/Latino Origin, Census 2000 and 2010 Estimate

Race and Hispanic/Latino Origin	Census 2000, Population	Percent of Population	Census 2010, Population	Percent of Population	Percent Change, 2000–2010
Total Population	**281,421,906**	**100.0%**	**308,745,538**	**100.0%**	**+9.7%**

The United States is changing to a majority–minority nation (Table 5–3). A recent census projection report states that by 2044, more than 50% of Americans will belong to a

minority group, or one other than non-Hispanic White. In some states, especially those bordering Mexico and some industrialized states in the eastern part of the country, the most current information reveals that this change already has occurred or will occur much sooner than 2044 (Colby & Ortman, 2015). See Display 5–1.

DISPLAY 5.1 HISPANIC POPULATION TREND IN THE UNITED STATES

In 2013, a record number of 41.3 million (or 13.1%) of the population were foreign born. Of the total immigrant population in the United States, 25.8% are from Mexico, 25.8% from Asia, 24% from Latin America and only 14.2% from Europe and Canada. The face of immigration has shifted, from Europe and Canada sending the largest proportion in the 1960s to the current larger influx from Mexico, Asia, and Latin America. The mean age of immigrants also differs by region of origin; the median age for those from Europe and Canada is 52 years, whereas Mexican immigrants have a median age of 39 years. Children of immigrants who are

born in the United States, considered second-generation Americans, constitute 11.7% of our U.S. population. The level of education of immigrants has risen steadily since the 1960s, with the most dramatic gains among those from Asia, Europe, and the Middle East. The unauthorized immigrant population has grown rapidly over the past three decades, hitting a peak at 12.2 million. It had since dropped to 11.2 million and continues to remain fairly steady at about 4% of the population. Unauthorized Mexican immigrants fell from a 6.9 million peak in 2007 to 5.9 million in 2012. It estimated that about one fourth of the foreign-born population in the United States are unauthorized immigrants; the vast majority are in the United States legally, and 41.8% are naturalized citizens (Pew Research Center, 2015).

A common political talking point is the number of infants born in the United States to unauthorized immigrants. This number has declined to 295,000 in 2013 from a high of 370,000 in 2006–2007. The 14th Amendment of the Constitution automatically grants the right to citizenship to anyone born within the United States Currently, there are approximately 4.5 million U.S.-born children under age 18 living with parents who are unauthorized immigrants. Also, these immigrants are now more likely to be long-term U.S. residents than in the past (Pew Research Center, 2015).

From Pew Research Center. (2015). Hispanic trends. Retrieved from http://www.pewhispanic.org

The fastest growing group is projected to be those people reporting two or more races, growing from 8 million in 2014 to 26 million in 2060. This would increase from 2.5% of the total U.S. population in 2014 to 6.2% by 2060. The second fastest growing group is projected to be Asians, growing from 5.4% of the total population in 2014 to 9.3% of the total population in 2060 (Colby & Ortman, 2015)

Hispanics surpassed the African American population as the largest minority group in the United States in 2010 and in the 2014 census, constituted 17.4% of the population with 55 million people (Office of Minority Health, 2015). This population group is expected to increase to 119 million in 2060. Although this is only the third fastest growing population group, they are expected to constitute 29% of the total population. Among African Americans, the Black population alone is expected to grow from 42 million in 2014 to 60 million in 2060. This would place the group at 14% of the U.S. population, well below the percent of Hispanics (Colby & Ortman, 2015). Asian–Pacific Islanders are expected to more than double their numbers, to 9.3% of the U.S. population; the American Indian and Alaska Native population is expected to be stable at or near 1% (Colby & Ortman, 2015).

Immigration patterns are strongly influenced by immigration laws established since the 1800s. The Immigration Reform and Control Act of 1986 (Public Law 99-603) and the

Immigration Act of 1990 (Public Law 101-649) set new limits on the number of immigrants admitted. These laws set annual numerical ceilings on certain immigrant groups while authorizing increases for highly skilled workers or family members of aliens who have recently achieved legal status. After the terrorist attacks on September 11, 2001, U.S. President George Bush suspended all immigration for 2 months. Suspicion about people from Middle Eastern countries permeated the nation—worsening the social climate for immigrants. More currently, political upheaval and war have sent refugees and migrants from the Middle East, South Asia, and Africa are flooding into Europe. Almost one half million migrants crossed boundaries in Europe during just the first 9 months of 2015, many seeking asylum from Syria's civil war (Park, 2015). As countries, including the United States, wrestle with the social and political issues, there is no coordinated effort to quickly find placements for the continual stream of people. The social climate in the U.S and many other countries is characterized by ambivalence about whether immigrants should be accepted and ambiguity about their status. The newcomers find an environment that is both welcoming and hostile. On the one hand, they may find tolerance of diversity in the United States—demonstrated by interest in ethnic food, cultural celebrations, and sensitivity to employees from different backgrounds. On the other hand, a backlash is demonstrated by a rise in hate crimes, national and local policies that limit services to undocumented immigrants, restriction in English as a Second Language (ESL) and bilingual education, and limits to potential class action suits challenging practices of the U.S. Citizenship and Immigration Services and Department of Homeland Security.

Although broad cultural values are shared by most large national societies, those societies contain smaller cultural groups—called subcultures. Subcultures are relatively large aggregates of people within a society who share separate distinguishing characteristics, such as ethnicity (e.g., African American, Hispanic American), occupation (e.g., farmers, physicians), religion (e.g., Catholics, Muslims), geographic area (e.g., New Englanders, Southerners), age (e.g., the elderly, school-age children), gender (e.g., women, men), or sexual preference (e.g., gay, lesbian). Within these subcultures are even smaller groups that anthropologists call microcultures. Microcultures have been described as collections of knowledge that is unique or characteristic of specific subgroups within a larger culture. People belonging to a microculture usually share much of what they know with others in the community as they hold a special cultural knowledge that is unique to the subgroup (Spradley et al., 2015). Examples of microcultures can range from a group of Hmong immigrants from Southeast Asia adopting selected aspects of U.S. culture to a third-generation Norwegian American community whose members share unique foods, dress, and values.

The members of each subculture and microculture retain some of the characteristics of the society from which they came or in which their ancestors lived, as noted by the eminent anthropologist Margaret Mead (1960). Some of their beliefs and practices—such as the food they eat, the language they speak at home, the way they celebrate holidays, or their ideas about sickness and healing—remain an important part of their everyday life.

American Indian or Native American groups have retained some aspects of their traditional cultures. Mexican Americans, Irish Americans, Swedish Americans, Italian Americans, African Americans, Puerto Rican Americans, Chinese Americans, Japanese Americans, Vietnamese Americans, and many other ethnic groups have their own microcultures.

Native American groups retain some aspects of their traditional culture. (Photo courtesy USA.gov)

Furthermore, certain customs, values, and ideas are unique to the poor, the rich, the middle class, women, men, youth, or the elderly. Many deviant groups, such as narcotics abusers, transient alcoholics, gangs, criminals, and terrorist groups, have developed their own microcultures. Regional microcultures, such as that of the White and Black Appalachian people living in the hills and hollows of Kentucky or West Virginia, also have distinctive ways of defining the world and coping with life. Other microcultures, such as those of rural migrant farm workers or urban homeless families, acquire their own sets of beliefs and patterns for dealing with their environments. Many religious groups have their own microcultures. Even occupational and professional groups, such as nurses or attorneys, develop their own special languages, beliefs, and perspectives.

Ethnocentrism

There is a difference between a healthy cultural or ethnic identification and ethnocentrism. Anthropologists generally note that ethnocentrism is an expression of the belief that one's culture of origin is the best approach to life. It is a reflection of judgment on the beliefs and practices of others using our native culture as a reference point (Spradley et al., 2015). It causes people to believe that their way of doing things is right and to judge others' methods as inferior, ignorant, or irrational. Ethnocentrism blocks effective communication by creating biases and misconceptions about human behavior. In turn, this can cause serious damage to interpersonal relationships and interfere with the effectiveness of nursing interventions (McFarland & Wehbe-Alamah, 2015).

People can experience a developmental progression along a continuum from ethnocentrism, feeling one's own culture is best, to ethnorelativism—seeing all behavior in a cultural context (Blair & Jansen, 2015). Some people may stop progressing and remain stagnated at one step, and others may move backward on the continuum. The left side of the continuum represents the most extreme reaction to intercultural differences: refusal or denial. On the right side is the characterization of people who show the most sensitivity to intercultural differences: incorporation (Fig. 5–1).

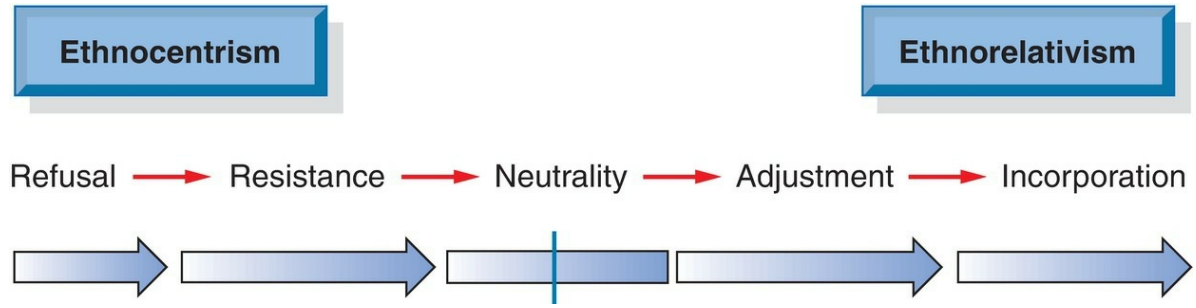

FIGURE 5–1 Cross-cultural sensitivity continuum. Being extremely ethnocentric (left of midpoint) and totally ethnorelative (far right) are reflected in the diagram. The steps toward ethnorelativism begin at the most ethnocentric view, with refusal and resistance. Neutrality is midpoint, and adjustment and incorporation bring the person to an ethnorelative perspective.

CHARACTERISTICS OF CULTURE

In their study of culture, anthropologists and sociologists have made significant contributions to the field of community health. Their findings shed light on why and how culture influences behavior. Five characteristics shared by all cultures are especially pertinent to nursing's efforts to improve community health: culture is learned, it is integrated, it is shared, it is tacit, and it is dynamic.

Culture is Learned

Patterns of cultural behavior are acquired, not inherited. Rather than being genetically determined, the way people dress, what they eat, and how they talk are all learned. Spradley et al. (2015) described that when born, we do not have culture and lack a system of beliefs, knowledge and patterns of behavior. In the family and community environment throughout our lives, we are part of a general system of learning in our home culture. For example, laughing and smiling are general human responses, but we learn from our culture when to laugh, when to smile, what is considered humorous. All humans can cry, but when we cry and how we cry is tied to our cultural practices.

Each person learns about culture through socialization with the family or significant group, a process called enculturation. As a child grows up in a given society, he or she acquires certain attitudes, beliefs, and values and learns how to behave in ways appropriate to that group's definition of the female or male role; by doing so, children are learning about their culture (Spector, 2013; Spradley et al., 2015).

Family socialization helps acculturate children to acquire shared values and attitudes. (Photo courtesy of CDC Photo Image Library.)

Although culture is learned, the process and results of that learning are different for each person. Each individual has a unique personality and experiences life in a singular way; these factors influence the acquisition of culture. Families, social classes, and other groups

within a society differ from one another, and this sociocultural variation has important implications (Andrews & Boyle, 2016). Because culture is learned, parts of it can be relearned. People might change certain cultural elements or adopt new behaviors or values. Some individuals and groups are more willing and able than others to try new ways and thereby influence change.

Culture is Integrated

Rather than being merely an assortment of various customs and traits, a culture is a functional, integrated whole. As in any system, all parts of a culture are interrelated and interdependent. The various components of a culture, such as its social mores or religious beliefs, perform separate functions but come into relative harmony with each other to form an operating and cohesive whole. In other words, to understand culture, single traits should not be described independently. Each part must be viewed in terms of its relationship to other parts and to the whole.

A person's culture is an integrated web of ideas and practices. For example, a nurse may promote the need for consuming three balanced meals a day, a practice tied to the beliefs that good nutrition leads to good health and that prevention is better than cure. These cultural beliefs, in turn, are related to the nurse's values about health. Health, the nurse believes, is essential for maximum energy output and productivity at work. Productivity is important because it enables people to reach goals. These values are linked to social or religious beliefs about hard work and taboos against laziness. Through such connections, these ideas and beliefs about nutrition, health, economics, religion, and family are all interrelated and work to motivate behavior.

For example, parents who are Jehovah's Witnesses may refuse a blood transfusion for their child. Their actions might seem irrational or ignorant to those who do not understand the parents' religious beliefs. However, the couple's choice represents behavior consistent with their cultural values and standards. The single behavior of refusing blood transfusions, when viewed in context, is seen to be part of a larger religious belief system and a basic component of the parents' culture. Even mothers' expectations for their children's development can vary between cultures (Damon, Borstein, & Leventhal, 2015)—something to keep in mind when we use developmental screening tools.

In some cultural groups (e.g., Muslims), modesty for women may make it uncomfortable and perhaps traumatic to be examined by a person of the opposite sex (Lovering, 2012). Asking certain Native American groups to comply with rigid appointment scheduling requires them to reframe their concept of time. It also violates their values of patience and pride (Spector, 2013). Before nurses attempt to change a person's or group's behavior, they need to ask how that change will affect the people involved through its influence on other parts of their culture. Extra time and patience or different strategies may be needed if change still is indicated. Nurses often may find, however, that their own practice system can be modified to preserve clients' cultural values.

Culture is Shared

Culture is the product of aggregate behavior, not individual habit. Certainly, individuals practice a culture, but customs are phenomena shared by all members of the group. More than 40 years ago, anthropologist George Murdock explained (1972, p. 258):

> Culture does not depend on individuals. An ordinary habit dies with its possessor, but a group habit lives on in the survivors and is transmitted from generation to generation. Moreover, the individual is not a free agent with respect to culture. He is born and reared in a certain cultural environment, which impinges on him at every moment of his life. From earliest childhood his behavior is conditioned by the habits of those around him. He has no choice but to conform to the folkways current in his group.

A culture's values are among its most important elements (see Chapter 4). A value is a notion or idea designating relative worth or desirability. For example, some cultures place value on honesty, loyalty, and faithfulness more than other traits. Also, there may be strong values against lying, stealing, and cheating—behaviors to avoid. Each culture classifies phenomena into good and bad, desirable and undesirable, right and wrong. When people respond in favor of or against some practice, they are reflecting their culture's values about that practice. One person may eagerly anticipate eating a steak for dinner; another, who believes that eating meat is sacrilegious or unhealthful, experiences revulsion at the idea of steak for a meal. Some American subcultures think that loud, vocal expressions are a necessary way to deal with pain; others value silence and stoicism. Some have high regard for speed and efficiency, whereas others prefer patience and thoughtfulness. Either way, values serve a purpose. Shared values give people in a specific culture stability and security and provide a standard for behavior. From these values, members know what to believe and how to act (Andrews & Boyle, 2016). The normative criteria by which people justify their decisions are based on values that are more deeply rooted than behaviors and, consequently, more difficult to change.

Knowing that culture is shared helps us to better understand human behavior. For example, a community health nurse tried unsuccessfully to persuade a mother to limit the amount of catnip tea she fed her infant. The infant was pacified with the tea and was not consuming a sufficient amount of infant formula, thus putting him at risk for nutritional deficiencies and developmental problems. The nurse discovered that the mother was acting in the tradition of her rural subculture, which held that catnip promoted good health as it acts as an antispasmodic, perhaps causing relaxation and resulting in a more contented infant with fewer symptoms of colic (Spector, 2013). The fact that all of the other mothers in her small rural community also used catnip with their babies proved a powerful deterrent to the change suggested by the nurse. Other members of the same culture frequently influence health behaviors. It is difficult for one person to eliminate a cultural practice, especially if reinforced by so many other members of the group. Group acceptance and a sense of membership usually depend on conforming to these shared cultural practices

(Spradley et al., 2015).

Community health nurses may need to focus on an entire group's health behavior to affect individual practices. In the example described, the pattern of consuming large amounts of catnip tea was modified after the nurse worked with the entire rural community. She began with a well-recognized cultural strategy: working through formal or informal leaders. She contacted the oldest woman in the community and discussed the cultural practice. The elder shared the group's beliefs that catnip tea is vital to the well-being of infants for the first 6 months. When the nurse explained her concerns about low formula intake and low weight gain, the community leader clarified that only 1 or 2 ounces of the tea a day was needed. The nurse and the community leader shared this information among the women, and, as a result, the mothers gradually reduced the amount of tea they gave their infants. Consequently, the clients' infants drank more formula and gained weight. A cultural tradition was retained while the health of the infants improved. The community health nurse could then use this new information and other supportive information from the community leader to improve the health of more infants (Spector, 2013).

Culture is Generally Tacit

Culture provides a guide for human interaction that is tacit—that is, mostly unexpressed and at the unconscious level. Members of a cultural group, without the need for discussion, know how to act and what to expect from one another. Culture provides an implicit set of cues for behavior, not a written set of rules. Spradley et al., (2015) explained that culture often lies below a conscious level because it is such a regular and pervasive part of the daily environment. It is like a memory bank in which knowledge is stored for recall when the situation requires it, but this recall process is mostly unconscious. Culture teaches the proper tone of voice to use for each occasion. It prescribes how close to stand when talking with someone and how one should appropriately respond to elders. Individuals learn to make responses that are appropriate to their gender, role, and status. They know what is right and wrong. As an example, one study's researchers found that children's storybooks authored by Native Americans portrayed humans as more connected to nature than did those by non-Native authors (Dehghani et al., 2013). All of these attitudes and behaviors become so ingrained—so tacit—that they are seldom, if ever, discussed.

Because culture is mostly tacit, realizing which of one's own behaviors may be offensive to people from other groups is difficult. It also is difficult to know the meaning and significance of other cultural practices. In some groups, such as American Indians or Islamic women, silence is valued and expected, but may make others uncomfortable. Offering food to a guest in many cultures is not merely a social gesture but an important symbol of hospitality and acceptance; to refuse it, for any reason, may be an insult and a rejection. Touching or calling someone by their first name may be viewed as a demonstration of caring by some groups, but is seen as disrespectful and offensive by others. Even how one trusts others in a group context is affected by cultural influences, and communities with multiple ethnic groups may not exhibit social cohesiveness (van der Meer & Tolsma, 2014). Consequently, community health nurses have a twofold task in developing cultural sensitivity: not only must we try to learn clients' cultures, but we also must try to make our own culture less tacit and more explicit. We must be more aware of our own biases and preconceived values and beliefs. Nurses bring both their professional and personal cultural history to the workplace, often developing unique values not shared with others who are not in the profession (Blais & Hayes, 2015). Cross-cultural tension can be resolved through conscious efforts to develop awareness, patience, and acceptance of cultural differences (Display 5–2).

DISPLAY 5.2 CULTURE SHOCK

An increasing number of immigrants and refugees from many different countries have been assimilated into American culture in recent years. Although they quickly adapt in many respects, such as learning the language and seeking housing and employment, they continue to operate within the framework of their own cultural beliefs and behaviors. The conflict between their culture and American culture often causes culture shock. This has been termed as a state of anxiety that may result from cross-cultural misunderstanding; people in culture shock may experience difficulty interacting with others in the new environment (Spradley et al., 2015). Immigrants and refugees find themselves in a strange setting with people who act in unfamiliar ways. Speaking their own language in their homes and retaining values and familiar practices all help to promote some sense of security in the new environment.

The same is true for nurses and others working in unfamiliar countries. No longer are the small but important cues available that orient a stranger to appropriate behavior. Instead, a person in a different culture may feel isolated and anxious and even become dysfunctional or ill. Immersion in the culture over time and learning the new culture are the major remedies. As adjustment occurs, old beliefs and practices that are still functional in the new setting can be retained, but others that are not functional must be replaced.

Culture is Dynamic

Every culture undergoes change; none is entirely static. Within every cultural group, some individuals generate innovations. More important, some members see advantages in doing things differently and are willing to adopt new practices. Each culture is an amalgamation of ideas, values, and practices from a variety of sources. This process depends on the extent of exposure to other groups. Nonetheless, every culture is in a dynamic state of adding or deleting components. Functional aspects are retained; less functional ones are eliminated.

When this adaptation does not occur, the cultural group may face serious difficulty. For example, Hmong teenagers from Southeast Asian refugee families in the United States are among the first generation to be raised in America. Their parents had high hopes for them to restore honor and pride to a displaced people, but the teens struggle to balance their American lifestyle with Hmong traditions. The stresses they feel as a result of the generational and cultural gaps between themselves and their parents are often overwhelming. Hmong community leaders, community health workers, school districts, law enforcement, and Hmong families have joined together to develop interventions to address these issues (see Perspectives: Voices from the Community). Recent prospective research indicates that ethnic identity is positively associated with self-esteem among Asian American adolescents, including Hmong community members (Gertner, Kiang, & Supple, 2014).

PERSPECTIVES VOICES FROM THE COMMUNITY

"*The European immigrants who emerged from the Ford Motor Company melting pot came to the United States because they hoped to assimilate*

into mainstream American society. The Hmong came to the United States for the same reason they had left China in the 19th century: because they were trying to resist assimilation. What the Hmong wanted here [in the United States] was to be left alone to be Hmong: clustered in all-Hmong enclaves, protected from government interference, self-sufficient, and agrarian (p. 183)."

—Fadiman, A. (1998). *The spirit catches you and you fall down: A Hmong child, her American doctors, and the collision of two cultures. New York, NY: Farrar Straus & Giroux*.

"*You are talking about parents who are medieval, coming to a country that is hundreds of years ahead of theirs. They're trying to catch up, but it's hard.*"

—Mymee (college instructor)

"*There is much research that shows people who stand in the middle of two cultures are really at risk of depression and anxiety.*"

—Valerie (psychologist)

"*The kids are constantly living between two cultures. At some point, they may give up.*"

—Leng (psychologist, Southeast Asian adult services center)

"*I think it's a topic that nobody wants to talk about. It's hard for me to say if the Hmong community is ready to deal with it.*"

—Xong (social worker, Hmong suicide task force)

"*We parents think we know only one way to raise our kids. We ignore that these children are living in America and are espousing everything that is American, good and bad.*"

—Andy (Hmong parent)

Adapted from Ellis, A. D. (2002, August 11). Hmong Teens: Lost in America [special report]. The Fresno Bee, 1–12.

Another example of problematic cultural adaptation is the case of the "one child rule" in China. In an effort to contain population growth, in 1979, China began limiting married couples to having only one child. For several years, the government strictly enforced this policy, with few exceptions. Because male offspring are more highly valued than female in the Chinese culture, there was a significant increase in the ratio of male to female births. Couples who had a female infant might choose to place the baby in an orphanage and make her available for adoption, and, although they are considered illegal, it is thought that a large number of sex-selective abortions occur. The goal of the government's policy was to change the Chinese culture from large-to small-family preference, and recent surveys indicate that this appears to be taking place. However, there are unplanned consequences of this cultural shift; inadvertently improving gender equality

in education of children (Lee, 2012). Another interesting finding is that mothers having only one child show a higher probability of being overweight (Wu & Li, 2012). In 2013, the government had relaxed the one-child policy for those spouses who were only children; however, only about 12% of eligible couples had applied to have a second child by May of 2015. In late 2015, the Chinese government announced its plans to permit married couples to now have two children. A government commission noted that this would help to reduce economic pressures from an aging population, and would also eventually lead to a larger labor supply. When asked about plans for more children, many Chinese citizens expressed an indifferent attitude. Many were concerned about the cost of an additional child, as well as the greater parenting burden, but were glad to see this change (Buckley, 2015).

Community health nurses must remember the dynamic nature of culture for several reasons. First, cultures and subcultures do change over time. Patience and persistence are key attributes to cultivate when working toward improving health behaviors. Second, cultures change as their members see greater advantages in adopting "new ways." Discussions of these advantages need to be conducted in a language understood by members and in the context of their own cultural value system. This is an important reason for nurses to develop an understanding of their clients' culture and to deliver culturally competent care (Andrews & Boyle, 2016; McFarland & Wehbe-Alamah, 2015). Third, it is important to remember that, within a culture, change may occur because of certain key individuals who are receptive to new ideas and are able to influence their peers. These key persons can adapt the change process, so that "new" practices are culturally consistent and fit with group values. Tapping into this resource becomes imperative for successful change. Finally, the health care culture is dynamic, too. Westerners are just beginning to appreciate the validity of many non-Western health care practices such as acupuncture, meditation, and the use of various therapeutic herbs and spices (e.g., turmeric, fenugreek). We can learn much from our clients and their cultures (Grandbois & Sanders, 2012; Spector, 2013) (see Perspectives: Voices from the Community).

ETHNOCULTURAL HEALTH CARE PRACTICES

Throughout history, people have relied on natural elements to treat various maladies that family, clan, tribe, or community members experience. Knowledge of culturally recognized practices or substances, such as berries, plants, barks, or rituals and incantations usually becomes the responsibility of one person in the community. This revered community leader is known as a medicine man/woman, healer, or shaman (Spector, 2013). As time passes, this person teaches the skills of recognizing and treating ailments or performing rituals to an apprentice, thereby continuing the healing knowledge and traditions.

In the following sections, we discuss how various geographic or ethnocultural groups view health care, including the biomedical, magicoreligious, and holistic views. You may encounter many distinctive ways that your clients manage their health and illness, so we will discuss selected folk medicines and home remedies, such as herbs, over-the-counter (OTC) drugs, and patent medications. In addition to these forms of treatments, there are complementary or alternative therapies (e.g., folk remedies) and various self-care practices. This section concludes with the community health nurse's role and responsibilities to provide culturally competent care in relation to caring for, respecting, teaching, and treating clients from different cultures.

The World Community

Beliefs about the causes and effects of illness, health practices, and health-seeking behaviors are all influenced by a person's, a group's, or a community's perception of what causes illness and injury and what actions can best treat or cure the health problem. The three major views in the world community are biomedical, magicoreligious, and holistic health beliefs (Spector, 2013).

Biomedical View

Western societies in general have a biomedical view of health and illness. The biomedical view relies on scientific principles and sees diseases and injuries as life events controlled by physical and biochemical processes that can be manipulated through medication, surgery, and other treatments. Examples of this view include the following beliefs:

- Elements, such as bacteria, fungi, or viruses, are causes of illness.
- Lack of certain elements, such as an adequate diet, calcium, or iron, causes other health problems, such as malnutrition, osteoporosis, or anemia.
- An accepted treatment for many physical ailments is to remove diseased organs, or to treat injuries from falls or accidents.

People living in countries where Western medicine is practiced believe that theirs is the best and, perhaps the only way, to deal with illness or injury. The dominant values presume that science is value free and not constructed by the social norms of the cultural group. The same is true, however, where Western medicine is not practiced and the social norms of the cultural group support the healing practices of that group (McFarland & Wehbe-Alamah, 2015; Spector, 2013). Many people, including community health nurses, are not open to other ways of looking at a person's wellness capabilities. As a result, clients may not receive culturally competent care from their caregivers. To be effective with clients, community health nurses must be knowledgeable and accepting of others' cultural practices.

Magicoreligious View

Magicoreligious themes of health and illness, which focus on the control of health and illness by supernatural forces, are prominent in some cultural groups. Diseases occur as a result of "committing sins" or "going against God's will." Good health is a gift from God, and illness is a form of punishment that affords an opportunity to be forgiven and to realign oneself with God. Prayer to God or other religious figures is used to cope with illness, seek intervention for healing, and ask for forgiveness and entrance into heaven, if death be God's will.

Some cultures mix traditional folk beliefs with organized religious practices and participate in forms of magic or voodoo. In cultures that have such beliefs, a hex or spell can be placed on another person through the use of incantations, elixirs, or an object

resembling the person. For some, illness results from a look or a touch from another person considered to have special powers or intent to harm (McFarland & Wehbe-Alamah, 2015; Spector, 2013). Later in this chapter, we discuss some specific health beliefs and practices common to cultural groups in North America.

Religious beliefs, an individual's spirituality, and how these factors interface with feelings of wellness and specific healing practices are personal and important to clients and cannot be separated from their culture. This makes it imperative for community health nurses to be familiar with folk beliefs commonly seen in their practice. Only then can culturally competent nursing care be provided.

Holistic View

Holistic health believers come from many different cultural groups and generally view the world as being in harmonious balance. If the principles guiding natural laws to maintain order are disturbed, an imbalance in the forces of nature is created, resulting in chaos and disease. For an individual to be healthy, all facets of the individual's nature—physical, mental, emotional, and spiritual—must be in balance.

Some cultural groups believe that all things in creation or the universe have a spirit and therefore are considered equal in value, purpose, and contribution (Grandbois & Sanders, 2012). Individuals have universal connectedness and are viewed as holistic beings. Persons are extensions of and integrated with family, community, tribe, and the universe. For example, a pregnant woman and her fetus are seen as integrally related and affecting each other. While physically they are part of a family, they are also two individual spirits in the process of becoming one.

Folk Medicine and Home Remedies

Many of us remember our mothers giving us hot herbal tea with lemon, or slathering on ointments and piling on blankets to lessen the effects of a mild illness. Many folk medicines and home remedies came about as a means of providing health care to family members when no medical care was available or deemed affordable.

Folk medicine is a body of preserved treatment practices that has been handed down verbally from generation to generation. It exists today as the first line of treatment for many individuals. Some clients may never plan to seek Western medical treatment but may share with you, the community health nurse, a practice they are using to treat a family member. Your response and actions may mean the difference between health and illness or injury. Some maternal–child health practices from the U.S. rural Midwest or South that may be encountered in community health nursing practice include the following (Andrews & Boyle, 2016; Spector, 2013):

- Not reaching above your head if you are pregnant, because doing so will cause the umbilical cord to strangle the baby

- Pregnant women eating handfuls of clay, dirt, or cornstarch
- Taping coins over a newborn's umbilical area to prevent hernias
- Giving catnip tea to infants because it saves their lives
- Holding a baby upside down by the heel to "wake up the liver"
- Not letting a cat in a room with a sleeping baby, because the cat will "suck the life" out of the baby

Home remedies are individualized caregiving practices that are passed down within families. Even individuals who routinely seek the guidance of a health care practitioner for diagnosis and treatment may try home remedies before seeking professional advice. Each of us has a set of home remedies our parents used on us that we are likely to use on our own children before or instead of calling the pediatrician. Examples include using baking soda paste on a bee sting, ice on a "cold sore," or cranberry juice to prevent a urinary tract infection.

Herbalism

Herbal remedies are increasingly in popularity.

Textbooks have been written on the many uses of medicinal herbs (Barrett, 2015; Gardner & McGuffin, 2013; Pizzorno, Murray, & Joiner-Bey, 2016). The use of some herbs has waxed and waned in favor. Some continue to be much touted, whereas others

have been designated as dangerous and to be avoided (Gardner & McGuffin, 2013; Medline Plus, 2015). Increasingly, the public is using herbal preparations in the form of self-selected OTC products for therapeutic or preventive purposes.

In an increasingly multicultural society, the source, form, and identity of many herbs, roots, barks, and liquid preparations become impossible for most community health nurses to distinguish. The most astute among us may be familiar with herbs used by one cultural group, whereas herbs used by another escape us. A book with pictures and descriptions, botanical form, purported indications and uses, and implications for nursing management is an important tool to keep handy when interacting with clients (Barrett, 2015). Basic safety questions that community health nurses should answer about an herb when teaching or interacting with families include the following:

- Is the herb contraindicated with prescription medications the client is taking?
- Is the herb harmful? Does it have negative side effects?
- Is the client relying on the herb, without positive health changes, while neglecting to get effective treatment from a health care practitioner?

Herbs are not regulated as drugs and are not risk free. Dosages are not standardized and are left to the individual. Quality of the product may be suspect. For these reasons, herbs must be used only in moderation and with caution, preferably with guidance by a health care practitioner.

Prescription and Over-the-Counter Drugs

The cautions mentioned about herbs can also apply to prescription and OTC preparations. First, they are not risk free. In this country, prescription drugs are reviewed and tested by the U.S. Food and Drug Administration's (FDA's) Center for Drug Evaluation and Research (CDER), and OTC drugs go through a somewhat less-rigorous process through the CDER's Division of OTC Drug Products. Many OTC drugs were once available only by prescription, and remain powerful medicines. All drugs can have major side effects, may be contraindicated in people with certain conditions, and may not be safe to use in combination with certain other drugs. Medication instruction and review is an important part of the community health nurse's role on home visits, especially with elderly clients (see Chapter 24).

Second, some new prescription medications are so expensive that clients cannot afford to take them as prescribed. Often, older, less expensive, and more frequently used drugs work as well as the newer, more expensive ones, which are heavily marketed by drug companies to health care practitioners and consumers. If you encounter clients who are unable to pay for drugs, you may need to advocate for them with health care providers to prescribe a less expensive medication or change to the generic form of the same drug, usually sold at a fraction of the cost. Some health care practitioners have samples of drugs available and may be able to use them for medically indigent clients. Many pharmaceutical

companies now have low-cost prescription assistance programs for those in need (Partnership for Prescription Assistance, 2015).

Third, the efficacy of medications must be assessed. At times, the use of a new drug or an additional drug does not have the intended effect. As someone who sees the clients managing their health at home over time, the community health nurse may be able to give the best information to the health care provider about the effectiveness of new medications for a particular client.

Complementary Therapies and Self-Care Practices

Complementary therapies (also called alternative medicine or alternative therapies) are practices used to complement contemporary Western medical and nursing care and are designed to promote comfort, health, and well-being (Snyder & Lindquist, 2014). The range of complementary therapies is broad and includes the following:

- Therapies (cancer diets, juice diets, fasting)
- Treatments (coffee enemas, high colonic enemas)
- Exercise activities (t'ai-chi, yoga)
- Exposure (aromatherapy, music therapy, light therapy)
- Manipulation (acupuncture, acupressure, reflexology)

Most cultural groups engage in some form of complementary therapy, either alone or in conjunction with Western medicine. Integrated health care is defined as the combination of complementary therapies with biomedical or Western health care (Snyder, Lindquist, & Tracy, 2014). Complementary therapies have become so commonplace today that many states are developing policies and guidelines for their use.

Consumers need to be well informed regarding the efficacy and safety of complementary therapies and how they can be true complements to other treatment modalities. The community health nurse should be aware of the variety of therapies available and how to get information for clients while remaining objective and supportive of the client's choices. At times, if a therapy contradicts the recommendations of the client's health care practitioner, the nurse may be in a position to provide the pros and cons of continuing the complementary therapy. On the other hand, the nurse may be able to suggest therapy forms that would complement Western medicine for the client, such as music therapy to promote relaxation and reduce stress or biofeedback for chronic pain management.

Self-care activities include complementary therapies, medications, and spiritual and cultural practices. They are uniquely individual for each person, as well as among different cultural groups. Chapter 19 includes a Self-Care Assessment Guide that may be helpful in assessing the self-care practices of families.

Role of the Community Health Nurse

When working with different cultural groups in the area of health care practices, the community health nurse can be an effective advocate for the client. First, however, the nurse must be prepared to speak knowledgeably about health care practices and choices. The nurse also must be able to assess the client or family adequately, so as to know what belief system motivates their choices. Finally, the nurse must be prepared to teach clients about the limits and benefits of cultural health care practices. The community health nurse should always individualize assessment and caregiving for the client within her culture and should not generalize about the client based on cultural group norms.

Preparation of the Community Health Nurse

To be effective when working with clients in the area of cultural health care and spirituality, the nurse must be prepared. Many ways exist for you to increase your cultural awareness and promote sensitivity to the differences among people from ethnocultural groups different from your own. You can acquire information from peers who are from the same cultural group as your clients; attend workshops or conferences on chosen cultural topics; read books on ethnocultural health care practices, herbalism, or complementary therapies; talk with clients about their views and practices and learn from them; keep an open mind and be curious about various practices; or attend community cultural events, such as Native American pow-wows, ethnic food events held in some cities, or Cinco de Mayo celebrations. There are textbooks, novels, and articles about cultures in the community in which one practices. For example, the classic book *The Spirit Catches You and You Fall Down* (Fadiman, 1998) describes a Hmong child, her American doctors, and the collision of two cultures. Universities offer courses in transcultural nursing, ethnic studies courses or programs, and cultural events that can be valuable. The experience of public health nurse Karin Urso, who worked with people from many different countries and cultures, illustrates the benefits of being open-minded (see From the Case Files I).

From the Case Files I

Learning About Other Cultures

I was always interested in learning about other countries and cultures. But, I didn't realize that an overseas assignment would teach me so much about myself in addition to other cultures and ways of living. The lessons were sometimes difficult, but always rewarding. I knew that my expectations would not always be met and, yet it did surprise me how different the experience was from what I had imagined it would be.

My job assignment, location, and team members changed frequently. Flexibility, comfort with ambiguity, a sense of humor, a deeper reliance upon my faith, patience, when results were not forthcoming, trust in others, and the ability to cross multiple cultures with some degree of ease were all skills that I developed over time. Most important to being successful at my job was to maintain the attitude of a "learner," not a "solver of problems" or the person "with all the answers." I made friends with people from all over the world who graciously accepted me into their lives, thus enriching mine. I learned that we all are different, but that every behavior has a reasonable explanation when you take the time to listen with your heart as well as with your ears. I found that I actually preferred other ways of doing and being while still maintaining those parts of my identity that were valuable to me. When I returned home, I found that my newly developed skills were still necessary—as I had changed and had to adjust to reentry into my home culture!

Karin Urso, PHN

Assessment

When beginning to work with a group or family, it is important for you to become as familiar with them as possible. In addition to a family assessment or an individual health assessment, you can enhance your aggregate care by doing an ethnocultural or self-care assessment. Such an assessment reveals information about day-to-day living, cultural/spiritual influences, traditional/cultural health care choices and practices, and cultural taboos. Often this type of information is most useful as you work with clients on a regular basis. Useful tools include the two cultural assessment reviews at the end of this chapter and the self-care assessment tool in Chapter 19.

Teaching

As you are aware from your studies and preparation, teaching is the most important role in nursing, both in acute care settings and in the home. When working with families as a community health nurse, teaching takes a good deal of your time, because health care education is vitally important to communities, groups, and families. However, teaching that is undertaken in ways that are incomplete, culturally inappropriate, or inadequate may be frustrating and even harmful to your clients. Becoming ethnoculturally focused and prepared to teach from the client's view of the world will start you in the right direction. The suggestions in Display 5–3 offer ideas for providing culturally competent care. Chapter 11 on health promotion and education will help prepare you as well.

DISPLAY 5.3 DEVELOPING CULTURAL COMPETENCE

First:	Know that culture is dynamic. It is a continuous and cumulative process. It is learned and shared by people. People exhibit cultural behaviors and values. Culture is creative and meaningful to our lives. It is symbolically represented through language and interaction. Culture guides us in our thinking, feeling, and acting.
Second:	Become aware of culture in yourself. Thought processes that occur within you also occur within others but may take on a different shape or meaning. Cultural values and biases are interpreted internally. Cultural values are not always obvious because they are shared socially with those you meet on a daily basis and are perceived through your senses.
Third:	Become aware of culture in others, especially among client groups you serve. This is best represented by the belief that there are many cultural ways that are correct, each in its own location and context. It is essential to build respect for cultural differences and appreciation for cultural similarities. Develop the ability to work within others' cultural context, free from ethnocentric judgments.

SELECTED CULTURAL COMMUNITIES

An examination of the meaning and nature of culture clearly underscores the need to recognize cultural differences and to understand clients in the context of their cultural backgrounds. Practically speaking, how can knowledge of cultural diversity be integrated into everyday community health nursing practice? What are the diverse cultural communities served by community health nurses? What are their differences? Do they share some features?

To provide insights and answers to these questions, this section describes 5 cultural communities, out of the more than 100 different ethnic groups living in the United States. Three are dominant in the United States; the other two represent populations native to North America and people from a Middle Eastern culture, an expanding group in the United States. These brief descriptions should not to be considered as a stand-alone guide to cultural competence; each culture is complex and unique, deserving of a more comprehensive study than is possible within the scope of this chapter. Many good references are available for nurses on cultural diversity (see References and Selected Readings).

Four of the groups highlighted represent those identified in *Healthy People 2020* (U.S. Department of Health and Human Services [U.S. DHHS], 2015). The fifth group, Arab populations, is presented because of the significant media attention people of the Middle East have received in recent years. *Healthy People 2010* (U.S. DHHS, 2015) described significant disparities among members of some of the five groups highlighted here. Several of the disparities are given in Table 5–4. *Healthy People 2020* objectives expand on the work done through *Healthy People 2010*.

Table 5–4 *Healthy People 2020*, Selected Objectives and Disparities

Healthy People 2020 Goals	Baseline Progress: Most Current Values (2012–2013)						
	Total	White	American Indian/A.N.	Hispanic/ Latino	Black	Asian	Native Hawaiian
AHS-1.1 Increase proportion of persons with medical insurance 100% of population	83.5%	83.7%	70.6%	69.3%	81.1%	85.8%	89.3%
PA-2.4 Increase proportion of adults engaged in physical activity (aerobic and muscle strengthening) 20.1% of population	18.2%	23.5%	23.8%	15.1%	20.0%	17.5%	—
NWS-9 Reduce proportion of adults who are obese 30.5% of population	33.9%	36.4%	—	42.6	48.4%	—	—
NWS-10.4 Reduce the proportion of 2- to 19-year-olds who are obese 14.5%	16.1%	14.0%	—	21.8%	22.1%	—	—
AH-5.1 Increase the proportion of students who graduate from high school in 4 y 87%	79%	87%	78%	75%	71%	—	—
SA-14.3 Decrease the proportion of adults binge drinking in past 30 d 24.4%	27.1%	28.1%	28.3%	28.6%	23.6%	14.4%	28.7%
TU-1.1 Decrease proportion of adults who are current cigarette smokers 12.0%	20.6%	20.2%	21.5%	11.7%	18.0%	9.4%	27.8%
MICH-1.3 Decrease infant mortality rate 6/1,000	6.7	10.4	7.6	5.0	11.1	4.1	4.1
MICH-9.1 Decrease percentage of infants born preterm 11.4% of live births	12.7%	10.2%	13.1%	11.3%	16.3%	10.2%	10.2%
FP-7.1 Increase the proportion of sexually active females (15–44) receiving reproductive health services in past 12 mo 86.5%	78.6%	76.1%	—	77.5%	84.8%	—	—

Native American Indians, Aleut, and Eskimo Communities

Native American mother and child.

Native American Indians and Alaska Natives (Eskimo communities residing in Alaska), the first known settlers of this continent, form a large cluster of tribal groups whose members are descendants of the original Native Americans who inhabited this country before White Europeans settled here. The earliest European explorers were the Vikings (circa 1010 AD). Various other Europeans followed in the 16th century (Spector, 2013). Native Americans, Aleuts, and Eskimos have adopted many European American values and practices, yet they preserve many aspects of their own culture.

Population Characteristics and Culture

Native Americans and Alaska Natives are a diverse group made up of different tribes and 562 federally recognized nations that speak approximately 250 languages. Eskimos, Aleuts, and Native Americans living in Alaska are known as Alaska Natives; those living in other states are known as Native Americans or American Indians. In this chapter, the term *Native American* is used to encompass all facets of this diverse group of people. Many people in this group identify with more than one race or ethnicity. In the 2010 census, an estimated 6.5 million people identified at least "part" Native American, whereas 4.0 million self-identified only as Native American or Alaska Native (Colby & Ortman, 2015). These people proudly identify themselves as being Native American, unlike in the past, when to claim Native American blood carried a social stigma. In addition to societal changes in the acceptance of Native Americans, financial incentives exist for many Americans who are recognized tribal members. Roughly 224 of the tribal governments receive revenue from gambling casinos—roughly half of all tribes have casinos in 28 states (Tribal Court Clearinghouse, n.d.). In 1988, when Congress passed the Indian Gaming Regulatory Act, casinos owned by Native Americans made $212 million; by 2015, a total of 486 gaming operations grossed $28.5 billion (National Indian Gaming Council, 2015). Some, but not all, tribes pay per capita payments to tribal members (Tribal Court Clearinghouse, n.d.).

Even though the poverty rate fell for Native Americans overall, it is over twice the U.S. average (Office of Minority Health, 2015), and unemployment is nearly three times the national rate—making Native Americans among the nation's poorest groups (Native American Rights Fund, n.d.). Although gaming and other ventures have improved access to health, education, and employment for most Native Americans, access still falls behind that of other U.S. citizens.

The population of Native Americans and Alaska Natives is primarily concentrated in 26 states in the United States, including Alaska and the Aleutian Islands (Spector, 2013). Many live on reservations and in rural areas; however, more than half live in urban counties and have greater difficulty accessing the health care available to them through Indian Health Service, a federal program providing comprehensive health care to Native Americans (Office of Minority Health, 2015). The largest numbers live in Oklahoma,

Arizona, California, New Mexico, North Carolina, and Alaska, as a result of forced westward migration (Spector, 2013). By 2050, the U.S. Census Bureau estimates about 4.5 million Native Americans will live in the United States, nearly double the number in 2000 (Colby & Ortman, 2015). Some of this increase can be attributed to official recognition of persons who can provide information linking them to a tribe or nation; if they are accepted, they can then declare themselves to be Native Americans.

Each tribe or nation has its own distinct language, beliefs, customs, and rituals. The community health nurse cannot assume that knowledge of one group can be generalized to others. Knowledge of various Native American cultures (Display 5–4) can assist nurses working with members of a specific tribe. For many Native American groups, large, extended family networks reinforce cultural standards and expectations and provide emotional support and practical assistance.

DISPLAY 5.4 SIMILARITIES AMONG NATIVE AMERICAN CULTURES

All of creation/universe has Spirit and is considered equal in value.
Everything is considered alive with energy and importance.
People have universal connectedness.
Harmony is a way of life based on cooperation and sharing.
Dignity of the individual, family, and community is valued.
Respect for advancing age is valued; elders are leaders.
There is present-time orientation, grounded in what is happening at the moment.
Symbolic arts and crafts are valued.
A strong sense of identity fosters resilience.
Generosity, harmony, and sharing are valued.
Religion is integrated into everyday life.
Herbal medicines and traditional healing practices are used.
Rituals and ceremonies are valued.
Silence is used as a way to practice presence and strength.
Thoughtful speech and patience are valued.
Cultural resilience is important when confronting stereotypes.

Adapted from Grandbois, D. M., & Sanders, G. F. (2012). Resilience and stereotyping the experiences of Native American elders. Journal of Transcultural Nursing, 23(4), 389–396;

Spector, R. E. (2013). Cultural diversity in health and illness (8th ed.). Upper Saddle River, NJ: Pearson Education.

Health Problems

Health problems among Native Americans tend to be both chronic and socially related. One third of Native Americans live in abject poverty and experience the afflictions associated with poor living conditions, including malnutrition, tuberculosis (TB), and high maternal and infant death rates (Office of Minority Health, 2015; Spector, 2013). The highest-ranking health problems in children include a postneonatal mortality rate double that of White infants (due largely to sudden infant death syndrome [SIDS], injuries, and congenital anomalies); overweight, obesity, and Type 2 diabetes; and morbidity and mortality as a result of unintentional and intentional injuries, often motor vehicle injuries (Office of Minority Health, 2015). For adults, diabetes, TB, and obesity all rank higher among Native Americans than in the general population. Deaths from TB (5 times higher), alcoholism (5 times higher), diabetes (almost 2 times higher), unintentional injuries (1.5 times higher), and suicide and homicide (combined, 1.6 times higher) are higher for Native Americans than other Americans (Office of Minority Health, 2015). Mortality from heart disease and cardiovascular disease is slightly higher than the general U.S. population (269.4 per 100,000 deaths compared with 267 per 100,000 deaths; Office of Minority Health, 2015). Poor sanitation, crowded housing, and low immunization levels contribute to the prevalence of a variety of communicable diseases.

Alcoholism is the major health problem of Native Americans. Both traditional/cultural and medical explanations exist for the disproportionate number of alcohol-related health problems in Native Americans. Tribal medicine men have attributed the problems of alcoholism to losing the community's loss of chance to make choices, and advocate for people to gain a sense of cultural identification in order to minimize or eliminate alcoholism (Spector, 2013). Medically, it appears that Native Americans have a much lower tolerance for alcohol and therefore demonstrate the effects of alcohol with lower amounts consumed. When individuals are under the influence of alcohol, other health and safety problems occur. Instances of domestic violence, child abuse and neglect, traffic injuries and deaths, and homicides are more frequent because of alcohol abuse. Along with these high rates of injuries and deaths, alcohol's destructive effects on the unborn lead to a high incidence of fetal alcohol syndrome (FAS) and fetal alcohol effects (FAE). Substance abuse is also prevalent among those living on reservations, and increasingly among youth using alcohol, tobacco, and other drugs (U.S. Substance Abuse & Mental Health Services Administration [U.S. SAMHSA], 2014).

Health Beliefs and Practices

Native Americans as a group prefer traditional healing practices and folk medicine to Western medicine. Most Native Americans today still seek out a medicine man or rely on traditional remedies before going to a health clinic. Many of their beliefs about health and illness have common traditional roots, regardless of tribe or location. Health and dietary practices are closely tied to cultural and religious beliefs. Beliefs about health reflect living in total harmony with nature. Cultural resilience has been identified as an important component of well-being in this cultural group (Grandbois & Sanders, 2012). The Earth is considered a living organism that should be treated with respect, as should the body (Spector, 2013). Native Americans practice purification rituals such as immersion in water and the use of sweat lodges to maintain their harmony with nature and to cleanse the body and spirit. The basis of therapy lies in nature, with herbal teas, charms, and fetishes used as preventive and curative measures (Gardner & McGuffin, 2013; McGaa, 2011). Depending upon location, tribes use available plants or herbs to treat illnesses. For instance, those in the West often used sage (or sagebrush) tea for sore eyes, stomachache, or the pain of childbirth.

Because of decades of racism and government paternalism, many Native Americans feel oppressed and dehumanized and carry considerable resentment and lack of trust toward Whites. As a result, many maintain a degree of separateness from overall American culture. Nurses must overcome these barriers through patience, acceptance, and respect for their clients' culture, as illustrated in the case study of the community health nurse, Sandra Josten, and her new client from a Native American community (see From the Case Files II).

From the Case Files II

Sandra's New Clients

As she drove down the dirt road and parked her car next to the community hall, Sandra Josten felt apprehensive. The previous public health nurse had alerted her about the difficulty of working with these Native American people: "This tribe is lazy and unappreciative. You can't get anywhere with them." Only through the urging of Mrs. Brown, an Indian community aid, had a group of the women reluctantly agreed to meet with the new nurse. They would see what she had to say.

Sandra's steps echoed hollowly as she walked across the wooden floor of the large room to the far corner where a group of women sat silently in a circle. Only their eyes turned; their faces remained impassive. Mrs. Brown rose slowly, greeted the nurse, and introduced her to the group. Swallowing her fear, Sandra smiled. She told them of her background and explained that she had not worked with Indian people before. There was a long silence. No one spoke. Sandra continued, "I'd like to help you if I can, maybe with problems about care of your children when they are sick or questions about how to keep them healthy, but I don't know what you need or want." Silence fell again. She would like to learn from them, she repeated. Would they help her? Again, Sandra felt an uncomfortable silence.

Then one woman began to speak. Quietly, but with deep feeling, she described several bad experiences with the previous nurse and the county social worker. Then others spoke up: "They tell us what we should do. They don't listen. They say our way is not good." Seeing Sandra's interest and concern, the women continued. One of their main concerns was their children's health. Another was the high incidence of accidents and injuries on the reservation. They wanted to learn how to give first aid. Other concerns were expressed. The group agreed that Sandra could help them by teaching a first-aid class.

In the weeks that followed, Sandra taught several classes on first aid and emergency care. She then began a series of sessions on child health. Each time, she asked the women to choose a topic or problem for discussion and then elicited from them their accustomed ways of dealing with each problem; for example, how they

handled toilet training or taught their children to eat solid foods. Her goal was to learn as much as she could about their culture and to incorporate that information into her teaching, which preserved as many of their practices as possible. Sandra also visited informally with the women in their homes and at community gatherings.

She learned about their way of life, their history, and their values. For example, patience was highly valued. It was important to be able to wait patiently, even if a scheduled meeting was delayed as much as 2 hours. It also was important for others to speak, which explained the Indian women's comfort with silences during a conversation. Other values influenced their way of life. Courage, pride, generosity, and honesty all were important determinants of behavior. These also were values by which they judged Sandra and other professionals. Sandra's honesty in keeping her promises enabled the women to trust her. Her generosity in giving her time, helping them occasionally with some household task, and arranging for childcare during classes won their respect.

The women came to accept her, and Sandra was invited to eat with them and share in tribal get-togethers. The women criticized and advised her on acceptable ways to speak and act. Her openness and patience to learn and her respect for them as a people had paved the way to improving their health. At first, Sandra felt that her progress was slow, but this slowness was an advantage. She had built a solid foundation of cross-cultural trust, and in the months that followed she saw many changes in her clients' health practices.

Blacks or African Americans

Some of the ancestors of Black Americans, or African Americans, originally came to this continent as free settlers as early as 1619, but most of the approximately 4 million who followed came as slaves in the 17th and 18th centuries, mostly from the west coast of Africa (Klein, 2012). Most Black Americans alive today were born in the United States; some, however, are immigrants from African countries. Other Black Americans come from the West Indies, the Dominican Republic, Haiti, and Jamaica, often to escape poverty or political persecution (Spector, 2013)

Population Characteristics and Culture

The U.S. Census Bureau estimated that African Americans numbered 45 million and constituted approximately 13.2% of the U.S. population in 2014. By 2060, the projected black population of the United States (including those of more than one race) is estimated to reach 74.5 million. Based on these projections, by that time, blacks would constitute 17.9% of the United States' total population (U.S. Census Bureau, n.d.a.) One third of the African American population is younger than 18 years of age. Slightly more than 8% of African Americans are older than 65 years, and most of them are women; in comparison, 13% of the total population is older than 65 years. Some 58% of Black children live with their mothers only, compared with 21% of White children (Office of Minority Health, 2015).

Despite improvements in the legal and social climate for African Americans, great disparities exist between them and White Americans (Office of Minority Health, 2015). In 2012, the average family income for African Americans was $33,762 and $56,565 for White families. More than 28% of African Americans live in poverty, compared with 1% of Whites. Although African Americans make up only 13.5% of the population, more than 50% of prison inmates are Black.

Educational and employment disparities also exist. Unemployment among African Americans is 10.3, compared with 4.8% for Whites (Office of Minority Health, 2015). Among people aged 25 years and older, 83% of Blacks and 92% of Whites have a high school education (Office of Minority Health, 2015). More than half of those African Americans with less than a high school education are not in the workforce, compared with 36% of Whites with a similar education. African American women acquire more educational training than their Black male counterparts do, but their earnings are lower than those of the men, as is also the case with White and Hispanic women compared with men in those groups. In a recent study of racial discrimination in the labor market for recent college graduates, the authors report finding strong evidence of differential treatment by race (Nunley, Pugh, Romero, & Seals, 2014).

Like Native Americans and Asian Americans, African Americans do not constitute a single culture; rather, this group forms a heterogeneous community. As with other large

ethnic and racial groups, many factors influence their culture, resulting in much diversity within the African American population. Among the variables determining specific microcultures within the African American community are economic level, religious background, education, occupation, social class identity, geographic origin, and residence in an integrated or segregated neighborhood. For community health nurses, this means that specific groups of African Americans have their own unique values, character, lifestyle, and health needs.

The primary language of most African Americans is English. Recent Black immigrants from Caribbean or other countries may retain the language of their country of origin, but usually learn to use English as well. Many African Americans speak nonstandard dialects of English, also called Black English or African American Vernacular English. These dialects evolved from *pidgin* English spoken during the era of slavery, and they have become a dynamic and meaningful language of their own. For some African Americans, this dialect symbolizes racial pride and identity—it can also be used to differentiate them from the mainstream culture (Spector, 2013).

Health Problems

African Americans have much higher mortality rates than do White Americans, with a life expectancy of 75.1 years (Arias, 2014). Life expectancy for Whites in 2010 was 78.7 years (Arias, 2014). The number for African Americans is the same as the life expectancy of Whites in 1980, revealing a 30-year lag for the Black population compared with the White population and demonstrates the inequality in mortality and life expectancy, an outcome of health care, economic, and educational disparity.

Stress and discrimination, poverty, lack of education, high rates of teen pregnancy, inadequate housing, and inadequate insurance for health care are among the risk factors influencing the health of this population. Female-headed households, single-parent births (most frequently among teenagers), and a limited presence of male role models have exacerbated family vulnerability. This situation is improving with a reported reduction of female-headed households with children under the age of 18 decreasing from 56% in 1985 to 52% in 2014 (U.S. Census Bureau, n.d.b.).

The major health problems for Blacks include cardiovascular disease and stroke, cancer, diabetes mellitus, cirrhosis, a high infant mortality rate (twice that of Whites), homicide, accidents, and malnutrition (Display 5–5). Leading causes of death for African Americans are heart disease, cancer, and stroke. As noted, infant death rates are higher in Blacks than in other groups (11.1 per 1,000 live births), leading many health departments to focus on services for African American pregnant women (Office of Minority Health, 2015). Mortality rates for communicable diseases, including acquired immunodeficiency syndrome (AIDS), also are higher for Blacks than for Whites. The incidence of TB in this population is rising, with many cases being diagnosed in conjunction with AIDS (see Chapters 8 and 26). Other infectious and parasitic diseases are three to six times more prevalent among

African Americans than among Whites (Office of Minority Health, 2015). Hypertension is a real concern in this population; 40.5% of men and 44.3% of women over the age of 20 report having hypertension. In the same age group, 70% of men and 80% of women are reported as overweight (Office of Minority Health, 2015). In two health-related areas, Blacks demonstrate a lower incidence than do Whites: suicide is 50% less prevalent among Blacks, and the rate of chronic obstructive pulmonary disease (COPD) is 20% to 30% less. All other leading causes of death are higher for Black populations, much of which can be attributed to lifestyle and poverty factors (Office of Minority Health, 2015). However, some genetic studies have shown significant differences between African Americans and Whites in those genes associated with hypertension and cardiovascular disease (Non, Gravlee, & Mulligan, 2012).

Blacks may have specific skin problems (e.g., keloids, melasma). In addition, sickle cell anemia and sickle cell trait occurs in Blacks, an inherited genetic trait thought to have originated in Africa as a defense against malaria (Spector, 2013).

DISPLAY 5.5 EXAMPLES OF CULTURAL PHENOMENA AFFECTING HEALTH CARE AMONG BLACK OR AFRICAN AMERICANS

Nations of Origin	Many West African countries (as slaves) West Indian Islands The Dominican Republic, Haiti, Jamaica
Environmental Control	Traditional health and illness beliefs may continue to be observed by "traditional" people
Biological Variations	Sickle cell anemia, hypertension, cancer of the esophagus, stomach cancer, coccidioidomycosis, lactose intolerance
Social Organization	Family: many single-parent households headed by females Large, extended family networks Strong church affiliations within the community Community social organizations
Communication	National languages Dialect: Pidgin French, Spanish, Creole
Spatial Distancing	Close personal space
Time Orientation	Present over future

Adapted from Spector, R. E. (2013). Cultural diversity in health and illness (8th ed.). Upper Saddle River, NJ: Pearson Education.

Health Beliefs and Practices

Although African Americans have assimilated into the more dominant non-Hispanic White American culture in the United States, some retain aspects of their ancestors' traditional values and practices. Some, for example, hold traditional African beliefs about health being a sign of harmony with nature and illness being evidence of disharmony. Evil spirits, the

punishment of God, or a hex placed on the person might account for this disharmony. Healers treat body, mind, and spirit. Prayer, laying on of hands, magic or other rituals, special diets, wearing of preventive charms or copper bracelets, ointments, and other folk remedies sometimes are practiced (Spector, 2013). African Americans have a high degree of religious involvement; 80% consider themselves to be either very or fairly religious. Higher levels of active religious participation are associated on average with less illness and better health (Lumpkins, Greiner, Daley, Mabachi, & Neuhaus, 2013). Church attendance for African Americans is significantly associated with positive health care practices, including mental health conditions such as depression and substance abuse (Hankerson & Weissman, 2012), as well as decreased pain in sickle cell anemia (Cotton, Grossoehme, & McCrady, 2012). Such an effect is even stronger for the chronically ill and uninsured subgroups. This is an important consideration when public health nurses plan programs targeting this population. Each African American community has its own set of health beliefs and practices that must be determined by the community health nurse before any interventions are planned.

Asian Americans

A third cultural cluster is composed of immigrants and refugees from various Pacific Rim countries, such as China, Korea, Japan, Thailand, Laos, the Philippines, Vietnam, and Cambodia (Display 5–6). Some Asian Americans have been transplanted fairly recently from their native countries and cultures to an entirely different culture, whereas others may have lived here many years or were born in the United States.

DISPLAY 5.6 ASIAN–PACIFIC POPULATIONS

Asian refers to:	Pacific Islander refers to:
Chinese	Polynesian
Filipino	Hawaiian
Japanese	Samoan
Asian Indian	Tongan
Korean	Micronesian
Vietnamese	Guamanian
Laotian	Melanesian
Thai	Fijian
Cambodian	Tahitian
Pakistan	Marshallese
Indonesian	Trilese
Hmong	
Mein	
Lahu	

Population Characteristics and Culture

In the 2010 census, more than 16.7 million Asians and Pacific Islanders were living in the United States, representing 5.5% of the total population (Jensen et al., 2015). The largest groups were Chinese and Filipinos, with more than 1.5 million persons from each country; Vietnamese numbered a close second. Other fairly large groups came from Korea, India, Laos, and Cambodia. Each group represents a distinct culture with its own unique challenges for community health nurses, as illustrated in the case study of the Kim family (see From the Case Files III).

From the Case Files III

The Kim Family

Armed with enthusiasm and pamphlets on pregnancy and prenatal diet, Paula Morrow, the community health nurse, began home visits to the Kim family. Paula's initial plan was to discuss pregnancy and fetal development, teach diet, and prepare the mother for delivery. Mr. Kim, a graduate student, was present to interpret, because Mrs. Kim spoke little English. Their two children, ages 1 and 3 years, played happily on the kitchen floor. The family offered tea to the nurse and listened politely as she explained her reasons for coming and asked, "How can I be most helpful to you? What would you like from my visits?"

The Kims were grateful for this approach. Hesitant at first, they hinted at Mrs. Kim's fears of American doctors and hospitals; her first two children had been born in Korea. None of the family had any experience with Western medicine. They shared some concerns about adjustment to living in the United States. It was difficult to shop in American food stores with their overwhelming variety of foods, many of which the Kims found unfamiliar. Mrs. Kim, who had come from a family whose servants prepared the food, was an inexperienced cook. Servants also had cared for the children, and her role had been that of an aristocrat in hand-tailored silk gowns.

Listening carefully, Paula began to realize the striking differences between her own culture and that of her clients. Her care plans changed. In subsequent visits, she determined to learn about Korean culture and base her nursing intervention on that knowledge. She learned about their traditional ways of raising children, the traditional male and female roles, and practices related to pregnancy and lactation. She respected their value of "saving face" and attempted never to offend their pride or dignity. As time went on, her interest and respect for their way of life won their trust. She inquired about their cultural practices before attempting any intervention. As a result, the Kims were receptive to her suggestions. Whenever possible, Paula adapted her teaching and suggestions to comply with the Kims' culture. For example, appropriate changes were made to Mrs. Kim's diet plan to incorporate her food preferences and cultural eating patterns. Because she was not accustomed to drinking milk, she increased her calcium intake by learning to prepare custards (which disguised the milk flavor) and by eating more portions of leafy, green vegetables. After 5 months, a strong, positive relationship had been established between this family and the nurse. Mrs. Kim delivered a healthy baby girl and looked forward to continued supportive visits from the community health nurse.

Whereas each Asian culture is distinct in language, values, and customs, many Asians share some general traits. Traditional Asian families tend to be patriarchal (the

father is the head of the household) and patrilineal (the genealogy is carried through the male line). Male members are valued over female members, and elders are respected. The male role generally is that of provider, whereas the female role is that of homemaker. Traditional Asians value achievement because it brings honor to the family name. Saving face or preserving dignity and family pride is important. Cooperation is valued over competition (McFarland & Wehbe-Alamah, 2015; Spector, 2013).

Health Problems

Leading causes of death among Asians include cancer, heart disease, and stroke (Office of Minority Health, 2015). Smoking is lower in this group (18% of males and 6% of females over age 18 smoke). Health problems for Asian Americans include malnutrition, TB, mental illness, cancer, respiratory infections, arthritis, parasitic infestations, and chronic diseases associated with aging. Suicide rates and stress-related illness are particularly high among Asian refugee groups who have had to flee their countries under stressful conditions and among teens born in the United States to Asian immigrants; many of these children have difficulty living between two cultures (Kim, Sangalang, & Kihl, 2012). However, Asians can view mental illness as shameful, and the stigma attached to it prompts them to express the mental illness as a disturbed bodily function or to hide it as long as possible (Kim et al., 2012; Spector, 2013).

Health Beliefs and Practices

Asian health beliefs vary among subcultures. Many Asians believe in the Chinese concepts of *yin* (cold) and *yang* (hot), which do not refer to temperature but to the opposing forces of the universe regulating normal flow of energy. A balance of yin and yang results in *qi* (pronounced *chee*), which is the desired state of harmony. Illness results when an imbalance occurs in these forces. If the imbalance is an excess of yin, then "cold" foods, such as vegetables and fruits, are avoided, and "hot" foods, such as rice, chicken, eggs, and pork, are offered. Some Asians view Western medicines as "hot" and Eastern folk medicines and herbal treatments as "cold," which explains why some groups practice both for balance. The Vietnamese have a similar hot-and-cold belief, but call it *am* and *dong*. Other Asian groups, such as the Filipinos, view illness as an act of God and pray for healing, reflecting their strong religious beliefs as Catholics or Muslims. The Khmer of Cambodia believe that illness reflects a deviation from moral standards, and the Hmong consider illness to be a visitation by spirits (Paniaguia 2014; Spector, 2013).

Many Asian groups have traditional healers, who, depending on the culture, may include acupuncturists, herbalists, herb pharmacists, spirit and magic experts, or a shaman. Most Asian cultures also exercise traditional self-care practices, including herbal medicines and poultices, types of acupuncture, and massage (Andrews & Boyle, 2016; Spector, 2013). Southeast Asians also practice dermabrasive techniques of coining, cupping, pinching,

rubbing, and burning. These methods are used to relieve symptoms such as headache, sore throat, cough, fever, and diarrhea by bringing toxins to the skin surface or compensating for heat lost. Because these techniques leave a bruise-like lesion on the skin, they can be mistaken for physical abuse (Chirali, 2014). Each client requires a careful cultural assessment (a detailed data-gathering about the client's cultural practices) before nursing action is implemented.

Hispanic Americans

A fourth cultural cluster constitutes groups who are of Hispanic or Latino origin and have immigrated to the United States, some many generations ago. More than half come from Mexico, followed by Puerto Rico, Cuba, the Dominican Republic, and Central and South America (Colby & Ortman, 2015; Spector, 2013). Those with Mexican and Central American backgrounds generally are referred to as Latinos. Depending on the region of the country, socioeconomic status, immigration or citizenship status, or age, members of this large minority group refer to themselves as Mexican American, Spanish American, Chicano, Latin American, Latin, Latino, or Mexican (Colby & Ortman, 2015; Spector, 2013). In this chapter, for convenience, the term *Hispanic* is used to encompass this entire diverse population.

The subgroups of Hispanics vary by their patterns of geographic distribution in the United States. Of the almost 55 million Hispanics in the United States, Mexicans are the largest percentage at 64.3%. Central and South Americans constitute almost 15%, and Puerto Ricans make up 9.4% and Cubans 3.7% of the Hispanic population. The states with the largest Hispanic populations include California (14.5 million), Texas (10 million), New York (3.5 million), Florida (4.5 million), and Illinois (2.1 million). The Hispanic population is young, with 33.2% under the age of 18, compared to 19.7% non-Hispanic Whites (Office of Minority Health, 2015).

Population Characteristics and Culture

With 55 million self-identifying Hispanics, this population is the largest ethnic group in the United States. People identifying Hispanic origin are predicted to number more than 119 million by 2060 (U.S. Census Bureau, n.d.a.).

The Hispanic population uses Spanish as its common and primary language; nonetheless, its diverse cultural and linguistic backgrounds account for diversity in dialects. Currently about 74% of the Hispanic population in the United States speaks Spanish at home (Office of Minority Health, 2015). Compared to Whites, Hispanics have lower achievement of a high school diploma (92% vs. 64%). In 2012, 25.4% of Hispanics, compared with 11% of Whites, lived at the poverty level (Office of Minority Health, 2015). Of particular note to public health nurses, Hispanics have the highest uninsured rates of any racial/ethnic group, with 19.9% not covered by any health insurance. Although this coverage rate has improved within the past 5 years, it continues to far exceed the rate for Non-Hispanic Whites at 7.6%, African Americans at 11.8%, and Asians at 9.3% (Smith & Medalia, 2015).

Hispanic people value extended, cohesive families. Families have generally been patriarchal, with male members perceived as superior and female members seen as a family-bonding life force. These traditional family structures are changing because of migration, urbanization, women in the workforce, and social movements. Spousal roles are becoming

more egalitarian (Andrews & Boyle, 2016; Spector, 2013). However, vestiges of the *macho* man and the self-sacrificing woman still are evident in Hispanic culture and continue to shape behavior (see From the Case Files IV).

From the Case Files IV

Maria Juarez

Maria Juarez, a 53-year-old Mexican American widow, was referred to a public health nursing agency by a clinic. Her married daughter reported that Mrs. Juarez was having severe and prolonged vaginal bleeding and needed medical attention. The daughter had made several appointments for her mother at the clinic, but Mrs. Juarez had refused at the last minute to keep any of them.

After two broken home visit appointments, the community health nurse made a drop-in call and found Mrs. Juarez at home. The nurse was greeted courteously and invited to have a seat. After introductions, the nurse explained that she and the others were only trying to help. Mrs. Juarez had caused a lot of unnecessary concern to everyone by not cooperating, she scolded in a friendly tone. Mrs. Juarez quickly apologized and explained that she had felt fine on the days of her broken appointments and saw no need "to bother" anyone. Questioned about her vaginal bleeding, Mrs. Juarez was evasive. "It's nothing," she said. "It comes and goes like always, only maybe a little more." She listened politely, nodding in agreement as the nurse explained the need for her to see a physician. Her promise to come to the clinic the next day, however, was not kept. The staff labeled Mrs. Juarez as unreliable and uncooperative.

Mrs. Juarez had been brought up in traditional Mexican American culture that taught her to be submissive and interested primarily in the welfare of her husband and children. She had learned long ago to ignore her own needs and found it difficult to identify any personal wants. Her major concern was to avoid causing trouble for others. To have a medical problem, then, was a difficult adjustment. The pain and bleeding had caused her great apprehension. Many Mexican Americans have a particular dread of sickness and especially hospitalization. Furthermore, Mrs. Juarez's culture had taught her the value of modesty. "Female problems" were not

discussed openly. This cultural orientation meant that the sickness threatened her modesty and created intense embarrassment. Conforming to Mexican American cultural values, she had first turned to her family for support. Often, only under dire circumstances do members of this ethnic/cultural group seek help from others; to do so means sacrificing pride and dignity. Mrs. Juarez agreed to go to the clinic because refusal would have been disrespectful, but her fear of physicians and her reluctance to discuss such a sensitive problem kept her from going. Mrs. Juarez was being asked to take action that violated several deeply felt cultural values. Her behavior was far from unreliable and uncooperative. With no opportunity to discuss and resolve the conflicts, she had no other choice.

Health Problems

Leading causes of death for the Hispanic population include heart disease, cancer, unintentional injuries (accidents), stroke, and diabetes. A large number of this population is uninsured and does not have a usual source of health care—31% for adults, almost 10% for children (Office of Minority Health, 2015). Health problems among the Hispanic population are complicated by experiences in their countries of origin, as well as by socioeconomic and lifestyle factors in this country. TB is high in this group, especially among those younger than 35 years of age. Hypertension, diabetes, and obesity are major concerns. Obesity is higher in Hispanics than Whites, and asthma, COPD, suicide, and liver disease also significantly impact Hispanics. Other problems include infectious diseases, particularly AIDS and pneumonia, parasitic infections, malnutrition, gastroenteritis, alcohol and drug abuse, unintentional injuries, and violence. Frequently, the most important health issues for Hispanics are related to the fact that the population is young and has a high birth rate at 97.7 per 1,000 births (Office of Minority Health, 2015). The rate of low-birth-weight infants is lower in Hispanics overall but higher among Puerto Ricans, for whom low birth weight occurs twice as often as in Non-Hispanic Whites. Puerto Ricans also experience disproportionate levels of asthma, infant mortality, and HIV/AIDS. Mexicans have higher rates of diabetes; they are 1.2 times more likely than Whites to be diagnosed with diabetes. Mexican women are 1.2 times more likely to be overweight or obese than White women (Office of Minority Health, 2015). Posttraumatic stress disorder is a major problem among refugees from Central and South America who have experienced war and physical and emotional torture.

Health Beliefs and Practices

Religion plays an important part in Hispanic culture. For most Hispanics, Catholicism is the dominant religion (e.g., 95% of Mexican Americans are Catholic), but religious beliefs often consist of a blend of Catholicism and pre-Columbian Indian beliefs and ideology, along with magicoreligious practices. Hispanics believe in submission to the will of God and that illness may be a form of *castigo*, or punishment for sins. They cope with illness

through prayers and faith that God will heal them. Their religion also determines the rituals used in healing; for example, *solito*, a condition of depression in women similar to a midlife crisis seen in the American culture, is treated by having the patient lie on the floor while her body is stroked by the *curandero* (native healer) until the depression passes. Latino culture includes beliefs that witchcraft (*brujeria*) and the evil eye (*mal de ojo*) are supernatural causes of illness that cannot be treated by "Anglo" or Western medicine. *Empacho*, a stomachache in children that occurs after a traumatic event, is treated by the *curandero* with herbal mixtures made into teas. After tender loving care and a bowel movement, the child is considered healed (Table 5–5). As with Asians, Hispanics use "hot" and "cold" categories of foods to influence their diet during illness. Many Hispanics tend to be present-oriented, and consequently are not as concerned as the mainstream culture about keeping to time schedules or preparing for the future (Giger, 2017; McFarland & Wehbe-Alamah, 2015; Spector, 2013).

Table 5–5 Hispanic Health Beliefs and Folk Diseases

Belief Name	Explanation/Treatment
Ataque	Severe expression of shock, anxiety, or sadness characterized by screaming, falling to the ground, thrashing about, hyperventilation, violence, mutism, and uncommunicative behavior. Is a culturally appropriate reaction to shocking or unexpected news that ends spontaneously.
Bilis	Vomiting, diarrhea, headaches, dizziness, nightmares, loss of appetite, and the inability to urinate brought on by livid rage and revenge fantasies. Believed to come from bile pouring into the bloodstream in response to strong emotions and the person "boiling over."
Bilong (hex)	Any illness may result from this; proper diagnosis and treatment requires consulting with a *santero* or *santera* (priest or priestess).
Caide de mollera	A condition thought to cause a fallen or sunken anterior fontanelle, crying, failure to nurse, sunken eyes, and vomiting in infants. Popular home remedies include holding the child upside down over a pan of water, applying a poultice to the depressed area of the head, or inserting a finger in the child's mouth and pushing up on the palate. (Note: According to Western medicine, these symptoms are indicative of dehydration and can be life threatening. The community health nurse role is imperative—to promoting hydration and definitive health care.)
Empacho	Lack of appetite, stomachache, diarrhea, and vomiting caused by poorly digested food. Food forms into a ball and clings to the stomach, causing pain and cramping. Treated by strongly massaging the stomach, gently pinching and rubbing the spine, drinking a purgative tea (*estafiate*), or by administering *azarcon* or *greta*, medicines that have been implicated, in some cases, in lead poisoning. (Note: The community health nurse must assess family for the use of these "medicines" and initiate appropriate follow-up.)
Fatigue	Asthma-like symptoms treated with Western health care practices, including oxygen and medications.
Mal de ojo	A sudden and unexplained illness including vomiting, fever, crying, and restlessness in a well child (most vulnerable) or adult. Brought on by an admiring or covetous look from a person with an "evil eye." It can be prevented if the person with the "evil eye" touches the child when admiring him or her if the child wears a special charm. Treated by a spiritualistic sweeping of the body with eggs, lemons, and bay leaves accompanied by prayer.
Pasmo	Paralysis-like symptoms in the face and limbs treated by massage.
Susto	Anorexia, insomnia, weakness, hallucinations, and various painful sensations brought on by traumatic situations such as witnessing a death. Treatment includes relaxation, herb tea, and prayer.

Arab Populations and Muslims

The final cultural community selected for this discussion is made up of groups of people who come from Arabic countries, especially those who espouse the Muslim religion. By comparison with the groups previously mentioned, the number of people from Arabic countries in the United States is small, but because of the terrorist attacks of September 11, 2001 and ongoing terrorism, as well as the wars in the Middle East, increasing racial and religious animosity has been directed toward people from this part of the world and against those who bear physical resemblance to members of these groups. This unwarranted ostracism has led to mental anguish and distress in Arab and Muslim communities (Giger, 2017). Factual information about these groups of people should dispel myths and alleviate fear.

About 4 million people of Arab descent live in the United States. For U.S. census purposes, Arabs are listed as White, and this may include those from Lebanon and Palestine, as well as Algerians, Moroccans, and Egyptians. (U.S. Census Bureau, 2011). Arab Americans have done very well economically, with many having college degrees, owning homes, and being employed as professionals or managers, with the accompanying incomes. Many Arab-Americans immigrants practice Islam and have expressed feeling misunderstood since the terrorist attacks on Washington, DC and New York in 2001 (Nimer, 2013).

A large percentage of Arabs own their own homes, are college graduates, and work as professionals, for example, in business, medicine, nursing, and education.

A common language (Arabic) and background unite them, yet only 18% of Muslims (followers of Islam) reside in Middle Eastern countries. Arabs are largely Christian or Muslim, although some Arabs may be Jews or Druze (Arab American Institute [AAI], 2015). Christian Arabs first began immigrating to the United States in the late 19th and early 20th centuries (mostly from Syria and Lebanon), but during the middle of the 20th century, Muslim Arabs began to emigrate in greater numbers (commonly from Palestine, Egypt, Iraq, and Yemen). Islam is the fastest-growing global religion, with more than 1

billion followers worldwide. The Council on American–Islamic Relations (CAIR, 2015) reports that there are 6 to 7 million Muslims living in the United States. Most Muslims live in China, India, and South Asia (CAIR, 2015). The tenets of Islam are interpreted more liberally in some nations and more strictly in others, but all practicing Muslims adhere to the five tenets of Islam in some fashion (Table 5–6).

Table 5–6 The Five Pillars (Tenets) of Islam

1. Faith	Declaration of faith (*shahada*) that there is no God but Allah and that Mohammad is the messenger of Allah
2. Prayer	Obligatory prayers five times a day at dawn, noon, mid-afternoon, sunset, and when night falls (called *salat*) link the worshipper to God. Prayers are led by a learned man who knows the Quran, as there is no hierarchical authority in Islam (like a minister or priest).
3. Almsgiving	This is like tithing and is a very important principle as all wealth is thought to belong to God. It is called *zakat*, and each Muslim is expected to pay 2.5% of his or her wealth annually for the benefit of others in need.
4. The Fast	To abstain from food, drink, and sexual intercourse during daytime (from dawn to sunset) throughout the 9th lunar month (Ramadan). It is a means of self-purification and spirituality. The sick, elderly, or pregnant/nursing women may be permitted to break the fast.
5. The Pilgrimage	The pilgrimage to Makkah (Mecca, or the Hajj) once in a lifetime for those who are physically and financially able to do so. About 2 million people go to Makkah every year (located in Saudi Arabia).

Population Characteristics and Culture

An Arab is generally defined as someone from 1 of the 22 Arab countries who speaks an Arabic dialect and shares the values and beliefs of an Arab culture (AAI, 2015). Arab Americans can trace their ancestry to the North African countries of Morocco, Tunisia, Algeria, Libya, Sudan, and Egypt, as well as the Western Asian countries of Lebanon, Palestine, Syria, Jordan, Bahrain, Qatar, Oman, Saudi Arabia, Kuwait, the United Arab Emirates, and Yemen. Iran is sometimes listed in this group, although Iranians generally consider themselves to be Persian, not Arab AAI, 2015. Assyrian/Chaldean/Syriac and sub-Saharan (Somalian and Sudanese) groups are also noted as Arab. In general, the beliefs and practices of people from such disparate and distant countries cannot be encompassed into one culture. Despite the fact that some of these countries are highly Westernized, enjoy natural resources such as crude oil and the riches that may follow, and are more liberal in following traditional cultural practices, others do not.

Arabs are mostly divided into two distinct religious groups: Muslims and Christians. Arabs generally value Western medicine, trust American health care workers, and do not generally postpone seeking medical care (Lovering, 2012). Several practices, however, are unfamiliar to most Americans. Many Arabic women stay at home and are not in the workforce. Families impose stricter rules for girls than for boys. After menarche, teenage girls may not socialize with boys. The adolescent female also begins to cover her head and perhaps wears a *hajab*, which takes the form of a modest dress and veil designed to diminish attractiveness and appeal to the opposite sex. Some Arab groups take this mode of dress to

extremes, not even allowing a woman's eyes to show out of the *hajab*. Modesty is one of the core values for Arabs; it is expressed by both genders, although more evidently by females (Lovering, 2012; Padela, Gunter, Killawi, & Heisler, 2012).

Within the Arabic population, strict sexual taboos and social practices exist. All sexual contacts outside the marital bond are considered illegal. Those known to have been involved in such activities can be socially rejected, or in some countries even put to death. The stigma of lost honor can continue with their families for generations to come. Another social practice, at times mistakenly related to the Islamic religion, is the practice of female genital mutilation. This is practiced in a few of the Arabic countries on the African continent and has spread to southern Egypt, but it is rare or nonexistent in other Arabic countries. This practice may include the removal of a young woman's labia, clitoris, or both, and it sometimes includes closing the vaginal opening by suturing. Such mutilation can result in prolonged labor and obstetric lacerations, along with urinary and fecal fistula (Berg & Underland, 2013).

Health Problems

Health problems among Middle Easterners are most frequently lifestyle related. These include poor nutritional practices, resulting in obesity, especially among women; smoking among men; and lack of physical exercise (Padela et al., 2012). In some rural areas, especially in Saudi Arabia, men and women chew tobacco, and an increase of oral cancers is seen. Major public health concerns for most Arabs are related to motor vehicle accidents, maternal–child health, TB, malaria, trachoma, typhus, hepatitis, typhoid fever, dysentery, and parasitic infection (Giger, 2017).

Most social restrictions are directed toward women and can affect their health. As mentioned earlier in this chapter, pregnancy can be complicated by genital mutilation, with infections and difficult deliveries. Childbearing continues up until menopause. There is often a desire to have more sons than daughters, and this may result in very large families and closely spaced pregnancies—often without the benefit of family planning. It is often debated whether birth control methods are sanctioned by Islam or not, but Akbar (2015) states that Muslims can reason for themselves, and notes that family planning is not forbidden by the beliefs of Islam. Abortion and infanticide are not accepted, however.

Health Beliefs and Practices

Traditional medicine is practiced in spite of the growth of Western medical services in some of the richer Arab nations. Traditional health care practices are much more common in the poorer Middle Eastern countries and in rural areas of all Arabic countries.

Muslims believe in predestination—that life is determined beforehand—and they attribute the occurrence of disease to the will of Allah. However, this does not prevent people from seeking medical treatment. Islamic law prohibits the use of illicit drugs, which include alcohol. Users of such substances are liable to trial, and those convicted of

smuggling substances into an Arab country can be sentenced to death in some cases. *Sharaf*, or honor, is an important concept in Arab American beliefs, and drug addiction, mental illness, or unwed pregnancy of a family member brings shame to the entire family (Padela et al., 2012). Conversely, when a member does something good or is recognized for an achievement, that honor is reflected on the family as a whole.

Cleanliness is paramount and ritualistic, especially before prayers and after sexual intercourse. The bodies of both genders are kept free of axillary and pubic hair. The left hand is used for cleaning the genitals and the right one is reserved for eating, hand shaking, and other hygienic activities. Muslims fast during Ramadan from sunrise to sunset, and this can include abstinence from all things (including medications or intravenous fluids). Illness can be an exception to this rule, but public health nurses should consult with a family elder or Muslim leader to encourage the client to continue with any necessary treatments. Also, Muslims pray several times daily, facing toward Mecca. Home visits should be planned so that prayers are not interrupted (Padela et al., 2012).

When caring for Arabs in clinics or at home, a nurse of the same sex as the client should be assigned. It is important to note that only women may discuss many topics (e.g., menstruation, family planning, pregnancy, and childbirth), and men are not included in these discussions.

Additional guidelines for nurses working with all immigrant groups include the following:

- Make no assumptions about a client's understanding of health care issues.
- Permit more time for interviewing; allow time to evaluate beliefs and provide appropriate interventions.
- Provide educational programs to correct any misconceptions about health issues; this can occur in clinics, mosques, schools, or homes.
- Provide an appropriate interpreter to improve communication with immigrants who do not speak English well.

TRANSCULTURAL COMMUNITY HEALTH NURSING PRINCIPLES

Culture profoundly influences thinking and behavior and has an enormous impact on the effectiveness of health care. Just as physical and psychological factors determine clients' needs and attitudes toward health and illness, so too can culture. Kark emphasized over 30 years ago that "culture is perhaps the most relevant social determinant of community health" (1974, p. 149). Culture determines how people rear their children, react to pain, cope with stress, deal with death, respond to health practitioners, and value the past, present, and future. Culture also influences diet and eating practices. Partly because of culturally derived preferences, dietary practices can be very difficult to change (McFarland & Wehbe-Alamah, 2015; Spector, 2013).

Despite its importance, the client's culture often is misunderstood or ignored in the delivery of health care (McFarland & Wehbe-Alamah, 2015). With the growth in non-White populations, it is essential that nurses, physicians and other professional health care providers are ready to interact with cultural diversity in their health care team members and in their clients (Andrews & Boyle, 2016). Especially in public health, the nurse must avoid ethnocentric attitudes and must attempt to understand and bridge cultural differences when working with others. It is important to develop knowledge and skill in serving multicultural clients and an ability to place clients' responses to experiences within the context of their lives, or else risk ineffectiveness in the face of a limited understanding and interpretation of client experience.

Overcoming ethnocentrism requires a concerted effort on the nurse's part to see the world through the eyes of clients. It means being willing to examine one's own culture carefully and to become aware that alternative viewpoints are possible. It also consists of attempting to understand the meaning other people derive from their culture and appreciating their culture as important and useful to them (Campinha-Bacote, 2011). Ignoring consideration of clients' different cultural origins often has negative results, as illustrated in From the Case Files IV discussion about Maria Juarez.

Culture is a universal experience. Each person is part of some group, and that group helps to shape the values, beliefs, and behaviors that make up their culture. In addition, every cultural group is different from all others. Even within fairly homogeneous cultural groups, subcultures and microcultures have their own distinctive characteristics. Further differences, based on such factors as socioeconomic status, social class, age, or degree of acculturation, can be found within microcultures. These latter differences, called *intraethnic variations*, only underscore the range of culturally diverse clients served by community health nurses.

Given such diversity, community health nurses face a considerable challenge in providing service to cross-cultural groups. This kind of practice, known as transcultural

nursing, means providing culturally sensitive nursing service to people of an ethnic or racial background different from the nurse's (Andrews & Boyle, 2016; McFarland & Wehbe-Alamah, 2015). Community health nurses in transcultural practice with client groups can be guided by several principles: develop cultural self-awareness, cultivate cultural sensitivity, assess the client group's culture, show respect and patience while learning about other cultures, and examine culturally derived health practices.

Develop Cultural Self-Awareness

The first principle of transcultural nursing focuses on the nurse's own culture. Self-awareness is crucial for the nurse working with people from other cultures (Andrews & Boyle, 2016; McFarland & Wehbe-Alamah, 2015). Nurses must remember that their culture often is sharply different from the culture of their clients. Cultural self-awareness means recognizing the values, beliefs, and practices that make up one's own culture. It also means becoming sensitive to the impact of one's culturally based responses. The community health nurse who assisted Mrs. Juarez in the fourth Case File discussion probably thought that she was being friendly, efficient, and helpful. In terms of her own culture, this nurse's behavior was intended to reassure clients and meet their needs. Unaware of the negative consequences of her behavior, the nurse caused damage rather than met needs.

To gain skill in understanding their own culturally based behavior, nurses can complete a cultural self-assessment by analyzing their own:

- Influences related to racial background
- Verbal and nonverbal communication patterns
- Values and norms (expected cultural practices or behaviors)
- Beliefs and practices

Start with a detailed list of values, beliefs, and practices relative to each point. Next, enlist one or more close friends to call attention to selected behaviors, to bring them to a more conscious level. Videotaping practice interviews with colleagues and actual interviews with selected clients creates further awareness of the nurse's unconscious, culturally based responses. Finally, ask selected clients to critique nursing actions in light of the clients' own culture. Feedback from clients' perspectives can reveal many of the nurse's own cultural responses.

Because culture is mostly tacit, as discussed earlier, it takes conscious effort and hard work to bring the nurse's own cultural biases or influence to the surface. Doing so, however, rewards the nurse with a more effective understanding of self and enhanced ability to provide culturally relevant service to clients (Andrews & Boyle, 2016; Spector, 2013).

Cultivate Cultural Sensitivity

The second transcultural nursing principle seeks to expand the nurse's awareness of the significance of culture on behavior. Nurses' beliefs and ways of doing things frequently conflict with those of their clients. A first step toward bridging cultural barriers is to recognize those differences and develop cultural sensitivity. Cultural sensitivity requires recognizing that culturally based values, beliefs, and practices influence people's health and lifestyles and need to be considered in plans for service (Campinha-Bacote, 2011; McFarland & Wehbe-Alamah, 2015). Mrs. Juarez's values and health practices sharply contrasted with those of the clinic's staff. Failure to recognize these differences led to a breakdown in communication and ineffective care. Once differences in culture are recognized, it is important to accept and appreciate them. A nurse's ways are valid for the nurse; clients' ways work for them. The nurse visiting the Kim family in the third case file discussion avoided the dangerous ethnocentric trap of assuming that her way was best, and she consequently developed a fruitful relationship with her clients.

As a part of developing cultural sensitivity, nurses need to try to understand clients' points of view. They need to stand in their clients' shoes and try to see the world through their eyes. By listening, observing, and gradually learning other cultures, the nurse must add a further step of choosing to avoid ethnocentrism. Otherwise, the nurse's view of a different culture will remain distorted and perhaps prejudiced (Andrews & Boyle, 2016; McFarland & Wehbe-Alamah, 2015). The ability to show interest, concern, and compassion enabled one nurse to win the trust and respect of the Native American women in the second case file example and told the Kims that their nurse cared about them. These nurses attempted to understand the feelings and ideas of their clients; in this way, they established a trusting relationship and opened the door to the possibility of their clients' adopting healthier behaviors

Assess the Client Group's Culture

A third transcultural nursing principle emphasizes the need to learn clients' cultures. All clients' actions, like one's own, are based on underlying culturally learned beliefs, values, and ideas (Andrews & Boyle, 2016; Spector, 2013). Mrs. Kim did not like milk because her culture had taught her that it was distasteful and she believed many Asians are lactose intolerant (Reicks et al., 2012). The Native American women's response to waiting or keeping someone else waiting was influenced by their valuing patience. There usually is some culturally based reason that causes clients to engage in (or avoid) certain actions. Instead of making assumptions or judging clients' behavior, the nurse first must learn about the culture that guides that behavior. During a cultural assessment (Giger, 2017), the nurse obtains health-related information about the values, beliefs, and practices of a designated cultural group. Learning the culture of the client first is critical to effective nursing practice. The Transcultural Assessment Model (Giger, 2017) proposes six interrelated factors for assessing differences between people in cultural groups (Fig. 5–2). Understanding these phenomena is a first step toward appreciating the diversity that exists among people from different cultural backgrounds. Interviewing members of a subcultural group can provide valuable data to enhance understanding (Andrews & Boyle, 2016).

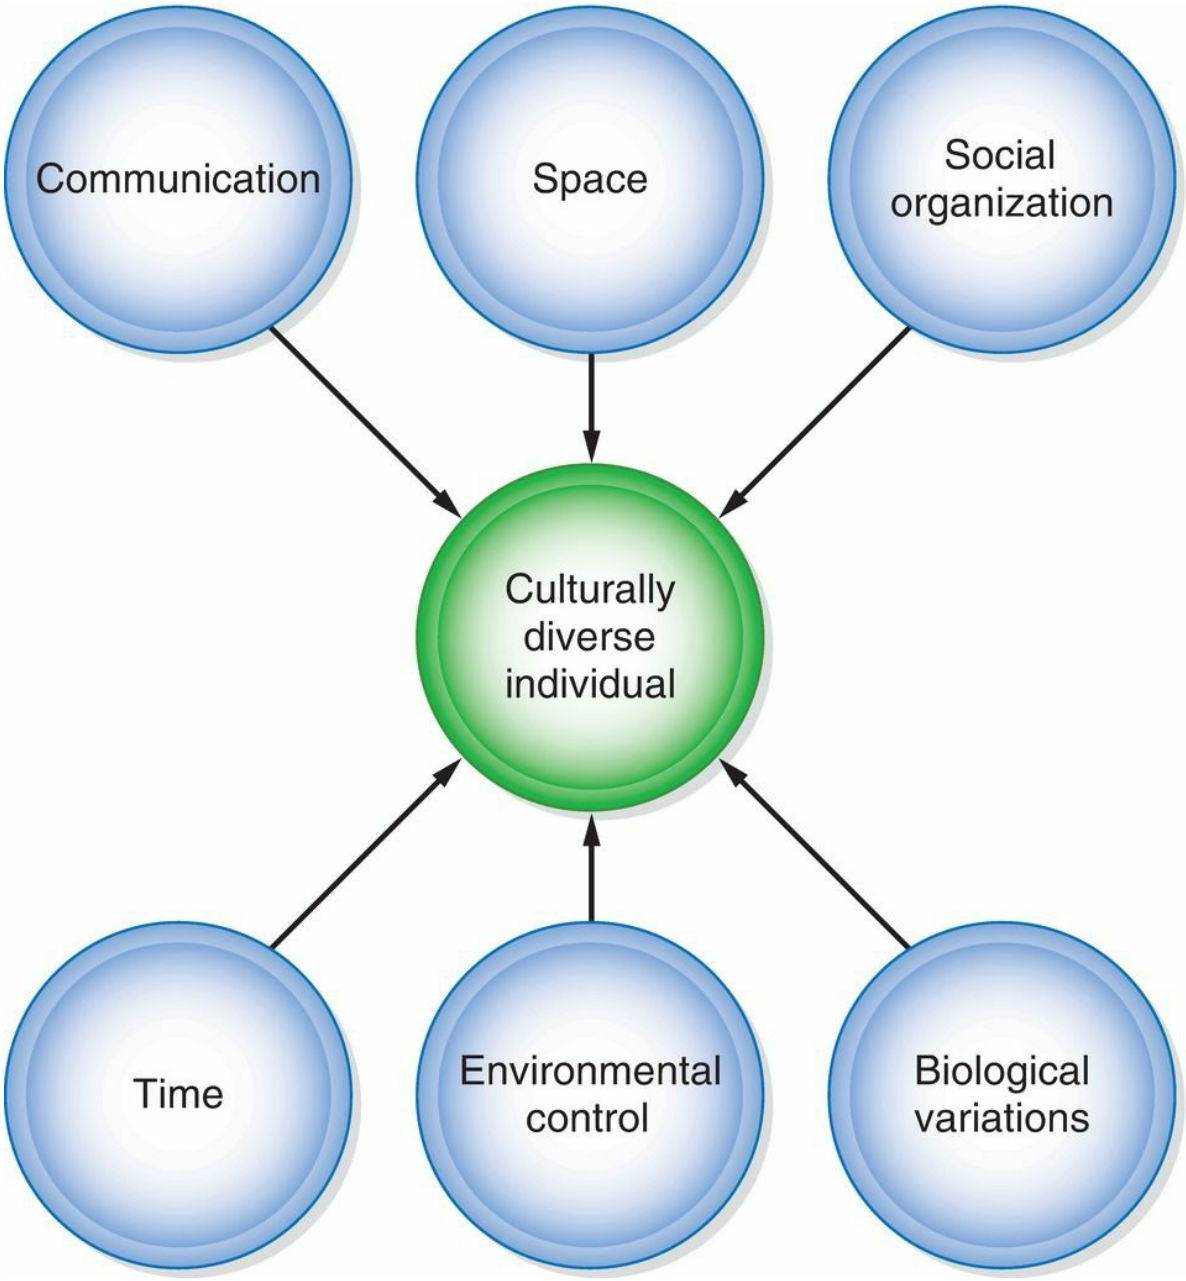

FIGURE 5–2 Components of the Giger and Davidhizar Transcultural Assessment Model showing the culturally diverse individual through communication, space, social organization, time, environmental control, and biologic variations. (Adapted from Giger, J. M. (2017). Culturally competent care: Emphasis on understanding the people of Afghanistan, Afghan Americans, and Islamic culture and religion. International Nursing Review, 49(2), 79–86, with permission.)

To fully understand a group's culture, it should be studied in depth. Immersion in a given culture is needed to better understand the patterns and teachings that shape individual behavior. The concept of diversity can be generally understood, but each individual group should be appreciated within its own cultural and historical context.

Practically speaking, however, it is not possible to study in depth all of the cultural

groups that the nurse encounters. Instead, the nurse can conduct a cultural assessment by questioning key informants, observing the cultural group, and reading additional information in the literature. The data can be grouped into six categories:

1. *Ethnic or racial background*: Where did the client group originate, and how does that influence their status and identity?
2. *Language and communication patterns*: What is the preferred language spoken, and what are the group's culturally based communication patterns?
3. *Cultural values and norms*: What are the client group's values, beliefs, and standards regarding such things as family roles and functions, education, child-rearing, work and leisure, aging, death and dying, and rites of passage?
4. *Biocultural factors*: Are there physical or genetic traits unique to this cultural group that predispose them to certain conditions or illnesses?
5. *Religious beliefs and practices*: What are the group's religious beliefs, and how do they influence life events, roles, health, and illness?
6. *Health beliefs and practices*: What are the group's beliefs and practices regarding prevention, causes, and treatment of illnesses?

The cultural assessment guide presented in Table 5–7 gives suggestions for more detailed data collection.

Table 5–7 Cultural Assessment Guide

Category	Sample Data
Ethnic/racial background	Countries of origin Mostly native born or U.S. born? Reasons for emigrating if applicable Racial/ethnic identity Experience with racism or racial discrimination?
Language and communication patterns	Languages of origin Languages spoken in the home Preferred language for communication How verbal communication patterns are affected by age, sex, other? Preferences for use of interpreters Nonverbal communication patterns (e.g., eye contact, touching)
Cultural values and norms	Group beliefs and standards for male and female roles and functions Standards for modesty and sexuality Family/extended family structures and functions Values regarding work, leisure, success, time Values regarding education and occupation Norms for child-rearing and socialization Norms for social networks and supports Values regarding aging and treatment of elders Values regarding authority Norms for dress and appearance
Biocultural factors	Group genetic predisposition to health conditions (e.g., hypertension, anemia) Socioculturally associated illnesses (e.g., AIDS, alcoholism) Group attitudes toward body parts and functions Group vulnerability or resistance to health threats? Folk illnesses common to group? Group physical/genetic differences (e.g., bone mass, height, weight, longevity)
Religious beliefs and practices	Religious beliefs affecting roles, childbearing and child-rearing, health and illness? Recognized religious healers? Religious beliefs and practices for promoting health, preventing illness, or treatment of illness Beliefs and rituals regarding conception and birth Beliefs and rituals regarding death, dying, grief
Health beliefs and practices	Beliefs regarding causes of illness Beliefs regarding treatment of illness Beliefs regarding use of healers (traditional and Western) Health promotion and illness prevention practices Folk medicine practices Beliefs regarding mental health and illness Dietary, herbal, and other folk cures Food beliefs, preparation, consumption Experience with Western medicine

Many cultural assessment guides can be found throughout the nursing literature. Nonetheless, a thorough cultural assessment may be too time-consuming and costly. Instead, the two-phase assessment process is proposed, as outlined in Table 5–8. Categories to explore in the assessment include values, beliefs, customs, and social structure components. Two methods that have proved highly effective for in-depth study of cultural groups are ethnographic interviewing and participant observation. Spradley (1979, 1980) provides classic descriptions of these methods.

Table 5–8 Two-Phased Cultural Assessment Process

Phase I—Data Collection	
Stage 1	Assess values, beliefs, and customs (e.g., ethnic affiliations, religion, decision-making patterns).
Stage 2	Collect problem-specific cultural data (e.g., cultural beliefs and practices related to diet and nutrition).
Stage 3	Make nursing diagnoses. Determine cultural factors influencing nursing intervention (e.g., child-rearing beliefs and practices that might affect nurse teaching toilet training or child discipline).
Phase II—Data Organization	
Step 1	Compare cultural data with: Standards of client's own culture (e.g., client's diet compared with cultural norms) Standards of the nurse's culture Standards of the health facility providing service.
Step 2	Determine incongruities in above standards.
Step 3	Seek to modify one or more systems (client's, nurse's, or the facility's) to achieve maximum congruity.

Show Respect and Patience While Learning About Other Cultures

The fourth transcultural nursing principle emphasizes key behaviors for the nurse to practice during the cultural learning process. Respect is the first behavior, and it is shown in many ways. When Sandra Josten involved the Native American women in decisions and gave them choices, she was showing respect. When the nurse gave positive recognition to the importance of the Kims' culture, she was showing respect. Attentive listening is a way to show respect and to learn about a client's culture. Within the United States, people of minority groups particularly need respect (Renzaho, Romios, Crock, & Sønderlund, 2013). At times, for groups with limited English skills and a community health nurse who is not bilingual, an interpreter who can assist with communication becomes a necessity (Display 5–7).

DISPLAY 5.7 INTERPRETER GUIDELINES

Hearing-impaired client helped by interpreter using sign language.

1. Unless the community health nurse is thoroughly effective and fluent in the client's language, an interpreter should be used.
2. Become familiar with your interpreters. Meet with them on a regular basis, because they provide both a window and a mirror when dealing with clients.
3. The interpreter must maintain confidentiality and can divulge nothing without the full approval of the client and community health nurse.
4. Evaluate the interpreter's style, approach to clients, and ability to develop a relationship of trust and respect. Try to match the interpreter to the client.
5. Maintain eye contact with and address the client, not the interpreter. Remember that clients may understand what is being said (to some degree) even if they don't feel comfortable speaking English.
6. Be patient. Careful interpretation often requires that the interpreter use long, explanatory phrases. Confirm the client's understanding and agreement to promote improved care.
7. Interpreters must interpret everything that is said by all of the people in the interaction but should inform the community health nurse if the content might be perceived as offensive, insensitive, or harmful to the dignity and well-being of the client.
8. When appropriate, encourage interpreters to explain cultural differences to the client and to yourself.
9. Interpretation conveys the content and spirit of what is said, with nothing omitted or added.
10. Volunteer interpreters receive no fee. Employed interpreters usually receive their fee or salary from the hiring agency. They should not accept money or favors from clients or the community health nurse. A sincere "thank you" is the most appropriate gratuity.

From Massachusetts General Hospital. (2015). Working with an interpreter. Retrieved from http://www2.massgeneral.org/interpreters/working.asp

A minority group is part of a population that differs from the majority and often receives different and unequal treatment. Their ways contrast with those of the dominant culture. It is difficult for them to retain pride in their lifestyles, or in themselves, when the majority culture suggests that they are inferior (McFarland & Wehbe-Alamah, 2015; Spector, 2013). This message may be only implied or even unintentional, as was the case for Mrs. Juarez in From the Case Files IV. The clinic's routine and the manner of the staff were not intended to show disrespect. They did, nevertheless, and Mrs. Juarez was intimidated and was unable to receive the help that she needed. Everyone needs respect to enhance pride, dignity, and self-esteem; it is an important contributor to good mental health. Showing respect also is an important means for breaking down barriers in cross-cultural communication. For community health nurses, culturally relevant care means practicing cultural relativism. Cultural relativism is recognizing and respecting alternative

viewpoints and understanding values, beliefs, and practices within their cultural context.

In addition to respect, patience is essential. It takes time to build trust and effect cultural change. It can be difficult to establish the nurse–client relationship when it involves two different cultures. Trust must be won, and winning it may take weeks, months, or years. Time must be allowed for both nurse and clients to learn how to communicate with one another, to test one another's trustworthiness, and to learn about one another. Change in behavior (learned aspects of the culture) occurs gradually. Some aspects of both the nurse's and the clients' cultures can, and probably will, change. The Kims' nurse, Paula Morrow, for example, modified some of her usual practices and adapted them to the Kims' culture and needs. They, in turn, began to assume some American practices and values. However, the process took several months. Time, respect, and patience help to break down cultural barriers (Campinha-Bacote, 2011).

Examine Culturally Derived Health Practices

The final transcultural nursing principle involves scrutiny of the client group's cultural practices, as they affect the group's health status. Once the community health nurse has assessed the culture of the client group, cultural practices affecting the health of the client group need to be examined. Are these behaviors preserving and enhancing the group's health, or are they harmful to their health? Some traditional practices, such as customary diet, birth rituals, and certain folk remedies, may promote both physical and psychological health. These can be considered healthful. Other practices may be neither harmful nor particularly health promoting but are useful in preserving the culture, security, and sense of identity of a particular ethnic group. And some traditional practices may be directly harmful to health. Examples include using herbal poultices to treat an infected wound or "burning" the abdomen to compensate for heat loss associated with diarrhea (Gardner & McGuffin, 2013; McFarland & Wehbe-Alamah, 2015).

Cultural assessment and aggregate health assessment must go hand in hand. If the group is experiencing a high incidence of low-birth-weight babies, pregnancy complications, skin infections, mental illness, or other evidence of health problems, these can be clues to prompt an examination of cultural health practices. Those that are clearly damaging to health can be discussed with group leaders and healers. In this situation, knowing the group's cultural norms for authority and decision-making can be helpful. Often, a cultural practice can be continued or modified while combined with Western medicine, so that respect for the culture is maintained while full treatment efficacy is accomplished (see From the Case Files V).

From the Case Files V

The Importance of Cultural Sensitivity

In Australia, well-intentioned government officials, including representatives of the health ministry, identified problems related to substandard housing among a particular aggregate of aboriginal people. To assist this community, the officials spent a great deal of time, energy, and finances planning and building homes for the Aborigines. The homes were small but modern and offered many of the conveniences that officials believed would improve the quality of life for the community.

The Aborigines were appreciative of the group's efforts and moved into their new homes. Before long, however, officials realized that one by one the community members were moving back to their "substandard" housing. When asked about their lack of appreciation for the improved lifestyle, the group informed the officials that

their watering hole was their lifeline and that the houses were not only uncomfortable to them but were too far from their watering hole. Soon, all of the aboriginal families had returned to living on the land, and the homes were part of a veritable ghost town in the middle of nowhere.

Questions

- Was the aboriginal community truly "poor," as the officials seemed to think?
- Discuss your perception of the following issues: Cultural imposition, cultural poverty, dignity and spirit.
- If you were part of an international health team assigned to return to the community to try again to improve their quality of life, what steps would you take to ensure that previous mistakes are not repeated?

SUMMARY

Community health clients belong to a variety of cultural groups. A culture is a design for living; it provides a set of norms and values that offer stability and security for members of a society and plays a major role in motivating behaviors. Cultural differences exist, and values of the dominant culture can result in power differentials that can affect the population health. The increase in and great variety of cultural groups reinforce the need for community health nurses to understand and appreciate cultural diversity. Ethnocentrism is the bias that a person's own culture is best and others are wrong or inferior. It can create serious barriers to effective nursing care. Understanding cultural diversity and being sensitive to the values and behaviors of cultural groups often is the key to effective community health intervention.

Culture has five characteristics: it is learned from others; it is an integrated system of customs and traits; it is shared; it is tacit; and it is dynamic. Every culture preserves its integrity by deleting nonfunctional practices and acquiring new components that better serve the group. To gain acceptance, nurses must strive to introduce improved health practices that are presented in a manner consistent with clients' cultural values.

Five transcultural nursing principles, drawn from an understanding of the concept of culture, can guide community health nursing practice: (1) develop cultural self-awareness, (2) cultivate cultural sensitivity, (3) assess the client group's culture, (4) show respect and patience while learning other cultures, and (5) examine culturally derived health practices.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Based on your own cultural background, how would you feel and what behaviors would you exhibit if you were:
   a. A client sitting in a clinic waiting room in a foreign country whose language you did not know?
   b. Part of a nutrition class being told to eat foods you had never heard about before?
   c. Visited in your home by a nurse who told you to discipline your child in a way that contradicted everything you had been raised to believe about parenting?
2. Describe three tacit cultural rules that govern your own behavior. How might these affect your interactions with clients from another culture?
3. What does the term *ethnocentrism* mean to you? Have you ever experienced someone else being ethnocentric in their attitude toward you? If so, describe that experience. Using the Cross-Cultural Sensitivity Continuum (see Fig. 5–1), explore where your own attitudes are on the continuum toward several of the cultural groups with which you regularly come in contact or from which you know people well.
4. Imagine that you are a PHN assigned to work with a Mexican American migrant population. What are the steps that you would take to gather the appropriate information to provide culturally relevant nursing service? What sources might provide that information?
5. A Hmong father who severely beat his 12-year-old son with a belt, leaving cuts and bruises, is charged with child abuse. "If I can't discipline my son, how can he be a good child?" said the father. What nursing responses would show respect for this cultural group's norms and values and yet be constructive in resolving the cultural conflict?
6. Find Web sites that elaborate on transcultural nursing and cross-cultural health care concerns. What is most surprising or interesting to you? What information is most helpful to you in your nursing practice (in the acute care setting or public health nursing)?
7. Interprofessional communication techniques among diverse health care disciplines are imperative to effective caregiving. How comfortable are you with knowing the linguistic style, practice, and research backgrounds of social workers, pharmacists, physical therapists, educators, psychologists, and others? Seek out a colleague from a different interprofessional discipline and discuss developing a "shared language."
8. Sample exam questions for material in this chapter:
   a. A new nurse in the health department comments that the elderly Vietnamese woman was "stupid" because she could not tell the nurse how long she had been coughing up blood. What is the best response you can give to the nurse?

1. “Some Asians are long-time smokers and the hemoptysis is probably from smoking.”
2. “That patient may be afraid of TB and not want to tell you. Try asking her a different way.”
3. “That patient does not look like she understands English, and I doubt it is blood; it is probably food.”
4. “Tell her to come back in 3 weeks, when the Vietnamese interpreter is here.”

b. Your caseload includes a Columbian refugee family who witnessed the torture of their neighbors before coming to this country. The mother reports through an interpreter that her 11-year-old son is misbehaving in school, does not sleep through the night, and has lost interest in games he used to enjoy. What is your best response?

1. In America, boys this age focus on their peers, and often develop interests outside their family. This is normal behavior.
2. It sounds like he is disobedient. You should set behavioral rules and be strict with him.
3. He is probably tired. You should go to our clinic doctor to get sleeping medication for him.
4. His behavior may be related to things he saw years ago. We have a doctor at the clinic that might be able to help with that.

Key for Sample Exam Questions

a. The correct response is (2). In the response, the nurse uses clinical knowledge about potential health problems in the ethnic group. The nurse suggests that the new employee use patience to achieve effective communication with the patient.

b. The correct response is (4). In the response, the nurse is using clinical knowledge about this population and mental or physical health problems for which they may be at high risk. The nurse is addressing the mother's concerns with a referral to rule out a posttraumatic stress condition.

2 UNIT

PUBLIC HEALTH ESSENTIALS FOR COMMUNITY HEALTH NURSING

6 CHAPTER

Structure and Economics of Community Health Services

"Healthcare is vital to all of us some of the time, but public health is vital to all of us all of the time."
—*C. Everett Koop*, Former U.S. Surgeon General

"There are 1011 stars in the galaxy. That used to be a huge number. But it's only a hundred billion. It's less than the national deficit! We used to call them astronomical numbers. Now we should call them economical numbers."
—*Richard Feynman* (1918–1988)

KEY TERMS

Universal coverage
Voluntary health agencies

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Trace historic events and philosophical developments leading to today's health services delivery systems.
- Outline the current organizational structure of the public health care system.
- Examine the three core functions of public health as they apply to health services delivery.
- Differentiate between the functions of public versus private sector health care agencies.
- Examine the public health services provided by selected international health organizations.
- Explain the influence of selected legislative acts in the United States on shaping current health services policy and practice.
- Explore how the structure and functions of community health services affect community health nursing practice.
- Define the concept of health care economics.
- Describe three sources of health care financing.
- Compare and contrast retrospective and prospective health care payment systems.
- Analyze the trends and issues influencing health care economics and community health services delivery.
- Explain the causes and effects of health care rationing.
- List the pros and cons of managed competition as opposed to a single-payer system.
- Discuss health care reform and its potential impact on community health nursing.
- Explain the philosophical implications of health care financing patterns on community health nursing's mission and values.

Nurses preparing for population-based practice need to be familiar with how the health care delivery system is organized and operates, because it is through this system that we are able to offer community health services (see Chapter 3). This system forms an organizing framework for the design and implementation of programs aimed at

improving the health of communities and vulnerable groups. It is within this system or framework that community health nurses labor, realize the opportunity to shape future health services, and develop innovative and more effective means of improving community health.

Nurses concerned with the delivery of needed community health services also must understand how those services are financed. In an era when health care costs are rising while resources are limited and providers are competing for scarce dollars, nurses must be well informed about the issues related to health care financing and about ways to obtain funding to address identified health needs in the community. The structure and economics of community health care are intertwined. Health care economics is a specialized field of economics that describes and analyzes the production, distribution, and consumption of goods and services, as well as a variety of related problems such as finance, labor, and taxation (Estes, Chapman, Dodd, Hollister, & Harrington, 2013). The goal of health care economics, much like that of public health, is to overcome scarcity by making good choices while providing essential services.

Service delivery systems directed at restoring or promoting the public's health have evolved over centuries. The structure, function, and financing of health care systems have changed dramatically during that time in response to evolving societal needs and demands, scientific advancements, more effective methods of service delivery, new technologies, and varying approaches to resource acquisition and allocation (Knickman & Kovner, 2015). Although progress has been made toward a healthier global society, many problems remain, particularly those of controlling health care costs, assuring equitable distribution and effectiveness of health services, and assuring the quality of and access to those services (Pan American Health Organization, 2016; U.S. Department of Health & Human Services [USDHHS], 2016b).

This chapter examines the current structure and functions of community health services in the United States and reviews historical and legislative events that influenced the planning for and the delivery of those services. It also provides an overview of health care economics and the ever-changing landscape of financial incentives and disincentives for enhancing the public's health.

HISTORICAL INFLUENCES ON HEALTH CARE

Despite centuries of change, some personal and community hygiene and health care practices have continued from the beginning of time. Many primitive tribes engaged in sanitary practices such as burial of excreta, removal of the dead, and isolation of members with certain illnesses. Treatment of the sick has always included using a variety of therapeutic agents administered by a "healer."

Whether health care practices were based on superstition, derived from survival needs, or primarily tied to religious beliefs is unknown. Nonetheless, records show that in India, Egypt, and the Middle East, as early as 3000 BCE, people were building drainage systems, using toilets and systems for water flushing, and practicing personal cleanliness (Rosen, 2015). The Hebrew hygienic code, described in the Bible in Leviticus circa 1500 BCE, probably was the first written code in the world and was the prototype for personal and community sanitation. It emphasized bodily cleanliness, protection against the spread of contagious diseases, isolation of "lepers," disinfection of dwellings after illness, sanitation of campsites, disposal of excreta and refuse, protection of water and food supplies, and maternal hygiene (Erwin & Brownson, 2017; Rosen, 2015). Even more advanced were the Athenians, circa 1000 to 400 BCE, who emphasized personal hygiene, diet, and exercise in addition to a sanitary environment, albeit for the benefit of the wealthy. Their successors, the Romans, added more community health measures, such as laws regulating environmental sanitation and nuisances and construction of paved streets, aqueducts, and a subsurface drainage system. In the Americas, the Inca people (from about 1100 CE to 1550 CE) included cities with clean water supplies and extensive sewage systems (Rosen, 2015).

The Middle Ages (from about 500 to 1500 CE) were distinguished by a public health change in Europe. People gathered in cities for protection, but the cities were unable to meet the needs of the growing population (Rosen, 2015). Farm animals were kept near crowded housing, sanitation systems were nonexistent, streets were not paved, and food and water supplies were insufficient. Contrary to popular belief, bathing was important in the Middle Ages (Polack & Kania, 2015). The ability to bathe, however, was likely limited for the lowest classes of society. These living conditions (overcrowding, poor nutrition, and a lack of hygiene) were ideal for the spread of disease.

Increased trade between Europe and Asia, military conquests, and Christian crusades to the Middle East brought diseases to European cities (Rosen, 2015). Bubonic plague, known as the Black Death, was the most devastating of the epidemics, reportedly killing more than 60 million people in the mid-1300s. Fear of the Black Death caused Venice to ban entry of infected ships and travelers—a form of quarantine. Quarantine is a period of enforced isolation of persons exposed to a communicable disease during the incubation period of the disease, to prevent its spread should infection occur. The first known official quarantine

measure was instituted in 1377, at the Port of Ragusa (now Dubrovnik, Croatia), where all travelers from plague areas were required to wait 30 days and to be free of disease before entry. This waiting period was then extended to 40 days, leading to the term quarantine.

For many years, people thought that diseases came from magical or religious sources. Because having a clean body was thought to reflect a "clean" (i.e., sin-free) soul, the inability to bathe regularly became associated with an image of the poor as morally corrupt (Polack & Kania, 2015). To some extent, the association between disease and behavior still exists today. Despite knowing the cause of disease, stigma regarding conditions such as leprosy and tuberculosis (TB) still exists, and some regard sexually transmitted diseases (STDs) and HIV/AIDS as punishment for immoral conduct (Erwin & Brownson, 2017).

During the 16th and 17th centuries, diseases were categorized and described in more detail (Rosen, 2015). Towns and cities continued to use quarantine to protect their populations from epidemics. Concern with sailors' health, followed by miners' health, led to early occupational health interventions. This was followed by new efforts at reform during the Enlightenment period, influenced by a growing emphasis on human dignity, human rights, and the search for scientific truth (Erwin & Brownson, 2017). Despite these improvements, serious problems persisted and new ones developed (Lindemann, 2010). Industrialization, masses of people moving to cities, and low regard for human life all contributed to deplorable living and working conditions. Hundreds of children who were poor died in England's abusive, yet socially approved, workhouses and apprentice system.

As early as the 16th century, London was one of the largest cities in the world, with the population tripling by the end of the 17th century (Cockayne, 2007). By the mid-18th century, noise from carriages and carts, animals, and vendors created a "hideous din" (Cockayne, 2007, p. 107). Air pollution from burning coal and wood for fuel caused Londoners to cough and spit. People "rarely washed their bodies and lived in the constant sight and smell of human feces and human urine" (Cockayne, 2007, p. 60). Householders dumped their refuse from windows or doors into the streets. Rivers and water supplies were seriously contaminated (Lindemann, 2010). Diseases, including cholera, typhus, typhoid, smallpox, and TB, took a tremendous toll on human life.

Around the turn of the 19th century, England's leaders became increasingly concerned about social and sanitary reform (Richardson, 1887). The term sanitation refers to the promotion of hygiene and prevention of disease by maintenance of health-enhancing (sanitary) conditions. The first sanitary legislation, passed in 1837, established vaccination stations in London. One of the most notable reformers, Edwin Chadwick, the father of modern public health, published his *Report on an Inquiry into the Sanitary Conditions of the Laboring Population of Great Britain* in 1842. His efforts resulted in passage of the English Public Health Act and establishment of a General Board of Health for England in 1848, as reported by Lewis (1952) more than a century later.

Dilapidated outhouse and debris behind old tenement building in New York City (around 1930).

John Snow, a London physician, investigated several cholera outbreaks in London neighborhoods (Rosen, 2015). In 1854, he was able to connect addresses of cholera deaths to a particular water source. Thus, Snow is considered one of the founders of epidemiology. His conclusions eventually led to changes in the practice of sewage dumping into the Thames River, thus improving London's morbidity and mortality from cholera (see Chapter 7). His 1855 work, *On the Mode of Communication of Cholera*, was a landmark public health contribution. Conditions improved, and scientific study advanced in England and, concurrently, in France, Germany, Scandinavia, and other European countries. England, however, set the pace for application of research, particularly with reference to public health measures, through steadily improved legislation. British laws subsequently became the pattern for sanitary ordinances in the United States.

PUBLIC HEALTH CARE SYSTEM DEVELOPMENT IN THE UNITED STATES

The current U.S. public health care system was long in developing (Trust for America's Health [TFAH], 2013). Most health-related services in the United States were initially reactive, responding to the pressure of immediate needs and uncoordinated from one locality to another. Over time, events and insights contributed to a gradually improving system of programs and services, along with recognition that the health of individuals was affected by the health of the wider community. (Table 6–1 highlights some of these changes.) Our current public health system is not really a single entity, but more of a loosely affiliated network of federal, state, and local health agencies that have been chronically underfunded.

Table 6–1 Changes in Health Status and Health Care Services

Turn of the 20th Century	Turn of the 21st Century
	Morbidity and Mortality
THEN	NOW
High communicable disease and mortality	High chronic disease morbidity and mortality
Little prevention	Old and new sexually transmitted diseases
Infrequent cure	Resurgence of TB
Life span of 47 y	Life span of 76 y
High infant mortality	Significant infant mortality
High maternal mortality	High teenage pregnancy
Alcohol abuse	Multiple substance abuse
Many undiagnosed and untreated conditions	New strains of multidrug-resistant diseases, long-term chronic illnesses, and disability
Causes of many diseases unknown	Increased emphasis on personal responsibility (e.g., smoking, overweight)
	Access to Health Care
Access primarily for those who could pay a fee	Access for those with health insurance
No health insurance	Insurance with co-payments; costs shifting from employers to employees; health care reform
Public health clinics for people who were poor and underserved	Free health clinics for uninsured (especially children)
Limited treatments available	Multitude of treatments with regular new advances
	Health Care Delivery System
Extended hospital stays	Short-term, acute care hospitalizations
Discharge on recovery	Recovery occurs at home or in a transitional setting.
Extended maternal and newborn hospitalization	Short-stay maternal and newborn care
Many home deliveries with lay assistance	Few home deliveries with skilled assistance
Handwritten charts and notes	Electronic records, bar-coded medication
Home care through not-for-profit agencies	Home care through not-for-profit and proprietary agencies
PHN begun in health departments	Shifting PHN role in health departments
Health departments provide personal care	Health department's personal care services now part of managed care systems
	Public health departments partner with health care systems to share data and offer expertise in population health

Precursors to a Health Care System

Early health care in the American colonies consisted of private practice, with occasional (but infrequent) governmental action for the public good (Erwin & Brownson, 2017). Action usually was in the form of isolated local responses to specific dangers or nuisances, such as the 1647 regulation to prevent pollution of Boston Harbor or the 1701 Massachusetts law requiring ship quarantine and isolation of smallpox patients. New York City, in the late 1700s, formed a public health committee to monitor water quality, sewer construction, marsh drainage, and burial of the dead. Physicians in the early 19th century had few tools at their disposal and could do little to change the course of illness. They made house calls, as most quality care was given in the home, not in hospitals (Cutler, 2005). The U.S. Constitution, adopted in 1789, made no direct reference to public health, nor did the federal government take an active stance on health matters. It was the responsibility of each sovereign state to manage its own health affairs. The first federal intervention for health problems was the Marine Hospital Service Act of 1798 (Rosen, 2015). It subsidized medical and hospital care for sick and injured merchant seamen, with the first marine hospital being located in Boston.

When Europeans came to the Americas, a scourge of epidemics, especially smallpox, cholera, typhoid, and typhus, caused deaths among the colonists but decimated the Native American population (Woodward, 1932). Extensive travel between colonies made local control of quarantine efforts ineffective. In 1837, Congress finally instituted the national port quarantine system, which was regulated and enforced by the Marine Hospital Service. Epidemics were quickly checked, causing society to recognize the benefits of uniform central government policy. However, improvements in public health and sanitation on a state and local level competed with other needs, such as police and fire protection (Greene, 2001; Lee, Teutsch, Thacker, & St. Louis, 2010). See Table 6–2 for examples of this.

Table 6–2 Societal Events and Situations Affecting Health Care Needs

Turn of the 20th Century	Turn of the 21st Century
Societal and Population Shifts	
THEN	NOW
Industrial society focusing on production	Postindustrial, service and information oriented
Rural to urban	Urban to suburban
Limited violence	Rampant violence and terrorism
Wide gaps between rich and poor	Widening gaps between rich and poor
Growing philanthropy	Declining support for charitable health care
Intense immigration from eastern Europe	Moderate immigration—Africa, Europe, Asia
Environment	
Overcrowded, unsanitary housing	Deteriorating inner-city neighborhoods
Unsafe workplaces, lack of worker safeguards	Environmental hazards in some workplaces
Rampant child labor	Homelessness
Poor public sanitation	Good public sanitation
Multiple health risks	Increasing environmental and behavioral risks
Skill Changes and Employment	
Farm to factory	Factory to service and information
Low wages	Improved but stagnant wages, limited benefits
Dramatic disparity in wages between men and women	Slowly resolving disparity in male/female wage differences
Not enough jobs	Downsizing, layoffs, corporate streamlining, failing companies
People Living in Poverty	
Women and children	Women, children, and the aged
Immigrants—European	Immigrants—Hispanic, Caribbean, Middle Eastern, and Asian
Migration—south to north	Seasonal migration of farm workers

Calls for Sanitary Reforms

The Shattuck Report (1850), a landmark document in the United States, made a tremendous impact on sanitary progress. Lemuel Shattuck, a physician and legislator, chaired a legislative committee that studied health and sanitary problems in the Commonwealth of Massachusetts. In 1850, he produced the *Report of the Sanitary Commission of Massachusetts*, describing the public health concepts and methods that form the basis for current public health practice. Shattuck advocated the establishment of state and local boards of health, environmental sanitation, collection and use of vital statistics, systematic study of diseases, control of food and drugs, urban planning, establishment of nurses' training schools (there were none before this time), and preventive medicine.

A similar report by John Griscom on conditions of workers who remained poor in New York City, published in 1845, concluded that illness, premature death, and poverty were directly related and were not the result of immoral or intemperate behaviors, as many public officials advocated. He recommended sanitary reform as did others, among them Barton, Jarvis, and Snow (Duffy, 1990). Almost 25 years passed before these recommendations were fully appreciated and implemented.

Recent Calls to Action

In 1988, the Institute of Medicine (IOM) published *The Future of Public Health*, highlighting the state of disarray in our current public health system and calling for improvements in the public health infrastructure—largely focusing on governmental responsibilities. In 2002, the IOM issued a new publication, *The Future of the Public's Health in the 21st Century*. This report called for expanding the responsibilities of the public health system beyond governmental agencies to include private and nongovernmental entities. The report outlined how partnerships could be formed with communities, businesses, the media, universities, and other components of the health care delivery system to expand the reach of public health and achieve the *Healthy People 2010* goals (IOM, 2002). Other needed changes included a spotlight on multiple determinants of health, a strong population focus, transdisciplinary utilization of evidence-based practice, better communication, and systems of accountability. The IOM again reported on the state of the U.S. public health system in 2012 with *For the Public's Health: Investing in a Healthier Future*. This report noted the need for additional focus on population-based prevention, rather than on clinical care, if the United States is to improve health outcomes. It also called for federal spending on public health to be doubled and that minimum public health services and costs should be determined. Public health departments are positioned to collaborate with community partners and solve existing health problems, but they do not receive enough funding to fulfill their mission. In the report, the IOM calls for stable, long-term financing of public health services. The IOM (2013) publication, *U.S. Health in International Perspective: Shorter Lives, Poorer Health*, provides a timely investigation of the misconceptions that persist about the performance and quality of our health care system.

About 75% of health care spending goes toward preventable conditions such as cardiovascular disease, diabetes, cancer, lung diseases, injuries, STDs, and vaccine preventable diseases, yet <5% of health care spending goes into prevention and public health (Mays, 2013). More research is needed to demonstrate the effects of public health services on population statistics for diabetes, tobacco use, vaccination rates, food safety, nutrition/physical activity, environmental health, and HIV/STD prevention (Mays, 2013). Sir Michael Marmot, a British professor of public health, researches the "social gradient" of health and life expectancy (Boseley, 2010, para. 3). He estimates that if all of their population had a college education, about 200,000 people over the age of 30 would not experience premature deaths; that equates to a 40% drop. Those premature deaths represent lost productivity and diminished tax revenues, so it benefits the entire population to help prevent these inequalities (see Chapter 25).

Official Health Agencies

The beginnings of an organized health care system in the United States came in the form of official health agencies, later called public health agencies. These were publicly funded and operated by state or local governments with a goal of providing population-based health services. Development occurred initially at the local level. Many cities established local boards of health in the late 1700s and early to middle 1800s. Among the earliest were those in Baltimore, Maryland (1798); Charleston, South Carolina (1815); and Philadelphia, Pennsylvania (1818). As their efforts expanded from handling public "nuisances" to dealing with epidemics and complex public health problems, local health boards recognized that full-time staffs were needed, and thus, health departments were formed. Louisiana was first in 1855; Massachusetts followed in 1869.

Again at the national level, the Marine Hospital Service gained a broader function, becoming the Public Health and Marine Hospital Service in 1902. Congress gave it a more clearly defined organizational structure and specific functions for its director, the Surgeon General. In 1912, it was renamed the U.S. Public Health Service (PHS) (USDHHS, 2016a).

Rapidly expanding through World War I and the Great Depression, the PHS strengthened its research activity through the National Institutes of Health (NIH, founded in 1912), added demonstration projects, and initiated greater cooperation with the states. Responding to increasingly complex needs, the NIH added programs significant to public health, such as the Children's Bureau (1912); the National Leprosarium at Carville, Louisiana (1917); examination of arriving aliens (1917); the Division of Venereal Diseases (1918); the Food and Drug Administration [FDA] (1927); and the Narcotics Division (1929), which later became the Division of Mental Hygiene. Title VI of the 1935 Social Security Act promoted stronger federal support of state and local public health services, including health workforce training (USDHHS, 2014a).

As health, welfare, and educational services proliferated, the need for consolidation prompted the creation of the Federal Security Agency in 1939. In 1953, the agency was enlarged and renamed the Department of Health, Education, and Welfare (DHEW), under President Eisenhower. In 1979, education was made a separate cabinet-level department, and the DHEW was renamed the U.S. Department of Health & Human Services (USDHHS, 2015). Other significant events include the establishment during World War II of the Communicable Disease Center in Atlanta, currently known as the Centers for Disease Control and Prevention (CDC), and the development after World War II of the National Office of Vital Statistics, now called the National Center for Health Statistics (NCHS) (CDC, 2015b).

Voluntary Health Agencies

The private sector responded first to health problems in the United States and continues to complement and supplement the government's role in providing health services. By the late 1800s, voluntary health agencies (sometimes called private agencies or nongovernmental organizations [NGOs]) began to emerge. They were privately funded and operated to address specific health needs. The first of these was the Anti-Tuberculosis Society of Philadelphia, which was formed in 1892 to educate the public and the government about TB, then causing 10% of all deaths. Other agencies followed: the National Society to Prevent Blindness was formed in 1908, the Mental Health Association in 1909, the American Cancer Society in 1913, the National Easter Seal Society for Crippled Children and Adults in 1921, and the Planned Parenthood Federation of America, also in 1921. In the late 1800s, organized charities such as the Red Cross, previously denounced for promoting dependent poverty, began to be recognized for their contributions to health and welfare. Philanthropy, too, became prominent with the establishment of the Rockefeller Foundation in 1913, followed by the Carnegie-Mellon, Kellogg, and Robert Wood Johnson Foundations (National Philanthropic Trust, 2016).

Health-Related Professional Associations

Many health-related professional associations have influenced the quality and type of community health services delivery. Among these, the National Organization for Public Health Nursing, from 1912 to 1952, significantly influenced early preparation for and the quality of public health nursing services (Abrams, 2004). The American Public Health Association (APHA), founded in 1872, maintains a prominent role in the dissemination of public health information, influence on health policy, and advocacy for the nation's health. Other nursing and community health organizations that have promoted quality efforts in community health include the Association of Public Health Nurses (APHN) (formerly the Association of State and Territorial Directors of Nursing), the Association of State and Territorial Health Officers (ASTHO), the National League for Nursing (NLN), the American Nurses Association (ANA), and the Association for Community Health Nursing Educators (ACHNE), among others (APHN, n.d.; Levin et al., 2008).

HEALTH ORGANIZATIONS IN THE UNITED STATES

Over the years, responsibility for meeting community health needs has shifted between private groups and governing institutions, each offering different viewpoints and benefits. Only within the last century have they gradually begun to work together to create a loosely structured system of health care (Rosen, 2015).

Turnock (2016) and others have noted the growing interdependence of the public and private sectors, and this partnership was encouraged by the IOM (2002). How does that system work today? What are its strengths and weaknesses? To answer these questions, its structure must first be examined. Structure is important because it becomes the operational base for assessment, diagnosis, planning, implementation, and evaluation of services— and it provides a framework for intersystem and intrasystem communication and coordination. Health services occur at four levels: local, state, national, and international. Like ever-widening concentric circles, these levels encompass broader populations. The organization of health services at each level can generally be classified as one of two types: public or private sector.

Public Sector Health Services

Government health agencies, the tax-supported arm of the public health effort, perform a vital function in community health practice. With their jurisdiction and types of service dictated by law, they coordinate and administer activities that often can be carried out only by group or community-wide action (e.g., proper sewage disposal, provision of sanitary water systems, or regulation of toxic wastes). Many community health activities require an authoritative legal backing to ensure enforcement—another useful function of public health agencies—in areas such as environmental pollution, highway safety practices, communicable disease control, and proper, safe handling of food. Official public health agencies provide important record-keeping services, including the collection and monitoring of vital statistics. They also conduct research, provide consultation, and sometimes financially support other community health efforts.

Core Public Health Functions

Public health agencies perform a wide variety of activities, but all can be grouped under one of three core public health functions (CDC, 2015a; IOM, 1988). These are assessment, policy development, and assurance (Table 6–3). As discussed in Chapters 1 and 3, public health nurses (PHNs) practice as partners with other public health professionals within these core functions.

Table 6–3 Core Public Health Functions Applied to Populations and People at Risk

Population-Wide Services

Assessment

- Health status monitoring and disease surveillance

Public Policy

- Leadership, policy, planning, and administration

Assurance

- Investigation and control of diseases and injuries
- Protection of environment, workplaces, housing, food, and water
- Laboratory services to support disease control and environmental protection
- Health education and information
- Community mobilization for health-related issues
- Targeted outreach and linkage to personal services
- Health services quality assurance and accountability
- Training and education of public health professionals

Personal Services and Home Visits for People at Risk

- Primary care for underserved and those people not served through health care system
- Treatment services for targeted conditions
- Clinical preventive services
- Payments for personal services delivered by others

Assessment refers to measuring and monitoring the health status and needs of a designated community or population. As a core function, it is a continuous process of collecting data and disseminating information about health, diseases, injuries, air and water quality, food safety, and available resources. This function helps to identify trends in morbidity, mortality, and causative factors. It identifies available health resources, unmet needs, and community perceptions about health issues. This is commonly done through community needs assessments (CDC, 2015a).

Policy development is the formation of a guide for action that determines present and future decisions affecting the public's health (CDC, 2015a). As a core public health

function, good public policy development builds on data from the assessment function and incorporates community values and citizen input. It provides leadership and administration for the development of sound health policy and planning. This can include local ordinances, as well as statewide initiatives (e.g., water safety, clean indoor air, alcohol regulation, etc.).

Assurance is the process of translating established policies into services (CDC, 2015a). This function ensures that population-based services are provided, whether by public health agencies or private sources. It also monitors the quality of and access to those services. Training for employees, to assure current knowledge, is another assurance function.

The roles of public health agencies vary by level, with each level carrying out the core functions in different ways to form a partnership in protecting the public's health (Turnock, 2015). International health agencies focus on issues of global concern, setting policy, developing standards, and monitoring health conditions and programs. At the national level, government health agencies engage in similar functions aimed at regional or nationwide concerns.

The federal level provides funds (e.g., through the Medicaid program, block grants, categorical grants) and develops policy (e.g., air pollution policy, occupational safety) but depends on the states to implement them. Agencies at the federal level also develop facilities and programs for special groups, such as Native Americans, migrant workers, inmates of federal prisons, and military personnel and veterans, whose health care is not the direct responsibility of any one state or locality (Erwin & Brownson, 2017; Turnock, 2015; U.S. Environmental Protection Agency, 2015). At the federal level, public health responsibilities include

- Assuring the capacity of all levels of government to provide essential public health services
- Acting when health threats span many states, regions, or the whole country
- Acting where the solution may be beyond the jurisdiction of individual states
- Acting to assist states when they do not have the expertise or resources to mount an effective response in a public health emergency (e.g., natural disaster, bioterrorism, emerging disease, etc.)
- Facilitating the formulation of public health goals in collaboration with state and local governments and other relevant stakeholders (e.g., *Healthy People 2020*)
- Acting transparently and accountably for public health investments
- Disseminating innovation and best practices from state and local public health (TFAH, 2006, p. 7)

State government health agencies function fairly autonomously while working within federal guidelines. They assess, develop, and monitor statewide health needs and services. Historically, they have been responsible for communicable disease control, vital statistics, laboratory services, environmental sanitation and hygiene, health education, and maternal–

child health, with the addition of categorical programs (e.g., heart disease, migrant health) in the 1950s (Erwin & Brownson, 2017). In the 1980s, block grants became the primary way to provide federal funding for state actions. While block grants gave states more flexibility to provide targeted services, they were also seen as a way to decrease overall federal support of public health services (Dilger & Boyd, 2014).

At the local level, a city government health agency, a county agency, or a combination of both assess, plan, and serve the health needs of that locality. Most local health departments (LHDs) are under county jurisdiction, with only a small percentage of cities (usually large cities) having LHDs. Some are city–county agencies or special districts, and most LHDs report to either local government councils or boards of health (Erwin & Brownson, 2017). In some states, LHDs also report to state public health agencies. In about 30% of states, LHDs are operated by the state health agency, which provides services locally, without city or county oversight (Turnock, 2016).

Unlike private organizations that tend to have a specific focus, government health agencies exist to accomplish a broad goal of protecting and promoting the health of the total population under their jurisdiction. Such a task requires a wide range of services and the combined talents of many types of professional disciplines. Among them are nurses, physicians, health educators, sanitarians, epidemiologists, statisticians, engineers, administrators, accountants, computer programmers, planners, sociologists, nutritionists, laboratory technicians, chemists, physicists, veterinarians, dentists, pharmacists, demographers, and meteorologists. Furthermore, public health agencies must function not only on an interdisciplinary basis but also on an interorganizational basis. Other government services (e.g., education) can meet their goals fairly autonomously, but public health cannot accomplish its important objectives without the collaboration of many agencies and organizations, both public and private (Turnock, 2015). To manage the HIV/AIDS epidemic, for example, public health agencies, educational institutions, welfare agencies, mental health programs, home care services, Medicaid, and private groups, among others, have been called upon to collaborate.

Many different government agencies contribute to the health of a community. Most obvious are the local and state health departments, which provide a variety of direct and indirect health services, including community health nursing. Other tax-supported agencies that sponsor health care or health-related services include welfare departments, departments of public works, public schools and hospitals, police departments, county agricultural services, and local housing authorities.

Local Public Health Agencies

At the grassroots level, government health agencies vary considerably in structure and function from one locality to the next. This partly results from variations in local needs and the size and resources of the community. For example, a rural community served by a county or state health department may have needs and services that differ widely from those

of a densely populated urban community (see Chapter 29). Differing health care standards and regulations, as well as the type and stipulations of funding sources, also contribute to variations in the structure and function of health agencies. Nonetheless, each local governmental health agency shares some commonly held responsibilities, functions, and structural features.

The primary responsibilities of the LHD are to assess the local population's health status and needs, determine how well those needs are being met, and take action toward satisfying unmet needs (Erwin & Brownson, 2017). Specifically, local government health agencies should fulfill these core functions as follows:

- Monitor local health needs and the resources for addressing them
- Develop policy and provide leadership in advocating equitable distribution of resources and services, both public and private
- Evaluate availability, accessibility, and quality of health services for all members of the community
- Keep the community informed about how to access public health services

The local health agency represents a critical level of health services' provision because of its closeness to the ultimate recipients—health care consumers. In a classic study by Barry, Centra, Pratt, and Giordano in 1998, a survey of LHDs revealed the top three expenditure categories were enforcing laws and regulations; informing, educating, and empowering people; and ensuring the provision of care. A systematic review of the literature by Hyde and Shortell (2012) included four studies that examined local public health expenditures. The authors found that expenditures were largely focused on providing services to individual patients and clients, with little spending on population-level programs.

The structure of the LHD varies in complexity with the setting. Rural and small urban agencies need a simple organization, whereas large metropolitan agencies require more complex structures to support the greater diversity and quantity of work.

Where a board of health exists, it holds the legal responsibility for the health of its citizens. About 70% of LHDs work with a board of health, and they are more commonly found with smaller populations (National Association of County and City Health Officials [NACCHO], 2014). An elected official may appoint board of health members (e.g., a mayor if the board of health serves a city or a board of supervisors if it serves a county), or voters may elect board of health members. In turn, the board of health often hires a health officer; about 65% do so (NACCHO, 2014). The health officer directs health department activities and usually has specialty training in public health (22%), nursing (32%), or medicine (12%). Most LHDs employ registered nurses (96%) and environmental health workers (85%). Other public health workers, such as nutritionists, health educators, statisticians, epidemiologists, social workers, mental health workers, physical therapists, veterinarians, or public health dentists, may be added as needs and resources dictate. The number of staff at LHDs can range from 5 to nearly 500, depending upon the size of the

agency and population served (NACCHO, 2014). Figure 6–1 depicts the organization of one LHD serving a population of approximately 300,000.

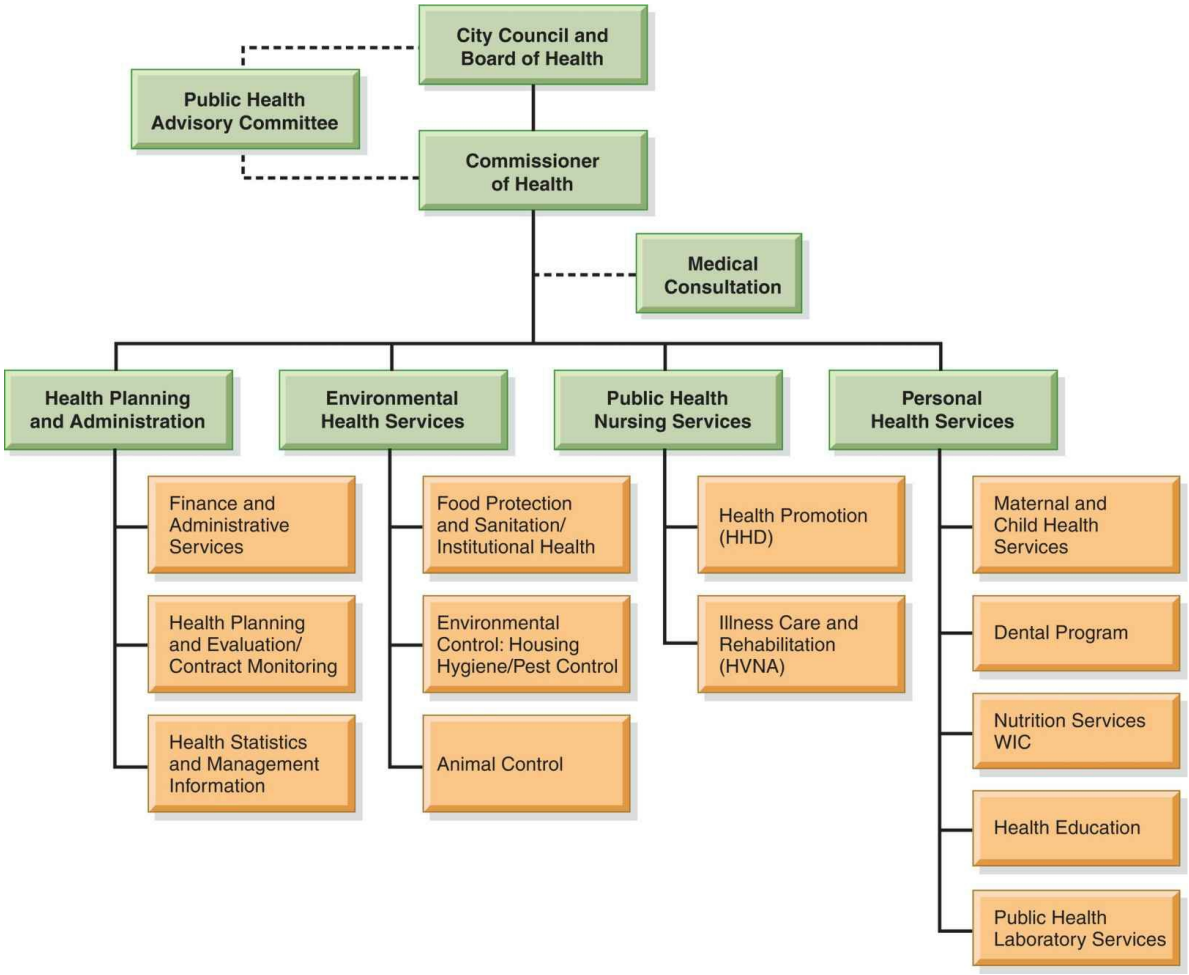

Figure 6–1 Organizational chart of a city public health department.

Revenues to support LHDs come from various sources. A small amount of money comes directly from the federal government, specifically between 2% and 7%, depending on LHD size (NACCHO, 2014). Additional federal funds are provided to LHDs via state health departments. These are known as federal "pass-through" dollars and are generally intended for federal programs delivered at the local level, such as family planning, HIV/AIDS services, or nutrition programs. Approximately 16% of LHD finances come from this source. State funds represent 21% of LHD budgets, and local sources constitute 26% (NACCHO, 2014). In the *2013 Profile of Local Health Departments*, NACCHO (2014) found that local sources made up 30% of LHD budgets. This increase in the percent of the budget coming from local sources reflects cuts in state funding; state health department budgets were cut in 48 states between 2008 and 2013 (TFAH, 2015). About 14% of LDH funds are reimbursement for clinical services, mostly from Medicaid (NACCHO, 2014). According to Turnock (2016), fees, reimbursements, and additional miscellaneous sources, such as state laboratory revenues and food supply supplements, make up the remaining portion of the budget (between 11% and 18%). Cuts in federal, state, and local spending for public health services have led to job cuts across the United States (TFAH, 2015). In 2011, more than half of LHDs reported that they decreased or

eliminated at least one type of service.

State Public Health Agencies

State-level government health agencies also vary in structure and in how they carry out the core functions. Each state, as a sovereign government, establishes its own health department, which in turn determines its goals, actions, and administrative structure. In 42% of states and territories (eight U.S. territories have health departments), the health department is part of a larger, umbrella agency (ASTHO, 2014). Other services in the umbrella agency may include public assistance, substance abuse services, and Medicaid reimbursement.

The state health department is responsible for providing leadership in and monitoring of comprehensive public health needs and services in the state. Most state health departments provide training or technical assistance to LHDs; common topics are disease prevention, tobacco, and disaster preparedness (ASTHO, 2014). State health agencies may also provide some direct services, particularly for populations served by small LHDs, such as HIV counseling and partner notification. A new role for state health agencies is state-level health insurance exchanges, developed under the Patient Protection and Affordable Care Act (ACA); a total of 20 health departments participated in implementing the exchange in the 28 states that did so.

General functions of state health departments include (Erwin & Brownson, 2017)

- Statewide health planning
- Intergovernmental and other agency relations
- Intrastate agency relations
- Certain statewide policy determinations
- Standards setting
- Health regulatory functions

Specifically, the IOM (1988) described the role of state government related to health. Summarized, it includes

- A statewide method of collecting and analyzing data to assess health needs
- Adequate statutory base for state health activities
- Statewide health objectives (holding localities accountable where power for implementation has been delegated)
- Statewide development and maintenance of essential personal, educational, and environmental health services
- Identification of problems that threaten the health of the state
- Support for local health services (when needed to achieve adequate service levels) through subsidies, technical and administrative assistance, or direct action

State public health agencies face a challenge in addressing the health-related issues

confronting them. Health care reform, uninsured and underinsured populations (those who are unable to pay for all or some medical services), long-term care, HIV/AIDS, emerging infectious diseases, and chronic disease are among the problems faced by most states. Clearly, state health departments must collaborate closely with other agencies, such as social services, education, public works, and the housing bureau, and the legislature, to effectively solve such problems. Thus, the solution of state health problems and delivery of health services requires the functioning of an interdependent network of organizations, many of which are not traditional health agencies. Fragmentation of public health roles and functions among different state agencies poses problems for coordinating the core public health functions at this level (Turnock, 2016).

Budgetary sources for a state health department include state-generated funds, federal grants and contracts, and fees and reimbursements. A large source of federal monies to the states comes through the U.S. Department of Agriculture (USDA), which supports the Women, Infants, and Children (WIC) program, a supplemental nutrition program that targets women who are pregnant or breast-feeding, infants, and children up to age 5 (see Chapter 21 for information about WIC). State health agencies often provide grant opportunities for LHDs (either from state funds or through federal grant monies awarded to states). Funding for state public health agencies comes mostly from federal funds (53% of revenue), with less than one quarter (24%) from general state funds (ASTHO, 2014). Other sources of funding are targeted state funds (10%), fees and fines (4%), and miscellaneous sources (9%).

Because the federal government provides the largest portion of state health agency funds, cuts in federal spending for public health have direct consequences for states. Federal funding for key public health agencies, such as the USDA, the CDC, the Health Resources and Services Administration (HRSA), has been reduced in recent years (TFAH, 2015). The USDA provided more than 50% of the federal money given to state health departments in 2011 (ASTHO, 2014). The CDC and HRSA provide most of their budgets to state health agencies, LHDs, and other public or private organizations (TFAH, 2015). In addition, the amount of spending is not distributed equally among the states. Federal funding spent on prevention in 2015 ranged from approximately $15 in Indiana to just over $50 in Alaska. The Milbank Memorial Fund, National Association of State Budget Officers, and Reforming States Group (2005), in the most recent information available, note that <1.7% of all state expenditures go toward population health (e.g., health promotion and chronic disease control). Most state public health expenditures in 2012 dealt with improving consumer health (27%), WIC programs (26%), and infectious (10%) or chronic disease (5%) control (ASTHO, 2014). Environmental health, disaster preparation and response, and quality of health services are also common public health expenditure categories.

Each of the 50 state health departments in the United States has a unique structure. Some are strongly centralized organizations, whereas others are decentralized. In most states, the appointed director or executive of the agency reports to a state board of health or directly to the governor. Some states have advisory boards that make health policy

recommendations and review departmental activities. Organizational structures vary from state to state, but there are usually several divisions or bureaus under the director. Those divisions most commonly found in state health department organizational structures are disease prevention and control, community health services, maternal and child health, health systems and technical services, laboratory services, environmental health, and a state center for health statistics. Figure 6–2 shows the organizational chart of one state health department. Significant variation occurs in the types of programs managed by state health agencies. In 2013, 100% of state health departments reported primary administrative responsibility for emergency preparedness, and nearly all reported administrative responsibility for maternal–child health services (98%) and vital statistics (98%) (ASTHO, 2014). Many state public health agencies regulate health care facilities and deal with food safety and some environmental health issues, especially in areas not covered by an LHD.

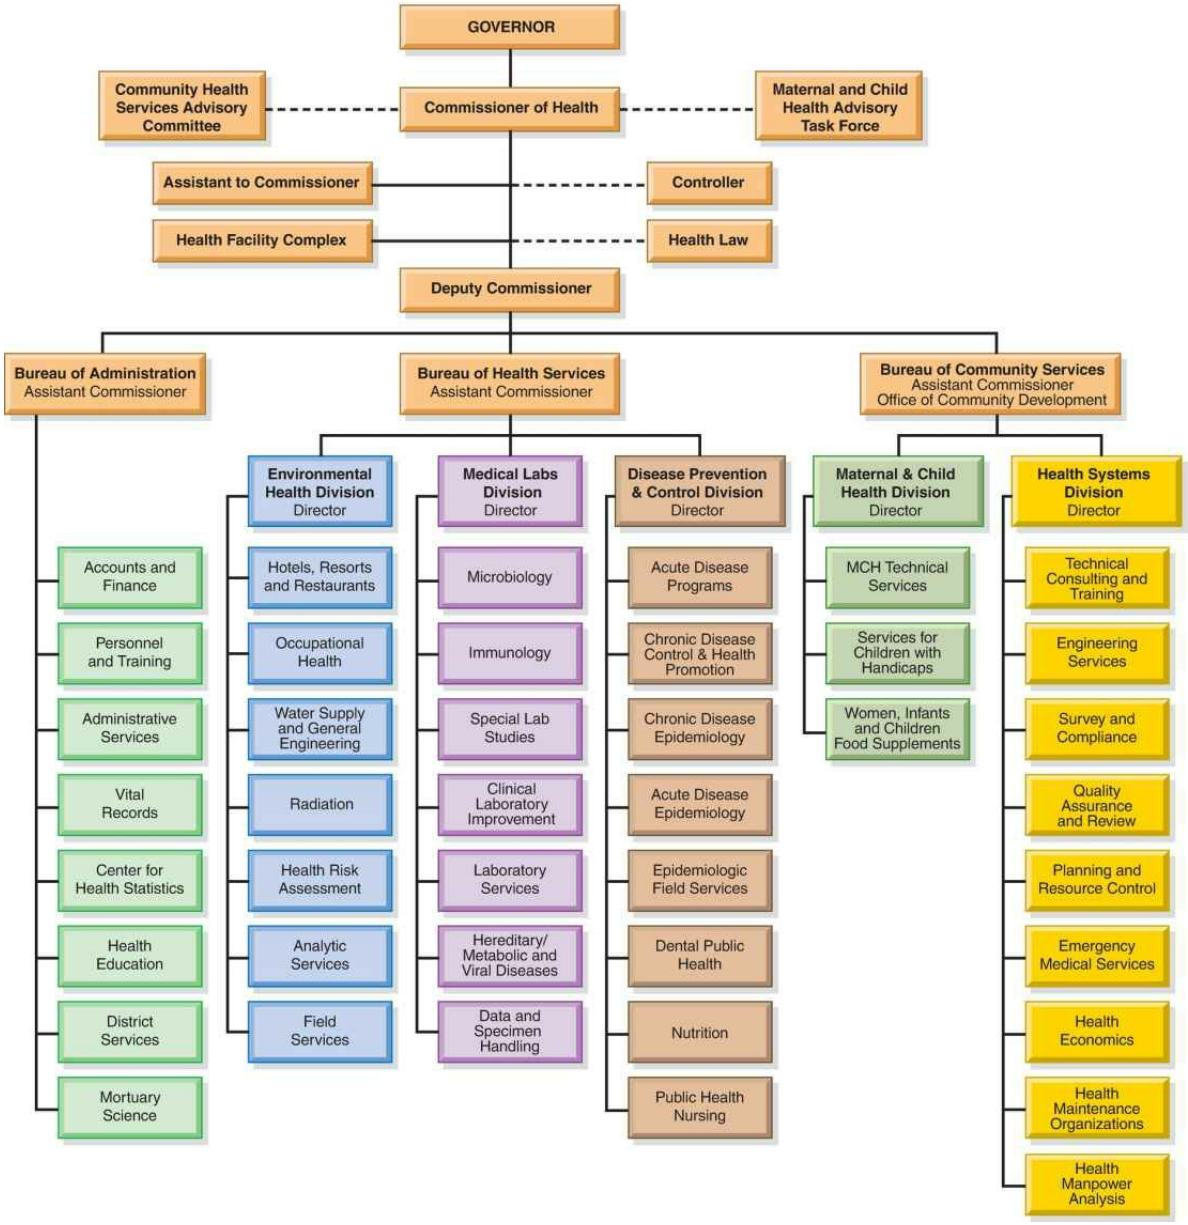

Figure 6–2 Organizational chart of a state public health department.

National Public Health Agencies

At the national level, public health organization can be clustered into four groups of government agencies:

- The Public Health Service (PHS)
- The U.S. Department of Health & Human Services (USDHHS)
- Federal departments that oversee areas that impact health, such as the Departments of Labor, Education, Agriculture, and Transportation, among others
- Federal agencies that focus on international health concerns, such as the U.S. Agency for International Development (AID) and the Office of International Health Affairs, which is part of the Department of State (Turnock, 2015)

CDC
CENTERS FOR DISEASE CONTROL AND PREVENTION
EDWARD R. ROYBAL CAMPUS
STOP
DEPARTMENT OF HEALTH & HUMAN SERVICES · USA

The Centers for Disease Control and Prevention (CDC) headquarters is located in Atlanta, Georgia.

The PHS is concerned with broad health interests across the United States. The Secretary of Health and Human Services (a cabinet-level position) has ultimate responsibility for the PHS. The PHS consists of the Office of Public Health and Science (headed by the Assistant Secretary for Health), the Office of the Surgeon General, and 10 regional offices across the country. The PHS has 11 functional branches: the Administration for Children and Families, the Centers for Medicare and Medicaid Services (CMS), the Administration on Aging, the CDC, the Food and Drug Administration (FDA), the National Institutes for Health (NIH), the Substance Abuse and Mental Health Services Administration (SAMHSA), the Agency for Healthcare Research and Quality (HRSA), the Indian Health Service, and the Agency for Toxic Substances and Disease Registry (ATSDR). One of its major functions through these 11 branches is the administration of grants and contracts with other government agencies, private organizations, and individuals. In some instances, the PHS provides hospital, clinical, and other types of health services, for example, for Native Americans and Eskimos through the Indian Health Service. Through the CDC and the NIH, it provides epidemiologic surveillance and numerous research programs. The FDA monitors the safety and usefulness of various food and drug products, as well as cosmetics, toys, and flammable fabrics (USDHHS, 2015). Much of the PHS is staffed by the Commissioned Core, which consists of over 6,700 uniformed health professionals (see Chapter 30 for more on the PHS Commissioned Corps).

Through its staff offices, the PHS offers other services. It has responsibility for the formation, planning, and evaluation of health policy; health promotion; health services management; health research and statistics; intergovernmental affairs; legislation; population affairs; and international health. It provides financial assistance to the states through grants-in-aid—monies raised by Congress through taxes for specific purposes. It also offers consultation through national advisory health councils and special advisory committees made up of lay experts. The PHS maintains 10 regional offices to make its services more readily available to the states. These offices are located in Boston, New York City, Philadelphia, Atlanta, Chicago, Dallas, Kansas City, Denver, San Francisco, and Seattle.

The second group of federal agencies concerned with public health is organized under the USDHHS. Assistant secretaries manage offices for Health, Administration, Financial Resources, Planning and Evaluation, Preparedness and Response, Legislation, and Public Affairs. Within the USDHHS, clusters of federal agencies deal with the needs of particular population groups, such as older adults (Administration on Aging), children (Administration for Children and Families), and Native Americans/Alaska Natives (Bureau of Indian Affairs), and government health insurance programs (USDHHS, 2015). Figure 6–3 is the organizational chart for USDHHS.

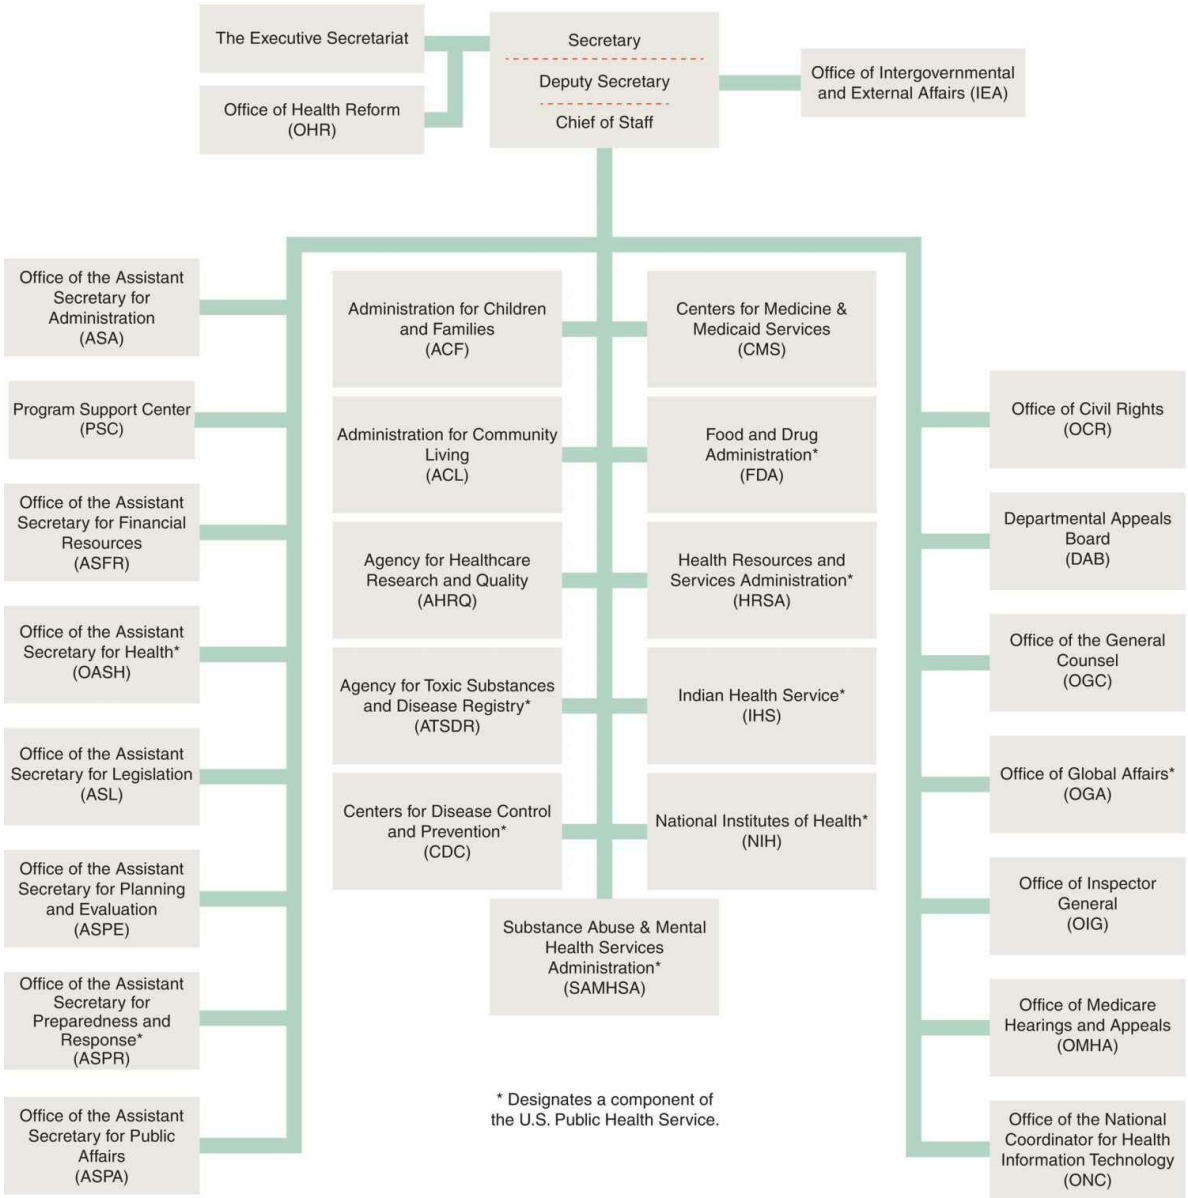

Figure 6–3 Department of Health and Human Services Organizational Chart, February 2016. (From U.S. Department of Health & Human Services. (2016). HHS organizational chart. Content created by Assistant Secretary for Public Affairs. Last reviewed February, 1, 2016. Retrieved from http://www.hhs.gov/sites/default/files/hhs-org-chart.gif)

Budgets and Funding for Public Health

U.S. government public health spending represented 2.6% of the total health spending in 2014 (CMS, 2015a). The per capita annual health expenditure in 2014 was $9,523 (CMS, n.d.b). Combining national, state, and local spending, public health funding in 2013 was 10% lower than prerecession levels in 2009 (TFAH, 2015). Yet, an IOM report in 2012 recommended an increase in public health spending to twice the amount spent in 2009 (APHA, 2012). This disproportionate funding for public health continues despite evidence that public health spending results in a significant return on investment. Mays and Smith

(2011) found that each 10% increase in local public health spending resulted in reductions in infant mortality, deaths due to chronic diseases, and deaths due to cancer.

In addition to health promotion, the PHS must be ready for disasters, bioterrorism events, and national epidemics. Unfortunately, evidence is mounting that the system is structurally weak and suffers from poor access and inconsistent preparation (IOM, 2002, 2012). To meet the needs of communities and the nation, new funding is needed. The ACA created a Prevention and Public Health Fund for state and local community assistance in promoting health and preventing disease (Healthcare.gov, 2011). The substantial investment—$15 billion over 10 years—also aids with early intervention to prevent later complications of illness. Community and clinical prevention, public health infrastructure, and primary care training are also part of this fund. However, the amount pledged to the fund has already been reduced to address other legislative priorities (Haberkorn, 2012). In addition, some public health leaders are concerned the fund will be used to offset cuts to other public health spending, rather than to fund innovation in public health programs. A study by Himmelstein and Woolhandler (2016a) found that public health's share of total health expenditures was 2.65% in 2014 and is projected to drop to 2.4% by 2023.

Funding for state public health agencies is largely federal (53%) and state (24%), but fees and fines generate about 4% of income and other sources account for the remainder (ASTHO, 2014). Some sources of federal funds include the CDC (16%), the Department of Health Services (7%), Medicaid (4%), Medicare (2%), HRSA (10%), the USDA (55%), the Environmental Protection Agency (3%), federal indirect funding (3%), and some grant funding from the Department of Homeland Security. Per capita expenditures for state agencies averaged $98 with consumer health, WIC, and infectious disease control accounting for 63% of all state public health agencies expenses. Others, in descending order, included environmental health, chronic disease, health service quality, preparedness, administration, public health laboratories, vital statistics, and injury prevention (ASTHO, 2014).

Private Sector Health Services

The nongovernmental and voluntary arm of the health care delivery system includes many types of services. Privately owned, nonprofit health agencies (most hospitals and social agencies) make up one large group. Privately owned (proprietary), for-profit agencies are another. Private professional health care practice, composed largely of physicians in solo or group practice, forms a third group. These make up the non–tax-supported, nongovernmental dimension of community health care.

Private health services are complementary and supplementary to government health agencies. They often meet the needs of special groups, such as those with cancer or heart disease; they offer an avenue for private enterprise or philanthropy; they are less constrained than are government agencies in developing innovations in health care; and they have been spurred to development, in part, by impatience or dissatisfaction with government programs (Erwin & Brownson, 2017). Their financial support comes from voluntary contributions, bequests, or fees.

For-Profit and Not-for-Profit Health Agencies

Proprietary health services are privately owned and managed. They may be for-profit or nonprofit. Many hospitals and nursing homes offer nonprofit services but must generate sufficient revenues to keep ahead of operating costs. Often, one or more special services offered by a hospital generate enough income to cover losses from more expensive programs or uncompensated care. As more hospitals have merged or been integrated into larger health conglomerates, the practice in many cases has been to establish a separate, for-profit corporation that generates revenues so that the basic organization can retain its nonprofit, tax-exempt status.

Examples of for-profit health services include a wide range of private practices by physicians, nurses, social workers, psychologists, and laboratory and radiology technologists. With the greater demand for home care services since the 1980s, the number of new, for-profit services (e.g., home care agencies, nursing personnel pools, and durable medical equipment supply companies) increased dramatically. Medicare's annual costs for home care services per enrollee went from $4 in 1969 to more than $300 by the late 1990s (Tyson, 2001). Partially in response to these escalating home care costs to Medicare, the Balanced Budget Act of 1997 was passed, and payments for home health care services to older adults dropped by 12.5% annually through the year 2000 (Meara, White, & Cutler, 2004). In 2000, Medicare payments for home health services changed to the prospective payment system, and a steep rise in the use of home health care began again (Medicare Payment Advisory Commission, 2014). From 2000 to 2009, Medicare spending for home health services increased approximately 10% each year, slowing in 2010. Spending decreased slightly in 2011 and 2012. Even with this increase, payments for home health services were only 3% of all Medicare spending in 2014 (Kaiser Family Foundation [KFF],

2015a).

Not-for-profit private health agencies are organizations that are established and administered by private citizens for a specific health-related purpose. Often, this purpose is seen as a special need either not addressed or served inadequately by government. An example is visiting nurse associations, which were formed to provide care for the sick in their homes. The contribution of the private, not-for-profit health agency then becomes complementary to public health services.

Three types of private, not-for-profit health agencies have specialized interests. Some, such as the American Cancer Society and the American Diabetes Association, focus on specific diseases. Others, such as the National Society for Autistic Children, Planned Parenthood Federation of America, and the National Council on Aging, focus on the needs of special populations. A third group, including agencies such as the American Heart Association and the National Kidney Foundation, is concerned with diseases of specific organs. All of these agencies are funded through private contributions. TFAH is a nonpartisan, nonprofit organization sponsored by foundation and individual support is focused on disease prevention and protection of individuals and communities.

Another group of private, not-for-profit agencies affecting health and health care includes the many foundations that support health programs, research, and professional education. Examples include the W.K. Kellogg Foundation, the Pew Charitable Trusts, the Robert Wood Johnson Foundation, and the Bill and Melinda Gates Foundation. Some agencies, such as the United Way, exist to fund other voluntary efforts.

Professional associations that work to improve the public's health through the promotion of standards, research, information, and programs constitute the third group of agencies. Examples are the American Public Health Association (APHA), Association of Public Health Nurses (APHN), Association of State and Territorial Health Officials (ASTHO), National Association of County and City Health Officials (NACCHO), National League for Nursing (NLN), American Nurses Association (ANA), Association of Community Health Nursing Educators (ACHNE), and the American Medical Association (AMA). These organizations are funded primarily through membership dues, bequests, and contributions.

Functions of Private Sector Health Agencies

The general functions of private sector health agencies may include (Stallworthy, Boahene, Ohiri, Pamba, & Knezovich, 2014)

- Detecting unmet needs or exploring better methods for meeting needs already identified
- Piloting or subsidizing demonstration projects
- Promoting public knowledge
- Assisting official agencies with innovative programs not otherwise possible

- Evaluating official programs and assuming a public advocacy role
- Promoting health legislation and policies
- Planning and coordinating to promote collaboration among voluntary services and between voluntary and official agencies
- Developing well-balanced community health programs that seek to make services relevant and comprehensive

Both public and private agencies are needed to maintain a viable public health system (Turnock, 2015, 2016). Future functions of both private and public sectors most likely will remain much the same. However, the structure of the organizations within both sectors is changing dramatically and will continue to do so as managed care organizations (MCOs) blur the lines between private and public sectors. The blurring of the private and public health care sectors has opened the doors to emerging creative health care services.

INTERNATIONAL HEALTH ORGANIZATIONS

The health of countries around the world cannot be ignored. Besides important humanitarian and moral concerns, there are pragmatic reasons for addressing health issues at the international level. Today, health—along with politics and economics—has become a global issue. Health care among most of the world's population continues to be based on traditional (non-Western) medicine. At the same time, technology is revolutionizing health practices via distance education, training, and telemedicine. Health care information technology has the potential to empower all nations, rich and poor, to enhance the health of their citizens, and many governments and private organizations collect data on a daily basis (Luna, Mayan, Garcia, Almerares, & Househ, 2014). To use all of these data, however, information systems need to be interconnected. Currently, data within one nation, let alone between nations, are generally fragmented. In addition, many countries lack the infrastructure needed to analyze the volume of data available.

It may not seem possible that the health of a resident of a country 9,000 miles away can affect that of a student from the United States or vice versa; however, when boarding an international flight for a school holiday, the student will likely be seated among people from many nations. Despite close scrutiny of airline passengers for passports, visas, customs regulations, weapons, and drugs, how can anyone know whether any passenger sitting near the student has an airborne communicable disease that is resistant to known antibiotics? (See From the Case Files I.)

From the Case FilesI

Medication-Resistant Tuberculosis, an International Problem

In 2007, the Centers for Disease Control and Prevention (CDC) ordered federal isolation (or quarantine)—something it hadn't done since 1963—for a 31-year-old Atlanta lawyer diagnosed with tuberculosis (TB). In his initial examination, Andrew Speaker says he was told he had TB but wasn't contagious or a danger to anyone else and was not forbidden to fly to Greece and Europe for his wedding and honeymoon; he was reportedly told by county health officials that they preferred that he didn't fly (Ogilvie, 2007; Ruger, 2010). The CDC contends that they instructed him not to travel abroad, but he ignored them (Kvinta, 2011). While he and his new wife were honeymooning, lab test results revealed that he had an extensively drug-resistant (XDR) strain of TB, and the CDC warned him not to take a commercial flight home but to turn himself over to Italian health authorities so that he could be isolated (Kvinta, 2011). However, he and his wife disregarded this admonition, flying back to Canada on Czech Air and then "sneaking" across the border to the United States. He was quarantined a day later and then sent to National Jewish Medical and Research Center in Denver, Colorado—a hospital with a long history of TB research and treatment. Several months later, new tests showed that his sputum samples were positive for multidrug-resistant (MDR) TB, with no signs of the XDR TB first noted on bronchoscopy samples. MDR TB is less resistant to antituberculosis medications and requires less intensive treatment than does XDR TB (Prasad, 2012). Mr. Speaker later had surgery to remove the infected lung and was subsequently diagnosed as noncontagious. At the time of the incident, the CDC recommended that fellow travelers on Mr. Speaker's transatlantic flights have TB tests to determine if they contracted the disease. This incident brought TB to the forefront and reinforced the concept of the world as a global community. It also highlighted international public health law and the need for countries to work together to protect the health of all citizens. Mr. Speaker filed suit against the CDC in 2009, claiming his privacy was invaded, but the U.S. District Court subsequently dismissed the lawsuit. In 2010, the U.S. Court of Appeals ruled that his lawsuit could go forward, but in 2012, his lawsuit was dismissed again because Speaker was not able to provide evidence to support his claim of a specific CDC employee releasing his name to the press (Chrysler, 2012).

In 2013, there were about 100 cases of multidrug-resistant TB (MDR TB) in the United States, and about 480,000 worldwide; treatment only works in about 10% of cases. Annually, over 1.5 million people around the world die from TB (Weber, 2015). Prompt diagnosis and treatment are essential to prevent these drug-resistant forms of TB (Chang & Yew, 2013). In 2010, the average cost of treatment for TB was $17,000; for MDR TB, it was $260,000; for XDR TB, the treatment cost jumps

to $554,000. In 2015, a woman from India with XDR TB flew to the United States and visited three states before she saw a physician for treatment of her illness. Hundreds of people could have been exposed to this frightening strain of TB, and it was theorized that she might have come to the United States because of the better chance of successful treatment available here (Weber, 2015). The CDC has a surveillance system that monitors epidemics around the world, and the World Health Organization has regulations in place to encourage its member nations to report and respond to various diseases of international concern (Ruger, 2010).

International cooperation in health dates back to early concerns for epidemics. In 1851, representatives from 12 countries met in Paris for the First International Sanitary Conference. They later established a more permanent organization, the Office International d'Hygiene Publique, in 1907. Epidemics in the Western Hemisphere also prompted representatives from 21 American republics to meet for the First International Sanitary Conference in Mexico City in 1902. In that same year, the International Sanitary Bureau was formed and, later, renamed the Pan American Sanitary Bureau. It is now called the Pan American Health Organization (PAHO) (World Health Organization [WHO], n.d.). See Chapter 16 for more on global health.

World Health Organization

The WHO, an agency of the United Nations, was developed to direct and coordinate the promotion of health worldwide. It was formed after World War II, in 1948, and assumed the functions of the League of Nation's health organization. The PAHO remained separate but became the WHO regional office for the Americas. The WHO began with 61 member nations, one of which was the United States. There are currently 194 member nations (WHO, 2016a). The mission of the WHO is to serve as the one directing and coordinating authority on international health. From its inception, it has influenced international thinking with its classic definition of health as "a state of complete physical, mental, and social wellbeing and not merely the absence of disease or infirmity" (WHO, 2016b, para. 1). The primary function of the WHO is to help countries improve their health status and services by assisting them to help themselves and each other. To accomplish this, it provides member countries with technical services, information from epidemiology and statistics reports, advisory and consulting services, and demonstration teams.

The WHO helps countries improve health services and the health of their citizens, such as

these Bangladeshi children examined during a smallpox search.

For 20 years, the WHO focused on achieving the Millennium Development Goals (MDGs), which stated that, by the year 2000, no individual in any country would have a level of health below an acceptable minimum (WHO, 1998). Progress was made, but not all goals were entirely met. Member nations then renewed goals for 2015 to "combat poverty, hunger, disease, illiteracy, environmental degradation, and discrimination against women" (WHO, 2015a para. 3). Currently, the MDGs are transitioning to a set of 17 Sustainable Development Goals (SDGs) (WHO, 2015b, 2016c). The SDGs, "comprise a broad range of economic, social and environmental objectives, and offer the prospect of more peaceful and inclusive societies" (p. 3). The SDGs build on the MDGs, which focused on population targets for health. The SDGs focus on equity and building a strong health infrastructure in all nations.

Headquartered in Geneva, Switzerland, the WHO has six regional offices (WHO, 2016d). The Regional Office for the Americas is located in Washington, DC. The other regional offices are in Copenhagen, Denmark (Europe); Cairo, Egypt (Eastern Mediterranean); Brazzaville, Congo (Africa); New Delhi, India (Southeast Asia); and Manila, Philippines (Western Pacific). Funding comes from member countries and from the United Nations. The WHO holds an annual World Health Assembly to discuss international health policies and programs. The organization publishes several periodicals of interest to the global community, which are available by subscription for a fee and in partial text through WHO's Web site (www.who.int/publications/en/) and include the following:

Bulletin of the World Health Organization—monthly
WHO Drug Information—quarterly
Weekly Epidemiological Record—weekly
Pan American Journal of Public Health—monthly

Pan American Health Organization

The PAHO, the central coordinating organization for public health in the Western Hemisphere, is the oldest continuously functioning international health organization in the world (PAHO, 2016). Its budget comes from assessments contributed by member states, augmented by funds from WHO, the United Nations, and other sources, including private donations.

As the World Health Organization's regional office for the Americas, PAHO disseminates epidemiologic information, provides technical assistance, finances fellowships, and promotes cooperative research and professional education (PAHO, 2016). Conferences convened by PAHO provide an opportunity for delegates from member nations to discuss issues of concern and plan strategies for addressing health needs. The most widely read journal published by PAHO is the *Pan American Journal of Public Health*, an open-access journal, published monthly (PAHO, 2016).

United Nations International Children's Emergency Fund

Organized in 1946, the United Nations Children's Fund, now called the United Nations International Children's Emergency Fund (UNICEF), was established initially as a temporary emergency program to assist the children of war-torn countries (UNICEF, 2016). That focus has broadened, and UNICEF is now a permanent agency for promoting child and maternal health and welfare globally, through a variety of programs and activities, including provision of food and supplies to underdeveloped countries, immunization programs in cooperation with the WHO, disease control (especially HIV/AIDS), creating protective environments for children, and the education of girls.

U.S. Agency for International Development

The USAID (2016) is the "lead U.S. Government agency that works to end extreme global poverty and enable resilient, democratic societies to realize their potential" (para. 1). USAID was formed in 1961 under the John F. Kennedy administration and lists goals of improving the health, education, and well-being of the populations of developing countries. Its initial focus was on technical and monetary assistance, changing to an agenda that addressed basic human needs in the 1970s.

USAID invests in methods to improve the lives of millions of men, women, and children by

- Investing in agricultural productivity so countries can feed their people
- Combating maternal and child mortality and deadly diseases like HIV, malaria, and tuberculosis
- Providing lifesaving assistance in the wake of disasters
- Promoting democracy, human rights, and good governance around the world
- Fostering private sector development and sustainable economic growth
- Helping communities adapt to a changing environment
- Elevating the role of women and girls throughout all our work (USAID, 2016, para. 3)

Other International Health Organizations

Many other organizations deal with health concerns at the international level. The United Nations Educational, Scientific, and Cultural Organization (UNESCO) goal is to assist people in forming peaceful and inclusive societies (UNESCO, 2016). UNESCO promotes sports, social integration, health, and education without regard to geographical borders or social classes. The World Bank addresses health problems through funding and technical assistance. The Food and Agriculture Organization (2016) works to achieve food security by ending hunger and malnutrition, eliminating poverty, and improving economic and social progress. It also promotes sustainable management of resources used to grow food (land, water, air, etc.). *Medecins Sans Frontieres*, or Doctors Without Borders (n.d.), is an international, neutral organization that sends emergency medical assistance to people in need because of war, epidemics, disasters, or denial of health care. Founded in France in 1971 by 13 doctors and journalists, it initially had 300 volunteer workers, including doctors, nurses, and other staff. MSF now has 30,000 employees around the world. The group was awarded the Nobel Peace Prize in 1999, in recognition of the humanitarian work of their medical staff. MSF has taken care of more than 100 million people in 80 countries. Doctors Without Borders is also known for speaking out—telling the world what they have seen and criticizing those who interfere with their impartial medical mission.

SIGNIFICANT LEGISLATION

During the past century in the United States, an ever-widening sense of responsibility for health in the public sector led to passage of an increasing amount of health-related legislation. Some acts are of particular significance to the financing and delivery of community health services (see list on thePoint). Early health-related legislation focused on particular population groups: merchant seamen (1798), Native Americans (1920), and mothers and infants (1921). During the Great Depression, the U.S. government enacted the first significant legislation that affected the health and well-being of a wide range of citizens (Rosen, 2015).

In 1935, the Social Security Act ensured greater public health programs and provided retirement income to participating workers age 65 years and older. The act also included aid to dependent children and unemployment insurance (Social Security Administration [SSA], n.d.). Later legislation provided federal support for expansion of hospitals; care for individuals with mental retardation; research and support for heart disease, cancer, and stroke; and training for health care personnel.

The landmark Medicare and Medicaid legislation in 1965 moved the federal government deeper into the role of financing health care, especially for many older adults and people living in poverty, who, prior to this time, either could not get services or had to rely on charity care (CMS, 2011). Health care legislation in the 1980s sought to contain health care spending, ensure the quality of health care, promote national health objectives, and facilitate data collection and research (see Display 6–1). More recent laws have protected the confidentiality of health records and made it easier for workers to continue insurance coverage after being laid off. As described earlier in this chapter, the ACA is the most recent legislation to impact health care financing in the United States (Knickman & Kovner, 2015).

DISPLAY 6.1 DATA COLLECTION SYSTEMS

The National Center for Health Statistics Data Collection Systems

Some collection systems of the NCHS are ongoing annual systems, and others are conducted periodically. There are two major types of data systems: those based on

populations (these data are collected by personal interview and examination) and those based on records, with data collected from vital and medical records.

National Health Interview Survey

The National Health Interview Survey is a continuous nationwide survey of illness and disability. It is the main source of data on the health of the U.S. population (nonmilitary, noninstitutionalized). This survey, which monitors the health of the nation, has been conducted since 1957.

National Health and Nutrition Examination Survey

The National Health and Nutrition Examination Survey (NHANES) provides physical, physiologic, and biochemical data related to nutrition of national population samples. Conducted for over 40 years, NHANES provided data that led to the development of pediatric growth charts, vitamin fortification of grains and cereals, and phasing out of lead-based gasoline. It also provided information about the link between cholesterol and heart disease and information on smoking, bone density, obesity, and changes in diet over time.

National Health Care Surveys

The National Health Care Surveys are a series of surveys of providers that yields clear information about health care services, patients, organizations, and providers.

National Ambulatory Medical Care Survey: Gathers data from nonfederal, office-based physicians giving direct patient care

National Hospital Ambulatory Medical Care Survey: Gathers data from physicians on ambulatory services by specialty and target population

National Hospital Care Survey: A new survey describing patterns of care delivery in hospitals and freestanding ambulatory surgery centers

National Hospital Discharge Survey: Provides annual data on such things as length of stay, diagnosis, procedures performed, and patient use patterns

National Survey of Ambulatory Surgery: Data on use and services given in hospital emergency and outpatient departments

National Home and Hospice Care Survey: Administrators and staff are personally interviewed to retrieve information about patients and discharges.

National Home Health Aide Survey: Information on home health aides employed by home health agencies and/or hospice

National Nursing Home Survey: Collects data about nursing home services, staff, and residents regarding need, level of care, costs, and use patterns

National Employer Health Insurance Survey: Provides estimates on employer-sponsored health insurance, the types of plans provided, and detailed information about the plans

National Nursing Assistant Survey: Information on nursing assistants employed by nursing homes.

National Survey of Residential Care Facilities: Information from a national sample of residential care facilities.

National Vital Statistics System

The National Vital Statistics System is the oldest survey and best example of public health intergovernmental data sharing. Vital statistics registries around the country provide uniform data to the national system on the following categories: births, marriages, divorces, deaths, and fetal deaths. Specific data are available through the following systems:

- Birth data
- Mortality data
- Fetal death data
- Linked birth/infant deaths
- National Mortality Followback Survey
- National Maternal and Infant Health Survey

National Survey of Family Growth

The National Survey of Family Growth assembles information on marriage and divorce, pregnancy, use of contraception, family life, infertility, and women's and men's health. The data are used to plan health programs and services.

National Immunization Survey

The National Immunization Survey is a list-assisted random digit–dialing survey employed to gather information on vaccination coverage rates for children between the ages of 19 and 35 months. A mailed survey follows the telephone call, and this produces timely estimates of the rates of recommended vaccine doses.

The Longitudinal Studies of Aging

The Longitudinal Studies of Aging are done as a collaboration between the NCHS and the National Institute on Aging. These studies measure changes in functional status, living arrangements, health, and the utilization of health services for persons aged 70 and above. They involve two cohorts of U.S. citizens moving through old age and the oldest ages.

State and Local Area Integrated Telephone Survey

The State and Local Area Integrated Telephone Survey collects in-depth data needed at the state and local levels to meet the needs of program planners, policymakers, and government agencies. Some of the topics researched include access to care, utilization

of services, health insurance coverage, perceived health status, and measurement of child well-being. The same random digit–dialing method employed by NIS is utilized on a regional basis.

President Bill Clinton made an unsuccessful attempt at universal health care during his first term in office. In 1997, the State Children's Health Insurance Program (SCHIP) was created to expand coverage to uninsured children at no or low cost, and this coverage was extended in 2009 under President Barak Obama (CMS, n.d.a). The ACA requires states to maintain the SCHIP through 2019. The Medicare Modernization Act of 2003, signed into law by President George W. Bush, added prescription drug benefits and disease screening to Medicare and promoted Health Savings Accounts (HSAs). President Barak Obama signed the ACA into law in 2010. The ACA enacted several health insurance reforms, which have made "healthcare more affordable, accessible and of a higher quality, for families, seniors, businesses, and taxpayers alike" (USDHHS, 2014a, para. 1).

Development of the Current Health Care System

In 1900, a total of 20% of infants died before they reached the age of 10, and life expectancy was about 47 years. Infectious diseases and poor sanitation and nutrition contributed to the poor outcomes. Physicians were not well trained, and the AMA had only 8,000 members (Public Broadcasting System, n.d.). Hospital infection rates were high, and most care was given in the home—and then only to those who could afford to pay for it or those who received charity care. (See From the Case Files II.)

From the Case FilesII

Hospital Care: Comparisons Between the 20th and 21st Centuries

In the 1890s, riots occurred in Milwaukee when a child suspected of having smallpox was ordered by a public health official to be taken by ambulance to a local hospital for isolation. One of the child's siblings had already died of smallpox in the same hospital, and his family did not want the second child to risk death at the same institution especially while upper- and middle-class children were quarantined in their own homes (not sent to isolation hospitals). A crowd of 3,000 or more people, carrying clubs, kept the ambulance attendants at bay. Why was there such concern about hospitalizing a sick child? When this occurred, hospitals were rife with infection, and doctors could do little to halt its spread. Also, the inequity of how smallpox cases were handled stirred feelings of injustice and discrimination (Cutler, 2005; Solnit, 2009).

In the early 21st century, are hospitals any safer? Almost half a million Americans die each year from preventable hospital errors—making this the third leading cause of death (Leapfrog Group, 2015). According to the (CDC, 2016), a total of 721,800 hospital-associated infections were reported in 2011. The Society of Actuaries projected the cost of medical errors in 2008 to be almost $20 billion (2010). Andel, Davidow, Hollander, and Moreno (2012) estimate an even higher number—$1 trillion annually—when they apply quality-adjusted life years (QALYs) to deaths from medical errors. With repeated calls for safety and quality improvement in our health care system, would you think that today's hospitals must be safer?

Can you be assured of good care when you or your loved one enters a hospital? In the case of a busy trauma center located in South Los Angeles, you might have reason for concern. Martin Luther King/Drew Medical Center was created after the 1965 Watts Riot, with a history of providing stellar neonatal care (95% of babies under 2 pounds survive) and excellent training for trauma surgeons—one fourth of U.S. military surgeons have trained there (Associated Press, 2004). But numerous problems began to be reported in the early 1970s; employees were inebriated on the job, and some stole medications from the pharmacy and sold them on the street. There were numerous cases of gross medical malpractice at a time when only one physician in a 5-year period was formally disciplined by the hospital (Kuypers & Gellert, 2012). The hospital came to be known as "killer King" (para. 28) because of the numerous deaths, unsanitary conditions, and employee absenteeism or working under the influence of drugs or alcohol. Nurses would leave the units with patients needing care, took meal breaks without authorization, or left their shifts early; they also turned off monitors. In one case, a toddler on a ventilator suffered "profound mental retardation" after his nurse left the floor for an early dinner and his ventilator

tubing was dislodged (Kuypers & Gellert, 2012, para. 34). An AIDS patient's monitors were turned off and the nurse falsified the patient records showing that she checked on him, but the patient died at 5 PM with no one in attendance. Emergency room and orthopedic units had to close because of staff not reporting for duty. Medication errors were made, and patients were instructed by nurses to sign waivers, releasing them from any disciplinary actions. The hospital hired a convicted child abuser as a physician assistant, as well as hiring hospital staff who were unlicensed and dropped or failed out of medical school. They failed to discipline physicians who administered lethal doses of medications, performed incorrect surgeries, grossly misdiagnosed patients, and delayed deliveries that resulted in babies' deaths or mental retardation (Kuypers & Gellert, 2012). Other mistakes included infusing a woman with HIV-infected blood, causing her to contract the disease, and slicing the throat of a teenaged shooting victim (Karlamangla, 2015).

Numerous incidents of patients in the ER going untreated and unnoticed were reported. A patient died in the ER after waiting 22 hours to be treated. The patient had a gangrenous leg, a pneumothorax, and was in kidney failure. Inpatient care was often no better, though, as a 46-year-old man admitted for meningitis was given chemotherapy medication for 4 days. Even after the pharmacy error was noted, nurses continued to give medications in error (at least 40 incidents). The patient subsequently lost vision in one eye. In 2007, a 43-year-old woman was admitted to the now-named Martin Luther King/Harbor Medical Center three times in 3 days complaining of intense stomach pain. Her diagnosis was listed as gallstones and she was prescribed pain medication and released each time. After the third discharge, she remained on the hospital grounds and was eventually taken to the ER by police, who were notified of a woman screaming for help. According to the police officers, From the Case FilesII (Continued)the ER triage nurse refused to help the woman, and she lay on the floor in severe pain for almost an hour. She "spit up a dark-colored substance, which her boyfriend said was blood" and security cameras showed a janitor mopping around her as she lay in agony on the floor (Rosenblatt, 2007, p. 11).

By fall 2007, after the federal government withdrew $200 million in annual funding, the hospital closed its doors (Ornstein, Weber, & Leonard, 2007). An urgent care center/outpatient clinic remained open. However, the community voiced concern over the closure. One study found "increased delays in access to care for needed medical services after the closure of Martin Luther King, Jr. Hospital" in a survey of older minority adults in South Los Angeles (Walker et al., 2011, p. 356). The Los Angeles County Board of Supervisors voted to reopen the hospital, with staffing by University of California physicians, and provided $50 million in start-up funding (CBS Los Angeles, 2011). In 2015, the new $250 million 131-bed King/Drew Medical Center opened its doors as the community celebrated. A mental health facility, outpatient center, and urgent care are also part of the new medical

campus (Jennings, 2015). The new hospital uses a team approach to patient care, with a nurse managing each team. Care coordinators work with every patient, not just those who are high-risk, and nurses do patient rounds with physicians every morning. Administrators reported careful vetting of physicians and have new technology such as beds that provide patient weights and other diagnostics that are digitally transmitted EHRs (Karlamangla, 2015). Will these improvements override the past problems and reputation? Time will tell.

What is different about these two scenarios is the reaction of the public. In the 1890s case, it was an angry mob trying to keep a child out of harm's way by not allowing ambulance personnel to take him to the hospital. In this century, it was the federal and local government who moved to close what was deemed an unsafe facility. Some in the community were happy to see the closure, especially those who lost loved ones to what they feel was substandard care. But many others were sad to see a much-needed neighborhood medical center close—its ER saw almost 50,000 patients in 2006—and they worked with county supervisors to build the new facility and encourage a culture of patient safety (CBS Los Angeles, 2011; Karlamangla, 2015).

As the public health system acted to improve water supplies, sanitation, and personal hygiene, the incidence of infectious disease began to diminish. Antibiotics, first widely available during World War II, and better-trained physicians began to change the health care system in the 1950s—although medical and surgical care was not at all sophisticated by today's standards. (See From the Case Files III.)

From the Case FilesIII

Care for Cardiovascular Patients

In developed countries, the most common cause of mortality is cardiovascular disease (CVD). In 2015, one third of worldwide deaths can be attributed to CVD. Although these statistics are daunting, it is important to note that in the 1940s, 50% of all U.S. deaths were due to CVD. Little was known about the causes of heart disease and stroke. Many people died from what most thought simply was the result of "old age." It wasn't until the Framingham Heart Study began in 1948 that the epidemiology of CVD was studied; this was the first longitudinal study of any kind in the United States. Initial findings were not reported until 1957, when a 400% greater incidence of coronary heart disease was noted in patients with blood pressures of ≥160/95 mm Hg (Mahmood, Levy, Vasan, & Wang, 2014). Later, stroke was also noted as a consequence of hypertension. A common rule of thumb for physicians of that time was to add the person's age (e.g., 60) to the baseline of 100 (totaling 160), as a "permissible" systolic blood pressure (p. 2003). In 1969, the Offspring Cohort was recruited and the study continued to gather data. In 1971, results were reported that demonstrated elevated systolic blood pressure as a predictor for heart failure and stroke. Control of hypertension was not formally incorporated into practice guidelines until 1977. Over the next decade or two, the focus widened to include prevention of CVD and not just treatment of those who already had developed it.

But this was not the case in 1932, when Franklin Delano Roosevelt ran for President and made his medical records public, including a blood pressure reading of 140/100 mm Hg. By the time of the WWII Normandy invasion in 1944, his blood pressure had risen to 186/108 mm Hg, and he was seen by one of a small number of cardiac specialists who noted that he had signs of slight cyanosis. He diagnosed him with "hypertension, hypertensive heart disease, and cardiac failure" but could only offer him digitalis to relieve some symptoms (p. 2001). His blood pressure rose to 240/130 mm Hg within a couple of months, and by the Yalta Conference with Churchill and Stalin in 1945, he appeared to be very ill. He died 2 months later "from cerebral hemorrhage with a blood pressure of 300/190 mm Hg" (p. 2001).

In 1950, the role that hypertension and high cholesterol levels played in heart disease was still unclear. Only when someone presented with chest pain were they then monitored for blood pressure and cholesterol control. Doctors frequently recommended that their patients cut down on salt consumption and lose weight.

They were also counseled to reduce their schedules and "rest around midday," as there were essentially no effective medications to treat these two problems (Cutler, 2005, p. 50; Jaquish, 2007). Cardiac patients were treated with absolute bed rest for a minimum of 6 weeks, morphine for pain, and oxygen. That was the state-of-the-art regimen prescribed for President Eisenhower after his heart attack in 1955 (Gilbert, 2008; Jaquish, 2007).

It was not until the Framingham Heart Study confirmed that hypertension leads to CVD, and oral antidiuretic medications were used to control it. In the 1950s and 1960s, epidemiologist Ancel Keys' research revealed that high cholesterol intake was also associated with CVD (Jaquish, 2007).

Today, bed rest is known to promote blood clots and is ineffective in treating myocardial infarctions (MIs). Quick, intensive therapy is the standard. Aspirin, heparin, beta (β)-blockers, and thrombolytic medications help to prevent and reduce blood clots, reduce the workload on the heart, and dissolve tiny clots in cardiac vessels (Zafari et al., 2016). Nitrates are given to reduce pain and the heart's workload. Other commonly administered medications include β-blockers, calcium channel blockers, antiplatelet medications, and continued anticoagulant therapies. Cardiac catheterization permits physicians to visualize arterial blockages. Percutaneous angioplasty to open the blocked arteries or coronary artery bypass graft (CABG) surgery is now routine; stents may also be used. Well-trained emergency medical service personnel and specialized cardiac intensive care units with highly expert nurses are found in most communities. Cardiopulmonary resuscitation (CPR) is promoted and automated external defibrillators (AEDs), now commonly placed in schools, shopping malls, government buildings, and other common spaces, have saved the lives of many victims of heart disease (Zafari et al., 2016). Because of all of these advances in the last 50 years, post-MI death rates have dropped by 75%. Antihypertensive and cholesterol-lowering medications, along with healthier lifestyles that include no smoking, regular exercise, and diets low in sodium and saturated fats, have also reduced the rates of hypertension and hyperlipidemia. Compared to 1950 rates, the age-adjusted mortality rate for CVD dropped 60% by the year 1996 (CDC, 1999). The rate of CVD death dropped 60% between 1997 and 2006 for adults without diabetes (American Heart Association, 2015).

With all of these advances over the past half-century plus, it is reasonable to expect increased health care costs. In return, more lives have been saved and extended. But, how much can we afford to pay for future improvements in health care? How many more new advances lie ahead? And, what will we receive in return for our investment?

Since the 1950s, U.S. citizens have come to expect longer lives made possible by medications and treatments that can cure or control a wide variety of diseases. At the same time, expanding technology and services provide a dizzying array of choices to health care consumers. These advances have come at a price, however. Health spending in 2013 was estimated at 17.4% of the U.S. gross domestic product (GDP)—the total amount of goods and services produced within a year (Keehan et al., 2015). To put that in perspective, health spending in 1960 was only at 5.0% (Catlin & Cowan, 2015). Keehan et al. (2015) predicts that health care spending will increase to 19.6% of U.S. GDP in 2024—meaning that almost one fifth of all goods and services produced in the United States will go toward health care. Total spending on health care services was $3.1 trillion in 2014 and is predicted to grow to more than $5 trillion in 2024. Viewed as a separate economy, the U.S. health care system would be the fifth largest economy in the world (Blumenthal & Osborn, 2013). Clearly, to gain a deeper understanding of this phenomenon, some basic economic concepts must be examined.

THE ECONOMICS OF HEALTH CARE

Health care economics can seem very complicated.

Economics is defined as the science of making decisions regarding scarce resources. It is concerned with the "production, distribution, and consumption of services" (Rambur, 2015, p. 8). Economics permeates our social structure—it affects and is affected by policies. Consequently, health is closely tied to economic growth and development, in that a healthy population is necessary for adequate national productivity. Ample evidence exists for a health–income gradient, as personal income (specifically poverty) is linked to health status, and is especially critical for children between the ages of 6 and 12 (Fletcher & Wolfe, 2012; deChesnay & Anderson, 2012).

Health economics can be better understood by examining the two basic theories underlying the science of economics: microeconomics and macroeconomics. In addition, concepts of health care payment must be understood.

Microeconomics

Microeconomic theory is concerned with supply and demand. Supply is the quantity of goods or services that providers are willing to sell at a particular price. Demand denotes the consumer's willingness to purchase goods or services at a specified price (Estes et al., 2013). In our free-market–driven economy, supply and demand is a key concept. Economists using microeconomic theory study the supply of goods and services: how we, as consumers, allocate and distribute our resources, and how those marketing goods and services compete. They further study how allocation and distribution affect consumer demand for these goods and services. The concepts of supply and demand are influenced by each other and, in turn, affect prices. In a simplified example, an increase in, or oversupply of, certain products usually leads to less overall consumption (decreased demand) and, usually, lowered prices. The opposite also is true. Limited availability of desired products means that supply does not meet demand, and prices usually increase. An example is the price of a gallon of gasoline. When demand for oil is high and supply begins to dwindle, the prices go up. When demand drops and supplies become more plentiful, prices go down to attract more purchasers. This occurs as long as there are no monopolies to artificially control prices, or only a few choices for goods and services that inhibit competition.

In health care, demand-side policies are enacted to reduce demand for health care (e.g., raising insurance deductibles and co-payments), and supply-side policies restrict the supply of resources (e.g., denial of coverage for specific services, utilization of preferred providers who practice within boundaries set by insurance companies) (Estes et al., 2013). Under the ACA, some traditional demand-side policies were removed to improve access to care. For example, preventive services must now be offered without deductibles or co-payments and insurance companies are limited in their ability to deny coverage for preexisting conditions (Healthcare.gov, 2015).

Microeconomic theory is useful for understanding price determination, resource allocation, consumer income, and spending distribution at the level of individuals and organizations (Estes et al., 2013). Microeconomic theory comes into play when health care competition increases, because the success of the supply-and-demand concept depends upon a competitive market. Issues such as cost containment, competition between providers, accessibility of services, quality, and need for accountability continue as targets of major concern in the 21st century. Several ACA provisions address these issues as well (Healthcare.gov, 2015). The law established the Center for Medicare and Medicaid Innovation, which will test ways to improve quality and efficiency of care. In addition, payments to hospitals and physicians will increase or decrease based on the quality of care provided, and all hospitals must publicly report several indicators of quality. Evaluation of how these provisions affect the supply and demand for health services is ongoing.

Macroeconomics

Macroeconomic theory is concerned with the broad variables that affect the status of the economy as a whole. Economists using macroeconomics study factors influencing aggregate demand and supply. In other words, it deals with production, consumption, investment, international trade, inflation, and unemployment on an aggregate level (Rice University, 2016). The focus is on the larger view of economic stability and growth. Macroeconomic theory is useful for providing a global or aggregate perspective of the variables affecting the total economic picture (Estes et al., 2013). Macroeconomic theory has been useful in providing a large-scale perspective on health care financing and led to various proposals for national health plans, health care rationing, competition, and managed care. For instance, when the United States compares overall health spending with countries across the world, it becomes clear that we spend a large percentage of our GDP on health care—more than any other country—and we often have worse indicators of health than do countries who spend much less, for example, lower life expectancy and higher infant mortality rates (Squires & Anderson, 2015). A report from the National Research Council and Institute of Medicine (NRC & IOM, 2013) cites a growing body of evidence that "Americans live shorter lives and experience more injuries and illnesses that people in other high-income countries" indicating a "U.S. health disadvantage" (p. 1) (see A Nursing Professor's Perspectives)

A NURSING PROFESSOR'S PERSPECTIVE

STRUCTURE AND EVALUATION OF CUBAN VERSUS THE UNITED STATES HEALTH CARE SYSTEMS

Despite being the closest island neighbor to the United States, Cuba could not be any more different compared to the U.S. related to cultural foundations. The political differences alone provide juxtaposition when surveying the two countries. Cuba is quite an intriguing country. Despite a lack of economic resources, Cuba enjoys health outcomes that meet and surpass many of those when compared to the United States. As a nurse involved in public health, it is always important to consider the structure of health care systems and how they shape health outcomes. Because Cuba presents a unique structure, evaluating the two countries and their health systems could prove to be a useful tool in identifying tools and interventions to improve health. The prevailing sentiment about Cuba since as long

as I could remember was that Cuba was an impoverished, communist country, and the thought of the United States is that it was the land of opportunity. When I had the chance to visit Cuba, I had the thought that it would be just that, a stark, poor contrast between the United States. However, I was struck by the health interventions I observed. When I drive around the United States, I see children and young families in parks, but in Cuba, older adults were enjoying group exercise classes. In the United States, I see older adults in retirement homes and communities, but in Cuba, I learned that older adults are supported through community-based older adult activity programs designed to engage and support their mental and physical needs. I was able to tour the Cuban equivalent of a U.S. multispecialty health care group, but the Cuba equivalent is 100% government funded and based in the community. This novelty is known as the policlinico and consisted of several nurses and physicians, physical and occupational therapy, Reiki, massage therapy, and a dental clinic. This was in one location, and the patients were able to move from one area of the clinic to the other without waiting for their appointment to be scheduled. In the United States, childhood immunizations are delivered in vaccine clinics and at the provider's office, but in Cuba, I saw vaccines being delivered door to door. Besides costly concierge physicians, I have not seen physicians in the United States visit patients in their home, but I walked around the community with a physician and a nurse that were able to meet children on the street and see that they were developing appropriately. The structure of the Cuban health care system is centered on the policlinico. This model was focused on preventative health care, and this differs from what we see in the United States where the health care model is really focused on caring for those that are ill. I was able to see how physicians and nurses are educated in Cuba, and this model allows for greater access and output of physicians. One school, funded by the Cuban government, supported the medical education of students from African, Central American, South American, and even students from the United States. This program provided the necessary medical education for the students to return to their home country and work to improve health and health outcomes. Although the United States has many medical schools and accepts students from across the globe, an entire school similar to the Latin American School of Medicine, where medical education is provided to foreigners free of charge, is unknown. Perhaps the most intriguing finding while visiting Cuba was learning of their initiatives to enhance maternal–child health. It was explained to me that many years ago, the Cuban government noticed that maternal–child health outcomes were extremely poor, and they worked toward creating systems to improve these outcomes. One of these interventions is called a maternity home. Maternity homes are places that high-risk pregnant women can live until they deliver their baby. The homes are residential and provide nutrition, medical, nursing, and social services care for the woman and her family. The goal of the maternity home is to provide a homelike environment where women can deliver full-term, healthy babies. In the United States, high-risk pregnant ladies are on home bed rest and must journey to the clinic for their obstetrics appointments or are hospitalized. Although there are distinct structural differences between the two countries and their health outcomes, there are opportunities to compare the two structures

and identify how culturally appropriate the interventions are comparing the U.S. approach to the Cuban approach and vice versa. Visiting Cuba was eye opening to cultural, political, and health approaches, and it provided food for thought as the United States strives to improve health for our citizens.

Colleen Marzilli, PhD, DNP, RN-BC, CCM, APHN-BC, CNE
Nursing Professor

A recent review of 13 high-income countries found that U.S. spending on health care (17.4% of GDP in 2013) was about 50% more than in France (11.6% of GDP; the second highest amount) and nearly double the spending in the United Kingdom (8.8% of GDP) (Squires & Anderson, 2015). At the same time, the United States had the lowest life expectancy, the highest infant mortality rate (nearly twice as high), and the highest prevalence of chronic disease. Possible reasons for the high spending in the United States include high rates of obesity, higher costs for prescription drugs and physician services, and frequent use of expensive technology (Squires & Anderson, 2015). High rates of adverse events (e.g., medication errors, receiving incorrect test results) are another indicator of the poor quality of care received despite high payments. Adverse events are also one reason for high health costs; estimates of preventable hospital costs in the United States range from $16 billion to $18 billion annually (Corrigan, Wakeam, Gandhi, & Leape, 2015). Recent interventions to improve hospital safety are beginning to show promise. The Agency for Health Research and Quality (2015) found a 17% decrease in hospital-acquired conditions from 2010 to 2013, saving approximately $12 billion in health care costs. Whereas those of us with adequate health insurance report good access to services and cutting-edge care from well-trained health care professionals, many of our fellow citizens experience significant barriers to care and a fragmented, poorly staffed health care system. See Figure 6–4 for a comparison of U.S. health care expenditure and health status indicators with eight other countries.

to 2013. (From Organization of Economic Cooperation & Development (OECD). (2016). Health statistics, selected OECD countries. Retrieved from http://stats.oecd.org/Index.aspx?DataSetCode=SHA)

The economics of health care encompasses both microeconomics and macroeconomics and an intricate and complex set of interacting variables. Health care economics is concerned with supply and demand: Are available resources sufficient to meet the demand for use by consumers? Are the resources expended achieving the desired outcomes? When health care resources are scarce or insufficient to address all needs (e.g., for programs and services for at-risk populations), how should they be applied? Should there be a move toward national health insurance (NHI) to improve our nation's health because a healthy population promotes productivity and a more robust economy?

Supply and Demand in Health Care Economics

We learned about supply-and-demand economics during our elementary school days. For instance, when you buy textbooks, you—as the purchaser—are able to determine the best value for your money (generally based on price, availability, and condition of the book), and you have choices of vendors (e.g., college bookstore, online bookseller, other students). As a student, you know when you will need specific textbooks, but as a health care consumer, do you always know when you will need health care services? As a health care consumer, can you truly be an efficient and effective purchaser of health care goods and services? How does a patient determine what services are needed, where to buy them, and how to evaluate the quality of the goods and services? Does health care truly represent a competitive free market, then? For instance, when purchasing a new flat-screen television, consumers often rely on word of mouth from friends and relatives, advice from experts, past experiences with brands, customer ratings on Web sites, and rating services like *Consumer Reports*. Also, we most often plan in advance for large purchases, like newer and bigger televisions, saving a little money each month to keep within our budget.

With health care, this is seldom the case; health care is typically unpredictable and often difficult to research (Ubel, 2014). Even with the growth of health information (and, often, misinformation) available on the Internet, physicians are still the system's main gatekeepers, and patients must trust that these care providers have the competence to appropriately diagnose and treat them, as well as coordinate necessary resources to provide quality health care. Further, they must trust that physicians will put patients' interests before their own (i.e., give them accurate information about risks and benefits and not induce them to have expensive procedures to enrich the provider). Now, enter health insurance companies and managed care into the mix—each agency likely pays a different price for the same service. Hence, health care purchases are not easily understood. In a free-market system, competition is an important factor, but is competition truly possible with employer-based health insurance that limits the choice of plans and providers?

In 1963, economist Kenneth Arrow wrote an influential article about health care economics detailing the lack of information in the medical marketplace (reprinted as Arrow, 2004; also cited in Krugman, 2009, 2011). The main points of the article noted that risk and uncertainty prohibit a true market economy in health care because consumers:

- Do not know when or if they will become ill—but they know they will need and want medical treatment, thus the demand for health insurance
- Do not know what services will be needed and what works best for their condition—thus the need for physicians
- Do not know about the quality of health care good and services—thus the need for government regulation (e.g., licensing, certification) and malpractice lawsuits
- Have an asymmetric level of information, compared to the insurer, about the likely demand for health care services, resulting in adverse selection (e.g., high-risk patients

are denied insurance or care) and market failure (e.g., inefficiencies and lack of appropriate competition)—although this is less severe in large group insurance plans that spread out the risk

Thus, a fundamental problem of the health care economy is the difficulty of any one person or organization (e.g., patient, physician, health plan, government) to act as an effective consumer of health care goods and services (Ubel, 2014). One area of health care, however, that has been thought to more closely follow the free-market supply-and-demand model is with cosmetic procedures, especially laser eye surgery (Herrick, 2013). Between 1992 and 2011, while the costs of health care increased approximately 118%, the cost of cosmetic surgeries increased only 30%—despite increases in demand and quality. The price of conventional LASIK eye surgery decreased about 25% between 1999 and 2011, whereas the price of newer, better quality laser eye surgeries in 2011 was nearly the same as the LASIK price in 1999. Report of a 30% decrease in LASIK procedures during the 2007–2009 recession and decreased Google queries for LASIK between 2007 and 2011 indicate that market forces have an impact on this procedure (Kuo, 2011; Stein, Childers, Nan, & Mian, 2013. FDA (2014) studies, first reported in 2008, indicated that 45% of patients developed visual symptoms following LASIK surgery (e.g., halos, dry eye, glare, starbursts). This new information was also thought to influence decreased Internet searches (Stein et al., 2013). Leonhardt (2014) argued that much of the slowdown in the growth of health care costs was due to economic trends (e.g., recession) rather than effects of the ACA. The LASIK evidence seems to echo that. These examples indicate that consumers influence the price of a service when they can accurately compare cost, quality, and services from different providers. It should be noted, however, that cosmetic and laser eye surgery are elective procedures, and this makes comparison between these procedures and other health care costs more complicated.

Health Insurance Concepts

Conventional economic theories posit that people pay small premiums monthly to offset the risk of large medical bills should they become seriously ill. This represents an *indemnity policy* (much like car or homeowners' insurance) and this is the type of health insurance first offered in the United States. In the past, patients could choose any doctor or hospital and submit the providers' bills to the insurance company for payment. Moral hazard is the term used by economists to explain how health insurance changes the behavior of people, resulting in more risk-taking and wasteful actions. They liken it to fire insurance without a deductible, noting that a person may be less careful about clearing brush from a house or may even resort to arson if it costs the owner nothing to have the home replaced. If a person has health insurance, many economists hypothesize, they are less likely to take good care of themselves, and if they don't pay for their health care (through premiums, co-payments, and deductibles), they are more likely to overuse it, although empirical evidence of this is sparse (Dranove, 2008; Nickitas, Middaugh, & Aries, 2016). In other words, economists theorize that insurance has a paradoxical effect and may lead to wasteful or risk-

taking behaviors. In this scenario, patients will demand expensive health care, even if it provides only the smallest benefit. The concept of moral hazard is the reason behind larger deductibles and co-payments—it is an effort to control wasteful or excessive use of health care resources.

A newer supposition states that consumers purchase health insurance not to avoid risk but to earn a claim for additional income (i.e., insurance paying for medical care) when they become ill and that co-payments and managed care actually work against the system by reducing the amount of income transferred to ill persons or limiting their access to needed services. Think about what would happen if you or your loved one were to suddenly need an expensive heart surgery or lengthy cancer treatment— without health insurance. You would want health insurance to protect against this possibility—to be able to pay medical bills without losing your assets (e.g., home, belongings). Houle and Keene (2014) found that individuals experiencing a decrease in health were almost three times as likely to default on a mortgage compared to those who did not report such a change. Having health insurance decreased the risk slightly. This substantiates the claim of a genuine risk of financial disaster when confronted with a serious medical emergency or long-term illness and helps explain why some economists argue that a focus on moral hazard in the insurance industry has actually worked against reducing health care costs (Stone, 2011). Another reason that moral hazard doesn't accurately apply to health insurance is that its effects may not be as predictable as in other instances of indemnity (Ubel, 2015). The case can surely be made that even those with unlimited insurance coverage don't just "check into the hospital because it's free" as noted in a classic article by Gladwell (2005, para. 11). Most people do not seek infinite numbers of mammograms, colonoscopies, or other invasive procedures or surgeries, for example.

Cost sharing, which includes co-payments and deductibles, divides the cost of health care services between insurance companies and patients. Insurance companies use cost sharing to prevent overuse of health services. The amount of a co-payment or deductible may change for some types of care, such as a visit to the ED. In a systematic review of the literature, Kiil and Houlberg (2014) found some evidence that cost sharing reduces the use of prescription medication, primary care and specialty office visits, and ambulatory care, possibly lowering overall health care costs. At the same time, is it possible that individuals are attempting to avoid higher costs by not following through on medical appointments or medication? Also, the effect of cost sharing on use of services is not equal. Individuals with low incomes decrease their use of medications and services more than do others. The ACA limits cost sharing for people with low or moderate incomes, in plans offered by employers and plans purchased through the marketplace (Healthcare.gov, 2015).

For some people, the cost-sharing component of their health insurance is so high that they are considered underinsured. They fall into one or more of three categories: (1) medical expenses totaling more than 10% of their yearly income, (2) annual income 200% of federal poverty level (FPL) with medical expenses >5% of yearly income, and (3) health insurance deductibles ≥5% of their annual income (Collins, Rasmussen, Beutel, & Doty,

2015). Prior to the ACA, about half of those underinsured and 58% of those without insurance reported problems paying for medical bills, being contacted by a collection agency about unpaid medical bills, and having to pay off medical bills over time (Schoen, Doty, Robertson, & Collins, 2011). They often exhausted their savings, ran up credit card debt, or else delayed necessary medical care to avoid going into debt. Woolhandler and Himmelstein (2013, p. 1122) reported that high deductibles for the privately insured "increased the risk of dying by 21%" among sicker, low-income patients but didn't cause problems for healthier, more affluent patients. Those gaining access through ACA-expanded Medicaid plans (projected to reach about 40%) will be "woefully uninsured" as many states have "reduced benefits, cut provider payments, and narrowed provider networks" (p. 1123). Even those with private insurance Bronze plans (minimum coverage allowed by ACA) will only have 60% of medical costs covered. This goes up to 70% for Silver plans; Gold plans, like most employment-based policies, will cover about 80% of medical costs. It is important to remember that people who have insurance, whether they have always had insurance or gained coverage through the ACA, may continue to have very high out-of-pocket costs for their income level and are essentially underinsured. Efficiency (or net benefit to consumers) of plans may need to include regulation of premiums (Glazer & McGuire, 2011) (see What Do You Think?).

What do *you* think?

If you make 399% over the poverty level in annual income ($45,900 in 2013) and are eligible for ACA premium subsidies, you are expected to pay about $4,361 for individual Bronze insurance premiums and about $4,167 in co-payments and additional deductibles. But, if you earn 401% over the poverty level ($46,100), subsidies are no longer provided and your premium would then be $10,585 annually, with capped out-of-pocket costs estimated at $6,250.

Do you think the higher cost sharing will ultimately reduce health care expenditures? International research has shown this method is generally not effective at controlling costs (Woolhandler & Himmelstein, 2013). Canada outlawed deductibles and co-payments in 1981 and has experienced slower growth in spending and more rapid improvements in health. They highlight that single-payer systems reduce administrative costs and Canada has demonstrated that costs can be controlled through other measures (e.g., negotiated physician fee schedules, global hospital budgeting). Scotland, with health costs half those of the United States, views patients as "owners of their healthcare system, not its customers" (p. 1123).

What do you think the United States should do to control costs and improve health?

Employer-Sponsored Health Insurance

Employer-sponsored health insurance is the leading source of coverage for nonelderly U.S. citizens. Historically, employers became the leading source of coverage because of three policy decisions in the 1940s and 1950s. First, during World War II, wage controls did not apply to health insurance, so employers used health insurance to lure workers from their competitors. Later, the U.S. government determined that health insurance could be part of collective bargaining. Finally, in 1954, the IRS exempted health insurance premiums paid by employers from federal income tax (Rook, 2015). In a 2015 annual survey, 57% of companies offered health insurance to their workers, unchanged from the previous year but considerably lower than the high of 69% in 2010 (KFF & Health Research and Educational Trust [HRET], 2015). However, only 79% of those workers are eligible for health coverage because of minimum work hours or mandatory waiting periods. Seventy-nine percent of those eligible participate in health insurance. Because not all employers offer health insurance, only about 56% of workers in the United States are covered by employer-sponsored health plans. Many small businesses do not offer employee health insurance because of the high costs.

In 2015, the average cost of group health insurance was $17,545 for a family policy and $6,251 for an individual (KFF & HRET, 2015). These figures are 4% higher than 2014 costs (wages increased <2% from 2014 to 2015). The cost for family coverage increased 61% from 2005 to 2015, and employee contributions for family coverage increased 83%. The average worker contributed about 28% of the premium for family coverage, and 16% for individual coverage in 2015. See Figure 6–5 for trends in health insurance premium costs as compared to wages and overall inflation.

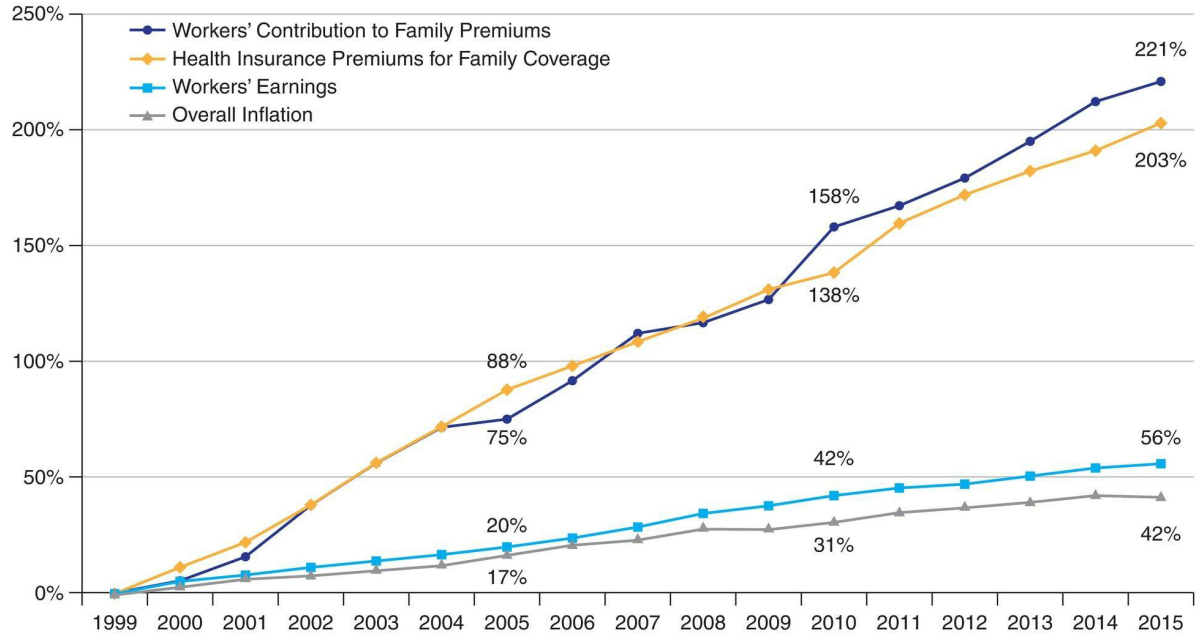

Figure 6–5 Increases in average annual premiums for health insurance, worker contributions, and earnings, 1999–2015.

(From Kaiser Family Foundation & Health Research & Educational Trust. (2015). Employer health benefits survey 2015. Retrieved from http://files.kff.org/attachment/report-2015-employer-health-benefits-survey)

The percent of employers offering health insurance decreased prior to the ACA but has not significantly decreased since implementation of its reforms (KFF & HRET, 2015). Employers are continuing to pass along some of the higher costs of health insurance to employees in the form of higher employee premiums, deductibles, co-payments, and stricter enrollment requirements. Workers having insurance that includes an annual deductible have increased from 55% in 2006 to 70% in 2010 to 81% in 2015 (KFF & HRET, 2015). Similarly, the percentage of covered workers enrolled in employer health plans with a deductible of $1,000 or more for single coverage increased from 10% in 2006 to 27% in 2010 to 46% in 2015.

Those people whose employers do not offer health insurance coverage or who are self-employed can purchase nongroup health insurance. However, premiums are greater than the worker's share of employer group coverage. The ACA has made purchasing a nongroup policy easier and subsidizes the premiums for eligible people. Even in states that did not expand Medicaid, a greater number of people with lower incomes purchased insurance on the federal marketplace (Sommers, Blendon, & Orav, 2016). Variations in costs were an issue prior to the ACA; one large-scale survey found that annual premiums for family coverage ranged from $2,325 to $9,201 and individual coverage varied (depending upon age) from $1,163 and $2,325 (KFF, 2008). Variation in costs has not been eliminated with the ACA, but the variation is geographical; specifically, costs vary by location, not within one location (Gabel et al., 2016). Premiums for benchmark plans increased 6% nationally from 2015 to 2016 but increased by 10% or more in 21 states and decreased in seven states and the District of Columbia. In addition, premiums increased more in suburban and rural

areas than in urban areas.

The cost of health insurance is a deterrent for many people. Prior to the ACA, only 4% to 11% of those at the lower income levels purchased nongroup health coverage (Bernard, Banthin, & Encinosa, 2009). Although coverage levels generally increase as income rises, only 25% of those earning 10 times the poverty level purchased health insurance. As of 2015, 32.3 million nonelderly people in the United States were uninsured (Garfield, Damico, Cox, Claxton, & Levitt, 2016). More than 25% of these individuals are likely eligible for coverage by Medicaid or CHIP. Another 22% could receive subsidies to purchase a nongroup plan from the marketplace. Approximately 42% are not eligible for any of the insurance options available under the ACA, as 15% are undocumented immigrants, 15% have an employer who offers an insurance plan, and 12% have an income too high to qualify for tax credits. The remaining people (about 10%) fall into a "coverage gap" because their state did not expand Medicaid. A survey by the KFF in December of 2014 found that many people who remained uninsured were not aware of the financial assistance available under the ACA (Garfield & Young, 2015). Some were incorrectly told that they were not eligible for assistance.

Further understanding of health economics and its impact on community health and community health nursing can be obtained by examining methods of health care finance, trends and issues influencing health care economics, and the effects of finance patterns on community health practice.

SOURCES OF HEALTH CARE FINANCING: PUBLIC AND PRIVATE

Financing of health care significantly affects community health and public health nursing practice. It influences the type and quality of services offered, as well as the ways in which those services are used. Sources of payment may be grouped into three categories: third-party payments, direct consumer payment, and private or philanthropic support.

Third-Party Payments

Third-party payments are monetary reimbursements made to providers of health care by someone other than the consumer who received the care. The organizations that administer these funds are called *third-party payers* because they are a third party, or external, to the consumer–provider relationship. Included in this category are four types of payment sources: private insurance companies, independent or self-insured health plans, government health programs, and claims payment agents (Estes et al., 2013).

Private Insurance Companies

Private insurance companies currently pay the majority of U.S. health care expenditures for those under age 65. Payments from private companies make up approximately 20% of total health care spending (CMS, 2015b). They market and underwrite policies aimed at decreasing consumer risk of economic loss because of a need to use health services. There are three types of private insurers. First are commercial stock companies that sell health insurance, usually as a sideline. They are private, stockholder-owned corporations that sell insurance nationally and are responsible to these stockholders for maintaining profit margins; examples are Aetna, Travelers, and Connecticut General (CIGNA). A second type of insurer operates in the national marketplace and is owned by policyholders—a *mutual company*. Examples are Mutual of Omaha, Prudential, and Metropolitan Life. The third type, *nonprofit insurance* plans, operate under special state-enabling laws that give them an exclusive franchise to the whole state (or a part of it) and to a specific type of insurance. For example, traditionally, Blue Cross sold only hospital coverage; Blue Shield, only medical insurance; and Delta Dental, only dental insurance. Being nonprofit, these companies were tax exempt and, at the same time, subject to tighter state regulation than were for-profit health insurance companies. However, although Blue Cross and Blue Shield (the Blues) originally began as employment-based, "community-rated" (i.e., each member received the same benefits and paid the same premiums despite their age or health) nonprofit health insurers, this changed as health insurance competition became stiffer and costs soared for employer health benefits (Healthcare.gov, n.d.a, para. 1). Unable to successfully compete with for-profit companies that employed traditional underwriting practices (i.e., charging more to those at higher risk), the Blues sought for-profit status so that some of their franchises could be publicly traded (i.e., sell stocks and raise capital). They often used this extra money to merge and expand market share and began adopting business strategies used by other for-profit companies. In 2004, two of these for-profit arms, Wellpoint and Anthem, merged to become the largest health insurer in the United States. The Blues nonprofit arms became virtually indistinguishable as profits moved to the forefront, and in 2015, California ordered that the tax-exempt status of Blue Shield of California be revoked and that the company be ordered file tax returns back to 2013 because of increasing profits ($3.19 to $4.18 billion from 2009 to 2014) and $13.6 billion in revenue reported in 2014 (Terhune, 2015; Varney, 2010). Many insurance plans, including the Blues, sought

"double-digit rate increases" to defray added costs of additional insured patients under ACA (Rappleye, 2015, para. 14). Today, about one third of Americans are covered by a health plan offered by the Blues (Blue Cross Blue Shield, 2016). Maintaining profits for stockholders means that insurance companies must control the *medical loss ratio*, or the money paid for health services. If they can reduce the amount paid for health care services, then profits are increased and the stock is more attractive to potential buyers. Four common ways that were used to reduce the medical loss ratio included (1) reduce covered services, (2) raise deductibles and co-payments, (3) exclude people with preexisting conditions, and (4) targeted marketing to young, healthy populations. Previously, insurers also resorted to *rescission* of coverage—or canceling coverage for failure to disclose a preexisting condition (often unrelated to the person's current health care problem) or some other means of disqualifying coverage after large medical claims have been filed (Healthcare.gov, n.d.b; Nelson, 2009). However, the ACA made this practice illegal, except in cases of consumer misrepresentation or fraud.

A recent trend in private insurance is the move to consumer-driven/high-deductible health plans with savings options such as health savings accounts (HSAs). Beginning in 2004, legislation provided for tax-exempt HSAs tied to high-deductible health insurance plans that can be rolled over yearly and move with the employee. The high deductibles (minimum of $1,000 for an individual and $2,000 for a family) allow for lower premiums, but the attendant HSAs can only be used on medical expenses—nothing else—or tax-exempt status is lost and a penalty is incurred (KFF & HRET, 2011). In 2015, about 15% of workers were covered by this type of plan, more than twice the 6% coverage in 2010 (KFF & HRET, 2015). Most plans require employees to pay coinsurance, a percentage of their total health costs (often 20% of charges)—rather than a fixed co-payment per office visit or prescription as in many other plans. The average annual deductible for these plans in 2015 was $2,196 for single coverage (KFF & HRET, 2015). Employers also pay lower premiums for employees enrolled in high-deductible health plans (HDHPs)—$4,539 for individuals and $11,719 for families compared to average employer costs of $5,332 and $12,761. Employers may or may not contribute to HSAs; about 60% of employers contribute to HSAs for single coverage and 57% for family coverage (KFF & HRET, 2015). The average contribution is $568 for individuals and $991 for families.

Most workers with employer-sponsored health insurance also have prescription drug coverage (more than 99%), with some cost sharing, such as co-payment or coinsurance (KFF & HRET, 2015). Only 12% are in plans that pay 100% of prescription drug costs after a deductible is met. Often, co-payments are based on tiered systems, for example, $10 co-payment for less expensive drugs in the first tier and $25 for slightly more expensive drugs in the second tier. These co-payments can affect medication adherence. A meta-analysis of studies of people with public insurance found that those with co-payments for prescriptions had 11% higher odds for nonadherence (Sinnott, Buckley, O'Riordan, Bradley, & Whelton, 2013). A systematic review of the literature concluded that lower (or no) co-payments for medications not only improved adherence and patient outcomes but

also decreased the use of other health care services (Kesselheim et al., 2015).

Independent or Self-Insured Health Plans

Independent or self-insured health plans underwrite the remaining private health insurance in the United States. These plans have been offered through a limited number of organizations, such as large businesses, unions, school districts, consumer cooperatives, and medical groups. Employers with self-insured plans take on all or a major part of the risk for health care costs of their employees. These plans may be self-administered or utilize third-party claims administrators. Minimum premium plans are another form of self-insurance for which employers pay medical costs up to an agreed-upon limit, and insurers assume responsibility for the excess claims (Bureau of Labor Statistics, n.d.). Sixty-three percent of employees receiving work-related insurance benefits were part of self-insured plans in 2015 (KFF & HRET, 2015). The ACA encourages self-insured employers to limit the overall value of their plans (Claxton & Levitt, 2015). This will result in employees having lower-cost health insurance options, which are not taxed, and (theoretically) higher wages, which are taxed.

Government Health Programs

Government health programs currently make up the largest source of third-party reimbursement in the United States. Payments from federal sources increased to 28% in 2014, from 26% in 2013 (CMS, 2015a). This increase is primarily due to the Medicaid expansion under the ACA, which is 100% funded by the federal government until 2017 (Healthcare.gov, 2015). State and local government spending was 17% of health care spending. As a whole, the proportion of government funding of health care in the United States is less than that of 34 other developed countries (Organization for Economic Cooperation & Development [OECD], 2015). In 2013, 48% of health care spending was estimated to be paid by public sources in the United States, compared with the Netherlands at 87%, United Kingdom at 83%, France at 79%, Japan at 83%, Canada at 70%, and Mexico at 51%. Whereas the percent of public money in the United States is low compared to other countries, overall public spending in the United States in 2013 was $4,197 per capita, more than any other country except Norway and the Netherlands (Squires & Anderson, 2015).

The U.S. government's four major health insurance programs are Medicare, Medicaid, the Federal Employees Health Benefits Plan, and the Civilian Health and Medical Program of the Uniformed Services. The largest programs are Medicare and Medicaid. In addition to payments from Medicare and Medicaid, the U.S. government reimburses safety-net hospitals and other entities involved in care of the uninsured. The Centers for Medicare and Medicaid (CMS, 2015b) anticipates spending $6.4 billion for uncompensated care in fiscal year 2016—exemplifying just some of the costs to taxpayers.

Medicare and Social Security Disability Insurance

Medicare plays an important part in protecting the health of Americans.

Medicare, known as Title XVIII of the Social Security Act Amendments of 1965, has provided mandatory federal health insurance since July 1, 1966, for adults aged 65 years and older who have paid into the Social Security system (CMS, 2015a). It also covers certain people with disabilities (regardless of age). Medicare is administered by the CMS (formerly the Healthcare Financing Administration) of the USDHHS. In 2014, Medicare covered more than 55 million people. The majority of recipients are age 65 or older (46.3 million), and Medicare paid health care costs of $618.7 billion. In 2015, 15% of total federal spending was for Medicare (KFF, 2016). Financing of Medicare is through general tax revenues (41%), payroll taxes (38%), premiums from beneficiaries (13%), and other sources. Out-of-pocket spending for Medicare beneficiaries was $5,368 in 2011, almost equally divided between medical/long-term care and premiums. About 85% of beneficiaries were over the age of 65; the remaining beneficiaries qualified for Medicare 24 months after they became eligible for Social Security Disability Insurance. These recipients are younger than age 65 and permanently disabled or chronically ill, including those with end-stage renal disease (added in 1973). Most enrollees are between the ages of 65 and 84, 16% are under age 65 (and qualify for Medicare because of a permanent disability), and 13% are age 85 and older. The Medicare population is projected to grow to 81 million by 2030, more than twice the number of recipients in 2000 (see Fig. 6–6).

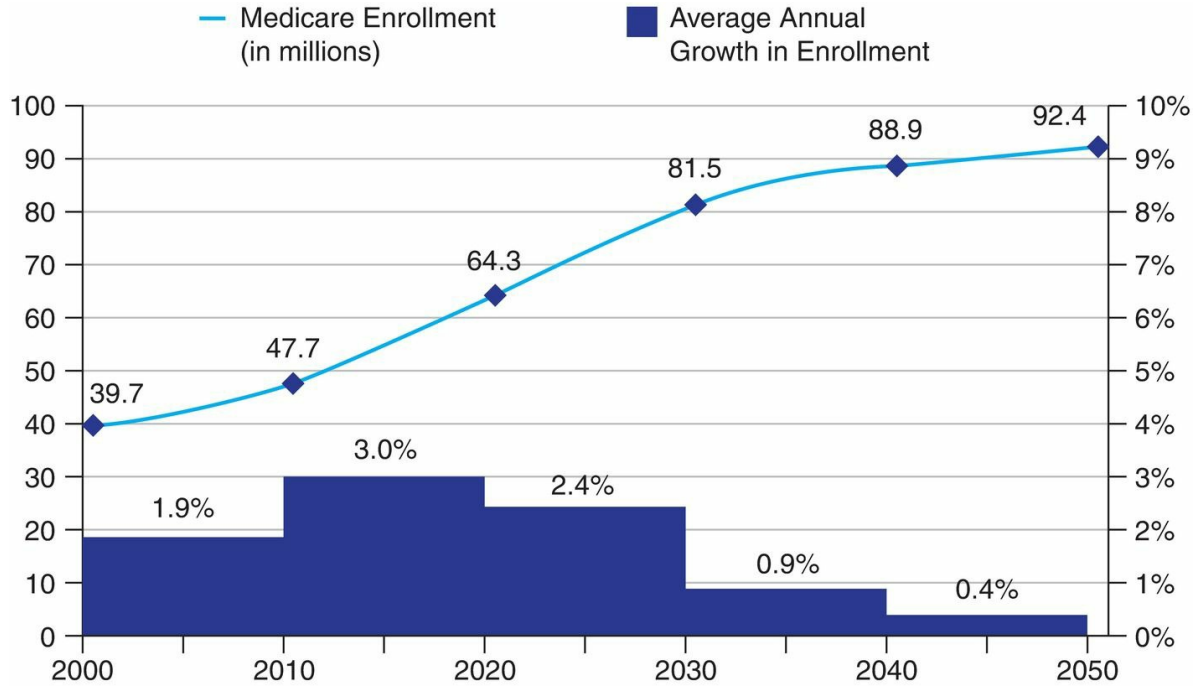

Figure 6–6 Projected change in Medicare enrollment, 2000–2050: Depicting growth in beneficiaries and decline in ratio of workers. (From Kaiser Family Foundation. (2015). Fact sheet: Medicare spending and financing. Retrieved from http://kff.org/medicare/fact-sheet/medicare-spending-and-financing-fact-sheet/. This information was reprinted with permission from the Henry J. Kaiser Family Foundation. The Kaiser Family Foundation, based in Menlo Park, California, is a nonprofit, private operating foundation focusing on the major health care issues facing the nation and is not associated with Kaiser Permanente or Kaiser Industries.)

Part A of Medicare, the hospital insurance program, covers inpatient hospitals, limited-skilled nursing facilities, home health, and hospice services to participants eligible for Social Security Disability Income (Cubanski et al., 2015). The 2015 deductible per episode (not annual) for Part A is $1,260, and some coinsurance costs apply. Part A is primarily financed through trust funds derived from employment payroll taxes. A total tax of 2.9% of employee wages is split between the employer and employee. These payroll taxes, along with interest earned on trust fund investments, provide the income for this program. In 2013, the payroll tax for employees was increased from 1.45% to 2.35% for individuals making more than $200,000.

Part B of Medicare, the supplementary and voluntary medical insurance program, primarily covers physician services but also covers home health care for beneficiaries not covered under Part A (Cubanski et al., 2015). The 2015 annual deductible was $147 and recipients pay 20% for services once the deductible is met. No out-of-pocket charges are applied for annual wellness visits or preventive services that are rated "A" or "B" by the U.S. Preventive Services Task Force (USPSTF). Part B is funded through general revenue and enrollee monthly premiums ($146.90 in 2015). For couples earning over $170,000

annually, premiums can range from $146.90 to $335.70; very few Medicare recipients pay the higher-income premiums.

Part C Medicare plans, also called Medicare Advantage, are private plans generously subsidized by the federal government (Cubanski et al., 2015). Part C plans are not supplemental to Part A and Part B—they take the place of Part A and Part B. Some may also cover vision, dental, and prescriptions. Most people enrolled in Part C pay the Part B premium and may also pay an additional amount to the private company. Part C plans must limit out-of-pocket expenses annually; the cap was $6,700 in 2015. This limit is only applied to Part C plans; Part A and Part B plans do not have a limit. Also unlike traditional Medicare, Part C plans use provider networks, which limit the choice of physicians or hospitals. They are regional, which may be problematic for seniors who want to spend winters in Florida and summers in Montana, for instance. There were approximately 18 Medicare Advantage plans available in each region in 2015; each is required to provide all benefits covered under Part A and Part B, but many offer additional services, including prescription drug coverage. Seniors can change their Part C plan during open enrollment periods or revert back to traditional Medicare Part A and Part B. In 2015, 15.7 million Medicare participants had Part C plans, nearly three times the number in 2003. Other types of Medicare plans include Medicare Medical Savings Account (MSA) plans, Medicare cost plans, Programs of All-Inclusive Care for the Elderly (PACE), and Medication Therapy Management (MTM) program; these are not available in all areas (Medicare.gov, n.d.a).

Forty-five percent of Medicare beneficiaries have supplemental coverage through a private company or employer retiree health insurance plans—known as *Medigap* coverage —added to Medicare Part A and Part B (Cubanski et al., 2015). Medigap coverage helps enrollees pay for out-of-pocket expenses. This supplemental coverage cannot be combined with Part C plans, because they already have a limit on enrollee cost sharing. People with Medigap coverage through their employers' retiree health plan generally pay lower premiums than people with coverage through a private company do. With rising costs of health care coverage, companies are increasing premium costs for retirees, offering new options, such as Medicare Advantage to replace traditional health plans, or paying only a set amount for health coverage and leaving retirees to purchase their own insurance.

Part D, the prescription benefit plan added through the Medicare Prescription Drug Improvement and Modernization Act of 2003, became available to seniors in 2006 (Cubanski et al., 2015). Offered by private companies (but supported by government funds), Part D plans can be combined either with Part A/Part B or with a Medicare Advantage plan (Part C) that does not cover prescriptions. Part D is primarily financed through general revenue and participant premiums. Seniors can change plans during open enrollment periods, and plans vary in coverage. Beneficiaries must review what prescriptions and what pharmacies each plan will cover when selecting a Part D plan. Each region has, on average, 30 plans available. Part D plans cost (on average) around $26 per month in 2006 and about $39 per month in 2015 (Cubanski et al., 2015). The premiums

for these plans vary by location and plan chosen. For instance, one can find a premium as low as $12.60 in New Mexico and one as high as $171.50 in Florida. Because of the high costs of Part D plans, people with incomes up to 150% of the FPL and limited assets (e.g., a home, a car) are eligible for low-income subsidies that pay for all or part of the Part D premium. Similar to Part B, enrollees with higher incomes (more than $85,000 for an individual) pay an additional fee as part of their Part D premium.

All part D plans must offer at least the standard benefit set by the U.S. government (Cubanski et al., 2015). In 2015, Part D beneficiaries pay a deductible of $320 and then pay 25% of prescription costs until total drug costs (costs paid by the plan and by the enrollee) reach $2,960. This is followed by a coverage gap, often called the "doughnut hole"; this ends when total drug costs reach the catastrophic coverage limit of $7,062 (~$4,700 in out-of-pocket spending). During the coverage gap, enrollees pay 45% of brand-name drug costs, and 65% of generic drug costs. Many enrollees have plans that provide some additional coverage during the gap period. Medicare is gradually phasing in subsidies in the coverage gap for brand-name drugs and generic drugs, reducing the beneficiary coinsurance rate from 100% in 2010 to 25% in 2020. This is called closing the gap, and ACA provisions over time will close the doughnut hole (Rice et al., 2014).

Briesacher et al. (2010) published a study of household spending on prescription drugs prior to Part D implementation. Medicare enrollees and their families spent a large portion of their income on housing, food, transportation, and personal care expenses, with little left over for medication expenses. Enrollees took, on average, four to five medications per week, leading to decisions to not adhere to medication instructions because they could not pay for them. Part D only partially alleviated this situation. A follow-up study by Naci et al. (2014) indicated that more Medicare beneficiaries could afford their prescription medications in the first three years after Part D implementation. After that, the recession led to economic hardships for many people, and the number of enrollees reporting that they did not take a medication because of its cost increased during the 2009 to 2011 time period. Part D does not benefit all racial and ethnic groups equally. Recipients from minority groups often have more difficulty obtaining a Part D plan and do not receive adequate assistance from plan administrators (Haviland et al., 2012). When the "doughnut hole" closes in 2020, some enrollees may still have difficulty purchasing brand-name drugs (Sacks, Burgess, Cabral, Pizer, & McDonnell, 2013). Finally, most beneficiaries do not choose the least expensive plan relevant to their health care needs (Zhou & Zhang, 2012).

The majority of Medicare beneficiaries participate in both Part A and Part B, often with supplemental private insurance, or they choose a Medicare Advantage plan (Part C). Less than 14% relied solely on Medicare coverage in 2010 (Cubanski et al., 2015). Some Medicare beneficiaries, especially those in need of long-term care, will also be enrolled in Medicaid. Although Medicare is generally viewed as a helpful program, there are concerns related to continued funding with an older population.

Average total Medicare expenditures grew from $5,080 per person in 1991 to $7,310 in 2001 and $11,728 in 2014 (Congressional Budget Office, 2005, 2009; Keehan et al.,

2015). Overall, spending per beneficiary increased at a rate of 7.0% between 2000 and 2010, compared to 1.0% between 2010 and 2014 (KFF, 2015c). The rate of growth is projected to be 4.1% annually from 2014 to 2024. Medicare spending, like most health care spending, is skewed in that 10% of beneficiaries are responsible for nearly 60% of total spending, representing $61,722 per capita (Cubanski et al., 2015). A study by Hellander, Himmelstein, and Woolhandler (2013) estimated that Medicare had overpaid private insurers (e.g., Medicare Advantage plans) $282.6 billion since 1985 and called for an end to privatization of Medicare. Capitation rates for Medicare Advantage plans are being reduced under provisions of the ACA, with a financial incentive for plans with higher-quality scores; those scoring poorly face penalties (Rice et al., 2014). Medicare home health costs have increased and quality has diminished, as the majority of home health agencies providing care for Medicare patients are now for-profit. Higher per-patient costs were demonstrated ($4,827 vs. $4,075), as these agencies had higher profits and administrative costs (Cabin, Himmelstein, Siman, & Woolhandler, 2014). An analysis of acute care costs for Medicare patients found that 10% of patients were responsible for more than 70% of total spending (Joynt, Gawande, Orav, & Jha, 2013). An interesting footnote involves unauthorized immigrants paying into the Medicare Trust Fund; this was estimated at between $2.2 and $3.8 billion more annually than what was withdrawn between 2000 and 2011 for a $35.1 billion surplus (Zallman et al., 2016). For more information on Medicare trends and concerns about its solvency, see Chapter 24.

Medicaid

Medicaid, known as Title XIX of the Social Security Amendments Act of 1965, provides medical assistance for children, pregnant women, parents with dependent children, seniors, and people with severe disabilities (Paradise, 2015; Paradise, Lyons, & Roland, 2015). Medicaid is an optional program for states, but all states currently participate. Over time, the scope of Medicaid increased, and states opting to provide Medicaid were required to implement each increase—or lose their federal Medicaid funding. Medicaid covered more than 71 million people in 2015, an increase of nearly 13 million since 2013, largely due to the Medicaid expansion under the ACA (CMS, 2015b). Spending for Medicaid was $495.8 billion. Because Medicaid covers so many people, many of whom have complex health needs, it is a large component of health care spending in the United States (Paradise et al., 2015). Medicaid covers 37% all children and 77% of children living below poverty level. It covers 20% of all Medicare beneficiaries and 64% of enrollees living in nursing homes. However, Medicaid only covers 35% of adults living below poverty level. Prior to the ACA, childless adults without disabilities were not eligible for Medicaid. Under the ACA, Medicaid was expanded to all nonelderly adults with incomes up to 138% of the FPL, $16,250 for an individual in 2015. Other changes made through the ACA were to extend Medicaid coverage for children in foster care until age 26 (equal to the requirement that private plans allow dependent children to remain on a parent's plan until that age). States also needed to make the Medicaid application process easier.

The ACA initially required all states to expand Medicaid. This was legally challenged by several states, leading to a Supreme Court case called *National Federation of Independent Business v. Sebelius* (KFF, 2012). On the last day of the 2011–2012 term, the court released their ruling: The Medicaid expansion was unconstitutional because it was highly coercive. Although states participating in Medicaid had been required to comply with all of its provisions, the Supreme Court ruling stated that this increase was too sudden and the penalty of withholding all existing Medicaid funds for noncompliance was too high. Thus, the Medicaid expansion became optional for states. Currently, 24 states have not expanded Medicaid coverage under the ACA, and Dickman, Himelstein, McCormick, and Woolhandler (2015) estimate that this led to 7.74 million people remaining uninsured. They project that there will be between 7,076 and 16, 945 more deaths resulting from this action, compared to states that opted in. And this will also result in 441,260 fewer Pap smears along with 420,273 diabetics unable to receive medications.

Medicaid spending is important to the U.S. health care system overall, paying $1 of every $6 of personal health spending (Paradise et al., 2015). The largest portion of Medicaid spending goes toward people with disabilities (42%) and older adults (21%). This group is only 24% of Medicaid enrollees. Nearly 10 million people are eligible for both Medicaid and Medicare, 14% of Medicaid enrollees. This small group uses 40% of all Medicaid spending. In addition to these high-cost groups, Medicaid finances

- 25% of all behavioral health care
- Nearly half of all births
- 50% of all long-term care expenses
- 35% of safety-net hospitals' income
- 40% of health center income

Medicaid is jointly funded between federal and state governments to assist the states in providing adequate medical care to eligible persons (Paradise et al., 2015). The federal government matches state Medicaid spending, and this is the largest source of federal funding for states. The federal government pays a portion of the costs, called the Federal Medical Assistance Percentage (FMAP). Historically, the FMAP is around 50%, but it is higher in poorer states; it can reach as high as 76%. The average FMAP, for all states, is 57%. The federal government will pay 100% of the expenses for care provided to people enrolled in Medicaid because of the ACA expansion through 2016, and 90% of these expenses after 2016. These rules, and other increased federal payments for specific groups, will raise the average FMAP to 64% (through 2016) and 62% (after 2016).

The funding model for Medicaid has benefits and problems. There isn't a limit on federal spending, so as states expand their Medicaid programs, more federal funding flows to states (Paradise et al., 2015). This allows Medicaid to expand during epidemics, natural or man-made disasters, or short economic downturns. At the same time, when the economy contracts, as in the recent recession, many more people become eligible for Medicaid at a time when state and federal funds are decreasing.

The states have some discretion in determining which population groups their Medicaid programs cover and the financial criteria for Medicaid eligibility, as well as the scope of services, rate of payment, and how the program will be administered, so long as they meet the minimum requirements set by the federal government (Paradise et al., 2015).

Medicaid mandatory services include the following (CMS, n.d.b):

- Outpatient and inpatient hospital services
- Early childhood screenings and well-child checkups (to age 21)
- Physician and nurse practitioner/certified nurse midwife services
- Lab and x-ray services
- Family planning services
- Tobacco cessation counseling for pregnant women
- Home health care and nursing home services for those over age 21 (including rehabilitation centers)
- Federally qualified health center and rural health clinic services
- Transportation to medical care

As with Medicare, Medicaid programs moved to a managed care concept, following mandates within the Balanced Budget Act of 1997, to attempt to restrain costs (Paradise et al., 2015). In 2015, more than half of Medicaid beneficiaries have managed care programs; in some states, a managed care plan is required. Medicaid beneficiaries are economically disadvantaged, frequently reside in medically underserved areas, and often have more complex health and social needs than other adults with higher incomes do. They often must choose between multiple plans, yet few providers, and may need to drive long distances to see specialists. Some managed care plans lack sufficient oversight, leading to fragmented services and poor health outcomes.

Medicaid is also a source of innovation in health care (Paradise et al., 2015). States implemented medical homes, care coordination, integration of physical and mental health care, and other "new" services earlier than private health plans. The flexibility built into the federal requirements for Medicaid, Medicaid rule waivers to test ideas, and the new Innovation Center in CMS (part of the ACA) allow states to develop new models of health care delivery.

Patient advocates (e.g., physicians, nurses, community leaders) often express concerns that many managed care plans (or state administrators) are more focused on keeping their costs down than on improving patient care. The system has wide variability in cost-effectiveness and quality (Paradise et al., 2015). Ensuring access and quality of care in a managed care environment will require fiscally solvent plans, established provider networks, education of providers and beneficiaries about managed care, and awareness of the unique needs of the Medicaid population. A key factor to Medicaid's future success is reimbursements to providers, both the amount of payments and administrative delays. Medicaid has historically reimbursed providers at a lower rate than Medicare and other

insurance programs and may require significant effort to file for reimbursement. States may also take a long time to make the reimbursement payment. These issues create burdens for clinics and private physician offices, leading to a lack of provider participation—and a lack of access to care for enrollees.

Despite these issues, Medicaid provides societal benefits. Medicaid coverage is associated with reduced rates of infant mortality and low-birth-weight infants (Paradise et al., 2015). In addition, providing coverage to children early in life leads to higher educational achievement, higher income, and decreased use of public programs. Medicaid coverage led to an increase in health-related quality of life and happiness in an Oregon study (Baicker et al., 2013). Medicaid enrollees were also less likely to report financial strain due to health care costs and more likely to have a usual place of care. Although there are access and quality problems with Medicaid, one large study examining differences between an uninsured population and those with Medicaid found that similar patients with Medicaid were more likely to see a physician at least once annually; among low-income populations with high blood pressure, those with Medicaid had greater awareness and control of hypertension (Christopher et al., 2016). This did not extend, however, to those with high cholesterol or with diabetes.

Children's Health Insurance Plan

Enacted as part of the Balanced Budget Act in 1997, the Children's Health Insurance Plan (CHIP) provides health coverage to uninsured children under age 19 for families caught in the gap between Medicaid and affordable health insurance (CMS, n.d.b). In 2013, the program covered 8.1 million children, spending more than $13 billion (Pew Charitable Trusts, 2014). CHIP decreased the rate of uninsured children from 15% in 1997 to 9% in 2012. All 50 states participate, but eligibility guidelines and covered services vary (CMS, n.d.b). The ACA extended funding for the program through 2015, and, after contentious debate, Congress passed a bill to reauthorize spending through 2017 (Kardish, 2015). The federal portion of CHIP spending increased with the ACA as well, to a state average of 93% of costs (Pew Charitable Trusts, 2014). The program is authorized, including currently eligibility guidelines, through 2019. However, congress will have to reauthorize funding after 2017.

Other Government Programs

In addition to third-party reimbursement, the government offers some direct health services to selected populations, including Native Americans, military personnel, veterans, merchant marines, and federal employees. Government support, largely through grants administered through the CDC, provides immunizations and well-child care, as well as prenatal care and other programs at the state and local level.

Payment Concepts in Health Care

Reimbursement for health care services generally has been accomplished through one of two approaches: retrospective or prospective payment. Conceptually, these approaches are polar opposites. It is helpful to understand their differences and their meaning for the financing and delivery of health services, past and present.

Retrospective Payment

A traditional form of reimbursement for any kind of service, including health care, is retrospective payment, which is reimbursement for a service after it has been rendered (Rambur, 2015). A fee may be established in advance. However, payment of that fee occurs after the fact, or retrospectively. This is known as the fee-for-service (FFS) approach.

In health care, limited accountability in the use of retrospective payment has created several problems (Estes et al., 2013). With third-party payers (e.g., insurance companies, the government) serving as intermediaries, neither consumers nor providers of health services were accountable for containing costs. Many physicians were unaware of the cost of tests and therefore did not hesitate to order repeated testing (Agrawal, Taitsman, & Cassel, 2013). Patients and providers alike often insisted on expensive tests and treatments, believing these to be the best option for patient care (Estes et al., 2013). As more advanced technology and new medications became available, costs increased. Third-party reimbursement also increased, along with other factors, to create an inflationary spiral of escalating costs.

A further problem associated with the FFS concept was its tendency to encourage sickness care rather than wellness services. Physicians and other providers were rewarded financially for treating illness and for providing additional tests and services. There were few incentives for prevention or health promotion in an industry that reaped its revenues from keeping hospital beds full and caring for the sick and injured. Although retrospective payment worked well in other industries, from a cost-containment as well as a public health perspective, it was problematic in health care.

Prospective Payment

Prospective reimbursement, although not a new concept, was implemented for inpatient Medicare services in 1983, in response to the health care system's desperate need for cost containment (Rambur, 2015). It has since influenced the Medicaid program, as well as private health insurers. The prospective payment form of reimbursement has virtually eliminated the retrospective payment system (Estes et al., 2013; Nickitas et al., 2016). Prospective payment is a payment method based on rates derived from predictions of annual service costs that are set in advance of service delivery. Providers receive payment for services according to these fixed rates, set in advance. Payments may be in the form of premiums paid before receipt of service or in response to fixed-rate (not cost) charges. To

correct unlimited reimbursement patterns and counteract disincentives to contain costs, prospective payment involves four classic steps (Dowling, 1979; Longest, 2016):

1. An external authority is empowered (by statute, market power, or voluntary compliance by providers) to set provider charges, third-party payment rates, or both.
2. Rates are set in advance of the prospective year during which they will apply and are considered fixed for the year (except for major, uncontrollable occurrences). The provider accepts the assignment of fees.
3. Patients, third-party payers, or both pay the prospective rates rather than the costs incurred by providers during the year (or charges adjusted to cover these costs).
4. Providers are at risk for losses or surpluses.

The concept of prepayment, or consumers paying in advance of health care, has existed for many years. As far back as 1933, prepaid medical groups were advocated to reduce costs and make services more accessible (Rambur, 2015). Examples of early plans were the Group Health Association of Washington, DC, the Health Insurance Plan of Greater New York City, and the Kaiser Plan (Knickman & Kovner, 2015; National Council on Disability, 2013). The success of these plans helped to influence the growth of the Health Maintenance Organization (HMO), a type of managed care discussed later in this chapter.

Prospective payment imposes constraints on spending and provides incentives for cutting costs. The federal government, as mentioned earlier, enacted a prospective payment plan (The Social Security Amendments Act of 1983; see Landmark Healthcare Legislation). The plan is a billing classification system known as diagnosis-related groups (DRGs). The system is based on about 500 diagnosis and procedure groups. It provides fixed Medicare reimbursement to hospitals based on weighted formulas. Flat rates of payment are based on average national costs for a specific group, adjusted annually, with some regional variations accounting for higher wages and other costs (Longest, 2016; Rambur, 2015). This system was enacted to curb Medicare spending in hospitals and to extend the program's solvency period. The regulatory approach of DRGs changed Medicare hospital reimbursement from a cost-based retrospective payment system, in which a hospital was paid its costs, to a fixed-price prospective payment system. It was designed to create incentives for hospitals to be more efficient in delivering services.

Indeed, the prospective payment system reduced Medicare's rate of increase in inpatient hospital spending and increased hospital productivity (Clifton, 2009; Rambur, 2015). Thought to reduce hospital stays and unnecessary admissions, the system however led to DRG creep or "upcoding" (i.e., classifying patients into more lucrative categories) and patient dumping (i.e., transferring patients whose reimbursement is expected to be lower than actual costs of services) in an effort to counteract the losses in revenue to hospitals that spend more on Medicare patients than they are reimbursed (Angeles & Park, 2009, para. 3). It also led to fierce competition among providers and mounting concern about quality of care—in hospitals, ambulatory settings, and home care. Kinney (2013) notes that the three major concerns faced by Medicare (and the ACA) are "cost and volume

inflation, quality assurance, and fraud and abuse" (p. 253). Whereas cost inflation was addressed by DRGs, quality was addressed in October 2008, when Medicare began withholding payments to hospitals for preventable errors in an effort to provide an incentive to prevent avoidable mistakes and improve patient care. The 10 preventable errors (often called "never events") included

1. Foreign objects retained after surgery
2. Air embolism
3. Incompatible blood transfusions
4. Stage III and IV pressure ulcers
5. Injuries sustained because of falls and trauma
6. Some types of poor glycemic control (e.g., diabetic ketoacidosis, hypoglycemic coma)
7. Catheter-associated urinary tract infections
8. Vascular catheter-associated infections
9. Surgical site infections
10. Deep vein thrombosis (DVT)/pulmonary emboli following a total knee or hip replacement (CMS, 2008, p. 2)

These changes were instituted at the request of Congress, and initially, many hospitals complained that their payments would be substantially reduced, especially for frail, complicated patients. However, even though Medicare did not pay for an initial pressure ulcer, for instance, the resulting medication-resistant staph infection or sepsis resulting from that bed sore was covered. In January 2009, CMS ceased all payments for cases involving wrong surgical procedures and surgery on the wrong patient or on the wrong body part. The days of paying physicians providing substandard care resulting in subsequent procedures, hospitalizations, and thus greater income have ended. The policy successfully reduced Medicare payments in fiscal years 2009 and 2010, saving $44 million (CMS, 2012). New quality reporting requirements were added, and policies for Hospital Value-Based Purchasing and hospital readmission rate reductions (CMS, 2012, 2013). The National Quality Forum (n.d.) has developed a lengthier list of serious reportable events (see Table 6–4).

Table 6–4 National Quality Forum List of Serious Reportable Events

Category	Events
1. Surgical or Invasive Events	Wrong surgery; surgery to wrong patient/site; retained foreign object; postop death
2. Product or Device Events	Serious injury or death from contaminated medications or devices (or devices used not as intended) or air embolism while in health care setting
3. Patient Protection Events	Inappropriate release/discharge (to unauthorized person if incapacitated); injury or death after patient disappearance; patient self-harm or suicide while in health care setting
4. Case Management Events	Serious injury or death because of unsafe administration of blood/products, "irretrievable loss of an irreplaceable biological specimen" (para. 19), medication error, not giving information or following up on x-rays, lab, or pathology results, during low-risk labor/delivery, or after a fall in health care setting. Also, stage III, IV, or not staged pressure ulcers after admission. Errors in artificial insemination (wrong egg/sperm)
5. Environmental Events	Serious injury or death to either patient or staff because of electric shock or burns during patient care; incidents with contaminated or wrong gas (or no gas available); serious injury or death with use of bedrails or restraints while in health care setting
6. Radiologic Events	Serious injury or death to either patient or staff related to metallic object in MRI areas
7. Potential Criminal Events	Care ordered/provided by someone impersonating a licensed health care professional; patient abduction; assault or sexual abuse of staff or patient in or on grounds of health care setting (and serious injury or death resulting from assault/abuse)

"Never events" are medical errors or adverse events that should not happen and are largely preventable (Agency for Healthcare Research & Quality, 2014, para. 1). An expanded list of 24 never events for hospitals—serious incidents that could have been prevented—was approved for nonpayment by Medicaid beginning in July 2012 for all states (in 2011, about 21 states had already begun nonpayment). The ACA changes this system from evaluating payments on a case-by-case basis to evaluating payments based on the rate of "never events." The goal was to reduce serious medical errors and preventable infections that should reduce costs and improve patient care. Some physician groups objected to this, as they noted that some complications are "not entirely preventable" (Galewitz, 2011, para. 6). Patients have benefitted from increased attention to the quality of care (KFF, 2015b). The number of hospital-acquired conditions decreased from 2010 to 2013, and 30-day hospital readmission rates decreased for Medicare enrollees from 2007 to 2013 (USDHHS, 2014b). Plans to expand nonpayment to other settings have yet to be implemented. Rather, the ACA includes incentive payments to primary care providers who meet quality goals. Debate continues about nonpayment outside of hospital settings and about which conditions should be included in the list of never events (see What Do You Think?).

What do *you* think?

What if you were to hire a glass company to replace a broken windshield in your car, and while completing the repair, they accidentally broke off your rear view mirror. Would you expect them to pay for that mistake? Or would you just absorb the cost yourself? In the past, we the taxpayers have been paying Medicare payments to hospitals and physicians who have made serious errors that have led to adverse

events, spiraling costs, and resulted in poor patient outcomes. Congress and others feel that this is unfair and have enacted legislation to stop paying for these types of errors or preventable events. Do you think this is fair? Can these conditions always be prevented? Are there extenuating circumstances that should be taken into account? Are there benefits to patients and taxpayers from holding health care providers accountable for errors and poor care?

Private insurers also moved to nonpayment for medical errors and never events, although the list of conditions varies by company (Sorensen, Jarrett, Tant, Bernard, & McCall, 2014). In 2009, Milstein reported that preventable complications within 90 days after inpatient surgery costs an average of between $11,797 and $19,480 for private insurers whose enrollees develop metabolic problems, pressure ulcers, or infections. In 2015, the average hospital costs for patients with inpatient surgery complications was calculated to be 119% higher (or $19,626) than for those without complications, and the average third-party reimbursement was 105% higher (or $18,497) for those patients with surgical complications. For hospitals, the profit margin dropped from 5.8% to 0.1% for those patients with complications (Healy, Mullard, Campbell, & Dimick, 2016).

A more vigorous version of prospective payment is *capitation*. As noted before, capitation refers to a fixed fee per person that is paid to an MCO for a specified package of services. Fees remain in effect until renegotiated, regardless of the number of services provided. Because profit margins are very tight, utilization, quality, and costs are carefully monitored (Nickitas et al., 2016).

The prospective payment concept has proved useful from a public health perspective. Prepaid services create incentives for providers to keep their enrollees healthy, thus reducing provider costs. A potential, indirect benefit from fixed rates and reduced costs is that more of the health care dollar is available to spend on prevention programs.

Claims Payment Agents

Claims payment agents administer the process for government third-party payments. That is, the government contracts with private fiscal agents to handle the claims payment process and function as an intermediary between them and the health care provider. More than 80% of the government's third-party payments have been handled by these private contractors, who sometimes are known as fiscal intermediaries (when processing Medicare hospital claims), carriers (when dealing with insurance under Medicare), or fiscal agents (as applied to Medicaid programs). As an example, Blue Cross and Blue Shield, in addition to being a private insurance company, has also acted as a claims payment agent for Medicare since its inception (Blue Cross Blue Shield, 2016).

Direct Consumer Reimbursement or Out- of-Pocket Payment

Another source of health care financing comes from direct fees paid by consumers. This refers to individual out-of-pocket payments made for several different reasons, such as payments made by individuals who have no insurance coverage (fees must be paid directly for health and medical services) or payments for limited coverage, insurance caps, and exclusions (services for which the consumer must bear the entire expense). For example, some individuals carry only major medical insurance and must pay directly for physician office visits, prescriptions, eyeglasses, and dental care. In other instances, the insurance contract may include a deductible amount that must be paid by the insured before reimbursement begins (e.g., $500 for individuals or $1,500 for a family). The contract may be established on a coinsurance basis, which determines a percentage to be paid by the insurer and the rest by the individual (e.g., 80/20 plans mean that individuals pay 20% of costs after deductibles are met). Or the individual may pay the remainder of a health service bill after the insurer has paid a previously agreed-on fixed amount, such as a fixed fee (known as a coverage cap) for a particular service (labor and delivery, knee surgery, etc.). In 2015, 11% of people between 19 and 64 years of age with private health insurance had high out-of-pocket costs, such as 10% or more of income or 7% or more if low income (Collins, Gunja, Doty, & Beutel, 2015).

Another important factor for those paying directly for their health care expenses is cost shifting. This practice of charging different prices to different consumers most often affects those without health insurance who are paying out-of-pocket for care (Coughlin, Holahan, Caswell, & McGrath, 2014). As health insurance plans or large companies contract with hospitals and physicians for services, they purchase these services at a reduced cost. Those without this "buying power" pay full price. For example, a $500 radiology procedure may be discounted to $225 for an insurance plan, but an individual paying out-of-pocket will pay the full price. This also can occur with government-sponsored plans. When Medicare payment changes to hospitals were instituted with the Balanced Budget Act of 1997, cost shifting to private patients in order to cover their losses became more difficult for those hospitals with large Medicare patient loads and more financial distress. Smaller hospitals with higher market power and a lower proportion of Medicare patients were found to be able to shift up to 37% of their cuts to private patients in a 2010 study by Wu. Other studies have found that cost shifting is uncommon (Frakt, 2011) and that lower Medicare payments actually resulted in lower costs for other payers (White, 2013). A review of research on hospital cost shifting concluded that evidence for cost shifting shows that if it does occur, it generally is not substantial (Robert Wood Johnson Foundation, 2011).

Private and Philanthropic Support

Private or philanthropic support, a third funding source, contributes both directly and indirectly to health care financing. Many private agencies fund programs, underwrite research, and provide benefits for people who otherwise would go without services. Charitable donations to nonprofit health care institutions, after a drop of 11% in 2009 compared to 2008, increased 7% in 2011 compared to 2010 (PRNewswire, 2013; Shinkman, 2010). Contributions were stable in 2012, with more than $8.9 billion raised. On average, 8% to 10% of hospital budgets come from charitable giving (Jones, 2012). Nearly one third of donations were major gifts from individuals or groups and 24.1% of donations came from businesses or foundations (PRNewswire, 2013). In addition, volunteerism, the efforts of numerous individuals and organizations that donate their time and services (e.g., hospital guild members), provides tremendous cost savings to health care institutions. It also enables many individuals to receive services, such as home-delivered meals or transportation to health care facilities, at no charge.

Philanthropic financing of health care has significantly decreased in the last two decades. Free medical clinics, beginning in the 1960s, have provided services to those without other sources of health care. They have helped many people but have also helped health care professionals by providing another place for research as well as a venue for teaching students outside the acute care setting. These clinics often rely on volunteer clinicians in addition to students. In 2010, free clinics in the United States served more than 1.8 million individuals (Swan & Foley, 2016).

Clinicians have historically provided uncompensated (charity) care to individuals outside of free clinics as well. The amount of charity care is decreasing, however. Much of this trend is explained by the increase in individuals covered by Medicaid (Sabik & Gandhi, 2013). Expanded insurance coverage due to the ACA has changed the amount of charity care provided by hospitals, too. Hospitals in the United States provide about $50 billion in charity care each year (DeLeire, Joynt, & McDonald, 2014). In 2014, because of increased insurance coverage under the ACA, hospitals saved an estimated $5.7 billion in charity care costs; nearly 75% of these savings are in states that expanded Medicaid.

TRENDS AND ISSUES INFLUENCING HEALTH CARE ECONOMICS

The High Cost of Health in the United States

The United States per person costs for health care in 2013 was over $9,255 (KFF, 2014), paid through a combination of public tax money, individual and corporate contributions to insurance plans, and other sources. In 2012, our costs were 42% higher than the second highest country, Norway. Not only do we pay almost twice the per capita expenditure of Canada and Germany and almost three times that of Japan and Italy, but also we have had one of the largest increases in health care spending since 1980. As noted earlier, health spending in 2013 was estimated at 17.4% of the U.S. GDP, whereas the United Kingdom spent only 8.8% of their GDP (KFF, 2014). U.S. tax-funded health care expenditures encompassed 64.3% of 2013 total health spending, and it is projected to rise to roughly two thirds by 2024. Private employer spending constituted 18.5% of health spending in 2001 but is projected to drop to 14.5% by 2024. Increased government share of spending on health care is largely due to the aging population and ACA spending on subsidies and Medicaid expansion (Himmelstein & Woolhandler, 2016b).

In 2010, the World Health Organization's *World Health Report* focused on health financing. The report notes that the composition of services needed to achieve good health for all people varies in different countries or regions. However, a strong health system requires accountability and oversight. The report estimates that between 20% and 40% of health care spending is the result of inefficiency and waste. The goal of universal coverage for health needs could be partially met by improving efficiency and using resources more effectively. It notes that, around the world, the high cost of medical care and lack of sufficient coverage causes "150 million people (to) suffer financial catastrophe annually while 100 million are pushed below the poverty line" (p. 8).

In a global comparison of health care costs totaling over $6.5 trillion, the WHO (2012) found that the United States had the highest total per person annual expenditure ($8,362), compared to global per person annual spending of only $948. An earlier WHO (2000) study found that the U.S. health care system was the "most expensive … in the world" largely because of high administrative costs (estimated then to range between 19.3% and 24.1%), the system of complex multiple payers, and the rising costs of prescription medications and advanced medical technology (p. 2). They also noted the shift from nonprofit to for-profit hospitals and the aging population as causative factors, along with the high proportion of people without insurance and the high cost of their untreated illnesses. WHO (2011) has outlined key components of well functioning health care systems, indicating some of the areas that are problematic for the U.S. system. A comparison study of hospital administrative costs among eight developed nations revealed that these costs made up over 25% of the U.S. total hospital expenditures. These costs in

England were 15.5%, and in Canada and Scotland about 12%. The researchers projected cost saving of over $150 billion in 2011 if our levels had been as low as Canada's (Himmelstein, Jun, et al., 2014). Another study examined the billing and insurance-related administrative costs of our fragmented system and noted that by moving to a more simplified system of financing health care, the United States could save over $350 billion a year, or almost 15% of total health care spending (Jiwani, Himmelstein, Woolhandler, & Kahn, 2014). The average physician is reported to spend almost 17% of their workweek in administrative duties, and this is rising with the increased use of electronic health records (EHRs) (Woolhandler & Himmelstein, 2014).

Why does health care cost so much? Explanations include the following:

- Medical malpractice costs and physicians' perceived need to practice *defensive medicine* by ordering excessive tests and x-rays. A landmark study found that this increased health care spending by 2.4% in 2008 (Mello, Chandra, Gawande, & Studdert, 2010). Defensive medicine is not evidence based and may even harm healthy patients (Hoffman & Kanzaria, 2014).
- An aging population and the greater prevalence of chronic disease (Knickman & Kovner, 2015; Shi & Singh, 2014).
- Advances in and the spread of medical technology; patient demand for cutting-edge technology and physician responsiveness both contribute to this problem (Chandra & Skinner, 2011; Hayden, 2014; Hoffman & Kanzaria, 2014). In 2009, Callahan reported economists' projections about the use of newer technologies leading to 40% to 50% of annual health care cost increases.
- Rapidly rising prescription drug costs (Cox, Kamal, Jankiewicz, Rousseau, 2016).
- High costs of insurance administration: The amount of private health insurance companies in the United States leads to higher costs compared to countries with a government-run insurance system (Mathauer & Nicolle, 2011).
- Ineffective, inappropriate, and inadequate health care leading to increased morbidity and mortality and costs; a "highly fragmented" health care system, large number of uninsured population, and restricted primary care and public health resources (IOM, 2001, 2013, p. 4).
- Those who have lived most of their lives without insurance have higher costs when they enroll in Medicare (Joynt et al., 2013). This would likely decrease if new beneficiaries were covered by insurance throughout their lives, and costs of uncompensated care would also decrease with universal coverage.

Many U.S. citizens believe that their health care system provides the most advanced medical care, which makes up for other deficits in the U.S. health care system. In fact, as noted above, use of the most advanced medical technology and medications is one cause of high health care costs in the United States. What does the U.S. health care system deliver for the price paid? The Commonwealth Fund (2015) studied the health systems in seven countries: Australia, Canada, Germany, the Netherlands, New Zealand, the United

Kingdom, and the United States. The U.S. health system ranked last or near last on access, efficiency, and equity. The WHO (2000) noted at the start of the 21st century that the United States was found to be "the only country in the developed world, except for South Africa, that does not provide healthcare for all of its citizens" (p. 3). In the United States, the patchwork quilt of private and public insurance—mostly tied to either employment or low-income status—makes it difficult for many people to get the care they need. The researchers noted that those without health insurance are "sicker and die younger than people with health insurance" (p. 4). Although the ACA has expanded health insurance coverage to many, there are still uninsured individuals in the United States. In 2012, 47 million Americans under age 65 were uninsured, but that number is expected to drop to 31 million by 2020 as a result of the ACA (Rice et al., 2014).

The news is not all bad; the United States ranked fifth overall in timeliness of care compared to other OECD countries in 2013 (Davis, Stremikis, Squires, & Schoen, 2014). People in the United States report low wait times for elective surgery despite having fewer acute care hospital beds compared to other countries (Mossialos, Wenzl, Osborn, & Sarnak, 2016). This might be because in the United States focus is on decreasing hospital stays, so space is available to bring in more new patients. In addition, the United States performs more ambulatory surgical procedures than other countries do (Mossialos et al., 2016). However, less than half (48%) of U.S. citizens can get a physician appointment on the same day; only Canada is lower at 41%. In Germany and New Zealand, more than 70% of people can be seen the same day they call for an appointment. Another good outcome is that the United States ranked first in 2000 among all WHO countries on *responsiveness*—a construct relating to how respectfully clients are treated. However, as noted in Chapters 5 and 25, for many racial and ethnic minorities, this is not the case.

The United States leads other countries in cancer screening and survival (Ho & Preston, 2010; NRC & IOM, 2013) and heart disease management, or control of cholesterol and blood pressure. Lower rates of mortality due to stroke and lower smoking rates, as well as higher household average income, also characterize positive comparisons; also, recent immigrants have better health than those of us who are native born (NRC & IOM, 2013). At the same time, the U.S. health care system scores very low in other areas, including medical errors (Ho & Preston, 2010). U.S. citizens do not have longer, healthier lives overall when compared to other high-income countries (NRC & IOM, 2013). The United States ranked 34th for overall life expectancy in 2011 and 31st in healthy life expectancy (the average number of healthy years expected in a population) in 2007 when compared to other WHO nations (Bezruchka, 2012).

In recent years, debate about the ACA has focused public attention on many issues with the U.S. health care system. In a study of OECD countries, only 25% of people in the United States reported that they felt the U.S. health care system worked well, compared with 40% in France (the next lowest) and 63% in the United Kingdom (Mossialos et al., 2016). Conversely, 27% of people in the United States reported that the U.S. system needed to be thrown out and rebuilt, compared with 12% in Norway, the second highest

country.

U.S. hospitals are increasingly using electronic health records (EHRs).

The U.S. health care system is changing. Promising improvements include an increase in the percentage of physicians (83%) and hospitals (76%) using EHRs according to Mossialos et al. (2016). Using an incentive program, the federal government will continue to push health care providers to increase the use and functions of EHRs. The use of EHRs permits examination of not just cost, but also operational and clinical performance, and a greater "emphasis on population-based patient care management" (Bodycombe, 2013, para. 2). Predictive modeling, using statistics from EHRs, can be used to determine high-risk patients and move them into interventions to more efficiently address their health care needs. It is also used to help address readmissions and control complications and costs. It will also be helpful in monitoring pain medication misuse and developing more complex health risk assessment data (Bodycombe, 2013). We encounter the use of some type of predictive modeling on an everyday basis. Google, Facebook, and others use analyses such as this to determine which ads or articles you may see when you login to Web sites. The use of statistics is improving health care in many ways.

To measure and monitor health care quality, the Commonwealth Fund developed a scoring method that compares actual performance to achievable performance (McCarthy,

How, Fryer, Radley, & Schoen, 2011). Comparing data from the 2011 scorecard to those reported in 2008, control of hypertension improved from 31% to 50% (although the benchmark rate is 75%). Cigarette smoking decreased from 21% to 17%, and pressure sores among short-stay nursing home residents dropped from 19% to 14%. Access to care and health insurance and the rising costs of care and insurance are growing concerns. The infant mortality rate in the United States is over 35% higher than the best state-level rates. These best state rates are two times higher than rates in many other industrialized nations. Childhood obesity and care for minorities and low-income populations are also troubling. Although the United States has made some progress, the goal of safe, effective, and high-quality health care remains unreached.

In order to reach benchmark performance levels of leading nations, states, or regions, the U.S. health care system would have to improve performance by 40% or more (McCarthy et al., 2011). If this were done, the following outcomes are possible:

- 91,000 fewer annual premature deaths from causes "amenable to health care"—this is twice the number of people dying in motor vehicle accidents (p. 15)
- 38 million more adults with access to a primary care provider
- 66 million more adults getting all recommended preventive care
- Savings of $1.6 to $3.1 billion in annual medical costs by improving control of hypertension and diabetes (reducing disease complications)
- Medicare savings of $12 billion annually by reducing hospital readmissions
- Savings of $55 billion by reducing health insurance administrative costs to the average of other countries with private–public insurance systems

Mossialos et al. (2016) reported health care comparisons across OECD countries and found that the United States ranked last on *amenable mortality levels* (deaths prior to age 75 that may be prevented through effective, timely health care). Other U.S. indicators included

- Among the lowest nations in the percentage of adults who smoke daily
- The highest percentage of adults who are obese
- A breast cancer 5-year survival rate among the three highest nations
- Childhood (measles) vaccination rates below average, but above-average flu vaccination rates for adults age 65 or older.
- The highest percentage of adults who were unable to access health care because of costs

Controlling Costs

The ACA has introduced many strategies to control the rise of health care costs, including increased funding for primary prevention strategies. A focus on primary prevention demands a paradigm shift in thinking about the practice and delivery of health care (see Chapter 1). It is one that fits more closely with the mission of public health. It expects that citizens are involved in their health care, are knowledgeable about their health status, can manage self-care practices, and can modify lifestyle behaviors to promote wellness. This creates a rich environment for community health nurses to collaborate with primary care practitioners and other health care professionals to control health care costs while providing quality care focusing on primary prevention. Our focus on illness and not health promotion or prevention has proven costly. Prevention should be at the forefront of a new era in health care. Trust for America's Health (TFAH) (2016) has developed 10 Top Priorities for a National Prevention Strategy:

1. Promoting Disease Prevention
2. Combating the Obesity Epidemic
3. Preventing Tobacco Use/Exposure
4. Preventing/Controlling Infectious Diseases
5. Preparing for Potential Health Emergencies/Bioterrorism Attacks
6. Recognizing the Relationship Between Health and U.S. Economic Competitiveness
7. Safeguarding the Nation's Food Supply
8. Planning for Changing Health Care Needs of Seniors
9. Improving the Health of Low-Income/Minority Communities
10. Reducing Environmental Threats (para. 4)

Access to Health Services: The Uninsured and Underinsured

Many services, preventive or illness focused, are not available to a large portion of our population. The U.S. Census Bureau (2010) reported that 50.7 million people (16.7% of the population) were uninsured in 2009. This was the first year to show an actual drop in the number of people with health insurance since tracking of these data first occurred in 1987. By 2014, the number of people who were uninsured decreased to 33 million or 10.4% of the population (U.S. Census Bureau, 2015).

The rate of those lacking health insurance varies by age group (U.S. Census Bureau, 2015). Of those age 65 or older, 1.4% report being uninsured, compared to 6.2% of children under the age of 19 and 14.3% of adults age 19 to 64. The uninsured rate is higher for children in poverty (8.6%) compared to children not in poverty (5.6%) and higher for Hispanics (19.9%), African Americans (11.8%), and Asians (9.3%) compared to non-Hispanic Whites (7.6%). Even after the Medicaid expansion under the ACA, variation in insurance coverage continues from state to state. Massachusetts has had the lowest uninsured rate for several years, which decreased slightly in 2014 to 3.3%. Texas has the highest uninsured rate (19.1%). Kentucky's rate decreased the most between 2013 and 2014, from 14.3% to 8.5%.

As described earlier, a significant portion of the population with insurance coverage is still considered underinsured. Difficulty paying the out-of-pocket costs creates the same lack of health care services experienced by the uninsured. For example, 46% of underinsured and 63% of uninsured reported that they did not see a doctor when they were ill, did not fill a prescription, or went without a recommended medical treatment or test (Schoen et al., 2011). This compared with only 28% of those who had adequate health care coverage. The ACA has helped increase the number of people who are insured; approximately 9 million fewer Americans were uninsured in 2014 than in 2013 (KFF, 2015b). But it has not completely resolved the problem of an underinsured population. In 2014, the Commonwealth Fund's Biennial Health Insurance Survey found that 23% of nonelderly adults with yearlong health insurance were underinsured, and this number was not significantly different compared to the survey's findings in 2010 and 2012 (Collins, Rasmussen, Beutel, et al., 2015). In addition, many underinsured have no dental or vision coverage, and few prescription drug benefits, yet still experience higher deductibles compared to insurance plans with these services.

Even those with Medicaid and Medicare can be underinsured. In 2013, more than 25% of Medicaid recipients and 65% of Medicare enrollees were underinsured (Magge, Cabral, Kazis, & Sommers, 2013). Although Medicaid recipients were less likely to be underinsured than were adults with private insurance, the Medicaid expansion in 2014 would not necessarily provide access to new enrollees with low income. A particularly vulnerable group is adults age 50 to 64 (Smolka, Multack, & Figueiredo, 2012). Although 85% of people in this age group were insured in 2012, 75% of those insured rely on

employer-sponsored plans. Workers with low and midlevel incomes often experience gaps in insurance coverage due to unstable job situations. Many employers do not offer health insurance to their employees, and a large number of the uninsured are employees of these companies (or their dependents). Finally, self-employed individuals may find it difficult to pay the high costs of insurance premiums without the benefit of group rates. Consequently, many of the self-employed can access health services only by purchasing expensive individual insurance policies with high deductibles and coinsurance or by making expensive out-of-pocket payments. Self-employed individuals are able to access insurance through ACA, but 48% of uninsured adults in 2014 stated that they did not have health insurance because of high costs (KFF, 2015a). There are subsidies available to offset insurance costs for those individuals below 400% of the poverty line (Collins, Gunja, Rasmussen, Beutel, & Doty, 2015).

Another issue related to access is where people receive care. Historically, they first saw their family physician when a new health concern arose. Prior to the ACA, a study found that 42% of visits for new health problems were made to a regular primary care physician whereas an average of 37% were made to the ED. Using the ED for a new, nonurgent health problem occurs for several reasons, including convenience, negative perceptions of non-ED sources of care, and the legal requirement that the ED provide care for everyone without regard for ability to pay (Uscher-Pines, Pines, Kellermann, Gillen, & Mehrotra, 2013). A study in Massachusetts indicated increased ED use after that state's health care reform implementation, occurring years before the ACA (Hosseini & Weinberg, 2014). In addition to increased cost, visits to the ED are a missed opportunity to establish a relationship with a primary care provider (Uscher-Pines et al., 2013). People who lack insurance or who are underinsured may experience more duplicate testing and poor chronic disease management, due to the lack of a medical home (seeing the same health care provider for regular care). While Medicaid patients often use the ED, the numbers of people with private insurance using EDs is increasing rapidly. From 1995 to 2008, 60% of the increased ED use was due to privately insured individuals; only 9% was due to the uninsured (Cunningham, 2011).

Medical Bankruptcies

A wide variety of medical issues can lead to financial insecurity and bankruptcy. If you don't have health insurance and you undergo emergency surgery for appendicitis, it may take a great effort to pay off your medical debt (or you may turn to high-interest credit cards). Even if you have health insurance, long-term cancer treatments will likely mean large out-of-pocket costs—and your inability to work may lead to further financial problems. Many people with significant financial stressors, such as medical debt, may not file for bankruptcy, because of either lack of financial resources for legal fees or other reasons. Middle-income groups are more likely to file bankruptcy, whereas lower-income groups are more often found to suffer from late payments that affect their credit scores and their subsequent ability to purchase a home or apply for credit (McCloud & Dwyer, 2011). Bankruptcy filings rose significantly from 1980 to 2004—as much as 360% (Himmelstein, Warren, Thorne, & Woolhandler, 2005; Cammarosano, 2015). Filings decreased drastically in 2007 and then began to rise again through 2011 (Cammarosano, 2015). In 2015, personal bankruptcy filings were nearly as low as they were in 2008. Medical debt is thought to be a major contributor to personal bankruptcy filings. In a classic study, Himmelstein, Thorne, Warren, and Woolhandler (2009) reported that 62% of bankruptcy filings were associated with medical expenses in a five-state study. This number has been widely cited—in academic journals, in the media, and in political speeches. A later study found that medical bankruptcies in Massachusetts increased by over 33% and in 2009, and 89% of the bankruptcy debtors and their families reported having health insurance whereas about 25% had recently had insurance coverage lapses. The bankruptcy rate increase in the state was lower than the national statistics (Himmelstein, Thorne, & Woolhandler, 2011). However, a national study using more recent data (2005–2013) found that medical bankruptcies accounted for about 18% to 25% of all bankruptcies (Austin, 2014). Although this estimate is much lower than 62%, Austin (2014) did find that medical debt was the single largest cause of personal bankruptcy. In a survey of Canadian bankruptcy filers, over 40% reported loss of income due to personal injury or illness-related work absences, and over 8% reported the income loss due to caregiving duties. Less than 7% had medical bills that totaled over $5,000 in the past two years. With Canada's socialized health system, researchers concluded that some bankruptcies occur because of work-related income losses rather than medical costs (Himmelstein, Woolhandler, Sarra, & Guyatt, 2014c).

Medical debt that doesn't lead to bankruptcy is still problematic. Cutshaw, Woolhandler, Himmelstein, and Robertson (2016) studied medical causes and consequences of home foreclosures in Arizona and found that about 10% of those affected were uninsured, but 28% reported a coverage gap within the previous 2 years. Medical debt or other medical causes were cited by 57%, and 54% stated that they incurred new debt in an effort to pay medical bills (10% had mortgaged homes). About 57% reported having a chronic condition, and over 50% had either delayed or missed medical visits. Five months

after the first data collection, 33% reported that they could not afford food, and 63% had new medical debts. A few respondents were homeless. Kalousova and Burgard (2013) found that people with medical debt were more likely to delay or miss needed medical care than people with other types of debt. Although medically related bankruptcies have dropped slightly, approximately 60% of bankruptcy filings are still due to medical debt, and the high-deductible insurance plans can strain family budgets. It is estimated that 10 million U.S. adults, having full health insurance coverage year-round, will struggle to pay off medical debts that they incur in 2013 (Mangan, 2013). This is further evidence that the underinsured, along with those individuals without health insurance, are in danger of financial disaster when confronted with a serious medical emergency or long-term illness.

Managed Care

The term managed care became popular in the late 1980s. It refers to systems that contract to coordinate medical care for specific groups in order to promote provider efficiency and control costs. Although the term *managed care* is relatively new, the concept has been practiced for many years through various models of alternative health care delivery. Managed care is a cost-control strategy used in both public and private sectors of health care. Care is *managed* by regulating the use of services and levels of provider payment. This approach includes using HMOs and PPOs. HMOs represent 14% of employer-sponsored group insurance and PPOs enroll about 52% of workers (KFF, 2015c).

In contrast to FFS models, managed care plans operate on a prospective payment basis and control costs by managing utilization and provider payments. The managed care model encourages the provision of services within fixed budgets, thus avoiding cost escalation. Because costs are tight, preventive services are generally encouraged, so that more expensive tertiary care costs can be avoided if possible.

Health Maintenance Organizations

Health maintenance organizations (HMOs) are systems in which participants prepay a fixed monthly premium to receive comprehensive health services delivered by a defined network of providers. A traditional HMO offers both health insurance and health care services (Corlette, Volk, Berenson, & Feder, 2014). HMOs typically cover a large group of individuals, generating a large amount of premium revenues, and strictly control use of services. Consumers and providers have often resisted the strenuous cost-containment policies of many HMOs, because of the limits placed on health care decisions. However, employers are often drawn to HMO alternatives to traditional FFS plans as a potential cost-saving method. But 2015 costs for employee health coverage are similar for HMO, PPO, and point-of-service (POS) plans (KFF, 2015c). Also, industry projections for HMO premium rates and cost increases vary little from other types of plans, ranging from 5.8% to 6.2%; for PPOs, the range is from 5.4% to 7.8%; and for consumer-driven/high-deductible health plans, it is about 7.9% (Managed Care Online [MCOL], 2015).

HMOs are the oldest model of managed care. Several HMOs have existed for decades (e.g., Kaiser Permanente), but many have developed more recently. HMO enrollees were told that they could benefit from lower-cost premiums, reduced cost sharing, and fewer administrative costs. From 1930 to 1965, the HMO movement, supported initially by the private sector, gradually gained federal backing. Group plans were included as a part of Medicare and Medicaid legislation. The skyrocketing employer health insurance costs of the 1980s and 1990s encouraged many companies to move from traditional insurance and FFS to HMOs. The number of HMO enrollees peaked in 1999 to 2000 but encompassed nearly 75 million in 2014 (MCOL, 2015). Currently, there are numerous HMOs with a variety of configurations. The unique set of properties of HMOs includes the following:

- A contract between the HMO and the beneficiaries (or their representative), the enrolled population.
- Absorption of prospective risk by the HMO.
- A regular (usually monthly) premium to cover specified (typically comprehensive) benefits paid by each enrollee of the HMO. Few additional charges are levied, because the payment mechanism is not FFS.
- An integrated delivery system with provider incentives for efficiency. The HMO contracts with professional providers to deliver the services due the enrollees, and the basis for reimbursing those providers varies among HMOs (Estes et al., 2013).

Official encouragement, government subsidies, and the pressures for cost control spurred the growth of HMOs. Some HMOs follow the traditional model, employing health professionals (e.g., physicians, nurses), building their own hospital and clinic facilities, and serving only their own enrollees. Other HMOs provide some services while contracting for the rest. HMOs have penetrated Medicare (29%) and Medicaid (67%) markets, as well as nearly all commercial insurance markets (MCOL, 2015). They have historically been viewed as a positive alternative delivery system because of their potential for conserving costs, which results from their emphasis on prevention, health promotion, and ambulatory care, and with a corresponding reduction in hospital and medical care utilization. However, there are questions as to whether the cost savings result partly from favorable selection of enrollees. Quality concerns also have been raised about the dangers of underserving enrollees in order to stay within payment limits (Sultz & Young, 2014). Scanlon, Swaminathan, Chernew, and Lee (2006) examined longitudinal data and found that HMO competition was related to consumer satisfaction surveys, but not necessarily to better quality of care for chronic conditions. Later research verified that increased HMO competition did not lead to improved HMO quality (Scanlon, Swaminathan, Lee, & Chernew, 2008). A study examining Medicare Advantage plans, which have a managed care model, with traditional FFS Medicare noted increased cost and little evidence for improved management of outpatient chronic conditions (Nicholas, 2009). Archer (2011) observes that the costs of private plans have increased more rapidly than Medicare, often driven by little true competition; lower administrative costs for Medicare also contribute to the cost differences. A large-scale, longitudinal study of 11 quality indicators found that Medicaid-managed care enrollees received lower-quality care than managed care commercial plan enrollees (Landon et al., 2007). The Medicare Rights Center (2010) reported that almost half of Medicare private plan disenrollment is due to problems with provider access and marketing abuse or misinformation. Problems related to coverage for medical services and transfer problems affected almost 40% of patients. As mentioned earlier, Medicare overpayments to private plans have been estimated to be in excess of $282.6 billion since 1985 (Hellander et al., 2013). A Cochrane review (Scott et al., 2011) found inconclusive evidence for the impact of financial incentives to primary care physicians on the quality of health care provided.

These concerns about HMOs and managed care in general have not gone unanswered.

The Health Insurance Portability and Accountability Act (HIPAA) and the Newborns' and Mothers' Health Protection Act are both significant pieces of legislation from 1996 addressing health care concerns among the nation's citizens. HIPAA, in addition to protecting the privacy of health information, strengthened rules protecting continued health care coverage when people changed jobs. Protection for newborns and mothers became necessary when many insurance companies covered a hospital stay for labor and delivery for 24 hours—for some, this meant 24 hours from admission, and infants and mother left the hospital in potentially unstable postdelivery conditions. Newborns would go home when younger than one day of age, in some cases so soon after birth that body temperature was not stabilized and the ability to suck and take breast milk or formula was not established. The Newborns' and Mothers' Health Protection Act eliminated these "drive-through deliveries," ensuring that mothers and newborns would have the right to remain in the acute care setting for at least 48 hours, covered by their insurance plan (see Landmark Healthcare Legislation). In response to concerns from managed care clients, the government developed a patient bill of rights stipulating the patient's right to timely emergency services, respect and nondiscrimination, as well as participation in treatment decisions and a more consumer-friendly appeals process.

Preferred Provider Organizations

A preferred provider organization (PPO) is another model of managed or coordinated care that developed earlier than the HMO (Knickman & Kovner, 2015). A PPO is a network of physicians, hospitals, and other health-related services that contract with a third-party payer organization to provide comprehensive health services to subscribers on a fixed FFS basis. Because of contractual fixed costs, employing organizations that subscribe can offer medical services to their employees at discounted rates. In PPOs, consumer choice exists. Enrollees have a choice among providers within the plan and contracted providers out of the plan. The PPOs practice utilization review and often use formal standards for selecting providers.

PPOs did not exist in their present form until after 1980. Enrollment in PPOs grew from about 10 plans in 1981 to more than 700 plans in the 1990s (Dranove, 2008). The number of people enrolled in PPOs also increased, from an estimated 10.4% of individuals with private insurance in 1988 to 40% by the late 1990s, with the numbers leveling off as the decade came to a close. As consumers became more frustrated with limits imposed by HMOs, they began to move toward PPOs that provide more choices. In 2014, 152.8 million people were enrolled in a PPO, more than twice the number in HMOs (MCOL, 2015). In 2015, PPOs were the most common form of health insurance offered by employers—with 72% of workers able to choose this type of policy (KFF, 2015c). Early use of PPOs appeared to promote cost savings, but the long-range cost-effectiveness of this model has yet to be fully proven. PPOs have been criticized in the past for their lack of vigorous case management—more often found in HMOs—and some larger plans have moved toward this model, especially in the case of chronic diseases, such as hypertension

and diabetes, or with palliative care (Kogut, Johnson, Higgins, & Quilliam, 2012). The ACA encourages comprehensive case management of chronic disease as one way to decrease hospitalizations and the cost of care. New methods of determining cost-effectiveness are being utilized to determine the realistic impact of population interventions (Arbel & Greenberg, 2016).

Point-of-Service Plans

Primary health care providers are chosen by patients of POS, PPO, and HMO plans.

A variation on the just-mentioned plans is the point-of-service (POS) plan, which permits more freedom of choice than a standard HMO or PPO. Enrollees choose a primary physician from within the plan (POS) who monitors their care and makes outside referrals when necessary. At an extra cost, enrollees can go outside the HMO or PPO network of contracted providers unless their primary physician has made a specific referral (Small Business Majority, 2012). It is a hybrid or combination of an HMO and PPO. In 2015, about 10% of employees were enrolled in POS plans (KFF, 2015c). See Figure 6–7 for a look at the trend in types of health plan coverage among those employees who are covered by their employers.

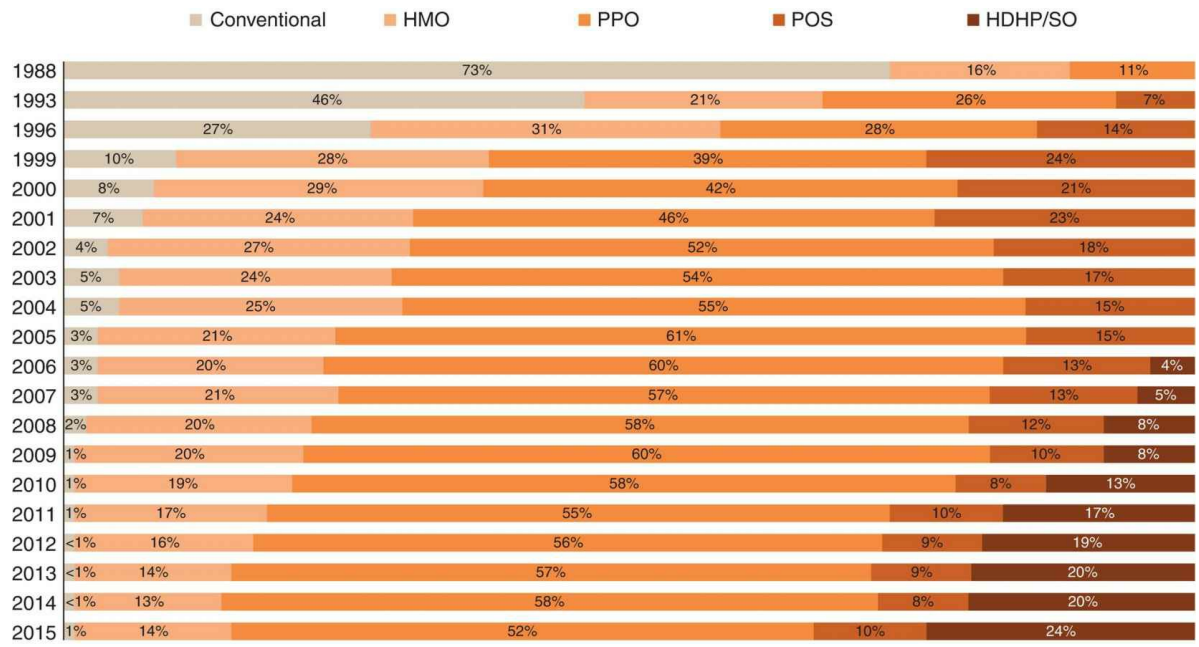

Figure 6–7 Distribution of health plan enrollment among covered workers, by type of plan, 1988–2015. (From Kaiser Family Foundation & Health Research & Educational Trust. (2015). Health Care Rationing

Health care in the United States is allocated based on price and the willingness and ability of patients to pay. In other words, patients are entitled to purchase a share of the medical services that they value. Social justice, in contrast, emphasizes the well-being of the community over the individual. Under this view, health care is regarded as a social good (as opposed to an economic good) that should be collectively financed and available to everyone regardless of ability to pay (Hoffman, 2013). The United States rations chiefly by price and the ability to pay (Hughes, 2011).

The concept of rationing in health care refers to limiting the provision of health care services. Rationing may occur according to a social justice or market justice model (Bowser, 2015). Rationing implies that resources are fixed or limited and, therefore, cannot meet every need. Scheunemann and White (2011, p. 1625) state "need is limitless and resources are not," thus there is a certain inevitability of rationing. Rationing in the United States today is more likely to be described with words such as quality, value, or evidence-based care (Ubel, 2015). The use of these words separates the need to distribute limited resources from the "emotional and historical baggage" attached to the word rationing (p. 15).

When rationing is based on social justice principles, it is a rational, fair and equal distribution of resources according to a clinical need or potential for effectiveness and is not based on income or where one lives. In this way, rationing focuses on the needs of the population more than the individual (Bowser, 2015). Rationing may occur by restricting people's choices, by denying access to services, or by limiting the supply of services or personnel. It may be overt, as in the oft-cited case of the United Kingdom, or more covert, as practiced by some health plans. When rationing is based on market justice principles, limited resources are distributed based on the ability to pay (Bowser, 2015). This has been the main model of rationing in the United States, as we have rationed by income, as access to health care has been based on ability to pay (Hughes, 2011).

Rationing may jeopardize the well-being of groups of individuals (Bowser, 2015). With limited resources for health services delivery, the government, insurers, and providers of health care services make rationing decisions to contain costs (Rosoff, 2014). This has included strict eligibility levels or monitoring the use of resources to ensure the most equitable distribution. In the past, private insurers engaged in rationing by excluding enrollees who are at greatest risk for health problems—and, thus, higher expenditures (Rosoff, 2014). This practice is no longer allowed under the rules of the ACA.

Advances in knowledge and technical capabilities through research and technology compound rationing decisions. When several individuals need an organ transplant and only one organ is available, what criteria should be used to select the recipient? Now that it is commonly accepted that certain lifestyle behaviors, such as smoking and alcohol consumption, or driving without restraints, create health risks, should people who engage in these activities pay a higher price for health care or be excluded from certain services? Should a younger person needing specialized surgery take priority over an older person needing similar care? There are no easy answers. Individual providers, insurance companies, governments, and consumers have struggled with these difficult ideas for years. With health care costs, the problems are even more complex. As health care spending rose, calls for rationing often intensified (Kelly & Cronin, 2011). Total health care spending was projected to rise to 25% of GDP by 2020, and 37% by 2050; it could even reach 49% by 2082 unless something were to be done, and this was a considerable impetus for health care reform (Rosoff, 2014). The spending for Medicare and Medicaid has grown rapidly. Over the last 30 years, Medicare spending has grown 2.4% per year faster than the GDP, and a 2009 predictive study by Friedman found that it could account for 31% of GDP in 2082 if no adjustments were made. Societal and medical advances have increased life expectancy and improved national welfare, but as spending continued to consume more and more of the GDP, more people have questioned if the costs outweighed the benefits. This may lead to limiting access to high-cost, low-benefit health procedures, such as expensive MRIs for rare conditions or conditions with no effective treatments or cures. Already, the organ allocation system controls or rations who gets an organ and when they get it; it is illegal to purchase an organ. Other types of rationing include congressional budget decisions; for instance, what proportion of the total budget goes to the Department of Defense versus

agencies dealing with health and human services or medical research. When it comes to rationing, Americans need to realize that some rationing must occur or we will face financial destruction, but our society is not accepting of the idea of rationing because of our individualistic value orientation and because we are often easily influenced by those having financial interests in opposing this discussion (Rosoff, 2014).

Oregon began an overt system of rationing in 1994. The state approached the problem pragmatically and openly. In an effort to reach universal coverage, Medicaid was expanded to cover all state residents with incomes below the FPL, and then health care services rationing was planned in order to pay for the increased public coverage. Community meetings were held, and over 1,000 citizens spoke out. Thirteen health-related values, under three headings, (1) value to society, (2) value to individuals at risk, and (3) essential to basic health care, were put forward. An original list of 709 medical services was decided upon. The state envisioned a plan for legislative determination of a cutoff point, depending on yearly budget allocations; the list changed yearly, and in 1995, 581 out of 745 procedures were covered (Perry & Hotze, 2011). In 1999, Oregon's Medicaid program covered 574 of 743 conditions, but in the early part of the 2000s, an economic downturn prevented further expansion of the Oregon Health Plan (OHP). Cuts were made and co-pays instituted that eventually led to unmet health care needs. In the year between 2002 and 2003, enrollment dropped more than 50%, and by 2007, it was down by 75% to 77% (Perry & Hotze, 2011). In 2007, the prioritized list became the basis of the essential benefits package and was divided into tiers. Lower-priority items had higher cost sharing, and higher-priority items (e.g., tobacco and substance abuse, obesity), although prevalent among the low-income population, did not focus on personal responsibility and risk behaviors or the individual's response to treatment. Faguet (2013) concluded that Oregon's health rationing plan was ineffective, as no real systematic rationing took place and coverage was actually more broad than the previous Medicaid plan, especially for dental and mental health services. Although more individuals were covered under the plan—only 11% were uninsured versus national rate of 16%—only minimal Medicaid savings were realized. The plan was underfunded, so cigarette taxes were increased and Medicaid clients were moved into managed care plans. Also, it was difficult for legislators were influenced by political influence of pressure groups and those seeking to game the rankings for their own benefit (Faguet, 2013). With the passage of ACA, Oregon has established Patient-Centered Primary Care Homes and regional Coordinated Care Organizations or networks of physicians, mental health and dental providers working under a capitated budget to provide coordinated and comprehensive services to OHP members. Financial incentives are offered for those patients needing chemical dependency, mental health, and chronic illness care (Howard, Bernell, Yoon, Luck, & Ranit, 2015). (See What Do You Think?)

What do *you* think?

Put yourself in the place of Manny Alvarez, a 23-year-old college student. He has a

particularly devastating form of cancer—a very rare form of sarcoma. His physician has worked diligently to find a chemotherapy that looks promising against his specific tumor cells, but it is not approved for his cancer. It is only FDA approved to treat leukemia. In order to find this drug, tumor specimens were taken from his knee and femur and tested against 200 other potential medications. He had tried a drug offered through an NIH clinical trial, but it was completely ineffective against his tumor. The leukemia drug killed his cancer cells in lab tests, but his insurance company, Blue Cross Blue Shield of Florida, has declined his claim for treatment. The reason given was because this was "not established as a standard of therapy" for his type of sarcoma. But the cost of the medication is at least $300,000 (Katz, 2015, para. 4).

What would you do? If Manny does not receive treatment, he will die. Is there a moral duty to give him the medication? The pharmaceutical company should be paid for their product, but where will Manny and his family get the money for his treatment? Is there an obligation for the insurance company to provide the treatment? Or, should they wait until more clear evidence of effectiveness is available? This is a very rare form of sarcoma, and no insurance company has unlimited resources. Also, there is no federal standard that offers "clear criteria for differentiating valid from invalid requests," so insurers follow their own rulebooks (Katz, 2015, para. 7).

Do you think we should have some type of federal standard that governs the rights of insurers to deny coverage or care?

Katz (2015) suggests that nonstandard care should be covered if a qualified physician documents a "desperate need for treatment," and there evidence that supports "potential efficacy" for a specific treatment (para. 8). Because of our collective fear of the word *rationing*, we do not engage in discussions about what should and should not be covered, and our health care system often engages in heroic, but misguided, measures in some very futile scenarios, especially with very ill patients near the end of their lives. If we chose not to ration health care, then Manny would receive treatment; but insurance companies could become financially insolvent. If we "choose to rational rationally," Manny could receive care depending upon the standards set. However, if we "ration irrationally," care will most often be denied to Manny and still provided in cases of "misguided futility" (para. 15).

Do you think we should have a debate about how we divide up our health care resources? Is rationing a dirty word, or something we need to examine as a society?

Competition and Regulation

Often, competition and regulation in health economics have been viewed as antagonistic

and incompatible concepts. Competition means a contest between rival health care organizations for resources and clients. Regulation refers to mandated procedures and practices affecting health services delivery that are enforced by law. In a society in which long-held values of freedom of choice and individualism reign supreme, competition provides opportunities for entrepreneurial endeavor, free enterprise, and scientific advancement. Yet, to promote the public good, oversee equitable distribution of health services, and foster community-wide participation, regulation also serves an important role.

Health care incorporates four major kinds of regulation (Longest, 2016; Sultz & Young, 2014):

- Laws
- Regulations
- Programs
- Policies

Laws that regulate health care include any legislation that governs financing or delivery of health services, such as legislation regulating Medicare reimbursement to hospitals. Regulations guide and clarify implementation; they are issued under the authority of law and are part of most federal health care programs. Examples include regulations governing project grants such as HMO development; formula grants, such as those provided under the Hill–Burton Act; and entitlements, such as Medicare and Medicaid. Regulatory programs are created from legislative enactments and are designed to accomplish specific goals, such as accreditation and licensing rules for hospitals, public health agencies, and other health service providers. Regulatory policies have a broader focus and involve decisions that shape the health care system by channeling the flow of resources into it and setting limits on key players' actions. Examples of regulatory policies are found by reviewing state or federal budget proposals for funding programs, such as health manpower training, research, and technology development (Kingdon, 2011; Longest, 2016). See Chapter 13.

From the 1950s through the 1970s, the federal government assumed an increasing role in regulating health services (Sultz & Young, 2014). First, federal subsidy of health care costs increased, and there was greater federal control of state programs. Health services became regionalized and more comprehensive. Federal appropriations supported operational as well as capital and planning costs. Health research and the training of health professionals gained greater federal support. Group medical practice multiplied as a cost-saving measure. More than 60% of the population was covered by some form of prepaid health insurance, largely because of the effects of Medicare and Medicaid. Interagency health planning cooperation increased, and health program evaluation improved. Neighborhood health centers, community mental health centers, and other programs were developed to improve health care access for everyone. Although costs rose, the period was one of relative economic stability that emphasized quality of care, with the federal government assuming a major role in regulating the planning, use, and reimbursement of

health care services.

In the early 1980s, government cost-control measures were greatly diminished as the Reagan era ushered in deregulation in many areas of debate (Sultz & Young, 2014). The passage of the Omnibus Budget Reconciliation Act caused dramatic changes affecting health care. The federal government, having failed to contain rising health care costs, shifted responsibility for the public's health and welfare back to state and local governments. Large amounts of federal funding for health research, health manpower training, and public health programs were withdrawn. Continued escalation of health care costs prompted a concentrated effort among public and private providers alike to find cost-containment measures. From all this grew the competition-versus-regulation debate.

The 1990s were characterized by numerous hospital mergers and nonprofit to for-profit status. The Clinton health plan failed to gain support and many hospitals downsized and reduced the number of nurses on staff. Managed care became more popular as a means of reducing employer premiums in the early 1990s, but by the late 1990s, as they restricted benefits, fears were raised about MCOs withholding necessary care and a consumer "backlash" resulted (RAND Health, 2010). Many states and the federal government enacted benefit laws between 1990 and 2002, in response to these concerns. We are still feeling the results of these changes, and one of the most obvious consequences deals with competition in health care.

Competition, its proponents say, offers wider consumer choice and positive incentives for cost containment and enhanced efficiency (Sultz & Young, 2014); that is, consumers are free to select among various health plans on the basis of cost, quality, and range of services. Competing providers must develop efficient production and distribution methods to stay in business, and consumers are more likely to use only necessary services, because of the required cost sharing that is part of the competition model. One downside is fragmentation of services, lack of coordination, and subsequent waste. Integrated delivery systems, such as Kaiser Permanente's fully integrated system or more loosely organized public–private partnerships, could lead to improved quality, outcomes, and reduced costs (Enthoven, 2009b; Mate & Compton-Phillips, 2014; Reich, Rapold, & Flatscher-Thöni, 2012).

Examples of competition have been very evident as more health plans, including HMOs and PPOs, vied with traditional insurance plans for subscribers: Currently, only one percent of workers are covered by their employers through a conventional insurance plan (KFF, 2015c). However, costs have not dropped substantially. Many hospitals, too, compete aggressively for patients. Some hospitals now advertise maternity care depicting a new mother and father having a candlelight dinner in the hospital with their newborn infant in the bassinet beside them. Some surgical centers advance the "hotel guest" concept, with beautifully appointed rooms, including meals and lodging for a guest. Some research has shown that a greater concentration of hospital markets can lead to higher prices, although prices can be lower when health plan market concentration is also high (Melnick, Shen, & Wu, 2011).

Although it may appear that competition offers the best service for the least cost, regulation advocates have for almost 20 years argued that there are at least four problems associated with the competition model: (1) consumers often do not make proper health care choices because of limited knowledge of health services; (2) competition may discriminate against enrolling certain consumers, especially high-risk, high-cost patients, thus excluding those who may need services the most; (3) the competition model may not encourage enough teaching and research—expensive elements of our present system; and (4) quality may be sacrificed to keep costs down.

Regulation advocates conclude that standardization and controls are needed to guarantee quality and equal access. Our capitalist system can be driven by profits, and the profit motive in health care can lead to excesses and higher costs for taxpayers and patients. The five largest health insurance companies posted $3.3 billion in profits between just the months of April and June 2011; however, nonprofit health insurer Blue Cross/Blue Shield of Illinois paid their CEO $16 million in 2012, and the Mayo Clinic's CEO made $2 million (Ubel, 2014). Leaders in the field have concluded that both competition and regulation are needed (Longest, 2016; Sultz & Young, 2014). With foresight, McNerney (1980) wrote, "It is rapidly becoming apparent that what we need is a proper balance between competition and regulation with more effective links [and] regulation [should be] used as a force to keep the market honest" (p. 1091).

HEALTH CARE REFORM

HMOs and PPOs have become accepted methods of delivering health care in the United States in the past 30 years. Over several generations, other methods have been considered, yet not passed by legislation and adopted as law. Health care reform became a reality in 2010, with the passage of the ACA. It is helpful to look at earlier attempts and thought processes that moved us toward this reality. Managed competition and universal coverage, as well as single-payer systems, have been part of the discussion in health care reform (Squires & Anderson, 2015).

Two plans worth further review are managed competition and universal coverage, with and without a single-payer system. The benefits and drawbacks of each are important to discuss here.

Managed Competition

The idea of managed competition, as a health care delivery method, was born from the controversy regarding competition versus regulation and was driven by the need for health care reform. Managed competition, it was hoped, would combine with market competition to achieve cost savings with government regulation to achieve expanded coverage. This idea, whose origin is credited to economist Alain C. Enthoven of Stanford University, has played a major part in debates on health care reform. It sought to address the two fundamental issues driving reform: cost containment and universal access to health care (Enthoven, 2009a).

Managed competition has been viewed as a market-based solution that places accountability for resolving the health care crisis with the insurance industry and with consumers. Insurers would be required to accept all applicants, without excluding those at more risk. At the same time, the insurers must control costs. Consumers would choose among competing health insurance plans, paying above fixed amounts paid by their employers to receive the best value. But for true competition, employers must offer real choices and a wide variety of plans. To do this, Enthoven and colleagues envisioned "regional insurance exchanges" that select health plans, manage risk selection, and establish equity rules, for example, those plans with sicker participants would be subsidized by plans with younger, healthier participants (Arrow et al., 2009, p. 493).

Another concept of managed competition is consumer choice, and consumers must be able to access information, so that they can make responsible choices and feel that they have purchased something of value for their money (Vaiana, 2011). Other common features of managed competition proposals include regulations that prevent screening out of high-risk enrollees, penalties for companies that try to achieve better risk pools, community ratings to prevent companies from setting rates by risk pool, and guaranteed coverage for all who apply. Another critical component involves management; some standardization must be established among benefit packages and an effort must be made to dismantle health care monopolies that endeavor to gain uneven market power—in other words, a more level playing field (Enthoven and Wynand, 2007; Mikkers & Ryan, 2014). There is also recognition that the transition period can be lengthy.

Proponents of managed competition cite many advantages. Managed competition would encourage insurance companies to compete on price and quality of services to attract enrollees. It would also offer consumers tax incentives to purchase the lowest-cost plans that meet minimum benefit requirements. Managed competition, although market driven, would be highly regulated to ensure quality and access. Cost-effectiveness and quality/outcomes information must be made available to consumers, although currently this information is not always easy to find or to decipher. Providers have not widely accepted systems of ranking on measures of quality. According to its proponents, managed competition, as a reform concept, would have the potential for reducing expenditures and

improving access to health care coverage and is being used successfully in other countries (Enthoven & Wynand, 2007; van Ginneken, Schäfer, & Kroneman, 2011).

Duijmelinck and van de Ven (2016) summarize the lessons to be learned from the U.S. experience with managed care: Health care providers are often the most critical toward this change, consumers will accept some loss of provider choice if lower premiums are provided, information should be provided to consumers about quality of in network and out of network providers, and quality indicators and national guidelines help promote acceptance of managed care. This highlights some of the problems and potential benefits regarding managed competition. Can market forces really work in the health care market? Similar models, such as HMOs and the Federal Employee Health Benefits Program, have failed to reign in ever-increasing health care costs (Sultz & Young, 2014).

Another major criticism of managed competition is its potential failure to provide equitable and universal coverage. It is possible that large employers would benefit financially under managed competition, but small businesses would find the cost burden heavy, and many individuals, such as the self-employed, could remain uninsured. A basic benefits package, critics argue, must address the special concerns affecting groups such as women and older adults, including coverage for long-term care, home care, mental health, dental care, and prescribed drugs. Competition among providers would be inefficient in rural areas, where there are fewer provider choices, such as county nursing agencies and isolated small-town hospitals scattered over great distances (Rice et al., 2014).

Universal Coverage and a Single-Payer System

A different approach to health care reform emphasizes universal health insurance coverage, often through a stronger role played by government. Some proponents of this system of health care promote a single-payer system that would replace the health insurance companies in the United States with a single, public sector insurer that would entitle all citizens to universal coverage (everyone would have health insurance of some type, ensuring better access to care). Efforts to accomplish this approach have been evident for many years.

Since the time of Teddy Roosevelt in 1912, NHI has been debated while its proponents have sought comprehensive health care protection, in particular, for the aged, children, and the needy. Presidents Roosevelt (both Theodore and Franklin), Truman, Nixon, Carter, and Clinton have all lobbied for some form of NHI or universal health coverage, and Senator Edward Kennedy was also a long-time supporter (Kingdon, 2011). Growing concern over the cost and accessibility of health services in the 1960s and again in the mid-1970s led to a renewed focus on NHI as a solution by which health insurance coverage could be provided for all citizens through a single-payer system or a mix of public and private insurers. Numerous attempts to pass some form of NHI resulted in piecemeal legislation that added various benefits for Social Security recipients. The Kerr–Mills bill (1960) set a precedent of public financing for older adults who were medically needy but not receiving public assistance. Medicare (1965) was the first compulsory NHI program in the United States. By 2001, it reached some 40 million people—only 16% of the total U.S. population.

Most other developed countries offer some type of NHI or attempt to provide universal health coverage to their citizens. Other countries believe that health care is a fundamental right, and provide it as a social service, unlike the United States, which tends to view it as a commodity that is only available based on one's ability to pay (IOM, 2013; Quadagno, 2010). The APHA (2010) has long been an advocate of universal health care, including a single-payer system, and they strongly endorsed passage of the ACA health care reform legislation.

Although many agree that insuring all U.S. citizens will improve overall national health and performance, the concept of a government-sponsored, single-payer system is controversial, as many think that this equates to socialized medicine; however, a single-payer system is more consistent with Medicare where the single payer is the government, but the care is provided by various private entities (physicians, nurse practitioners, hospitals, clinics). A socialized system is more like the Veterans Administration where care and payment are both provided by the government (Rovner, 2016). Even though polls have often revealed that people were dissatisfied with the health care system before health care reform (ACA), they generally reported being satisfied with their own arrangements for health care—and they were uncomfortable with the idea of a government-controlled health

plan. A 2016 Kaiser Health Tracking poll revealed that 36% of people want to "build on the existing law" to make it more affordable and accessible to greater numbers of citizens, and 24% would like to see universal coverage guaranteed to all through a single government health plan (McCanne, 2016, para. 1). However, 16% would like to completely do away with the ACA, and 13% would like its replacement to be a Republican-sponsored plan. A 2013 survey of 1,151 adults making ED visits in Massachusetts found that the majority would prefer NHI over the health care reform instituted there 7 years earlier. This was true across demographic groups, although the majority of respondents were non-White and low income. NHI garnered high levels of support among those who were not satisfied with their current health plans, those who couldn't buy medications because of the high cost, and those who reported delaying medical care (between 81.2% and 87.3%). Saluja et al. (2016) concluded that this level of support indicated that the ACA does not completely meet the needs of underserved individuals.

The "Medicare-for-all" plan promoted by Senator Bernie Sanders is favorable to 53% of Democrats. Semantics is important, as 49% of those polled viewed socialized medicine as negative, but only 38% found guaranteed universal coverage to have a negative connotation (McCanne, 2016). Logic indicated that single-payer plans could provide cost savings from reduced overhead and administrative costs. But other questions remained, such as: What is the best way to provide universal coverage? Should health insurance still be linked to employment? How can the expense be funded? Should citizens become more responsible for their health outcomes? How can quality be ensured and costs managed? (See Table 6–5).

Table 6–5 Health Care System Comparisons: Australia, Canada, France, Germany, Japan, Sweden, and United States, 2014

Country	Type of Coverage Model	HC % of GDP	Average Annual Growth Rate	Per Capita Out-of-Pocket	Practicing MDs/1,000 People	Average MD Visits/Capita	Number Hospital Beds Per Capita	MRI Machines/ Million People	MRI Exams/ 1,000 People	MD Use of EHRs	Obesity	Life Expectancy at Birth
Australia	NHI	9.1%	2.4%	$ 731	3.31	6.9	3.40	15.0	26.0	92%	28.3%	79.27
Canada	NHI	10.9%	2.4%	$ 690	2.48	7.9	1.72	8.8	53.7	56%	25.4%	78.35
France	Bismarck	11.6%	1.4%	$ 320	3.08	6.7	3.39	8.7	82.0	67%	14.5%	77.41
Germany	Bismarck	10.3%	2.0%	$ 627	3.96	9.7	5.38	n/a	n/a	82%	n/a	77.11
Japan	Bismarck	10.3%	3.5%	$ 483	2.29	13.0	7.94	46.9	n/a	n/a	3.6%	79.20
Sweden	Beveridge	9.6%	1.9%	$ 678	3.92	n/a	1.95	n/a	n/a	88%	11.8%	77.92
United States	Private/public no universal coverage	16.9%	2.4%	$1,045	2.46	4.0	2.56	34.5	104.8	69%	35.3%	75.64

Institute of Medicine (IOM). (2013). U.S. health in international perspective: Shorter lives, poorer health. Washington, DC: National Academies Press.

In testimony to Congress, experts from the Commonwealth Fund and other groups encouraged the design of a universal health care system that meets four criteria: improves access to care, has the potential to slow cost increases and improve efficiency, improves equity in the system, and has the potential to improve health care quality (Collins, 2007; Collins et al., 2007; Kingdon, 2011). Some politicians proposed expanding Medicare, Medicaid, and the CHIP programs or focusing more on prevention and individual responsibility. Other groups supported a system of tax credits, employer and individual taxes, and a more transparent evaluation of costs and quality. Aspects of each of these ideas are included in the ACA (see Perspectives: Health Care Reform).

PERSPECTIVES HEALTH CARE REFORM

The Patient Protection and Affordable Care Act (ACA) was signed into law by President Barak Obama on March 23, 2010. Provisions included expanded coverage of dependent children on parents' health insurance until age 26, and care for screenings/preventive services, along with a prohibition on canceling policies for those who become ill. However, many provisions of the act did not become fully implemented until 2014, and others are still in the process of being fully implemented (Gaynor, 2013; Rice et al., 2014). Key provisions of the ACA include the following:

Private Insurance Coverage Expansion

- *An individual mandate requires health insurance (private or public) for every American and documented immigrant. Those choosing not to get health insurance are subject to an annual financial penalty of $695 for an individual and $2,085 for a family (or 2.5% of income) by the 2016 deadline. The penalties will be recovered from federal income tax refunds. Subsidies, offered on a sliding scale, help uninsured families and individuals purchase private insurance through health insurance exchanges.*
- *Health insurance exchanges may be accessed online (state or federal) and must offer the same minimum benefit packages (i.e., ambulatory and emergency services, hospitalization, maternity/neonatal care, pediatric care, mental health/substance abuse services including behavioral health counseling, prescription drugs, rehabilitation services/devices, laboratory, and preventive/wellness services along with management of chronic diseases). Preexisting conditions may no longer be a consideration (Rice et al., 2014).*

- *Insurance premiums can vary only by age, by geographical location, and, in some cases, by smoking status. Insurers may not set annual or lifetime policy limits, and they must return 80% of premiums either to the policyholders or provide them additional health benefits. However, Day, Himmelstein, Broder, and Woolhandler (2015) found that the medical loss ratio (or overhead spending) for private insurers had not substantially changed during a 3-year period before the ACA and a 3-year period after ACA.*

Changes in Medicaid and Medicare

- *Medicaid coverage was extended to those making 138% of the federal poverty level.*
  - *Federal government pays 100% of the expansion cost to states at first, and then, the amount drops to 90% by 2020 (ANA, 2014).*
  - *The Supreme Court ruled that states had the right to determine if they wanted to participate in the Medicaid expansion, and, by 2016, 31 states (and the District of Columbia) chose to do so.*
- *Medicare now offers preventive services without co-payments, and the prescription drug coverage gap (doughnut hole) will eventually be closed.*
  - *Capitation rates for Medicare Advantage plans will be reduced, and bonuses will be given to plans that reach high-quality scores; penalties will be incurred for those with low-quality scores.*
  - *Independent Payment Advisory Board will make cost-containment recommendations if fee-for-services expenses growth more than 1% more than the GDP. Congress may override the recommendations (Rice et al., 2014).*

Changes for Employers

- *Large employers (100 employees) must offer health insurance by 2015. Those with 50 to 99 employees must offer health insurance by 2016. Monthly penalties can range from $2,160 to $3,240 divided by 12 months per employee who either was not provided health insurance or was provided insurance that did not meet minimum requirements (KFF, 2015a). Some tax credits are offered to small employers who offer coverage. The Cadillac Tax for expensive health plans will go into effect by 2020 (Himmelstein, Ariely, & Woolhandler, 2014; Woolhandler & Himmelstein, 2016).*

Changes for Health Care Providers

- *Scholarships/loans offered to primary care physicians who are willing to work in underserved areas (Rice et al., 2014). Grant funding for nursing education, and other nursing workforce grants, was expanded (ANA, 2014).*

- *Providers are encouraged to become part of Accountable Care Organizations (ACOs), or voluntary groups/networks of hospitals, home health agencies, pharmacies, physicians, and other health care providers that offer "coordinated, high-quality care" to patients without duplication of services or medical errors (CMS, 2015b, para. 1). The Medicare Shared Savings Program also encourages ACOs but provides no specific instructions about their structure (Brill, 2015).*
    - *Since 2011, 744 ACOs have formed and about 6 million Medicare patients are part of an ACO. Incentives are given for keeping patients healthy, controlling costs, and providing quality care. A hope for ACOs is that burgeoning costs for care of our aging population will be controlled. Some large private insurers have created ACOs. They seem similar to HMOs, but patients are not required to remain within the ACO and may see providers outside that network (Gold, 2015).*
    - *ACOs much meet four quality standards—patient/caregiver experiences, patient safety/care coordination, preventive health services, and chronic disease populations (Rice et al., 2014).*
    - *Some are concerned that the integrated systems created by ACOs may lead to a monopoly when it comes to raising costs or that providers will be pressured to control costs at the expense of quality because of financial incentives offered (Rice et al., 2014). The Federal Trade Commission monitors health care enforcement and mergers (Brill, 2015). Research has demonstrated that financial rewards have caused problems with motivation and performance in health care settings (Himmelstein, Ariely, et al., 2014). Physician governance is needed to avoid this, but medical education must also include more content on processes of care delivery and managing costs (Dranove, 2014).*

Changes for Consumers

- *Individuals and families with incomes of $200,000 and $250, 000, respectively, will begin to pay higher taxes on investment and unearned income in 2013.*
    - *They will also pay higher payroll taxes that will be used to finance Medicare (Rice et al., 2014).*

Some economists and researchers feel that the ACA is a move in the right direction but does not go far enough and may actually end up causing problems because of narrow markets and high premiums and deductibles. Many encourage a single-payer system of national health plan to reduce administrative costs and better control rising health care costs (Dranove, 2012; Gaffney, Woolhandler, & Himmelstein, 2016; Gaynor, 2013).

Some states initiated legislation to extend coverage to uninsured residents. Massachusetts required all residents above a set income level to get insurance coverage from their employer or purchase it individually; adults earning up to 150% of FPL and children

of parents earning up to 300% of FPL are fully subsidized by the state. Results are mixed; more people are insured, but costs have not been curbed. Before this legislation, about 94% of residents were insured; currently, 98% of residents (and 99.8%of children) are covered. The percentage of private employers providing employee health insurance rose from 70% to 77%, and companies with more than 11 full-time employees are expected to contribute to health insurance or face penalties. Increased costs to the state in the 2010 budget were only 1%, but a cost shift burden from employers to individuals is problematic. Medical bankruptcies rose by over 33% between 2007 and 2009 but are currently lower in Massachusetts than in other states (Falla, n.d.). Although most residents are supportive of the law, and 88% of physicians in a recent survey stated it improved care or didn't affect the quality of care, per capita health care spending is projected to be almost twice the current rate by 2020 for this precursor to the ACA (Khan, 2011). Primary care providers are also stretched thin with additional patients seeking physician gatekeepers, and safety-net hospitals have also been shortchanged as funds have been diverted to help pay for the costs of health care reform (Norbash, Hindson, & Heineke, 2012).

With the lack of quality health outcomes in the United States, as described above, even if everyone received health insurance, how could quality be assured? Some believe that the overall performance of the health care system should improve as everyone gains access to care. However, a system that provides incentives to *both* providers and patients to use services efficiently and effectively produces the best results (Bouffard, 2015; Collins, 2007; Collins et al., 2007). Providing information to consumers is another component of quality assurance, and this is sorely lacking. But information is becoming more readily available. For instance, since 2000, the Leapfrog Group (n.d.) has promoted *transparency* through surveys of standard measurements and practices to enable comparisons and reimbursement incentives to encourage quality and efficiency. Scores for local hospitals can be reviewed at the Leapfrog Web site (http://www.leapfroggroup.org/compare-hospitals). The quality of insurance plans, measured by the Health Plan Employer Data and Information Set (HEDIS), includes information on patient satisfaction, data on risk factor control, and procedures such as prescribing β-blockers after heart attacks and is monitored by the National Committee for Quality Assurance (NCQA). Nursing students are aware of the Quality and Safety Education for Nurses (QSEN) project that provides a basis for continuous quality improvement and health care safety (Case Western Reserve University, 2014). Other systems of quality measurement, like health outcomes, the process of care, and adherence to standardized guidelines, are still required. The ACA requires hospitals, providers, and insurance plans to include quality ratings on their Web sites, increasing transparency (Dash, Corlette, & Thomas, 2014).

Health Care Reform: Making the Change

Health care reform advocates march in Washington, DC.

The cry for health care reform is not new. In a classic study, Perkins examined the work of the 1927 to 1932 Committee on the Costs of Medical Care. More than 75 years ago, the committee defined *costs* as the major problem and *business models of organization* as the major solution (Perkins, 1998).

A standard set of benefits, set by law and enjoyed by the entire population, regardless of age, health, income, and employment status, is an important health care reform element. Many countries have successfully implemented such a package under a plan called a *statutory model*. Various versions of this model have worked well in Austria, France, Belgium, Japan, Germany, Israel, Poland, the Netherlands, and Switzerland. In this model, health insurance falls under the rubric of social security and is funded through government-mandated payroll premiums or taxes. Payment is made to private sector health insurers, from a fund called a *sickness fund* in some countries (IOM, 2013). Individuals select among nationwide plans and choose their doctor and hospital and can switch plans when desired. This statutory model eliminates the need for separate programs such as Medicaid and Medicare. It also provides uniform and comprehensive benefits (Estes et al., 2013). See Display 6–2 for a description of four models of health care and a comparison of health systems in five developed countries.

DISPLAY 6.2 MODELS OF HEALTH CARE AND HOW FIVE OTHER COUNTRIES PROVIDE HEALTH CARE

According to Reid (2010), there are four models of health care:

1. *Bismarck Model*—This is named after the Prussian Chancellor, Otto von Bismarck, who proposed this model as part of the 19th century unification of Germany. Private insurance (funded by employers and employee payroll deductions) and private health care providers characterize this system. Many hospitals are also private, and everyone is covered. There are over 200 funds that pay for services, but there are strict controls on medical fees and services to keep costs down. Belgium, Germany, Japan, and Switzerland have this type of health care system.
2. *Beveridge Model*—This is inspired by the British social reformer, William Beveridge, who envisioned a system of health care both financed and provided by the government through taxes. Like using the public library, services are not billed but are provided as a public service. Hospitals, clinics, and physicians are part of the governmental system, but some private physicians are paid fees by the government. The government is the single payer in this system, and this is how costs are controlled. It has been called socialized medicine, but that is actually more representative of the U.S. Veterans Administration system. This type of health care system is found in Great Britain, Hong Kong, Italy, Span, and many Scandinavian countries.
3. *National Health Insurance Model*—This is considered to be a hybrid of the Beveridge and Bismarck models. The government pays for services from private health care providers through an insurance system paid for by taxpayers. This is considered universal health care, and savings are achieved through lower administrative, marketing, and underwriting costs. Better prices are negotiated, and covered services are sometimes limited or patient wait times may be increased. Canada's health care system uses this model, and Australia, South Korea, and Taiwan have variations of this model.
4. *Out-of-Pocket Model*—This system is found in less developed countries where the rich can afford health care services and the poor cannot afford care (about 160 of the world's 200 countries). In rural areas of Africa or South American, for instance, "hundreds of millions of people go their whole lives without ever seeing a doctor " (p. 19). The government has no system of care or type of plan

to cover citizens. Examples include Cambodia, Egypt, and India where 73% to 91% of health care costs are paid out-of-pocket by patients.

Reid (2010) notes that the United States has some components of each of these models. The Bismarck Model can be found among American workers with employer-sponsored health insurance. The Beveridge Model applies to those Americans who are military personnel and veterans, as well as Native Americans using the Indian Health Service. Medicare recipients participate in a plan very similar to the National Health Insurance Model, as there are low administrative costs and almost universal involvement. For those Americans who still remain uninsured after ACA, they rely on care in emergency departments or charity clinics or are required to pay out of pocket for their care.

Germany

Percentage of GDP spent on health care: 10.7%

Average family premium: $750 per month (depending on income)

Co-payments: 10 euros ($15) every 3 months; some patients exempt

- German Statutory Health Insurance began in 1883. Germans buy insurance from private, nonprofit sickness funds. Fund manager pay is based on enrollment, and there is competition for members as well as negotiations with physicians for competitive pricing.
- Single-payment system. Physician salaries are two-thirds U.S. salaries, but medical school is free and malpractice insurance costs are much lower.
- Choice of physician (can see specialists first), hospital, long-term care facility and medication and dental.
- The richest 10% can opt out and purchase for-profit insurance that pays physicians higher fees (so they may see patients sooner); Germans living in poverty receive public assistance in paying sickness fund premiums.

Great Britain (United Kingdom)

Percentage of GDP spent on health care: 8.3%

Average family premium: Tax-funded, no additional cost

Co-payments: None for most services; some dental and vision co-pays; 5% for prescriptions (exempt for older adults and children)

- National Health Service (NHS) since World War II (funded from general revenues). This is considered "socialized medicine" as the government both pays for and provides health care services. Hospital physicians are paid salaries from taxes, and family physicians' salaries are based on the numbers of patients seen. A few specialists work outside the NHS, seeing private-paying patients.

- Low administrative costs and no claims to review or bills to collect. Family physicians provide medical homes and make referrals to specialists. They are paid bonuses for keeping their patients well and focusing on prevention. Well-designed system, but chronically underfunded
- Tax-based, free at point of service (covers ambulatory care, hospital, medications, long-term care, vision)
- Choice of physician; generally short waiting times for appointments, but longer waiting lists for elective referrals to specialists. Government reforms are making care more competitive and providing wider choices. Hospitals now compete for NHS funds and patients can choose where they want treatment for many procedures.

Japan

Percentage of GDP spent on health care: 8%

Average family premium: $280 per month, with employers paying over 50% of this

Co-payments: Procedures (30%), but total amount paid per month is capped per income level

- Japan utilizes a "social insurance" system, and all citizens are mandated to have health insurance (through employers or from nonprofit, community-based plans). Public assistance is given to those unable to afford insurance. Physicians and most hospitals are in the private (not public) sector, and most health insurance is private.
- There are no gatekeepers, as in the UK system, and Japanese may go to any specialist as often as they wish without first seeing a family physician. The Ministry of Health negotiates with physicians on pricing every 2 years.
- Japan, perhaps partially because of diet and lifestyle, has excellent health statistics (e.g., life expectancy).
- Because there is no gatekeeper, there is no incentive for patients to have a medical home. Because they have been successful in cost containment, 50% of hospitals now have budget losses.

Switzerland

Percentage of GDP spent on health care: 11.6%

Average monthly family premium: $750 paid by patients, with government assistance for people who are poor

Co-payments: 10% of the cost of services ($420 per year cap)

- Switzerland employs "social insurance," which began with a national referendum in 1994. At that time, 95% of their population was insured, but all

citizens are now required to have health insurance. They have universal coverage, despite being a capitalistic society with large pharmaceutical and insurance industries.
- Insurance companies are forbidden from making a profit on basic care and cannot "cherry-pick" enrollees. They do make profits on supplemental insurance.
- Insurers negotiate with providers (e.g., hospitals, physicians), but the government sets prescription prices. Some, but not all, plans require physician gatekeepers; others give discounts to patients who use medical homes.
- The Swiss have the second most expensive system (still much less spent than the United States), and prices of medications are higher than in other euro countries. (Some Swiss drug companies are said to make 33% of their profits in the U.S. market.)

Taiwan

Percentage GDP spent on health care: 6.3%

Average family premium: $650 per year for a family of 4

Co-payments: Prescriptions (20% of cost, up to $6.50); outpatient care ($7); dental and traditional Chinese medicine ($1.80); many exemptions apply (e.g., preventive services, major diseases, childbirth, care for veterans/children/those living in poverty)

- In 1995, Taiwan adopted the "National Insurance Model." Insurance is mandatory for all citizens, and there is one, government-run health insurer. Employers and workers split premiums, and other citizens pay flat rates for insurance (with government assistance). Care for veterans and people who are poor is subsidized by the government. This system is similar to Canada and Medicare in the United States.
- Health insurance was extended to 40% of the uninsured population, and health care spending was actually decreased. Any physician can be seen without a referral, and smart cards are used to store medical history and for billing purposes. Public health officials are also assisted in monitoring standards, and Taiwan's administrative costs are the lowest in the world.
- Taiwan does not bring in enough money to cover all medical care provided. The parliament must approve insurance premium increases, and it has only done this once since 1995.

How do you think these systems compare with the U.S. health care system between 1965 and 2009? How do they compare with health care reform (ACA)? Which one of Reid's models, or combination of models, do you think would be most effective in the United States?

Reid, T. R. (2010). The healing of America: A quest for better, cheaper, and fairer health care. New York, NY: Penguin Books.

Other issues include making the system more accountable, eliminating adverse risk selection, and providing informed choices to consumers. Furthermore, health reform must focus on the central question: Is there coverage for the promotion of health and prevention of illness or simply payment for the diagnosis and treatment of those who are already ill? Research has shown that public health interventions have been found to be consistently more cost-effective than medical services, yet past health reform has often paid minimal attention to this critical issue (Shroufi et al., 2013; Tanner, 2015). In addition, our frequent emphasis on medical care cost containment does not take into account the social determinants of health that need to be addressed outside the health care system. PHNs can play an influential role in emphasizing health promotion services as being central to future health reform efforts through political involvement and policy development.

Designers of health reform have faced a difficult challenge in reconciling these conflicting views. As a result, elements of both models have been used to shape an improved system. Recent health care reform includes an incremental plan that allows for a flexible transition and opportunities for states to experiment with approaches. With the successful passage of HR 3590 (Public Law [PL] 111–148), *The Patient Protection and Affordable Care Act*, on March 23, 2010, and the March 25 passage of HR 4872 (PL 111–152), *Health Care and Education Affordability Reconciliation Act of 2010*, amending HR 3590, the long journey toward health care system reform crossed a threshold. Both pieces of legislation are referred to as the *Affordable Care Act* (ACA). Although by no means a grand vision for change with its incremental implementation, it has been called "among the most consequential pieces of social policy passed since the Great Society" of Lyndon Johnson in the 1960s (Klein, 2011, para 5).

Beginning in 2010, dependent coverage for adult children was extended to age 26, and prohibition on lifetime limits on coverage and preexisting conditions for children, along with tax credits to small employers (25 employees or less) providing health insurance began, among other things. In 2011, grants were awarded to states to investigate current tort litigations, and to small employers to establish wellness programs, as well as implementation of 50% discounts on Medicare Part D brand-name prescriptions from pharmaceutical manufacturers. An Innovation Center within CMS was created, and a national quality improvement strategy developed. Small businesses have been allowed to keep insurance plans in effect—"grandfathering"—and about 72% of those with 100 or fewer workers have done so (KFF, 2012). In 2012, the Medicare Independence at Home Demonstration program was created and other cost-cutting measures came into effect, along with enhanced collection and reporting of data. Adoption of a single set of operating rules for verification of eligibility and claims status, enrollment, premium payments, and referrals began in 2013, as did increased Medicaid payments to primary care providers.

More dramatic reforms occurred the following year, including the creation of an essential health benefits package and permission for states to have an option to create a Basic Health Plan for uninsured residents making between 133% and 200% of the FPL. As of 2014, all U.S. citizens and legal residents are now required to have health coverage, with a phased-in penalty for those not covered. Employers with 50 or more employees who do not offer health coverage will be assessed a fine of $2,000 per full-time employee (first 30 excluded). Employers with more than 200 employees must automatically enroll all employees into health insurance plans. American Health Benefit Exchanges and Small Business Health Options Program Exchanges have been created, and deductibles for health plans in small group markets have limits of $2,000 for individuals and $4,000 for families. Waiting periods for full coverage is limited to 90 days. After 2015, states could form health care choice compacts and allow insurers to sell policies in any state in the compact after January 2016. Additional Medicare payment reductions for hospital-acquired infections began in 2015, and an excise tax on employers who offer "Cadillac health plans" (i.e., 40% on values >$10,200 for individuals and $27,500 for families) are scheduled for 2020 and are considered by some economic researchers to harm middle-class families making between 2009 incomes of $38,550 to $100,000 but will not affect the wealthy (Himmelstein, Ariely, et al., 2014). For a summary of the ACA, see http://kff.org/health-reform/fact-sheet/summary-of-the-affordable-care-act/.

The ACA has been described as "consumer-friendly" because applicants in each state will be screened for all available health subsidy programs and enrolled through a standardized process. Coordination and seamless transition between programs is the goal. Uniform income rules and forms, along with streamlined enrollment, will make administrative functions simpler and less costly. Paperless verification is required through secure Web portals, where information can be securely exchanged. The goal is to help individuals better understand their choices, as well as access and maintain health coverage. Families were able to apply online, but early on, it became clear that many needed assistance. Coordination between insurance exchanges, Medicaid, and CHIP provides for better coverage (Rosenbaum & Riley, 2012). Also, exchanges have the power to remove insurers who abuse the system or provide inadequate service.

Rapidly rising health care costs cannot be reined in overnight. Projections by 2030, with health care reform, are expected to be only 0.5% lower than they would have been without reform. But the federal budget deficit is projected to be $100 billion less after the first decade of ACA and $1 trillion less in the decade beyond 2020. Total health care expenditures could even end up $600 billion less in the first decade. There is flexibility and a focus on quality improvement that should help restrain unnecessary growth in health care costs. In controlling costs, new fraud and abuse measures in both Medicare and Medicaid are being instituted, and administrative savings should occur with standardization and electronic records (Orszag & Emanuel, 2010; RAND Health, 2011). An Independent Advisory Board (comprising experts and stakeholders) is assisting in controlling Medicare costs and has the power to make changes in the system without waiting for Congress to act

(Klein, 2011). As Medicare's costs per capita exceed a prescribed threshold (general inflation plus 1% after 2018), this advisory board is empowered to develop and propose new policies for reducing inflationary costs that will be implemented by USDHHS, unless Congress enacts legislation resulting in similar cost savings (Orszag & Emanuel, 2010). The Patient-Centered Outcomes Research Institute will provide additional information on effectiveness of treatments and interventions, and the Innovation Center at CMS will develop, evaluate, and test new programs and policies that reduce cost and enhance care for Medicaid and Medicare patients. Improved value and quality outcomes are the proposed benefits of these three innovations (Orszag & Emanuel, 2010). ACA also increases incentives for change that will improve patient care and outcomes (e.g., hospital readmissions, hospital-acquired infections) and improve coordination of care (e.g., bundled payments to MDs and hospitals for patients with chronic illnesses, accountable care organizations, medical homes). These changes in the delivery of health care, as well as cost-control reforms suggested by economists, health policy experts, and physicians, are hoped to achieve cost reductions while providing expanded health insurance coverage (Orszag & Emanuel, 2010; RAND Health, 2011). Others note that lower payment increases to physicians seeing Medicare patients and reductions for insurers participating in Medicare, along with the increased Medicare tax on higher-income earners, will save the system money but will be largely offset by expenditures in Medicaid expansion, small business and exchange credits, and other expenses (Klein, 2011). Only time will tell; if the reform is dynamic and flexible, as touted, perhaps we can stay a step ahead of costs.

Not everyone is convinced that health care reform is a good idea. Republican legislators have continued to threaten repeal but have failed to provide a viable alternative solution. As of January 2012, 19 states have passed legislation that opposes at least some elements of the ACA, and 45 states had filed over 200 measures either proposing alternative policies or opposing elements of health reform. Several lawsuits over the "individual mandate" (penalty for not purchasing health insurance) have been field. In June, 2012, the Supreme Court ruled that that the ACA individual mandate was constitutional and constituted a tax, as those who do not obtain health insurance coverage are required to pay a penalty ("shared responsibility payment") to be collected by the IRS (p. 2). At the same time, it found the Medicaid expansion "unconstitutionally coercive of states" and ruled that the Secretary of Health and Human Services could not enforce this provision by withholding more than expansion Medicaid funding to states that choose to opt out of the Medicaid expansion outlined in the ACA (Musumeci, 2012, para. 1). See Perspectives: Why Did the Obama Administration Succeed With Health Care Reform?

PERSPECTIVES WHY DID THE

OBAMA ADMINISTRATION SUCCEED WITH HEALTH CARE REFORM WHEN OTHERS DID NOT?

President Bill Clinton had tried, unsuccessfully, to pass health care reform legislation during his time in office. Many other presidents had also tried this, beginning with Theodore Roosevelt, and including Truman, Nixon, and Carter. President Franklin D. Roosevelt's Social Security program and President Lyndon B. Johnson's reforms leading to Medicare and Medicaid coverage were large policy leaps, but access was not afforded all Americans.

Kingdon (2011) explains that the enormous size of the American health care system (about one sixth of our total economy), with many stakeholders (patients/consumers, health care providers, hospitals and clinics, pharmaceutical/managed care and insurance companies), makes change difficult. There are also many special interest groups among the stakeholders, as well as business interests, labor unions, and professional organizations, that control powerful lobbying interests in the nation's capital and across the country.

Also, our governmental system (separation of powers, legislative rules) makes it difficult to pass significant legislative changes—like health care reform—unless there is overwhelming support behind it. Americans also are not fond of higher taxes or big government programs, and most of them (about 85%) already had employer- sponsored or government health insurance. So, how was it possible to make policy changes despite these seemingly high odds? Kingdon (2011, p. 241) divides it into problems, policies, and the political stream leading to the "open window" permitting policy changes in health care reform (see Chapter 13 for more on Kingdon's Model).

Problems:

- *Rising costs of health care, health insurance, and coverage gaps*
- *Rising long-term national debt and concerns over entitlement programs (e.g., Medicaid, Medicare, Social Security)*
- *Several academic studies/economic reports on our inefficient health care system*
- *Aging population and "baby boomer" increases in retirements*
- *Great Recession and loss of 700,000 jobs, along with employer-sponsored insurance for many*
- *Globalization revealed America's economic disadvantage compared to countries with national health plans (labor unions and businesses ultimately both agreed on need for changes)*

These problems existed, to a lesser degree, during President Clinton's term. However, they became much more pressing issues during President Obama's first years in office.

Policies:

- *It is important to forge a "consensus on policy options before a window opens" (p. 236).*
    - *Because health policy experts held markedly different views on how to solve the problem of health care reform during President Clinton's term, this was difficult to achieve. His wife, Hillary Clinton, led a task force on reform, but meetings were held in private and consensus was difficult to achieve. The final plan was "unfamiliar and untested" (p. 236) and was shot down by insurance companies, professional associations, and business interests.*
    - *Policy experts had achieved some agreement by the time President Obama was elected and common views on the individual mandate, leaving private health insurance intact and expanding access to government insurance, were widely supported. Also, Congress was given the responsibility of drafting the legislation. This was not a "top-down" approach but allowed for conversation and consensus building in committees, as well as fostering public discussion.*
    - *A similar approach was already in place in Massachusetts, which gave coverage to most residents of the state and was generally popular, despite some problems.*

Political Stream:

- *Health care had been a topic of debate during the 2008 election, with both Democratic candidates (Obama and Clinton) discussing it.*
- *Democrats now had a majority in the Senate and had enough votes so that they could prevent the opposition's filibuster. They also had a majority in the House. This was also the case when President Clinton was first elected, but not enough Senators to prevent a filibuster.*
- *Since President Clinton's attempt at reform, many of the interest groups involved had formed coalitions and were more open to reform. Members of President Obama's administration immediately began to meet with them and broker a "good deal" (p. 240).*
    - *Drug companies discounted prices for Medicare and gave up other income, and physicians, hospitals, AARP, and other groups also found common ground. Insurance companies had to give up their cost savings by using preexisting conditions to exclude individuals and lifetime caps on coverage; in return, they received new customers because of the individual mandate. Others that had opposed the Clinton reform were now neutral.*
- *The "strategic decision" (p. 240) to have Congress, not the administration, draft the health care reform bill helped build consensus—this was a lesson learned from the Clinton attempt at reform with an administration task force and bill that did not involve assistance from Congress in its development.*
    - *Some downside to this stance included a variety of bills that had to be melded*

into one final bill in order to be passed by both houses of Congress. At times, the Congress needed a nudge to keep things moving along, and this made it difficult for the administration that had promised a hands-off approach.

- *Some congressional opponents veered off course with wild claims of "death panels" and other off-the-wall misrepresentations.*

With all of the pieces in place for President Obama, he moved quickly, before the "open window" closed. Despite attempts to repeal the legislation and several court challenges, the Patient Protection and Affordable Care Act was signed into law March 23, 2010. The U.S. Supreme Court upheld the majority of its provisions on June 28, 2012.

What are your views on this legislation and why? Did it go too far, or not far enough?

EFFECTS OF HEALTH ECONOMICS ON COMMUNITY HEALTH PRACTICE

Health economics has significantly affected community health and community health practice by advancing disincentives for efficient use of resources, incentives for illness care, and conflicts with public health values.

Disincentives for Efficient Use of Resources

All of the system structures that directly or indirectly promote cost escalation and prevent cost containment contribute to disincentives for efficient use of resources. For example, retrospective financial reimbursement, with its lack of setting limits, encourages spending on nonessential tests and treatments and drives up costs. Tax-deductible employer contributions for health care coverage and nontaxable employee health benefits encourage unnecessary use of services and result in cost increases. Some economists propose limiting or doing away with employer-sponsored health insurance tax deductions (Dranove, 2012). Lack of cost sharing by consumers and of financial risk for decisions made by providers may create further disincentives to keep costs down (Knickman & Kovner, 2015).

Public health has been affected in several ways. Abuse of resources in some parts of the system leads to depletion in other areas. The trend of diminished federal and state allocations has had profound effects on community and public health programs, and severe budget cuts have affected even basic public health services. The ACA has forced public health agencies to reexamine their traditional programs and seek new avenues for the provision of services, along with new revenue sources, and new collaborative health care partners (Hester et al., 2015). Public health agencies may need to consider working with other providers in Accountable Care Organizations and providing their expertise in community assessment and design of population-based interventions.

Incentives for Illness Care

The traditional U.S. health care system tends to promote illness, because health care providers have primarily been rewarded for treating problems, not for preventing them. Hospitals derive more income when their beds are full of sick or injured people. Health insurance plans compete, not by lowering costs or increasing quality but by avoiding the sick and seeking healthy enrollees—leaving many without access to necessary health care (IOM, 2013; Rambur, 2015).

The bulk of most reimbursable health services centers on treating illness or disability in hospitals, nursing homes, and ambulatory care facilities, using physicians or skilled nursing care in the home (home health services)—situations in which the individual must play the role of patient. Our disease-focused system of health care has been a basic problem, but, with ACA, that focus is moving more toward preventive services and cost-effective, quality care (IOM, 2013). Most preventive care is woefully inadequate and largely overlooked by both practitioners and patients alike: Remember, about half of all U.S. adults receive recommended health screening tests annually (Shires et al., 2012); health promotion nursing activities, such as comprehensive prenatal, maternal, and infant care; health education; childhood immunizations; and home services to enable older adults to live independently have not always been consistently covered by most insurers but are now generally covered through the ACA (Rice et al., 2014).

A system that has historically financially supported illness care affects public health practice in several ways. The number and severity of health problems in a community increase when individuals postpone care because they cannot afford visits to the doctor or clinic. Also, it has been more difficult in the past to encourage community clients to assume responsibility for their own health and to engage in self-care, prevention, and active health promotion. Furthermore, such illness-oriented incentives have created a basic societal valuing of illness care that, conversely, devalues wellness care. Health promotion and disease prevention efforts now need to be emphasized. In communities where a greater proportion of community health practice is spent in the treatment of disorders and rehabilitation, resources for prevention and health promotion need to be developed (Hester et al., 2015).

Prepayment methods and the growth of managed care have been positive moves in the direction of a more wellness-oriented financial incentive structure. An HMO has the incentive to offer preventive and health-promoting services, such as early detection and treatment of symptoms, regular physical examinations, and health teaching, because the HMO loses money when it must pay out for expensive tertiary care. With health care reform, there is a change in focus as newer *accountable health care organizations* proliferate, and a variety of innovative, evidence-based programs, such as the YMCA's Diabetes Prevention Program, become more widely available. In this yearlong, group-based program, trained lifestyle coaches promote physical activity and healthy eating with prediabetic

individuals. Over 30 different health plans now include this program in their coverage, as it has shown that participants lost 5% to 7% of body weight and their chance of developing diabetes greatly decreased (Frist & Rivlin, 2015).

Managed Care and Public Health Values

Initially, MCOs focused on event-driven cost avoidance. Strategies included decreasing inpatient days, decreasing specialty physician use, using physician extenders, and implementing provider discounting. This evolved into a second stage, in which the principal objective was to control resource intensity and improve the delivery process. Strategies used to meet this objective included capitation of specialist costs, controls on units of service, patient-focused redesign, clinical pathways, and total quality management. But emphasis is shifting to a focus on health promotion and population health. Community assessments are an important part of this approach, so that high-risk groups can be identified and provided early interventions. Case management of individuals with chronic illness is also a focus.

Community health assessments could become standard quality tools for not only public health interventions but also health care in general (Feldman, Hile, & Weinberg, 2011). The ACA requires hospitals to conduct regular community assessments, and many have partnered with LHDs to do so (NACCHO, 2014). Community assessments establish the baseline health status of a community and measure changes in the health of the community over time. Community health assessments must include source information that is both primary (health status assessment surveys, focus groups, and satisfaction surveys) and secondary (data collected by public health agencies and state agencies, such as birth rates, mortality rates, and incidence of communicable diseases in the community). Health care reform legislation includes a requirement for community needs assessment every three years for state-licensed, tax-exempt health organizations such as hospitals and imposes a $50,000 annual penalty if this is not done. Prioritization of health needs and a description of community resources are to be included, as in input from those with expertise in public health (Adams, 2011). See Chapter 15 for more on Community Assessment.

Improving the health status of a community mandates that health care agencies be actively involved in accurately assessing the community's health status and the major issues facing the community. This involves health teaching and health promotion, as well as developing community action plans to promote collaboration and focus on early intervention and treatment (Brownson, Baker, Leet, Gillespie, & True, 2011). Are these not the proposals that public health advocates have been making for more than a century?

Competition in health care is a reality with which public health practice must cope. Although competition offers several benefits, it poses some dilemmas for community health that may be difficult to resolve. Values underlying the competition model can be in direct conflict with several basic public health values (Erwin & Brownson, 2017). With the new focus on coordination and collaboration in health care reform, this emphasis on competition may be diminished.

Public health is committed to serving all persons in need, regardless of ability to pay.

Traditionally, the competition model has focused on individuals and has been oriented to the present. Public health is concerned with aggregates and is future oriented, emphasizing prevention. Competition establishes relatively fixed limits for service, whereas public health must remain flexible if it is to respond to the health needs of the entire population. These dramatic differences are beginning to blur and, out of necessity, will continue to be less adversarial and more collegial. By shifting their focus to public health as a systems outcome, health care insurers can create several positive changes, including a safe environment, wholesome nutrition, healthy lifestyle, adequate education, sufficient income, meaningful spirituality, challenging work, recreation, and functional families (Brownson et al., 2011). As more people are covered by ACA, public health department clinics may scale down or chose to "claim reimbursement from private and public insurance" (Bovbjerg, Ormand, & Waidman, 2011, p. 1). Public health needs to embrace EHRs, big data, and research that validate interventions and services; we also need to get better at communicating our value in promoting the nation's health (Bovbjerg et al., 2011).

Over time, a greater number and variety of services have been offered through public health agencies. An early nurse-directed diabetes management program at a county public health clinic in Los Angeles County reflects the potential benefits of public health services for clients of MCOs and other private health care plans. PHNs were able to significantly reduce the numbers of urgent care and ED visits, along with hospitalizations, for diabetic patients from a minority population (Davidson, Ansari, & Karlan, 2007). Another example is the University of Pittsburgh Medical Center Health Plan program utilizing certified diabetes educators as "hub resources to a network of diverse care management services" (Siminerio, DePasquale, Johnson, & Thearle, 2015, p. 71). Through the use of patient-centered medical homes, ongoing staff training and support, and teaching and collaboration with community members (e.g., nursing homes, mobile clinics, coaches/community education programs), mean A1C reductions were noted in high-risk patients and staff reported greater confidence in their ability to work with diabetic patients. Working together, better health can be achieved for large numbers of patients.

IMPLICATIONS FOR COMMUNITY HEALTH NURSING

The structure and functions of the health care delivery system, as well as particular legislative acts, have had a significant impact on community health nursing. PHNs have had to adapt to a constantly changing system. They have developed innovative modes of service delivery, such as community-based nursing centers for health education, counseling, and screening of low-income populations. They have learned to practice in a variety of settings extending beyond homes, worksites, schools, churches, clinics, and voluntary agencies. They have acquired skills in teamwork, leadership, and political activism. They have recognized the importance of outcomes research to document the value of nursing interventions with at-risk populations (Kulbok, Thatcher, Park, & Meszaros, 2012). As with public health agencies, PHNs will need to become adept at EHRs. The benefits include the use of a common language, a better connection between nursing assessment and interventions, as well as meaningful use of data to recognize trends, patterns, and quality indicators. PHNs in the state of Washington began using a Web-based EHR coordinated with the Omaha System to "extract meaningful data and measure outcomes" (Plemmons, Lipton, Fong, & Acosta, 2012). This enabled them to show administrators that services and resources were being used appropriately and effectively. PHNs were also able to use the data to better guide their practice, strategic planning, and in policy development. Data collected through this program include source of referral, demographic information, initial patient assessment (knowledge, behavior, status ratings for problems identified), and any changes noted on subsequent visits. Increased patient referral, outreach, data collection, and nurse performance, along with improved patient care, have been noted by PHNs. Community nurses should recognize the benefits accrued with the use of EHRs and promote their use. See Chapter 10 for more on EHRs.

At the national, state, and local level, community health nursing has important ties to both private and public health agencies. When serving in the public sector, nurses often provide consultation, serve on boards, volunteer their services, or collaborate with private sector health organizations to ensure quality and access of care to the broader community. Examples include joint efforts to promote certain types of health legislation and collaboration to produce and disseminate health education materials targeting specific populations (Bowman et al., 2012; Evans, 2013). Sometimes, public health nursing services operate within a single organization that combines public and private sector organization and funding. An example is the Metropolitan Visiting Nurse Association of Minneapolis, Minnesota, which is a combined public–private agency supported by taxes and voluntary funds (MVNA, 2014).

Community health nurses also have many opportunities to serve in international health. Some work with the WHO, PAHO, or other agencies to assist in direct care projects such as famine relief, immunization efforts, or nutritional screening and education

programs (see Chapter 16). Other nurses serve as health planners, assist with policy development, conduct collaborative needs assessment projects and research efforts, or engage in program development (Kulbok et al., 2012).

SUMMARY

Many factors and events have influenced the current structure, function, and financing of community health services. Understanding this background gives the community health nurse a stronger base for planning for the health of the population under her care.

Historically, health care has progressed unevenly, marked by numerous influences. Primitive practices of early centuries were replaced with more advanced sanitary measures by the Greeks and Romans. The Middle Ages saw a serious health decline in Europe, with raging epidemics leading to extensive 19th-century reform efforts in England and, later, in the United States.

Organized health care in the United States developed slowly. Public health problems, such as the need for isolation of persons with communicable diseases and control of environmental pollution, prompted the gradual development of official interventions. For example, quarantines to control the spread of communicable disease were imposed in the late 1700s. Sanitary reform was pursued more vigorously during the 1800s. Local and then state health departments were formed starting in the late 1700s. By the early 1900s, the federal government had assumed a more active role in public health, with a proliferation of health, education, and welfare services.

For years, efforts to address community health needs have been made by public agencies and private individuals. These two arms of service were not well coordinated in the past. Only gradually and recently have they begun to work together to form an emerging health care system.

The public arm of health services includes all government, tax-supported health agencies and occurs at four levels: local, state, national, and international. Each level deals with the health needs of the population encompassed within its boundaries. Each level has a different structure and set of functions. Public health services include three core public health functions: assessment, policy development, and assurance.

Private health services are the unofficial arm of the community health system. They include voluntary nonprofit agencies as well as privately owned (proprietary) and for-profit agencies. Their financial support comes from voluntary contributions, bequests, or fees. Private health organizations often supplement and complement the work of official agencies.

The delivery and financing of community health services have been significantly affected by various legislative acts. These acts have prompted such innovations as health insurance and assistance for people who are poor, elderly, or disabled; money to train health personnel and conduct health research; standards for health planning and delivery; health protection for workers on the job; and the financing of health services.

Health care economics studies the production, distribution, and consumption of health care goods and services to maximize the use of scarce resources to benefit the most people.

This science underlies the financing of the health care system. It is influenced by microeconomics as well as macroeconomics.

Health care is funded through public and private sources, which fall into three categories: third-party payers, direct consumer payment, and private support. Health care services have been reimbursed either retrospectively, typical of FFS plans, or prospectively, typical of most preferred provider organizations (PPOs) or managed care plans.

Several trends and issues have influenced community health care financing and delivery and are important in understanding health care economics and helping to improve community health. They include cost control, financial access, managed care, health care rationing, competition and regulation, managed competition, universal coverage, a single-payer system, and health care reform.

The changing nature of health care financing has adversely affected community health and its practice two ways: (1) because the health care system traditionally has reimbursed only for treatment of people who are ill or disabled, with no reward for health promotion and prevention efforts, it has promoted incentives to focus only on illness care; and (2) the competition model, which has long driven up health care costs and eliminated many from being able to afford health care services, has generated a conflict with the basic public health values of health promotion and disease prevention for all persons. Health care reform has reduced the number of uninsured Americans, but access for many people is still difficult. Some health policy experts feel that reform did not go far enough, and that waste still exists. The United States remains the only industrialized nation without some type of universal health coverage. We also rank significantly lower than most other developed countries on health indicators, such as infant mortality and life expectancy, and we spend the highest percentage of GDP on health care.

PHNs can lead the effort in making health care more accessible to all citizens and encourage policies and practices that promote health, rather than reward illness. The ability to utilize data provided through EHRs can be helpful to PHNs in developing programs and interventions. PHNs can serve in many capacities and in private or government settings, including work with international health organizations.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. If possible, interview someone at your local health department. How do the services offered compare with those listed in this chapter? How do PHNs in this agency incorporate the core public health functions?
2. Look up your state health department's Web site. Compare its functions with the core public health functions described in this chapter. Identify areas where improvement may be needed.
3. If possible, conduct an interview on-site or by telephone with someone at a private health agency, voluntary agency, or community-based NGO. Compare the agency's functions with those listed in this chapter for private health agencies. Describe how this agency works collaboratively with public health agencies and other community organizations. What is the role of the nurse in this agency? How does the role compare to PHNs in the local public health agency?
4. Look up various international health agencies online. Explore Web sites that discuss current international health care issues. What topics are of current concern? For example, are new epidemics or emerging strains of a virus being highlighted? What could (or should) a community health nurse in your local community do with this information?
5. With your classmates, debate the pros and cons of a strong federal role in health care provision, as opposed to decentralized (state and local) control.
6. Interview two consumers about their perception of the problems and strengths of our health care system. What are their thoughts and feelings about health care reform (the Affordable Care Act [ACA] enacted in 2010)? Select people who represent distinctly different age groups and life situations, such as a single 25-year-old mother of three children making minimum wage and a 75-year-old widower.
7. Form two teams and debate the advantages and disadvantages of managed competition as opposed to mandatory universal coverage. What are the advantages and disadvantages of a single-payer system? Is further health care reform feasible in the United States? What is the most efficient way of ensuring universal coverage, as evidenced by other countries?
8. Locate recent articles and legislation on health care reform, strengths and weakness of the public health system, and the uninsured population. What are the most common themes on each issue? What most surprised you about your results?
9. Talk with your classmates and other students at your college or university about their access to health care and if they have some type of health insurance. Does your campus have a student health center? What services are offered there? What are the average costs to students?

Epidemiology
Global health patterns
Host
Immune-privileged
Immunity
Incidence
Morbidity rate
Mortality rate
Natural history
Nosology
Pandemic
Prevalence
Reservoir
Risk
Vector
Web of causation

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Explore the historical roots of epidemiology.
- Explain the host, agent, and environment model.
- Describe theories of causality in health and illness.
- Explain a *web of causation* matrix that assists you with recognizing multicausal factors in disease or injury occurrences.

- Define immunity and compare passive immunity, active immunity, cross-immunity, and herd immunity.
- Explain how epidemiologists determine populations at risk.
- Identify the four stages of a disease or health condition.
- List the major sources of epidemiologic information.
- Distinguish between incidence and prevalence in health and illness states.
- Use epidemiologic methods to describe an aggregate's health.
- Discuss the types of epidemiologic studies that are useful for researching aggregate health.
- Use the seven-step research process when conducting an epidemiologic study.

Epidemiology is a "discipline that describes, quantifies, and postulates causal mechanisms for diseases in populations, and develops methods for the control of diseases" (Friis & Sellers, 2014, p. 8). Epidemiology examines determinants and distribution of diseases, disabilities, morbidity, and mortality, as well as health. It is a specialized form of scientific research that can provide health care workers, including community health nurses, with a body of knowledge on which to base their practice and methods for studying new and existing problems. The term is derived from the Greek words *epi* (upon), *demos* (the people), and *logos* (knowledge); the knowledge or study of what happens to people. Epidemiologists ask such questions as the following:

- What is the occurrence of health and disease in a population?
- Has there been an increase or decrease in a health state over the years?
- Does one geographic area have a higher frequency of disease than another?
- What characteristics of people with a particular condition distinguish them from those without the condition?
- What factors need to be present to cause disease or injury?
- Is one treatment or program more effective than another in changing the health of affected people?
- Why do some people recover from a disease and others do not?

Epidemiology is the scientific discipline that studies the "distribution and determinants of health-related states or events in specified populations, and the application of this study to the control of health problems" (U.S. Department of Health and Human Services [USDHHS], 2012, pp. 1–2). It is data driven and relies on an unbiased and systematic approach to collecting and analyzing and interpreting data. It draws on methods from other areas, such as biostatistics and informatics. It also includes principles from the biologic, social, and economic and behavioral sciences.

Epidemiology offers community health nurses a specific methodology for assessing the health of aggregates. Furthermore, it provides a frame of reference for investigating and improving clinical practice in any setting. For example, if a PHN goal is to lower the incidence of sexually transmitted diseases/infections (STDs/STIs) in a given community, such a prevention plan requires information about population groups. How many STD cases have been reported in this community over the past year? What is the expected number of STD cases (the morbidity rate)? Which members of the community are at

highest risk of contracting STDs? To be effective, any program of screening, treatment, or health promotion regarding STDs must be based on this kind of information about population groups. Whether the community health nurse's goals are to improve a population's nutrition, control the spread of human immunodeficiency virus (HIV), deal with health problems created by a flood, protect and promote the health of battered women, or reduce the number of automobile crash injuries and fatalities at a specific intersection, epidemiologic data are essential.

HISTORICAL ROOTS OF EPIDEMIOLOGY

Most of the early contributions to epidemiology were made by physicians who sought the cause of disease through methodical observation and conducting experiments to test their theories of new treatment methodologies. The work of these physicians formed the basic concepts that served as a foundation for the science of epidemiology.

Early Physician–Epidemiologists

The roots of epidemiology can be traced to Hippocrates (460 to 375 BCE), a Greek physician who is sometimes referred to as the first epidemiologist. Hippocrates tried to explain disease occurrences from a rational, rather than a supernatural, viewpoint. His essay, *On Airs, Waters, and Places*, suggested that environmental and host factors (e.g., lifestyle behaviors) might influence disease development (USDHHS, 2012). Basic epidemiologic concepts introduced by Hippocrates included observations of how diseases spread and affect populations. He looked at diseases in relation to time and season, place, environmental conditions and disease control. His main contribution to epidemiology is the emphasis on epidemiologic observation.

Thomas Sydenham (1624 to 1689) advanced strong empirical approaches to medicine and close observations of disease. He developed a classification of fevers that plagued London in the 1660s and 1670s. He advocated for exercise, fresh air, and a healthy diet as treatments and remedies that were not in vogue among other physicians at the time (Merrill, 2013).

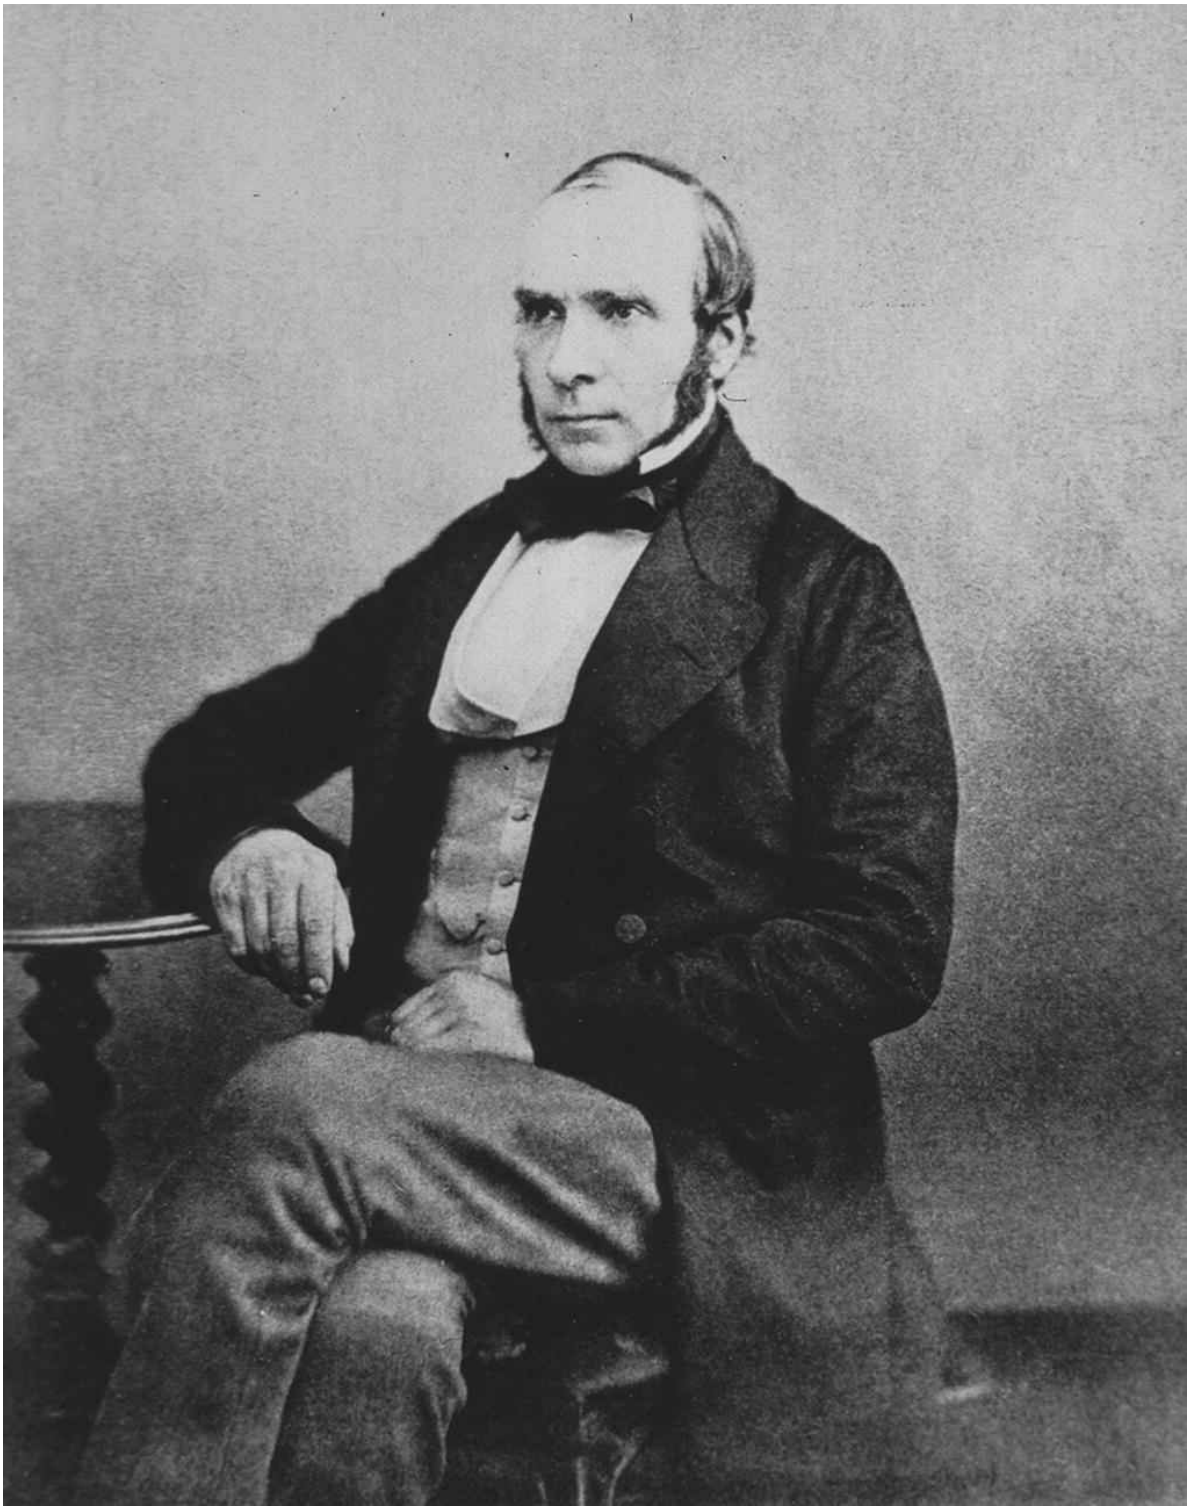

FIGURE 7–1 John Snow.

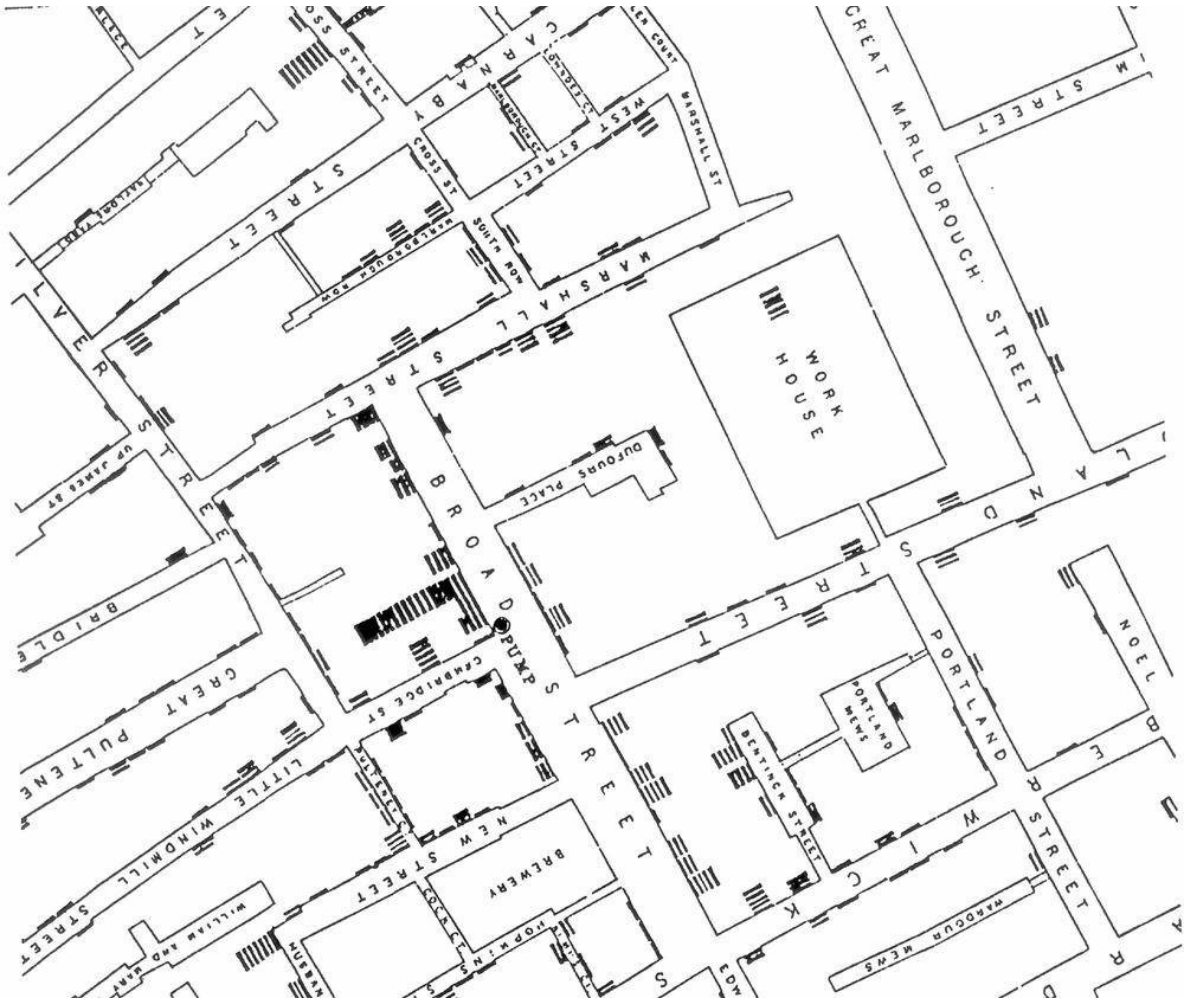

FIGURE 7–2 Spot map. (*Source*: http://www.cdc.gov/ophss/csels/dsepd/ss1978/lesson1/section2.html; Snow, J. (1936). Snow on cholera. London, UK: Humphrey Milford/Oxford University Press.)

James Lind (1716 to 1794) identified the effect of diet on disease based on clinical observations and experimental design. He identified that the spread of scurvy among British naval seamen was effectively addressed by eating oranges and limes. This practice gave rise to the use of the term "limeys" for British seamen (Merrill, 2013).

Edward Jenner (1749 to 1823) invented a vaccination for smallpox based on observations and experiments by Benjamin Jesty, a farmer/dairyman. Jesty noticed that his dairymaids never got smallpox, but did develop cowpox from the cows they milked. He theorized that by getting cowpox, dairymaids were protected from developing smallpox. Jenner applied this theory in developing the smallpox vaccine (Merrill, 2013).

Ignaz Semmelweis (1818 to 1865) was the clinical director of the Viennese Maternity Hospital in the mid-1800s when many women died from childbed (puerperal) fever shortly after giving birth. This is an infection of female reproductive tract that often begins at the uterine wall. Through careful clinical observation, retrospective study, and the collection and analysis of maternal death data, he concluded that it wasn't the actual labor that was

the cause, but bacterial contamination during the doctors' pelvic examinations immediately after performing autopsies of infected and decaying bodies without first washing their hands. Semmelweis instituted the use of chlorinated lime in hand washing between patient examinations. As a result, maternal deaths plummeted to 1.3% in 1848 from a high of 12.1% in 1842 (Merrill, 2013).

John Snow's (1813 to 1858) approaches, concepts, and methods used to identify the cause of cholera in 1800s London were his greatest contributions to the field of epidemiology. He conducted a descriptive epidemiologic investigation of a cholera outbreak in London's Soho district, and an analytic epidemiologic investigation of a cholera epidemic by comparing death rates of those getting their water from either the Lambeth Water Company or the Southward and Vauxhall Water Company. His spot (or dot) mapping of cholera cases, which plotted where cholera deaths were occurring, helped to characterize when the epidemic started, peaked, and subsided. The removal of the handle from the Broad Street pump (so people could not get water from that public water pump) was the control measure that finally stopped the epidemic. Because of Snow's many contributions to epidemiology, he became known as the Father of Epidemiology (Merrill, 2013) (see Figs. 7–1 and 7–2).

Florence Nightingale: Nurse Epidemiologist

Nursing's epidemiologic roots can be traced to Florence Nightingale (1820 to 1910). Wanting to make nursing a respectable profession, Nightingale advocated training in science, strict discipline, attention to cleanliness, and the development of empathy for patients. She also established a nursing school at London's St. Thomas Hospital, and is commonly referred to as "The Lady with the Lamp" for nursing soldiers throughout the night during the Crimean War (Florence Nightingale Museum, n.d.).

Her detailed records, morbidity (sickness) statistics, and careful description of the health conditions among the soldiers fighting in the Crimean War represent one of the first systematic descriptive studies of the distribution and patterns of disease in a population. She used wedge-shaped graphs that were shaded and colored to illustrate preventable deaths of the hospitalized Crimean soldiers, compared with hospitalized soldiers in England at the time. The sophisticated level of detail in her studies heralded her as the first nurse researcher. She conducted an exhaustive study of the health of the British Army and published several reports about her findings that resulted in creating changes in hygiene and overall treatment of patients. Her monitoring of disease mortality rates was used to improve sanitary methods in hospitals that led to decreased death rates. Nightingale used applied statistical methods for displaying data, and introduced a new way for improving medical and surgical practices. During her lifetime, Queen Victoria recognized Nightingale's contributions to nursing and epidemiology; she was awarded the highest civilian medal, the Order of Merit, and was the first woman to receive it (Merrill, 2013; Florence Nightingale Museum, n.d.). Florence Nightingale learned to "use statistics as evidence" to gain the attention of politicians and powerful people in her quest for hospital and public health reforms, and she was aided in that effort by William Farr (Schiotz, 2015, p. 3).

William Farr

William Farr (1807 to 1883) served as the Compiler of Abstracts in the Office of the Registrar General for England and Wales. He created the first national vital statistics system. He also began compiling vital statistics data on an annual basis, which included analyses of causes of death and assessments of mortality by occupation. To support his work, he developed a nosology (classification of diseases) from which today's International Classification of Diseases (ICD) developed. His collaborative work with contemporaries helped to advance the value of epidemiology for controlling diseases. His epidemiologic investigations into the spread of cholera supported John Snow's efforts to control its spread. He collaborated with Florence Nightingale in her British Army studies, publicizing the value of vital statistics. He supported Greenhow's systematic studies in occupational epidemiology and Seaton's analyses of the efficacy of smallpox vaccinations. This work later formed the scientific basis for English public health policy that lasted for over 50 years. By careful analysis of mortality data and disease patterns among different geographical areas, he "called attention to the connection between socioeconomic class and disease" (Lilienfeld, 2007; Schiotz, 2015, p. 5).

Eras in the Evolution of Modern Epidemiology

Modern epidemiology can be described as having four distinct eras, each based on causal thinking, sanitary statistics, infectious-disease epidemiology, and chronic-disease epidemiology. In light of new research, the eco-epidemiology era is emerging.

Early causal thinking was dominated by the *miasma theory,* which had its origins in the work of the Hippocratic School and was formally developed in the early 1700s. This theory held that a substance called *miasma* was composed of malodorous and poisonous particles generated by the decomposition of organic matter and was the cause of disease. Prevention based on this theory attempted to eliminate the sources of the miasma or polluted vapors. Despite the faulty reasoning, this type of prevention had positive consequences because it made people aware that decaying organic matter can be a source of infectious diseases. This theory dominated until the first half of the 19th century (Schiotz, 2015).

Similarly, the pioneering work of John Snow in identifying the source of cholera in England in the mid-1800s was based on a faulty assumption that the climate was involved. Even so, he was able to trace the source of the infectious agent to the water supply and brought public attention to the link between sanitary conditions and disease. We owe much to these individuals; that they didn't understand the exact mechanisms in disease causation does not lessen their pioneering work in applied epidemiology.

The era of infectious-disease epidemiology was dominated by the *contagion theory* of disease, which developed during the mid-18th century. Prompted by the development of increasingly sophisticated microscopes, this theory attempted to identify the microorganisms that cause diseases as a first step in prevention. It inspired various theories of immunity, and even prompted some initial attempts at vaccination against smallpox. Additionally, once an agent had been identified, measures were taken to contain its spread. Fumigating ships to kill rats, protecting wharf buildings and human habitations from rats, and removing rat food supplies from easy access were all measures taken to protect the public by further preventing the spread of plague bacilli. Based on the work of Louis Pasteur, Jakob Henle, and Robert Koch (see Koch's Postulates Display 7–1), the contagion theory was refined and became best known as the *germ theory of disease* that was predominant from the late 19th century through the first half of the 20th century (McKenzie, Pinger, & Kotecki, 2012).

DISPLAY 7.1 KOCH'S POSTULATES

1. The microorganism must be observed in every case of the disease.
2. It must be isolated and grown in pure culture.
3. The pure culture must, when inoculated into a susceptible animal, reproduce the disease.
4. The microorganism must be observed in, and recovered from, the experimentally diseased animal.

King, L. S. (1952). Dr. Koch's postulates. Journal of Historical Medicine, 350–361. As cited in Friis, R. H., & Sellers, T. A. (2014). Epidemiology for public health practice (5th ed., p. 38). Burlington, MA: Jones and Bartlett Learning.

In the era of infectious-disease epidemiology, scientists viewed disease in terms of a simple cause-and-effect relationship. Finding a single cause (e.g., plague bacilli) and attacking it (e.g., eliminating rats) seemed to be the solution for preventing many diseases. In the case of bubonic plague, this approach appeared to be quite effective. However, scientific research eventually revealed that disease causation was much more complex than first suspected. For example, although most members of a group might be exposed to the plague, many did not contract it.

With bubonic plague, as with many other infectious diseases, host characteristics can determine both the spread of the disease and its individual impact. Not everyone in a population is at equal risk; it is now known that untreated bubonic plague has a case fatality rate of 40% to 70%, meaning that about half of those who contract the disease and are not treated will eventually die. Furthermore, the agent and course of transmission can be quite complex. Although a flea carries the bacilli from rats to humans in bubonic plague, many infectious diseases spread directly from one human being to another. Finally, the environment must be considered as part of the cause of disease. Evidence suggests that the plague originated in the high plains of Asia and spread to other parts of the world (Centers for Disease Control & Prevention [CDC], 2014). However, questions remain as to whether the bacillus spread from rats to ground squirrels or had always been part of the squirrels' ecology.

After World War II, the causative agents of major infectious diseases were identified, methods of prevention were recognized, and antibiotics were added to the arsenal to fight communicable diseases. The focus then became understanding and controlling the new chronic disease epidemics, ushering in the era of chronic disease epidemiology. Researchers completed case–control and cohort studies, to be discussed more fully later, that linked the causative factors of cholesterol levels and smoking with coronary heart disease (CHD) and associated smoking with lung cancer. Today, the major causes of mortality in the United States are noninfectious diseases. In 2012, the top two leading causes of death, heart disease and cancer, accounted for 46.5% of all deaths. Chronic lower respiratory diseases (3rd), cerebrovascular diseases (4th) and unintentional injuries (5th) accounted for 15.7% of all deaths in 2012. Alzheimer's disease (6th), diabetes mellitus (7th), influenza and pneumonia (8th), kidney disease (9th), and suicide (10th) together accounted for 11.6% of deaths in

2012 (Heron, 2015). As you can see, infectious agents are not to blame for most of today's major health problems. See more in Chapters 23 and 24.

We are entering a new era of *eco-epidemiology*, distinguished by transforming global health patterns and technological advances. Global health patterns, the route, form, and virulence in which diseases appear in countries around the world, with consideration of environmental, ecologic, human, technologic, and political factors, are in transformation. With this, new and emerging infections are now a concern, as is the spread of medication-resistant diseases. See more in Chapters 8, 9, and 16. The West Nile virus, sudden acute respiratory syndrome (SARS), influenza A (H1N1), multidrug-resistant tuberculosis (MDR TB), HIV, and Ebola virus disease (EVD) illustrate this transformation. In most cases, causative organisms and critical risk factors are known, yet diseases occur, spread, and suddenly appear in countries or regions previously free of them (Bain & Awah, 2014). We know which social behaviors need to change, but we are at a loss about how to create a climate of permanent change, even when entire populations are at stake. For example, we know how to prevent the transmission of HIV, yet thousands of new cases are reported each year. How can preventive practices be promoted among populations at risk for communicable diseases? The same situation is true for many current chronic diseases. For instance, how many nurses smoke? Do you exercise as often as you know you should? Do you know your cholesterol level, and eat appropriate foods accordingly? Do you regularly use sunscreen? What are we missing to effectively change social behaviors?

Developments in technology drive research, primarily in biology and biomedical techniques and in information system capabilities. For example, genetic influence in some cases of insulin-dependent diabetes is linked to human leukocyte antigens (HLAs) and particular combinations of this gene variant can predict risk of Type 1 diabetes, whereas other combinations either cause no problems or may be protective (National Institute of Diabetes and Digestive and Kidney Diseases, 2014). HIV, tuberculosis, and other infections can be tracked from person to person through identifying the molecular specificity of the organisms. BRCA1 and BRCA2 genes have been found to cause about one-quarter of hereditary breast cancers and up to 10% of all breast cancers, as well as 15% of ovarian cancers, and genetic screening tests are used to screen for these genes (National Cancer Institute, 2015).

On a broader scale, using new technology, we are now able to track the geographic distribution of disease and correlate those data with other important health risks. For instance, using these geocoding systems, overweight and obesity in children can be correlated with other factors, such as after-school recreation opportunities, distribution of fast food restaurants, farmer's markets, or socioeconomic status. (See Chapter 10 for more on technology in public health). The possibilities of learning through technology have just begun in this current epidemiologic era. Table 7–1 summarizes the four eras in the evolution of modern epidemiology.

Table 7–1 Eras in the Evolution of Modern Epidemiology

Era	Paradigm	Analytic Approach	Prevention Approach
Sanitary statistics (1800–1850)	Miasma: poisoning from foul emanations	Clustering of morbidity and mortality	Drainage, sewage, sanitation
Infectious disease epidemiology (1850–1950)	Germ theory: single agent related to specific disease	Laboratory isolation and culture from disease sites and experimental transmission/ reproduction of lesions	Interrupt transmission (vaccines, isolation, and antibiotics)
Chronic disease epidemiology (1950–2000)	Exposure related to outcome	Risk ratio of exposure to outcome at individual level in populations	Control risk factors by modifying lifestyle (diet), agent (guns), or environment (pollution)
Eco-epidemiology (emerging)	Relations within and between localized structures organized in a hierarchy of levels	Analysis of determinants and outcomes at different levels of organization using new information systems and biomedical techniques	Apply both information and biomedical technology to find leverage at efficacious levels

Adapted from Susser, M., & Susser, E. (1996a). Choosing a future for epidemiology: I. Eras and paradigms. American Journal of Public Health, 86(5), 668–673; Susser, M., & Susser, E. (1996b). Choosing a future for epidemiology: II. From black box to Chinese boxes and eco-epidemiology. American Journal of Public Health, 86(5), 674–677.

Epidemics

An epidemic refers to a disease occurrence that clearly exceeds the normal or expected frequency in a community or region. In past centuries, epidemics of cholera, bubonic plague, and smallpox swept through community after community, killing thousands of people, changing the community structure, and altering the lifestyle of masses of people. When an epidemic, such as the bubonic plague (also called pneumonic plague or the Black Death) or HIV/AIDS, is worldwide in distribution, it is known as a pandemic.

Epidemic and pandemic diseases clearly prompted the development of epidemiology as a science. Epidemiology became a distinct branch of medical science through its concern with massive waves of infectious diseases. While epidemiology provides public health with the tools to investigate disease outbreaks, it also provides strategies for controlling disease to prevent future outbreaks. Despite hundreds of years of experience with disease outbreaks, new diseases arise all the time, challenging us to come up with new methods. Eradication would be ideal, but sometimes it may take a long time, or it may not happen at all. Read about smallpox eradication in Chapter 16.

Historically, as the threat of the great epidemic diseases declined, epidemiologists began to focus on other infectious diseases, such as diphtheria, infant diarrhea, typhoid, tuberculosis and syphilis. They also studied diseases linked to occupations, such as scurvy among sailors and scrotal cancer among chimney sweeps. In recent years, epidemiologists turned to the study of major causes of death and disability, such as cancer, cardiovascular disorders, AIDS, violence, mental illness, accidents, arthritis, and congenital defects (Remington & Brownson, 2011).

Ebola Virus Disease: A 21st Century Disease Epidemic

As of December 2, 2015, the Centers for Disease Control and Prevention (CDC) reported a total of 11,864 laboratory confirmed cases of Ebola in Guinea, Sierra Leone, and Liberia, with a total of 8,764 deaths (73.9%) since the Ebola epidemic started in March 2014 (CDC, 2015a). The most recent death occurred in November 2015, when an outbreak occurred after Liberia was declared disease free for 2 months. According to the World Health Organization (WHO), Liberia has recorded more than 4,800 deaths during the worst and largest Ebola outbreak in history (Paye-Layleh, 2015). Two imported cases, including one death, and instances of locally acquired cases in two nurses were reported in the United States (CDC, 2015b). See Chapter 8 (Fig. 7–3).

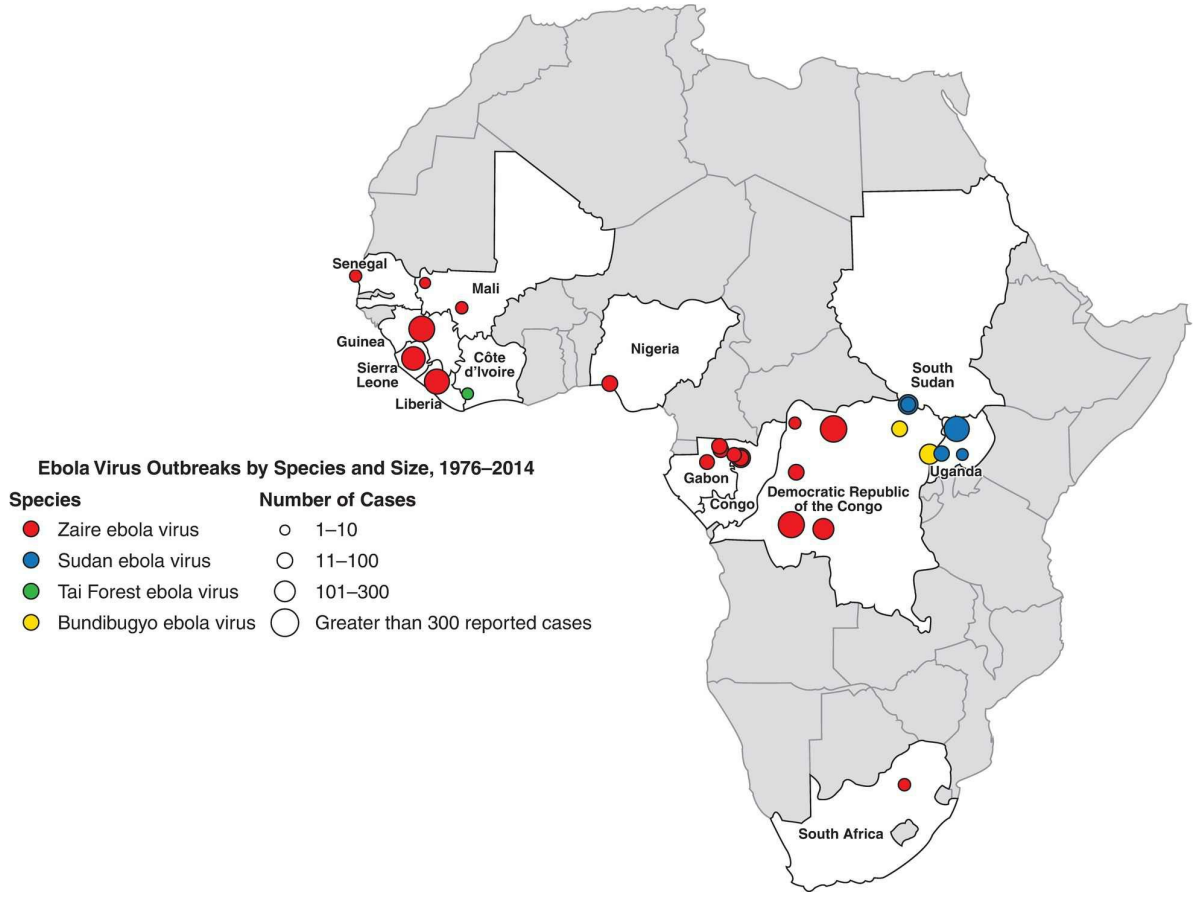

FIGURE 7–3 Cases of Ebola virus disease in Africa, 1976 to 2015. (*Source*: http://www.cdc.gov/vhf/ebola/outbreaks/history/distributionmap.html#modalIdString_CD

Ebola virus disease (EVD) is a viral hemorrhagic fever (VHF) that is characterized by fever, diarrhea, and unexplained bleeding (bruising, petechiae, bloody stools, mucosal hemorrhage) and is definitively diagnosed at reference laboratories that have advanced biocontainment capability, such as the CDC. Early clinical diagnosis minimizes potential nosocomial spread. Antiviral therapy is useful, with intensive supportive care, and those infected must be cared for under strict contact precautions, including hand hygiene, double gloves, gowns, shoe and leg coverings, and face shield or goggles. Airborne precautions should be instituted, and at minimum, a fit-tested, HEPA filter–equipped respirator (e.g., N-95 mask) and a battery-powered, air-purifying respirator (PAPR), or a positive pressure-supplied air respirator, should by worn by personnel sharing an enclosed space within 6 feet of a VHF patient (CDC, 2015c).

VHFs are a diverse group of illnesses caused by RNA viruses. The four viral families are *Arenaviridae, Bunyaviridae, Filoviridae, and Flaviviridae*. The *Filoviridae* family includes the Ebola and Marburg viruses. There are five species of the Ebola virus (Zaire, Sudan, Bundibugyo, Reston, Ivory Coast—now known as Taï Forest). The Reston virus has not caused disease in humans. The first recognized EVD outbreak caused by the Zaire and Sudan species occurred in 1976, and an outbreak of 316 cases from a single index case occurred in Zaire in 1995. Subsequent outbreaks from the Zaire virus (*Zaire ebolavirus*)

and Sudan virus (*Sudan ebolavirus*) occurred in Gabon, Ivory Coast, Uganda, Democratic Republic of Congo (DRC) (former Zaire), and Sudan, with the last reported Ebola-Zaire epidemic in the DRC reported in 2007. The Reston virus (*Reston ebolavirus*) was isolated from monkeys in 1989, and caused outbreaks in nonhuman primate facilities. Although the Reston virus (*Reston ebolavirus*) is not recognized as a human pathogen, exposed animal handlers did seroconvert without manifesting clinical disease. In 2008, humans also seroconverted without clinical disease when exposed to pigs infected with Ebola-Reston in the Philippines. At that time a scientist also contracted the Taï Forest virus (*Taï Forest ebolavirus*) after working with postmortem tissues, became ill, but fully recovered. The Bundibugyo virus (*Bundibugyo ebolavirus*) was responsible for a 2007 outbreak in Uganda, and recent data implicated bats as the likely reservoir, but initial mode of spread to humans and the ecology of these diseases remain unclear. Scientists do not know why it occurs intermittently (CDC, 2015c; United States Army Medical Research Institute of Infectious Diseases, 2011) (Fig. 7–4).

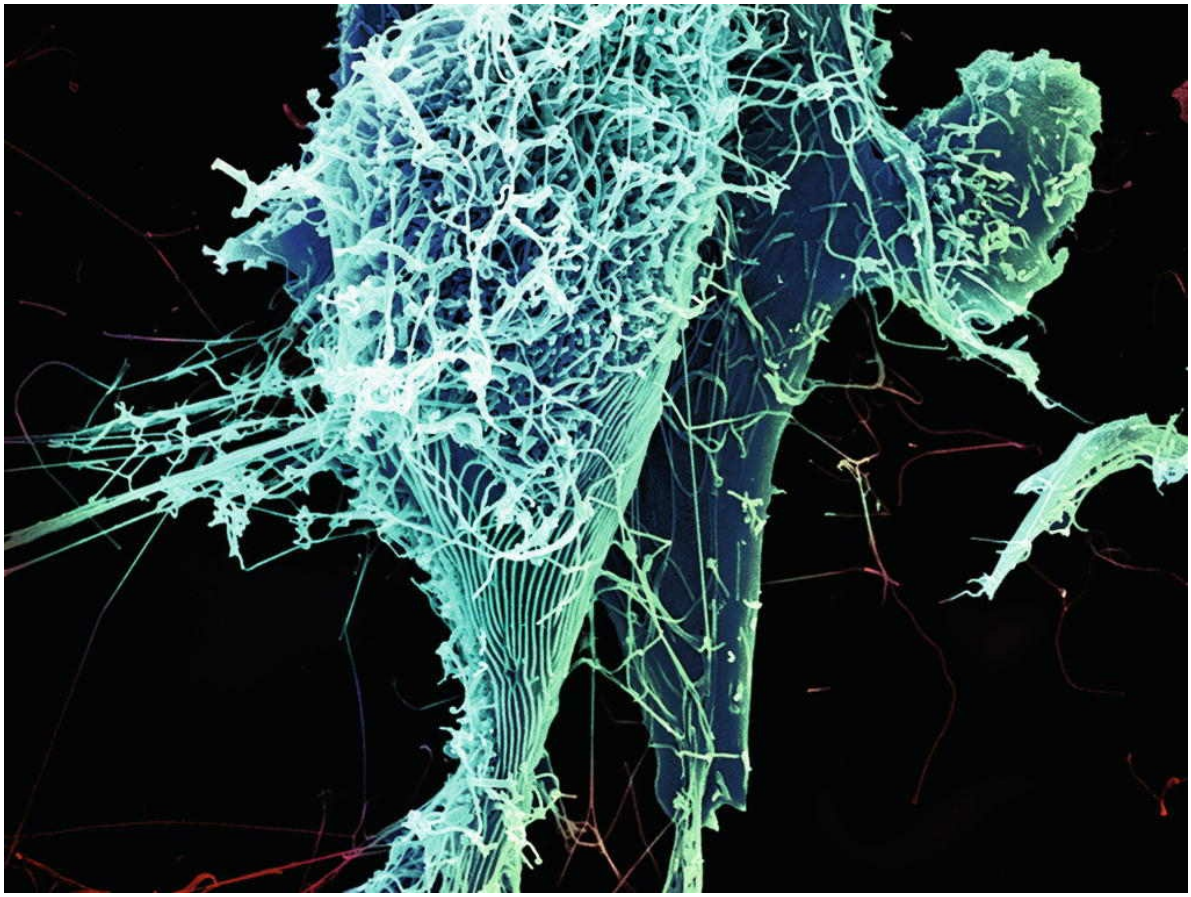

FIGURE 7–4 Ebola virus (string-like Ebola virus was peeling off an infected cell). (*Source*: http://images.nigms.nih.gov/index.cfm?event=viewDetail&imageID=3619)

Studies have found, however, that the Ebola virus lives in fruit bats and can infect humans through contact with bodily secretions (e.g., blood and sweat). Once people are infected, they can pass the virus to other humans through direct exposure to bodily fluids

(Kahn, 2015). In a Guinea village in 2014, an EVD outbreak in which a toddler had died was blamed on a bat-filled tree. Children would catch and play with the bats. Before any definitive testing of the bats could be done, the tree was burned down and the villagers ate all the bats (Geggel, 2014). Investigations into the 2014 outbreak have uncovered the eating of bushmeat as a potential mode of transmission. Bushmeat is any animal killed for food (including bats). Because Africans often have no alternative, they frequently eat bushmeat. People hunt gorillas, chimpanzees, and other animals that may have been infected eating the droppings from bats that have been identified as an Ebola vector, or carrier (Cooney, 2014).

Of greater concern was the *New England Journal of Medicine* report that there was now molecular evidence that EVD can be sexually transmitted. While the Ebola virus is detectable in the bloodstream only during acute illness, the virus may persist in the body within immune-privileged sites (e.g., eye, testes; where inflammatory immune response does not occur following exposure to an antigen). Ebola RNA has been detected in breast milk up to 15 days, in vaginal secretions up to 33 days, in ocular aqueous humor up to 98 days, and in semen up to 101 days after disease onset. Specifically, with semen, the Ebola virus has been cultured from samples 40, 61, and 82 days after disease onset when the virus has been cleared from the blood (Mate et al., 2015).

This long-term persistence of the virus in the semen of survivors provides opportunities for sexually transmitting the disease even when the outbreak may be deemed officially over. In this report, the WHO and the CDC advised survivors of EVD to abstain from sexual intercourse or to use condoms for at least 3 months after the onset of EVD (Mate et al., 2015). However, the CDC has since advised that condoms should be worn correctly and consistently every time until further information becomes known (Christie et al., 2015; Rettner, 2015).

Furthermore, WHO's criteria of a 42-day cut-off period for declaring a country "Ebola free" (after the last confirmed case tests negative for the virus) has been questioned. In the November 2015 Liberia outbreak, individuals have tested positive for Ebola antibodies while testing negative for the virus, suggesting the possibility of human-to-human transmission from previously undocumented or mildly symptomatic cases. Recent reports that the virus can linger in semen (Deen et al., 2015), breast milk, and the eye for as long as 9 months after survivors recover, and the differing behaviors of the different Ebola strains have caused the WHO to add a 90-day high-surveillance phase to those countries passing the 42-day cut-off period. Additionally, animal-to-human transmission in endemic areas (where disease is most frequently found), such as Sierra Leone, Liberia, and Guinea, cannot be adequately addressed because of "an animal reservoir of unknown origin," thus making it impossible to eradicate the disease in those areas (Thomas, 2015a, para. 5).

While the overall case fatality rate is high for EVD (52%), it can vary by geographic location (e.g., 42% for Sierra Leone, 66% for Guinea) (WHO, 2014a). Survivors from the 2014 outbreak are starting to report serious sequelae. About half of EVD survivors report what is now referred to as the "post-Ebola syndrome." Reports include blurred vision,

retro-orbital pain, hearing loss, sleep disturbances, neurological abnormalities, memory loss, arthralgias (joint pain), confusion, difficulty swallowing, and chronic health problems. These health issues can persist for more than 2 years. The most severe involve the eyes where viral genome or infectious virus have been found, causing pressure, uveitis (inflammation), and even blindness. The virus has not been found in tears, reducing the potential for infecting others (Mackay, 2015).

EVD is a prime example of how epidemiology can help characterize an infectious disease so it can be controlled to prevent its spread. Knowing that EVD can be sexually transmitted has led the CDC to advise EVD survivors to use condoms indefinitely in order to prevent this mode of transmission. Another mode of transmission, such as the eating of bushmeat, however, is not so easy to address. This will probably require a broader approach with public health education and culturally sensitive strategies to assist this population in finding alternative food sources.

Furthermore, there is much more to learn about Ebola before it can be eradicated.

Periodic outbreaks in which previous known modes of transmission no longer apply have left researchers puzzled, questioning their expertise (Beaubien, 2015). Genomic sequencing of the Ebola virus has revealed a high mutation rate without changing the characteristics of the virus itself. This technology has been useful in matching new viral infections to earlier ones, but has not been sufficient to help eradicate the disease (Thomas, 2015b). However, as we learn more about the virus, control measures can be implemented. For example, WHO has issued a protocol for the safe management of dead bodies and burial of those who have died from suspected or confirmed EVD (WHO, 2014b).

CONCEPTS BASIC TO EPIDEMIOLOGY

The science of epidemiology draws on certain basic concepts and principles to analyze and understand patterns of occurrence among aggregate health conditions.

Host, Agent, and Environment Model

Through their early study of infectious diseases, epidemiologists began to consider disease states generally in terms of the *epidemiologic triad*, or the *host, agent, and environment model*. Interactions among these three elements explained infectious and other disease patterns.

Host

The host is a susceptible human or animal who harbors and nourishes a disease-causing agent. Many physical, psychological, and lifestyle factors influence the host's susceptibility and response to an agent. Physical factors include age, sex, race, and genetic influences on the host's vulnerability or resistance. Psychological factors, such as outlook and response to stress, can strongly influence host susceptibility. Lifestyle factors also play a major role. Diet, exercise, sleep patterns, and healthy or unhealthy habits all contribute to either increased or decreased vulnerability to the disease-causing agent (Fletcher & Fletcher, 2012).

The concept of resistance is important for public health nursing practice. People sometimes have an ability to resist pathogens. This is called *inherent resistance.* Typically, these people have inherited or acquired characteristics, such as the various factors mentioned earlier, that make them less vulnerable. People who maintain a healthful lifestyle may not contract influenza even if exposed to the flu virus. Resistance can be promoted through preventive interventions that support a healthful lifestyle.

For example, Walker et al. (2011) demonstrated that participants (n = 7,867) taking multivitamins with folic acid during the early second trimester were 63% less likely to have preeclampsia. In another study, folic acid supplementation and higher dietary folate intake during pregnancy were found to reduce the risk of preeclampsia (Wang et al., 2015). If confirmed by additional studies, multivitamin use with folic acid could be recommended as a preventive measure for preeclampsia. The American Academy of Pediatrics (AAP, 2015) and the U.S. Public Health Service already recommend that women capable of becoming pregnant take 400 μg of folic acid each day to prevent neural tube defects such as spina bifida. Further study may reveal other benefits from the use of folic acid during pregnancy.

Agent

An agent is a factor that causes or contributes to a health problem or condition. Causative agents can be factors that are present (e.g., bacteria that cause tuberculosis, rocks on a mountain road that contribute to an automobile crash) or factors that are lacking (e.g., a low serum iron level that causes anemia or the lack of seat belt use that contributes to the extent of injury during an automobile crash) (Fig. 7–5).

FIGURE 7–5 Old paint cans may be a source of lead and other toxins.

Agents vary considerably and include five types: biologic, chemical, nutrient, physical, and psychological. Biologic agents include bacteria, viruses, fungi, protozoa, worms, and insects. Some biologic agents are infectious, such as Influenza virus or HIV. Chemical agents may be in the form of liquids, solids, gases, dusts, or fumes. Examples are poisonous sprays used on garden pests and industrial chemical wastes. The degree of toxicity of the chemical agent influences its impact on health. Nutrient agents include essential dietary components that can produce illness conditions if they are deficient or are taken in excess. For example, a deficiency of niacin can cause pellagra, and too much vitamin A can be toxic. Physical agents include anything mechanical (e.g., chainsaw, automobile), material (e.g., rock slide), atmospheric (e.g., ultraviolet radiation), geologic (e.g., earthquake), or genetically transmitted that causes injury to humans. The shape, size, and force of physical agents influence the degree of harm to the host. Psychological agents are events that produce stress leading to health problems (e.g., war, terrorism).

Agents may also be classified as infectious or noninfectious. Infectious agents cause communicable diseases, such as AIDS or tuberculosis—that is, the disease can be spread from one person to another. Certain characteristics of infectious agents are important for community health nurses to understand. Extent of *exposure* to the agent, the agent's *pathogenicity* (capacity to cause disease in the host), its *infectivity* (capacity to enter the host and multiply), its *virulence* (severity of disease), *toxigenicity* (capacity to produce a toxin or poison), *resistance* (ability of the agent to survive environmental conditions), *antigenicity* (ability to induce an antibody response in the host), and its structure and chemical

composition all influence the effect of the agent on the host (Friis & Sellers, 2014). Chapter 8 examines the subject of communicable disease in greater depth. Noninfectious agents have similar characteristics in that their relative abilities to harm the host vary with type of agent and intensity and duration of exposure (Fletcher & Fletcher, 2012).

Environment

The environment refers to all the external factors surrounding the host that might influence vulnerability or resistance. The physical environment includes factors such as geography, climate and weather, safety of buildings, water and food supply, and presence of animals, plants, insects, and microorganisms that have the capacity to serve as reservoirs (storage sites for disease-causing agents) or vectors (carriers) for transmitting disease. The psychosocial environment refers to social, cultural, economic, and psychological influences and conditions that affect health, such as access to health care, cultural health practices, poverty, and work stressors, which can all contribute to disease or health (Fletcher & Fletcher, 2012).

Host, agent, and environment interact to cause a disease or health condition. For example, the agent responsible for Lyme disease is the spirochete *Borrelia burgdorferi*; humans of all ages are susceptible hosts, along with dogs, cattle, and horses. Ticks (a vector) that feed on wild rodents and deer transfer the spirochete to human hosts after feeding on them for several hours. Environmental factors, such as working or playing in tick-infested areas, influence host vulnerability. The host, agent, and environment model, shown in Figure 7–6, offered plan for intervention for the epidemiologists who first studied Lyme disease in 1982. As soon as the agent was identified, measures could be taken to keep the spirochete from infecting human hosts, such as wearing protective clothing or tick repellent in tick-infested areas and promptly removing the attached ticks (Heymann, 2014).

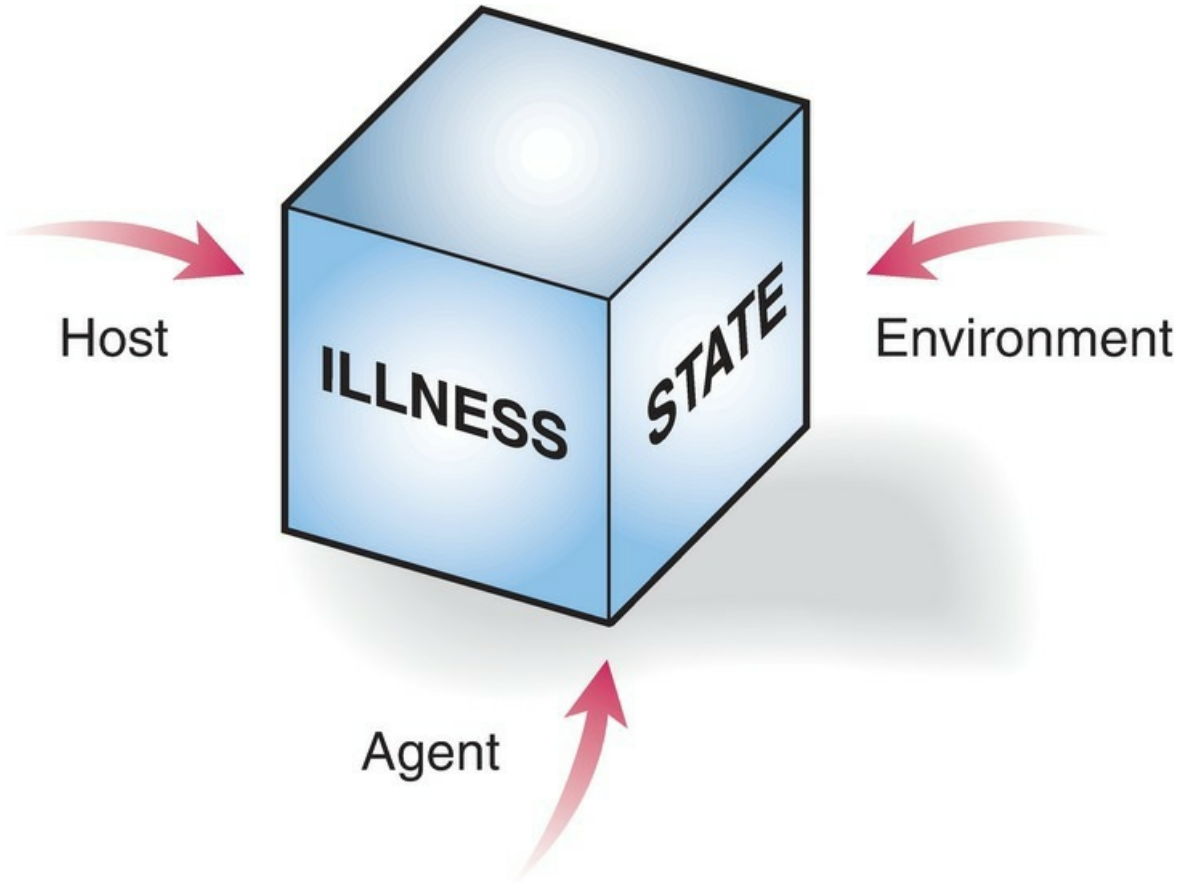

FIGURE 7–6 Epidemiologic triad. Epidemiologists study the causal agent, the susceptible host, and environmental factors that contribute to an illness, an injury, or a wellness state. Intervention may focus on any of these three to prevent the spread of illness or to improve health in a population.

In another example, the West Nile virus, which was widespread in Africa and the Middle East, arrived in the United States in 1999 and began to spread. The first reported cases were in New York, where 45 people were infected. In that year, the region experienced a total of 59 hospitalized cases of West Nile disease, resulting in seven deaths (Sejvar, 2003). By 2006, West Nile virus had been reported in 43 states and the District of Columbia, with a total of 4,269 cases and 177 deaths. In 2011, there were 690 confirmed cases and 43 deaths in the United States. As of January 2012, only Alaska, Hawaii, and Oregon had no confirmed presence of the virus in humans, birds, animals, or mosquitoes (CDC, 2015f). The infected mosquitoes (vector) pass the virus on to birds, humans, or horses through bites. Many dead birds in an area may mean that the virus is circulating between the bird and mosquito populations and should be reported. In humans and animals with intact immune systems, the virus is usually destroyed in the bloodstream. If the virus survives in the body, it can infect membranes around the spinal cord and brain and cause encephalitis. Those at highest risk are the elderly, children, and people with impaired immune systems (CDC, 2015f).

Prevention of West Nile virus infections includes avoiding mosquito bites by applying

insect repellent containing *N*,*N*-diethyl-meta-toluamide (DEET) when outdoors; wearing long-sleeved clothing and long pants treated with DEET-containing repellents; staying indoors at dawn, at dusk, and in the early evening; eliminating standing water sources where mosquitoes lay their eggs; reporting dead birds; and ensuring that an organized mosquito control program exists in the area (CDC, 2015f). Using the model in Figure 7–6, can you categorize each of these six recommendations by their target (host, agent, or environment)?

Causality

Causality refers to the relationship between a cause and its effect. A purpose of epidemiologic study has been to discover causal relationships, in order to understand why conditions develop, and to offer effective prevention and protection (Fletcher & Fletcher, 2012). As scientific knowledge of health and disease has expanded, epidemiology has changed its view of causality. The following section discusses some of those changes in thinking that began in the 1960s and is being continually refined.

Chain of Causation

As the scientific community's thinking about disease causation and the tripartite model (host–agent–environment) grew more complex, epidemiologists began to use the idea of a chain of causation (Fig. 7–7). The chain begins by identifying the reservoir (i.e., where the causal agent can live and multiply). With plague, that reservoir may be other humans, rats, squirrels, and a few other animals. With malaria, infected humans are the major reservoir for the parasitic agents, although certain nonhuman primates also act as reservoirs (Heymann, 2014). Next, the agent must have a portal of exit from the reservoir, as well as some mode of transmission. For example, the bite of an *Anopheles* mosquito provides a portal of exit for the malaria parasites, which spend part of their life cycle in the mosquito's body; the mosquito in this case is the mode of transmission. The next link in the chain of causation is the agent itself. Malaria, for example, actually consists of four distinct diseases caused by four kinds of microscopic protozoa (Heymann, 2014). The next link is the portal of entry. In the case of malaria, the mosquito bite provides a portal of exit as well as a portal of entry into the human host.

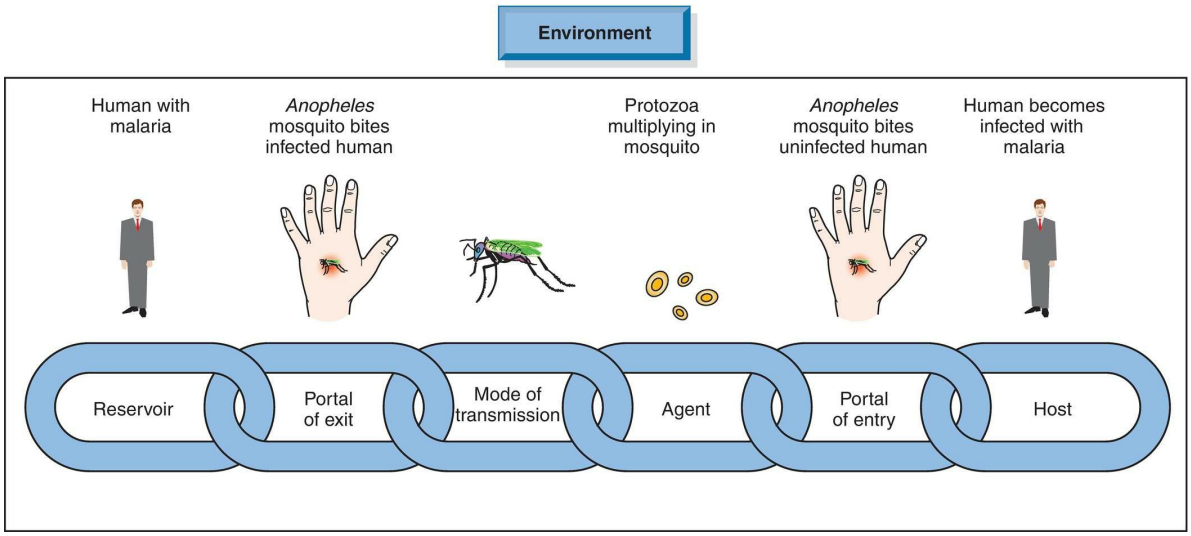

FIGURE 7–7 Chain of causation.

The box surrounding the chain of causation in Figure 7–6 represents the environment, which can have a profound influence at almost any point along the chain. Consider the impact of environmental factors on the 1934-to-1935 malaria epidemic in Sri Lanka (an island country in the Indian Ocean off southern India). Historically, malaria occurred frequently in the dry northern area, where sparse vegetation allowed pools of water to be exposed to the sun, providing excellent breeding grounds for the *Anopheles* mosquito. In contrast, the more populous southwestern area usually had heavy monsoon rains and was relatively free from malaria. In 1934, however, a severe drought changed this environment drastically; throughout Sri Lanka, rivers almost dried up, leaving stagnant pools of water for mosquito breeding. Widespread crop failure caused the population to become badly undernourished, which added to conditions that would foster a malaria epidemic. The epidemic occurred in October 1934, affecting 2 to 3 million people and causing 80,000 deaths. The environment must certainly be seen as a major part of this causal chain (Karunaweera, Galappaththy, & Wirth, 2014). See Chapter 9.

Causation in Noninfectious Disease

With the availability of vaccines and antibiotics to thwart most infectious diseases in the United States and the developed world, attention shifted to the causes of noninfectious diseases such as cancer and diabetes. A new causal paradigm was clearly needed. The linear thinking embodied in models such as the *chain of causation* was insufficient in understanding the causes of these emerging health threats. Beginning in the 1950s, there was a growing interest in the role smoking played in the development of lung cancer. In 1964, the publication of *Smoking and Health: Report of the Advisory Committee to the Surgeon General of the Public Health Service* concluded that smoking caused lung and laryngeal cancer in men (U.S. Public Health Service, 1964). Fifty years later, the Surgeon General released *The Health Consequences of Smoking—50 Years of Progress: A Report of the Surgeon General, 2014*. Additional findings further implicate smoking, such as causing liver

and colon cancer, diabetes mellitus and rheumatoid arthritis, as well as general adverse health effects from inflammation and impairment of immune function. The report further states that those exposed to secondhand smoke were at increased risk of stroke, and that smoking increases a smoker's risk of dying from cancer and other diseases (USDHHS, 2014).

In 1856, John Stuart Mill formed three methods of hypothesis formulation for determining disease etiology. These methods include method of difference, method of agreement, and method of concomitant variation. In 1965, Sir Austin Bradford Hill proposed expanding on Mill's postulates about causality by developing nine criteria to evaluate the relationship between environmental exposure and potential health outcomes. The criteria can be used with infectious disease as well as noninfectious disease. These elements are summarized below:

1. *Strength of association*: This refers to the ratio of disease rates in those with and without the suspected causal factor. A strong association would be noted if rates of disease are much higher in the group with the factor than in the group without it.
2. *Consistency of association*: An association is demonstrated in varying types of studies among diverse study groups (i.e., replication).
3. *Specificity*: A cause leads to one effect (not always the case in noninfectious diseases).
4. *Temporality*: Exposure to the suspected factor must precede the onset of disease (i.e., time order or time sequence).
5. *Biological gradient*: This relationship is demonstrated if, with increasing levels of exposure to the factor, there is a corresponding increase in occurrence of the disease (i.e., dose–response relationship).
6. *Biological Plausibility*: The hypothesized cause makes sense based on current biologic or social models (i.e., it is possible).
7. *Coherence of explanation*: The hypothesized cause makes sense based on current knowledge about the natural history or biology of the disease (i.e., scientific knowledge).
8. *Analogy*: Similarities between the association of interest and others (e.g., potential links to birth defects from new drugs is a concern because we already recognize this potential from the use of the drug thalidomide during the 1950s and early 1960s).
9. *Experiment Evidence*: Experimental and nonexperimental studies support the association (e.g., reduced tobacco use in a population should lead to reduced lung cancer rates; Merrill, 2013).

The elements described by Hill are still utilized by epidemiologists and provide the fundamental principles PHNs can use to evaluate evidence of disease causation in all types of published reports, both scientific and lay. In health education, these principles can be utilized to teach disease causation risk, especially when the evidence is not yet complete. For instance, a pregnant teen asks a nurse if she should drink diet soda while she is pregnant. The nurse can share with her that the evidence to date supports the safety of

artificial sweeteners for most adults (experiment), but that it is probably not wise to drink diet soda while pregnant. When she asks why (because there isn't any reported risk), the nurse can respond that any chemical has the potential to cause harm (plausibility and analogy), and the effects on a growing fetus (biologic gradient) are often unknown until decades later (temporality and experiment).

Multiple Causations

As health care professionals began to understand the complexity of many of the infectious and noninfectious disease threats, they came to realize that causation was never completely straightforward. Even with long-recognized contagious diseases like cholera, the organism was only part of the equation. Factors such as availability of clean water, the number of trained nurses and doctors, the overall nutrition of the population, and even political upheaval could influence the spread of disease and the number who ultimately died. Causation was beginning to be viewed as multifactorial. Fortunately, with recognition of the complexity of each health threat, came multiple opportunities to find solutions. The following section discusses the complexity of causal factors on health outcomes and implications for reduced morbidity and mortality.

Web of Causation

In the 1960s, the concept of multiple causation emerged to explain the existence of health and illness states and to provide guiding principles for epidemiologic practice. A causal paradigm that gained attention was referred to as the web of causation. The implication was that intervention (or breaking of the web at any point nearest to the disease) could profoundly impact the development of that disease (Fletcher & Fletcher, 2012; Merrill, 2013). This was a significant shift in thinking about disease and health, positing that the combination of multiple factors was the deciding factor in the development of poor outcomes. This refinement in causal thinking also provided opportunities for health care interventions at a variety of levels. Another common term used for this approach is *causal matrix*.

Utilizing the multicausal approach, Figure 7–8 depicts a causal matrix for infant mortality. Data from birth and death certificates were used to identify the complex interactions among multiple causal factors that produce a negative health condition leading to infant mortality. Another example (Fig. 7–9) shows a web of causation for automobile crashes. All of the numerous factors involved must be considered when diagramming a web of causation. Speed, faulty equipment, heavy traffic, confusing traffic patterns, road construction, poor visibility, weather conditions, driver inexperience, and drinking or drug use, in any combination, can cause an automobile crash.

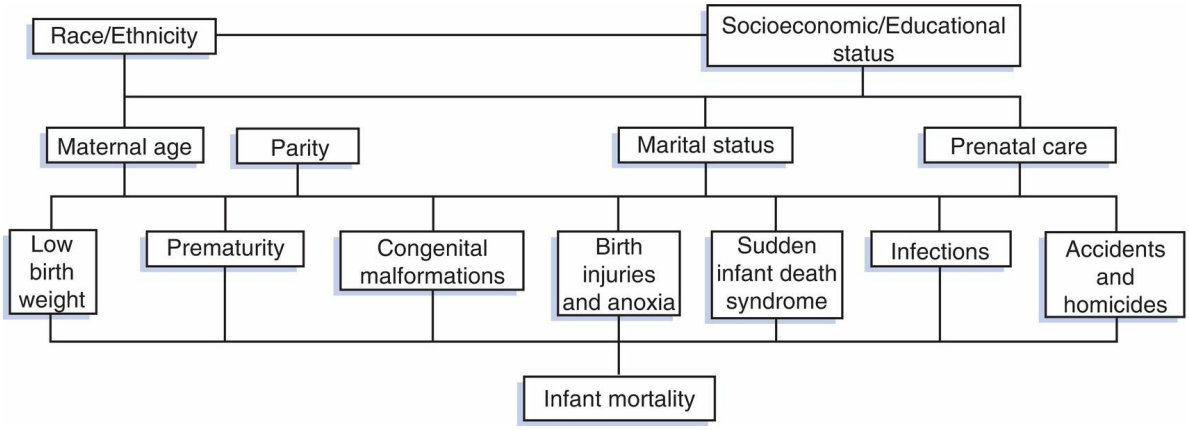

FIGURE 7–8 Web of causation for infant mortality.

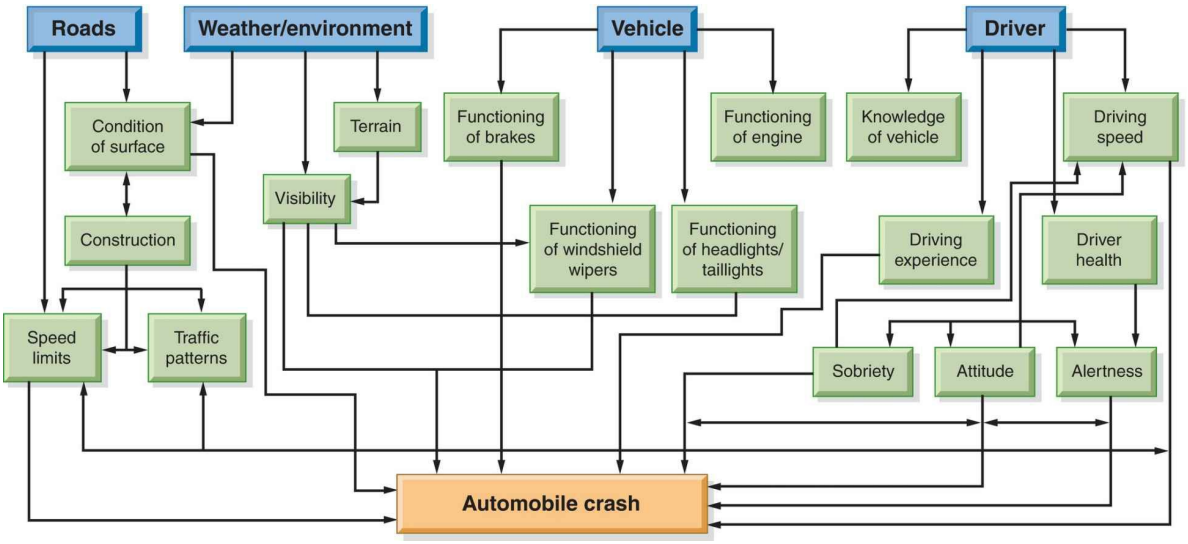

FIGURE 7–9 Web of causation for automobile crashes.

All health conditions can be diagramed to depict a matrix of causation. A communicable disease that has one clearly identified organism as the agent has the ability to be diagramed based on factors such as availability of emergency services (treatment), diagnostic skill of health professionals (early diagnosis), availability of medications and vaccines to treat the disease (reduced morbidity), and community communication networks (public awareness). Any of these factors could greatly influence the progression of disease within the community.

Association is a concept that is helpful in determining multiple causalities. Events are said to be associated if they appear together more often than would be the case by chance alone (see Perspectives). Such events may include risk factors or other characteristics affecting disease or health states. Examples are the frequent association of cigarette smoking with lung cancer, obesity with heart disease, and severe prematurity with infant mortality. The study of associated factors suggests possible causality and points for intervention. Contemporary epidemiologists continue to explore new and more comprehensive ways of viewing health and illness. The associations among lifestyle, behavior, environment, and

stress of all kinds and the ways in which they affect health states are gaining importance in epidemiology (Fletcher & Fletcher, 2012).

PERSPECTIVES CONDUCTING AN EPIDEMIOLOGIC INVESTIGATION

Adult Lead Poisoning from the Use of an Asian Remedy for Menstrual Cramps—Example of an Epidemiologic Investigation

During a free lead-screening event, sponsored by a nursing school community health promotion center, a 33-year-old Cambodian woman who brought her two children to the center to be tested for lead poisoning also participated in being tested. She was found to have an elevated blood lead level (BLL) of 44 μg/dL, and a confirmatory BLL 1 month later of 42 μg/dL. The children and her husband were found to have normal BLLs. This woman was referred by the director of the health promotion center for follow-up to the Connecticut Department of Public Health.

As the Connecticut Adult Blood Lead Surveillance Program's Adult Lead Registry and Case Management Coordinator, I was responsible for compiling and analyzing BLL data from Connecticut laboratories performing these tests, and to follow up on any reports of elevated lead levels, such as this woman who was identified through a community screening event sponsored by a nursing school.

Although ideally there should be no lead in the blood, levels below 10 μg/dL are considered normal (because of ambient exposures), and any value above 10 μg/dL was considered abnormal and required follow-up regarding the cause. The Connecticut Adult Lead Poisoning Program is funded by the CDC's Adult Blood Lead Epidemiology and Surveillance Program (ABLES), with a primary interest in studying and reducing occupational exposure to lead. In this particular case, occupational exposure was ruled out (she was not working), but an epidemiological investigation was still conducted to identify the source of lead exposure.

The woman was requested to send in any possible causes of lead exposure to the state health department. All these materials (tea, cosmetics, medicinal herbs, medication, etc.) were forwarded to the state laboratory for testing. Everything came back negative except for the little red pills (Koo Sar pills) the woman was taking for menstrual cramps. The investigation took many months to complete because the woman, who lived in Connecticut, bought these pills in Chinatowns located in New York City and San Francisco. Follow-up with the New York City Health

Department and San Francisco Health Department resulted in an additional contact with the California State Health Department.

All health departments involved also tested the Koo Sar pills they obtained for lead, and were found with varying amounts of lead. Eventually it was determined that lead was not a listed ingredient of these pills but a contaminant during the manufacturing process. The investigation was reported in an issue of the CDC's *Morbidity and Mortality Weekly Report*. This report led to a greater awareness among public health professionals, health care providers, and environmental workers of the potential for lead poisoning from herbal remedies.

In the host, agent, and environment model, a shifting emphasis of investigation over time may be noted. Early epidemiologists worked to identify and manage the causative

agent; the focus of concern was the disease state. The emphasis then shifted to the host: Who was susceptible? What characteristics led to susceptibility? Through immunization and health promotion, efforts were made to improve host resistance. Increasingly, however, public health workers came to realize the limitations imposed on individual control of health. Even individuals who are in the best of health cannot withstand toxic agents in the workplace—for example, nuclear wastes in the atmosphere from power plant accidents—or other debilitating conditions created by modern society. More and more, public health professionals are studying the environment and looking for methods to change conditions that contribute to illness. See Chapter 9.

Immunity

Immunity refers to a host's ability to resist a particular infectious disease–causing agent. This occurs when the body forms antibodies and lymphocytes that react with the foreign antigenic molecules and render them harmless (Fletcher & Fletcher, 2012). For public health nursing, this concept has significance in determining which individuals and groups are protected against disease and which may be vulnerable. Four types of immunity are important in community health: passive immunity, active immunity, cross-immunity, and herd immunity.

Passive Immunity

Passive immunity refers to short-term resistance that is acquired either naturally or artificially. Newborns, through maternal antibody transfer, have natural passive immunity that lasts up to 1 year for certain diseases (CDC, 2015d). This maternally provided protection seems to work best with measles, rubella, and tetanus, and less well with other diseases (e.g., polio and pertussis). Artificial passive immunity is attained through inoculation with antibody products to provide temporary resistance. Examples of such products include immune globulin (hepatitis A and measles), hyperimmune globulins (hepatitis B, rabies, tetanus, and varicella), and hyperimmune serum (equine antitoxin for use with botulism and diphtheria). These products are used to boost a susceptible person's immunity, and administration must be repeated periodically to maintain immunity levels (CDC, 2015d) (Fig. 7–10).

Active Immunity

Active immunity is long-term and sometimes offers lifelong resistance that is acquired either naturally or artificially. Naturally acquired active immunity comes through host infection. That is, a person who contracts a disease often develops long-lasting antibodies that provide immunity against future exposures. Artificially acquired active immunity is attained through vaccine inoculation. Such vaccines are prepared from killed (inactivated) or live attenuated (weakened) organisms administered to artificially produce or increase immunity to a particular disease (CDC, 2015d). The concept of active immunity underlies public health immunization programs that have successfully kept polio, diphtheria, smallpox, and other major diseases under control worldwide.

Cross-Immunity

Cross-immunity refers to a situation in which a person's immunity to one agent provides immunity to a related agent as well. The immunity can be either passive or active. Sometimes, infection with one disease, such as cowpox, gives immunity to a related disease, such as smallpox. The concept of cross-immunity has also been useful in the development and administration of vaccines. Inoculation with a vaccine made from one disease-causing

organism can provide immunity to a related disease-causing organism. Field trials in Uganda and Papua, New Guinea and a study in India in the 1990s examined the administration of *bacille Calmette-Guérin* (BCG) vaccine, which is used to prevent tuberculosis, to people who had been exposed to Hansen's disease (leprosy). The vaccine against *Mycobacterium tuberculosis* appeared to provide these individuals with a degree of cross-immunity to the related infectious agent, *Mycobacterium leprae,* and prevented their contracting disease (Heymann, 2014).

Herd Immunity

Herd immunity describes the immunity level that is present in a population group. A population with low herd immunity is one with few immune members; consequently, it is more susceptible to a particular disease. Nonimmune people are more likely to contract the disease and spread it throughout the group, placing the entire population at greater risk. Conversely, a population with high herd immunity is one in which the immune people in the group outnumber the susceptible people; consequently, the incidence of a particular disease is reduced (Merrill, 2013; Willingham & Helft, 2014). The level of herd immunity may vary with diseases. For instance, a level of community immunity of between 83% and 85% may be necessary for rubella, but for diphtheria a level of 85% may be effective (Merrill, 2013; Willingham & Helft, 2014). Mandatory preschool immunizations and required travel vaccinations are applications of the herd immunity concept. A figure in Chapter 8 provides a depiction of herd immunity.

FIGURE 7–10 Child with red, watery eyes and a rash.

Risk

To determine the chances that a disease or health problem will occur, epidemiologists are concerned with risk, or the probability that a disease or other unfavorable health condition will develop. For any given group of people, the risk of developing a health problem is directly influenced by their biology, environment, lifestyle, and system of health care (McKenzie et al., 2012). A person's inherited health capacity, the environment lived in, the person's lifestyle choices, and the quality and accessibility of the health care system either negatively or positively affect health, thereby increasing or decreasing the likelihood that a health problem will occur. Negative influences are called *risk factors.* For example, low-birth-weight babies (biology, environment, and system of health care) tend to be at greater risk for health problems, as are people who smoke cigarettes, have diets high in cholesterol, and are sedentary (lifestyle). The degree of risk is directly linked to susceptibility or vulnerability to a given health problem.

Epidemiologists study populations at risk. A *population at risk* is a collection of people among whom a health problem has the possibility of developing because certain influencing factors are present (e.g., exposure to HIV) or absent (e.g., lack of childhood immunizations, lack of specific vitamins in the diet), or because there are modifiable risk factors present (e.g., cardiovascular disease). A population at risk has a greater probability of developing a given health problem than other groups do. Epidemiologists measure this difference using the *relative risk ratio,* which statistically compares the disease occurrence in the population at risk with the occurrence of the same disease in people without that risk factor.

$$\text{Relative risk ratio} = \frac{\text{Incidence in exposed group}}{\text{Incidence rate in unexposed group}}$$

If the risk of acquiring the disease is the same regardless of exposure to the risk factor studied, the ratio will be 1:1, and the relative risk will be 1.0. A relative risk >1.0 indicates that those with the risk factor have a greater likelihood of acquiring the disease than do those without it; for instance, a relative risk of 2.54 means that the exposed group is 2.54 times more likely to acquire the disease than the unexposed group. This statistic may be used, for example, to compare the incidence of heart disease among smokers (smoking is a risk factor) with the incidence among nonsmokers, assuming that all other factors are the same. The relative risk ratio assists in determining the most effective points for community health intervention in regard to particular health problems. It also provides a more easily understood method for explaining the risk of certain behaviors in the development of illness or injury to the public (Gordis, 2014).

Natural History of a Disease or Health Condition

Any disease or health condition follows a progression known as its natural history; this refers to events that occur before its development, during its course, and during its conclusion. This process involves the interactions among a susceptible host, the causative agent, and the environment. The natural progression of a disease occurs in four stages as they affect a population—susceptibility, preclinical (subclinical) disease, clinical disease, and resolution (Fig. 7–11). The last stage, resolution, includes recovery, disability, or death (Gerstman, 2013).

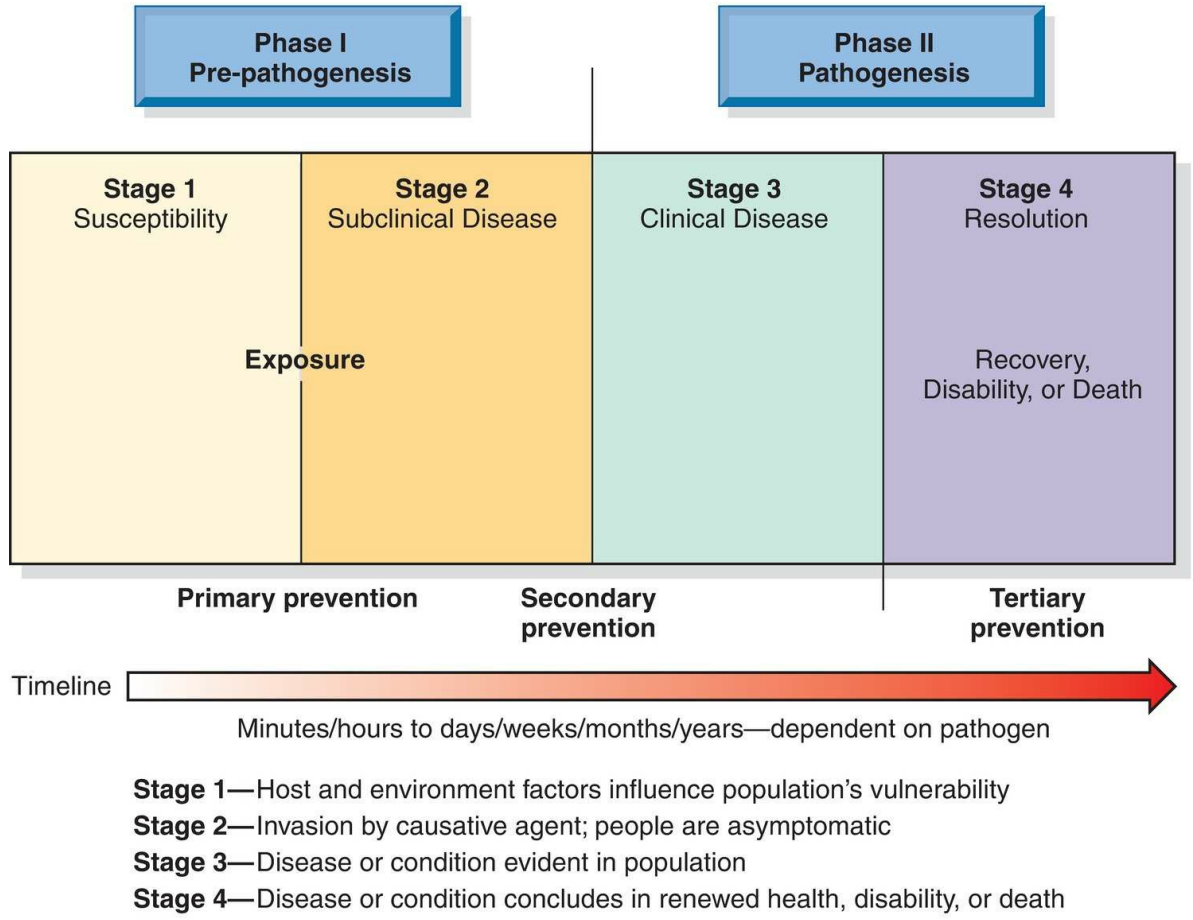

FIGURE 7–11 Natural history stages of a disease. (Adapted from Gerstman, B. B. (2013). Epidemiology kept simple: An introduction to traditional and modern epidemiology (3rd ed.). Hoboken, NJ: John Wiley & Sons Ltd.)

Susceptibility Stage

The first stage is *susceptibility*. During this state, the disease is not present and individuals have not been exposed. However, host and environmental factors could very likely influence people's susceptibility to a causative agent and lead to development of the disease. Infection occurs when a pathogen invades body cells and reproduces. Usually, infection leads to an immune response. If the immune system's response is effective, then the infection will be eliminated or contained and the disease will not occur (History of Vaccines, 2014).

Subclinical Disease Stage

The stage of *subclinical disease* begins when individuals have been exposed to a disease but are as yet asymptomatic. It is followed by an *incubation period*, during which the organism multiplies to sufficient numbers to produce a host reaction and clinical symptoms. Vulnerable children who have been exposed to chickenpox (varicella) but do not yet display signs of fever or lesions are in this stage. For diseases caused by infectious agents, the

incubation period is relatively short, hours to months. One noteworthy exception to this is infection with HIV, which has an incubation period of 1 to 3 months, with progression to AIDS (acquired immunodeficiency syndrome) from 1 to 15 years or longer (Heymann, 2014). In other conditions caused by noninfectious agents, the time from exposure to onset of symptoms, known as the *induction period* or *latency period*, is often years to decades. For example, children exposed to radiation may have a 5-year latency period for leukemia. Lung cancer caused by exposure to asbestos may have a latency period of up to 40 years between exposure and detection of the disease.

Clinical Disease Stage

During the *clinical disease stage,* signs and symptoms of the disease or condition develop. In the early phase of this period, the signs may be evident only through laboratory test findings, such as tubercular lesions on radiographs or premalignant cervical changes evident on Papanicolaou (Pap) smears. Later in this stage, acute symptoms are clearly visible, as in the case of widespread enterocolitis in a salmonellosis (food poisoning) outbreak. In this early clinical stage or early discernible lesions stage, evidence of the disease or condition is present and diagnosis occurs (Heymann, 2014).

Resolution Stage

In the *resolution stage,* the disease or health condition causes sufficient anatomic or functional changes to produce recognizable signs and symptoms. Disease severity may vary from mild to severe. The disease may conclude with a return to health, a residual or chronic form of the disease with some disabling limitations, or death. This can also be called the *advanced disease stage,* because the disease or condition has completed its course (Gerstman, 2013).

Community health nurses can intervene at any point during these four stages to delay, arrest, or prevent the progression of the disease or condition. Primary, secondary, and tertiary prevention can be applied to each of the stages (see Levels of Prevention Pyramid).

LEVELS OF PREVENTION PYRAMID

SITUATION: Apply the levels of prevention during the four stages of the natural history of a disease to eradicate or reduce risk factors (examples of possible conditions provided).

GOAL: Using the three levels of prevention negative health conditions are avoided,

or promptly diagnosed and treated, and the fullest possible potential is restored.

TERTIARY PREVENTION		
Rehabilitation	**Primary Prevention**	
	Health Promotion and Education	*Health Protection*
• Reduce the extent and severity of a health problem to minimize disability • Restore or preserve function	• Training for employment—homeless population • Group treatment and rehabilitation—adolescent drug users • Food, shelter, rest/sleep, exercise	• Health services • Immunizations as needed

SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
The third stage in the natural history of disease, the early pathogenesis or onset stage: • Screening programs—breast and testicular cancer, vision and hearing loss, hypertension, tuberculosis, diabetes	• Initiate prompt treatment • Arrest progression • Prevent associated disability

PRIMARY PREVENTION	
Health Promotion & Education	**Health Protection**
May include • Nutrition counseling—diabetes • Sex education—pregnancy • Smoking cessation—lung cancer	May include • Improved housing and sanitation—waterborne diseases • Immunizations—communicable diseases • Removal of environmental hazards—accidents

Epidemiology of Wellness

The public health science of epidemiology has traditionally studied the occurrence of disease and health problems. Because of their devastating effect on the health of populations, infectious diseases such as plague, cholera, and AIDS, as well as chronic illnesses such as heart disease or cancer, and fatal or debilitating injuries all require a continued epidemiologic focus. Nonetheless, the need to examine the epidemiology of wellness grows increasingly urgent, for if we continually examine and uncover new health promotion practices and encourage them, we can focus on wellness at the ideal primary level of prevention. See Chapter 11 on health promotion.

Epidemiology has moved from concentrating only on illness to examining how host, agent, and environment are involved in wellness at various levels. In response to an escalating need for improved methods of health planning and health policy analysis, epidemiology has developed more holistic models of health (Kiefer, 2015). These evolving epidemiologic models are organized around four attributes that influence health: (1) the physical, social, and psychological environment; (2) lifestyle with its self-created risks; (3) human biology and genetic influences; and (4) the system of health care organization. In the United States, *Healthy People 2020* (USDHHS, 2015) and greater recognition of the importance and cost-effectiveness of illness prevention and health promotion are driving new efforts to develop policy and research initiatives that can improve the public's health (see Display 7–2). There is also growing recognition of the collective impact of social determinants of health on health outcomes and conditions, not merely their individual role. Social determinants of health are "conditions in the environments in which people are born, live, play, worship, and age that affect a wide range of health, functioning, and quality of life outcomes and risks" (CDC, 2015e). Population disparities result when these social determinants disproportionately impact individuals owing to race/ethnicity, socioeconomic status, gender, age, disability status, sexual orientation, and geographic location (USDHHS, 2015, para. 6). See Chapters 15 and 25 for more on this.

Epidemiological Focus Objectives

Data and Information Systems

PHI-7—Increase the proportion of population-based Healthy People 2020

objectives for which national data are available for all major population groups

PHI-7.1—Increase the proportion of population-based Healthy People 2020 objectives for which national data are available by race and ethnicity

PHI-7.2—Increase the proportion of population-based Healthy People 2020 objectives for whichnational data are available by sex

PHI-7.3—Increase the proportion of population-based Healthy People 2020 objectives for which national data are available by socioeconomic status

PHI-8—Increase the proportion of Healthy People 2020 objectives that are tracked regularly at the national level

PHI-8.1—Increase the proportion of Healthy People 2020 objectives that have at least one data point

PHI-8.2—Increase the proportion of Healthy People 2020 objectives that have at least two data points

PHI-8.3—Increase the proportion of Healthy People 2020 objectives that are tracked at least every 3 years

PHI-9—(Developmental) Increase the proportion of Healthy People 2020 objectives for which national data are released within 1 year of the end of data collection

PHI-10—Increase the number of States that record vital events using the latest U.S. standard certificates and report

PHI-10.1—Increase the number of States that record vital events using the latest U.S. standard certificate of birth

PHI-10.2—Increase the number of States that record vital events using the latest U.S. standard certificate of death

PHI-10.3—Increase the number of States that record vital events using the latest U.S. standard report of fetal death

Public Health Organizations

PHI-11—Increase the proportion of Tribal and State public health agencies that provide or assure comprehensive laboratory services to support essential public health services

PHI-12—Increase the proportion of public health laboratory systems (including State, Tribal, and local) that perform at a high level of quality in support of the 10 Essential Public Health Services

PHI-13—Increase the proportion of Tribal, State, and local public health agencies that provide or assure comprehensive epidemiology services to support essential public health services

PHI-14—Increase the proportion of State and local public health jurisdictions that conduct a public health system assessment using national performance standards

PHI-15—Increase the proportion of Tribal, State, and local public health agencies that have developed a health improvement plan and increase the proportion of local health jurisdictions that have a health improvement plan linked with their State plan

PHI-16—Increase the proportion of Tribal, State, and local public health agencies that have implemented an agency-wide quality improvement process

PHI-17—Increase the number or proportion of Tribal, State and local public health agencies that are accredited

From U.S. Department of Health and Human Services. (2016). Healthy People 2020: Public health infrastructure. Retrieved from http://www.healthypeople.gov/2020/topics-objectives/topic/public-health-infrastructure/objectives?topicId=35

Wellness models that at first focused on individual behavior now include approaches that encompass aggregates. A variety of wellness models can be found for groups of seniors (see Chapter 24), in occupational health settings (see Chapter 31), at innovative schools where wellness programs for children and teens are initiated (see Chapter 22), and throughout the services provided for beginning and growing families (see Chapter 21). Programs designed for aggregates focus on a wellness approach to growth and development. Examples include programs for pregnant teens and for infant and child development (e.g., Healthy Start, Head Start) that are funded by state and federal monies. Societal changes, such as the aging population, the technological revolution, the global economy, environmental threats, health care reform with its focus on prevention, and the health and wellness movements, are driving these new approaches. See Chapter 12.

The four stages of the natural history of disease can apply to an understanding of any health condition, including wellness states. In stage one, *susceptibility*, people can become amenable to healthier practices and improved health system organization. In stage two, *subclinical*, a community can learn about these health-promoting behaviors. Stage three, *clinical disease stage*, could be a period of trying out the beneficial policies and activities, and stage four, *resolution*, could encompass full adoption and a higher level of well-being for the community. This approach has important implications for preventive and health-promotion practices in community health nursing.

Community health nursing can play a primary role in the investigation and identification of factors that not only prevent illness but also promote health. This means sharpening skills in epidemiologic research to uncover the factors that contribute to a full measure of healthful living. The time for an epidemiology of wellness has come.

Causal Relationships

One of the main challenges to epidemiology is to identify causal relationships in disease and health conditions among populations. As was previously suggested, the assessment of causality in human health is difficult at best; no single study is adequate to establish causality. Causal inference is based on consistent results obtained from many studies. Frequently, the accumulation of evidence begins with a clinical observation or an educated guess that a certain factor may be causally related to a health problem (Gordis, 2014).

A *cross-sectional study* (which explores a health condition's relation to other variables in a specified population at a specific point in time) can show that the factor and the problem coexist. For example, one classic study compared the incidence of gonorrhea in a 55-block area in urban New Orleans with a "broken window index," which measured housing quality, abandoned cars, graffiti, trash, and public school deterioration (Cohen et al., 2000). Broken windows theory is a symbol of lack of social control in neighborhoods and has been used to predict crime and social isolation (Aiyer, Zimmerman, Morrel-Samuels, & Reischl, 2015). The broken window index predicted the variance for gonorrhea rates more accurately than did a poverty index measuring income, unemployment, and low education.

A *retrospective study* (which looks backward in time to find a causal relationship) allows a fairly quick assessment of whether an association exists. Such studies use existing data that have been recorded for reasons other than research, and are generally less expensive and labor intensive. One disadvantage is that the data may not be collected with a research outcome in mind. An example of a short-term retrospective cohort study occurred with an outbreak of *Giardia* among members of a golfing club in Massachusetts. Cases had already begun to diminish before the health department became involved. They examined the facilities and found both an adult pool and a kiddie pool at the golfing club; best guess was that a child in could have contaminated the kiddie pool with *Giardia*-shedding stool. They questioned adults by asking if they spent any time in the kiddie pool, and this gave them the number of people exposed to the kiddie pool, along with the number of them who developed *Giardia*, versus the ones exposed to the adult pool and the number of them who developed *Giardia*. There were 9 additional cases per 100 people for those who used the kiddie pool than those who did not, and they calculated the risk ratio as 3.27 (Boston University School of Public Health, 2015).

A *prospective study* (which looks forward in time to find a causal relationship) is crucial to ensure that the presumed causal factor actually precedes the onset of the health problem. The prospective approach is concerned with current information and provides a direct measure of the variables in question. For example, in the Nurses' Health Study (Channing Laboratory, 2013) many prospective analyses of numerous risk factors that impact health were performed. Studies have found the following:

Alcohol: One or more drinks a day increases the risk of breast cancer; two or more drinks a day increase the risk of colon cancer; high consumption increases the risk of hip

fracture.

Diet: Higher intake of red meat increases the risk of premenopausal breast cancer and colon cancer. Mediterranean-type diets reduce risk of incident CHD and stroke. Refined carbohydrates and trans fats increase the risk of CHD. Higher vegetable intake (green leafy vegetables) reduces the risk of cognitive impairment.

Obesity: Increases the risk of breast cancer among postmenopausal women (postmenopause weight loss reduces the risk). A positive relationship was found between weight (BMI) and the risk of CHD and stroke. Weight gain after age 18 increases the risk of stroke and CHD; it also increases the risk of colon cancer, cataracts and age-related macular degeneration (AMD). It is protective against hip fracture owing to extra hip padding.

Oral Contraceptive Use: Current use increased the risk of breast cancer and CHD, and reduced the risk of colon cancer, hip fracture, and high-tension glaucoma, as well as "wet" AMD.

Physical Activity: >3 hours per week of physical activity reduces the risk of breast cancer, CHD, and stroke (walking), as well as colon cancer and risk of hip fracture (walking). Moderate physical activity reduces the risk of cognitive impairment.

Postmenopausal Hormones: With more than 5 years of estrogen plus progestins taken, the risk of breast cancer is increased. It is also increased with more than 10 years of estrogen alone. Current use increases the risk of stroke and reduces the risk of CHD among recently menopausal women. Reduced risk of colon cancer and of hip fracture and high-tension glaucoma and "wet" AMD was found for current users.

Smoking: Has a strong positive association with CHD and stroke, and the risk can be reduced within 2 to 4 years of smoking cessation. Smoking increases the risk of colon cancer, hip fracture, and cataracts, along with "wet" AMD.

Other factors: Family history of breast cancer, high breast density, high circulating hormone levels, and shift work all increased the risk of breast cancer. Snoring is associated with a modest but significant increased risk of CHD and stroke. Diabetes, as well as rotating night shifts, increased the risk of hip fracture, as well as the risk of glaucoma and cataracts. Type 2 diabetes and higher insulin levels in women without diabetes increases the risk of cognitive impairment. Positive family history and African heritage increases the risk of glaucoma (Channing Laboratory, 2013).

Studies such as these provide a mechanism to evaluate a variety of factors that precede the development of disease and then assess issues of association and ultimately causation.

Finally, if ethically possible, an *experimental study* (in which the investigator controls or changes factors suspected of causing the condition and observes results) is used to confirm the associations obtained from observational studies (in which the investigator merely observes data or people without controlling or changing any factors). It often requires many years to accumulate enough evidence to suggest a causal relationship. An example of this may be manufacturing plants that agree to participate in CHD prevention. One plant gets

the intervention—education and screening for CHD—and the other serves as a control with no intervention given. Years later, the incidence of CHD is measured and the numbers for the two groups are compared to determine if the intervention may have made a difference (BMJ Publishing Group, 2015).

Epidemiologically, a causal relationship may be said to exist if two major conditions are met: (a) the factor of interest (causal agent) is shown to increase the probability of occurrence of the disease or condition as observed in many studies in different populations, and (b) evidence suggests that a reduction in the factor decreases the frequency of the given disease. The synthesis of data begins by selecting as many of the various types of epidemiologic studies of the problem as possible. After those studies that are not methodologically sound are discarded, the studies are reviewed. The better the data meet the criteria outlined by Hill (discussed earlier), the more likely it is that the factor of interest is one of several causes of the disease (strength of association, consistency, specificity, time sequence, biologic gradient, plausibility, coherence, experiment, and analogy).

The goal of any epidemiologic investigation is to identify causal mechanisms that meet Hill's nine criteria for disease causation and to develop measures for preventing illness and promoting health (Gordis, 2014). The PHN may need to gather new data for this type of investigation, but pertinent existing data should be thoroughly examined first. This type of information can be obtained from a variety of sources, which are discussed in the next section.

SOURCES OF INFORMATION FOR EPIDEMIOLOGIC STUDY

Epidemiologic investigators may draw data from any of three major sources: existing data, informal investigations, and scientific studies. The public health nurse will find all three sources useful in efforts to improve the health of aggregates. See Chapter 15 on community assessment for more on sources of data.

Existing Data

A variety of information is available nationally, by state, and by section (e.g., county, region, census tract, metropolitan statistical area [MSA]). This information includes vital statistics, census data, and morbidity statistics on certain communicable or infectious diseases. Local health departments often can provide these data on request. Public health nurses seeking information on communities may find local health system agencies helpful. These agencies collect health information for groups of counties within states and interact with health planning authorities at the state level. They have access to many types of information and can give advice on specific problems. One newer source of data is social media. (See Population-Focus on Epidemiology and Social Media.)

Vital Statistics

Vital statistics refers to the information gathered from ongoing registration of births, deaths, adoptions, divorces, and marriages. Certification of births, deaths, and fetal deaths are the most useful vital statistics in epidemiologic studies. The community health nurse can obtain blank copies of a state's birth and death certificates to become familiar with the information contained in each (Displays 7–3 and 7–4). Much more information is recorded on the death certificate than the fact and cause of death on the death. Birth certificates also can provide helpful information (e.g., weight of the infant, amount of prenatal care received by the mother), which can be used to identify high-risk mothers and infants.

MEDICAL AND HEALTH INFORMATION

41. RISK FACTORS IN THIS PREGNANCY (Check all that apply)

Diabetes
☐ Prepregnancy (Diagnosis prior to this pregnancy)
☐ Gestational (Diagnosis in this pregnancy)

Hypertension
☐ Prepregnancy (Chronic)
☐ Gestational (PIH, preeclampsia)
☐ Eclampsia

☐ Previous preterm birth

☐ Other previous poor pregnancy outcome (Includes perinatal death, small-for-gestational age/intrauterine growth restricted birth)

☐ Pregnancy resulted from infertility treatment-If yes, check all that apply:
☐ Fertility-enhancing drugs, Artificial insemination or Intrauterine insemination
☐ Assisted reproductive technology (e.g., in vitro fertilization (IVF), gamete intrafallopian transfer (GIFT))

☐ Mother had a previous cesarean delivery
If yes, how many _____

☐ None of the above

42. INFECTIONS PRESENT AND/OR TREATED DURING THIS PREGNANCY (Check all that apply)
☐ Gonorrhea
☐ Syphilis
☐ Chlamydia
☐ Hepatitis B
☐ Hepatitis C
☐ None of the above

43. OBSTETRIC PROCEDURES (Check all that apply)
☐ Cervical cerclage
☐ Tocolysis

External cephalic version:
☐ Successful
☐ Failed

☐ None of the above

44. ONSET OF LABOR (Check all that apply)
☐ Premature Rupture of the Membranes (prolonged, ≥12 hrs.)
☐ Precipitous Labor (<3 hrs.)
☐ Prolonged Labor (≥ 20 hrs.)
☐ None of the above

45. CHARACTERISTICS OF LABOR AND DELIVERY (Check all that apply)
☐ Induction of labor
☐ Augmentation of labor
☐ Non-vertex presentation
☐ Steroids (glucocorticoids) for fetal lung maturation received by the mother prior to delivery
☐ Antibiotics received by the mother during labor
☐ Clinical chorioamnionitis diagnosed during labor or maternal temperature ≥38°C (100.4°F)
☐ Moderate/heavy meconium staining of the amniotic fluid
☐ Fetal intolerance of labor such that one or more of the following actions was taken: in-utero resuscitative measures, further fetal assessment, or operative delivery
☐ Epidural or spinal anesthesia during labor
☐ None of the above

46. METHOD OF DELIVERY

A. Was delivery with forceps attempted but unsuccessful?
☐ Yes ☐ No

B. Was delivery with vacuum extraction attempted but unsuccessful?
☐ Yes ☐ No

C. Fetal presentation at birth
☐ Cephalic
☐ Breech
☐ Other

D. Final route and method of delivery (Check one)
☐ Vaginal/Spontaneous
☐ Vaginal/Forceps
☐ Vaginal/Vacuum
☐ Cesarean
If cesarean, was a trial of labor attempted?
☐ Yes
☐ No

47. MATERNAL MORBIDITY (Check all that apply)
(Complications associated with labor and delivery)
☐ Maternal transfusion
☐ Third or fourth degree perineal laceration
☐ Ruptured uterus
☐ Unplanned hysterectomy
☐ Admission to intensive care unit
☐ Unplanned operating room procedure following delivery
☐ None of the above

NEWBORN

NEWBORN INFORMATION

48. NEWBORN MEDICAL RECORD NUMBER

49. BIRTHWEIGHT (grams preferred, specify unit)
_____ 9 grams 9 lb/oz

50. OBSTETRIC ESTIMATE OF GESTATION:
_____ (completed weeks)

51. APGAR SCORE:
Score at 5 minutes: _____
If 5 minute score is less than 6,
Score at 10 minutes: _____

52. PLURALITY - Single, Twin, Triplet, etc.
(Specify)_____

53. IF NOT SINGLE BIRTH - Born First, Second, Third, etc. (Specify) _____

54. ABNORMAL CONDITIONS OF THE NEWBORN (Check all that apply)
☐ Assisted ventilation required immediately following delivery
☐ Assisted ventilation required for more than six hours
☐ NICU admission
☐ Newborn given surfactant replacement therapy
☐ Antibiotics received by the newborn for suspected neonatal sepsis
☐ Seizure or serious neurologic dysfunction
☐ Significant birth injury (skeletal fracture(s), peripheral nerve injury, and/or soft tissue/solid organ hemorrhage which requires intervention)
9 None of the above

55. CONGENITAL ANOMALIES OF THE NEWBORN (Check all that apply)
☐ Anencephaly
☐ Meningomyelocele/Spina bifida
☐ Cyanotic congenital heart disease
☐ Congenital diaphragmatic hernia
☐ Omphalocele
☐ Gastroschisis
☐ Limb reduction defect (excluding congenital amputation and dwarfing syndromes)
☐ Cleft Lip with or without Cleft Palate
☐ Cleft Palate alone
☐ Down Syndrome
☐ Karyotype confirmed
☐ Karyotype pending
☐ Suspected chromosomal disorder
☐ Karyotype confirmed
☐ Karyotype pending
☐ Hypospadias
☐ None of the anomalies listed above

56. WAS INFANT TRANSFERRED WITHIN 24 HOURS OF DELIVERY? 9 Yes 9 No
IF YES, NAME OF FACILITY INFANT TRANSFERRED TO: _____

57. IS INFANT LIVING AT TIME OF REPORT?
☐ Yes ☐ No ☐ Infant transferred, status unknown

58. IS THE INFANT BEING BREASTFED AT DISCHARGE?
☐ Yes ☐ No

15. RACE—American Indian, Black, White, etc. (Specify)
16. DECEDENT'S EDUCATION (Specify only highest grade completed)
Elementary/Secondary (0-12) College (1-4 or 5+)

PARENTS
17. FATHER'S NAME (First, Middle, Last)
18. MOTHER'S NAME (First, Middle, Maiden Surname)

INFORMANT
19a. INFORMANT'S NAME (Type/Print)
19b. MAILING ADDRESS (Street and Number or Rural Route Number, City or Town, State, Zip Code)

DISPOSITION
20a. METHOD OF DISPOSITION: Burial Cremation Removal from State Donation Other (Specify)
20b. PLACE OF DISPOSITION (Name of cemetery, crematory, or other place)
20c. LOCATION—City or Town, State
21a. SIGNATURE OF FUNERAL SERVICE LICENSEE OR PERSON ACTING AS SUCH
21b. LICENSE NUMBER (of Licensee)
22. NAME AND ADDRESS OF FACILITY

SEE DEFINITION ON OTHER SIDE

PRONOUNCING PHYSICIAN ONLY
Complete items 23a-c only when certifying physician is not available at time of death to certify cause of death.
23a. To the best of my knowledge, death occurred at the time, date, and place stated. Signature and Title
23b. LICENSE NUMBER
23c. DATE SIGNED (Month, Day, Year)

ITEMS 24-26 MUST BE COMPLETED BY PERSON WHO PRONOUNCES DEATH
24. TIME OF DEATH M
25. DATE PRONOUNCED DEAD (Month, Day, Year)
26. WAS CASE REFERRED TO MEDICAL EXAMINER/CORONER? (Yes or no)

CAUSE OF DEATH
27. PART I. Enter the diseases, injuries, or complications that caused the death. Do not enter the mode of dying, such as cardiac or respiratory arrest, shock, or heart failure. List only one cause on each line.
Approximate Interval Between Onset and Death
IMMEDIATE CAUSE (Final disease or condition resulting in death)
a. DUE TO (OR AS A CONSEQUENCE OF):
Sequentially list conditions, if any, leading to immediate cause. Enter UNDERLYING CAUSE (Disease or injury that initiated events resulting in death) LAST
b. DUE TO (OR AS A CONSEQUENCE OF):
c. DUE TO (OR AS A CONSEQUENCE OF):
d.

SEE INSTRUCTIONS ON OTHER SIDE

PART II. Other significant conditions contributing to death but not resulting in the underlying cause given in Part I.
28a. WAS AN AUTOPSY PERFORMED? (Yes or no)
28b. WERE AUTOPSY FINDINGS AVAILABLE PRIOR TO COMPLETION OF CAUSE OF DEATH? (Yes or no)

29. MANNER OF DEATH: Natural Accident Suicide Homicide Pending Investigation Could not be Determined
30a. DATE OF INJURY (Month, Day, Year)
30b. TIME OF INJURY M
30c. INJURY AT WORK? (Yes or no)
30d. DESCRIBE HOW INJURY OCCURRED
30e. PLACE OF INJURY—At home, farm, street, factory, office building, etc. (Specify)
30f. LOCATION (Street and Number or Rural Route Number, City or Town, State)

SEE DEFINITION ON OTHER SIDE

CERTIFIER
31a. CERTIFIER (Check only one)
CERTIFYING PHYSICIAN (Physician certifying cause of death when another physician has pronounced death and completed Item 23)
To the best of my knowledge, death occurred due to the cause(s) and manner as stated.
PRONOUNCING AND CERTIFYING PHYSICIAN (Physician both pronouncing death and certifying to cause of death)
To the best of my knowledge, death occurred at the time, date, and place, and due to the cause(s) and manner as stated.
MEDICAL EXAMINER/CORONER
On the basis of examination and/or investigation, in my opinion, death occurred at the time, date, and place, and due to the cause(s) and manner as stated.
31b. SIGNATURE AND TITLE OF CERTIFIER
31c. LICENSE NUMBER
31d. DATE SIGNED (Month, Day, Year)

32. NAME AND ADDRESS OF PERSON WHO COMPLETED CAUSE OF DEATH (ITEM 27) (Type/Print)

REGISTRAR
33. REGISTRAR'S SIGNATURE
34. DATE FILED (Month, Day, Year)

DEPARTMENT OF HEALTH AND HUMAN SERVICES — PUBLIC HEALTH SERVICE — NATIONAL CENTER FOR HEALTH STATISTICS — 1989 REVISION

Retrieved from http://www.cdc.gov/nchs/data/dvs/death11-03final-acc.pdf

Sources for vital statistical information include state Web sites, local and state health departments, city halls, and county halls of records (see list of Internet resources on *thePoint*). Statistics regarding general aggregate morbidity and mortality for specific states are available from the Centers for Disease Control and Prevention (CDC) at the national level (National Center for Health Statistics [NCHS]). State statistics are obtained from

state health departments, and county information (specific cities or census tracts) can be obtained from either the state or the county health department.

Census Data

Data from population censuses taken every 10 years in many countries are the main source of population statistics. This information can be a valuable assessment tool for the PHN who is taking part in health planning for aggregates. Population statistics can be analyzed by age, sex, race, ethnic background, type of occupation, income gradient, marital status, educational level, or other standards, such as housing quality. Analysis of population statistics can provide the community health nurse with a better understanding of the community and help identify specific areas that may warrant further epidemiologic investigation. Data from the 2010 Census can be found on the U.S. Census Bureau Web site, and is an easily accessed source of population-level data.

Reportable Diseases

Each state has developed laws or regulations that require health organizations and practitioners to report to their local health authority cases of certain communicable and infectious diseases that can be spread through the community (Heymann, 2014). This reporting enables the health department to take the most appropriate and efficient action, for instance, in the case of food-borne illnesses. All states require that diseases subject to international quarantine regulations be reported immediately. However, many of these diseases (e.g., plague, cholera, yellow fever, polio) are virtually unknown now in developed countries (WHO, 2015). Health care professionals have not had experience identifying another reportable disease, smallpox, because no cases have been reported since 1977 (CDC, 2007; Scheibner, 2012). In 1980, the World Health Organization (WHO) declared the global eradication of smallpox after more than 10 years of international effort. (Chapter 17 discusses the concern over the use of smallpox as a bioterrorism threat.)

The World Health Organization (2007) has numerous other diseases under surveillance (e.g., tuberculosis, malaria, viral influenza), and these must also be reported. The World Health Organization's *International Health Regulations* (2nd ed.), published in 2005, remains in effect. Review efforts are under way to determine whether or not these regulations need updating. A review committee is set to finalize its work in Geneva in May 2016. If it is determined that updating is needed, it will take several years to complete a revised document (Hofmann, T. D., *personal communication*, November 24, 2015).

Other reportable diseases (numbering between 20 and 40 in each state) are usually classified according to the speed with which the health department should be notified. Some should be reported by phone or e-mail, others weekly by regular mail. They vary in potential severity from varicella (chickenpox) to rabies and include AIDS, encephalitis, measles, meningitis, pertussis (whooping cough), syphilis, and toxic shock syndrome (MedlinePlus, 2013). Community health nurses should obtain the list of reportable diseases

from their local or state health department office. Following up on occurrences of these diseases is a task frequently assigned to public health nurses working for local health departments. Chapter 8 includes an example of a Confidential Morbidity Report (CMR) used to report and track communicable diseases at the local, regional, and national levels.

Disease Registries

Some areas or states have disease registries or rosters for conditions with major public health impact. Tuberculosis and rheumatic fever registries were more common when these diseases occurred more frequently. Cancer registries provide useful incidence, prevalence, and survival data, and assist the community health nurse in monitoring cancer patterns within a community. Community health nurses can access these registries through state health department Web sites.

At the federal level, the Agency for Toxic Substances and Disease Registry (ATSDR, 2014) maintains four registries of major public concern: the World Trade Center Health Registry (comprehensive and confidential health survey of those directly exposed to fallout and debris on September 11, 2001), the National Amyotrophic Lateral Sclerosis (ALS) Registry (population-based registry to assist scientists in the study of this disease), the Katrina and Rita Exposures Registry (KARE; monitors people who lived in trailers provided by federal agencies after hurricanes Katrina and Rita), and the Rapid Response Registry (collects and shares information with state, local, and federal public health and disaster response agencies regarding exposures or potential exposures to harmful substances during catastrophic events).

Also at the federal level, the Surveillance, Epidemiology, and End Results (SEER) Program of the National Cancer Institute collects and publishes cancer incidence and survival data from population-based cancer registries that cover a portion of the U.S. population (National Cancer Institute, n.d.).

Surveillance Systems

The Centers for Disease Control and Prevention (CDC) maintains various surveillance systems to monitor diseases so it can develop and evaluate control strategies. The data from its two most popular systems are used by public health entities to determine which populations are most affected, and to evaluate the effectiveness of interventions to address disease entities, many of which are chronic in nature.

The Behavioral Risk Factor Surveillance System (BRFSS) conducts an ongoing state-based telephone survey of the civilian, noninstitutional adult population. The survey ascertains the prevalence of high-risk behaviors, such as excessive alcohol consumption, cigarette smoking, physical inactivity and lack of preventive health care, such as screening for cancer. Results are published on a periodic basis in the Mortality and Morbidity Weekly Report (MMWR)'s CDC Surveillance Summaries, and are available online at http://www.cdc.gov/brfss/

The Youth Risk Behavior Surveillance System (YRBSS) monitors six categories of priority health-risk behaviors in young adults, as well as the prevalence of obesity and asthma with the use of the national Youth Risk Behavior Survey (YRBS). The survey is conducted every 2 years with 9th to 12th grade students in public and private schools. The survey includes questions about unintentional injuries and violence, tobacco use, alcohol and other drug use, sexual behaviors that contribute to unintended pregnancy and STDs, unhealthy dietary behaviors, and physical inactivity. Results are available online at http://www.cdc.gov/healthyyouth/data/yrbs/index.htm (McKenzie et al., 2012).

Environmental Monitoring

State governments, through health departments or other agencies, now monitor health hazards found in the environment. Pesticides, industrial wastes, radioactive or nuclear materials, chemical additives in foods, and medicinal drugs have joined the list of pollutants (see Chapter 9 for a detailed discussion). Concerned community members and leaders view these as risk factors that affect health at both community and individual levels. Public health nurses can also obtain data from federal agencies such as the Food and Drug Administration (FDA), the Consumer Product Safety Commission, the Environmental Protection Agency (EPA), and, as previously mentioned, the ATSDR.

National Center for Health Statistics Health Surveys

The National Center for Health Statistics (NCHS) furnishes valuable health prevalence data from surveys of Americans. Published data are also frequently available for regions. Examples are as follows:

- The National Health Interview Survey (formerly known as National Health Survey) was established by Congress in 1956, and provides a continual source of information about the health status and needs of the entire nation. The National Health Interview Survey includes interviews from approximately 43,000 households each year and provides information about the health status and needs of the entire country (NCHS, 2015a).
- The National Nursing Home Survey primarily samples institutional records of hospitals and nursing homes; it provides information on those who are using these services, along with diagnoses and other characteristics (NCHS, 2015b).
- The National Health and Nutrition Examination Survey (NHANES) reports physical measurements on smaller samples of the population and augments the information provided by interviews. It also provides prevalence information on injuries, diseases, and disabilities that appear frequently in the population (NCHS, 2015b).
- The National Survey of Family Growth (NSFG) focuses on fertility and family planning as well as other aspects of family health (NCHS, 2015b).

Other studies investigate vital statistics events and characteristics of ambulatory patients in physicians' community practices. Each of these nationally sponsored efforts suggest ways in which community health nurses can examine health problems or concerns affecting their communities (see From the Case Files). Interviews, physical examinations of subsets of community members, and surveillance of institutions, clinics, and private physicians' practices can be carried out locally after needs are identified and funds made available. Other sources may be found in data kept routinely, but not centrally, on the health problems of workers in local industries or the health problems of schoolchildren; a key issue for many community health nurses. Existing epidemiologic data can be used to plan parent education programs, health promotion among students, and almost any other type of service.

From the Case Files I

Public health nurses working for a local or county health department will find themselves more involved with program planning than direct patient care. Many times they will be asked to help develop a health education program based on what is affecting the community the most. Many times the health department is limited by budgetary constraints or the reporting requirements of grant funders.

Let's say your health department has been given the opportunity to apply for funding from three sponsoring organizations. The choices are to develop public health education programs about alcohol consumption, smoking cessation, and community HIV testing. In an upcoming department meeting you are asked to make a case for and against for applying for the funding of each of these programs.

In preparing for this presentation, what specific types of data would you recommend to the department? What would be the sources of this data? Are those sources from local, state, or national resources? How could Healthy People 2020 help frame this presentation?

POPULATION-FOCUS ON EPIDEMIOLOGY AND SOCIAL MEDIA

Most of us use some form of social media daily. But, did you know that epidemiologists and PHNs have used Twitter and Yelp in food-borne illness investigations? Traditionally, most investigations begin with either a physician report to the local health department or a self-report called in by someone who became ill after eating out at a restaurant or a food truck. But, two large progressive health departments found ways to utilize social media to assist them in these epidemiological investigations.

In Chicago, the health department and civic partners established a Web site, FoodBorne Chicago (https://www.foodbornechicago.org), to more quickly identify and respond to complaints on Twitter about possible signs and symptoms of food-borne illness. An algorithm was used to identify tweets that would later be reviewed by staff members (e.g., diarrhea, vomiting, stomach cramps after ingesting food prepared outside homes). Replies to identified tweets were made by staff members, inviting Twitter users to report the illness and giving them the Web site link. Submitted forms from the Web site went to the city's 311 system. Over a 10-month period, 270 tweets complained of symptoms related to food-borne illness, and 3% noted visits to the emergency room or a physician as a result. Web site complaints totaled 193, but the number of those originating from Twitter could not be identified. Almost 9% of these sought medical care. All of the complaints identified a total of 179 restaurants, and 133 locations had unannounced health inspection visits. This represented 6.9% of all food establishment health inspections due to complaints during that time. Almost 92% of the 133 inspections led to at least one violation; this is similar to rates of the other inspections during the study period. However, 20.3% of the inspections prompted by the study had a minimum of one critical violation (high-risk or immediate hazard) versus 16.4% for the other inspections. A total of 21 restaurants were closed after failing FoodBorne Chicago inspections, and 33 with critical violations corrected them and were cleared on later inspections. Thirty tweets were linked directly to a "corresponding complaint" by clicking on "reply tweet" to fill in the form (p. 684). FoodBorne Chicago has made their open-source software available on GitHub, and is working with both New York City and Boston on adapting their program for use in these cities.

Harris, J. K., Mansour, R., Choucair, B., Olson, J., Nissin, C., & Bhatt, J. (2014). Health department use of social media to identify foodborne illness: Chicago, Illinois, 2013–2014. Morbidity and Mortality Weekly Report, 63(32), 681–685.

In New York City, health department staff noticed patron reports of illness after eating at the same restaurant they were investigating for a recent gastrointestinal disease outbreak; most of these had not been reported to the health department. Thinking that this might be a reliable source for population-based investigation into food-borne illnesses, the New York City Department of Health and Mental Hygiene worked with Yelp to use data mining software to download weekly data that met the following criteria: (a) symptoms occurred after a meal, (b) symptoms occurred within 4 weeks of the posted review, and (c) two or more people became ill (or one person with symptoms of severe neurologic illness). Of about 294,000 reviews, 468 were identified as possibly meeting the criteria for a recent illness, after an epidemiologist specializing in food-borne illness reviewed 893 potential postings. Messages were sent through Yelp that the reviewers contact the health department for a telephone interview. Ultimately, 27 out of 129 accepted the request, and 3 outbreaks causing 16 illnesses were discovered. The food in question included shrimp and lobster cannelloni, a house salad, and macaroni and cheese spring rolls from three different restaurants. These establishments were inspected, and multiple violations were found. Although the city has a 311 service for reporting nonemergencies to city agencies, most reviewers who were informed of this service did not know about it (78%). The 311 system identifies outbreaks in about 1% of reported cases, whereas the Yelp reviews netted 3% in this pilot project. Daily review feeds are now being provided by Yelp, and the health department is investigating links to other review sites and multiple complaints to a particular restaurant in an effort to get better data and resolve violations more quickly.Harrison, C., Jorder, M., Stern, H., Stravinsky, F., Reddy, V., Hanson, H., … Balter, S. (2014). Using online reviews by restaurant patrons to identify unreported cases of foodborne illness: New York City, 2012–2013. Morbidity and Mortality Weekly Report, 63(20), 441–446.

Centers for Disease Control and Prevention Reports

The CDC issues the *Mortality and Morbidity Weekly Report (MMWR)*. This publication presents weekly summaries of disease and death data trends for the nation. It includes reports on outbreaks or occurrences of diseases in specific regions of the country and international trends in disease occurrences that may affect the U.S. population. Most health departments subscribe to this publication, which provides important information both for epidemiologists and PHNs. It is also available free online from the CDC at http://www.cdc.gov/mmwr/index.html

The CDC also provides administrative, research, and technical support for the Community Preventive Services Task Force, which maintains the "Guide to Community Preventive Services" Web site. This Web site houses the official collection of all the CPSTF findings and the systematic reviews upon which they are based. It is offered as a free resource to help public health nurses and other public health professionals choose programs and policies to improve health and prevent disease within the communities with whom they work (Community Preventive Services Task Force, 2015).

For example, before a public health education program is developed to address a community health problem, program planners can access the Web site to review programs that have already been developed to address a similar issue and have been evaluated for program effectiveness. Such a literature review can form a more scientific foundation for developing new programs that may address a similar problem but with a different target population. This can reduce trial and error efforts that may not be cost-effective, given the limited funding that may be available for program development. Currently available topics include "Adolescent Health, Alcohol—Excessive Consumption, Asthma, Birth Defects, Cancer, Cardiovascular Disease, Diabetes, Emergency Preparedness, Health

Communication, Health Equity, HIV/AIDS, STDs/STIs, Pregnancy, Mental Health, Motor Vehicle Injury, Nutrition, Obesity, Oral Health, Physical Activity, Social Environment, Tobacco, Vaccination, and Violence and Worksite" (Community Preventive Services Task Force, 2015, para. 1).

Informal Observational Studies

A second information source in epidemiologic study is informal observation and description. Almost any client group encountered by the community health nurse can trigger such a study. If, for example, the nurse encounters an abused child at a clinic, a study of the clinic's records to screen for additional possible instances of child abuse and neglect could lead to more case finding. If several cases of diabetes come to the attention of a nurse serving on a Navajo reservation, a widespread problem might come to light through informal inquiries about the incidence and age at onset of the disease among this Native American population. Informal observational study often raises questions and suggests hypotheses that form the basis for designing larger-scale epidemiologic investigations.

Scientific Studies

The third source of information used in epidemiologic inquiry involves carefully designed scientific studies. The nursing profession has recognized the need to develop a systematic body of knowledge upon which to base nursing practice. Systematic research is becoming an accepted part of the community health nurse's role. Findings from epidemiologic studies conducted by or involving nurses are appearing more frequently in the literature. The Cochrane Database of Systematic Reviews (CDSR) is the most popular resource for systematic reviews in health care and includes a section on public health. Its Web site is searchable by topic or Cochrane Review Group. Additionally, the Web site includes reviews, methods studies, technology assessments, and economic evaluations (Wiley Online Library, 2015). Systematic reviews can routinely be found in many professional journals and the aforementioned Community Guide. Systematic studies, as well as informal studies and existing epidemiologic data, can provide the community health nurse with valuable information that can be used to positively affect aggregate health.

METHODS IN THE EPIDEMIOLOGIC INVESTIGATIVE PROCESS

The goals of epidemiologic investigation are to identify the causal mechanisms of health and illness states and to develop measures for preventing illness and promoting health. Epidemiologists employ an investigative process that involves a sequence of three approaches that build on one another: descriptive, analytic, and experimental studies. All three approaches have relevance for community health nursing (see Chapter 4 for a more detailed description).

Descriptive Epidemiology

Descriptive epidemiology includes investigations that seek to observe and describe patterns of health-related conditions that occur naturally in a population. For example, a community health nurse might seek to learn how many children in a school district have been immunized for measles, how many home births occur each year in the county, how many cases of STDs have occurred in the city in the past month, or how many automobile crashes have occurred near the community high school. At this stage in the epidemiologic investigation, the researcher seeks to establish the occurrence of a problem. Data from descriptive studies suggest hypotheses for further testing. Descriptive studies almost always involve some form of broad-based quantification and statistical analysis (Gordis, 2014). An example of a descriptive epidemiological study looked at work organization, physical and mental health, and quality of life among a population of Hispanic female farm workers in North Carolina (Arcury, Grzywacz, Chen, Mora, & Quandt, 2014). This cross-sectional study surveyed 319 female farm workers over a 2-year period, and found that heavier job demands (e.g., increased psychological demands, heavier loads, awkward posture) were correlated with higher depressive and musculoskeletal symptoms. When workers had little job control or were lower skilled, these symptoms were higher. If there was a safety climate and greater support from supervisors, fewer depressive symptoms were found. Chapter 29 has more on migrant health.

Counts

The simplest measure of description is a count. For example, an epidemiologic study to assess the impact of the routine 2-dose varicella vaccination program on death due to the disease used the National Vital Statistics System data for 2008–2011, the first years of the routine 2-dose varicella vaccination program, and characteristics of varicella deaths reported to CDC during 1996–2013, using the 2008–2011 Mortality Multiple Cause-of Death records. Calculated rates were used to compare the prevaccine and mature 1-dose varicella vaccination program eras. Findings include an 87% reduction from the prevaccine years, with an annual average age-adjusted mortality rate for varicella as the underlying cause to be 0.05 per million population during 2008–2011. Varicella deaths among persons aged <20 years declined by 99% in 2008–2011 when compared with prevaccine years, and a 70% decline when compared to 2005–2007. Of the 83 deaths reported to the CDC, 24 (29%) were among those who were immunocompromised. Authors concluded that the vaccine program significantly reduced varicella disease burden (Leung, Bialek, & Marin, 2015).

Obtaining a count of this type always depends on the definition of what is being counted and when it was counted. This particular count, for example, utilizes a large database that takes time to be made public and therefore may not provide a current picture of actual deaths. Use of this type of data should always consider the time delay involved. If a community health nurse needs more current information within a specific community or

state, hospital records or death certificates may be another source. However, before making use of any statistics, whether from official state offices, the Census Bureau, or a health agency, it is necessary to determine what the information represents.

Rates

Rates are statistical measures expressing the proportion of people with a given health problem among a population at risk. The total number of people in the group serves as the denominator for various types of rates. To express a count as a proportion, or rate, the population to be studied must first be identified. For instance, total West Nile virus fatalities in the United States for 2011 were 43 out of 690 confirmed infections (CDC, 2015f). If those deaths are considered in relation to the total number of cases in the country, there will be one rate; if, however, those fatalities are considered in relation to the total population, there will be a quite different rate. It is important when reviewing rates that you understand which measures are being compared.

In epidemiology, the population represents the universe of people defined as the objects of a study. Because it is often difficult, if not impossible, to study an entire population, most epidemiologic studies draw a sample to represent that group. Sometimes, it is important to seek a random sample (in which everyone in the population has an equal chance of selection for study and choice is made without bias). At other times, a sample of convenience (in which study subjects are selected because of their availability) is sufficient. In many small epidemiologic studies, it may be possible to study almost every person in the population, eliminating the need for a sample. Several rates have wide use in epidemiology (Gordis, 2014). Those most important for the public health nurse to understand are the prevalence rate, the period prevalence rate, and the incidence rate.

Prevalence

Prevalence refers to all of the people with a particular health condition existing in a given population at a given point in time. The *prevalence rate* describes a situation at a specific point in time (McKenzie et al., 2012). If a nurse discovers 50 cases of measles in an elementary school, that is a simple count. When this number is divided by the total number of students in the school, the result is the prevalence of measles. For instance, if the school has 500 students, the prevalence of measles on that day would be 10% (50 measles/500 population).

$$\text{Prevalence rate} = \frac{\text{Number of persons with a characteristic}}{\text{Total number in population}}$$

The prevalence rate over a defined period of time is called a *period prevalence rate*:

$$\text{Period prevalence rate} = \frac{\text{Number of persons with a characteristic during a period of time}}{\text{Total number in population}}$$

Incidence

Not everyone in a population is at risk for developing a disease, incurring an injury, or having some other health-related characteristic. The *incidence rate* recognizes this fact. Incidence refers to all new cases of a disease or health condition appearing during a given time. Incidence rate describes a proportion in which the numerator is all new cases appearing during a given period of time and the denominator is the population at risk during the same period (Gordis, 2014). For example, some childhood diseases give lifelong immunity. The school children having had such diseases would be removed from the total number of children at risk in the school population. Three weeks after the start of a measles epidemic in a school, the incidence rate describes the number of cases of measles appearing during that period in terms of the number of persons at risk:

$$\frac{200}{1{,}000} \text{ or } \frac{200 \text{ new cases}}{1{,}000 \text{ persons at risk}}$$

The health literature is not always consistent in the use of the term *incidence;* sometimes, this word is used synonymously with *prevalence rates,* and the reader must take this into consideration.

$$\text{Incidence rate} = \frac{\text{Number of persons developing a disease}}{\text{Total number at risk per unit of time}}$$

Another rate that describes incidence is the attack rate. An *attack rate* describes the proportion of a group or population that develops a disease among all those exposed to a particular risk. This term is used frequently in investigations of outbreaks of infectious diseases such as influenza. If the attack rate changes, it may suggest an alteration in the population's immune status or that the disease-causing organism is present in a more or less virulent strain (Gordis, 2014).

Computing Rates

To make comparisons between populations, epidemiologists often use a common base population in computing rates. For example, instead of merely saying that the rate of an illness is 13% in one city and 25% in another, the comparison is made per 100,000 people in the population. This population base can vary for different purposes from 100 to 100,000. To describe the morbidity rate, which is the relative incidence of disease in a population, the ratio of the number of sick individuals to the total population is determined. The mortality rate refers to the relative death rate, or the sum of deaths in a given population at a given time (Gordis, 2014). Display 7–5 includes formulas for computing rates commonly used in community health.

DISPLAY 7.5 COMMON EPIDEMIOLOGIC RATES

General Mortality Rates

$$\text{Crude Mortality Rate} = \frac{\text{Number of Reported Deaths During 1 Year}}{\text{Estimated Population as of July 1 of Same Year}} \times 100{,}000$$

$$\text{Cause-Specific Mortality Rate} = \frac{\text{Number of Deaths From a Stand Cause During 1 Year}}{\text{Estimated Population as of July 1 of Same Year}} \times 100{,}000$$

$$\text{Case Fatality Rate} = \frac{\text{Number of Deaths From a Particular Disease}}{\text{Total Number With the Same Disease}} \times 100$$

$$\text{Proportional Mortality Ratio} = \frac{\text{Number of Deaths From a Specific Cause Within a Given Time Period}}{\text{Total Deaths in the Same Time Period}} \times 100$$

$$\text{Age-Specific Mortality Rate} = \frac{\text{Number of Persons in a Specific Age Group Dying During 1 Year}}{\text{Estimated Population of the Specific Age Group as of July 1 of Same Year}} \times 100{,}000$$

Specific Rates for Maternal and Infant Populations

$$\text{Crude Birth Rate} = \frac{\text{Number of Live Births During 1 Year}}{\text{Estimated Population as of July of Same Year}} \times 1{,}000$$

$$\text{General Fertility Rate} = \frac{\text{Number of Live Births During 1 Year}}{\text{Number of Females Aged 15 44 as of July of Same Year}} \times 1{,}000$$

$$\text{Maternal Mortality Rate} = \frac{\text{Number of Deaths From Pureperal Causes During 1 Year}}{\text{Number of Live Births During Same Year}} \times 100{,}000$$

$$\text{Infant Mortality Rate} = \frac{\text{Number of Deaths Under 1 Year of Age for Given Year}}{\text{Number of Live Births Reported for Same Year}} \times 1{,}000$$

$$\text{Perinatal Mortality Rate} = \frac{\text{Number of Fetal Deaths Plus Infant Deaths Under 7 Days of Age During 1 Year}}{\text{Number of Live Births Plus Fetal Deaths During Same Year}} \times 1{,}000$$

The goal of descriptive studies is to identify the patterns of occurrence of any health-related condition. They can be *retrospective* (identify cases and controls, then go back to review existing data) or *prospective* (identify groups and exposure factors, and then follow

them forward in time). In a descriptive study of child abuse, for example, the investigator would note the age, gender, race or ethnic group, and physical and emotional conditions of the children affected. In addition, data would be collected that described the economic status and occupation of parents, the location and setting of abusive behavior, and the time and season of the year when abuse occurred. In the retrospective study on reported varicella deaths, the investigators described the age, sex, ethnic background, and birthplace of victims and other information. Describing facets of these deaths provides information for further study and suggests avenues for intervention or prevention.

Analytic Epidemiology

A second type of investigation, *analytic epidemiology*, goes beyond simple description or observation and seeks to identify associations between a particular human disease or health problem and its possible causes. Analytic studies tend to be more specific than descriptive studies in their focus. They test hypotheses or seek to answer specific questions and can be retrospective or prospective in design (Merrill, 2013). Analytic studies fall into three types: prevalence studies, case–control studies, and cohort studies.

Prevalence Studies

When examining prevalence, it is helpful to remember that the health condition may be new or may have affected some people for many years. A *prevalence study* describes patterns of occurrence, as in the study of varicella-related deaths. It may examine causal factors, but a prevalence study always looks at factors from the same point in time and in the same population. Hypothesized causal factors are based on inferences from a single examination and most likely need further testing for validation (Fletcher & Fletcher, 2012; Merrill, 2013).

Case–Control Studies

A *case–control study* compares people who have a health or illness condition (number of cases with the condition) with those who lack this condition (controls). These studies begin with the cases and look back over time (retrospectively) for presence or absence of the suspected causal factor in both cases and controls (Merrill, 2013). In a case–control study, researchers explored if exposure to endocrine-disrupting chemicals and carcinogens in occupational environments increases breast cancer risk. Comparison was made between 1,005 breast cancer cases referred by a regional cancer center and 1,146 randomly selected community controls. The study found that across all sectors, women in jobs with potentially high exposures to endocrine disruptors and carcinogens had an elevated breast cancer risk (OR = 1.42 for 10 years of exposure direction). The risk varied by occupational environment, and premenopausal breast cancer risk was highest for automotive plastics (OR = 4.76) and food canning (OR = 5.70) (Brophy et al., 2012).

Cohort Studies

A *cohort* is a group of people who share a common experience in a specific time period. Examples are a group of the elderly or the employees of an industry. In epidemiology, a cohort of people often becomes a focus of study. Cohort studies, rather than measuring the relationship of variables in existing conditions, study the development of a condition over time. A cohort study begins by selecting a group of people who display certain defined characteristics before the onset of the condition being investigated (Gordis, 2014). In studying a disease, the cohort might include individuals who are initially free of the disease

but were known to have been exposed to a particular factor. They would be observed over time to evaluate which variables were associated with the development or nondevelopment of the disease. These types of studies are often utilized with environmental hazard exposures, as with the Health Registry and the National Toxic Substance Incidents Program discussed earlier (ATSDR, 2014). These sources of data provide the capability to conduct a cohort study on postexposure disease development and enable those affected to access the most current information on their exposure risks.

In 1993, the Women's Health Study, a 10-year national longitudinal, experimental, cohort study involving nearly 40,000 female health professionals was initiated (National Institutes of Health, 2012). Sponsored by the National Heart, Lung, and Blood Institute and the National Cancer Institute, it consisted of a randomized trial evaluating the benefits and risks of low-dose aspirin and vitamin E in the prevention of cancer and cardiovascular disease. Depending on the random assignment of the women, participants took 100 mg of aspirin or placebo and 600 IU of vitamin E or placebo every other day. This was a double-blind study: neither the participants nor the researchers knew which subjects were taking the study drugs or placebos. The study was funded through 2009 to provide observational follow-up of study participants. The study findings were that women over age 65 might benefit from low-dose aspirin to prevent strokes. The aspirin regimen was not effective in preventing a first heart attack or death from cardiovascular causes. With respect to cardiovascular health and vitamin E, there was no demonstrated benefit or risk.

In practice, the various types of studies just discussed are frequently mixed. A case–control study may include description and analysis with a retrospective focus; a cohort study may be conducted prospectively or retrospectively. The Women's Health Study is an example of a case–control study, a cohort study, and an experimental study. Flexibility is essential to allow the investigator as much freedom as possible in choosing the most useful methodology.

Experimental Epidemiology

Experimental epidemiology follows and builds on information gathered from descriptive and analytic approaches. In an experimental study, the investigator actually controls or changes the factors suspected of causing the health condition under study and then observes what happens to the health state (Merrill, 2013). In human populations, experimental studies should focus on disease prevention or health promotion rather than testing the causes of disease, which is done primarily on animals.

Experimental studies are carried out under carefully controlled conditions, and must be approved by an Institutional Review Board (IRB). The investigator exposes an experimental group to some factor thought to cause disease, improve health, prevent disease, or influence health in some way (as in the Women's Health Study). Simultaneously, the investigator observes a control group that is similar in characteristics to the experimental group but without the exposure factor. See Chapter 4 for more on experimental research studies.

The public health nurse should be alert for opportunities to conduct experimental studies in the course of working with groups. A study need not be elaborate to provide important data for future nursing practice. For example, a community health nurse can provide focused instruction to 20 new mothers encouraging them to breast-feed and then compare the health of their infants with infants of 20 mothers in the same service area who use formula.

A nurse can look at the number of automobile crashes at an intersection having a traffic light compared with a similar intersection that has stop signs. Based on the results of the investigation, the nurse may bring the information to the city council and petition for a traffic light at the intersection. Study results can be used to bring about change in the community and are not limited to communicable or chronic diseases. Improving community safety is also an essential outcome.

An expanding area of experimental epidemiology involves the use of computers to simulate epidemics. With mathematical models, it is possible to determine the probabilities of various aspects of disease occurrence (Honner, 2014; Yang et al., 2015). This approach is making an increased contribution to epidemiologists' knowledge of etiology and prevention.

Occasionally, an experiment occurs naturally, thus affording the researcher a chance to make important discoveries. John Snow discovered such a "natural experiment" in London in 1854 (as discussed earlier in the chapter). In his seminal study of an epidemic of cholera, he observed one group that contracted the disease and another that did not. Closer inspection revealed that the major difference between these groups was their water supply. See Chapter 9 for an example from Flint, Michigan's lead-contaminated water.

A *community trial* is a type of experimental study done at the community level. Geographic communities are assigned to intervention (experimental) or nonintervention (control) groups and compared to determine whether the intervention produces a positive

change in the community (Merrill, 2013). Community trials can be extremely expensive and are not undertaken unless there is substantial evidence that the intervention will make a difference at the aggregate level. There are times when these community trials occur spontaneously, and it is important for the community health nurse to recognize these opportunities. For instance, one community public health department institutes an aggressive campaign to educate health care workers on the signs of elder abuse. Selecting a similar community where that level of training is not available, the community health nurse can then compare the rates of elder abuse reporting between these two communities. If you were conducting this research, what outcome would you expect in the community with the enhanced training? Where could you obtain this information? Think about what other measures you might also want to compare between these two communities.

CONDUCTING EPIDEMIOLOGIC RESEARCH

The community health nurse who engages in an epidemiologic investigation becomes a kind of detective. First, there is a problem to solve, a puzzle to unravel, or a question to answer. The nurse begins to search for basic information, for clues that might help answer the question. Information is never self-explanatory, and, like a detective, the nurse must analyze and interpret every additional clue. Slowly, there is a narrowing of possible suspects until the causes of a particular disease, the consequences of a prevention plan, or the results of treatment are identified. On the basis of this investigation, the nurse can draw further conclusions and make new applications to improve health services.

As discussed previously, epidemiologic studies are a form of research. The steps outlined here are similar to those discussed in Chapter 4. Epidemiologic research involves seven steps. Everything from an informal study in the course of nursing practice to the most comprehensive epidemiologic research project can be undertaken with these steps: (1) identify the problem, (2) review the literature, (3) design the study, (4) collect the data, (5) analyze the findings, (6) develop conclusions and applications, and (7) disseminate the findings.

Although research in the PHN role is covered in Chapter 4, the analysis of one epidemiologic study reinforces the integration of research in the nurse's role.

Identify the Problem

Community health nurses are constantly confronted with threats to the health and well-being of the community. Almost daily, questions are raised, puzzles presented, and problems identified. Pregnant women who smoke or use cocaine threaten the health of their unborn children: What can be done to reduce this behavior? Rape is increasing: What can be done to prevent such violence or to bring aid to victims? Children are injured and die from bicycle accidents: Why do these occur and how can they be prevented? Many farm workers have been killed or injured in farm equipment accidents: What can be done to prevent them? Any threat to the health of a group offers fertile ground for epidemiologic investigation. One example is study conducted by public health nurses in an effort to address the disproportionate burden of asthma among low-income and African American children (Sweet, Polivka, Chaudry, & Bouton, 2014). The purpose of the study was to improve asthma symptoms by attempting to control indoor triggers (Fig. 7–12).

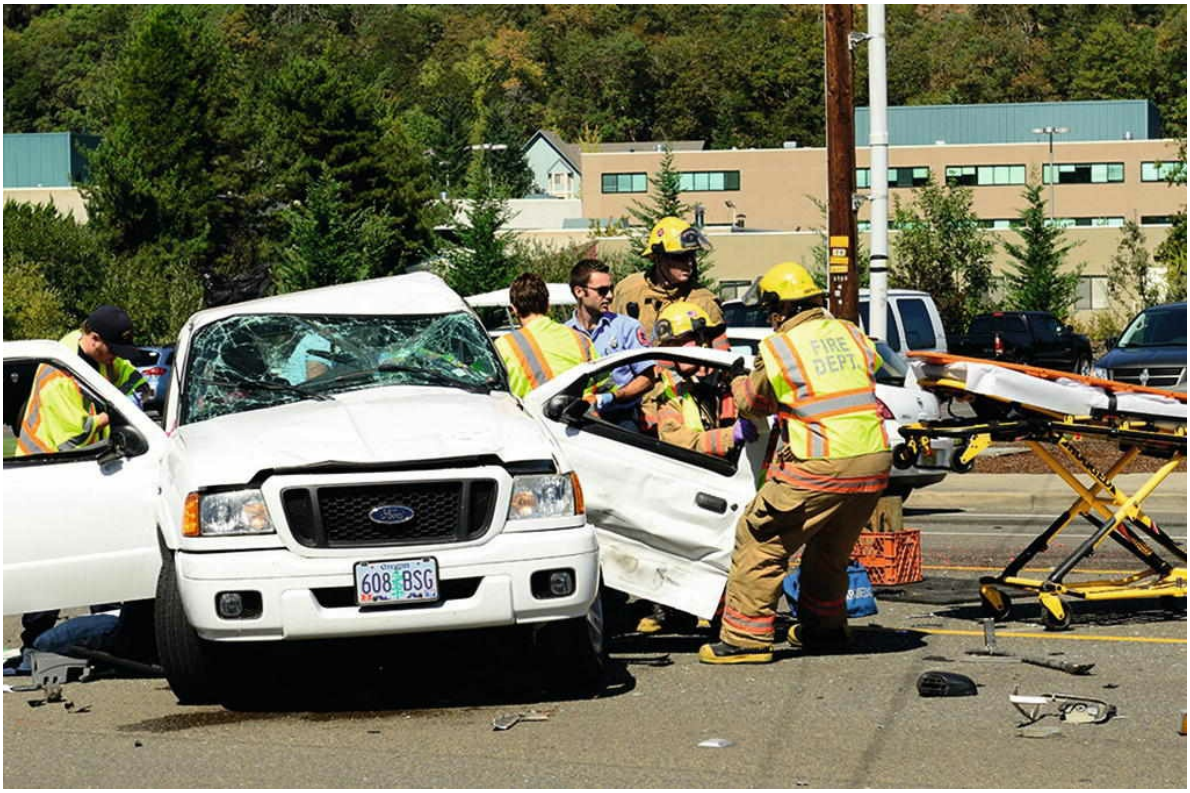

FIGURE 7–12 Firefighters extricating victims of an automobile crash.

Review the Literature

Sometimes, after identifying a problem, health professionals rush to take immediate action without reviewing solutions that have been tried previously. Every epidemiologic investigation should begin with a review of the literature. Even discovering that little research has been done on the problem can be valuable information. A good source for conducting a literature review is the Community Guide Web site (see Internet resources on *thePoint*). Conversely, if many studies have already been conducted in the area, this information can help narrow the study to areas that have not previously been investigated or allow researchers to replicate earlier studies to confirm findings in a different setting. One of the most valuable sources in the literature is the systematic review, which evaluates research studies done on specific topics. Sweet et al. (2014), in preparing for their interventional study with families of children with asthma, examined factors that may lead to asthma disparities, home-based intervention studies, and the role of nurses in interventional studies on asthma. They found that adverse home environments, with pest infestations, poor ventilation, dampness and mold, smoking in the home, and exposure to dust mite allergens, increased the likelihood of children developing asthma. They also noted that home-based interventions had generally shown promise in helping to relieve asthma symptoms, as well as emergency room visits and hospitalizations. Interventions provided by nurses were not common, as most of them involved community health workers.

Design the Study

The first step in designing a study is to formulate one or more specific questions to answer or hypotheses to test. Sometimes, the question or hypothesis emerges from the review of the literature; it also may be developed through the researcher's own analysis and hunches. It is a good idea to write out one or more hypotheses to test or questions to answer.

The next step is to plan what study type (descriptive, analytic, or experimental) or combination of study types, best suits the goals of the research and how the study will be conducted. Will the data be collected retrospectively from existing records, or will new data be collected? Who will conduct interviews? What kinds of data will be needed to measure the outcomes of intervention?

The purpose of the Sweet et al. (2014, p. 244) study was to evaluate an intervention designed for "low-income families of children with asthma in an urban setting." Further, they wanted to determine both short-term and long-term impact on asthma severity, if caregivers' quality of life was impacted, and household activities that were asthma triggers, along with families' use of asthma management techniques. This was a large study: 115 participants with pre- and posttest data, conduced over a 3-year period. After referral from various community sources (MDs, school nurses, children's hospitals), a registered sanitarian determined safety hazards and asthma triggers per a home assessment. Such things as smoking, pets, pests, mold, ventilation, presence of clutter, and overall cleanliness were reported. Then, a PHN made a home visit (sometimes along with a health educator) and "provided comprehensive education" on how to control asthma triggers in the home and mediate asthma symptoms (p. 245). An action plan was discussed with the families; bedding supplies, a HEPA vacuum cleaner, cleaning supplies, and safety supplies were provided, along with pest control information and supplies. If needed, assistance with structural problems was provided by a community agency (e.g., repairing bathroom vents, removing mold). One or two additional home visits were made over the next 2 to 4 weeks, as well as 1 to 2 phone calls.

Collect the Data

The PHN then needs to begin to gather data from available sources that are pertinent to the research topic. For example, demographic data are available online from the U.S. Census Web site, and health-related data are available from the National Center for Health Statistics. Geographic-based behavioral risk factor data are available from the Behavior Risk Factor Surveillance System Web site. Geographic information systems (GIS) data are available from the CDC, the U.S. Geological Survey, and the Environmental Protection Agency, as well as state and local agencies and nongovernmental organizations (Sheldon Margen Public Health Library, 2014). Data about a particular community may be available from the state, county, or local health departments, upon request.

Once you have gathered whatever you can from available sources, you then may have to develop data collecting tools to gather additional information. The Community Guide Web site may provide ideas about how to collect data for a particular purpose (e.g., assessment, evaluation, pilot testing), and what works and doesn't work. Development of data collection tools should start with why the data are being collected and what data are needed at the end of the study. This will help determine what kinds of data collection are most suited (e.g., mail surveys, telephone surveys, online surveys, face-to face surveys, focus groups, etc.) in order to gather the data.

There are many freely available data collection tools online. The most popular in use today is SurveyMonkey (https://www.surveymonkey.com/). It is free to use for gathering survey data from small populations (e.g., 10 questions, 100 responses), with limited online analysis. More ongoing data gathering for larger populations requires a paid subscription. As with any data collection tool, pros and cons to the method used needs to be considered. For example, disadvantages with the use of Internet surveys include biased respondent demographics, inability to probe, and poor response rates (DJS Research Ltd., 2014).

In the asthma intervention study, pretest and posttest evaluations were done. The sanitarian verbally administered the baseline survey at the initial home assessment, and a PHN did the posttest survey 6 months later by phone. Assessment tools had been developed in previous studies conducted by some of the researchers (Polivka, Chaudry, Crawford, Bouton, & Sweet, 2011) to record the child's age, race/ethnicity, and the caregiver's education, employment status, and relationship to the child (e.g., mother, father, grandmother). Short-term indicators were chosen (i.e., asthma episodes within prior 2 weeks, number of days with no asthma symptoms or waking at night, number of days quick-relief asthma medication was used, and number of days that asthma limited the child's activity). Hospitalizations, emergency room visits, school days missed, and days of work missed by caregiver were chosen as long-term indicators. A survey that assessed the caregiver's quality of life was used. Asthma-related trigger activities that could be controlled within the home were assessed (e.g., smoking, using bathroom vents to reduce moisture, use of cleaning products without fragrances). Also, asthma management activities, like the

use of a spacer with inhalers and the adherence to an asthma action plan, were assessed (Sweet et al., 2014).

Analyze the Findings

In most epidemiologic studies, data analysis consists of summarizing the findings, computing rates and ratios, and displaying the findings in tables and graphs. At this stage, the data are used to address the original question or test the original hypothesis. Was the hypothesis supported or not supported by the data? Summarized data can also generate more questions or indicate areas that warrant further investigation.

Develop Conclusions and Applications

Stating conclusions is an outcome of analysis and interpretation. The investigators summarize the results and their meaning for the purpose of making this information useful to other health services providers. Many times, research has direct practical application for improving health services, continuing or discontinuing services, or conducting future research. It is also important to describe mistakes made and lessons learned about study design and other aspects of the research and to propose further areas of study, to assist future investigators.

Returning to the asthma intervention study, Sweet et al. (2014) used descriptive statistics to analyze their data. They compared pre- and posttest results on the key outcomes (e.g., asthma severity, asthma triggers in the home, asthma management activities, caregiver quality of life). They used statistical tests to determine the significance of their findings.

Disseminate the Findings

Finally, research findings should be shared. The audience for the reporting of findings should be considered during the development of the study to ensure that the concerns and questions of the audience will be addressed by the study. Of course, if the study is being sponsored, then the purpose for the study is clear, making the dissemination of the findings easier. Sponsorship, however, can affect how the findings are perceived. In medical research, financial conflicts of interest (e.g., pharmaceutical-funded studies) can negatively impact the value of the findings (Johnston, 2015). Nevertheless, information gained from epidemiologic studies must be disseminated throughout the professional community to strengthen the knowledge base for improved practice and to promote future research.

A research article was written and submitted to a public health nursing journal and accepted for publication (Sweet et al., 2014). Results of this study showed significant reductions in "asthma symptom days, nighttime awakenings, days with activity limitation, and albuterol use" (p. 243). The number of school days missed, caregiver work days missed, and the number of emergency room visits was significantly lower; the quality of life for caregivers was significantly improved. Asthma triggers were reduced, and this home-based intervention was deemed successful in meeting the goals and objectives outlined for this population. Because the researchers disseminated this research by writing a journal article, you and your clients benefit from their hard work and knowledge.

SUMMARY

Epidemiology is the study of the distribution and determinants of health, health conditions, and disease in human population groups. It shares with public health nursing the common focus of the health of populations. It is a specialized form of scientific research that can provide public health professionals with a body of knowledge on which to base their practice and methods for studying new and existing problems. To understand epidemiology, one must first understand some basic epidemiologic concepts: the host, agent, and environment model; causality; immunity; the natural history of disease or health conditions; risk; and prevention strategies.

Community health nurses can use three sources of information when conducting epidemiologic investigations: existing epidemiologic data, informal investigations, and carefully designed scientific studies.

Epidemiology employs three investigative approaches: descriptive studies, analytic studies, and experimental studies. Although studies can be either retrospective or prospective, some merely describe existing conditions (descriptive studies), whereas others seek to explain causes (analytic studies). Experimental studies seek to confirm causal relationships identified in descriptive and analytic studies. Analytic studies can be of three types: prevalence, case–control, or cohort. In practice, all these types of studies often become combined in various ways. They also make use of quantitative concepts such as count, prevalence rate, incidence rate, mortality rate, and various types of morbidity (sickness) rates.

Epidemiologic research includes seven steps: (1) identifying the problem, which is usually a threat to the population's health, (2) reviewing the literature to determine what other studies have found, (3) carefully designing the study, (4) collecting the data, (5) analyzing the findings, (6) developing conclusions and applications, and (7) disseminating the findings.

Thinking epidemiologically can significantly enhance community health nursing practice. Epidemiology provides both the body of knowledge—information on the distribution and determinants of health conditions—and methods for investigating health problems and evaluating services.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Identify an aggregate-level health problem in your community. Using the host, agent, and environment model, explains who the host is, what the causative agents are, and what environmental factors have promoted or delayed the development of the problem. When needed, consider vector control programs that may be needed or enhanced.
2. Select an aggregate health (wellness) condition, such as preschoolers' normal growth and development or elders' healthy aging, and list all the causal factors that might contribute to this healthy state. Now, plot these schematically in a diagram to show the web of causation model for this condition.
3. Using the same health condition that you selected in the previous exercise, describe the natural history of this condition, outlining its four stages. Identify three preventive nursing interventions, one for each level of prevention that could apply to this condition.
4. Select an article that reports an epidemiologic study from a recent nursing or public health journal, and record your responses to the following questions:

- What prompted the study, and what was its purpose?
- Was it descriptive, analytic, or experimental research?
- Was the study design retrospective or prospective?
- Why did the investigators choose this design?
- What existing sources of epidemiologic data did this study use? List all sources specifically, such as *Morbidity and Mortality Weekly Report* or incomes by household in census data.
- What were the study findings? Identify the population group that will benefit from this research.

5. Interview one or more practicing public health nurses in your community, and identify an aggregate-level problem that needs epidemiologic investigation. Propose a rough draft study design to research this problem.
6. Search for local or national news regarding a new disease threat (e.g., Zika virus), an example of a food-borne illness outbreak (e.g., bacterial contamination of produce), or another example requiring epidemiological investigation. Work with a small group of classmates to develop a hypothetical case investigation and a potential epidemiological plan for action. Are there specific environmental factors that should be considered? If possible, watch for the resolution of the issue (e.g., conclusions of the investigation, public health recommendations).

8 CHAPTER

Communicable Disease Control

"The diseases of the present have little to do with the diseases of the past, save that we die of them".
Agnes Repplier (1855–1950), Essayist and Biographer

"There are only two things a child will share willingly; communicable disease and its mother's age".
Benjamin Spock (1903–1998), Pediatrician and Author

KEY TERMS

Active immunity
Antigenic shift
Cocooning
Communicable disease
Direct transmission
Disease control
Fomites
Herd immunity
Immunization
Incubation period
Indirect transmission
Infectious
Isolation
Novel
Passive immunity
Quarantine
Reservoir
Ring vaccination
Screening
Surveillance
Vaccine
Vector

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Discuss the nurse's role in communicable disease control.
- Describe the three modes of transmission for communicable diseases.
- Identify major communicable diseases in the United States.
- Explain the strategies used for the three levels of prevention in communicable disease control.
- Explain the significance of immunization as a communicable disease control measure.
- Delineate the major concerns of parents who choose not to vaccinate their children.

- Describe major issues that affect the control and elimination of tuberculosis (TB).
- Discuss specific ways to prevent sexually transmitted diseases, including HIV/AIDS.
- Discuss the consequences of biologic terrorism with weapons such as anthrax and smallpox.
- Discuss ethical issues affecting communicable disease and infection control.

Communicable diseases pose a major threat to public health and are of significant concern to community/public health nurses. A communicable disease is caused by an infectious agent, such as a virus or bacteria, and can be transmitted from one source to another. Transmission to a susceptible host can occur directly either from person to person or animal to human, or transmission may occur indirectly through a reservoir such as contaminated water (Centers for Disease Control and Prevention [CDC], 2014e; Heymann, 2015). Some noncommunicable diseases can also be caused by infectious agents, such as tetanus, but cannot be transmitted from one source to another (CDC, 2014e). Jurisdictional laws and regulations define the infectious and noninfectious diseases to be reported to local, state, and territorial public health departments (CDC, 2015q). The National Notifiable Diseases Surveillance System allows sharing of notifiable disease information nationally and between jurisdictions for surveillance, control, and prevention purposes (CDC, 2015q).

Knowledge of communicable diseases is fundamental to the practice of community/public health nursing because these diseases typically spread through communities of people. Understanding the basic concepts of communicable disease control, as well as the numerous surrounding issues, helps a public health nurse work effectively to prevent and control communicable disease in populations and groups. It also helps nurses teach important and effective preventive measures to community members, advocate for those affected, and protect the well-being of uninfected persons (including health care workers and nurses themselves).

In the last century, numerous changes occurred in the lives of people both nationally and globally related to issues of public health. Communicable disease control is recognized as one of the 10 great public health achievements of the 20th century (CDC, 2013c, 2013e). In the early 1900s, the top three causes of death were pneumonia, tuberculosis (TB), and diarrheal or enteric diseases. Then, control measures including improved sanitation and hygiene, vaccinations, and use of antibiotics and other antimicrobials, along with improved surveillance systems, have all contributed to a significant reduction of infant and child mortality and a nearly 30-year increase in life expectancy overall (National Institute on Aging, 2015). During the first decade of the 21st century, new vaccines reduced the number of serious illness and death due to pneumococcal infection and reduced rotavirus-related hospitalizations among children. Deaths related to other vaccine-preventable diseases (VPDs), including hepatitis A, hepatitis B, and varicella, were also reduced during this 10-year time period (Hinman, Orenstein, & Schuchat, 2011). In addition, improved public health infrastructure and changes in prevention strategies resulted in a 30% reduction in TB and a 58% reduction in bloodstream infections related to central lines. Improved testing has allowed more people with human immunodeficiency virus

(HIV)/acquired immune deficiency syndrome (AIDS) to be identified and receive lifesaving treatment earlier. Rabies control efforts have resulted in the elimination of canine rabies in the United States (CDC, 2011a). The Centers for Disease Control and Prevention is charged to protect Americans against threats of disease, both in the United States and abroad (CDC, 2014k).

But, new challenges in communicable disease control have emerged:

- New and reemerging communicable diseases that threaten the health of populations around the world. Examples include a pandemic of H1N1 influenza in 2009–2010 resulting in over 12,000 deaths in the United States, an outbreak of Ebola in West Africa in 2014 resulting in over 11,000 deaths, and an emergence in 2015–2016 of the Zika virus in the Americas, which, at the time of this writing, was suspected of causing microcephaly in babies born to women who contracted the mosquito-borne illness during pregnancy, as well as West Nile virus and corona viruses such as MERS and SARS (CDC, 2014c, 2016c, 2016f; Heymann, 2015).
- Threat of vector-borne pathogens such as Rift Valley fever and dengue fever emerging in the United States as a result of changes in climate (CDC, 2014d).
- Development of antibiotic-resistant strains of bacteria around the world that threaten the public's health as well as pose significant occupational health risk for health workers. Examples include multi- and/or extreme drug-resistant TB (MDRTB, XDRTB), HIV/AIDS, malaria, and methicillin-resistant Staphylococcus aureus, or MRSA (WHO, 2016c, 2016i).
- The threat of bioterrorism, which involves the use of biologic agents with the intent to cause harm (Heymann, 2015). An example of this is the deliberate delivery of anthrax spores through the U.S. mail in 2001. See Chapter 17 for more on emerging infections and bioterrorism.

This chapter provides information to help you better understand communicable diseases in communities and around the globe. It describes ways to plan and implement appropriate prevention interventions, including immunization of children and adults, environmental interventions, community education, screening programs, and disease investigation and case/contact finding. Ethical issues of communicable disease control are also discussed. A list of communicable disease information sources useful to you, the community/public health nurse, is also provided.

BASIC CONCEPTS REGARDING COMMUNICABLE DISEASES

Communicable diseases have challenged health care providers for centuries. Exposure to infectious agents can occur out in the community or within health care settings (Heymann, 2015). The threat of these diseases has led to the development of important nursing and medical preventive measures, such as infection control measures including hand washing, use of personal protective equipment, safe handling of contaminated sharp equipment, and appropriate disposal of potentially infectious materials, to community sanitation and the development of vaccines and use of antimicrobial medications (Heymann, 2015).

Evolution of Communicable Disease Control

Although communicable diseases are no longer the leading cause of death in the world, they continue to pose a serious threat. Three of the top 15 causes of death continue to be infectious illnesses. These are HIV, diarrheal diseases, and TB (WHO, 2014). In 2012, 1.5 million people died from HIV/AIDS and another 1.5 million people died from diarrheal illnesses (WHO, 2014). Over 900,000 people died of TB in that same time period (WHO, 2014).

Bubonic plague, caused by *Yersinia pestis*, is one example of how communicable diseases have changed the course of history. The first documented pandemic plague occurred in 541 AD. The next 200 years saw over 25 million deaths due to plague (CDC, 2015t). In 1334, the great plague pandemic, known as "Black Death," killed 60% of the European population. Now, this deadly disease can be controlled through early identification and treatment with antibiotics. *Y. pestis* has been used as a weapon during wars over the centuries. Weaponization of *Y. pestis* remains a threat today (CDC, 2015t).

Historically, as countries became industrialized, increased productivity, trade, and economic growth also brought on the four D's of disruption, deprivation, disease, and death. Industrialization brings large numbers of people close together in condensed living conditions. Trade brings populations together, exposing them to infectious agents they had not previously seen. These conditions, combined with poor sanitation leading to contaminated water supplies and infestation of disease-carrying insects or rodents, have all contributed to devastating epidemics in the past and continue to pose a threat today in developing countries. Planning for built environments that support health and safety is critical for mitigating the risk for disease outbreaks in developing urban regions (Neiderud, 2015).

Control of infectious disease began when microorganisms were identified as the source of these illnesses. In the 20th century, public health measures began to be implemented, resulting in significant achievements in the control of infectious diseases. These interventions included improvements in sanitation and hygiene, animal and pest control, vaccination, and infectious disease detection through testing, monitoring, and treatment with antimicrobials (Rosner, 2010).

Not until the 1700s and 1800s were the causative organisms for various infectious diseases recognized through the assistance of increasingly sophisticated microscopes. With these discoveries came early attempts to create ways to prevent the spread of such organisms, either by decreasing their power or by eliminating them. Pasteurization of milk was invented, and efforts to eliminate rats from ships and food storage areas began. These measures commenced a global effort to eliminate communicable diseases (Schlipköter & Flahault, 2010).

In 1945, as the United Nations (UN) was being formed, they identified a need for a global health program. By 1948, the World Health Organization (WHO, 2016f) came into

existence. The WHO continues to be a very active part of the UN. They provide multifaceted services such as promoting health across the lifespan by working toward improving health systems; addressing communicable and noncommunicable diseases; working on emergency preparedness, surveillance, and response; and providing corporate services through their 150 offices around the world (WHO, 2016a). See more on global health in Chapter 16.

Also mentioned in Chapter 6 is the Centers for Disease Control and Prevention (CDC), which is a branch of the U.S. Department of Health and Human Services (USDHHS). Originally tasked with the elimination of malaria in war areas, it has evolved over the years into a health promotion and disease prevention agency. It is recognized globally for its partnerships in disease surveillance, research, data collection, and analysis, as well as for responding nationally and globally with peer agencies to disease outbreaks (CDC, 2012b). Smallpox, caused by the *variola* virus, is a classic example of a communicable disease control success story. The *variola* virus had been associated with devastating epidemics throughout the centuries. Smallpox became endemic in Europe in the 18th century and was responsible for 300 to 500 million deaths worldwide during the 20th century (Thèves, Biagini, & Crubezy, 2014). Smallpox first responded to a crude vaccine that was developed in the 18th century. The vaccine was studied and perfected and used globally for decades. A major worldwide eradication campaign began in 1967, under the direction of the WHO (Heymann, 2015). The last naturally acquired case of smallpox in the world occurred in Somalia in 1977, and WHO certified global eradication 2 years later (Heymann, 2015). In 1980, the World Health Assembly declared the eradication of smallpox and made a call to cease smallpox vaccinations around the globe (WHO, 2016b). Outside of a small accidental laboratory-related outbreak in 1978, there have been no cases of smallpox since that time (Heymann, 2015).

Despite strides in controlling major disease outbreaks, the threat of biologic warfare using smallpox, anthrax, plague, or other disease organisms raises concerns about how to prepare for the future (Heymann, 2015). The Global Health Security Agenda, an international partnership among nearly 50 participating nations, began in 2014. The goal of this program is to make the world safe and secure from biological threats by bringing nations together to address this issue and making security a top priority among global leaders (Global Health Security Agenda, 2015). Strategies include prevention, detection, and response (Globalhealth.gov, n.d.). This collaborative includes partnerships among both governmental and nongovernmental stakeholders. The U.S. commitments to this agenda include participation from U.S. Department of Health and Human Services, U.S. Department of Defense, U.S. Department of Agriculture, and U.S. Department of International Development (Globalhealth.gov, n.d.). Partnerships are with the governments of neighboring Canada and Mexico, as well as almost 50 other countries around the world.

Surveillance is key to security from biological threats. Health care service providers and laboratories are required to submit reportable information to the local health department. Local health jurisdictions can voluntarily send this information to the CDC National

Notifiable Diseases Surveillance System (NNDSS). This system includes an electronic means of sharing surveillance information in place in all 50 states and the District of Columbia, allowing them to send case notifications to NNDSS quickly and securely (CDC, 2015r). The United States, South Africa, and Thailand have led the Global Health Security Agenda (GHSA) in working toward development of a laboratory surveillance system that would allow laboratories across each nation to detect harmful pathogens, both known and new threats, safely and accurately (CDC, 2014f).

Community Health Nurse's Role: Process of Investigating Reportable Communicable Diseases

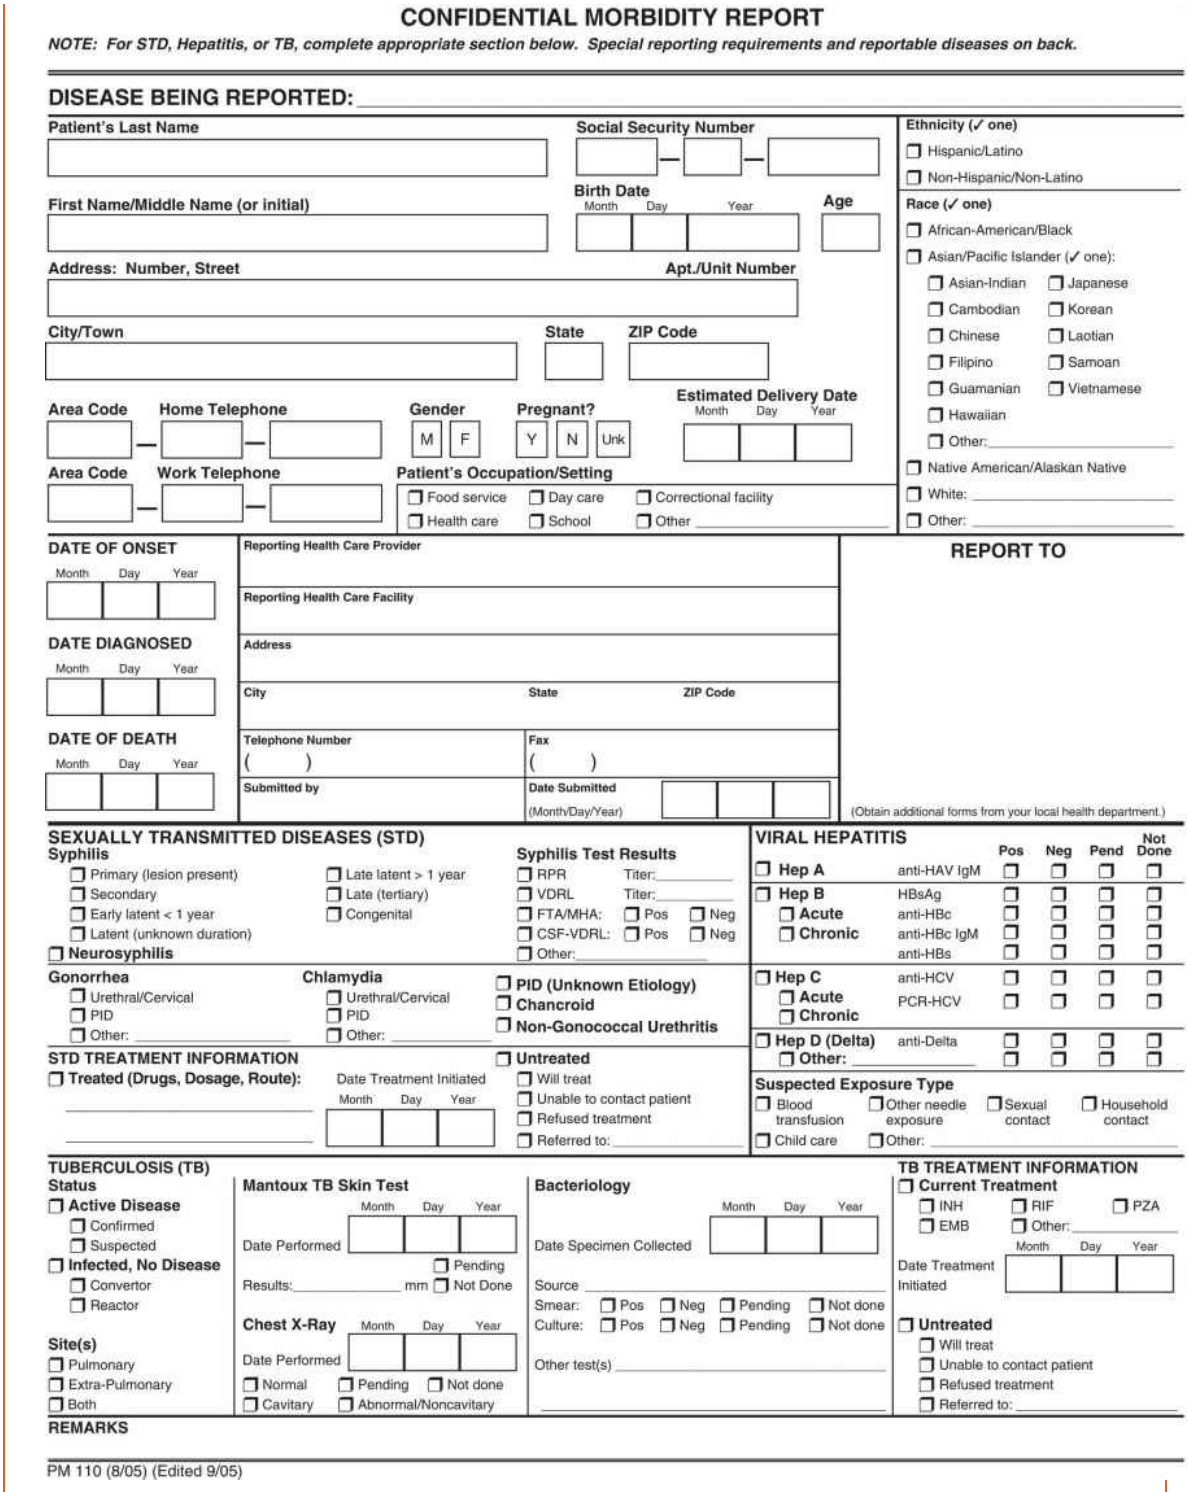
Diseases in humans are reported to the local health authority (Heymann, 2015) (Fig. 8–1). Each state has a State Health Department, but not all states have local level sites like a county health department. Some of the state and/or local health departments utilize a combination of nurses, epidemiologists, and communicable disease investigators. The CDC and WHO provide guidance documents that assist state public health agencies to develop investigation policies and procedures for the local level investigator to use. The local investigation process must meet the requirements of the state and federal reporting laws that derive from state, federal, and global health regulations. Individual states utilize the national notifiable infectious disease list as the guidance for developing the state's reportable diseases and may add to this list as they choose, reflecting the types of conditions that are unique to a state or region of the United States (CDC, 2012b). State health departments commonly specify two other circumstances that must be reported: any outbreak or unusually high incidence of any disease and any occurrence of an unusual disease of public health importance (CDC, 2015r). A core function of the CDC is to provide support to any local, tribal, territorial, or state health department to prepare or respond to any health threat (CDC, 2014i). This support comprises information, training, and staff, tools so that local health departments can respond promptly (CDC, 2014i). The CDC is also available to each individual citizen via mail, phone, or the Internet. You can reach them at:

FIGURE 8–1 PHN interviews a health center nurse during TB/HIV investigation.

Centers for Disease Control and Prevention
1600 Clifton Rd., Atlanta, Georgia 30333
800-CDC-INFO (800-232-4636); TTY: (888) 232-6348, 24 hours/every day E-mail: cdcinfo@cdc.gov

The local health department/agency is the initial point of notification of a communicable disease investigation. If a person is identified in one jurisdiction but had been exposed in another, the health agency receiving the report should notify the health agency where the exposure occurred so an investigation can be conducted in the originating region (Heymann, 2015). In most states, reporting known or suspected cases of a reportable disease is generally considered to be an obligation of:

- Physicians, dentists, nurses, and other health professionals
- Medical examiners
- Administrators of hospitals, clinics, nursing homes, schools, and nurseries



Some states also require or request reporting from:

- Laboratory directors
- Any individual who knows of or suspects the existence of a reportable disease

Each state has a disease report form; California uses a form titled *Confidential Morbidity Report*. Display 8–1 is an example of a reporting form. Each local health department or agency will investigate a specific disease using a protocol set by the local, state, or federal public health official. Reportable diseases must be reported to the state health department. Notifiable diseases are voluntarily reported by the state to the CDC (CDC, 2015j). The list of notifiable conditions is updated annually.

DISPLAY 8.1 CONFIDENTIAL MORBIDITY REPORT

CONFIDENTIAL MORBIDITY REPORT

Disease investigation requires a systematic approach. The nurse may be assigned to work on individual cases of a disease or several cases that make up a cluster or outbreak. Whether it is a single case of illness in a small town or a multijurisdictional outbreak, similar investigation steps are followed. The investigation will require surveillance to

identify additional people who might be infected, determining the possible source of the infection and the means of transmission, identifying others who are at risk so screening and prevention measures can be implemented, preventing further transmission, and monitoring the response to these interventions (Heymann, 2015). In the event of an outbreak, the response should also include confirmation of the outbreak, establishment of a task force to serve as the command-and-control center of the response, communication with the public, managing care for those who are ill, and conducting an outbreak investigation (Heymann, 2015).

Prior to contacting an individual for an interview:

- Review the information received from the mandated reporter for completeness.
- Clarify that the disease is suspect or lab confirmed. Some infections can be reported if they meet a set of clinical criteria or are part of a larger outbreak and a case definition has been defined.
- Review the case definition. A case is the individual who either has a laboratory-confirmed reportable disease or meets the clinical definition in an investigation.
- Review the disease information—reservoir, incubation period, infectious period, symptoms, and treatment. Also, know the methods of control. Be prepared to provide education to the client while also conducting the investigation.
- Many diseases have specific questionnaires that are useful when interviewing the client. Review the questionnaire prior to contacting the client so you understand the intent of the investigation and know the questions you will ask the client to answer. This will allow you to focus on the investigation and can help set the client at ease.
- If no questionnaire exists, you may have to write a narrative report including the information related to onset of illness, symptoms, medical evaluation, treatment if received, recovery state, and individuals the person has been in contact with depending upon the nature of the disease.
- Display 8–2 provides an example of a generic disease investigation form.

SAMPLE GENERIC DISEASE INVESTIGATION FORM

Name: _____ DOB/age: _____

Address: _____

Telephone(s): _____

Race/ethnicity: _____ Occupation: _____ Gender: _____

Risk Factors

Recent travel outside U.S.?_____ Outside of the County? _____

If yes, location(s) & date(s) _____

Was client born in U.S.?_____

If no, country of birth _____ Year arrived in U.S. _____

In 10 days prior to this illness, has individual participated in the following activities? If yes, please explain.

Attended a social gathering _____

Was food served? If yes, list foods consumed _____

Eaten at restaurants, including fast-food restaurants _____

_____

Eaten rare/raw animal products, home-canned /unusual foods _____

_____

Visited a day care or medical facility _____

Had visitors in his/her home? _____ Were any of them ill? _____

If yes, sex and dates of illness _____

Drunk water from/or swam/bathed in pools, lakes, hot tubs, etc. _____

If yes, where and when: _____

What is usual source of drinking water? _____

Does client have contact with domestic or wild animals? _____

Were any animals sick? If so, date of contact _____

I. Comments:

Clinical Information

Date/time of onset: _____ Duration of symptoms: _____

Symptoms: (check all that apply)

☐ Fever _____

☐ Chills ☐ Nausea ☐ Vomiting ☐ Abdominal Cramps

☐ Diarrhea ☐ Headache ☐ Neck Stiffness ☐ Cough

☐ Runny Nose ☐ Shortness of Breath

Others: _____

_____

_____

Did client see health care provider? _____

If yes, name of provider, phone and date seen _____

What was diagnosis? _____

Was any lab work ordered? _____

If yes: Test: _____ Results _____

Test: _____ Results _____

Test: _____ Results _____

Was any medication prescribed? _____

Was client hospitalized? _____ Where _____

What was outcome? _____

Does client have any chronic illnesses? List _____

What medications does client normally take? _____

Does client use any home remedies? _____

Allergies to foods or medications _____

Recent immunizations _____

Is client aware of anyone else with similar symptoms? _____

If yes, please give identifying information _____

Females: Are you pregnant? _____ If yes, EDC _____

Is there any other information you think may be important for us to know regarding this Illness?

_____

_____

Initial telephone contact by _____ Phone: _____ Date: _____

Person conducting the interview: _____ Phone: _____ Date: _____

Conducting the interview:

- Maintaining a neutral and nonjudgmental attitude during the interview process will elicit information more readily, especially when discussing an STD, for example.
- The interview may be by telephone or in person. The way an interview is pursued depends upon the department protocol and/or disease being addressed.
- Introduce yourself and explain the purpose of the confidential nature of the interview.
- Eliciting what the individual knows about the disease may give the nurse an idea of the individual's knowledge base and what education or reeducation to provide.
- Gathering the information by using a disease-specific questionnaire may lead to a possible source of the disease, or to additional infected contacts.
- The nurse will contact individuals identified as possibly infected by the identified case. By pursuing contacts, the possibility of outbreak status may appear.

Surveillance of communicable diseases is the next step. The WHO defined surveillance as the ongoing, systematic, collection, analysis, and interpretation of health data (WHO, 2016h). Surveillance allows for early identification of public health emergencies and evaluation of the effectiveness of public health interventions, and is used to help inform policy changes (WHO, 2016h). Contact tracing can identify additional people who are also affected (Heymann, 2015). Information obtained by the nurse during the interview is sent from the local investigation to the next higher level of government for analysis and interpretation. If an outbreak is occurring, it may be from the next level of government that assistance is garnered (Heymann, 2015). Next is disease control. Disease control measures are determined by the characteristics specific to the disease. Public health nurses must understand the characteristics of the infectious agent so that appropriate control measures can be implemented. Prompt, appropriate action could minimize or even prevent an outbreak. Control measures may include testing, counseling, education, environmental modifications such as draining standing water, vaccination, treatment, or prophylaxis as appropriate (Heymann, 2015).

Effective surveillance and control can lead to *elimination* and *eradication* of a disease in many cases. The 1989–1992 International Task Force for Disease Eradication defined the terms of disease elimination and eradication. Elimination is the stopping of a disease in a defined geographical region, whereas eradication is the extinction of a naturally occurring disease (Carter Center, 2016). Eradication eliminates the need for further control measures (Carter Center, 2016). An example of elimination is that there are no natural cases of polio in the Americas. An example of eradication of a disease is smallpox. See Chapter 16 for more on global eradication of infectious diseases.

Modes of Transmission

Transmission of a communicable disease describes how disease is passed from person to person or from another source to a person. Transmission can occur by direct or indirect methods (Heymann, 2015).

Direct Transmission

Direct transmission occurs by immediate transfer of infectious agents from a reservoir to a new susceptible host. This can be through either direct contact or droplet spread. Direct contact with the source could include touching, biting, kissing, or sexual intercourse—that is, contact with oral secretions, blood, or other potentially infectious fluid, such as the drainage from a skin lesion. Coughing or sneezing secretions into the face of a susceptible individual can transmit respiratory infections, such as measles or pertussis, by way of droplet spread. Close proximity of <1 m is required, like sharing the space in a car or small room, to transmit an organism from one person to another (Heymann, 2015) (see Fig. 8–2).

FIGURE 8–2 Sneeze in progress—revealing the plume of droplets expelled in a large cone-shaped array. (From Centers for Disease Control and Prevention. Public Health Image Library. Photo Image ID #11161—James Gathany.)

Airborne Transmission

Airborne transmission occurs through droplet nuclei—the small residues that result from

evaporation of fluid from droplets emitted by an infected host. Sneezing and coughing are common examples of airborne transmission. Because of the small size and weight of droplet nuclei, they can remain suspended in the air for long periods before they are inhaled into the respiratory system of a host. Small particles of dust from soil containing fungus spores may cling to clothing, bedding, or floors. The spores may become separated from dry soil by the wind and then be inhaled by the host (Heymann, 2015).

Indirect Transmission

Indirect transmission occurs when the infectious agent is transported within contaminated inanimate materials called fomites, including toys, sharp objects, tissues, or even water or food. This type of indirect transmission is also referred to as *vehicle-borne transmission*. The infectious agent may or may not need to multiply while in the inanimate material (Heymann, 2015). Chapter 9 describes both the government's role and the nurse's role in helping to prevent food and water contamination by infectious agents (Heymann, 2015). Another way infectious disease can be transmitted indirectly is by insects. Insects may carry disease on their feet or expel it through their digestive tract. This mechanical transmission does not require the infectious organism to multiply. Insects can also transmit disease when the infectious agent has propagated within the insect (Heymann, 2015). This requires an incubation period for the infectious agent to be passed to the host. Examples of this cycle are malaria that is transmitted by mosquitoes or Lyme disease transmitted by ticks. These modes of transmission that involve insects or animals are called vector-borne transmission (Heymann, 2015).

Vector Transmission

When transmission occurs through a vector (i.e., a nonhuman carrier such as an animal or insect), it is known as vector- borne transmission. Vector-borne diseases are a major public health concern (CDC, 2014a). Transmission can be through a bite of the insect (e.g., mosquito) or animal (e.g., rat) or exposure to the infected animal's body fluids, such as the urine from the Hantavirus-infected rodent (Heymann, 2015). Insects such as mosquitoes, fleas, and ticks are responsible for transmission of malaria, plague, and Lyme disease. Rabies and Hantavirus are examples of vector-borne illnesses passed to humans from animals.

Of all the infectious diseases, vector-borne illnesses are the most complex to prevent and control (CDC, 2014a). Control strategies directed toward vector-borne diseases typically involve community education and environmental measures to hinder the vector from reaching the host.

Control strategies may include the following:

- Reduce the population of insects.
- Eradicate rodents that carry diseases, such as rats.
- Use of mechanical or chemical barriers to protect from exposure to vectors, such as mosquitoes or ticks—for example, sprays or mesh bed nets.

- Public education about preventive and protective measures, including avoiding vector habitats, and how to respond when exposed to a vector to prevent disease from developing.

Food- and Water-Related Illness

Food- or water-related illness can be caused by bacteria, viruses, or parasites, such as *Salmonella*, *Shigella*, *Escherichia coli* 0157, listeriosis, and *Campylobacter*, the protozoan agent *Giardia*, and the viral agent hepatitis A (Heymann, 2015). Toxins released in response to bacteria in the intestines can also result in severe illness. Ingestion of the pathogenic organism sets in motion the events of a food- or water-related intestinal illness or even death. The contamination can occur at the source (e.g., contamination by animal waste being introduced into the food or water chain) or through unsanitary food handling or practices. This fecal–oral route results in the ingestion of fecal material. Food storage at improper temperatures can also create an environment allowing microorganisms to grow.

Most commonly, exposure to contaminated food or water results in symptoms related to gastrointestinal function, including diarrhea, nausea, vomiting, stomach cramps, and bloating. Fever may accompany these infections as well. Onset of symptoms may occur within a few hours after exposure or not until days or even weeks later, depending on the microorganism. This time interval between exposure and onset of symptoms is called the incubation period.

Microorganism contamination of food resulting in human illness occurs as a result of either infection or intoxication. Infection is related to a pathogen that occurs through ingestion of food contaminated with adequate doses of *Salmonella*, *Shigella*, *E. coli*, or other pathogens. The cycle begins when the infectious agent multiplies and grows in the food medium. The agent subsequently invades the host after ingestion of the food. Then infection occurs—which is the entry and development or multiplication of an infectious agent in the body. Infection is usually accompanied by an immune response, such as the production of antibodies with or without clinical manifestation. The infectious organism produces illness by direct irritation of the normal gastrointestinal mucosa. By contrast, intoxication is caused by the production of toxins as a by-product of the normal bacterial life cycle. This commonly occurs when cooked food is left standing at room temperature. Or it can occur when the bacteria is living on the skin of a food preparer who inadvertently inoculates the food. It is ingestion of the toxin, rather than the microbe itself, that produces the illness (Heymann, 2015). One well-recognized example is the neurotoxin botulinum that is produced by the bacteria *Clostridium botulinum*.

The distinction between infection and intoxication is relevant for a number of reasons. Toxins may be difficult to isolate and identify, particularly in the absence of the bacteria; some suspected food-borne illnesses go unidentified for this reason. Although the bacteria may be killed after heating of foodstuffs before consumption, some bacteria-produced toxins are stable at normal cooking temperatures, so that food cannot be rendered safe even

though it has been thoroughly cooked. Bacteria established in the human gastrointestinal system may require medical treatment to be eradicated. In contrast, individuals with food intoxication typically require supportive care while in the process of ridding themselves of the toxin (Heymann, 2015).

Food- and water-related outbreaks can impact large numbers of people. Such outbreaks serve to remind all community health practitioners of the continuing need to teach and observe the most basic methods for preventing food and water contamination. Display 8–3 summarizes correct methods for maintaining the safety and cleanliness of food.

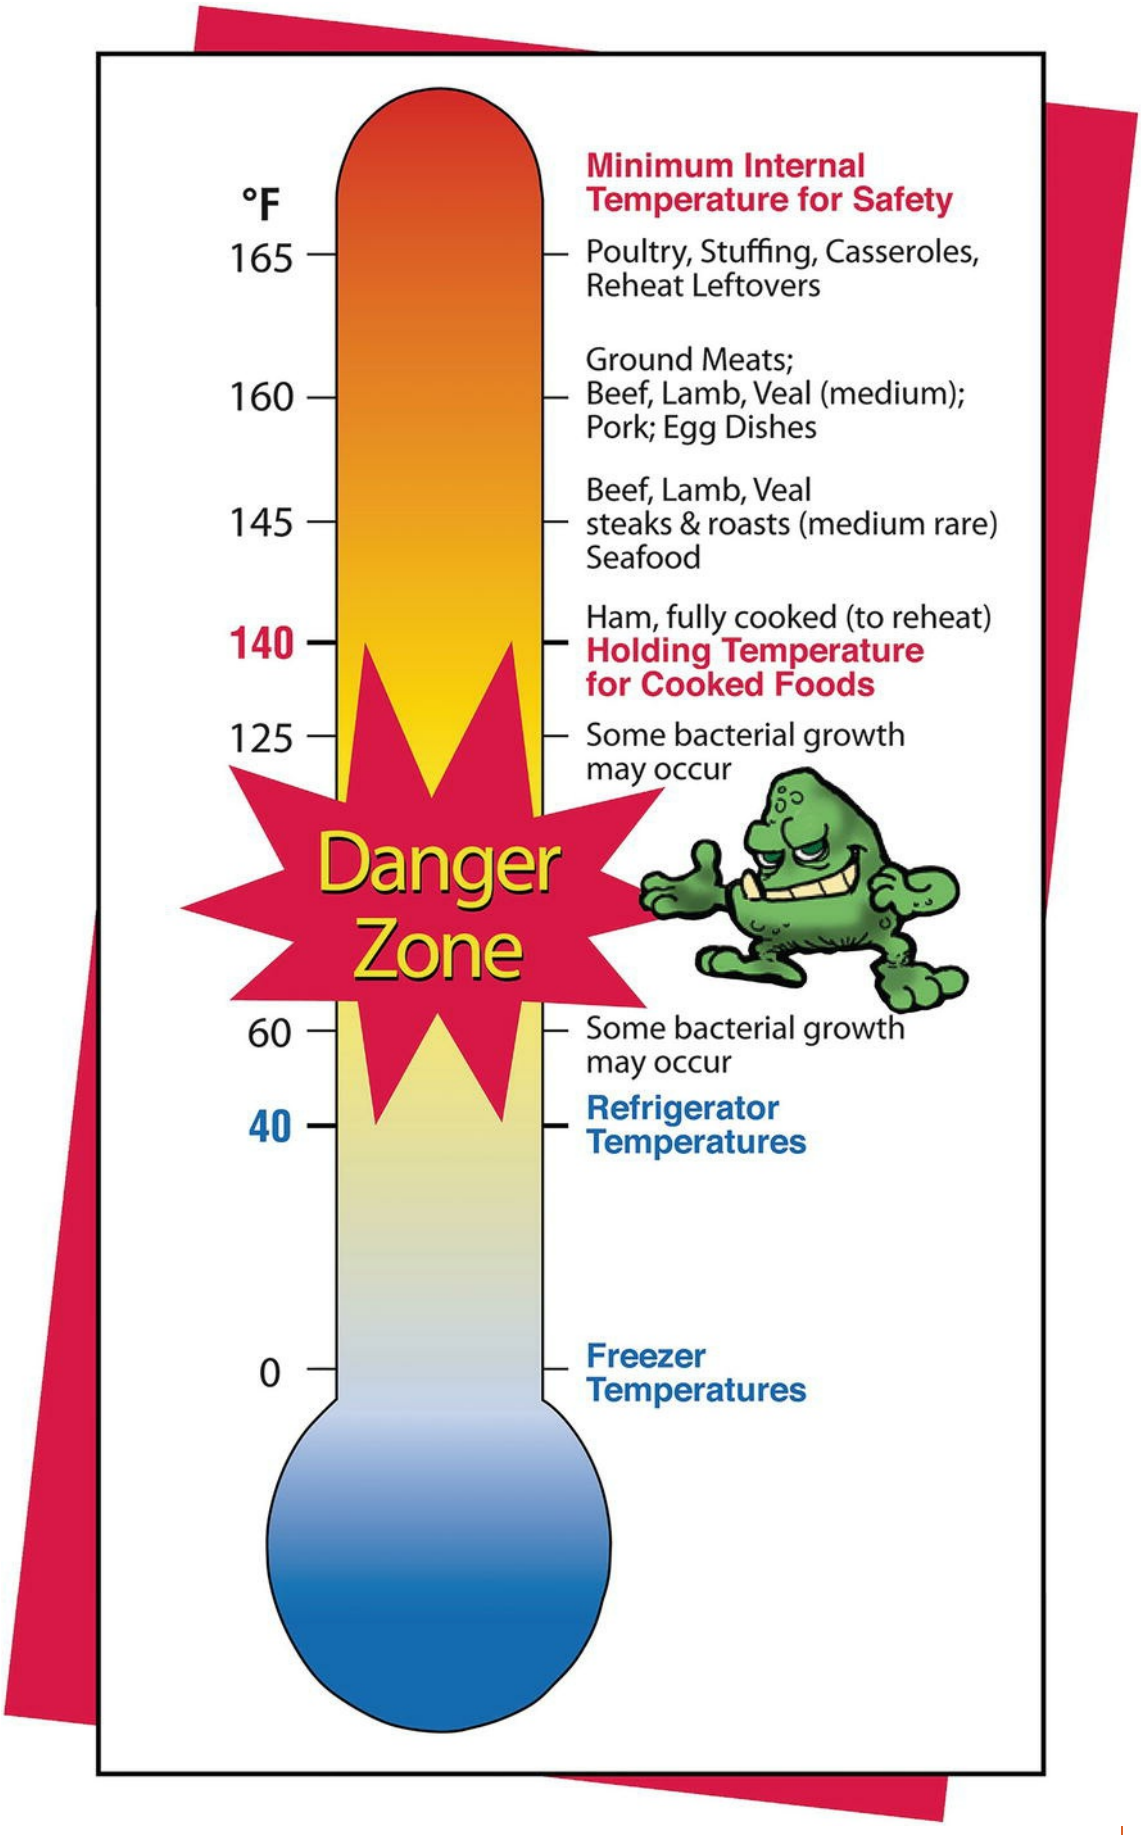
DISPLAY 8.3 CORRECT METHODS FOR PRESERVING THE SAFETY AND CLEANLINESS OF FOOD

Before handling food:

- Wash hands and all food preparation surfaces and utensils thoroughly with soap and water.

When preparing food:

- Wash foods that are to be eaten raw and uncooked thoroughly in clean water. This includes foods that are to be peeled that grow on the ground or come in contact with soil.
- Cook all meat products thoroughly.
- Do not allow cooked meats to come in contact with dishes, utensils, or containers used when the foods were raw and uncooked.



When storing leftover foods:

- Cool cooked foods quickly; store under refrigeration in clean, covered containers.

When reheating leftover foods:

- Heat foods thoroughly. Bacteria contaminating food grow and multiply in a temperature range between 39°F and 140°F.

The most important aspect of food- or water-related diseases for nurses in community health is to recognize that outbreaks of illness affecting large numbers of people can occur, despite well-recognized standards for decontamination of water supplies and safe commercial food preparation. The public health nurse may notice they have received similar reports of illness that requires looking for a common source. This may necessitate a higher level of investigatory assistance, such as the state health department (CDC, 2011b). Outbreaks may not be detectable by local surveillance means alone because of the mobility of individuals or the routine transportation of foods from one state or country to the other. It may not be identified as an outbreak until the various reports of illness and laboratory reports from affected communities (or in one if it is a local outbreak) are processed and forwarded to a public health laboratory, and then onto the state public health laboratory. It is at this point that the sentinel surveillance system is triggered. Some states have local county public health laboratories that may make the identification of organism clusters. Unfortunately, many states or regions rely primarily on the state public health laboratory for organism identification, which has the potential for delays (CDC, 2011b).

The CDC has a system of surveillance called PulseNet, a program designed to identify organisms that may come from a same source, allowing outbreaks to be identified and sources to be eliminated (CDC, 2013a). This program uses laboratory testing to connect food-borne illness cases. Currently, 87 laboratories participate in this program with at least one lab in each state. Testing is conducted to match ill people in different states using pulsed-field gel electrophoresis to identify the DNA fingerprinting of the various organisms. A cumulative database of over 0.5 million bacterial isolates are stored in the system (CDC, 2013a). When a common source is identified, the food regulatory agency can work with the facility to clean up the problem or close the facility down.

An example of one PulseNet success story occurred in 2014 when this system identified a rare fingerprint of *Salmonella* Newport in specimens from ill patients. This prompted multiple health departments to initiate an investigation. Chia powder was determined to be the common source. Chia powder was being used in people's smoothie drinks. Public health investigators included questions about Chia powder in their questionnaires and identified additional cases in the United States and in Canada. The product was pulled from shelves, eliminating the source from the food supply (CDC, 2014b).

MAJOR COMMUNICABLE DISEASES IN THE UNITED STATES

Community health nurses encounter any number of communicable diseases in their practice. Many are reportable, but some are not—although they are just as transmittable to others as the reportable infections. As mentioned previously, each state department of health has the capacity to determine which diseases will be reportable based upon the federal reportable disease list. These diseases are frequently diagnosed and treated in the community care setting rather than the hospital. The following sections discuss some of the more common communicable diseases, but the list is not inclusive of all that are reportable. Diseases are presented in groups by similarity, rather than by virulence or prevalence.

Influenza (Seasonal or Novel) and Pandemic Preparedness

Influenza (flu) is identified as an acute communicable viral disease of the respiratory tract. Symptoms include fever, headache, myalgia, prostration, coryza, sore throat, and cough. The influenza virus undergoes minor genetic mutations from year to year, and these changes are referred to as antigenic drift. Periodically, the influenza A virus will transform drastically, which is referred to as antigenic shift. Most people around the world would not have antibodies to protect them from this novel (new) strain, thus making a large percentage of the population susceptible, leading to a pandemic (Heymann, 2015). Influenza A virus causes the most severe and widespread disease (pandemics); influenza B causes milder disease outbreaks; and influenza C is connected with only sporadic cases of milder respiratory disease. Influenza is usually seasonal in nature but may be found year round if testing is done. Each year, a vaccine is developed to prepare for the upcoming flu season. The strains used in the vaccine is based on the influenza strains identified through the WHO's ongoing surveillance as those currently circulating around the globe (Heymann, 2015).

Influenza derives its importance from the rapidity with which epidemics evolve, the widespread morbidity, and the seriousness of complications, specifically pneumonias (Heymann, 2015). Influenza, an Italian word that means *influence of the cold*, has been recognized since 412 BC and was first described by Hippocrates (Heymann, 2015). It existed throughout the early centuries, and about 30 probable pandemics have been documented in the past 400 years. Three have occurred in the 20th century— in 1918, 1957, and 1968. The 1918 "Spanish flu" pandemic was the most devastating, with 20% to 40% of the world population affected and an estimated death toll of 50 million worldwide; in the United States, roughly 675,000 died (Flu.gov, n.d.). This novel influenza strain spread easily from person to person, resulting in devastating morbidity and mortality rates around the globe. The most recent influenza pandemic occurred in 2009 when the novel strain, H1N1, emerged. Estimates of infection rates range between 43 million and 89 million people, and between 8,800 and 18,300 deaths worldwide are attributed to the flu (Flu.gov, n.d.).

Influenza infections occur primarily in the winter months, affecting individuals in all age groups and causing thousands of deaths and hospitalizations annually in the United States alone. Children have the highest rates of infection, but individuals aged 65 years and older, children younger than 2 years of age, pregnant women, and those with certain medical conditions have the highest rates of serious morbidity, hospitalization, and mortality. Older adults account for more than 90% of the deaths related to influenza and pneumonia (Heymann, 2015).

Community health nurses play a major role in primary prevention. Universal immunization is recommended for *all people 6 months of age and older*. In the elderly, immunization may be less effective in preventing illness but can still be of importance

because it may reduce the severity of disease. With immunization, the incidence of complications and death among the elderly is reduced. Children younger than 6 months cannot receive the vaccine, so they need to be protected by immunization of the individuals surrounding them. It is important that community/public health nurses promote immunization of those who may suffer the poorest of outcomes and their caretakers:

- Health care workers and personal care providers
- Children younger than 5, but especially children younger than 2 years old
- Adults 65 years of age and older
- Pregnant women
- Individuals with asthma
- Those with chronic disease of any system of the body (neurologic, cardiac, pulmonary, hematologic, renal, hepatic, immune, or metabolic, endocrine, and anyone on long-term medication for an illness)

The injectable influenza vaccine is inactivated. The nasally inhaled version is a live attenuated vaccine and is licensed for use in people ages 2 to 49 years (Heymann, 2015; see Fig. 8–3). The vaccine should be given every year *before* influenza is expected in the community. The season can begin as early as October, so vaccinating in September may be indicated, but usually it begins by the end of October in most of the United States. For those living or traveling outside the United States, timing of the immunization should be based on the seasonal patterns of influenza in the area to which they are traveling (Heymann, 2015). Influenza immunization clinics are frequently planned and organized by or with the local public health agency, with the injections usually administered by community/public health nurses.

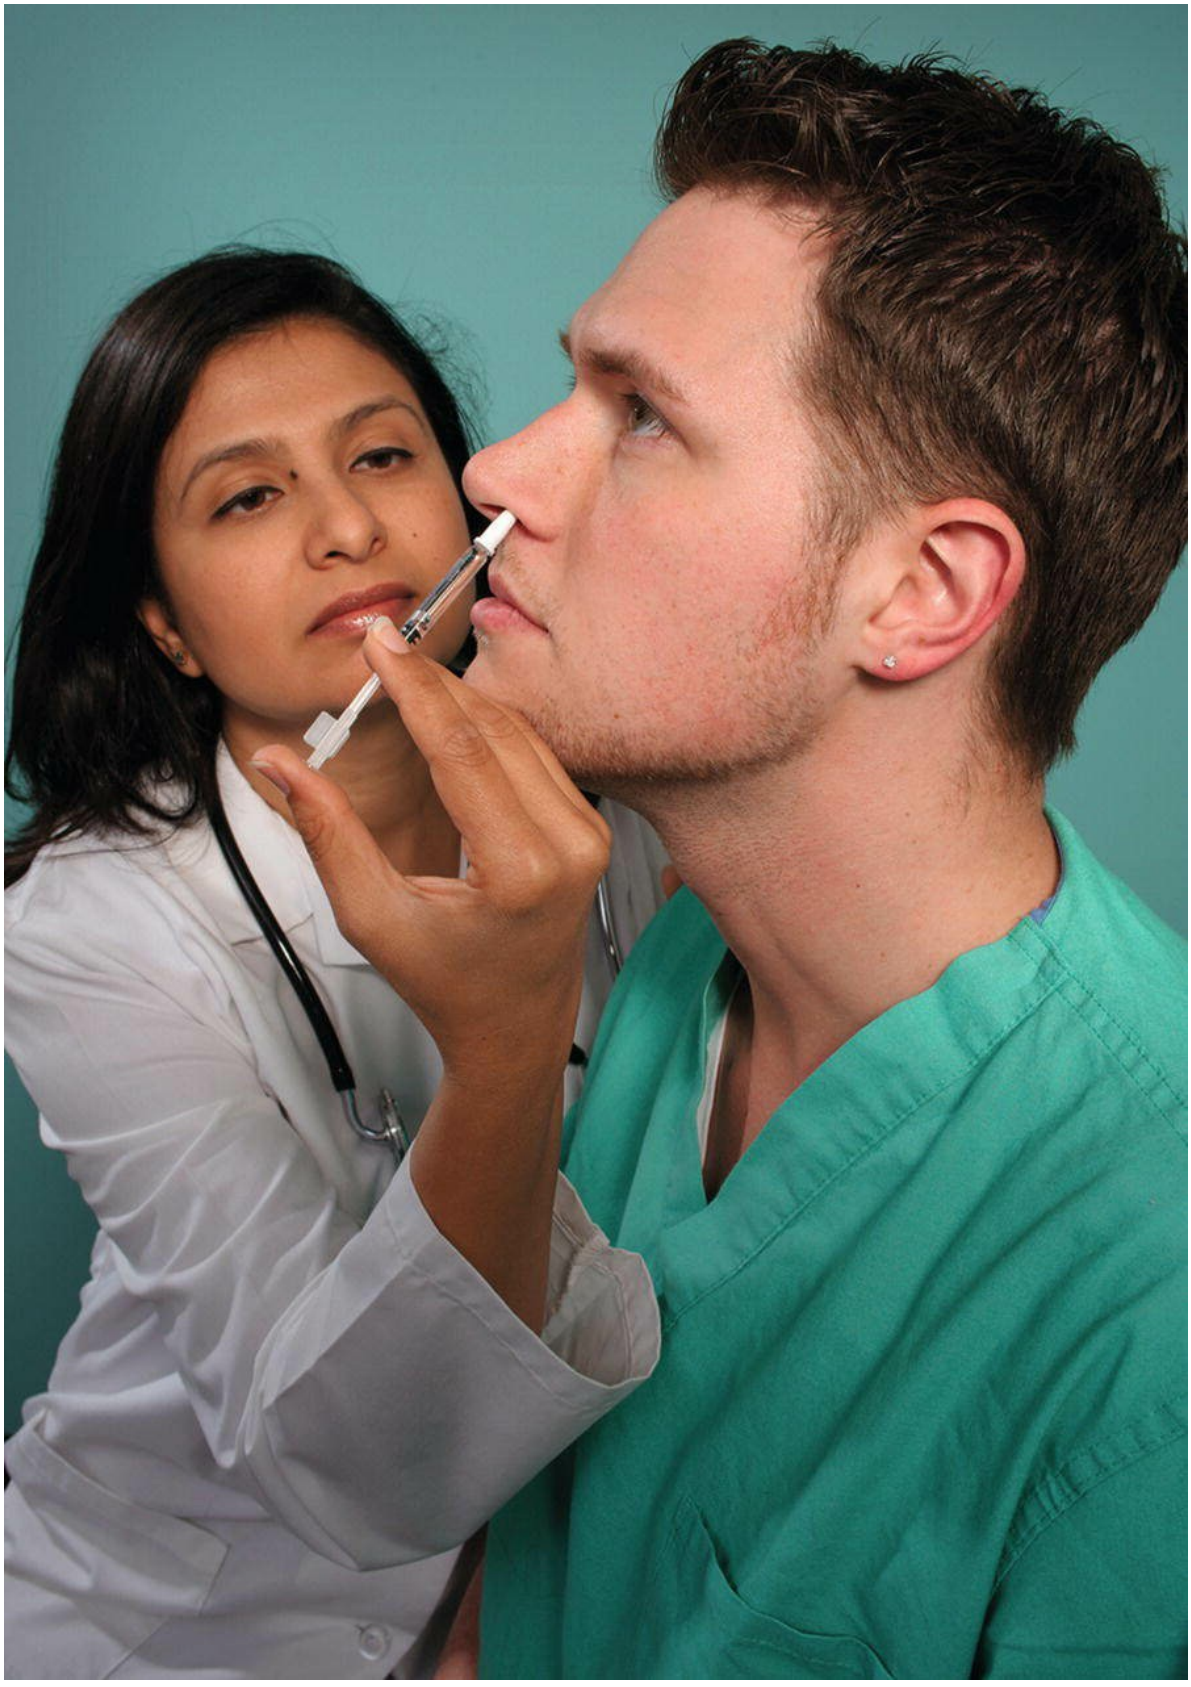

FIGURE 8–3 Administration of nasal spray flu vaccine. (From Centers for Disease Control and Prevention. Public Health Image Library. Photo Image ID #11864—James Gathany.)

Influenza pandemics occur when a flu subtype has not circulated previously (novel strain) or has reemerged in a population that has never been exposed (CDC, 2015h). The 2009 H1N1 pandemic provides an example of the emergency response to a pandemic event. On April 15, 2009, the first case of H1N1 strain influenza was diagnosed in the United States. Ongoing cases of this novel strain were being reported across the United States and around the world into the summer of 2010. There was a rapid response by the WHO and the CDC in investigating, typing the strain, and initiating the production of a vaccine. Production of a vaccine began by April 21 and on April 26, the federal government declared a public health emergency (Flu.gov, n.d.). Within 6 months, a monovalent (single-strain) vaccine was available to the public. Eighty million doses were administered during that first season, which minimized the impact of this pandemic event (Flu.gov, n.d.).

The WHO's Global Influenza Surveillance and Response System (GISRS) is an integrated surveillance system that maintains constant vigilance for new influenza viruses. It monitors the evolution of influenza viruses; provides recommendations about diagnostic testing, vaccine development, antiviral susceptibility, and assessment of vulnerable populations; and alerts when a virus is identified to have potential for creating a pandemic (WHO, 2016e). This program began in 1952 and now involves 143 institutions from 113 WHO member states.

FluNet is an Internet-based tool for worldwide influenza surveillance. This program allows for the electronic submission of influenza data from participating global laboratories. Real-time data can be accessed through this resource. As new data arrive and are verified, the maps and tables are revised to give users an up-to-date overview of the influenza situation. Data are provided remotely through the GISRS, the WHO regional databases, and other designated laboratories. Only designated users can submit data, but the results—graphics, maps, and tables of influenza activity on a global scale—are available to the general public. FluNet has expedited the sharing of information on influenza patterns and virus strains and is becoming an essential tool in preparing for and preventing influenza pandemics. Collaborating Influenza Surveillance Centers have created a task force of influenza experts to develop a plan for the global management and control of influenza pandemics. These influenza experts and world public health leaders work diligently to prevent another influenza pandemic similar to the devastating outbreak of 1918 (WHO, 2016d). See more on global disease surveillance in Chapter 16.

Pneumonia

Pneumonia is a pulmonary infection that causes inflammation of the lobes of the lungs, bronchial tree, or interstitial space. It is an important cause of death among the elderly and infants. There are a number of infectious agents that can cause pneumonia. In the United States, the most common bacterial cause of pneumonia is *Streptococcus pneumoniae* (pneumococcus), and the most common viral causes are influenza, parainfluenza, and respiratory syncytial viruses. Symptoms of pneumonia include sudden onset with a shaking chill, fever, pleural pain, dyspnea, a productive cough of "rusty" sputum, and tachypnea. The onset is less abrupt in elderly individuals who may present with fever, shortness of breath, and altered mental status. In infants and young children, fever, vomiting, and convulsions may be the initial symptoms. The diagnosis may need to be confirmed by radiographic studies (Heymann, 2015).

Community-acquired pneumonia is a significant cause of morbidity and mortality. The incidence of pneumonia is highest in winter. An increased incidence of pneumonia often accompanies epidemics of influenza. In the United States and Europe, morbidity rates range between 30 cases per 100,000 adults and 100 cases per 100,000. Incidences are higher among people living in poverty or who have poor nutrition. Case fatality rates of pneumococcal pneumonia range from 5% to 35% and are 10% for children living in developing countries. Children under the age of 6 months who live in developing countries have a 60% fatality rate. Globally, pneumonia kills more than one and a half million children younger than 5 years of age each year. This is greater than the number of deaths from any other infectious disease, such as AIDS, malaria, or TB (Heymann, 2015). Hospital admissions and mortality related to pneumonia are far more common among people older than age 65; the mortality rate is approximately 50%. Although this is not a reportable infectious disease, it can nevertheless have a great impact upon the community (Heymann, 2015).

Pneumonia can be spread by several means (e.g., droplets, direct oral contact, fomites that are defined as any inanimate objects freshly soiled with respiratory discharges). People most susceptible to pneumonia are infants, the elderly, and people with a history of chronic diseases, a compromised immune system, or any condition affecting the anatomic or physiologic integrity of the lower respiratory tract. Malnutrition and smoking also increase risk (Heymann, 2015).

Two vaccines are available to help protect against pneumonia. The pneumococcal protein–polysaccharide conjugate vaccine protects against 10 or 13 of the most common pneumonia serotypes and is included as part of the routine vaccination schedule for infants. The 23-valent pneumococcal polysaccharide vaccine (PPV23) is available for high-risk groups, ages 2 years old and up. High-risk groups include those with chronic diseases, those with immunosuppressing health conditions, or those who are asplenic. Reimmunization is recommended only for high-risk children or adults over 65 years who received their first

vaccine before age 65 and at least 5 years has passed since the previous vaccine. The vaccine is not effective in children younger than 2 years of age and is not recommended for the healthy population between the ages of 2 and 65 years. For these people, education about preventing pneumonia is a major part of the community/public health nurse's role (Heymann, 2015).

Hepatitis

Of the five viral hepatitis infections that constitute serious liver disease, the three most commonly reported types are hepatitis A, B, and C. Infection with hepatitis is an ongoing global epidemic. Substantial progress is being made in the elimination of hepatitis viruses through the primary prevention practices of education and immunization with hepatitis A and B vaccines.

Hepatitis A

Hepatitis A is caused by infection with the hepatitis A virus (HAV). It occurs worldwide and is sporadic and epidemic, with cyclic recurrences affecting children and young adults most frequently. Case rates are highest in areas with poor sanitation. This includes Central and South America, the Caribbean, Mexico, Asia (except Japan), Africa, and southern and eastern Europe (Heymann, 2015). The disease is transmitted from person to person by the fecal–oral route with an incubation period of 28 days; however, onset of illness can range between 15 and 50 days after exposure to the virus. Hepatitis A is characterized by the abrupt onset of symptoms including fever, malaise, anorexia, nausea, and abdominal discomfort, followed by jaundice in more severe cases. Children may be asymptomatic. Mild illnesses last 1 to 2 weeks; more severe cases last 1 month or longer. It is generally a self-limited disease that does not result in chronic infection or chronic liver disease. Recovery from HAV usually confers immunity for the individual. Hepatitis A is identified by the presence of immunoglobulin M antibodies against HAV in the serum of acutely or recently ill individuals. Upon diagnosis, providers are mandated to report hepatitis A to the local health agency (Heymann, 2015). Sensitive occupations include food handlers and health care personnel because of the risk of transmission to others in the course of their work (CDC, 2015s).

In areas of the world where environmental sanitation conditions are poor, endemic infection may exist and cause infection at an early age. In this setting, the majority of adults have immunity due to previous exposure. In industrialized countries, cases will tend to occur in the older population rather than children, in households of the infected, and among travelers returning from countries where the disease is endemic. At times, common-source outbreaks are related to contaminated water, food contaminated by infected food handlers, raw or undercooked shellfish harvested from contaminated water, or contaminated produce. Outbreaks of hepatitis A may warrant mass vaccination outreach with the hepatitis A vaccine or immunoglobulin (Heymann, 2015).

An inactivated hepatitis A vaccine has been available for use since 1995 (CDC, 2015s). Administered in a two-dose series, these vaccines induce protective antibody levels in virtually all who are immunized. Ninety-five percent of immunized adults develop immunity after the first dose and nearly 100% seroconvert after the second dose (CDC, 2015s). This has been a boon to eliminating this disease as a public health problem in the

United States. The vaccine is recommended as a routine vaccine for children and, as of 2005, was made available to children older than 12 months. Community/public health nurses play an important role in the prevention and control of this disease. Offering hepatitis A vaccine to travelers, conducting case investigations, providing education, and identifying potential sources and exposed contacts that need referral or assistance in obtaining postexposure prophylaxis and vaccination are vital to preventing and controlling this disease (CDC, 2015s).

Hepatitis B

Hepatitis B is a serious disease. The hepatitis B virus (HBV) is often a lifelong infection and may cause cirrhosis (scarring) of the liver, liver cancer, liver failure, and death. In a very few cases, the infection will resolve, conferring immunity (Heymann, 2015). This is a blood and body fluid pathogen; common transmission patterns are parenteral, sexual, and perinatal transmission from mother to newborn (CDC, 2015s).

Hepatitis B is a global problem. Approximately 2 billion people have evidence of resolved or current HBV infection, and 240 million people are chronic carriers of the virus. Approximately 600,000 people die each year because of hepatitis B infection. Rates are highest in China, Southeast Asia, most of Africa, most of the Pacific Islands, parts of the Middle East, and in the Amazon basin (CDC, 2015s). In countries where hepatitis B has the highest endemic rates, the primary cause of infection is from mother to fetus (Heymann, 2015). The chance of a child developing a chronic HBV infection is 90% if infected at birth, 20% to 50% if infected between 1 and 5 years of age, and only 1% to 10% if infected after the age of 5 years (Heymann, 2015). Symptoms of HBV range from unnoticeable to fulminating and include anorexia, vague abdominal discomfort in the right upper quadrant, nausea and vomiting, light or gray-colored stools, dark urine, arthralgia, arthritis, and rash, often progressing to jaundice (CDC, 2015s). Infants rarely present with symptoms, and <10% of children and only 30% to 50% of adults present with jaundice. The diagnosis is confirmed by the presence of specific antigens to HBV in serum (Heymann, 2015).

Immunization is the most effective way of preventing HBV transmission. The hepatitis B vaccine has been available in the United States since 1981. Since then, rates of HBV infection in the United States have declined by 75% (CDC, 2015s). Almost all infections would be prevented if hepatitis B vaccines were administered to all newborns and infants (Heymann, 2015). After receiving the recommended three doses of vaccine, 95% of infants and children develop immunity whereas only 90% of adults become immune. By age 65 years, only 75% become immune (CDC, 2015s). Infants born to HBV carrier mothers are at an extremely high risk for developing hepatitis B. Hepatitis B vaccination and one dose of hepatitis B immunoglobulin within 24 hours of birth, and completing the three-dose series at one to 2 months and at 6 month of age, is 85% to 95% effective (CDC, 2015s). Community/public health nurses have an important role in the prevention and control of hepatitis B. Most importantly, this role includes teaching that encourages immunization

compliance, particularly following up on immunization of infants born to mothers with chronic HBV status, and consistent adherence to universal precautions, especially for people in high-risk lifestyles or occupations.

Hepatitis C

Hepatitis C (HCV) causes a complex infection of the liver and is one of the leading known causes of liver disease in the United States. Seventy-five percent to 85% of people with acute HCV develop chronic disease (Heymann, 2015). It is a common cause of cirrhosis and hepatocellular carcinoma, as well as liver transplantation. It is believed that 3.5 million people in the United States, and 130 to 170 million people worldwide, are infected with HCV (CDC, 2015n; Heymann, 2015). Most HCV infections result from the sharing of contaminated needles or other equipment used for injecting drugs.

Symptoms are similar to those of hepatitis A and B and may be unrecognizably mild or people can present with fulminating symptoms. Only 20% to 30% of people develop symptoms (Heymann, 2015). Many infected people are unaware that they are infected because of lack of symptoms (CDC, 2015n). Diagnosis depends on the detection of antibody to HCV. Testing does not distinguish between acute and chronic disease (Heymann, 2015). Testing is recommended for those individuals at greater risk for HCV infection. These include:

- People born between 1945 and 1965.
- People who inject drugs, including those who injected once or a few times in the past and do not consider themselves drug users.
- Individuals who received transfusions or organ transplants before 1992 and recipients of blood from a positive donor.
- People with selected medical conditions, including recipients of clotting factors before 1987, people undergoing chronic hemodialysis, and those with persistently elevated alanine aminotransferase levels.
- People diagnosed with HIV/AIDS.
- People with symptoms of liver disease.
- Those exposed to HCV-positive sources, such as through needle sticks, sharps, or mucosal exposures.
- Children born to HCV-positive mothers; testing should be done after child is 18 months old to avoid detecting mother's antibodies (CDC, 2015n).

There is currently no vaccine for HCV. The public health nurse's role is primarily supportive, encouraging testing for people who identified as having HCV infection risk factors and referring individuals for care and treatment and to support/educational groups. As with HBV, teaching adherence to universal precautions in the home is important as well (CDC, 2015n). Public health nurses can also educate at-risk populations about risk reduction behaviors (Heymann, 2015).

HIV/AIDS

The *Human Immunodeficiency Virus (HIV)* is a retrovirus that attacks the body's immune system. HIV is contracted through exposure to blood and body fluids from an infected person by a susceptible person. Transmission can occur during unprotected sex, sharing of contaminated needles, and placental transmission from mother to fetus and may also be transmitted through blood or blood components. Two types have been identified: type 1 (HIV-1) and type 2 (HIV-2). These viruses are relatively distinct serologically and geographically, but they have similar epidemiologic characteristics. The pathogenicity of HIV-2 appears to be less than that of HIV-1, and antibodies can be detected in <1 month after exposure whereas onset of AIDS symptoms may take 1 to 15 years (Heymann, 2015). The age at the time of infection has been found to influence the time frame of AIDS symptoms onset, with older people having a more rapid onset than those who acquire the virus at a younger age (Heymann, 2015).

This disease was first recognized in the early 1980s and the retrovirus was identified in 1983. At that time, no treatment existed. Without effective treatment, HIV is highly fatal (Heymann, 2015). An HIV-infected individual may remain symptom free for long periods, but viral replication is active during all stages of infection. The virus destroys the hosts T cells, making it difficult to fight other infections. Opportunistic infections and cancers appear. At this point, the disease has progressed to AIDS (CDC, 2015o). Although there is no cure for HIV/AIDS, HIV infection is now treated with antiretroviral medications and is viewed by many to be a chronic, manageable disease process, especially in the developed world (Heymann, 2015). HIV continues to devastate populations of people who do not have access to life-extending medical care and medications. Seventy-one percent of those affected by AIDS are living in sub-Sahara Africa. The Caribbean countries of Haiti and the Dominican Republic are other areas heavily impacted by this epidemic (Heymann, 2015). Estimates indicate that in 2013, 35 million people were living with HIV/AIDS worldwide; there were 2.1 million new cases and 1.5 million AIDS-related deaths (Heymann, 2015).

Acquired Immune Deficiency Syndrome (AIDS) is a severe, life-threatening condition, representing the late clinical stage of infection with HIV, in which there is progressive damage to the immune and other organ systems—particularly the central nervous system. AIDS has been delayed or deferred in many individuals by the use of medications during the HIV stage of the spectrum. AIDS reporting is obligatory in most countries (Heymann, 2015).

Public health nurse interventions may include education about risk reduction behaviors for those who are at risk but not yet infected. For those who are infected, public health nurses can provide education about treatment, noting that with early initiation of appropriate treatment, a person with HIV can expect to live almost as long as an uninfected person. Nurses can also play a role in promoting good health for those who are infected, helping them access care, and advising them on how to prevent transmitting the virus to

others (CDC, 2015o).

Tuberculosis

TB is a disease primarily of the lungs and larynx, caused by the *Mycobacterium tuberculosis* (MTB) complex, *M. africanum*, *M. tuberculosis*, and *M. canettii*. These are all Gram-positive bacilli. TB can also infect other parts of the body; it is then referred to as *extrapulmonary TB* (outside of the lungs). Extrapulmonary TB occurs in approximately 15% to 30% of all active cases (Heymann, 2015). TB has two stages: latent infection, which is noninfectious to others, and active disease, which is highly infectious to others. The person with latent infection has become infected with the bacilli but has not yet developed active disease. A person with active disease has symptoms of TB. Symptoms of TB include a prolonged cough, fatigue, loss of appetite, weight loss, and night sweats. The cough may begin as a dry cough but then progresses to purulent sputum. The development of hemoptysis indicates progressed disease. A chest x-ray may reveal pulmonary infiltrates or cavitation in the upper lobes. Fibrotic changes and reduced lung volume may indicate advanced disease (Heymann, 2015).

TB is airborne and is spread by droplet nuclei, sprayed from the mouth by coughing, sneezing, laughing, yelling, singing, or any way in which air is expelled vigorously from the lungs through the mouth. A person can be infectious as long as they have viable TB bacilli in their sputum (Heymann, 2015). Infection occurs after inhaling the bacilli exhaled by a person with active TB. Communicability depends upon the duration of the exposure with the infected person as well as the proximity or closeness and ventilation within the space where the exposure occurred. The incubation time for TB is approximately 10 to 12 weeks (Heymann, 2015). Exposure to TB does not lead to actual disease in all cases. A latent period may persist for many years before the infected person develops disease and becomes infectious, if ever.

Most individuals exposed to people with TB do not become infected. Of those who do, all but about 5% to 10% will remain disease free. The remaining 90% harbor the organism in a latent stage; although they are not infectious, these individuals represent a persistent pool of potential cases in a population. The likelihood of being among the 10% who develop clinical infectious disease is variable, depending on the initial dose of infection and certain other risk factors (Heymann, 2015). Groups at increased risk include children younger than 3 years of age, adolescents and young adults, the aged, the immunosuppressed, and those who are early in their infection (<2 years). Health factors can contribute to the development of active TB. Poor nutrition, health status, and chronic illness like diabetes can inhibit the immune system's ability to prevent TB activation from the latent TB dormant state (Heymann, 2015). Figure 8–4 shows the geographic distribution of TB in the United States.

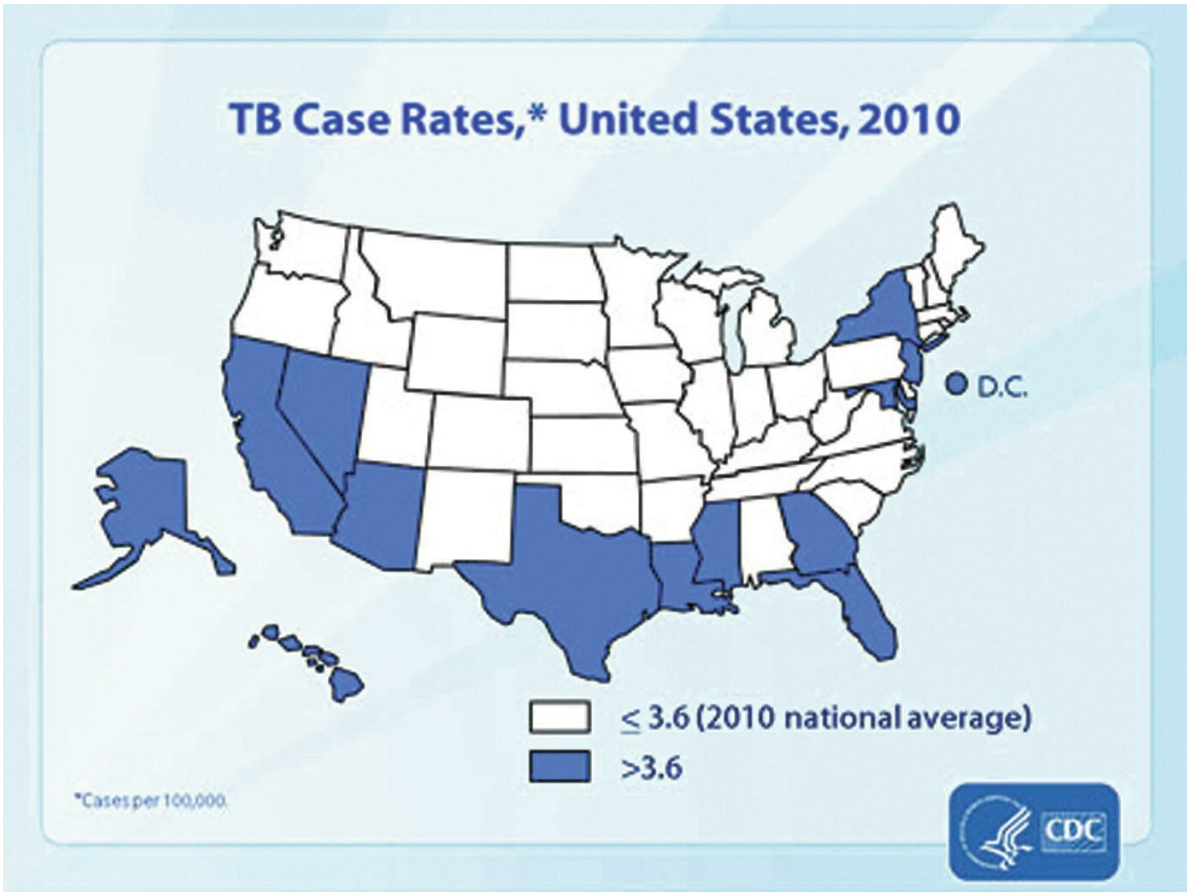

FIGURE 8–4 Reported TB cases in the United States, 1982–2014, and TB case rates by state. (From Centers for Disease Control and Prevention (CDC). (2014). Trends in tuberculosis, 2014. Retrieved from http://www.cdc.gov/tb/publications/factsheets/statistics/tbtrends-2014.pdf)

Once almost eradicated, TB has reemerged as a serious public health problem. Nearly one third of the world's population is infected with latent TB (Heymann, 2015; WHO, 2016e). There were a total of 8.6 million cases of active TB in 2013 (CDC, 2015o). Over 95% of all cases of TB are occurring is developing countries with the highest rates found in sub-Sahara Africa (Heymann, 2015). In 2014, over 9,420 new TB cases were reported in the United States, representing a rate of 2.96 cases per 100,000 people. This rate was 2.2% lower than in 2013. Rates continue to drop since 1953, when national reporting was instituted; however, this drop is the smallest decline in rate in the past decade (CDC, 2015u). This illness continues to be a significant health threat in many parts of the world. There are sharply disparate rates among foreign-born and racial/ethnic minority populations. In the United States, 66% of the reported TB cases in 2014 were among foreign-born individuals. The rate of foreign-born TB cases in the United States was 13 times greater than the rate among those born in the United States (CDC, 2015o). Rates per 100,000 people were highest among Asian (17.8 cases) and Native Hawaiian and other Pacific Islanders (16.9 cases), whereas the White population had the lowest rates (0.6 cases). Rates among African Americans, Alaska Natives, and Hispanics/Latinos were 5.0 cases for

all three groups (CDC, 2015o).

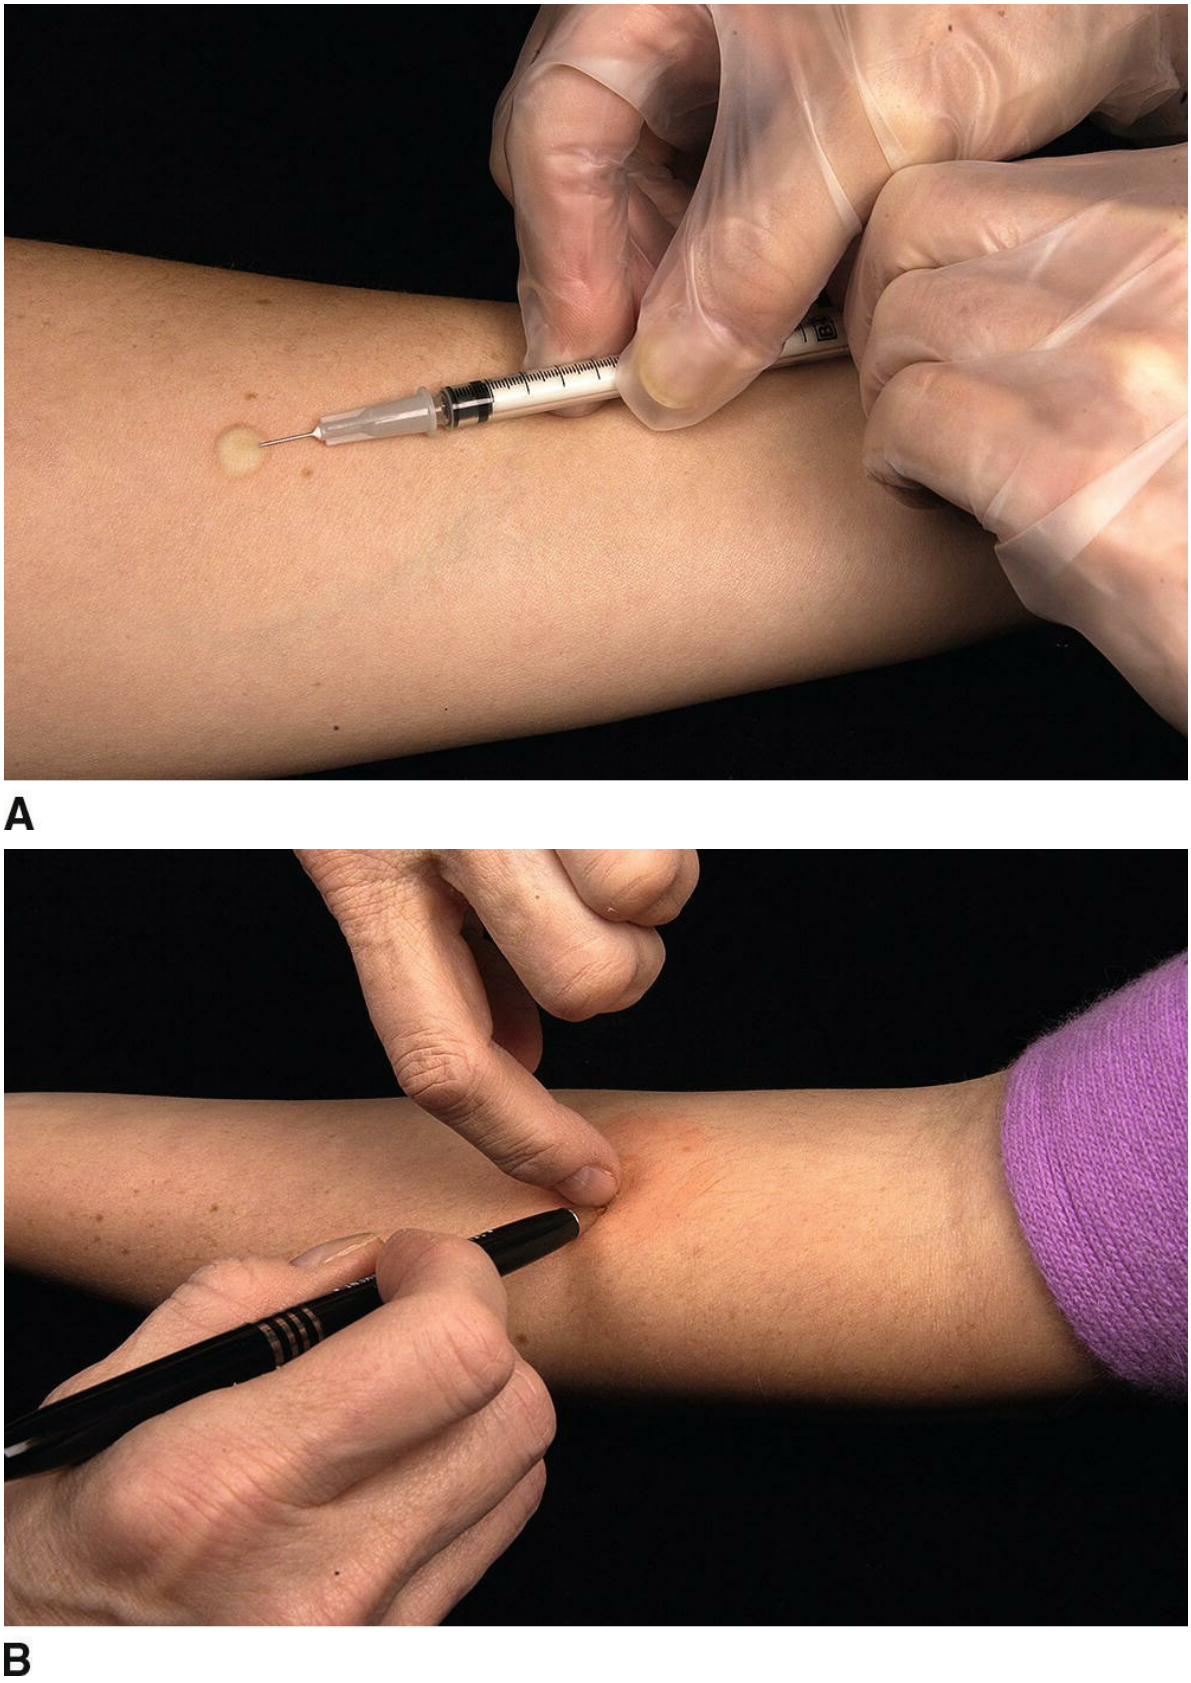
The WHO characterizes global TB burden into three categories: TB rates, multiresistant TB and TB with HIV coinfection. Fourteen countries fell into all three of the high-burden categories; they are Angola, China, Democratic Republic of Congo, Ethiopia, India, Indonesia, Kenya, Mozambique, Myanmar, Nigeria, Papua New Guinea, South Africa, Thailand, and Zimbabwe (WHO, 2016i).

HIV infection contributes dramatically to the development of active TB. People with HIV/AIDS can develop active TB within weeks after exposure to the mycobacterium, and the disease progresses much faster than in those with a normal, competent immune system. The risk of developing active TB increases from the 10% lifetime risk for the general population to 15% each year, if they are not receiving antiretroviral treatment (Heymann, 2015). It is critical to rule out active disease before treating a person with HIV/AIDS for latent TB infection to also reduce the risk of developing drug-resistant TB (CDC, 2011f; Heymann, 2015).

Screening

TB infection can be detected by screening through either a skin test or blood testing. The tests can only be used to identify a person who has been infected at some point; they do not differentiate between latent and active disease.

Tuberculin skin test (TST): The Mantoux TST can detect if a person is infected with *M. tuberculosis* 2 to 8 weeks after infection (CDC, 2014g). Using the Mantoux technique, the nurse injects 0.1 mL of 5 TU purified protein derivative (PPD) solution through the intradermal route. The reading must be conducted within 48 to 72 hours after the test had been administered. Interpretation of the results is based on measurement of induration and recorded in millimeters. Induration is described as the raised, hard area (redness is not considered part of the reaction). Results are considered positive based on various factors (CDC, 2014g). See Figure 8–5A and B for information on the correct administration, reading, and interpretation of TB skin tests.



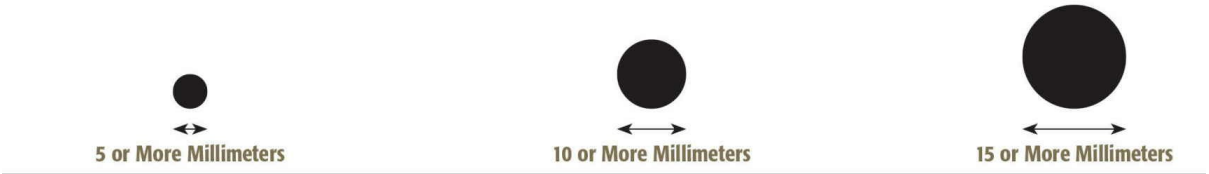


Figure 8–5 A and B: Mantoux tuberculin skin test. (From Centers for Disease Control and Prevention (CDC) (2013). *Tuberculosis: 2012 surveillance slides*. Retrieved from http://www.cdc.gov/tb/statistics/surv/surv2012/slides/surv24.htm)

Special considerations: Nurses should not administer the TST to individuals who report a previous positive TST. The BCG vaccine, used in TB-endemic countries to protect infants and young children from life-threatening TB illness, may cause a reaction to the TST. The effect of BCG often wanes over time; however, repeated TST may boost the reactivity in a BCG-vaccinated person. The results should be interpreted based on risk stratification regardless of BCG history. Two-step TST testing may help to identify an infected person who might otherwise not be detected owing to a waning immune response because too much time had lapsed since a previous TST. The two-step approach allows the immune system to wake up and respond using a booster effect (CDC, 2014g). See Table 8–1 with instructions on reading TB skin tests and Table 8–2 for TB classification system.

Table 8–1 Classification of the Tuberculin Skin Test Reaction

5 or More Millimeters	10 or More Millimeters	15 or More Millimeters
An induration of **5 or more millimeters** is considered positive for: • IHIV-infected persons • Recent contacts of persons with infectious tuberculosis (TB) • People who have fibrotic changes on a chest radiograph • Patients with organ transplants and other immunosuppressed patients (including patients taking a prolonged course of oral or intravenous corticosteroids or TNF-α antagonists [tumor necrosis factor])	An induration of **10 or more millimeters** is considered positive for: • People who have come to the United States within the last 5 years from the areas of the world where TB is common (e.g., Asia, Africa, Eastern Europe, Russia, or Latin America) • Injection drug users • Mycobacteriology lab workers • People who live or work in high-risk congregate settings • People with certain medical conditions that place them at high risk for TB (silicosis, diabetes mellitus, severe kidney disease, certain types of cancer, and certain intestinal conditions) • Children younger than 5 years • Infants, children, and adolescents exposed to adults in high-risk categories	An induration of **15 or more millimeters** is considered positive for: • People with no known risk factors for TB

From Centers for Disease Control and Prevention. (2013). Core curriculum on tuberculosis: What the clinician should know (6th ed.). Table 3.2 interpreting the TST reaction. Retrieved from http://www.cdc.gov/tb/education/corecurr/pdf/chapter3.pdf

Table 8–2 Classification System for Tuberculosis (TB)

Class	Type	Description
0	No TB exposure ***Not*** infected	• No history of TB exposure and no evidence of *M. tuberculosis* infection or disease • Negative reaction to tuberculin skin test (TST) or interferon gamma release assay (IGRA)
1	TB exposure No evidence of infection	• History of exposure to *M. tuberculosis* • Negative reaction to TST or IGRA (given at least 8 to 10 weeks after exposure)
2	TB infection No TB disease	• Positive reaction to TST or IGRA • Negative bacteriological studies (smear and cultures) • No bacteriological or radiographic evidence of active TB disease
3	TB clinically active	• Positive culture for *M. tuberculosis* • Positive reaction to TST or IGRA, plus clinical, bacteriological, or radiographic evidence of current active TB
4	Previous TB disease (***not*** clinically active)	• May have past medical history of TB disease • Abnormal but stable radiographic findings • Positive reaction to the TST or IGRA • Negative bacteriologic studies (smear and cultures) • No clinical or radiographic evidence of current active TB disease
5	TB suspected	Signs and symptoms of active TB disease, but medical evaluation **not** complete

From Centers for Disease Control and Prevention. (2013). Core curriculum on tuberculosis: What the clinician should know (6th ed.). Table 2.8 TB classification system. Retrieved from http://www.cdc.gov/tb/education/corecurr/pdf/chapter2.pdf

Interferon gamma release assays (IGRAs): There are two IGRA tests, the QuantiFERON test (QFT) and the T-spot test. The IGRA test detects the immune response to TB proteins in the blood (CDC, 2014g).

Advantages of IGRAs:

- Necessitates only one visit to be tested
- Twenty-four-hour turnaround time on results
- Does not boost responses measured by subsequent tests
- Is not affected by health care provider's interpretation of the results
- No false-positive results from past immunization with BCG vaccine

Disadvantages and limitations of IGRAs:

- Blood samples must be processed within 8 to 30 hours after collection.
- Collecting or transporting errors of the blood specimens or in running and interpreting the assay can decrease the accuracy of IGRAs.
- Limited data on the use of IGRAs to predict who will progress to TB disease in the future.
- Limited data on the use of IGRAs for:
    - Children younger than 5 years of age
    - Persons who had been recently exposed to *M. tuberculosis*
    - Immunocompromised persons
    - People requiring serial testing
- Tests may be expensive.

IGRAs are preferred for people who are not likely to return for reading of TST and

people who have a history of receiving BCG vaccine. The TST is preferred for children under the age of five (CDC, 2014g).

Diagnosis of Active TB

Diagnosis of suspected active TB disease is initially based on the presence of acid-fast bacilli (AFB) in the sputum. Confirmation is determined by culture that reveals MTB. The culture test also provides information about drug susceptibility that informs the decisions for treatment (Heymann, 2015). A full examination should also be conducted, including obtaining a chest radiograph and reviewing the person's history of risk factors and symptoms.

Prevention and Intervention

The public health nurse can apply all three levels of prevention when working with TB clients. According to the CDC Division of TB Elimination (DTBE) (CDC, 2011d), a well-functioning TB control program must focus resources on those at risk for TB exposure and treating latent TB and active TB. Isoniazid therapy for individuals who are infected with TB but have no evidence of active disease has been shown to be highly effective in preventing progression to infectiousness and clinical symptoms. Isoniazid (also known as INH) is a key component of the treatment for active disease (CDC, 2016d; Heymann, 2015).

Risk factors for active TB can be poor health (HIV/AIDS, chronic disease), lack of access to health care, poverty, malnutrition, and fear of deportation (nonresident status). Prevention and rapid treatment of infection can help prevent active TB and the possible emergence of drug-resistant TB. The functional aspect of the program should ideally strive for:

- Standardized public health practices for investigating, case and contact finding, as well as care and treatment.
- Case management of care and treatment of the individual with TB to ensure medication compliance and barriers to treatment completion are dealt with so treatment completion will occur.
- Close monitoring for sputum conversion in people with active disease, in order to adjust medication as necessary.
- A high completion-of-therapy rate within 1 year after diagnosis.
- Assurance of adequate funding and a dedicated TB control infrastructure.

When candidates for drug therapy are identified, it is essential to provide program support to ensure that the maximum number of individuals comply with their medication regimen for the full duration of therapy. One of the most effective ways to achieve a high completion-of-therapy rate is through directly observed treatment (DOT). DOT is a public health strategy of delivering TB treatment so that the patient is observed taking the

medications each day. The benefits of DOT include timely completion of treatment, prevention of drug resistance, and preventing further transmission (California Department of Public Health [CDPH], 2014). In endemic countries, such as Africa, directly observed treatment short course (DOTS) is used. This strategy assures treatment success because the client takes the medication in the presence of a health care worker. The DOT(s) strategy has been demonstrated to work when it is implemented universally with all active TB patients within the county, and it is supported by the CDC and in turn by state and local health departments. It is not mandatory, but health officers may use the laws surrounding TB prevention and public protection to institute policy and statute to mandate its use. By using DOT(s) with the client with active TB, there is a reduction in ongoing potential sources of infection in the community (CDC, 2016d; Moonan et al., 2011).

The DOT approach is obviously labor-intensive, but according to the WHO, it has made a difference in fighting the spread of this disease. The more difficult clients are those who do not realize their personal or social responsibility for health and those who do not have the resources to focus on health when there are other stressors or diversions in their life. For these reasons, clients such as alcohol and drug abusers, transient homeless people, and people stressed by socioeconomic problems may become the source for new cases of TB. DOT therapy ensures that clients take a daily or intermittent dose of prescribed medication, locating them wherever they may be—in neighborhood bars, sleeping on the sidewalk, in a homeless shelter, or in a drug rehabilitation center. Most health departments and TB control programs have a percentage of their clients receiving DOT therapy, with licensed staff or community health workers assigned to administer the TB drug regimen. These outreach workers and sometimes public health nurses meet the people where they are, school, shelter, church, bar, or job, wherever it supports adherence to the mediation regimen. These ancillary staff members are often former program participants, trained and supervised by professional health workers. A program like DOTS needs sustained political commitment, with the governments of nations recognizing the long-term benefits of providing the resources and staff necessary to ensure its proper implementation (CDC, 2011d, 2016d; Moonan et al., 2011).

Multidrug-Resistant Tuberculosis

Epidemiologists and communicable disease specialists cite a number of factors that contribute to the development and spread of TB strains resistant to one or more of the standard arsenal of TB drugs. Strains now exist that are resistant to almost all of the standard anti-TB drugs. According to the WHO, one in four persons contracting XDRTB dies rapidly, within months from the disease. Chief among the factors contributing to drug resistance seems to be the political and social response to declining rates of TB over past decades, which has resulted in funding cuts for surveillance, treatment, and research and a premature sense that TB was defeated. Figure 8–6 demonstrates the disproportionate prevalence of MDRTB in foreign-born persons. On an individual case basis, the most common means by which resistant organisms are acquired is by noncompliance with therapy for the full, recommended period. As previously mentioned, the DOTS intervention can help those with TB successfully treat and cure the disease (Moonan et al., 2011; WHO, 2016g). Figure 8–6 compares MDRTB rates among people born in the United States and those born in other countries now living in the United States.

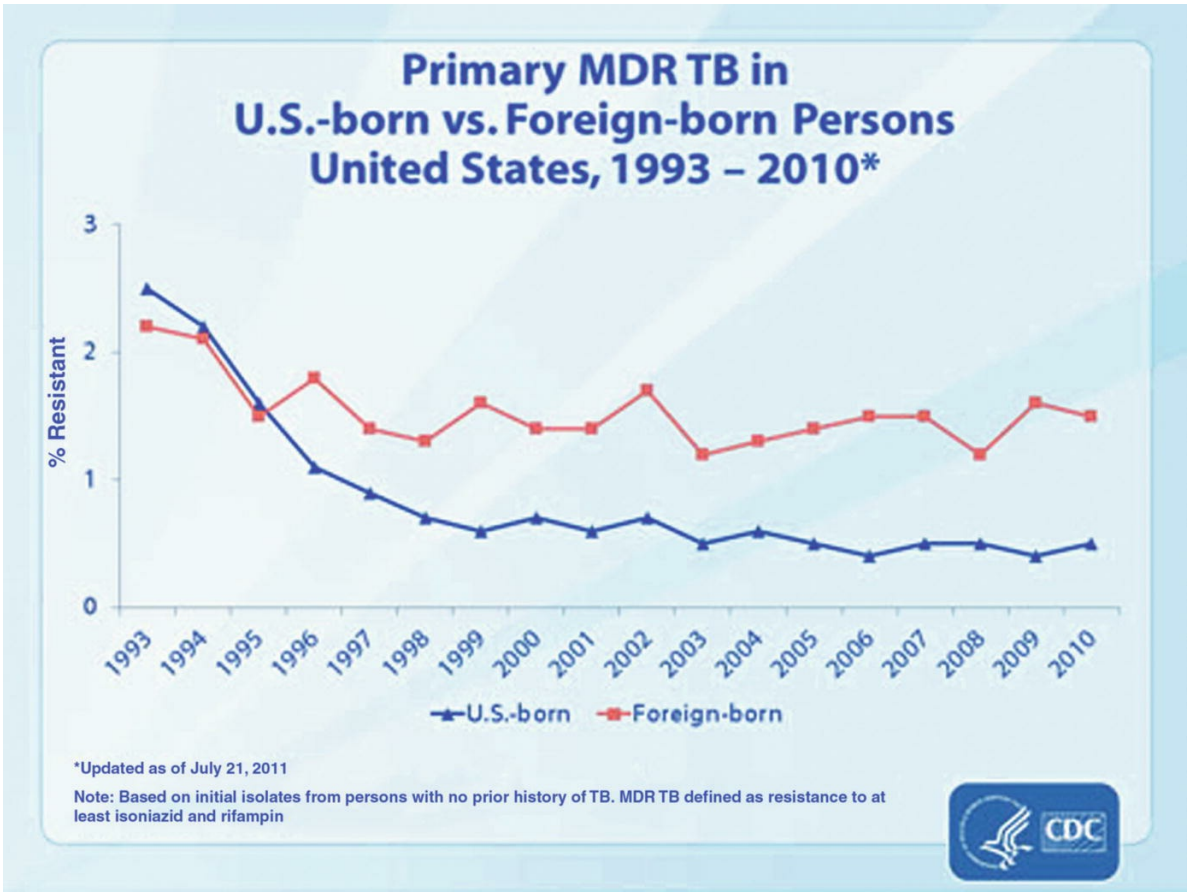

FIGURE 8–6 Multidrug-resistant TB patterns: comparison of U.S.-born and foreign-born persons, 1993–2012. (From Centers for Disease Control and Prevention (CDC). (2013). Tuberculosis: 2012 surveillance slides. Retrieved from http://www.cdc.gov/tb/statistics/surv/surv2012/slides/surv24.htm)

Clients with HIV and TB

HIV infection is associated with an increased possibility of developing primary TB after exposure to a source. The person living with coinfection of latent TB infection and HIV infection has a 50% higher risk of developing active TB than the immunocompetent individual (Heymann, 2015).

People with HIV infection and TB infection should be counseled thoroughly about the benefit of preventive treatment and possibility of TB activation without treatment. For HIV-infected people, preventive therapy usually consists of isoniazid daily for up to 1 year (the usual regimen for preventive therapy is 6 to 9 months). These clients must be monitored closely for effectiveness of the preventive therapy and for tolerance to isoniazid. This drug has the capacity to develop adverse reactions or negative side effects. Isoniazid can cause hepatitis or damage the liver; close monitoring and regular follow-up are necessary to detect early symptoms such as nausea, vomiting, abdominal pain, fatigue, and dark urine signifying bleeding. Any combination of these symptoms is sufficient to initiate liver function tests (Heymann, 2015).

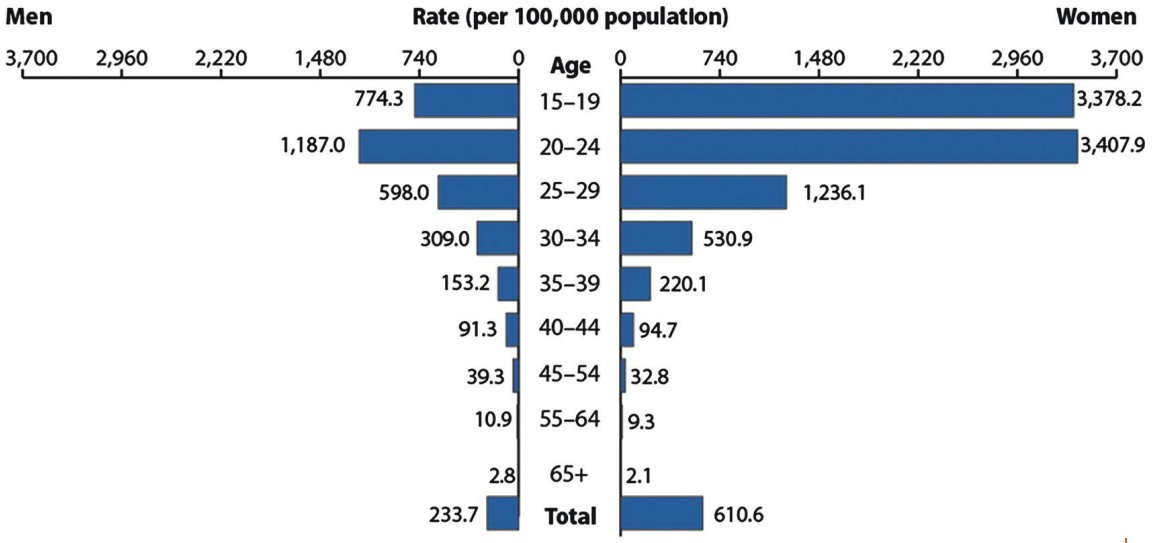
The HIV-positive client may not have the ability to react to a skin test for TB because of a weakened immune system. Therefore, other methods to determine TB status are employed. If it is determined that TB disease is present, HIV-infected clients should begin a regimen of drugs according to the accepted national and global medication schedule used in their country. The client should be closely monitored for response to treatment; if they do not seem to be responding, they should be reevaluated. Drug sensitivity is key to correct and successful treatment.

TB Case Management

Community health nurses have a responsibility to individuals who are HIV infected and also infected with TB, to experience a successful TB treatment regimen. As previously mentioned, a component of a successful TB program is case management of care and treatment, which includes monitoring for adherence to treatment, administering medications (either directly through DOT or through DOT supervision by ancillary staff), interviewing the individual for signs and symptoms of adverse reactions, collecting lab specimens in a timely manner and monitoring for culture conversion, monitoring for overall health and well-being, educating, and making referrals (CDC, 2011f).

Sexually Transmitted Infections

Chlamydia



Chlamydia trachomatis (CT) infections are the most commonly reported notifiable STD in the United States (CDC, 2015i). In 2014, more than 1,440,000 cases of *Chlamydia* were reported in the United States; however, estimates of actual numbers of infection indicate that there may be 2.86 million actual cases each year. The numbers are likely underrepresented because of the lack of symptoms in most cases. Only 10% of men and 5% to 30% of women with confirmed *Chlamydia* reported having symptoms. This illness is transmitted through sexual contact and through maternal transmission to their newborn (CDC, 2015i). *Chlamydia* is a public health concern because while it remains a "silent" disease for those who are asymptomatic, serious complications can impact women. These complications include pelvic inflammatory disease (PID), fallopian tube issues including ectopic pregnancy and infertility, and chronic pain in the pelvis (CDC, 2015i). Infection during pregnancy can lead to preterm delivery or complications for the newborn including conjunctivitis or pneumonia (CDC, 2015i).

This infection affects young people as the majority of new cases are among people between the ages of 15 and 24. Estimates are that 1 in 20 young women in the United States are infected with CT (CDC, 2015i). Disparities exist, resulting in infection rates among Black individuals that are 6.7 times higher than the rates of White individuals.

Screening programs have been extremely effective in reducing the overall *Chlamydia* burden and reducing rates of PID in women (CDC, 2015d). The use of the highly sensitive nucleic acid amplification (NAAT) urine tests is easy and more acceptable to most individuals who may be symptomatic or asymptomatic (CDC, 2015d). As a result of increased screening efforts in many settings outside of the medical office, reported rates of *Chlamydia* continue to increase, especially in women aged 15 to 24 years (Display 8–4).

DISPLAY 8.4 *CHLAMYDIA*—RATES OF REPORTED CASES BY AGE AND SEX, UNITED STATES, 2014

From Centers for Disease Control and Prevention. (2015). 2014 Sexually transmitted diseases surveillance. Retrieved from http://www.cdc.gov/std/stats14/figures/5.htm

The current CDC (2015i) guidelines for screening recommendations are as follows:

- Yearly screening of all women who are sexually active and 24 years old or younger.
- Women older than 24 years old who have a new sexual partner or multiple partners or whose partner has been diagnosed with an STD.
- Screen all pregnant women at their first obstetrical visit.
- Routine screening of men is not generally recommended; however, screening should be considered among men who have sex with men in settings with high rates of CT infection.

Recommended antibiotics for treatment of *Chlamydia* include azithromycin, doxycycline, levofloxacin, or ofloxacin. Erythromycin may cause gastrointestinal side effects resulting in nonadherence to the treatment regimen (CDC, 2015d). Barriers exist to successful prevention, diagnosis, and treatment of *Chlamydia*. Stigma surrounding seeking care, access to affordable care, and completion of extended antibiotic treatment may keep individuals from getting care and treatment. Using a one-dose treatment is far more acceptable than two to three times a day for 7 days treatment plan (CDC, 2011e).

Treating partners disrupts the transmission of disease by preventing reinfection to the person who had received treatment as well as preventing infection of other partners (CDC, 2015d). Some health departments use the Internet to anonymously notify partners of possible exposure to an STD (CDC, 2015e). Another strategy is to use patient-delivered partner treatment or expedited partner treatment (EPT). This entails the giving of either a prescription or medication to the infected patients to, in turn, give to their sex partner. This intervention has been shown to be more effective than encouraging the patient to notify the partner(s) to seek testing and treatment. Each state may have its own legal requirements related to this treatment option; the nurse needs to review and understand

their states' law (CDC, 2015e). Another aspect to this method of treatment is to provide very specific written instructions that include self-administration of the medication, warnings about pregnancy and allergic reactions, when to seek medical care, and how to prevent reinfection (CDC, 2015e). However, for men who have sex with men, this practice is not as customary, as there may be other coinfection issues needing evaluation and treatment, such as HIB infection (CDC, 2015e). To minimize the risk for reinfection, clients should be instructed to abstain from sexual intercourse until all of their sex partners have been treated and advised to use condoms as a continued STD prevention method. Testing for cure of infection depends upon the type of antibiotic used and if the person is pregnant or not (CDC, 2015d).

Gonorrhea

The causative agent of gonorrhea (GC) is the gonococcus bacteria—*Neisseria gonorrhoeae*. GC is the second most commonly reported notifiable disease in the United States with 350,062 cases reported in 2014 (CDC, 2015a). Rates had been decreasing with a historic low of 98.1 cases per 100,000 people in 2009; however, since then, there has been an uptick of reported GC cases. In 2014, rate was 110.7 per 100,000. Ninety-three percent of cases were among people 15 to 44 years old. Compared to the rate of reported GC among Whites, the rate was 10.6 times higher in Blacks, 4.2 times higher in American Indian/Alaska Natives, 2.7 times higher in Native Hawaiians and other Pacific Islanders, and 1.9 times higher in Hispanics. Between 2010 and 2014, rates of reported GC infection among men had increased whereas rates among women had decreased. This increase may be due to either increased transmission or increased testing among men (CDC, 2015a).

Gonorrhea commonly manifests in men as a purulent drainage from the penis, accompanied by painful urination within 2 to 7 days after an infecting exposure. Women infected with GC are often asymptomatic or the symptoms such as vaginal discharge or bleeding after intercourse may be so mild as to go unnoticed (Heymann, 2015). Progression of untreated GC in women can lead to serious reproductive system involvement including PID, infertility, or ectopic pregnancy. Disseminated gonococcal infection presents with a petechial or pustular lesions and requires hospitalization for treatment. These patients should be evaluated for complications such as endocarditis and meningitis. Screening criteria are similar to those of *Chlamydia*; refer back to previous section on *Chlamydia* (Heymann, 2015).

Antimicrobial resistance is a great concern when treating GC. In 2007, treatment recommendations switched from the use of fluoroquinolone to cephalosporin because of an emergence of a fluoroquinolone-resistant strain of *N. gonorrhoeae* (CDC, 2015f). Then in 2010, concerns over emerging resistant GC prompted the CDC to recommend dual therapy, combining cephalosporin with azithromycin or doxycycline. Resistance to cefixime, a third-generation cephalosporin, appeared in Asia, Europe, South Africa, and Canada, causing further changes in dual treatment guidelines advising the exclusive use of ceftriaxone and azithromycin (CDC, 2015f). GC can be transmitted to neonates during

delivery and presents 2 to 5 days after delivery. This can result in ophthalmia neonatorum and sepsis. Most states have a law that requires a prophylactic agent be given to all infants after delivery to prevent ophthalmia neonatorum. Infants born to mothers infected with GC who had not received treatment are at high risk for infection. Treatment during pregnancy is the best way to prevent GC infection in the newborn (CDC, 2015f).

Sex partners need to be referred to a medical provider for testing and treatment, but if this is not possible, EPT can be used. This is not the preferred partner treatment course for men who have sex with other men owing to concerns of coexisting STD infection including HIV (CDC, 2015f). Once again, it is best to refer to your state's regulations surrounding this method of treatment.

Syphilis

Syphilis is a sexually transmitted infection caused by the spirochete, *Treponema pallidum*. This disease is characterized by three distinct stages. Approximately 3 weeks after exposure, a primary lesion called a *chancre* characteristically appears as a painless ulcer at the site of the spirochete entry point. This first stage is considered primary syphilis. After 4 to 6 weeks, the chancre heals without treatment and is replaced by the development of a more generalized secondary macular-to-papulosquamous skin eruption, classically appearing on the soles of the feet, palms of the hands, and trunk. This rash is often accompanied by fever, sore throat, lymphadenopathy and fatigue. This stage is secondary syphilis. These secondary manifestations can resolve spontaneously within weeks or may persist up to 12 months. During the primary and secondary stages, the spirochete invades the central nervous system. If untreated, a latent period follows, which may last from weeks to years. One third of those infected who do not receive treatment progress to tertiary syphilis. These latent stages are referred to as latent, late latent, and tertiary or neurosyphilis. In the early latent stage, recurring lesions may appear. The third stage is associated with severe systemic involvement, disability, and abnormalities in the cerebral spinal fluid, deafness, meningitis, cranial nerve palsy, or even death (Heymann, 2015).

Transmission of syphilis occurs when a person is exposed to the spirochetes through direct contact with the lesions that are present during the primary or secondary stages of the disease. Syphilis can be transmitted from an infected mother to the fetus during pregnancy. Congenital syphilis can result in fetal death, premature birth, death of the newborn, or a variety of complications including failure to thrive, anemia, lesions, and CNS symptoms. Infection can also occur through blood transfusions if the donor was in the early stages at the time of the donation (Heymann, 2015).

The incidence of syphilis had been declining, with the lowest rates in 2000 and 2001 at 2.1 cases per 100,000 reported, but the number of cases increased to 6.3 cases per 100,000 in 2014. Increased incidence has been seen among men, especially impacting the population of men who have sex with men. The highest rates of syphilis in 2014 were among both men (31.1 cases per 100,000) and women (4.5 cases per 100,000) between the

ages of 25 and 29. Rates of congenital syphilis also increase between 2013 and 2014 (CDC, 2015c).

Penicillin is the treatment of choice for syphilis. Patients should be instructed to avoid sexual contact until the treatment is completed and the lesions have resolved; contacts should also receive treatment. For patients with primary syphilis, contacts are defined as sexual partners within the 3 months prior to onset of symptoms; for secondary syphilis, this time period should extend to 6 months prior to onset of symptoms and for those with tertiary syphilis, 1 year for early latent and long-term partners for those diagnosed in the late latent stage. If an infant is diagnosed with congenital syphilis, all immediate family members should be treated (Heymann, 2015). Anyone diagnosed with syphilis should also be evaluated for other STDs.

Genital Herpes

Genital herpes is an STD caused by the herpes simplex viruses type 1 (HSV-1) and type 2 (HSV-2) and is one of the most common STDs in the United States. Most genital herpes infections are caused by HSV-2; however, rates of HSV-1 genital herpes are increasing among college students. Most people with HSV-2 remain undiagnosed because of the symptoms being mild causing the person to not recognize a need to seek medical care (CDC, 2015b). When the infection first occurs, symptoms are systematic and may include fever and malaise, and bilateral lesions appear on the cervix or external genitalia in women or the external genitalia in men. The anus or rectum can be affected in those who engage in anal intercourse. These lesions may last 2 to 3 weeks (Heymann, 2015). The infection can remain in the body indefinitely. Subsequent outbreaks can present in areas beyond the initial exposure site. These lesions are usually unilateral, less severe, and less frequent and resolve more quickly than the primary lesion (Heymann, 2015). HSV can be diagnosed through isolation of the virus, DNA detection through polymerase chain reaction (PCR) testing, or through tests that detect HSV antigens. Viral isolates can be typed to determine whether the infection is due to HSV-1 or HSV-2 (Heymann, 2015).

There is no cure for HSV; however, antiviral medications can prevent or reduce the duration of an outbreak and can reduce the risk of transmission to uninfected sexual partners (CDC, 2015l). If a pregnant woman becomes infected late in the pregnancy, delivery by cesarean section is often advised to reduce the risk of transmission to the neonate. Women who have a history of HSV is <1%, and a cesarean section is only advised if an active lesion is present at the time of delivery. Antiviral therapy can be given to the pregnant woman at 36 weeks gestation to suppress the virus to help reduce the need for a cesarean section birth (Heymann, 2015).

Viral Warts

Condyloma acuminata, verruca vulgaris, papilloma venereum, and the common wart are all forms of a viral disease caused by the *human papillomavirus* (HPV) and manifested by a

variety of lesions found on the skin or mucous membranes (Heymann, 2015). Lesions found on the throat or respiratory tract are referred to as recurrent, respiratory papillomatosis. Those found in and around the genital region are condyloma acuminata, otherwise known as genital warts (Heymann, 2015). HPV is transmitted through direct contact, through contact with fomites, or from an infected mother to her neonate during vaginal birth. Genital warts are sexually transmitted via skin-to-skin contact. The incubation period is usually 2 to 3 months (Heymann, 2015).

More than 120 HPV types have been identified and at least 40 of these types of the virus are sexually transmitted. Whereas most infections with HPV are asymptomatic and self-limiting, some can persist and progress to cancer of the oropharynx, anus, cervix, vulva, vagina, or penis (CDC, 2015l). HPV is the most common STD. Each year, 14 million people are infected with HPV, mostly teenagers and young adults, and approximately 17,600 women and 7,300 men are diagnosed with HPV-related cancer. Cervical cancer is the most common HPV cancer among women, affecting approximately 11,000 women annually; 4,400 of them die each year. Oropharyngeal cancer is the most common HPV cancer among men, striking approximately 7,200 men each year (CDC, 2015p). Sexually active individuals are at risk for contracting any one or several of the types of genital warts that exist. Because few produce the actual bumpy, visual signs of warts and some produce no notable symptoms, many cases go undiagnosed. This asymptomatic state leads to ongoing transmission between or among sexual partners (CDC, 2015g). Cervical screenings, such as the Papanicolaou (Pap) smear, are recommended for women between the ages of 21 and 65 (CDC, 2015l). If cervical changes are seen, colposcopy and biopsy may be necessary (Heymann, 2015).

Treatment may include curettage, trichloroacetic acid, cryotherapy with liquid nitrogen, or surgical debunking for larger lesions. Patient-applied treatment may include immunomodulator creams or ointments, but topical treatments may not be appropriate for pregnant women (Heymann, 2015).

Three vaccines are available for the prevention of HPV infection. These vaccines are available to both female and males, and recommendation for administration is between the ages of 11 and 12. They can be given after that age if a person had not been previously vaccinated. Females can receive any of the vaccines; however, males must only receive the quadrivalent or 9-valent HPV vaccine. It is preferable that the vaccine be given prior to onset of sexual activity (CDC, 2015p). Condom use is also recommended to prevent transmission of HPV; however, condoms may not give full protection (CDC, 2015p) (see Chapter 22).

Sexually Transmitted Disease Prevention and Control

Human history has been shaped by disease, and all historical events played a part in creating the preconditions for epidemics. Of all the communicable diseases, perhaps none are as closely interrelated with human activities and attitudes as STDs. Many have occurred in epidemic proportions; most have existed for centuries.

The public health nurse needs to be concerned with the fact that minority populations, as well as women and children, suffer an inordinate STD burden (USDHHS, 2016). The medically underserved, particularly the poor and marginalized, as well as ethnic and racial minorities shoulder a disproportionate share of this problem. And this disparity in health burden is due to social conditions that affect minorities. These include inability to pay for needs services, distrust of the health care system, and fear of discrimination from health care providers (CDC, 2014j). It is important for PHNs to consider the root causes of inequities so that they may be exposed and addressed. Racism has had a long-lasting impact on health in the United States for over 300 years. Nurses need to realize the basic human need to feel accepted. They need to expose the health consequences of chronic stress caused by inequality based on skin color and be involved in intervening in this process (Penman-Aguilar, Harrison, & Dean, 2013). Access to health care is only one part of the equation. Where one lives also has a great impact on their overall health as neighborhoods with appropriate housing, adequate amenities and minimal crime have higher trajectories than do poorer neighborhoods where crime is rampant and resources are limited (Penman-Aguilar et al., 2013). Public health efforts need to be monitored to measure the impact that public health interventions, programs, and policies have on the problem. Personal stories and consistent messages help persuade the public and the policymakers to demand change, for example, by telling a compelling story. The communities need to be included as equal partners with health departments in order to work together and address the health issues they face. Community health nurses can think outside of the box to identify participants that these partnerships may include (Penman-Aguilar et al., 2013) (see Chapters 5 and 25).

As noted earlier in this chapter, women also have higher risk of serious complications from STDs. These include PID, sterility, ectopic pregnancy, and cancer associated with HPV. Children can also be affected by exposure to maternal STDs, resulting in fetal and infant death, birth defects, blindness, and mental retardation. Undiagnosed and untreated STDs result in over 24,000 women becoming infertile each year in the United States. Factors associated with this increased risk are asymptomatic STDs resulting in underdiagnosis or undertreatment, along with gender disparities and age disparities, with young adults having the highest rates of STDs (USDHHS, 2016). Nurses need to be involved in accomplishing the *Healthy People 2020* goal of promoting healthy sexual behaviors, strengthening capacities within communities, and increasing access to quality services (USDHHS, 2016) (see Chapter 21).

Infectious Diseases of Bioterrorism

The deliberate release of biological agents into society with the intent to cause harm is a real risk. Release could come in the form of an overt or a covert event (Heymann, 2015). An overt event would be one in which the public or the authorities are made aware of the threat prior to the release. Such an announcement could result in hysteria and overwhelm the public health system (Heymann, 2015). A covert attack is never announced, but there might be an unusual increase in the number of cases of a respiratory illness or a food-borne illness. Multiple agencies across the nation and around the world need to work together for preparation, surveillance, and response to such a threat (Heymann, 2015). Public health nurses are in a position that allows them to allay fears, provide the public with correct information, and help people in the decision-making process to consider immunization in the event of a possible terrorist attack. A variety of disease-causing organisms may be weaponized. However, anthrax and smallpox, two biological agents that have a history of being used as terrorist weapons, will be discussed here.

Anthrax

Shortly after the terrorist attacks of September 11, 2001, the U.S. population was further terrorized by a deliberate release of anthrax agent into the postal service system. Several people who handled or delivered the infected mail inhaled and touched anthrax spores that had been concealed in envelopes. As a result, 22 people were infected and five died, and 32,000 were identified as potentially exposed and were treated with antibiotics as a precaution (Heymann, 2015).

Anthrax spores are found in nature in the digestive tracks of herbivores and can be found in the soil. Infection in humans is sporadic in most developed countries (Heymann, 2015). There are infrequent and sporadic human infections in most industrialized countries. It is an occupational hazard among workers who process animal hides, hair, bone and bone products, and wool in some countries, leading to it being referred to as *woolsorter disease* and *ragpicker disease* (Heymann, 2015).

In humans, anthrax is an acute bacterial disease that affects mainly the skin or respiratory tract. The two main forms—cutaneous anthrax and inhalation anthrax—account for most human anthrax cases. The case fatality rate for cutaneous anthrax is 5% to 20%. The skin becomes itchy where exposed; a lesion becomes papular and then vesicular. In 2 to 6 days, a depressed black eschar, surrounded by extensive edema, develops. The infection may spread to the lymph system and cause septicemia. With inhalation anthrax, the initial symptoms are mild and may include fever, mild cough, chest pain, and malaise. The disease can then progress to respiratory distress, fever, and shock. There is an 85% fatality rate with inhalational anthrax; however, antimicrobial therapy and supportive therapy could reduce this rate (Heymann, 2015).

The causative organism *Bacillus anthracis* is a Gram-positive, encapsulated, spore-

forming agent found in livestock and wildlife as the main reservoirs. The incubation period for cutaneous infection is 5 to 7 days, but for inhalational anthrax, it can vary between 1 and 45 days (Heymann, 2015). Person to person transmission is rare, but articles and soil contaminated with spores may remain infective for decades, and so, these items must be appropriately disposed (Heymann, 2015).

A vaccine that protects against cutaneous and inhalational anthrax exists. This vaccine is generally used only for those laboratory scientists handling specimens and some veterinarians who may have work-related exposure risk (Heymann, 2015).

Smallpox

The variola virus causes smallpox and is transmitted from person to person. Initial infection begins with a febrile prodromal period that includes a fever of 104°F, malaise, headache, abdominal pain, and vomiting (Fig. 8–7). This would be followed by the eruption of a deep-seated rash that transitions from macular to papular, and then, lesions become vesicles and pustules. Eventually, these scab over and fall off approximately 3 to 4 weeks after onset (Heymann, 2015). It was passed from person to person through respiratory droplets or skin inoculation. It is most easily spread by droplet during the first week after the rash has developed (Heymann, 2015).

Figure 8–7 No longer commonly seen, the maculopapular rash of smallpox is very distinct.

Smallpox is a disease from our history books. A global eradication campaign had pushed smallpox into extinction. The last known naturally occurring case of smallpox was in Somalia in 1977. Smallpox was declared globally eradicated in May of 1980. Officially, the smallpox virus presently exists at only two places: the CDC in Atlanta and the State Research Centre of Virology and Biotechnology in Koltsovo, Novosibirsk Region, Russian Federation. These samples remain available in the unlikely case of reemergence of smallpox disease (Heymann, 2015).

A vaccine made from the vaccinia virus exists. The vaccinia virus, or also known as cowpox, is a similar organism that confers protection to smallpox. In 1798, Edward Jenner was able to demonstrate that the vaccinia virus could be used to protect people from smallpox (WHO, 2016b). Smallpox vaccination has risks. It is not a benign vaccine, and some experts allege that the morbidity associated with the vaccine has been understated.

Serious complications include eye infection or blindness if the vaccinated person has the vaccine virus on the hand and touches the eye, severe rash leading to scarring or even death, encephalitis, or preterm birth or fetal demise if the virus becomes transmitted to a fetus during pregnancy (CDC, n.d.). One to two deaths per 1 million recipients of the vaccine can be expected, and 52 per 1 million may experience a life-threatening reaction (CDC, n.d.; Heymann, 2015). Less severe but more common side effects include the formation of satellite lesions, regional lymphadenopathy, fever, headache, nausea, muscle aches, fatigue, and chills. In addition, the vaccine is contraindicated for those who are immunosuppressed, those with eczema, and for pregnant women (Heymann, 2015) (Fig. 8–8).

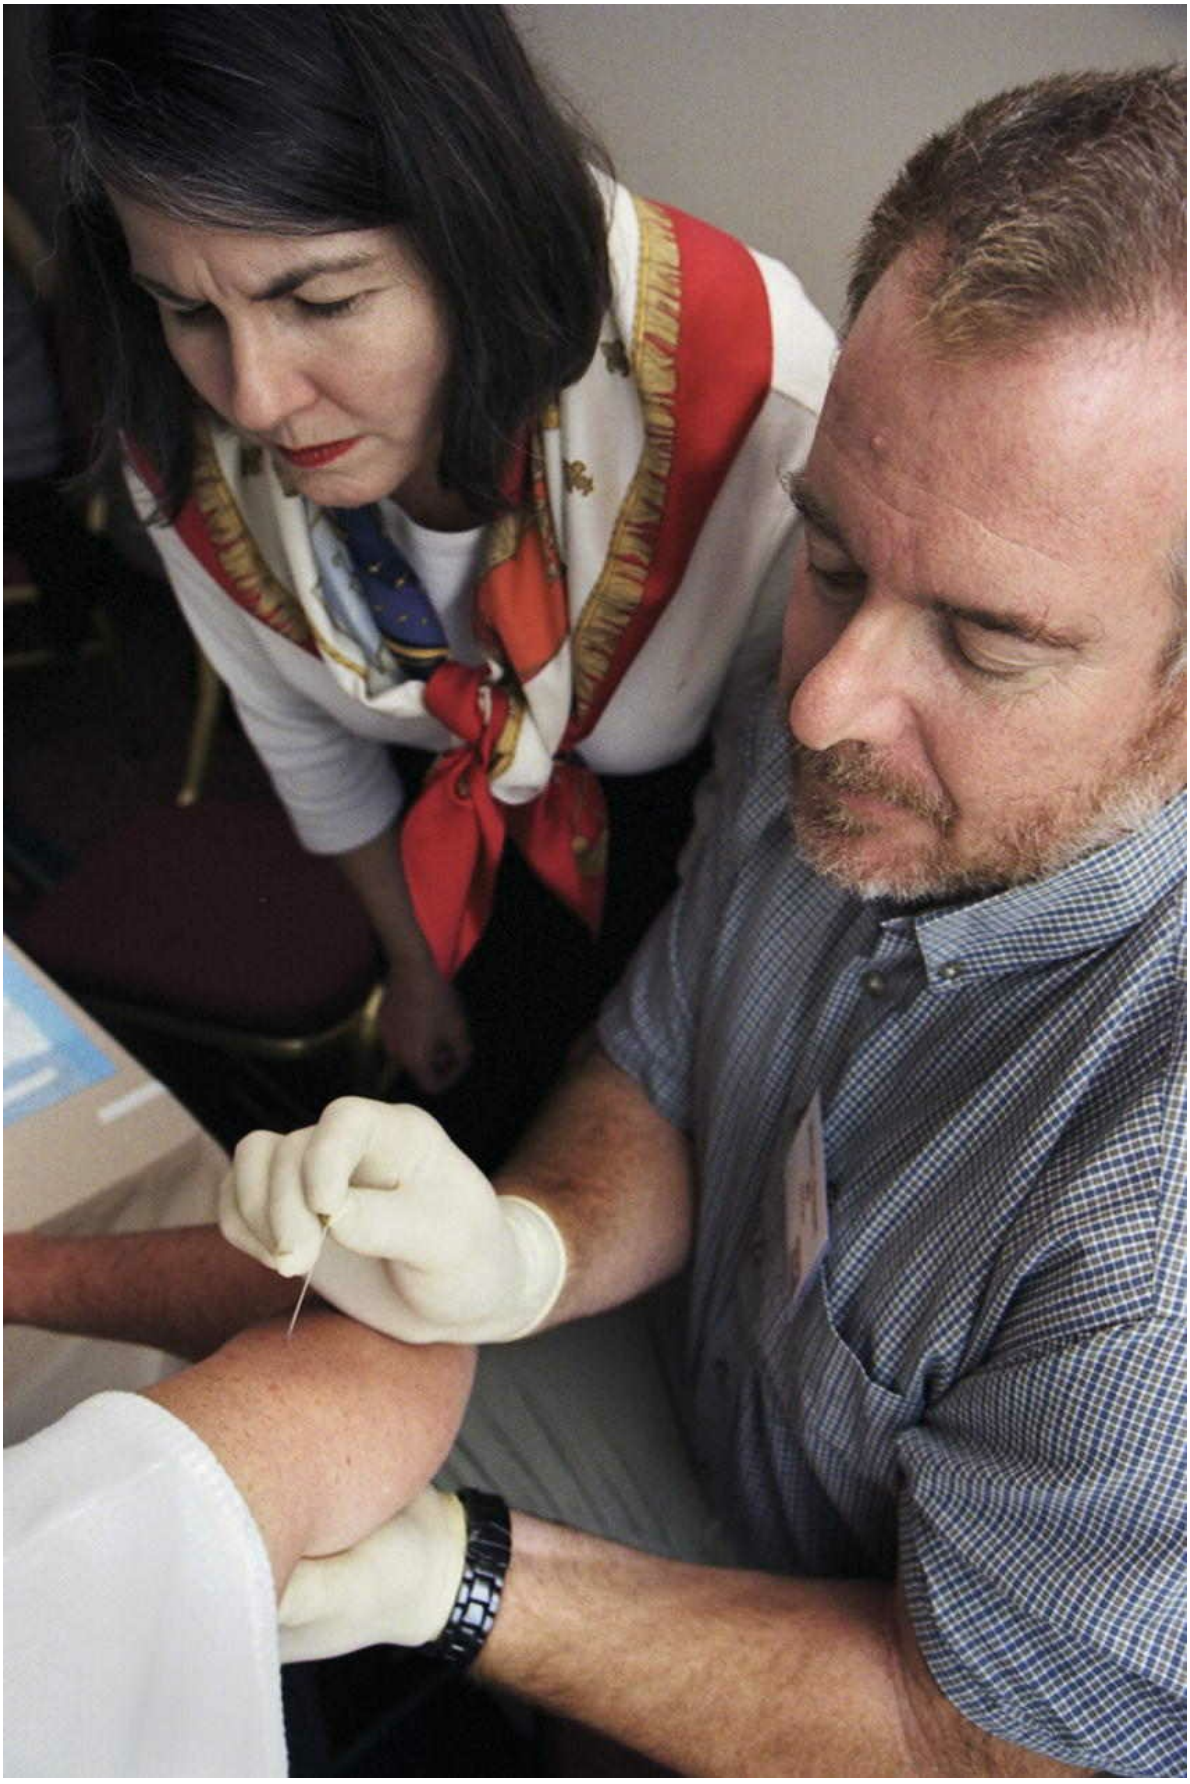


Figure 8–8 Smallpox inoculation of public health worker. (From Centers for Disease

Control and Prevention. Public Health Image Library. Photo Image ID #2825—James Gathany.)

Routine immunization against smallpox is no longer recommended for the general public because, at this point in time, the risk of harm from the vaccine is considered to be greater than the risk of contracting the disease. Laboratory workers who work in high-risk areas may still obtain the vaccine (Heymann, 2015).

The response plan for smallpox exposure may utilize the previously successful ring vaccination strategy— containing an outbreak by rapidly isolating and vaccinating people who have had close, face-to-face contact with the victim. This method refers to a ring of people around the exposed or ill person. Contacts would be monitored daily for fever and isolated if a fever develops (Heymann, 2015).

PRIMARY PREVENTION

In the context of communicable disease control, two approaches are useful in achieving primary prevention: (a) immunizations and (b) education using mass media with targeted health messages to aggregates.

Education

Health education in primary prevention is directed both at helping individuals understand their risk and at promoting healthy behaviors. Chapter 11 deals more extensively with the concepts of learning theory and the variety of health education approaches and materials available to community/public health nurses today.

Targeting Meaningful Health Messages to Aggregates

To effectively deliver a health promotion and disease prevention message, the message must reach the target (at-risk) population (Fig. 8–9). This requires correct identification of the target populations and characteristics specific to this audience in terms of educational level, salience of the issue, involvement of the target audience with the issue, and access of the target audience to the media channels used. Cultural issues affect people's interpretation of messages and must be considered in the presentation of a disease-prevention message to ethnic and racial minority groups. A target market is defined as a group of people with the same needs, interests, and behaviors. Public health practitioners can use marketing strategies to reach out to target populations (CDC, 2011c). Marketing is based on the principles of exchange, paying a price for goods or services. The price may be money, effort, or time. The goods are the outcomes, such as good health.

Figure 8–9 A targeted health message in Africa: Stop Transmission of Polio (STOP) campaign volunteer's bicycle equipped with a vaccine-carrying satchel with the message "Kick Polio out of Africa."

To adapt health messages to specific population subgroups, include the following:

1. Develop educational materials from the community perspective, reflecting respect for community values and traditions, relevance to community needs and interests, and participation of the community in the preparation and use of the materials.
2. Materials must be related to the delivery of health services that are available, accessible, and acceptable to the target population.
3. All materials must be pretested and have demonstrated attractiveness, comprehension, acceptability, ownership, and persuasiveness.
4. Materials must have a readability level for the intended audience.

Ways to Communicate

Social media, made up of tools such as Facebook and Twitter, offers the ability to engage a large number of participants in an interactive, collaborative, and synchronous manner (Heldman, Schindelar, & Weaver, 2013). Practitioners can reach populations where they might not easily arrange to meet face-to-face. Social media allows people from diverse populations to meet. It also makes sharing of information easier; however, nurses need to take steps in order to ensure that patients' privacy is maintained. This approach can also be integrated with other public health communication strategies. Unfortunately, public health organizations are not utilizing social media engagement to its full potential (Heldman et al., 2013). Nurses can explore ways that social media can be used to augment current public health communication approaches. Chapters 10 and 12 have more information on social marketing and using technology to reach various populations.

Immunization

The extended life expectancy that has been enjoyed during the 20th century was largely due to the expansion of immunization programs that are provided to families. Immunizations are a cost-effective public health intervention that offers a high return on investment. Examples of the benefits gained through immunization programs include saving 33,000 lives and preventing $14 million in lost income from disease while also saving $9.9 billion in health care costs and $33.4 billion in indirect costs (USDHHS, 2014). Immunization and control of infectious diseases remain a national focus through *Healthy People 2020* (USDHHS, 2014). Table 8–3 highlights select objectives related to immunization and infectious diseases.

Table 8–3 Healthy People 2020

Immunization and Infectious Diseases: Select Objectives	
IID-1	Reduce, eliminate, or maintain elimination of cases of vaccine-preventable diseases
IID-5	Reduce outpatient visits for ear infections where antibiotics were prescribed to young children
IID-6	Reduce outpatient visits where antibiotics were prescribed for the sole diagnosis of the common cold.
IID-7	Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children
IID-11	Increase routine vaccination coverage levels for adolescents
IID-14	Increase the percentage of adults who are vaccinated against zoster (shingles)
IID-17	Increase the percentage of providers who have had vaccination coverage levels among children in their practice population measured within the past year
IID-18	Increase the percentage of children under age 6 whose immunization records are in fully operational, population-based immunization information systems (IIS)
IID-22	Increase the number of public health laboratories monitoring influenza virus resistance to antiviral agents
IID-24	Reduce chronic hepatitis B virus (HBV) infections in infants and young children (perinatal infections)
IID-27	Increase the percentage of persons aware they have a hepatitis C infection
IID-28	(Developmental) Increase the percentage of persons who have been tested for HBV within minority communities experiencing health disparities

From U.S. Department of Health and Human Services. Office of Disease Prevention and Health Promotion. (2016). Healthy People 2020 topics & objectives: Immunization and infectious diseases objectives. Retrieved from http://www.healthypeople.gov/2020/topics-objectives/topic/immunization-and-infectious-diseases/objectives

Challenges still exist. Over 42,000 adults and 300 children die each year from VPDs. Pockets of communities with low vaccination rates among the children exist across the country. In addition, new and emerging diseases may develop to which a vaccine might not yet be developed (USDHHS, 2014).

The Advisory Committee on Immunization Practices (ACIP) reviews the schedule for administration of vaccines for various populations and age groups. The ACIP consists of 15 experts in the field of VPD. The Secretary of the USDHHS chooses the members of this group; it functions to guide and advise on immunization practices (CDC, 2013b). The ACIP provides vaccine recommendations based on research and scientific data related to vaccine safety and efficacy for adult and child vaccines. Recommendations include age

when vaccines should be given, dosage, number of doses, time intervals between doses, and precautions and contraindications (CDC, 2013b). They also make recommendations during times of disease outbreaks and vaccine shortages. An example is an outbreak of pertussis (whooping cough) in 2012. More than 14,000 people had become infected and 14 babies died of pertussis. Given that young infants cannot receive the first dose of pertussis until they are 2 months old and their immunity would still be developing as they receive subsequent doses, ACIP made recommendations that people who would be near infants get a pertussis immunization so they would be protected and reduce the risk of exposing the infant to the disease until the infant would be old enough to receive the series and develop immunity (CDC, 2013b).

The majority of American society has accepted immunizations as a part of overall health care. However, there are some who challenge the notion of immunizing their children for many reasons. Some oppose government mandates and the sheer number of vaccinations, and others want to veer from the recommended spacing schedule for alternative immunization spacing and will eventually complete the childhood series. Although the ACIP may set the recommendations for immunizations, there are no laws mandating a child be immunized. There are varying laws in each state that may allow for exempting immunizations for various reasons, religion, philosophy, or medical. Not all states accept all of these reasons. The public health nurse should look to their state's immunization agency for the accepted exemption criteria (Immunization Action Coalition, 2013). This subject is further discussed under the section Barriers to Immunization Coverage.

In 1993, the CDC initiated the first National Immunization Survey, and in April of 1994, the first national data set obtained. This data set analyzed the immunization rates of children. Currently, there are data collection surveys for children, adolescents, and adult immunization rates. In 2013, 83% of children represented in the survey who were 19 to 35 months of age had received four doses of DPT, DT, or DTaP vaccine; 93% had received three doses of polio vaccine; 92% had received one dose of MMR; 82% had received the primary series and a booster of *Haemophilus influenza* type b (HIB); 91% had received three doses of hepatitis B; 91% had received 1 dose of varicella vaccine; and 82% had received four doses of Pneumococcal conjugate vaccine (CDC, 2015k). In the teen population, ages 13 to 17 years, vaccination rates of HPV were low with 60% of the girls and 40% of the boys having been vaccinated (CDC, 2015v). HPV vaccine rates were higher in Hispanic girls than in White girls and higher among girls living in poverty than those living at or above the poverty line. In adults, HPV rates were 63.9% in adult women ages 19 to 26, whereas the HPV vaccination rate in male adults was5.9% in the male adults in the same age category. Rates of Tdap vaccination in women under the age of 60 years old were 24.2%, and herpes zoster vaccination rates in adults, 60 years or older, were 24.2% (Williams et al., 2015).

Health care providers, public health nurses, and school nurses are in positions to review records, educate families, and provide opportunities for a child to obtain immunizations.

Nurses need to realize the effect that negative information available on the Internet and in the media can have on parents' decisions about immunization for their children. In an effort to determine the type of information parents may find on the Internet, one group of researchers conducted Google searches using negative, neutral, and positive search terms related to vaccinations. When negative search terms were used, 37.5% of the recommendations on Web sites retrieved were against vaccination, and 12.5% on those with neutral search terms (Ruiz & Bell, 2014). Researchers noted that if parents are seeking information on the Internet about vaccination risks, they are likely to discover more Web sites perpetuating negative myths and recommending against childhood vaccination. Even though a Cochrane systematic review of a small number of randomized control trials that involved face-to-face education for parents about childhood vaccination had inconclusive results, reviewers noted that talking to parents during health care visits was most likely helpful (Kaufman et al., 2013). It is important for nurses to take the time during their busy workday to talk with parents about their children's immunizations (Donovan & Bedford, 2013; Kestenbaum & Feemster, 2015). Nurses need to listen carefully to the parents' concerns, express empathy, answer their questions, and provide evidence-based information from reputable sources. Parents appreciate nurses who spend time with them and respectfully listen, even if the nurse does not agree with the parents' beliefs.

One common question a parent may have is "Are the vaccines safe?" Nurses can provide information about the safety trials that the vaccines undergo prior to release to the public. They can also advise parents of possible side effects and how to care for the child if side effects do arise. Another concern expressed by the parent is "I'm worried about giving so much at one time; how does that affect my child's immune system?" Nurses can assure parents that the small dose in the vaccine is not nearly as much as children are exposed to in everyday life (Donovan & Bedford, 2013; Dube et al., 2013). Parents may believe that the diseases no longer exist and so vaccination is not needed. Although incidences of diseases have declined, other than polio, they still exist in the natural setting. These diseases can easily resurface and many of them can be life threatening. Parents may also ask why their child should get vaccines at such a young age. Nurses need to explain that to decline giving the immunization at the time they are eligible, the visit becomes a lost opportunity. Their unvaccinated child will not be protected and will be vulnerable until they have completed the series (Donovan & Bedford, 2013). One last question parents commonly ask is if the preservatives or additives will harm their baby. The nurse could explain why the preservative is added to the vaccine. Public health nurses should be aware of any state law prohibiting the administration of a vaccine that contains thimerosal to a newborn. See From the Case Files.

From the Case Files

Perspectives, PHN: Personal Belief Exemption and Immunization

A whooping cough (pertussis) outbreak occurred in a small rural community. Whooping cough is a VPD. It is highly contagious and can have devastating outcomes in the very young and very old. In this community, the population is not very ethnically diverse, but it is philosophically diverse. Many community members are against vaccinating their children. The outbreak of pertussis occurred in a small charter school, where the majority of the children were unvaccinated for reasons of parental personal belief objections. Personal belief exemption to vaccination is an option for a family. Unfortunately, with a large unvaccinated population, as in this school, the spark of a contagious, vaccine-preventable infection can spread rapidly. This is what happened in this school, with 22 cases of pertussis among children and family members. The school had to be closed a week early for winter break to help halt continued disease spread. Three waves of illness occurred in this school from November to April.

One might think the entire problem rests with the group of individuals who will not vaccinate their children, but this is not what was discovered upon investigation. The issue of personal belief exemption was discussed among public health nurses and school nurses in this community. The issue was discussed with parents and teachers at the charter school. The two highlights from our discussions were that parents signed the exemption either out of true conviction or out of frustration that the school was hounding them to get their child vaccinated. For whatever reason, some parents just cannot seem to make the time to get the necessary immunizations completed. These parents can be the high-risk families who keep a school nurse busy. It was discovered that in some of the schools with high-risk families, the personal belief exemption was signed in order to keep staff from pestering them.

So, to which group do you extend your efforts as a public health nurse? The answer is both. The parents who will not vaccinate their children will not be convinced otherwise. Parents who chose the easy way out may need more assistance. The county's immunization coordinator, the community's immunization coalition, and the school nurses determined that the school secretaries were the point of entrance to school registration. It was discovered that these individuals needed an in-service on how to properly offer the exemption to a family and what information parents would need to make an informed decision before signing the exemption.

The immunization coordinator developed an education tool that explained to the parents their responsibility to the community at large if their child were to

become ill with a vaccine-preventable illness. The document covered points such as the family having a medical plan with their physician, learning how to care for and isolate the child, working with a public health nurse, and so on (see Display 8–5). The school secretaries were asked to give this document to parents who were interested in the exemption, as well as community resource information for families who may not have access to affordable immunizations.

The parents at the charter school were very accepting of the information on what to do for an ill child, and the school secretaries expressed relief regarding dealing with parents who may want to exempt out for convenience rather than conviction.

Karen, PHN

DISPLAY 8.5 WHAT PARENTS SHOULD KNOW WHEN SIGNING A PERSONAL BELIEFS AFFIDAVIT EXEMPTION OF IMMUNIZATION

- Measles, mumps, rubella, chicken pox, pertussis, diphtheria, polio, *Haemophilus influenza* type b, hepatitis A, and hepatitis B are infectious to others and are avoidable through immunization.
- Please educate yourself to the symptoms and possible complications that can arise from a vaccine-preventable disease (VPD). Information for parents about these diseases may be found at the National Immunization Program site http://www.cdc.gov/nip/or by calling *Insert Local County Public Health Department Name & Phone Number*.
- These diseases have many symptoms that require close monitoring and care so that complications are minimized. It is essential to have a plan of care, coordinated with your health care provider, to act upon the mildest to most severe symptoms of the disease.
- The school or school nurse is responsible for maintaining a list of the school children who have parent-signed exemption to immunization for medical, religious, or personal belief. This list allows the school nurse to quickly identify any child who is at risk of exposure to a VPD.
- An unimmunized child will be excluded from school by the County Health Officer when a VPD is identified in the school. The ill child will also be excluded from school.

- When a child is excluded from school, it is the responsibility of the parent or guardian to keep the child isolated* from the public at large to prevent spread of infection to the community.
- VPDs are considered reportable communicable diseases under the Health and Safety Codes of California. If your child contracts one of these diseases, a public health nurse will contact you. Be prepared to provide information about the illness to the investigator. This information is confidential.
- The parent or guardian is also at risk of contracting any of these diseases when exposed to an ill child. If unimmunized, the parent or guardian may also be considered exposed and incubating the disease, because this may continue the cycle of infection to others. This in turn requires that the parent or guardian remain in isolation from the community through the incubation period.
- The child who is exposed to the disease may be offered preventive medication or immunization to prevent the disease from occurring—either may keep the child from being excluded from school.

_____ _____

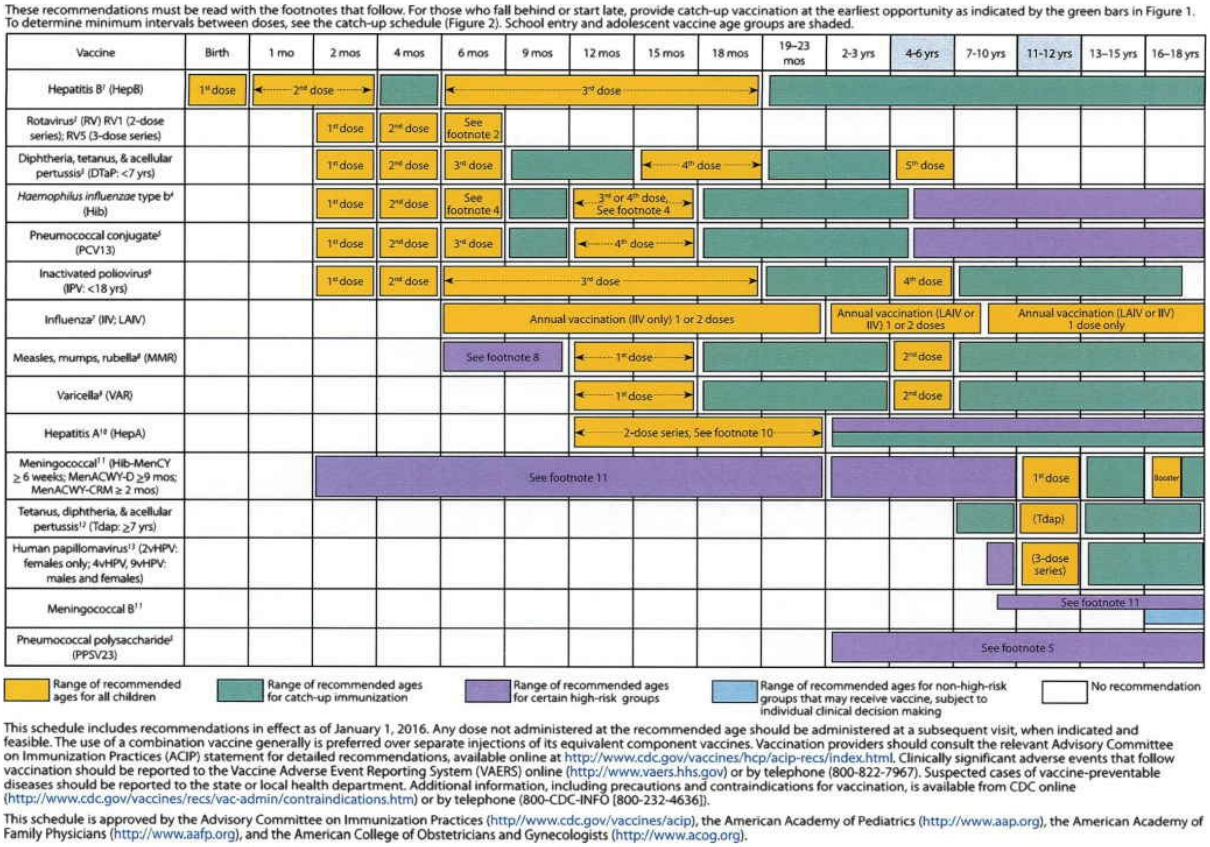
Parent signature Date

*The isolation time frame is determined by the county health officer. Isolation means that the exposed or ill child cannot leave home except for medical care. No social gatherings!

Vaccine-Preventable Diseases

VPDs, such as hepatitis A and B, *H. influenza* type b, measles, polio, diphtheria, pertussis, influenza, and chickenpox, are a few examples of diseases that can be prevented through immunization. Immunization causes the body to become immune to an infectious agent. The immunity allows the body to tolerate the presence of material that is foreign, such as a virus or bacteria. The immune system develops a defense against the invading infectious agent or antigen. Vaccination initiates this process (Hamborsky, Kroger, & Wolfe, 2015). Immunity may be either passive or active. Passive immunity is short-term resistance to a specific disease-causing organism; it may be acquired naturally (as with newborns through maternal antibody transfer) or artificially through inoculation with pooled human antibody (e.g., immunoglobulin) that gives temporary protection. Active immunity is long-term (sometimes lifelong) resistance to a specific disease-causing organism; it also can be acquired naturally or artificially. Naturally acquired active immunity occurs when a person contracts a disease, whereas artificial immunity occurs when a person receives an inoculation of an antigen through a vaccine. Both prompt an immune response that stimulates the development of long-lasting antibodies that provide immunity against future exposure to that antigen (Hamborsky et al., 2015).

A vaccine is a preparation made from either a live organism or an inactivated form of the organism. Live attenuated vaccines are made from weakened wild virus organisms that



are able to replicate but generally not make the person ill. It only takes a small amount to initiate an immune response, and the organisms must replicate to be effective. Inactivated vaccines are made from a viral organism that has been inactivated by heat or chemicals. These vaccines cannot replicate in the recipient (Hamborsky et al., 2015). The more similar the vaccine is to the actual agent, the better the immune response to the vaccine. Currently, measles, mumps, rubella, vaccinia, yellow fever, rotavirus, and intranasal influenza are all live attenuated vaccines (Hamborsky et al., 2015).

Because of the success of immunization strategies, few practicing nurses in the United States today have treated clients with tetanus or diphtheria, or even measles, although some may have cared for clients with residual polio disabilities. However, VPDs still exist in force in the developing world, and outbreaks occur in the United States in groups of nonimmunized or susceptible populations. Some people may be medically exempt from immunization, and others may decline immunization for religious or personal reasons. Some states are tightening the use of these exemptions in an effort to prevent disease outbreaks. For instance, California now requires that all children attending school or daycare be fully immunized, unless a physician deems that they are exempt owing to medical reasons. This was spurred by an outbreak of measles at Disneyland, lobbying efforts from professional health care organizations, and concern over the continuing abuse of personal exemptions (Crawford, 2015).

Schedule of Recommended Immunizations

A schedule for the administration of childhood vaccinations, based on recommendations by the ACIP, the American Academy of Pediatrics (AAP), the American Academy of Family Physicians, and the CDC, is published annually (Table 8–4). The CDC also provides "catch-up" schedules for children not receiving their first immunizations at birth, according to the standard schedule. Current recommendations call for a child to receive 10 different vaccines or toxoids (many in combination form and all requiring more than one dose) in six or seven visits to a health care provider between birth and school entry, with boosters in the preteen to early teen years (Hamborsky et al., 2015).

Table 8–4 Recommended Immunization Schedules, Ages 0 to 18 (2016)

From U.S. Department of Health & Human Services (USDHHS). (2016). Recommended immunizations schedules for persons aged 0 through 18 years, United States, 2016. Retrieved from http://www.cdc.gov/vaccines/schedules/downloads/child/0-18yrs-child-combined-schedule.pdf

Factors influencing the recommended age at which vaccines are administered include the age-specific risks of the disease, the age-specific risks of complications, the ability of persons of a given age to produce an adequate and lasting immune response, and the potential for interference with the immune response acquired from passively transferred maternal antibodies. In general, vaccines are recommended for the youngest age group at risk whose members are known to develop an acceptable antibody response to vaccination (Hamborsky et al., 2015).

Revisions in recommendations for vaccine administration may be revised in certain circumstances. For example, it is now recommended that infants receive hepatitis B vaccine at birth, whether or not their mothers have a positive or negative response to the hepatitis B surface antigen. This approach will catch any infant born to mothers who lack prenatal testing or who may live in households with individuals with unknown hepatitis B status (Heymann, 2015).

Herd Immunity

Herd immunity, or community immunity, is central to understanding immunization as a means of protecting community health. As described in Chapter 7, *herd immunity* is the immunity level present in a particular group or community of people. If few immune

persons exist within a community (i.e., if herd immunity is low), then the spread of disease is more likely (see Fig. 8–10). However, if there are more individuals in the community who are immunized (i.e., if herd immunity is high), this helps minimize the chance that an unvaccinated person will become ill (Heymann, 2015). See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

"Cocooning" to Protect Unvaccinated Infants

Over the past years, a practice known as cocooning has gained increased attention as a means to prevent communicable diseases, such as influenza and pertussis, in unvaccinated and incompletely vaccinated individuals. It can be thought of as a form of herd immunity within a small group of people such as a family or childcare setting. Infants and children who are at high risk for infection, but not old enough or have other health conditions that prevent them from being immunized, are the target groups for protection. The goal is to immunize (especially for influenza or pertussis) close family and friends or frequent contacts to reduce the risk of exposing the vulnerable person to these diseases (CDC, 2015m).

The PHN has an opportunity to evaluate the emerging research related to the cocoon approach and determine if their community could benefit from this strategy in reducing VPD outbreaks and poor outcomes for the infant at risk. A number of questions must be addressed in considering whether cocooning is a viable option in a community:

Does this approach actually reduce infections in the target population and where is the evidence?

What is the risk to the household members being vaccinated?

What is the cost of this program?

Are there unintended consequences from this approach, such as delayed immunizations in the target population?

Innovations are an important source of improved health-promoting practices and should not be discouraged, but as always, solid research evidence is vital. With limited health care dollars, efforts must target the most cost-effective and proven methods possible. Only time and research will show whether cocooning can be an effective tool in the public health arsenal.

Assessing Immunization Status of the Community

Immunization rates still need to be improved. Nurses need to work to ensure that all those who need vaccines are receiving them. Laws have been implemented requiring students to receive vaccines prior to entering school. Community/public health nurses need to assess their community to identify the barriers to receiving the immunizations. These may include transportation issues, financial constraints, or perhaps personal belief barriers such as religion or culture. It may even be that the health care provider is not promoting vaccination according the ACIP schedule. This section will review approaches to address vaccine hesitancy. This hesitancy can lead to reemerging VPDs (Kestenbaum & Feemster, 2015).

It is important to recognize that all clients who refuse vaccination are not all the same. They may have very different concerns. Clients who choose to be unvaccinated or undervaccinated can lead to public health concerns. Antivaccination movement began in the 1950s in response to the smallpox vaccine. There was a belief that the government was impeding on their individual liberties. The subsequent drop in vaccination rates resulted in an increase in smallpox cases in the next two decades. The movement began to emerge again in the early 1990s when the Internet provided a means for disseminating information and groups of concerned parents began pressuring states to expand exception laws; it continues today (Domachowske & Suryadevara, 2013; Ruiz & Bell, 2014).

Although complete refusal to obtain any vaccines is not common, vaccine hesitancy, the intention to delay or avoid vaccines administration as recommended by the ACIP guidelines, is seen quite often. Parents may decide to hesitate or refuse for a variety of reasons. Some parents may be concerned that their child is receiving too many vaccines at one visit, or they may believe that the risk for VPDs is no longer valid, and, in some cases, they may be obtaining their information from noncredible sources. Others may be hesitant for religious reasons. Antivaccinators may feel strongly about vaccination as their personal choice, whereas others may challenge the scientific evidence supporting vaccination (Domachowske & Suryadevara, 2013; Dubé et al., 2013; Kestenbaum & Feemster, 2015).

Nurses and other health care providers should engage families who are hesitant about vaccines in open conversation. This may be a challenging task when a parent is confrontational with the health provider or perhaps even attempting to change the mind of the health care provider. Some who seemed adamant about refusing the vaccine may even decide to accept the vaccine after an honest discussion because they felt that they were heard and their questions were answered.

One approach is called “ASK” (Acknowledging, Steering, and Knowing). The first step is to acknowledge the parents’ concerns and then steer the conversation to provide answers and knowing the facts. Another strategy is called “CASE” (Corroborate, About, Science, Explain). Acknowledge the concerns and have a respectful conversation with the parent. Then, be sure the parent is aware of how the health care provider is knowledgeable on the topic (tell them about yourself and your level of expertise). Third is to refer to the scientific evidence, and the final step is to explain and advise, following the ACIP guidelines (Domachowske & Suryadevara, 2013). These may be time-consuming but the effort may

pay off if a parent is able to accept the vaccine for their child.

Offering vaccines at home visiting and WIC offices has also been found to be effective. Another strategy is to work with providers. The AFIX (Assessment, Feedback, Incentives, and Exchange) is designed to help providers recognize the problem. This is accomplished by assessing the current immunization rates within the office to show the provider an accurate picture of their rates. The CDC has computer programming to assist with this process. The next stage is to provide feedback to the provider about their progress in increasing their vaccination rates. This needs to be conveyed in a nonjudgmental way, but it is useful because it helps guide where to go for the next steps. Incentives help to motivate the provider to make the needed changes. The final phase is exchange of information where they can share with other providers about what worked for them (Hamborsky et al., 2015).

Planning and Implementing an Immunization Campaign

Immunization campaigns targeting specific subgroups can be effective if they include the following: (a) community assessment for the target group(s) and (b) assessment of and planning for the needs of the target group(s), such as transportation, need for language interpreters, provision of child care, or dealing with high illiteracy rates. Successful outreach efforts are motivated by the desire to reach the target population, even if specific or unusual accommodations must be made. Clinics can be scheduled and held at times and places specifically intended to make the service more accessible and convenient to the target group. Materials in multilingual form can be obtained through the state's immunization agency or the CDC. The CDC and state immunization agencies have campaigns throughout the year for the public health nurse to participate in and provide to the public. Tool kits with the materials and tips for planning and implementing are available through the state immunization agency (Hamborsky et al., 2015). Display 8–6 outlines an example of the necessary steps and considerations for administering an immunization campaign in a community setting.

DISPLAY 8.6 ADMINISTRATIVE ASPECTS OF IMMUNIZATION CAMPAIGNS

Study the Target Community

- Assess disease incidence and level of immunization coverage.
- Identify the target group.

- Assess conditions in the community: Is the target group scattered or localized?
- Assess level of community involvement and awareness of the problem.
- Identify means of communicating with target group: through the media or through leaders or other.
- Consider political and social structure of the community. Identify important leaders.
- Identify sites for immunization clinics that are appropriate, accessible, and available.

Plan the Immunization Campaign

- Review budget for immunization services.
- Determine goals for clinic performance or outcome measures.
- Communicate with target group to notify them of need and promote involvement and participation.
- Estimate needs for vaccines and supplies and obtain them. Plan care of vaccines before, during, and after clinic.
- Develop team coordination among staff.
- Plan clinic logistics: Available supply of needed materials, medical waste disposal, anaphylaxis supplies, records and means of clinic registration, staffing, floor plan for traffic control, and efficient management of crowds.
- Prepare staff with information regarding objectives for clinic, criteria for who shall not be immunized, and mechanisms for referral of clients with other health needs.

Publicity

- Inform target group of date, location, and times of immunization clinic.
- Provide information on reasons for and benefits of (and contraindications to) immunization.
- Encourage parents to bring existing immunization records to clinic.
- Provide contact information for those with questions or inquiries.

Immunization Clinic

- Registration system and records (for parent and clinic) ready.
- Registrar or assistant(s) ready to assist parents not familiar with language of paperwork.
- Parent education: informed consent, reporting of adverse reactions, and date next vaccine due.
- System for call back, follow-up.
- System for dealing with other health issues and/or adverse events.

Evaluation of Campaign

- Assess numbers of immunizations given in relation to goals.
- Assess suitability of approach in identification of target group, selection of sites, means of communication with group, availability of resources, and so forth.
- Invite parental as well as community and staff feedback.
- Evaluate results in relation to expenditures.

Adult Immunization

Many people assume that vaccinations are for children only. Well-advertised influenza vaccination campaigns in recent years have, to some extent, helped to correct this notion.

Adults face risk for becoming infected with a VPD if they are unimmunized or underimmunized. Some of the immunizations that wane, meaning that the protection disappears over time, are tetanus, pertussis, influenza, and pneumococcal. Other vaccines are specific for adults, such as the varicella zoster, otherwise known as the shingles vaccine. The CDC (2016a) provides an adult immunization schedule of recommendations. See Chapter 23 for adult vaccination schedule and adult screenings.

Substantial numbers of VPDs still occur among adults despite the availability of safe and effective vaccines (Appel, 2011). Community health nurses should be aware of factors that may contribute to low vaccination levels among adults:

1. Cost and reimbursement can be a barrier.
2. Insufficient tracking methods for adults as compared to those in place for children.
3. Although statutory requirements exist for vaccination of children, no such requirements exist for all adults.
4. Health care providers may not be current with the adult-recommended immunizations or not consider vaccination at the time of the visit, leading to missed opportunities to vaccinate.
5. Comprehensive vaccination programs have not been established in settings where healthy adults congregate (e.g., the workplace, senior centers).
6. Clients and providers may fear adverse effects after vaccination.

Pertussis is a disease that adults can acquire and pass onto infants, children, and other vulnerable individuals. Because of recent pertussis epidemics, adults are strongly encouraged to receive a dose of Tdap (CDC, 2016b; Domachowske & Suryadevara, 2013).

Shingles is the later version of dormant chickenpox. Shingles appear along the dermatomes, are painful, and can be debilitating (Domachowske & Suryadevara, 2013). The varicella–zoster (shingles) vaccine has been available to adults 60 years or older since 2006 and is protective for shingles. The vaccine is licensed for adults 50 years or older;

however, the ACIP recommends not making it available to anyone under 60 owing to limited availability of the vaccine and the low incidence of shingles in that age category (Domachowske & Suryadevara, 2013).

Adults may require immunizations to prevent infection in the event of an occupational exposure to blood, blood products, or other potentially contaminated body fluids. The Occupational Safety and Health Administration (OSHA) has established the requirements for hepatitis B immunization for those whose professions may put them at risk (OSHA, 2011).

All persons should also receive a tetanus vaccine every 10 years unless they experience sharp object injury. If such a wound is sustained, the individual should receive a booster of a tetanus toxoid–containing vaccine on the day of the injury only if more than 5 years has elapsed since the last tetanus toxoid–containing dose (Heymann, 2015).

Other reasons for promoting adult vaccination include pneumococcal vaccine for adults over the age of 65 (or for those who smoke or have a history of high-risk conditions, such as heart disease, diabetes, or chronic respiratory diseases), international travel (possibly requiring vaccines specific to the destination), or suspected failure of earlier vaccines to produce lasting immunity (Domachowske & Suryadevara, 2013).

International Travelers, Immigrants, and Refugees

As Americans interact more and more with their neighbors in other parts of the world, the incidence of Americans with tropical or imported diseases also rises (Fig. 8–11). Within about 36 hours of boarding an airplane, any destination in the world can be reached. An average flight can equal the incubation period of some infectious diseases, and before the onset of symptoms are realized, microbial agents could be spread around the globe.

Figure 8–11 Careful planning is needed when traveling internationally.

Travelers can take steps to protect themselves prior to embarking on their journey to new and exotic places. Information is available on the CDC Travelers Health Web site so that potential travelers can stay healthy while on their trip and remain healthy upon their return (CDC, 2016e). Travelers can also make an appointment for a consultation with a tropical medicine or travel clinic to prepare for their international travel. At a minimum, all international travelers should take steps to be adequately immunized as required by international health practices. These steps include being immunized with the recommended vaccines for the particular area of the world, having the necessary chemical prophylaxis on hand (i.e., antimalarial medications as prescribed), and being knowledgeable about food and water hygiene precautions as well as basic first aid for the care of simple injuries (CDC, 2016e). Every year, countless travelers who neglect to take the recommended travel vaccines or medications end up with generally preventable illnesses, which can cost them time, money, and their health (CDC, 2015w).

Refugees and international travelers who arrive in the United States may be unfamiliar with U.S. health systems, health precautions, and practices. Refugees and immigrants must follow prescribed guidelines including extensive health screening mandated by U.S. immigration laws, immunizations and treatment, as appropriate (CDC, 2013d). More than ever before, community health nurses have professional contact with these new Americans, whether close to their time of arrival or later, in schools, immunization clinics, or other locations. Visitors from other countries may also require the assistance of other community health professionals. For this reason, public health nurses are encouraged to develop and maintain a global perspective on communicable diseases. See Chapter 16 for more information on global health.

SECONDARY PREVENTION

Two approaches to secondary prevention of communicable disease are possible: (a) screening and (b) disease case and contact investigation and notification (previously discussed).

Screening

The term screening is used in community health and disease prevention to describe programs that provide disease-testing opportunities to detect disease in groups of asymptomatic, apparently healthy individuals. Common screening measures can include prenatal hepatitis B, urine *Chlamydia* and GC, and Mantoux TSTs for TB infection. For HIV, several screening tests are available—including oral fluid testing, rapid fingerstick, or the more sensitive screening enzyme immunoassay. The HIV screening tests must be confirmed by a supplemental test such as the Western blot or an immunofluorescence assay when positive results arise (Heymann, 2015). The public health nurse must follow the five C's when conducting HIV/AIDS screening: consent, confidentiality, and counseling, correct results, and connect to care. Screening is a secondary prevention method because asymptomatic cases can be discovered and provided with prompt early treatment. Pregnant women can also be identified and treated to prevent infection to the neonate (Heymann, 2015)

It is important to remember that the screening test itself is not diagnostic but rather a method to identify those persons with positive or suspicious test findings that then require further medical evaluation or treatment. Public health nurse working with clients in a screening setting must be prepared to clearly and correctly explain to individuals that screening tests are not definitive and that positive findings require subsequent investigation before diagnostic conclusions can be drawn.

Criteria for Screening Tests

Some important criteria are used in deciding whether to carry out a screening intervention in a community. They include validity and reliability and predictive value and yield.

Validity and Reliability

The screening test must be valid and reliable. *Validity* refers to the test's ability to accurately identify those with the disease. *Reliability* refers to the test's ability to give consistent results when administered on different occasions by different technicians.

Predictive Value and Yield

The *predictive value* of a screening test is important for determining whether the screening intervention is justified. *Yield* refers to the number of positive results found per number tested. The predictive value and the yield of screening tests become important in planning screening programs for communicable disease detection and prevention because they can help planners locate screening efforts in areas or within population groups that are known to be at high risk for the disease. The predictive value of screening tests increases as the prevalence of the disease increases. For example, a screening test for TB among refugees would have a greater predictive value and yield than would TB screening in the population at large, owing to a higher endemicity of TB in many countries outside of the United States.

Epidemiologic criteria for screening interventions for the detection of health problems include the following:

- Is the disease an important public health problem?
- Is there a valid and reliable test?
- Is there an effective and tolerable treatment that favorably influences the early stages of the disease?
- After a positive screening result, are facilities for diagnosis and treatment available and accessible?
- Is there a recognizable early asymptomatic or latent stage in the disease?
- Do clear guidelines for referral and treatment exist?
- Is the total cost of the screening justifiable compared with the costs of treating the disease if left undiscovered?
- Is the screening test itself acceptable?
- Will screening be ongoing?

The ethics or values represented by these statements include a clear and unwavering respect for the dignity and worth of individuals across racial, gender, religious, sexual, tribal, ethnic, and geographic lines. They include a commitment to ensuring that resources are allocated to areas where they will have the most benefit in preventing disease and

premature death. Socioeconomically disadvantaged persons are often at greatest risk for disease, yet they are the least likely to receive screening services because of financial barriers, including lack of health insurance coverage for preventive care (CDC, 2011d, 2012c). See Chapter 7 for more on epidemiology.

TERTIARY PREVENTION

The approaches to tertiary prevention of communicable disease include care and treatment of the infected person, isolation and quarantine of the infected person, and safe handling and control of infectious wastes.

Care and Treatment

Communicable diseases have care and treatment specific to the disease. As mentioned previously, with respect to investigation, the nurse needs to understand the disease, the treatment and follow-up requirements, and the educational component to discuss with the infected person. There are many information resources for the community health nurse to utilize, such as the CDC and state agency resources (CDC, 2012a). The public health agency may have policies and protocols for the community health nurse to utilize as well.

Providing Services for Special High-Risk Populations

The Lesbian, Gay, Bisexual, and Transgender (LGBT) community bears a disproportionate burden of sexually transmitted diseases, particularly among men. Sixty-three percent of the new HIV infections in 2010 were among men who have sex with men. In addition, gay and bisexual men represent 75% of the cases of primary and secondary syphilis. Whereas men are generally at a lower risk for cancer due to HPV, men who have anal sex are 17 times more at risk for anal cancer (CDC, 2014h). Primary prevention measures can include vaccination and use of condoms. Secondary prevention includes screening for HIV and other STDs. Tertiary care involves treating the infection. Fear of bias in provider offices presents a barrier to accessing screening and treatment services. Public health nurses can educate providers about the need to be culturally sensitive to members of the LGBT community and to incorporate LGBT-friendly practices such as nongender questions on patient history forms and nongender bathrooms (CDC, 2014h). This is an example of how nurses can collaborate with health care team members to provide patient-centered care resulting in improved outcomes and reduced harm among a vulnerable population (Case Western Reserve University, 2014).

Isolation and Quarantine

Communicable disease control includes two methods for keeping infected persons and noninfected persons apart to prevent the spread of a disease (Fig. 8–12). Isolation refers to separation of the infected persons (or animals) from others for the period of communicability to limit the transmission of the infectious agent to susceptible persons. Quarantine refers to restrictions placed on healthy contacts of an infectious case for the duration of the incubation period to prevent disease transmission if infection should develop (Heymann, 2015).

Figure 8–12 Personal protective equipment (PPE) used in a mock Ebola treatment unit. Exposed skin is to be avoided, as it presents an opportunity for possible infection.

Safe Handling and Control of Infectious Wastes

The control of infection in community health also relies upon the proper disposal of contaminated wastes. The CDC and the OSHA support and encourage *universal precautions* that stress that health care workers think of all blood and body fluids and materials that they may come in contact with as potentially infectious (OSHA, 2011). Although universal precaution observance is primarily considered while the nurse is giving hands-on treatment or care to a patient, keeping these principles in mind while making community health visits in the primary and secondary setting is paramount to the safety of both the client and the nurse (Heymann, 2015).

Universal precautions include the following:

- Hand washing after contact with the client or with potentially contaminated articles and before care of other clients
- Bagging and discarding articles contaminated with infectious material into an appropriate labeled container before it is sent for decontamination
- Use of proper personal protective equipment while dealing with an individual in isolation. This isolation is based on the mode of transmission of the specific disease, which may include strict isolation, contact isolation, respiratory isolation, TB isolation (AFB isolation), enteric precautions, or drainage/secretion precautions.

Infectious waste is waste capable of producing an infectious disease. The agency notes that for waste to be infectious, it must contain pathogens with sufficient virulence and quantity so that exposure to the waste by a susceptible host could result in an infectious disease. Requirements for medical waste disposal are for waste to be segregated into categories of:

- Used and unused sharps
- Cultures and stocks of infectious agents
- Human blood and blood products
- Human pathologic, isolation, and animal waste

Although incineration has long been recognized as an efficient method for disposing safely of sharps and other contaminated medical waste, fewer incinerators are available now because of increasing regulation of emissions and particularly those regulations related to burning chemical wastes (Heymann, 2015; OSHA, 2011).

Four key elements of an infectious waste management program are applicable to community practice:

1. Health professionals must be able to correctly distinguish waste that poses a significant infection hazard from other biomedical waste that poses no greater risk than general municipal waste, and such infectious waste must be clearly defined.

2. The waste management program must have administrative support and authority to institute practice guidelines and provide the containers and other resources needed for safe disposal of infectious wastes.
3. Handling of the infectious wastes must be minimized. Containers should be rigid, leak resistant, and impervious to moisture; they should have sufficient strength to prevent rupture or tearing under normal conditions; and they should be sealed to prevent leakage. Containers for sharps must also be puncture resistant.
4. An enforcement or evaluation mechanism must be in place to ensure that the goal of reducing the potential for exposure to infectious waste in the community is met.

USING THE NURSING PROCESS FOR COMMUNICABLE DISEASE CONTROL

As mentioned in Chapters 4 and 7, the nursing process has steps similar to the research process and the epidemiologic process when approaching any health problem or condition. Therefore, using the nursing process to achieve communicable disease control should be an important and natural process for community health nurses.

Assessment

The first step of the nursing process—assessment—aligns itself with case identification and case finding in communicable disease control. The community health nurse must use all assessment skills and tools available during contact with clients, so as not to overlook the possibility of a communicable disease. Assessment must be comprehensive, producing physical, social, and environmental data. There is no place for assumption. At times, a nurse can become lulled into the usual patterns of inquiry, and this oversight may prove fatal to the client. An example follows:

"Baby Josephine is irritable," says the mother. "Well, babies sometimes are," says the nurse. "How are you feeding her? Show me how you hold her. Does she sleep well? Try rocking her in the rocking chair before bedtime. And burp her more frequently. I'll check back with you in 2 weeks." Did the nurse record the baby's temperature, look at her for a rash, compare present weight with last weight, ask about bowel habits or vomiting, inquire about illnesses in the family, check on breast-feeding technique or watch while the mother demonstrated formula preparation, inspect the family's water source, ask about other foods the baby is eating, and so forth?

Broader inquiry into such a simple statement from the mother in this example may lead to the discovery of a life-threatening, undiagnosed communicable disease.

Assessment in the broader sense with respect to communicable disease control relates to the surveillance for disease. As mentioned previously, communicable diseases are reportable and the public health nurse may be the first to notice a trend in a rise in a particular disease rate.

Diagnosis

This may include identification of the problems associated with the specific communicable disease for the individual (e.g., pain, need for isolation, risk for further infection), the family (e.g., family support systems/stressors, strains of caregiving, preventing spread of infection to others), and the community (e.g., prevention of spread of infection in schools, workplaces, other social settings). Diagnosis of a specific communicable disease may be made through laboratory confirmation, but nursing diagnosis will extend beyond that and include physical, emotional, social, and care needs of the individual, family, and community.

Planning

The planning step in the nursing process involves different activities, depending on whether the intervention is for an individual, family, group, or entire community. At the individual level, the nurse may assist a client or family to obtain an immunization or definitive treatment. Or the nurse may assist the client through education about self-care related to disease symptoms that provide relief and in reducing the chance of transmitting the disease to others in the family or community. With groups and communities, planning interventions include the collaboration with community members and/or organizations. Whether a teen immunization campaign is proposed or a flu shot day is planned for senior citizens, there are location, staff, and supplies to prepare, which may include writing grants, establishing contracts, and training and orienting staff, before implementation can begin.

Implementation

During the implementation step, the nurse actually takes the action that was identified as necessary during assessment and planning. In the implementation step, the nurse may actually deliver the service or may supervise other staff or volunteers, as with a large immunization event. Implementing plans with small groups or families may involve arranging for transportation, so that several people can get to the immunization site or can be seen by a primary care provider. It may include gathering clinical specimens for laboratory analysis from a family recovering from a *Salmonella* infection. Education on primary prevention to prevent future infections is an essential part of the implementation phase. Agency record keeping, state-required contact investigation, and reports to the next level of government oversight of a communicable disease are essential in this phase.

Evaluation

Evaluation is an essential step in the nursing process with all services community health nurses provide. When dealing with communicable diseases, it is most important to determine whether actions have achieved the established goals. Have the outcomes been accomplished? Are all family members immunized? Are all family members free of the disease? Do families know how to prevent the diseases recurring? What needs to be done now to keep the community safe from communicable diseases? Are there funding issues, programs nearing completion that need support, or growth of services needed that can be addressed before a critical need occurs? These are examples of questions that need answers during evaluation. The community health nurse who is concerned with the health and safety of the community applies the steps of the nursing process to reach healthy community goals.

LEGAL AND ETHICAL ISSUES IN COMMUNICABLE DISEASE CONTROL

The threats presented by communicable diseases can bring public safety and ethical considerations to a crossroad. Public health interventions to protect the public often overlap individual rights (Phua, 2013). The communitarianism concept of what is good for the whole is good for the parts might be applied to public health practice. Considerations for ethical public health practice should include overall benefit to society, collective action, communitarianism, fairness in distribution of burden, harm principle, and paternalism, liberty-limiting continua, social justice/fairness, and global justice. In addition, ethical issues of autonomy, beneficence, nonmaleficence, and justice also need to be taken into consideration (Phua, 2013). Community/public health nurses must balance these ethical principles while working with the community to control the spread of infectious diseases. An example of this conflict might occur while conducting contact investigation for an STD. The nurse must be mindful to conduct the investigation while maintaining confidentiality of the index case. Another example is mandating immunizations resulting in exclusion of unvaccinated children from a school setting (Phua, 2013). Public health practitioners walk a fine line to protect the rights of the individual while also protecting the health and safety of the community.

Enforced Compliance

Legally, the responsibilities of public health officials in communicable disease control include the police power to enforce compliance with treatment or restrict the activity of infectious people to protect the welfare of others (CDPH, 2013). Regulations that enforce compliance with disease prevention strategies are a justifiable restriction if the measures proposed are demonstrably effective and grounded in ethical principles (CDPH, 2013). Due process protects individuals from government intrusion, particularly ensuring that fundamental fairness has been implemented in situations requiring imprisonment (CDPH, 2013).

Confidentiality, Privacy, and Discrimination

The health officer has the duty to provide communicable disease control, examine the patient, and take steps to prevent the spread of the disease to others (CDPH, 2013). To carry out communicable disease interventions, client needs for confidentiality and privacy must be ensured. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rules, last revised in 2003, note that reports must be made to public health in order to protect the public's health. These rules allow for disclosure of only that information needed to protect the public. Information may also be disclosed to a person at risk of contracting an illness, without disclosing identifying information about the source. Only the minimum amount of information to allow the person to obtain the necessary care can be disclosed (USDHHS, n.d.).

Human society has a long-standing aversion to infectious diseases. Ostracism, which in the past included people with leprosy and other contagious conditions, has shifted to discrimination against people with TB or AIDS, for example. People are protected from discrimination under the Americans with Disability Act but not with respect to posing a public health treat, such as with the contagious state of TB (U.S. Equal Employment Opportunity Commission, 2011).

SUMMARY

Communicable diseases pose a major threat to the public's health and have done so since the beginning of humankind. In today's world, such diseases are transmitted globally as the result of mobile populations, increased urbanization, and international travel. Communicable diseases can be transmitted through direct contact from one person to another or indirectly through contaminated objects (air, water, food) or a vector (animal or insect). Communicable diseases affect all types of people and have worldwide significance.

Ideally, prevention of communicable diseases is accomplished through primary prevention methods such as utilizing mass media education campaigns, one-on-one education, and immunization. Knowledge of VPDs, the schedule of vaccinations, a community's immunization status, herd immunity, barriers to immunization coverage, planning and implementing immunization campaigns, adult immunizations, and the immunization needs of international travelers, immigrants, and refugees has been discussed. Health care workers need to practice universal precaution and the safe handling of infectious wastes to maintain worksite safety.

Secondary prevention activities of screening and disease investigation are steps taken when primary prevention activities have failed. Tertiary prevention is needed to ensure additional people are not infected and those who are ill receive care and treatment. Ongoing disease transmission can be interrupted through treatment, isolation, or quarantine.

Becoming familiar with the major communicable diseases affecting our nation is essential baseline information for community health nurses. TB, resurging since the 1980s, may be one of the biggest public health problems in the new millennium. Nurses must be aware of the populations at risk, how the disease is prevented, and the use of appropriate interventions during diagnosis and treatment. Issues compounding the control of TB are twofold: increasing infections with MDR strains, and the increasing number of people with TB and HIV/AIDS, making diagnosis and treatment more complicated.

A second major disease, HIV/AIDS, was first identified in the 1980s. With the success of antiviral drugs, HIV/AIDS is becoming a chronic disease for clients in industrialized nations, with an average life expectancy of 10 to 15 years after diagnosis. Africa is deeply affected by the massive numbers of women and children who are HIV positive, without access to the life-prolonging drugs available to people in developed nations.

STDs threaten the health and lives of millions of citizens. At greater risk are the sexually active, nonmonogamous. Control of STDs can be accomplished through effective screening, treatment, contact investigation, and aggressive public education. Several common STDs were discussed, including GC, syphilis, *Chlamydia*, genital herpes, and viral warts.

Hepatitis is more common than HIV and can lead to life-threatening events, such as

cirrhosis and liver cancer. Yet, these diseases do not garner the attention they need. Most of the public is unaware of the types of hepatitis, prevention, transmission, and treatment. Vaccines for two of the forms (hepatitis A and hepatitis B) are available.

Influenza and pneumonia are "old" diseases that cause increased morbidity. These diseases cause the most morbidity and mortality in the frailest citizens—the immune compromised, very young, and the very old—although vaccines are available to prevent them.

Smallpox (an eradicated disease) and anthrax have been identified as potential bioterrorism weapons. The community/public health nurse has several areas of responsibility in regard to bioterrorism. First, the nurse must know the signs and symptoms of potential infectious diseases used as weapons. Also, the nurse has a responsibility to the community to allay fears about bioterrorism and to provide information about prevention.

Community/public health nurses use the nursing process in their important role with regard to all populations at risk for communicable diseases. Nurses concerned with communicable disease control must recognize who is at risk, where the potential reservoirs and sources of infectious disease agents are located, what environmental factors promote their spread, and what are the characteristics and vulnerability of community members and groups. Community health nurses must work collaboratively with other public health professionals to establish immunization and education campaigns, work to improve community communicable disease control policies, and develop a broad range of services for at-risk community members.

Ethical issues in communicable disease control include enforced compliance, the justifiability of screening, preservation of confidentiality and privacy, and the avoidance of discrimination against infected people.

ACTIVITIES TO PROMOTE CRITICAL THINKING

1. Interview a professional in your local or state health department who works in communicable disease control. Determine (a) how he conducts communicable disease surveillance, (b) what diseases must be reported in your state, and (c) which communicable diseases are posing the greatest threat to the health of your state's citizens. Compare this information to national statistics.
2. Compare a recent issue of *Mortality and Morbidity Weekly Report* with the same issue published 5 years earlier, in terms of cases of specific notifiable diseases in the United States. Which diseases appear to be increasing? Decreasing? Select one disease and read at least one recent publication on this subject to determine the reasons for its rise or decline.
3. Through your local health department or county office of education, determine the percentage of preschool children that are immunized in your city or county. Is this a safe level of herd immunity? Propose some recommendations for preserving or raising this level.
4. Select one high-risk population discussed in this chapter, and list the factors that make this group vulnerable to communicable disease. Use at least one other published source to enhance your understanding. Propose one nursing intervention (such as a specific screening or educational program) and outline how it might be best accomplished.
5. Interview a professional who works in STD services or with the HIV-infected population. Determine what methods he or she uses for contact investigation. How does this health care worker preserve privacy and confidentiality? What measures have proved most effective in reaching contacts? How do they evaluate the success of their program?
6. Access the CDC Web site (http://www.cdc.gov) and browse the site to learn about its various services. Are there special travelers' warnings in certain countries at this time? What are some of the CDC's current concerns regarding communicable diseases? Select a communicable disease and identify the number of cases presently reported. Return to the same Web site 1 month later. Has the incidence of the disease increased or decreased?

9 CHAPTER

Environmental Health and Safety

"When we try to pick out anything by itself, we find it hitched to everything else in the Universe."
John Muir (1838–1914), Naturalist

KEY TERMS

Bioaccumulation
Biomonitoring
Brownfields
Built environment
Climate change
Ecology
Ecomedicine
Endocrine disrupting chemicals (EDCs)
Environmental epidemiology
Environmental justice
Epigenetics
Exposure pathway
Health disparities
Integrated pest management (IPM)
Precautionary principle
Risk assessment
Risk management
Social determinants of health
Superfund
Sustainability
Toxicology

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Apply the ecological perspective to human and environmental relationships.
- Discuss concepts of prevention and upstream approaches to health impact and environmental health.
- Discuss guiding documents for public health nursing.
- Discuss how the core functions of public health can be applied to public health nursing.
- Relate the effect of environmental hazards to human health.
- Describe how nurses can collaborate with other professionals, government agencies, and communities to reduce environmental threats to health.

The World Health Organization (WHO, 2015c, para. 1) defines health as "a

complete state of physical, mental, and social wellbeing" and environment, as it relates to health, as "all the physical, chemical, and biological factors external to a person, and all the related behaviors" (WHO, 2015a, para. 1). The ability to live in a healthy environment increases not only the number of years of a healthy life but also one's quality of life. In nursing, the concern for the environment dates back to Florence Nightingale who reminds us in her *Notes on Nursing: What It Is and What It Is Not* (1860/1969) that health is dependent upon clean air, clean water, safe food, noise, and light. Increasingly, a number of environmental factors have been recognized as detrimental to health including exposures to hazardous materials in air, water, food, and soil, the rise in development and use of synthetic chemicals not well tested for safety, the adverse effects of natural and man-made disasters, and, more recently, the built environment. The most recent version of Healthy People, *Healthy People 2020*, uses the WHO definition of environmental health and explains that this includes not only the study of the direct pathological effects of various chemical, physical, and biological agents but also the effects on health of the social and broader environment, including urban development, housing, industry, transportation, and agriculture (United States Department of Health and Human Services [USDHHS], 2015b).

ENVIRONMENTAL HEALTH AND NURSING

Nurses are charged to incorporate knowledge of the environment into their nursing practice. Historically, public health and occupational health nurses (OHNs) have been leaders in this effort through their work in homes, in communities, and with governmental organizations. Despite this history, there is a need for increased nursing knowledge, environmental health assessment, engaging with community members to address environmental health issues and policy, and advocacy efforts among public health nurses (PHNs). During the past two decades in particular, several documents challenge nurses to advance their environmental health nursing knowledge and skills. In 1995, the Institute of Medicine report, *Nursing Health and the Environment* (Pope, Snyder, & Mood, 1995), addressed nursing education, practice, and research. The Agency for Toxic Substances and Disease Registry (ATSDR) launched their "Nursing and the Environment" initiative. Public health nursing led the profession with the publication of the *Environmental Principles for Public Health Nursing* in 2005 (see Table 9–1). The American Nurses Association (ANA) produced the *ANA's Principles of Environmental Health for Nursing Practice and Implementation Strategies* in 2007 (see Table 9–2). And most recently, in 2015, the ANA, in *Nursing: Scope and Standards of Practice*, built upon a new standard first introduced in 2010—Standard 17 Environmental Health (see Display 9–1). These guiding documents and initiatives call for all nurses to incorporate environmental health into all areas of nursing practice.

Table 9–1 Guiding Documents: Environmental Health Principles for Public Health Nursing

Environmental Health Principles for Public Health Nursing
1. Safe and sustainable environments are essential conditions for the public's health.
2. Environmental health is integral to the role and responsibilities of all PHNs.
3. All PHNs should possess environmental health knowledge and skills.
4. Environmental health decisions should be grounded in sound science.
5. The precautionary principle is a fundamental tenet for all environmental health endeavors.
6. Environmental justice is a right of all populations.
7. Public awareness and community involvement are essential in environmental health decision-making.
8. Communities have a right to relevant and timely information for decisions on environmental health.
9. Environmental health approaches should respect diverse values, beliefs, cultures, and circumstances.
10. Collaboration is essential to effectively protecting the health of all people from environmental harm.
11. Environmental health advocacy must be rooted in scientific integrity, honesty, respect for all persons, and social justice.
12. Environmental health research addressing the effectiveness and public health impact of nursing interventions should be conducted and disseminated (p. 5).

From American Public Health Association, Public Health Nursing Section. (2005). Environmental health principles & recommendations for public health nursing. Washington, DC: Author, with permission.

Table 9–2 ANA's Principles of Environmental Health for Nursing Practice

All nurses are to be aware of the principles of environmental health for nursing. We are to integrate these principles into our practice, education, and research.
1. Knowledge of environmental health concepts is essential to nursing practice (p. 17).
2. The precautionary principle guides nurses in their practice to use products and practices that do not harm human health or the environment and to take preventive action in the fact of uncertainty (p. 18).
3. Nurses have a right to work in an environment that is safe and healthy (p. 20).
4. Healthy environments are sustained through multidisciplinary collaboration (p. 22).
5. Choice of materials, products, technology, and practices in the environment that impact nursing practice are based on the best available evidence (p. 23).
6. Approaches to promoting a healthy environment reflect a respect for the diverse values, beliefs, cultures, and circumstances of patients and their families (p. 24).
7. Nurses participate in assessing the quality of the environment in which they practice and live (p. 25).
8. Nurses, other health care workers, patients, and communities have the right to know relevant and timely information about the potentially harmful products, chemicals, pollutants, and hazards to which they are exposed (p. 27).
9. Nurses participate in research of best practices that promote a safe and healthy environment (p. 29).
10. Nurses must be supported in advocating for and implementing environmental health principles in nursing practice (p. 30).

From American Nurses Association (ANA). (2010). ANA's principles of environmental health for nursing practice with implementation strategies (2nd ed.). Silver Spring, MD: Author, with permission.

DISPLAY 9.1 AMERICAN NURSES ASSOCIATION, PUBLIC HEALTH NURSING: SCOPE AND STANDARDS OF PRACTICE

Standard 16. Environmental Health

"The registered nurse practices in an environmentally safe and healthy manner" (p. 62).

The Registered Nurse

1. Has knowledge of current environmental health issues and strategies
2. Promotes a safe and healthy workplace and professional practice environment

for populations, for communities, and for individual clients

3. Assesses the environment in the practice setting to identify health risk factors (e.g., chemical, biological, physical)
4. Promotes the safe, cautious, and proper use/disposal of products in the community setting
5. Communicates information about both environmental health risks and strategies to reduce exposure to peers, families, consumers of health care, and the wider community
6. Applies the precautionary principle and current research to ascertain if a practice, policy, or product is a threat to human health or the environment
7. Works with others to promote "healthy communities" (p. 62)
8. Works toward promoting "sustainable environmental health policies and conditions" through partnerships with other professionals and agencies
9. Critically appraises media coverage of issues/ incidents relating to environmental health
10. Serves as an advocate for implementing principles of environmental health in public health and nursing practice

Adapted from American Nurses Association (ANA). (2013). Public health nursing: Scope and standards of practice (2nd ed.). Silver Spring, MD: Author.

Brief History of Occupational/Environmental Health Movement in Nursing

Since the time of Florence Nightingale, nurses have considered the environment of the home, hospital, or community as a factor for health and illness. However, the specific role of nurses in occupational and environmental health first occurred in the workplace. Nurses who worked with hazardous exposures in the workplace were often called industrial nurses. Now those who work in industry are called OHNs where they both assess worker's health status and work to ensure worker safety and prevent adverse health effects from hazards in the workplace. With specific education and training in toxicology, epidemiology, workplace hazards, regulations, and prevention strategies, OHNs can be certified through the American Board of Occupational Health Nurses (see Chapter 31). Public health has included environmental health as a central aspect of health promotion and disease prevention. More recently, the nursing profession has responded to the call of nurses to establish environmental health competencies for nursing practice.

In 1995, the Institute of Medicine released the report of their meeting on *Nursing, Health, and the Environment* (Pope et al., 1995) that called for nurses to become more knowledgeable about the scientific principles of the relationship between health and environment, to advance their assessment and referral skills for environmental hazards, to advocate for patients and communities, to reduce adverse health effects, and to understand policy and legislation related to environmental health. More specifically, the report called for nurses to recognize pathways of exposure, prevention and control strategies, and the importance of research to develop sound and effective interventions. Interventions would include education and appropriate risk communication (Pope et al., 1995).

From 1995 until 2008, in response to this pivotal report, many schools and colleges increased their capacity to include environmental health into the nursing curriculum. In addition, nurses in practice incorporated environmental health into practice and were instrumental in making significant change in practice settings to reduce hazardous exposures to both health professionals and patients. Nursing research to address nursing interventions for environmental health increased, and nurses became involved in a number of policy and advocacy efforts.

In December 2008, 50 nurse leaders representing a range of nursing organizations including the American Public Health Association (APHA) Public Health Nursing Section, the Association of Community Health Nursing Educators (ACHNE), the Association of Public Health Nurses (APHN), and ANA met to develop an agenda for environmental health nursing. The organization, Alliance of Nurses for Healthy Environments (ANHE), was formed to advance nursing knowledge of environmental health and engage nurses in collaboration to advance environmental health nursing (ANHE, 2015a). Four workgroups were formed: education, research, practice, and advocacy/policy. Since that time, a number of initiatives have placed environmental health at the forefront for nursing education and

practice. The ANHE Education Workgroup developed competencies for nursing practice in 2009 (Leffers, McDermott-Levy, Smith, & Sattler, 2014). Working collaboratively with the ANA, Standard 16: Environmental Health was included in the second edition of *Nursing: Scope and Standards of Practice* (ANA, 2010) and revised for the 2015 edition (ANA, 2015b). Since the publication of the 2010 Standard 16: Environmental Health, all nurses must incorporate environmental health principles into nursing practice. In addition to the success of the development of competencies and standards, the nurses who work with ANHE have advanced their advocacy and policy voice, prepared research priorities for environmental health nursing, and held conferences and workshops for nursing practice, education, and advocacy efforts (ANHE, 2015b). Although PHNs have been at the forefront of environmental health nursing, the new competencies provide guidance for all types of nursing practice and can be applied in many community and acute care settings.

Guiding Documents

In addition to the previously mentioned *Environmental Health Principles for Public Health Nursing* (APHA, 2005), the *ANA Principles of Environmental Health for Nursing Practice* (ANA, 2007), and the *Scope and Standards of Nursing Practice* (ANA, 2010; ANA, 2015b), nurses are guided by other public health documents. These include the federal guidelines from the surgeon general report on Healthy People and the core functions of public health (Centers for Disease Control and Prevention [CDC], 2015b).

Healthy People 2020 Initiatives

In 1979, the surgeon general released a report, *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention,* to set goals for improving health for the nation. In 1990, the Healthy People initiative set specific objectives to reduce disease, promote health, and improve healthy years of life. The revisions in 2000, 2010, and most recently for *Healthy People 2020* continue this focus upon targets for health improvement. This document provides guidance for nurses to identify targets for health and is used for many public health nursing interventions. The *Healthy People 2020* framework offers specific goals and objectives for environmental health. The overall goal is to "promote health for all through a healthy environment" (USDHHS, 2015b, para. 1). The most recent release of the *Healthy People 2020* Environmental Health objectives focuses in six areas that include

- Outdoor air quality
- Surface and groundwater quality
- Toxic substances and hazardous wastes
- Homes and communities
- Infrastructure and surveillance
- Global environmental health (para. 3)

A number of health conditions are linked to poor air quality such as respiratory disease, cardiovascular disease, and cancer. Toxins found in water have been linked to neurological problems, endocrine disruption, and cancer. Although not all mechanisms for disease from toxic exposures are fully understood or studied, various hazardous chemicals have been linked to birth defects, neurological problems, endocrine disruption, and cancer (USDHHS, 2015a). See Display 9–2 for a full listing of the *Healthy People 2020* Environmental Health objectives.

DISPLAY 9.2 *HEALTHY PEOPLE 2020* OBJECTIVES FOR ENVIRONMENTAL HEALTH TOPIC AREAS

Goal: Promote health for all through a healthy environment.

Topic and Number Objective

Outdoor Air Quality

EH-1 Reduce the number of days the air quality index (AQI) exceeds 100, weighted by population and AQI.

EH-2 Increase use of alternative modes of transportation for work.

EH-3 Reduce air toxic emissions to decrease the risk of adverse health effects caused by airborne toxics.

Water Quality

EH-4 Increase the proportion of persons served by community water systems who receive a supply of drinking water that meets the regulations of the Safe Drinking Water Act (SDWA).

EH-5 Reduce waterborne disease outbreaks arising from water intended for drinking among persons served by community water systems.

EH-6 Reduce per capita domestic water withdrawals with respect to use and conservation.

EH-7 Increase the proportion of days that beaches are open and safe for swimming.

Toxics and Waste

EH-8 Reduce blood lead levels in children

EH-9 Minimize the risks to human health and the environment posed by hazardous sites.

EH-10 Reduce pesticide exposures that result in visits to a health care facility.

EH-11 Reduce the amount of toxic pollutants released into the environment.

EH-12 Increase recycling of municipal solid waste.

Healthy Homes and Healthy Communities

EH-13 Reduce indoor allergen levels

EH-14 Increase the proportion of homes with an operating radon mitigation system for persons living in homes at risk for radon exposure.

EH-15 Increase the percentage of new single-family homes (SFH) constructed with radon-reducing features, especially in high-radon-potential areas.

EH-16 Increase the proportion of the Nation's elementary, middle, and high schools that have official school policies and engage in practices that promote a healthy and safe physical school environment.

EH-17 (Developmental) Increase the proportion of persons living in pre-1978 housing that has been tested for the presence of lead-based paint or related hazards.

EH-18 Reduce the number of U.S. homes that are found to have lead-based paint or related hazards.

EH-19 Reduce the proportion of occupied housing units that have moderate or severe physical problems.

Infrastructure and Surveillance

EH-20 Reduce exposure to selected environmental chemicals in the population, as measured by blood and urine concentrations of the substances or their metabolites.

EH-21 Improve quality, utility, awareness, and use of existing information systems for environmental health.

EH-22 Increase the number of states, territories, tribes, and the District of Columbia that monitor diseases or conditions that can be caused by exposure to environmental hazards EH-23.

EH-23 Reduce the number of new schools sited within 500 ft of an interstate or federal or state highway.

Global Environmental Health

EH-24 Reduce the global burden of disease due to poor water quality, sanitation, and insufficient hygiene.

Importance of Environmental Health for Nursing

Nurses are essential to improve environmental health through nursing education, research, and practice. The ANHE offers reasons why nurses are important to environmental health that include the role of nurses in promoting healing and safe environments for people. Nurses work with diverse populations in homes, workplaces, and communities and are the largest population of health care providers in the United States with almost 3 million registered nurses. In addition, nurses are in one of the most trusted professions, are able to communicate complex information to their patients and communities, and interact with many other health care organizations and in policy setting roles (Smith, 2015).

CONCEPTS AND FRAMEWORKS FOR ENVIRONMENTAL HEALTH

Ecology

Ecology can be defined as the study of the interactions and relationships between living organisms and their environments. Ecosystems are dynamic communities of plant, animal, and microorganisms as well as the nonliving environments in which they live. No organism, including humans, can live removed from their ecosystem or other species. Ecosystems help regulate water, gases, waste recycling, nutrient cycling, pollination, infectious disease, climate, and biology as well as provide recreational and cultural opportunities for human use (Frumkin, 2010; Wright & Boorse, 2013). The scientific study of ecosystems provides the science to understand the synergistic relationship between humans and the environment and why knowledge of environmental health is so important for nurses. The term ecomedicine refers to the adverse human impact upon the environment that, in turn, creates new patterns of disease and poverty (Science and Environmental Health Network [SEHN], 2015a). Specific threats to the environment for human health are discussed using a sustainability perspective.

PHNs find that the science of ecology has been applied to social ecological perspectives that identify not only the physical environment but also the social and cultural factors that exist for populations. In public health, the ecological model of population health is used to illustrate that determinants of health (biological, behavioral, and environmental) interact to affect health (Friis, 2012). In addition, the *Healthy People 2020* approach emphasizes the need to include social, cultural, and environmental conditions into assessments for health determinants. Health behaviors occur within various levels of the ecological model and must be considered to clearly identify the most effective interventions for health promotion (USDHHS, 2015a). See Figure 9–1: Ecological Model of Public Health.

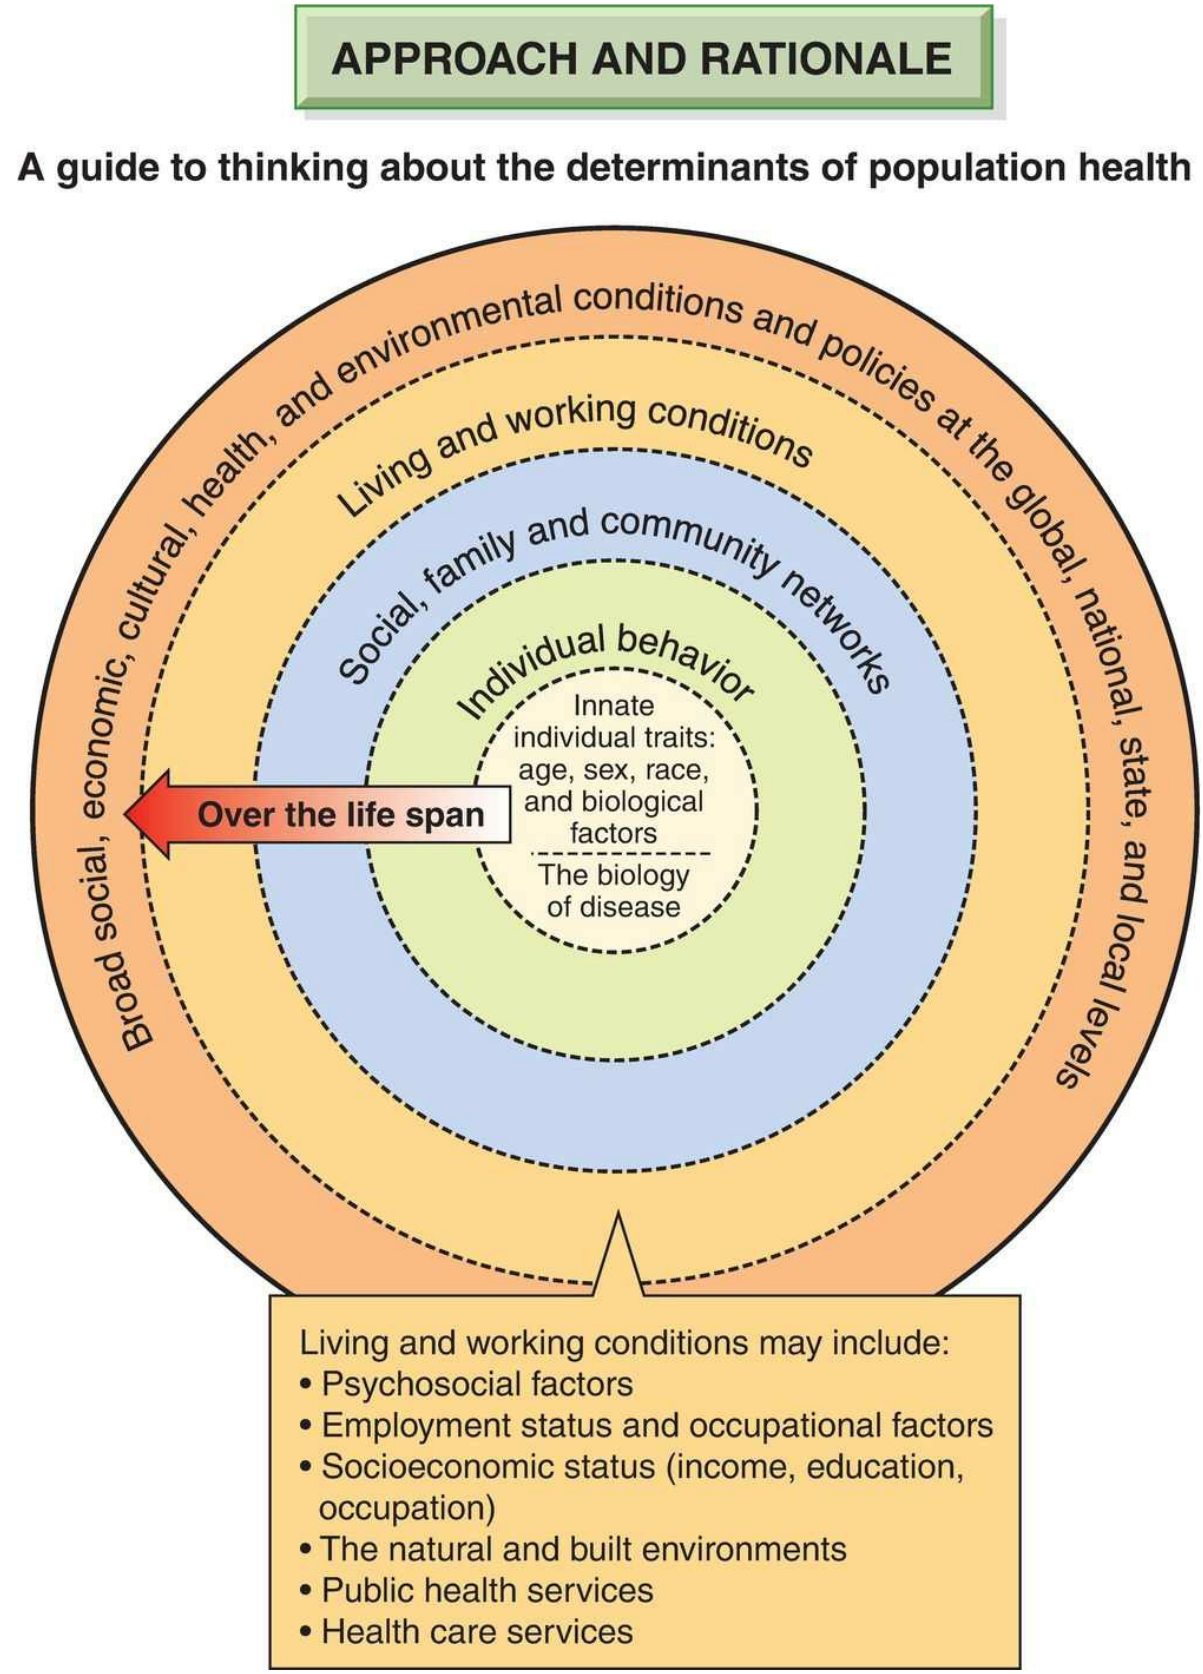

Figure 9–1 Ecological model for public health.

Sustainability

Sustainability is based upon the principle that human beings and the natural environment must coexist harmoniously for human survival (U.S. Environmental Protection Agency [EPA], 2015p). When the concept of sustainability is applied to human systems, it is evident that the public must protect the environment and promote healthy characteristics in the population and communities in which they live. Currently, much of human/environment interactions are not sustainable in that energy use exceeds supply and pollutants are changing the natural landscape of plant and animal life and threatening both human life and ecosystems. Solutions to improve sustainability for humans and the environment include strategies that are socially desirable, economically feasible, and ecologically viable (Wright & Boorse, 2013). One example of how increased human demands for energy impact sustainability is the increased use of fossil fuels for home heating and cooling. The increased use of coal, for example, increases air pollution from the toxic emissions released in coal-fired power plants that are often referred to as greenhouse gases and that contribute to climate change. Current estimates indicate that the global need for oil has exceeded available resources that are not sustainable. Further in this chapter, you will learn about the work of nurses to address the health risks associated with hydraulic fracturing. This, too, is a concern for sustainability that impacts human health. Concerns about the depletion of natural resources, disruption of nutrient cycles, widening economic disparities between the rich and poor, and climate change are key issues addressed in the EPA's *Framework for Sustainability Indicators at EPA* (2015l).

Sustainability is an important concept in relationship to nursing and health. The U.S. health care industry is a $2.5 trillion enterprise that contributes to 8% of all greenhouse gases and 7% of all carbon dioxide emissions. Hospitals generate as much as 5 million tons of solid waste annually; much of that includes hazardous materials. Nurses were instrumental in the formation of Health Care Without Harm, a leading organization that promotes environmentally responsible health care (Health Care Without Harm, 2015a). The ANA (2015a) has long supported efforts to address medical and pharmaceutical waste. For example, Denise Choiniere, MS, RN, launched the sustainability effort at the University of Maryland Medical Center (UMMC) in 2007 and now serves as the UMMC Director of Materials Management and Sustainability; Beth Schenk, PhD, MHI, RN, serves as the Nurse Scientist and Sustainability Coordinator with Providence Health Services St. Patrick Hospital in Montana. Director Choiniere, who was employed as a cardiac care nurse at the hospital, led efforts to begin a Green Team and build the sustainability program. The UMMC has won numerous awards for their efforts to move toward sustainability in environmentally preferred purchasing, safer chemicals, use of green cleaners, farmers' market and sustainable food options, green commuting, waste reduction, energy conservation, and building design (Boone, 2012). In Dr. Schenk's role with her shared appointment at Washington State University, she seeks to advance environmental stewardship in health care and promote research for sustainability (Washington State

University, 2015). Efforts are ongoing to advance nursing knowledge for sustainability in health care (Butterfield et al., 2014; Woeber, 2013).

While these examples highlight the work of two nurse leaders for large health care systems, nurses who work in community settings must comply with best practices for waste disposal as well as greening their practice environments. Pharmaceutical waste is a serious concern for nurses who work in home and school settings. This topic is more fully addressed in the section about water contaminants.

Upstream Focus

Many PHNs incorporate an "upstream" focus into their work with populations. That approach emerged from the seminal publication by John McKinley in 1979, *A Case for Focusing Upstream*, which identifies root causes of disease and manufacturers of illness. It considers socioeconomic factors and also the environmental origins of disease and health problems. To illustrate this, he uses examples in the food and tobacco industries (McKinley, 1979). PHNs work in prevention and health promotion areas, but an upstream approach moves our thinking to those factors that are at the institutional and system level rather than looking solely at healthy lifestyle issues: in other words, "upstream" from the identified problem or issue. For example, a program to improve heart health in a community using a lifestyle approach would promote healthy diets, increased physical activity, and smoking cessation. An upstream focus looks at the social factors such as secondhand smoke in public places, unhealthy food choices available in schools and other public places, and how the built environment promotes or impedes safe outdoor physical activity. Two related concepts for environmental health nursing are health disparities and the social determinants of health. This focus for public health and environmental health nursing was introduced in a classic article by Butterfield (2002) who reminds the nursing profession that nurses, particularly PHNs, with a presence in worksites, homes, schools, and other community settings can serve to reduce risks. PHNs are often the "sentinels of surveillance" (Butterfield, 2002, p. 33) who detect unusual illness patterns and respond to environmental emergencies in work and community settings. With emphasis upon data estimates that as much as 33% of disease occurrence is attributable to environmental exposures, and that the prevalence of environmentally linked health problems such as asthma, neurological problems, certain cancers, and birth defects are all on the rise, a case can be made for why nurses must use an upstream framework to assess, monitor, educate, advocate, and create policies to reduce environmental health risks. Butterfield (2002) identifies three specific opportunities for nurses to impact these health threats: (1) by nursing presence in hospitals, clinicians worksites, schools, and home settings, (2) because nurses have skills to translate technical information into messages that nonhealth professionals can understand, and (3) because nurses have skills to promote health at both the individual and community level. Strategic actions that can be considered as part of an upstream framework are to include the following components:

- Use of an environmental health history in nursing assessments in order to create better tracking of environmental exposures
- Embedding of environmental health information into nursing practice settings
- Increases in educational efforts to inform individuals and families of environmental health hazards
- Knowledge of information
- Engaging in environmental health research in order to advance our understanding of etiology and prevention

- Advocating for individuals and groups who are at specific risks

By using an upstream approach, PHNs can impact the prevalence of disease by intervening where the root causes exist (Butterfield, 2002).

Health Disparities

Health disparities are a serious concern for overall health in the United States and globally. As noted in the discussion of upstream approaches to health, environmental factors are basic determinants of health and well-being. However, great inequities occur between the environments of people with higher incomes and those of low-income communities, people of color, and tribal populations. Complex relationships exist between genes and environment that are related to social determinants of health (National Institute of Environmental Health Sciences [NIEHS], 2015a). Disparities that may be directly correlated with environmental exposures include rates of asthma among children, elevated blood lead levels (EBLLs), cancers that are linked to environmental exposures, and lung diseases among adults. Disproportionate exposures to pesticides, toxic chemicals in the workplace, poor indoor air quality in schools, and lead in housing have all been linked to the social determinants of health. At the federal level, the U.S. government responds to this important concern for health disparities related to children's health through the President's Task Force for Environmental Health and Safety Risks to Children. This interagency effort includes 17 federal departments and White House Offices that include the EPA and Departments of Agriculture, Health and Human Services, Education, Energy, Housing and Urban Development (HUD), Justice, Labor, Transportation, and Homeland Security to identify priority health and safety risks along with recommending interagency actions to address them (EPA, 2015v). Issues that are being addressed include climate change, racial and ethnic asthma disparities, healthy homes, and chemical exposures.

Social Determinants of Health

According to the WHO, social determinants of health are defined as "the conditions in which people are born, grow, live, work, and age. These circumstances are shaped by the distribution of money, power and resources at global, national, and local levels" (2015b, para. 1). Frequently, these are referred to as the conditions in which people are born, grow, live, work, and age or environments where people live, labor, learn, pray, and play (Children's Health Protection Advisory Committee [CHPAC], 2013b). Social determinants of health include a number of social factors that affect families and communities such as education, housing conditions, options for safe and active transportation, access to health care services, access to healthy food, employment and income, neighborhood environment and safety, and the quality of the built environment such as parks, buildings, and green spaces (CHPAC, 2013a). These social factors and nonchemical stressors contribute to the inequities in health outcomes, burden of disease, and quality of life.

Environmental Justice

Closely related to social determinants of health is the issue of environmental justice. The EPA defines environmental justice as "the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies" (EPA, 2015i, para. 1). The key difference between social determinants and environmental justice is that the former addresses social factors that contribute to health disparities, whereas environmental justice is responsive to the inequities in the distribution of environmental hazards and exposure risks. The federal government took action to address environmental injustice though President Clinton's Executive Order 12898 in 1994 (EPA, 2015i). In communities across the United States, people of color, low income, and tribal communities bear a higher burden of exposures to environmental risks where they live (Bullard, Johnson, & Torres, 2011). Communities throughout the United States exhibit examples of environmental injustice where racial and ethnic minorities living in low-income communities are disproportionately affected by toxic exposures (Arnold, 2014; EPA, 2015j; Lougheed, 2014). Children are at particular risk in such disadvantaged communities where they have cumulative risk from exposures in homes, schools, and neighborhoods. Developmental and behavioral factors make children more vulnerable to environmental contaminants, and they have little control over where they live, what they eat, or the socioeconomic factors of their lives. Poor and minority children, who are more likely to live in neighborhoods with incinerators, industrial plants, toxic waste sites, and poor quality housing, show higher rates of asthma, learning disabilities, and EBLLs than do nonminority children and those who come from more affluent families (Leffers et al., 2016). A variety of factors contribute to environmental health disparities; those living in affected areas experience challenges related to physical infrastructure, vulnerability/susceptibility, proximity to sources or environmental hazards, unique exposure pathways, multiple cumulative environmental burdens, chronic psychosocial stress, and diminished capacity to participate in decision-making (Bullard, 2005; Nweke et al., 2011). Communities are able to promote healthier environments through a multifaceted approach to community development, community organizing, and community empowerment by working with advocacy groups, networking, and educational programming (Whitehead, 2015).

Nurses who work in communities observe the impact of health disparities with those people living in poverty or of minority status bearing the greatest health burdens. Through community-based participatory research, partnering with local organizations and collaborating with community members, nurses can build relationships with community members that strengthen their voice to address the environmental risks they face. PHNs' skills in building relationships with community members, working collaboratively with community partners, and advocating for change through governmental programs make them important contributors to environmental justice work (Leffers et al., 2016).

The Partnership for Sustainable Communities is an alliance of three federal agencies, the EPA, the Department of Transportation (DOT), and HUD. Reference to this initiative is made in several places in this chapter. An important feature of this program is that by taking a broad approach across housing, transportation, and aspects of the built environment, the federal government is able to promote health and address environmental justice concerns (EPA, 2015h; Partnership for Sustainable Communities, 2015). See Displays 9–3 and 9–4 for further sources of environmental health information.

DISPLAY 9.3 ENVIRONMENTAL HEALTH REGULATORY AGENCIES

EPA

This federal agency was established in December 1970 for the purpose of standard setting, monitoring, and enforcement of environmental protection in order to work for a cleaner and healthier environment for America. The agency works to ensure that Americans are protected from risks to health in their homes, schools, and workplaces. The agency relies on the best scientific evidence to promote the development of policies to protect the environment and health and enforces federal laws to protect human health.

http://www.epa.gov/aboutepa/history/publications/print/origins.html

FDA

The Food and Drug Administration (FDA or USFDA) is an agency of the USDHHS that regulates food safety, dietary supplements, prescription and over-the-counter pharmaceuticals, cosmetics, biopharmaceuticals, blood transfusions, and tobacco products.

CPSC

The U.S. Consumer Product Safety Commission (CPSC) was created in 1972 as an agency of the U.S. government to protect the public from risks of injury or death from consumer products. Commonly reported products are cribs, toys, household chemicals, and power tools but include any commercially traded product. As an independent agency, the CPSC does not report to any other agency of the U.S. government.

http://www.cpsc.gov/about/about.html

OSHA

The Occupational Safety and Health Administration (OSHA) was created in 1970 as a regulatory federal agency of the United States to assure safe working conditions. OSHA sets and enforces standards for health and safety in work environments.

http://www.osha.gov/

DISPLAY 9.4 ENVIRONMENTAL HEALTH RESOURCES

ATSDR: Agency for Toxic Substances and Disease Registry

ATSDR is a federal public health agency of the USDHHS and division of the CDC. Using science, ATSDR serves the public to take responsive public health actions, by providing information to prevent harmful exposures and diseases.

http://www.atsdr.cdc.gov/

ANHE: Alliance of Nurses for Healthy Environments

ANHE is an organization for nurses and health care providers to promote health through knowledge, networking, and action. Their envirn.org Web site and Environmental Health textbook serve as an active learning environment for learning essential environmental health information from experts and connecting with others. Through workgroups that focus upon education, research, practice, and policy/advocacy, nurses can increase their capacity for environmental health nursing.

http://envirn.org/

CDC: Centers for Disease Control and Prevention

The overall mission of the CDC "is to collaborate to create the expertise, information, and tools that people and communities need to protect their health—through health promotion, prevention of disease, injury and disability, and preparedness for new health threats" (http://www.cdc.gov/about/organization/mission.htm). In the area of environmental health, they include topics related to air quality, air pollution, biomonitoring, children's health, climate and health, environmental health sciences, rodent control,

sun protection, and water. Additionally, they address specific risks such as asbestos, carbon monoxide, lead, mold, natural disasters, radiation, smoking and tobacco use, and wildfires.

http://www.cdc.gov/Environmental/

NLM: National Library of Medicine

The United States Library of Medicine is the worlds' largest medical library. Their Web site offers a large number of resources useful for nurses to learn about environmental health.

TOXNET is a large set of databases on environmental health, toxicology, hazardous chemicals, and toxic releases. It also includes a household products database.

TOXMAP is an environmental health e-map that allows the user to explore toxic chemical releases and hazardous waste sites from the EPA's Toxics Release Inventory (TRI) and the Superfund National Priorities List (NPL).

TOX TOWN is an interactive site that includes a variety of settings from town, to city, to farm, to port to U.S. border lands. In each setting, the user is able to view nontechnical descriptions of chemicals, how the environment affects human health, and other Internet resources on topics useful to the user. The color, graphics animation, and sounds make it an effective strategy to each adolescent, educators, and the general public about environmental exposures.

NIEHS: National Institute of Environmental Health Sciences

The NIEHS is a part of the National Institutes of Health (NIH), which is an institute of the Department of Health and Human Services (DHHS). The mission is to understand how the environment influences health. To accomplish this, NIEHS focuses upon research, global health, and research training.

http://www.niehs.nih.gov/

NIOSH: National Institute for Occupational Safety and Health

The National Institute for Occupational Safety and Health (or NIOSH) is a U.S. federal agency that is responsible for both conducting research and translating knowledge into recommendations for the prevention of work-related injury and illness. Created in 1970 in response to the Occupational Safety and Health Act, 1970, NIOSH was established to help ensure safe and healthful working conditions.

http://www.cdc.gov/NIOSH/

OSHA: Occupational Safety and Health Administration

The OSHA was created in 1970 as a regulatory federal agency of the United States to assure safe working conditions. OSHA sets and enforces standards for health and safety in work environments.

http://www.osha.gov/

Precautionary Principle

The precautionary principle states that in the absence of clear data that indicate the safety of an action, chemical, or material that poses a threat to human health, it should not be used. The origin of the precautionary principle is from Germany, and it was used as early as 1970 to restrict the impact of potentially toxic air emissions. In the United States, the adoption of this perspective that was used in Europe grew during the 1990s and culminated in 1998, when an interdisciplinary team met in Wisconsin at the Wingspread Center to address the environment and human health. The *Wingspread Statement on the Precautionary Principle* is rooted in precaution, scientific uncertainly, and human rights. The Wingspread Statement posits that based upon the release and use of toxic substances, the failure of environmental regulations to adequately protect human health, and evidence that supports adverse human health effects from environmental exposures, implementation of the precautionary principle is necessary. The principle states, "When an activity raises threats of harm to human health or the environment, precautionary measures should be taken if some cause and effect relationships are not fully established scientifically. In this content the proponent of an activity, rather than the public, should bear the burden of proof" (SEHN, 2015b, para. 2).

The precautionary principle has been applied to public health and its core functions. First, the core function of *assessment* includes two essential services: (1) monitoring health status and (2) the diagnosis and investigation of health hazards in the community. Environmental health surveillance is supported by this principle. Most certainly, the role of risk assessment that is central to environmental health meets the concern for evidence to determine the safety of activities that can pose environmental threats to health. *Policy development* addresses the guidance from the precautionary principle through the essential services that inform and educate the public, mobilize the community to address health issues, and develop policies to address those issues. The precautionary principle engages scientists to analyze and develop policies in order to ensure health based upon sound evidence. The core function of *assurance* requires that policies be enforced. The principle charges that, instead of a focus upon remediation, those activities that could be harmful should not be undertaken (Chaudry, 2008). The application of the precautionary principle to public health nursing can be noted in the *Environmental Health Principles and Recommendations for Public Health Nursing*, where principle 5 states that the precautionary principle is a "fundamental tenet for all environmental health endeavors" (APHA, 2005, p. 5). Chaudry (2008) reports that the precautionary principle is relevant for public health nursing interventions that include surveillance, community organizing, and advocacy and must be incorporated into nursing practice. Stokowski (2014) emphasizes that nurses should be "environmental health stewards" (para. 1).

Specific Vulnerabilities

Various groups are at more risk during specific periods of physical development, through comorbid health issues, or from issues related to where they live, work, or attend school. Exposures for pregnant women create a number of risks to both mother and fetus and can produce lifelong or intergenerational adverse outcomes. Some of these effects include fetal loss, low birth weight infants, menstrual abnormalities, recurrent miscarriage, malformations of the reproductive system, reduced fertility, hormonal changes, intrauterine growth restriction, altered semen quality, and alterations in onset of puberty (Chalupka & Chalupka, 2010; Chan, Chalupka, & Barrett, 2015; Leffers, 2015).

Infants and children are at risk for a number of reasons related to their stage of physical development, behavioral factors, and specific environments such as neonatal intensive care units (NICUs), schools, and homes. Children's exposures begin in utero when many pollutants reach the developing fetus. Although breast-feeding is the best source of nutrition for infants, many chemicals, such as polychlorinated biphenyls (PCBs), dichlorodiphenyltrichloroethane (DDT), dioxin, and benzene, have been identified in breast milk. The stage of physical development of the respiratory, neurological, and excretory systems can all lead to increased risk of exposure and decreased ability to metabolize toxins. Childhood behaviors such as hand-to-mouth exploration, crawling and playing on or near the ground, and use of toys all contribute to specific vulnerability to hazards. Toxic materials on floors or in soil where children play and playthings (e.g., pressure-treated wood, toys, and paints) can all increase risk for childhood exposures. Exposures to lead, mercury, and PCBs increase the risk for developmental disabilities. Studies suggest that the rise in attention deficit hyperactivity disorder (ADHD), as well as antisocial and aggressive behavior diagnoses, can be attributed to the harmful effects of neurotoxic agents in the environment (Kalkbrenner, Schmidt & Penlesky, 2014; Landrigan & Goldman, 2011).

Prenatal Exposure to EDCs and Effect on Future Generations

Evidence indicates that many chronic diseases arise from complex interactions between the environment and the genes (Fig. 9–2). Epigenetics is the field of study that examines the gene–environment interaction to study the processes where genes are expressed differently as a result of environmental influences (EPA, 2015k). Endocrine disrupting chemicals (EDCs) mimic or block natural hormones in the human body and are linked to changes in genes inherited by offspring (Engel & Wolff, 2013; English, Healy, Jagais, & Sly, 2015). One example of epigenetic change was the use of DES (diethylstilbestrol) to treat women at risk of miscarriage. Female offspring of mothers who took DES showed increased rates of vaginal adenocarcinoma. This type of cancer is now linked to the estrogen taken by their mothers during pregnancy (Malahingahiah et al., 2015). In addition, a long-term follow-up study of 4,653 women who were exposed to DES in utero (comparison group of 1,927 women not exposed) found that those women exposed to DES while in utero were 1.42 to

3.77 times more likely to suffer from reproductive problems such as infertility, spontaneous abortion, preterm delivery, loss of second-trimester pregnancy, ectopic pregnancy, preeclampsia, stillbirth, gynecological conditions such as early menopause, grade 2 or higher cervical intraepithelial neoplasia, and breast cancer at 40 years of age or older (Hoover et al., 2011). Experts argue that the genetic changes that result from epigenetic processes because of developmental exposure to environmental stressors create negative effects on the health of future generations and contribute to rising rates of neurological conditions, alterations in reproductive organ development, and cancer (Grandjean et al., 2015).

Figure 9–2 Pregnant women should avoid exposure to EDCs.

CORE FUNCTIONS OF PUBLIC HEALTH

In 1988, the Institute of Medicine convened to address what they called "the disarray of public health" and developed the mission, role of government in fulfilling this mission, and specific responsibilities for level of government. This resulted in the core functions of public health and the 10 essential services. The core functions, assessment, policy development, and assurance, will be applied to the important aspects of environmental health for public health nursing. Assessment includes the investigation of health hazards, surveillance of health issues such as disease or injury, examining causes, and assessing needs. Policy development relies upon science for decision-making and educates people to create community involvement in order to develop polices. Assurance is a function that seeks innovative solutions to health issues, guarantees necessary services are provided, and provides oversight to policy implementation (Institute of Medicine, 1988, p. 19). See Chapter 3.

PHNs fulfill these functions but extend them by their strong emphasis upon education for health promotion, disease prevention, as well as advocacy by integrating nursing knowledge and practice into these functions. In addition, PHNs work collaboratively with others in the community to promote health for the people they serve. This chapter will review essential environmental health information for PHNs using the core functions as an organizational framework.

Some of the most commonly recognized areas of public health nursing practice where nurses address environmental impacts upon health are in schools, homes, and the broader community, with issues such as the built environment. School nurses have been leaders in addressing indoor air quality in schools particularly as rates of asthma in children rise (EPA, 2015cc). Many collaborate with the U.S. EPA and their *IAQ Tools for Schools* program (EPA, 2015n). More recently, in response to the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), school nurses are serving as advocates for integrated pest management (IPM) programs for pest prevention without increasing exposure to harmful toxins. PHNs have been part of the Healthy Homes Initiative (HHI). Occupational health nurses (OHNs) have served to educate, enforce safety standards, monitor health, and advocate for workers' health. At the community level, PHNs are involved with efforts to reduce pediatric obesity by participation in efforts to improve the built environment through safe walking paths, advocating for safe parks and recreational areas, and in reducing exposure to pesticides in playgrounds (Gilden, 2011).

LEVELS OF PREVENTION PYRAMID

Situation: *Healthy People 2020* Pesticides Exposures

TERTIARY PREVENTION	
Rehabilitation	**Primary Prevention**
Call Poison Control Center at 1-800-222-1222 HAZMAT teams Disaster preparedness	Health Education: Educate employers and workers about the Material Safety Data Sheets to understand hazardous chemicals Health Protection: Advocate for safe use of pesticides and prepare for emergencies
SECONDARY PREVENTION	
Early Diagnosis	**Prompt Treatment**
Recognition of early signs or pesticide poisoning. Laboratory screening for pesticide toxicity (blood or urine samples)	Poisoning signs can be seen, for example, vomiting, sweating, or pinpoint pupils. Symptoms are any functional changes in normal condition that can be described by the victim of poisoning and may include nausea, headache, weakness, dizziness, and others. National Pesticide Information Center http://npic.orst.edu/ingred/index.html
PRIMARY PREVENTION	
Health Promotion and Education	**Health Protection**
Educate community members to reduce exposures to pesticides in their homes and outdoor areas. Educate employers and workers about the Safety Data Sheets to understand hazardous chemicals.	Advocate for community level policy to restrict exposures to hazardous chemicals in pesticides in public places and use IPM for schools and playgrounds Advocate for safe use of pesticides and prepare for emergencies

Assessment

The breadth of environmental health information available exceeds the scope of this chapter. Our discussion is organized around the settings where people live, work, and go to school, the routes of exposure, the types of hazards, and the health effects of environmental toxins. In particular for nurses in the community, it is important to identify priority concerns for the locations where people spend the majority of their time (home, work, school) to better prepare health promotion and disease prevention interventions. To help the learner, we begin with some common types of exposures and the resultant adverse health effects. Later in the chapter, we will discuss the settings and common exposures there. While community assessment and epidemiology are essential skills for public health nursing, the ability to perform critical assessments for environmental health requires background in the environmental health sciences.

Sciences for Environmental Health

Environmental health sciences include environmental epidemiology, toxicology, risk assessment, and risk management. In Chapter 7, you have learned about the principles of epidemiology. Environmental epidemiology is a particular branch of epidemiology that focuses upon environmental exposures and the risks that contribute to adverse health effects such as cancer, developmental disabilities, neurological problems, reproductive health issues, or death. Environmental epidemiology seeks to understand the specific vulnerabilities of population groups, to understand how toxic exposures adversely affect health, and to contribute to public health policies that address risk and risk management (National Cancer Institute, 2015).

Toxicology is the "study of how the body processes the toxicants to which it is exposed and of the ultimate effects of these toxicants in the body" (Maxwell, 2014, p. 18). Toxicants are those substances that are harmful and made by humans or result from human activities, in contrast to toxins that are naturally produced. By studying the physical properties of chemicals, scientists are able to examine the toxicity of chemicals as manifested by enzyme inhibition, cytotoxicity, inflammation, necrosis, immune hypersensitivity or immune suppression, neoplasia, and mutagenic reactions. These processes should be familiar to nurses as they parallel the effects and adverse effects of pharmacotherapeutic chemicals. Chemicals are classified as alcohols, solvents, heavy metals, oxidants, and acids and may be found as industrial wastes, agricultural chemicals, waterborne toxicants, air pollutants, or food additives. Factors such as dose level and timing can make a difference in efficacy or toxicity of a drug; dose and timing can also affect the toxicity of chemicals. Toxicity is affected by factors such as gender, age, lifestyle, diet, genetics, and disease states. Further, exposure pathways, or the route by which a chemical enters the body, can affect toxicity, absorption, and metabolism. For example, children have less well-developed metabolic processes and are less able to detoxify chemical exposures. Likewise, older adults have reduced defense mechanisms in their lungs, skin, and other systems that make them more prone to adverse health effects (Leffers, 2015). Nurses can learn more about toxicology through the National Library of Medicine (2011) TOXNET site available at http://toxnet.nlm.nih.gov/.

It is important to understand that although health care screening does not test for most hazardous chemicals, some studies highlight the importance of biomonitoring. Biomonitoring refers to body burden of toxic chemicals or, more precisely, the "standard for assessing people's exposure to toxic substances as well as for responding to serious environmental public health problems" (CDC, 2015d, para. 1). Nurses can learn more about the CDC National Biomonitoring Program on the CDC Web site (CDC, 2015e).

Risk assessment is a process that uses scientific information by identifying and evaluating adverse events to aid in judgments about hazards in the environment. The process uses hazard identification, the dose response assessment, and exposure assessment to

characterize risk. As scientists identify health risks from epidemiology and toxicology, government agencies must determine how to regulate hazards. For example, the EPA uses risk assessments to "characterize the nature and magnitude of health risks to humans (e.g. residents, workers, recreational visitors) and ecological receptors (e.g. birds, fish, wildlife) from chemical contaminants and other stressors that may be present in the environment" (EPA, 2015d). Risk management requires that judgments be made about the significance of those risks (Frumkin, 2010; Maxwell, 2014).

Public Health Nursing Assessments

In public health nursing practice, nurses routinely complete a variety of assessments for individuals, families, groups, and communities. There are a number of assessment tools available to help guide both PHNs and the people they serve in order to assess environmental health risks.

What do *you* think?

How many chemicals do you come in contact with on a daily basis? Of particular interest to nurses is the study conducted by Physicians for Social Responsibility (PSR) and titled *Hazardous Chemicals in Health Care: Snapshot of Chemicals in Doctors and Nurses*. This study involved the testing of 20 American doctors and nurses from a variety of practice settings for six chemicals or chemical groups totaling 62 chemicals. Each participant was found to have at least 24 hazardous chemicals in their bodies. This study is significant not only to health care workers but also to their patients who are exposed to the same health care environments and chemicals (PSR, 2015). In addition, the Environmental Working Group (EWG) (2012) video, *10 Americans*, referenced in the "How safe is your home and hospital?" exercise at the end of this chapter is a compelling argument for body burden and the importance of biomonitoring. Blood draws from a random sample of 10 Americans showed that they had 287 chemicals in their bloodstream representing exposures from waste products, commonly used chemicals in the home, as well as more than 200 chemicals and pesticides that were banned more than 30 years ago (EWG, 2012).

Individual Assessments

At the individual level, individuals should complete a personal environmental health exposure assessment. Ideally, this should be part of every health visit, workplace assessment, or other health history. Though humans share some characteristics for environmental exposures, their individual risks from work, home, school, and recreation all contribute to their overall risk. The ATSDR provides continuing education credits for learning about a variety of environmental risks and how to take an exposure history. This is available at their Web site (http://www.atsdr.cdc.gov/csem/conteduc.html). In addition, they created an environmental exposure history card using the mnemonic "I PREPARE" to aid nurses and other health professionals in adding environmental health exposure questions to patient assessment. This tool that is both brief and easy to remember can be incorporated into any health assessment easily. Pocket-sized guides are available for order on the ATSDR Web site (see Table 9–3).

Table 9–3 Environmental Health Assessment “I PREPARE”

Mnemonic Cue	Examples of Questions
I Investigate potential exposures	Have you ever felt sick after coming in contact with a chemical, pesticide, or other substance? Do you have any symptoms that improve when you are away from your usual location (e.g., home or work)?
P Present work	Are you exposed to solvents, dusts, fumes, radiation, loud noise, pesticides, or other chemicals? Do you know where to find Safety Data Sheets on chemicals that you work with? Do you wear personal protective equipment? Are work clothes worn home? Do coworkers have similar health problems?
R Residence	When was your residence built? What type of heating do you have? Have you recently remodeled your home? What chemicals are stored on your property? Where does your drinking water come from?
E Environmental concerns	Are there environmental concerns in your neighborhood (i.e., air, water, soil)? What types of industries or farms are near your home? Do you live near a hazardous waste site or landfill?
P Past work	What are your past work experiences? What is the longest job held? Have you ever been in the military, worked on a farm, or done volunteer or seasonal work?
A Activities	In what type of activities and hobbies do you and your family engage in? Do you burn, solder, or melt any products? Do you garden, fish, or hunt? Do you eat what you catch or grow? Do you use pesticides? Do you engage in any alternative healing or cultural practices?
R Referrals and resources	Use these key referrals and resources: Agency for Toxic Substances and Disease Registry www.atsdr.cdc.gov Association of Occupational and Environmental Clinics www.aoec.org Environmental Protection Agency www.epa.gov Safety Data Sheets https://www.osha.gov/Publications/HazComm_QuickCard_SafetyData.html Occupational Safety and Health Administration www.osha.gov Local Health Department, Environmental Agency, Poison Control Center
E Educate	Are materials available to educate the patient? Are alternatives available to minimize the risk of exposure? Have prevention strategies been discussed? What is the plan for follow-up?

From Agency for Toxic Substances and Disease Registry. (n.d.). Environmental exposure history. Retrieved from http://www.atsdr.cdc.gov/asbestos/site-kit/docs/IPrepareCard.pdf

While completing an individual assessment, it is important to consider those exposures specific to the workplace, school, or neighborhood. Workplace exposures are often addressed by OHNs and include not only physical hazards such as injuries from machinery, burns, falls, and crushing injuries but also hazardous exposure to toxic chemicals, particulate matter in the form of dust, VOCs and aerosols, heavy metals, and other chemicals that can contribute to poor indoor air quality (EPA, 2015o). See Chapter 31.

School nurses often address children's and adults' exposures in school settings, but it is very important for PHNs to identify potential risks in order to educate parents about environmental hazards in the school setting. Similar to the workplace, many schools have issues of poor indoor air quality with the increased use of synthetics in building materials

and reduced access to outdoor air. Neighborhood exposures affect individual health, but are discussed in the community assessment section of this chapter. Specifically important to assess for hazards among school-aged children are the routes taken to school and playgrounds. See Chapter 30.

Home Assessments

PHNs generally conduct home assessments when making a visit to a client's home for case finding, follow-up, screening, or other public health services. Home assessments often involve looking for safety hazards in the home, but do not always include potential hazardous environmental toxic exposures. Families can be exposed to a number of serious environmental toxins in their own homes. Allison Del Bene Davis, PhD, RN created a *Home Environmental Health and Safety Assessment Tool* at the University of Maryland Environmental Health Education Center that is easy to use and addresses key exposure topics (Davis, 2007). These are grouped in areas such as the home itself, source of heat, gas appliances, source of water and lead pipes, fire safety, and carbon monoxide detector. This is available at http://envirn.org/pg/file/read/4387/home-environmental-health-amp-safety-assessment-tool. The EWG (2015) offers a *Healthy Home Checklist* available on their Web site, and the National Center for Healthy Housing (2015) published their checklist as well. In addition, PHNs must assess the home for environmental tobacco smoke, possibility of asbestos in the home, lead paint, and other hazardous materials. PHNs should ensure that the family has their home tested for radon (EPA, 2015x, 2015w). Likewise, family members should be reminded to safely dispose of their mercury thermometers and any other devices containing mercury. Cleaning products, paints, varnishes, strippers and other home remodeling materials, gardening fertilizers and pesticides, pest management insecticides and other materials, air fresheners, and presence of mold and moisture can all be sources of exposure in the home and land around the home (Butterfield, Hill, Postma, Butterfield, & Odom-Maryon, 2011). Pets can bring pesticides applied to lawns and gardens into the home, and adults and children can carry pesticides into the home on their shoes (see Chapter 29). Finally, a home assessment should address nearby environmental hazards or potential sources of hazards such as coal-fired power plants, farms, industries, brownfields (properties where pollutants, contaminants, or hazardous substances may be present), toxic waste sites, highways, and contaminated waterways (EPA, 2015f). Frequently, these hazards are visible in the neighborhood, but often, there are hidden routes of exposure from contaminated groundwater, ambient air, and contaminated soil. See Table 9–4 for Common Hazards in the Home Setting.

Table 9–4 Common Hazards in the Home Setting

Hazard	Source	Exposure Pathway	Risk Groups	Health Effects
Asbestos	Asbestos is a fiber that has been used for insulation and as a fire retardant Used in shipbuilding and other occupational exposures to metal work	Inhalation	Children of metal workers Home residents	Lung cancer (mesothelioma) and lung disease
Arsenic	Used in pressure-treated wood, was formerly used in industrial sites, can be present in soil and water	Drinking water Inhalation from indoor or outdoor air	Children playing in playgrounds with pressure-treated wood, those with contaminated water supply	High levels are lethal. Exposure can cause decreased red and white blood cells
Carbon monoxide	Colorless and odorless gas that is a by-product of combustion from home heating sources as well as automobiles housed in attached garage	Inhalation	Persons with respiratory and cardiovascular disease	Unconsciousness and death due to hypoxia
Environmental tobacco smoke	Cigarette smoking	Inhalation	Those people in area where smoking occurs in indoor space/home	Lung disease; lung cancer; cardiovascular problems
Formaldehyde	Carpeting, particle board, glues, adhesives used in home construction, or decorating Also some personal care products	Inhalation		Cancer
Lead	Paint used prior to 1978; leaded gasoline prior to ban in 1970s; ceramics, pottery, pipes, soil; some alternative medical therapies	Ingestion from dust in home or soil	Children	Nervous system
Mold	Normal growth of fungi in and outside of home Can produce VOCs	Spores travel in the air Inhalation	Those people most sensitive to molds	Respiratory symptoms
Pests	Mites, cockroaches	Inhalation, physical contact with droppings	Children and those with asthma	Exacerbation of asthma
Pesticides	Used in homes and outside lawns and gardens to protect plants from pests, home from insects	Indoor or outdoor air; inhalation Dermal absorption	Children All people exposed	Specific types of pesticides have been linked to neurological problems, others to cancer, and many as EDCs.
Radon	Naturally occurring radioactive gas	Seeps into homes through cracks in foundation of home; inhalation	Residents of home	Lung damage particularly lung cancer
Solvents such as paint thinners, varnishes, and resins (ethers)	Dry cleaning, home improvements	Inhalation Percutaneous absorption	Home residents	Neurological problems renal, liver, and reproductive effects
Personal care products	Shampoo, soaps, cosmetics	Percutaneous	Individuals using them, children, adolescents	Varied EDCs, cancer, and neurological effects
Volatile organic compounds (VOCs)	Alcohols, ketones, and esters that are present in thousands of products such as paint thinners, cleaning supplies, pesticides, building materials, office equipment, copiers, printers, glues, adhesives	Inhalation	Those exposed in indoor settings	Eye, nose, and throat irritation; headaches; kidney damage; and central nervous system disorders

Community Assessments

A comprehensive community health assessment considers environmental factors in a number of ways. In Chapter 15 of this book, community health assessment is introduced with a focus on aspects of the community that promote health or provide risks to health.

Environment refers to more than the natural environment but also includes the built environment, that is, all structures (homes, schools, workplaces, and business areas), roadways, and parks or recreational areas. It includes waste disposal areas and changes in land use for agriculture and other purposes. The impact of the built environment includes both indoor and outdoor physical environments, which in turn affect social environments where people live, work, and engage with others (Lopez, 2012).

Community assessment is central to public health nursing practice and to the core functions of public health. For environmental health, it is imperative that nurses incorporate key assessment data into the overall assessment in order to identify community risks from environmental sources. Typically, a *windshield* or walking survey is very useful for observation of environmental hazards (see Chapter 15). By incorporating knowledge of likely hazards in the community, the PHNs can identify many possible toxins simply by observation while traveling in the community. Various tools have been developed to assist nurses in their work. Though most community assessment tools address environment, it is important that PHNs also consider specific threats for areas more broadly assessed. For air quality, nurses should look for visible sources of air pollution from smokestacks, identify exhaust from various vehicles, and learn of significant industries, power sources, and incinerators in the community. To better understand water quality, PHNs must identify the source of drinking water as public or private, understand water treatment and quality, recognize evidence of pollution and whether there are fish alerts for local waterways, examine stagnant water and possible vectors, and identify issues related to sewer function and possible overflow and contamination as well as likelihood of floods and other water emergencies. Land use is another area for possible exposures. Nurses must assess not only the current land use but also how the land was formerly used. Superfund refers to funding made possible by the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 to address those contaminated areas of the United States that needed to be remediated; the EPA administers the funding. Well-known examples are Love Canal in New York State and Times Beach, Missouri. Nurses must be aware of such sites in their communities that are listed on the National Priorities List and can be located by searching on the EPA Web site (EPA, 2015ee). Brownfield sites refer to real "property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant" (EPA, 2015g, para. 2). These sites may remain undeveloped in communities but can also be redeveloped for public or private use. Playgrounds and schools that have been built upon former brownfield sites alarm community residents who often express concerns for the safety of their children. The EPA Brownfields Program seeks to ensure that the hazards are removed prior to redevelopment. The EPA also promotes the successful redevelopment of sites such as the redevelopment of a former petroleum storage terminal used from 1922 until 1977 into the Festival Pier in Pawtucket, RI. The former brownfield was dismantled and the land donated to the city where it sat unused and contaminated. In the spring of 2015, the Rhode Island Department of Environmental Management completed cleanup activities, removing contaminated soil and capping the entire property. Redevelopment of the area included

planting of trees to remediate the groundwater and creating recreational areas for picnics, fishing, boat ramps, and viewing area for the annual Dragon Boat Races (EPA, 2015dd). This example is not unique, but one of thousands of instances of urban and rural communities nationwide that address the risks in their community and have a voice to advocate for the citizens of their localities.

Built Environment

The built environment refers to all aspects of our human environment that are not naturally occurring and includes not only the physical structures (e.g., dams, roadways, buildings) but also the features that contribute to social cohesiveness or disruption (Fig. 9–3). For the last decade, environmental health experts have called for a shift from a focus on disease causation that can result from a lack of discipline and poor lifestyle choices, to a focus that examines how the built environment contributes to health (Jackson, 2012; Srinivasan, O'Fallon, & Dearry, 2003). Evidence suggests that many physical and mental health problems are related to the built environment, such as asthma, cardiovascular disease, lung conditions, obesity, and cancer. Efforts to conduct research that demonstrates the positive effect of well-designed communities with safe walking and biking paths, environmentally safe public transportation, public spaces to encourage social interaction, and accessible green spaces for recreation will provide evidence to help increase efforts for improving the built environment for better health. Neighborhoods must be designed to encourage social interaction such as parks with shady areas that encourage people to congregate, ponds and trees that also help our ecological environment, and safe walkways and bikeways for access (Jackson, 2012).

Figure 9–3 Neighborhoods, or the built environment, can contribute to population health or illness.

PHNs also must assess the quality of the housing stock. Buildings that were constructed prior to 1978 are likely to have lead-based paint. Homes or buildings constructed between 1930 and 1950 are likely to have asbestos in the insulation as well as in the hot water and steam pipes (U.S. Consumer Product Safety Commission, n.d.). The overall condition of the community indicates sanitation factors, safe waste disposal, and contamination sources in the community. The location of schools, playgrounds, and public transportation and access to green spaces should be part of the community assessment. Examination of the overall community environment provides community health nurses with essential information about how the residents can use the environment to maintain health or how the residents are more likely to be at risk for adverse health outcomes. See Perspectives: A Student Viewpoint of Community Health Nursing, Environmental Health.

PERSPECTIVES—A STUDENT VIEWPOINT OF COMMUNITY HEALTH NURSING, ENVIRONMENTAL HEALTH

I am a senior nursing student who works as a collegiate aide in the hospital while I

complete my nursing program. This semester I am learning about environmental health in my public health nursing course. We learned about the work of nurses to improve health care environments. I recalled a story my mother told me about when she was a nursing student and worked as a student aide years ago. She had been exposed to a cleaning product used on the floors that had been left in the hallway and overturned onto the stairway where she walked to her unit. She had a severe skin reaction to the cleaning product and had to visit employee health. This really got me thinking about all the chemicals used in the hospital where I work. I decided to see if my hospital had a Green Team and if nurses were involved with it. Once I began my quest, I found that indeed my hospital had a Green Team and was hard at work to improve purchasing in order to reduce harmful exposures and increase the use of safer products for hospital use, as well as efforts to reduce medical waste. I decided to learn more about products and looked first at the USDHHS Household Products Database http://householdproducts.nlm.nih.gov/ to learn more about the types of exposures that I and my patients might have in the hospital setting. I looked at the personal care products, the cleaners, pesticides, and maintenance products and thought how many are used regularly in the hospital. Because there were no nurses on the Green Team, I contacted the Green Team, and they invited me to come to one of their meetings. From the team members, I learned about two organizations, Practice Greenhealth (https://practicegreenhealth.org/) and Health Care Without Harm (https://noharm.org/) that both work to improve health care settings to be safer and more sustainable. As a student, I was thrilled to be part of the work and have now invited members of the unit where I work to join in as well. Though I have not decided what area of nursing might be my future professional focus, I know that I will include environmental health in my work!

Anna, senior nursing student

Sustainable Communities

Community assessments can provide evidence that a community is striving to be sustainable in practices to promote health for community members and to protect the natural environment. The President's Council in 1993 defined sustainable communities as "healthy communities where natural and historic resources are preserved, jobs are available, sprawl is contained, neighborhoods are secure, education is lifelong, transportation and health care are accessible, and all citizens have opportunities to improve the quality of their lives" (Clinton, n.d., para. 8). This definition uses examples that are often considered causes of unsustainable practices such as urban sprawl that increases automobile use, use of highways, and the likelihood of agricultural practices that increasingly use pesticides and products to produce larger yields of food (EPA, 2015j). Many communities have made a commitment to become more sustainable in their city design and practices. One example is Oakland, California where the city established a "Sustainable Oakland" program in 1997.

Oakland had suffered from poor land use planning that created many sources for toxic exposures, noted by high rates of asthma and other environmentally related health problems (Jackson, 2012). Their goal is to provide city residents opportunities to live safe, happy, and healthy lives through sustainable development. They focus upon buildings, energy, climate, housing, land use, transportation, waste, natural resources, health, safety, education, and economic prosperity. The city has been recognized as a bicycle-friendly city, a top ten city by the National Resource Defense Council, a top ten sustainable city, and recognition for solar efforts, storm management, and climate protection. Recent activities include the Energy and Climate Action Plan and the Sustainable Oakland 2013 to 2014 Report (City of Oakland, California, 2015). See Population Focus.

POPULATION-FOCUS ON SUSTAINABLE COMMUNITIES

In public health nursing, the focus on community or population is often used synonymously. In contrast to clinical experiences early in undergraduate nursing education, the community/public health nursing curriculum uses a population approach to assessment and planning (Callen et al., 2013). Most nursing theories focus upon individual or families as the focus of nursing care. Fawcett and Ellenbacker (2015) propose a conceptual model for population health and nursing practice. They define a population focus as "life span wellness and disease experiences of aggregate groups of people residing in local, state, national or international geographic regions or those population with common characteristics." (p. 290). Conceptual model elements include upstream factors, socioeconomic environment, physical environment, population factors, genetic factors, behavioral factors, physiological factors, resilience, health state, health care system factors, providers, organizations and institutions, hospitals, inpatient and outpatient clinics, community health centers, home health care agencies, payers, policies, nursing activities, population-based nursing practice processes, culturally appropriate wellness, promotion, restoration and maintenance, culturally appropriate disease prevention, population health outcomes, population-level wellness, population-level functional status, population-level life expectancy, population-level mortality, and population-level quality of life. The upstream factors look at social determinants of health; socioeconomic factors such as income, education, and employment; and physical environment factors such as atmosphere, air, pollutants, weather, housing, radiation, and the built environment. These upstream factors help nurses to understand the broad population-level factors that impact communities. Like root cause analysis, a

systems approach used by hospital staff to analyze adverse events, analysis of upstream factors helps to determine underlying problems. Current emphasis upon sustainable communities by agencies such as the EPA include indicators such as land use, walkability, access to recreational areas, crime rates, access to healthy food options, brownfield remediation, transportation, bicycle accessibility, and housing. Bridgeport, Connecticut, set goals to become Green 2020 with grant funding from three federal agencies: the EPA, DOT, and Housing and Human Development. The video available at https://www.sustainablecommunities.gov/video/bridgeport-connecticut helps us learn how sustainable communities can promote health and address population health.

Callen, B., Smith, C., Joyce, B., Lutz, J., Brown-Schott, N., & Block, D. (2013). Teaching/learning strategies for the essentials of baccalaureate nursing education for entry-level community/public health nursing. Public Health Nursing, 30(6), 537–547.

Fawcett, J. & Ellenbacker, C. H. (2015). A proposed conceptual model of nursing and population health. Nursing Outlook, 63(3), 288–298.

Climate Change

Climate issues are a great concern for health. In the community assessment, the nurse can note the presence of animal and insect vectors that can transmit disease. With climate change, there have been changes in the distribution of infection due to global warming. For example, locally transmitted malaria has been reported in Florida, Georgia, and Texas. Scientists track these changes and note that health professionals must be aware of the changing patterns of disease transmission from warming trends. In addition, there will likely be risks related to food and water quality and availability, heat stress for those most vulnerable, increased air pollution, and severe weather-related events. Vulnerable populations such as infants, children, and older adults must be protected from the impacts of climate change (U.S. Global Change Research Program, 2015). Severe weather events such as flooding, droughts, hurricanes, and tornados require emergency preparedness and disaster response from the public health sector. Specifically, PHNs must be prepared for surge events with skills such as the ability to (1) be personally prepared, (2) comprehend state and local disaster plans, (3) conduct a rapid needs assessment, (4) investigate outbreaks, (5) perform public health triages, (6) communicate risk effectively, (7) participate effectively in mass dispensing interventions, and (8) respond post event to the debriefing and public health impact of the event (Polivka et al., 2008).

Nurses are working to disseminate timely and accurate information for nursing practice through resources and collaboration with national organizations. All nurses must understand the implications of climate change upon health. The ANHE offers information about the work of Laura Anderko, PhD, RN; Stephanie Chalupka, EdD, RN, PHCNS-BC, FAAOHN; and Brenda M. Afzal, MS, RN, all nurses with public health expertise that collaborated with the Catholic Health Association (ANHE, 2015c). With funding from the U.S. Climate Action Network, nurses also developed a set of modules to address clean air

and climate available on the ANHE Web site (ANHE, 2015a). This includes an opportunity for continuing education credit based upon a workbook and three video modules. In addition, the U.S. Global Change Research Program releases the full report, *Impacts of Climate Change on Human Health in the U.S.: A Scientific Assessment,* for the public in early 2016.

Land Use

Topics that must be considered to address land use for a community health assessment include zoning regulations and enforcement, industries and their toxic releases, types of transportation with an emphasis upon sidewalks, bikeways, public transportation, recreational space including green space, what fertilizers or pesticides are applied to the fields, safe play areas for children, and information regarding a tree ordinance to promote health environments (EPA, 2015j). School locations should be examined for accessibility by foot or bicycle, surrounding area, and the use of pesticides on school fields. The community should be assessed for commercial lots, their safety and use, and vacant lots or unused property. Specific commercial businesses such as gas stations, auto repair shops, and dry cleaners are often sources of toxic exposures. If the community has agricultural areas, these must be assessed for irritation practices, use of pesticides, runoff, and land use practices. In addition, waste can be a source of environmental hazards so PHNs must assess the presence of landfills or municipal waste incinerators, medical waste incinerators, and municipal trash collection or presence of dumpsters throughout the community.

Recent evidence suggests that land use and transportation patterns and plans can influence the health of the community. The design of a city, community, or neighborhood affects physical activity, automobile dependence, ability of those of older age and those with physical disabilities to navigate the community, and opportunities for children to walk to school. Community design also highlights concerns for environmental justice when those who live in areas of low accessibility and high exposure to pollution are more likely to be of minority status or living in poverty. Researchers call for further research that will include walking as an indicator of community health; measuring physical activity levels and contributory factors; examining the public health consequences of public safety design choices; determining the types and determinants of travel to school; examining the influence of community design on risk of injury; explaining the influence of community design on emissions of overall and specific pollutants; measuring physical activity, mobility, and social integration in persons with disabilities; characterizing social equity and health outcomes in relation to community design; and examining the influence of physical setting characteristics on mental health. For example, zoning codes that require minimum requirements for parking areas per housing unit but do not require sidewalks promote dependence upon automobile travel that increases air emissions and poor air quality, possible water contamination from auto exhaust, risk of injury, or death and reduce opportunities for safe areas for physical activity (Dannenberg et al., 2003; Jackson, 2012;

Lopez, 2012).

Types of Toxic Exposures

Air

Air quality is a major variable in the health of populations. Those geographic areas that suffer poor air quality demonstrate higher rates of disease and adverse health effects. As we have discussed, climate change contributes to air pollution and adversely affects health. Ambient air, the air humans breathe, can be affected by a number of air pollutants. Air pollution is composed of a number of materials such as aerosols, criteria air pollutants (carbon monoxide, lead, ground-level ozone, nitrogen dioxide, sulfur dioxide, particulate matter), volatile organic compounds (VOCs), hydrofluorocarbons, as well as radon and other gases that contain toxins harmful to health. In response to the Clean Air Act of 1970, air quality is monitored by the EPA. The public is informed of air quality through the AQI that is often reported in media sources on a daily basis. The AQI measures the criteria air pollutants in communities to see if they exceed the national air quality standard set by the EPA. The EPA publishes a *Plain English Guide to the Clean Air Act* available on their Web site for the public to learn more about air quality (EPA, 2015u, 2015ff).

Reports from the EPA monitoring of air pollution indicate that from 1990 to 2010, the overall levels of the six major pollutants measured by the federal government (carbon monoxide, ozone, sulfur dioxide, nitrogen dioxide, lead, and particulate matter) declined by a high of 83% for lead and a low of 17% for ozone because of cleaner cars, industries, and consumer products. However, millions of people live in areas that exceeded the national ambient air quality standard (NAAQS) set by the EPA (2012b). Additionally, as discussed earlier, climate can adversely affect outdoor air quality.

The outdoor and indoor air humans breathe can be affected by a variety of factors. Ambient air, or that air that is composed of gases such as nitrogen, oxygen, argon, carbon dioxide, hydrogen, neon, helium, and other gases, is part of the atmosphere. It also contains moisture and particulate matter. The amount of hazardous matter that is contained in ambient air is the reason that the Clean Air Act of 1970 was created. In an effort to inform citizens about the air quality in their own community, the EPA created the AQI as seen in Table 9–5. The AQI is a tool to report daily air quality in communities. It is calculated for four of the six criteria air pollutants (ground-level ozone, particle pollution, carbon monoxide, and sulfur dioxide) with an emphasis upon how these affect health. On their Web site, they provide a guide for citizens to understand the importance of monitoring the ambient air, what the six criteria air pollutants are and how they affect health, and efforts to monitor air quality to provide public health advisories (EPA, 2015c). See Table 9–5: Air Quality Index.

Table 9–5 Air Quality Index

AQI Value	Level of Health Concern	Color
When AQI is in this range…	Air quality conditions are….	As symbolized by this color
0–50	Good	Green
51–100	Moderate	Yellow
101–150	Unhealthy for sensitive groups	Orange
151–200	Unhealthy	Red
201–300	Very unhealthy	Purple
301–500	Hazardous	Maroon

AIRNow. (2016). Air Quality Index (AQI)—A guide to air quality and your health. Retrieved from http://www.airnow.gov/index.cfm?action=aqi_brochure.index

Each category corresponds to a different level of health concern. The six levels of health concern and what they mean are:

- •"Good" AQI is 0–50. Air quality is considered satisfactory, and air pollution poses little or no risk.
- •"Moderate" AQI is 51–100. Air quality is acceptable; however, for some pollutants, there may be a moderate health concern for a very small number of people. For example, people who are unusually sensitive to ozone may experience respiratory symptoms.
- •"Unhealthy for sensitive groups" AQI is 101–150. Although general public is not likely to be affected at this AQI range, people with lung disease, older adults, and children are at a greater risk from exposure to ozone, whereas persons with heart and lung disease, older adults, and children are at greater risk from the presence of particles in the air.
- •"Unhealthy" AQI is 151–200. Everyone may begin to experience some adverse health effects, and members of the sensitive groups may experience more serious effects.
- •"Very unhealthy" AQI is 201–300. This would trigger a health alert signifying that everyone may experience more serious health effects.
- •"Hazardous" AQI >300. This would trigger a health warning of emergency conditions. The entire population is more likely to be affected.

Environmental Protection Agency. (2016). Air quality index (AQI) basics. Retrieved from http://www.airnow.gov/index.cfm?action=aqibasics.aqi

PHNs must understand the adverse effects of ambient air pollution in order to assess, monitor, and advocate for those most vulnerable that includes children, people with lung disease, older adults, and even healthy individuals who are active outdoors. Health effects include irritation of the respiratory system with inflammation of the cell lining. This makes the lungs more susceptible to infection. Air pollution can also exacerbate asthma and cause chronic lung disease, reduced lung function, and permanent lung damage. In addition, air pollution causes increased risk of cardiac disease, in particular acute myocardial infarctions and arrhythmias (EPA, 2015c). Indoor air quality is particularly important for home, school, and workplace assessments. During advisories when the ambient AQI is high and people are asked to remain inside, humans are exposed to those pollutants that commonly affect indoor air. Air pollution in homes occurs from exposure to heating or combustion sources such as oil, coal, kerosene or wood, radon gas, secondhand smoke from cigarettes, building materials and furniture that contains pressed wood products, carpeting and adhesives that emit VOCs, asbestos in insulation, cleaning products, paints, varnishes, and

paint removers, personal care products, and other sources used around the home such as pesticides. Mild health effects might be headaches and nausea; the more serious health effects include damage to the liver, kidneys, and central nervous system, as well as cancer. In addition, molds, dust, and known asthma triggers in the home can not only exacerbate the asthma symptoms but also cause irritation to those with heart and lung conditions. Air quality in school buildings is very important for staff, teachers, and students. More than 56 million children and adults spend up to 6 to 8 hours in elementary and secondary school each day. In particular, children are at increased risk for a variety of reasons. Young children are more likely to spend time on or near the floor where toxins are likely to settle; they use more hand-to-mouth behavior, and they take in more air per size than adults. Although exposures can be the same as in the home, those who attend or work in schools are in the same air environment for 6 to 8 hours or more where they are exposed to the toxins for long periods of time (EPA, 2015bb). Nurses who work in the school setting can access information through the EPA Web site to aid in assessments and interventions in order to improve air quality in schools. A comprehensive guide to healthier school environments is available on their Web site (EPA, 2012c). In addition, the EPA offers guidance for healthy buildings that includes information on design, construction, renovation, cleaning, and maintenance as well as efficiency improvement advice (EPA, 2015o). See Evidence-Based Practice.

EVIDENCE-BASED PRACTICE

Local and Global Issues

What Must PHNs Know About Climate Change?

The Obama Administration, the EPA, and the APHA all call for the public health community and for health care providers to play a critical role in addressing issues of health protection and climate solutions. An important role for community and PHNs is that of disaster preparedness (also see Chapter 17 for more information on this important topic). The report, Climate Change and Health: Is There a Role for the Health Care Sector?, provides important information to help nurses learn about health risks from climate change (Anderko, Chalupka & Afzal, 2012). Because climate change has increased the number of climate events globally, such as hurricanes, flooding, forest fires, and severe storms, we witness an increase in not only in the number disasters but other health impacts as well. These impacts include

poor birth outcomes, malnutrition, water quality and disease, vector-borne diseases, respiratory diseases, and psychological impacts. Certain vulnerable populations such as infants, children, and older adults are at higher risk for adverse health outcomes as well at those living in poverty. This is a global health issue for all nurses.

Polivka, Chaudry, and Crawford (2012) concur that this is an important role for nurses, in particular PHNs. To address this, they surveyed 786 practicing PHNs (with a response rate of n = 176) to identify their knowledge and attitudes regarding climate change. The majority of the sample identified air quality–related illnesses, flooding-related displacement, vector-borne diseases, and mental health conditions as health impacts of climate change, but they did not identify food and water impacts. However, the respondents did acknowledge a role for PHNs to address the health impacts of climate change for the populations they serve. The evidence indicates that all nurses and in particular PHNs across the globe must have the knowledge and skills to address health impacts of climate change in their practice.

EVIDENCE-BASED PRACTICE

Indoor Air Quality in Schools

School environments can influence child health. This has been demonstrated in research studies. For example, environmental triggers have been shown to worsen asthma symptoms in children. The Louisiana Asthma Management and Prevention Program initiated an Asthma-Friendly Schools project that addressed improvement in the school environment, along with individualized asthma action plans and school policy changes in order to improve asthma outcomes in 70 public schools. After the changes to improve indoor air quality (and reduce asthma triggers), institution of policy changes that permitted students to carry asthma medication with them, and the improved adherence to asthma action plans, researchers noted that asthma-related symptoms and problems were improved (Nuss et al., 2016).

Traffic-related air pollution has been associated with adverse health effects, including decreased cognitive development in schoolchildren attending schools in close proximity to high-traffic areas (Sunyer et al., 2015). Canadian researchers wanted to know if changes in the timing of outdoor air intake might reduce the

concentration levels of traffic-related pollutants in schools. They changed the ventilation timing so that it did not move air into schools during periods of rush hour traffic and studied it over a 2-month period in four school buildings. They noted statistically significant reductions in most pollutant concentrations with this intervention and recommended timing changes for outdoor air intake ventilation, especially for schools near high-traffic areas or major roadways (MacNeil et al., 2015).

MacNeil, M., Dobbin, N., St-Jean, M., Wallace, L., Marro, L., … Wheeler, A. J. (2015). Can changing the timing of outdoor air intake reduce indoor concentrations of traffic-related pollutants in schools? Indoor Air. doi: 10.1111/ina.12252

Water

The human body is composed of upward of 50% to 60% water. So too, water is necessary for human survival. In public health, the concern is for safe water consumption; safe lakes, rivers, and streams for recreation; and safe waterways to support animal and plant life necessary for transport of nutrients and ecology of the environment. Globally, the availability of clean water is becoming a very serious threat to human survival. Globally, 748 million people lack access to safe water, and in 2012, approximately 2.5 million did not have access to an improved sanitation facility creating threats to safe water (United Nations, 2015). Poverty is linked with lack of access to clean water and sanitation globally (Fig. 9–4). Reports identify the lack of safe drinking water as the leading cause of hunger, disease, and poverty worldwide (Global Water, 2015).

Figure 9–4 Clean water is vital to life and health.

Water in the environment is available in two forms: surface water and groundwater. Lakes, rivers, and streams are examples of surface water, as is the surface run off from rainfall. Groundwater is found in underground aquifers that run beneath the surface of the

earth. Both are sources of contamination or pollution. Drinking water is available from both surface and groundwater. Surface water sources include lakes, streams, and municipal reservoirs for water use. Underground sources include aquifers that run beneath the ground level and are reached via wells and springs. Many municipalities use reservoirs and other surface sources for their water supply, whereas in many areas, people must rely upon wells to provide their source of water. Safe drinking water is essential for human health. Public water systems provide water for community members through pipes for human consumption. More than 90% of Americans are served by public water systems. Public water systems are monitored and regulated through the EPA. These regulations require that public water suppliers protect consumers from microorganisms that are harmful to health. The EPA does not regulate private sources of water from private wells, and individual users must be responsible for monitoring their own wells. As a result, those using private wells are likely to have fecal contamination or microorganisms in their water as well as a number of toxic agents that are linked to bladder, kidney, and liver cancers (Friis, 2012). See From the Case Files I: Flint, Michigan.

From the Case Files I

Flint, Michigan

The public health of citizens in Flint, Michigan, was compromised when the city changed its water supply in April 2014 from Lake Huron water supplied by Detroit to the Flint River, in a temporary attempt to save money while waiting for a new pipeline to be built to Lake Huron. Flint was once a booming automotive manufacturing area and the site of early labor strikes and conflicts. Now, the plants are closed and jobs are scarce. Since 1980, 77% of jobs from manufacturing were lost and currently 42% of Flint children live in poverty compared to 16.2% for the state and 14.8% for the nation. It has some of the highest levels of violent crime, preterm birth/infant mortality, domestic violence, and illicit drug use in the state, as well as some of the poorest health outcomes (Hanna-Attisha, LaChance, Sadler, & Schnepp, 2016). It is also marred by the effects of largely unrestrained industrial pollution from the industries that dominated the area for 80 years, as "huge amounts of lead and other toxins were pumped into the air, water, streams, and ground" (Rosner, 2016).

After the water supply switch, residents noted concerns with the taste, odor, and color of the water in their homes. Flint's water system was old (with estimates of 10% to 80% of it with lead plumbing), and the city has struggled to maintain basic services in the face of declining tax revenues and high unemployment. By August 2015, researchers had found high levels of lead in the Flint water supply, noting that

the water was likely corroding the plumbing lines (Edwards, 2015). In October 2015, the Flint water supply was switched back to Detroit water from Lake Huron, but by then, 80 Legionnaires disease cases (and 10 deaths) were noted. Investigators are examining the possible relationship of corroding pipes and the potential growth and spread of the *Legionella* bacteria (Keuhn, 2016). In January 2016, President Obama declared federal emergency status to help resolve the water issues.

In the meantime, researchers from Flint's Hurley Children's Hospital conducted a spatial analysis of risk and pre–/post–water system change blood lead levels for over 700 Flint children tested in their facility. They found statistically significant changes in EBLL in blood collected between the months of January to September 2014, compared to blood drawn from January to September 2015. Before the water system change, 2.4% of Flint children had EBLL, but after the change, the proportion increased to 4.9%; those children living in outside Flint with no change in water source had no significant changes and low levels of lead in both samples. There were also statistically significant changes noted on demographic data, with higher proportions of African American children and greater levels of socioeconomic disadvantages. The "preexisting disparity in lead poisoning" broadened for those children living in Flint, especially for those with high levels of lead in their home water supply (Hanna-Attisha et al., 2016).

PHNs and others are concerned about the current situation, as well as the long-term consequences of lead exposure for the citizens of Flint, Michigan. Given the recent findings of the potential for multigenerational epigenetic changes in grandchildren linked to lead exposure in pregnant women, this environmental exposure has exponential potential for harm (Sen et al., 2015).

What is the role of the public health nurse in addressing this issue?

Which primary, secondary, and tertiary interventions could be applied?

What are the ethical issues involved in this case?

Can you identify issues related to environmental justice in this case?

Water can become contaminated from a number of sources, including both point and nonpoint sources. Point sources are those that can be traced to one source, such as a wastewater facility release into municipal water or discharge from an industrial site. Nonpoint sources are runoff from agricultural areas, gasoline stations, and other contaminants carried by rain and waterways. Some common water contaminants are microbial (frequently cryptosporidium and giardia), and to rid public water systems of microorganisms, disinfection processes are used. These disinfectants that are chlorine based produce disinfection by-products that can also be hazardous to health. Additionally, other inorganic (such as nitrogen derivatives, arsenic, lead, fluoride, cadmium, and mercury) and organic chemicals (commonly organophosphates, phthalates), as well as radionuclides, are frequent contaminants (EPA, 2015b, 2015h, 2015aa). More recently, there is a global concern about pharmaceutical waste contaminants in water. In a landmark study by the U.S. Geological Survey (2015a) in 1999 to 2000, chemicals such as medications for humans and animals, natural and synthetic hormones, metabolites, pesticides, insecticides, plasticizers, and fire retardants were found in 80% of the streams sampled (Health Care Without Harm, 2015b; U.S. Geological Survey, 2015b). Not only are pharmaceuticals used by humans, excreted in their urine, and discarded into locations where they can reach water supplies but also animals are fed hormones and antibiotics in animal feeding operations that also leach into water supplies (Hribar, 2010; Snyder, Westeroff, Yoon, & Sedlak, 2003). PHNs must be aware of this source of water contamination that puts vulnerable population groups such as the growing fetus, infants and children, older adults, and those with compromised immunity at great risk (Marcoux & Vogenburg, 2015). Organizations such as Health Care Without Harm seek to address the pharmaceutical waste issue through measures that address production, use, discharge, and disposal, treatment in wastewater facilities, and collection of unused medications (Health Care Without Harm, 2015b).

Finally, a risk to community water supplies occurs in the communities where hydraulic fracturing (fracking) occurs. Methane, benzene, and other chemicals have been found in the groundwater in communities where fracking takes place (McDermott-Levy, Katkins, & Sattler, 2013). This can occur either from the actual fracturing process or from the pits used to store fluid waste. See From the Case Files: Fracking.

From the Case Files II

Fracking

Scenario

Pleasantville is a small community in rural northeastern Pennsylvania where the local citizens have become concerned about their drinking water as a result of hydraulic fracturing (fracking) activities. In your work in the local community hospital, you have noted more patients with skin rashes and complaints of gastric distress. Fracking, as the hydraulic fracturing process is commonly referred to, is a process to extract natural gas from deep underground for public use. This process has the potential to contaminate air and water from chemical sources such as methane, benzene, and other hydrocarbons and pose health risks to community members as well as those workers involved in extraction operations. In 2012, the ANA passed a resolution, "Nurses' Role in Recognizing, Educating, and Advocating for Healthy Energy Choices," that states nurses must be knowledgeable about the health risks involved with fossil fuel energy. It is important not only for nurses who work in the community but also for all nurses in regions where there are fracking operations, to include appraisal of exposure risk to air or water from drilling operations into their patient assessments (McDermott-Levy, Katkins, & Sattler, 2013). Because the local community shows great trust for nurses and seeks advice from nurses in hospitals, schools, and community settings, it is important for all nurses to understand and provide education for community members about this health concern.

Questions

1. How might you learn more about hydraulic fracturing and the associated health risks?
2. Describe the role of the nurse working in communities where hydraulic fracturing occurs.
3. Read the article by McDermott-Levy et al. (2013) from the American Journal of Nursing and identify 3 implications for nursing practice.
4. How might you identify issues related to environmental justice in this scenario?

McDermott-Levy, R., Katkins, N., & Sattler, B. (2013). Fracking, the environment, and health: New energy practices may threaten public health. American Journal of Nursing, 133(6), 45–51.

Food

Food quality and safety is essential to human health. Food quality refers to the relative nutritional value, cost, and variety of food available. The CDC estimates that each year more than 3,000 people die from food-borne illness and one in six Americans become ill from food consumption (CDC, 2015a). PHNs frequently work closely with environmental sanitarians in state and local health departments who routinely monitor food establishments for their safety in order to prevent exposure to microbial agents that cause food-borne illness (CDC, 2015c). Environmental issues that affect food quality extend beyond the microbial exposures and include the availability of adequate nutritious food, chemical exposures through food additives and from agrichemicals and antibiotics, contaminated food from diseased animals, and improper food handling. Pesticides are ubiquitous in the environment and are transmitted to humans through foods (EPA, 2015b). Fresh fruits and vegetables must be thoroughly washed to remove pesticide residue. In addition, antibiotics fed to animals in animal feeding operations are transmitted through this food (EPA, 2015t).

Risks occur at all points from food production to food consumption. For example, agrichemicals such as chemical fertilizers and pesticides are applied in the production of fruits and vegetables, while hormones and antibiotics are often fed to animals in animal feeding operations. Pesticides have been found in foods, particularly in strawberries, blueberries, and apples (Chiu et al., 2015; Gilden, Huffing, & Sattler, 2010). After production, many foods are processed for market. Food additives such as dyes and flavors provide the color and often improve flavor of foods. Leavening and thickening agents improve consistency, while preservatives keep food from spoiling on the shelf. Many of these additives can be harmful to health with examples being linked to cancer and endocrine disruption. Recently, there is a concern about genetically modified foods being marketed. These concerns not only address the safety of the food for human consumption

but also raise questions about the ecological impact and sustainability. Although the U.S. Department of Agriculture sets policy for practices such as this, many organizations call for a more thorough examination of the consequences of this practice (EPA, 2015z; Whitney, Maltby, & Carr, 2004). In addition, food is often irradiated to kill microorganisms. Although many experts cite the safety of this process that can reduce the risk of microbial contamination, there can be concern about the use of radiation in any form for the workers and local community members (CDC, 2015c). After production, food is stored, transported, and prepared for sale in markets. At each phase of this food cycle, there are risks from improper food handling, refrigeration, or time in transit that affect the quality and safety of the food.

Microbial outbreaks are common from a variety of bacteria (shigella, salmonella, campylobacter, *E. coli*) and parasites (*Cryptosporidium parvum*, amoeba) (CDC, 2015c). Although the public often hears about these outbreaks through the media, they may not be as aware of the risks from chemical contaminants. The USFDA is charged with the responsibility to ensure the safety of food produced, shipped, imported, and sold in the United States. This includes the monitoring of not only microbial toxins but also chemicals such as lead and cadmium, pesticides, food additives, and packaging (EPA, 2015e; FDA, 2015b). Although the FDA operates to insure that the genetically modified foods meet the same safety standards as other foods, the technology used to modify or engineer new food varieties from plant and animal breeding techniques is expanding rapidly (FDA, 2015a).

Vulnerable Groups

PHNs must also be aware of the increased vulnerability of certain groups. For example, pregnant women are likely to transmit their exposure to chemicals, pesticides, and toxins to the unborn fetus, children are more susceptible to hazards from food because of their immature gastrointestinal systems and increased food intake per size compared to adults, and those with altered immunity due to cancer, diabetes, and other health conditions are more likely to be affected by food exposures.

In addition, the effect of climate change upon weather extremes (droughts, foods, and storms), changes in rainfall and water supply for soil, and the ecology of microbial growth will have negative impacts upon the food supply. Extreme weather events increase the likelihood of chemical contaminants and pesticide exposures from runoff that occurs with flooding. Agriculture and fisheries industries are sensitive to specific climate conditions related to changes in temperature and levels of CO_2 in the atmosphere. Globally, these changes can also affect human health. Scientists report the risks for waterborne and food-borne pathogens in drinking water, seafood, and fresh produce from climate variability and the potential for ecological changes that can affect watershed and drainage (EPA, 2015a).

Exposure to waterborne and food-borne pathogens can occur via drinking water (associated with fecal contamination), seafood (due to natural microbial hazards, toxins, or wastewater disposal), or fresh produce (irrigated or processed with contaminated water).

Weather influences the transport and dissemination of these microbial agents via rainfall and runoff and the survival and/or growth through such factors as temperature. Federal and state laws and regulatory programs protect much of the U.S. population from waterborne disease; however, if climate variability increases, current and future deficiencies in areas such as watershed protection, infrastructure, and storm drainage systems will probably increase the risk of contamination events. Knowledge about transport processes and the fate of microbial pollutants associated with rainfall and snowmelt is key to predicting risks from a change in weather variability (Cann, Thomas, Salmon, Wyn-Jones, & Kay, 2013; Smith et al., 2015).

Toxic Waste

WASTE MANAGEMENT. Individuals, families, schools, governmental agencies, health care facilities, and industries all create waste that must be managed to minimize environmental impact and to protect human health. The EPA reports that in 2012, Americans generated about 251 million tons of trash, a rate higher than all other countries. However, Americans also recycled and composted 87 million tons of these waste products. In response to efforts nationwide to reduce, reuse, and recycle, the average amount of waste per person sent to landfills has decreased during the last 50 years and the percent of municipal solid waste generated and sent to landfills decreased from a high of 89% in 1980 to <54% in 2012 (EPA, 2015r). As landfills enlarge, many municipalities have chosen to incinerate municipal waste. Waste incineration produces particulate air pollution and releases toxins into areas where they affect water and food sources.

More problematic for human health are the hazardous wastes that are produced. These wastes include solvent wastes, dioxins, and wastes from electroplating and other metal finishing operations, wastes from oil refineries, organic chemicals, pesticides, explosives, lead processing materials, and wood preservatives. Communities may be burdened with many brownfield sites, as well as those listed on the National Priorities List of hazardous sites as Superfund sites (EPA, 2015ee). Humans are exposed to these chemicals if they are aerosolized into the ambient air, leach into groundwater or wells, and reach the soil where children play or crops are produced. What is particularly dangerous for human exposure is the fact that most community members are unaware of the hazards in their communities.

TOXIC WASTE AND COMMUNITIES. Many nurses have become aware of communities affected by toxic waste through films such as *A Civil Action* and *Erin Brockovich*. Both films highlighted real community stories where community residents were exposed to hazards through the water they drank from public water systems. In the first movie, released in 1998, residents of Woburn, Massachusetts, were exposed to trichloroethylene (TCE) through contamination of the town's water supply. The hazardous chemical leached from buried storage at the site of a former tannery and affected residents of the community; it was later identified as the source of a leukemia cluster in the community. The latter film, released in 2000, depicted the true story of Erin Brockovich,

who worked for an attorney that brought suit against Pacific Gas and Electric for the contamination of the residential water supply with hexavalent chromium used to prevent rust in the machinery at the plant near Hinkley, California. Hexavalent chromium is a known carcinogen. The suit represented more than 1,000 people affected by the release of hexavalent chromium in their water (Penningroth, 2010). Residents still have concerns about residual pollution in their community (Esquivel, 2015).

Nurses should be knowledgeable about the toxic hazards in their own communities and those where the patients and families they care for reside. Through the EPA Superfund Web site (EPA, 2015ee), nurses can assist community members in learning about Superfund sites that impact their communities. Further, on the EPA Brownfields Web site, nurses and community members can learn about *Brownfields Near You* (EPA, 2015f).

Radiation

Humans are exposed to radiation in a variety of forms. Risks and forms of radiation are generally categorized as ionizing and nonionizing radiation. Ionization refers to the process where the atomic particle (ion) breaks away from the nucleus of the atom. Ionizing radiation occurs in natural forms as radon gas and cosmic radiation from the atmosphere. Radon is a leading cause of death from lung cancer. As an odorless gas, it can seep into the foundation of homes from the ground and expose home residents to the radiation effects. Nonionizing radiation refers to radiation from sources such as infrared, microwave, and radio wave radiation (EPA, 2015m, 2015o, 2015w). Nurses should be sure that community members are educated about the risks of radon and carbon monoxide. Personal radon and carbon monoxide detector kits are available at hardware and home improvement stores for use in homes, and their use can save lives as well as prevent disease exposure. Community members can access the EPA's *A Citizen's Guide to Radon: The Guide to Protecting Yourself and Your Family from Radon* from the their Web site (EPA, 2012a). Interactive maps for radon zones in the United States are also available from the EPA (2015hh).

Policy Development

Community health nurses, once informed about the risks to health through environmental exposures, participate in the other core functions of public health for environmental health nursing. Policy development is the core function that addresses the need for legislation to protect human health but also the opportunities for nurses to engage communities to address their own health and create policy specific to their needs (CDC, 2015b).

Nurses must be a catalyst for change in order to protect community members from hazards in the environment. To advocate for change, PHNs must be informed about the hazards in the community, existing legislation that protects people in the community, and governmental and nongovernmental groups in communities that can be partners in the efforts to protect health (Benton, 2012; Gilden, 2003). To advance nursing knowledge in Michigan, *The Nurse and the Environment: Tools for Action (NETFA)* program was developed to increase nurse's knowledge of environmental risks and promote advocacy for change (Ortner, 2004). High school students have participated in a curriculum designed by Stanford University faculty members focusing on upstream issues affecting population health and the need for advocacy in dealing with environmental issues (Curran, Ned, & Winkleby, 2014).

Nurses can begin their advocacy work by writing letters to their legislators to support strengthening laws as the Toxic Substances Control Act (TSCA) or the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). Recommendations to reform TSCA include roles for nurses to lobby their legislators but to also inform community members about the need for reform (Denison, 2009; Farquhar, 2014; Sattler, 2011). Additionally, letters to local newspapers and periodicals can remind community members of safe practices in the home and personal use of chemicals. Nurses can present testimony at public forums or hearings (Waddell, Audette, DeLong, & Brostoff, 2016). As knowledgeable and trusted members of the community, PHNs help to educate and empower community members; nurses in many other settings are also realizing the benefits of population-based advocacy (Benton, 2012; Christopher, Duhl, Rosati, & Sheehan, 2015; Snell, 2015; Waddell et al., 2016).

PHNs can organize public educational programs in schools and agencies in their community to inform the public about local hazards in their homes, schools, and communities and to learn about resources to help reduce their exposures (EPA, 2015y). In order to facilitate community involvement in environmental health issues, nurses can help build coalitions in the community to partner with other organizations to promote healthy communities. PHNs serve on local and national committees and boards to advocate for change. Examples of agencies where nurses play an advocacy role are the Children's Environmental Health Network, the EPA Children's Health Protection Advisory Committee, Just Green Partnership, local and country environmental groups, state nurses association environmental affairs committees, EPA Pesticide Committee, and Health Care Without Harm, to name just a few. Nurses engaged in environmental health research can

share the findings of successful environmental health nursing interventions to promote policy change (Snell, 2015).

In order for nurses to function effectively as advocates for safer environments, it is essential to be aware of important legislation for environmental health. To learn more about important legislation for environmental protection, see Display 9–5 for a list of laws enacted in the United States. Nurses can also use the *EnviRN* Web site to follow current advocacy efforts in nursing practice (ANHE, 2015b). An example where nurses participated in important advocacy work was the People's Climate March in September 2014, where many nurses marched to support action to address climate change. Nurses joined the Safer Chemicals, Safer Families Stroller Brigade in 2013, where nurses across the United States took action to promote healthier environments by calling attention to the Safe Chemicals Act (S.696) of 2013. This legislation would improve the regulation of chemical toxins that are currently regulated under the Toxic Chemicals Safety Act (TSCA) of 1976. The limitation of TSCA is that more than 60,000 of the 80,000 chemicals in use today are not tested for safety because of the fact that their safety was "grandfathered" in 1976 (ANHE, 2015a). See Display 9–5.

DISPLAY 9.5 IMPORTANT ENVIRONMENTAL PROTECTION LEGISLATION

Clean Air Act 1972

The Clean Air Act (CAA) was established in 1972 to exact controls on air quality through regulation of both stationary (industrial) sources and mobile sources. Through this act, the National Air Quality Standards were created, and the EPA was created and assumed the regulatory responsibility for monitoring these standards. Although this legislation has been amended at various times since 1970, it continues to be the major source of control for air pollution.

Occupational Safety and Health Act (OSHA) 1970

In 1970, Congress passed the Occupational and Safety Health Act to protect workers and promote workplace safety. This act served to protect workers in their place of employment from hazards to their safety and health. This act is regulated through the OSHA and is supported by the work of the NIOSH. It is designed to protect workers from exposure to toxic chemicals, heat or cold stress, and mechanical

dangers in the workplace, unsafe noise levels, or unsanitary conditions.

FIFRA 1972

Congress passed an early version of the FIFRA in 1947. Through this act, EPA regulates pesticides through the registration process of chemical manufacturing and enforcement of compliance with banned or unregistered pesticides.

Safe Drinking Water Act 1974

Congress passed the Safe Drinking Water Act (SDWA) in 1974 to protect health by ensuring that water quality of the public water supply would comply with water quality standards. This act is regulated by the EPA to oversee that state and local water supplies meet standards. This act has been amended since 1974 and threats to safe water are reviewed regularly. Primary contaminant sources include human and animal waste, pesticides, hazardous chemicals, and some naturally occurring hazards that get into the water supply.

Toxic Substances Control Act 1976

The TSCA passed in 1976 addresses the production, use, and disposal of specific chemicals, but various materials such as food, drugs, pesticides, cosmetics, and personal care products are excluded.

Clean Water Act 1977

The Clean Water Act (CWA) provides basic structure for regulating discharges of pollutants into the waters of the United States as well as regulating quality standards for surface waters. Wastewater standards are set and regulated to control hazardous contamination of water.

Comprehensive Environmental Response, Compensation, and Liability Act (Superfund) 1980

Superfund is the name given to the environmental program established to address abandoned hazardous waste sites. The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), commonly referred to as Superfund, is a program created to fund remediation of hazardous waste sites. CERCLA was created in response to the discovery of toxic waste dumps in the 1970s. By taxing the petroleum and chemical industries, the funds were provided for the cleanup of the most damaging toxic waste sites.

Emergency Planning and Community Right to Know Act 1986

This act is often referred to as “Community Right to Know.” This legislation helps

communities to ensure environmental safety from hazardous chemicals. Through state and local planning, communities establish emergency planning committees. This act enables the pubic to gain access to information to increase their knowledge of chemicals in individual locations, their uses, and how they are released into the environment.

Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations Executive Order 12898 of 1994

Executive Order 12898 focuses attention to the human and environmental health effects of actions upon minority and low-income populations to achieve environmental protection for all. This legislation was developed because of the disproportionate exposures to environmental toxins experienced by people of color, tribal populations, and low-income populations.

FIFRA Amended, 1996

FIFRA was established to provide regulation of pesticides for distribution and use in the United States. In order to register a pesticide, it is necessary to provide evidence that there will not be adverse effects upon the environment, including humans. EPA's Office of Pesticide Programs regulates the use of pesticides.

Protection of Children from Environmental Health Risks and Safety Risks Executive Order 13045 of 1997

As a result of this executive order, the EPA established the Office of Children's Health Protection to ensure that toxic exposures do not adversely affect children. Because of various physical, developmental, behavioral, and social factors, children are more vulnerable to environmental threats in the environment.

Assurance

The regulatory function for policy ensures that appropriate services are provided. This public health function demands that PHNs must incorporate environmental health principles into practice (ANA, 2015b; Polivka & Wills, 2014). For example, a nurse can educate families to reduce their risks from environmental hazards in the home, an OHN will ensure that safety regulations are followed in the work settings, or a school nurse can ensure that indoor air quality is monitored for the school setting. Assurance guarantees that policy and regulatory functions are followed through the provision of essential services. Nurses are vital to assuring that essential services are provided in the community. The following examples illustrate how community nurses fulfill the assurance function.

Home

People spend large amounts of time in their homes where environmental hazards contribute to serious adverse health effects and death. To assure that all nurses have essential information about environmental risks to health in home settings, competencies for nursing education include home assessment strategies (ANHE, 2015d; Leffers et al., 2015). Nurses who work with families and in communities participate in research programs and collaborative projects that can impact home environments. To address some of the health issues, particularly for children, the U.S. Department of Housing and Urban Development (USHUD) created the HHI to protect children and their families from health and safety hazards in their homes (Ashley, 2015; USHUD, 2015b). The program targets multiple childhood diseases and injuries in the home by using a comprehensive approach. Some of the environmental health concerns addressed by the HHI are lead, carbon monoxide, pesticides, radon, mold, home safety, and asthma. In Ohio, PHNs collaborated with other professionals (program manager, health educator, sanitarians, community outreach worker) through a Healthy Homes Program Grant to perform housing control assessments, education, and interventions in housing units. The interventions included home visits and education, and they were found to reduce asthma symptoms, schools days missed, work days missed, and the number of emergency room visits for asthma events (Polivka, Chaudry, Crawford, Bouton, & Sweet, 2011). A Healthy Homes program headed by PHNs in Baltimore, Maryland, focused upon home assessments for environmental health risks (lead, asthma triggers, carbon monoxide, pesticide use, environmental tobacco smoke, and source of heating in the home). Other components of the program were educational sessions to review home environmental health risks and a targeted hazard reduction intervention (USHUD, 2015a, 2015b). In Lowell, Massachusetts, PHNs were involved in a Healthy Homes grant to improve training and education among community and faith-based organizations to develop culturally appropriate home assessments and educational tools for a culturally diverse population in the community (USHUD, 2015a, 2015b, 2015c). See QSEN: Focus on Quality.

Severe Weather Events

A second area for nurses to assure that essential services are provided to community members is in response to severe weather events (Figs. 9–5 and 9–6). Although studies indicate that nurses are involved in disaster response, results indicate that nurses are not always prepared for their role in emergency response (Baack & Alfred, 2013; Usher et al., 2015; Yan, Turale, Stone, & Turini, 2015). In 2015, extreme weather events caused damage and destruction across the United States. During 2015, severe blizzards in the north began in January with Winter Storm Juno, followed by almost 900 confirmed tornados such as the devastation centered in Moore, Oklahoma, in March. More tornados occurred during the spring and summer, causing damage in many areas of the country. Serious flooding of the Mississippi and Missouri Rivers, among others, caused serious damage from Washington State to areas of the south in Texas and South Carolina. Extreme heat and drought contributed to wildfires that destroyed almost 10 million acres of land in California, Oregon, Washington, Idaho, Montana, Wyoming, and Texas. Serious earthquakes occurred in Nepal, Chile, and Afghanistan. Although the United States did not experience severe earthquakes in 2015, during the past decade, notable earthquakes occurred in Alaska, Arkansas, California, Colorado, Oklahoma, Oregon, and Virginia (U.S. Geological Survey, 2015a). Although none were as serious as those reported in other parts of the world, the loss of power from earthquakes and hurricanes put many people at risk from natural disasters. See Perspectives: Hurricane Katrina Stories From a Survivor and a Rescuer.

Figure 9–5 Severe weather, like tornadoes, can have a serious impact on the environment

and population health.

Figure 9–6 Severe weather, like tornadoes, can have a serious impact on the environment and population health.

PERSPECTIVES HURRICANE KATRINA STORIES FROM A SURVIVOR AND A RESCUER

I lived in New Orleans during Hurricane Katrina. It was a horrible time for me and for my young children. I called 911 and told them "I am in the attic of my house with my 4 kids. The water is touching my feet now, and none of us can swim. I have a 4-week-old baby." The person on the other end of the phone told me to put my baby in a box, and to put that box on a high beam in the attic. They couldn't promise that someone would come soon to rescue us; I wanted someone to come right away and help us get to safety. I finally realized that no one was coming. I sent my oldest son out an attic window and onto the roof. A man we didn't know finally came by in his boat. He had been searching for other people who were stranded, and he helped us get to a shelter. I was sad that our house and all of our possessions were lost, but I was so relieved that we were together and finally on safe ground.

Tisha, hurricane survivor

No amount of preparation or disaster drills can actually train you for the real thing. After Katrina hit, the power was out and the streets were flooded. I had been called in to work when we knew the storm was going to be a bad one and told that I would be there for a "few days." I had to leave my family and my home without knowing what might happen while I was gone. I work for New Orleans EMS, and we were in bad shape; underfunded and underequipped; we had no capacity for the surge that hit us. For a time, I tended to evacuees in the Super Dome. Then I shifted to assisting with the helicopter rescues of patients at a flooded hospital. After that, it was another 36 hours at the Super Dome, helping to get those evacuees on buses to take them out of the city and to safer shelter. At that point, the 911 dispatchers were completely exhausted from nonstop calls, and some of us gave them a break and took over the phones. Those calls were haunting. Most of the time, we could do nothing. One elderly woman was desperate because her husband depended on oxygen and she couldn't change the tank. Another woman cried because her baby was no longer breathing and she needed paramedics. There was no way to get help to them. A week after the flooding began, we rode the streets, trying to find people who had called 911 and whose cases were backlogged. Some of them we found and helped; others were dead. Bodies of a few of the dead were washing onto streets and freeway on-ramps. No one could rush to pick them up, because we were focusing on those still living. Some of my coworkers lost their homes and were left only with the clothes on their backs. Others lost pets, and some had to find their family members who were forced to leave the area suddenly and were unable to make contact with them. The stress from these horrible weeks took a toll, as some of our coworkers later developed various cancers and many suffered from PTSD. This experience sent many of us into private practice or out of the state, but for those of us who stayed in public service, it has reinforced our commitment to never let this happen again.

Anonymous, EMS Worker

Adapted from Sternberg, S. (2015, August 28). Battle scarred: The personal stories of the Katrina rescuers. Retrieved from http://www.usnews.com/news/articles/2015/08/28/battle-scarred-the-personal-stories-of-the-katrina-rescuers

While Chapter 17 discusses disasters and the role for public health, there are some specific issues related to environmental risks that occur after severe weather events and are important for community health nurses. These include power outages, safe water and food supply, wastewater, mold, and toxic exposures. For example, when there is a power outage, many families depend upon generators to supply electricity. These can be a source of carbon monoxide poisoning if not effectively functioning or not well ventilated. During cold weather, families may use wood or kerosene for heat that can pose danger of fire, explosion, and asphyxiation from carbon monoxide, but kerosene heaters can also emit other pollutants including carbon dioxide, nitrogen dioxide, and sulfur dioxide. In

particular, pregnant women, asthmatics, individuals with cardiovascular disease, older adults, and young children are at particular risk from these toxic emissions. Nurses must inform community members of safety in the home when using alternate sources of heat or power (Wisconsin Department of Health Services, 2015). If a home is without power, there is a risk for food storage and safety. If the home has a well and water pump, there may not be access to water during the power outage. Community members should be informed of issues related to safe storage of food and the need to dispose of improperly refrigerated foods.

Homes that have septic systems may find that they have overflowed if there is any flooding from a severe storm. It is important to understand when it is safe to return to well or septic system use after ground-level flooding. Floods also pose a problem to residents who have water enter their homes. Standing water can cause mold and mildew, possibly harm home furnaces, pose a risk of fire, and release toxins into the water and air. Small children and older adults are at more risk of environmental exposures during and after a natural disaster and the public health nurse must address not only emergency planning but also safe remediation strategies to avoid toxic exposures among community members (EPA, 2015s).

Food Safety in the Community

Another area where nurses can assure health and safety for environmental health risks is for food safety. Although you learned about health risks from food, it is necessary to be able to advise individuals and families about this important information. PHNs participate in efforts to ensure food safety through the prevention of food-borne illness. A great resource for families and community members is the Partnership for Food Safety Education (2015) that promotes safe food handling and education for both children and adults. However, as discussed earlier, food can also be a source of hazardous chemicals both from pesticides and fertilizers used and also from other chemicals found in soil, packaging, and cookware (EPA, 2015t). Nurses can be a resource to ensure that community members learn about the specific risks, particularly in their own localities, and identify ways to decrease their risk. The EPA produces a booklet entitled *Citizen's Guide to Pesticides and Pesticide Safety* that is available from their Web site (EPA, 2015t). The booklet is written to help nonprofessionals understand pesticides. Although it is not directly focused upon pesticides in food, it helps community members understand the hazards present in pesticides and strategies to reduce their use and to ensure safety when using pesticides. The Pesticide Action Network (2011) uses data from the USDA Pesticide Program to identify commonly applied pesticides for many foods. Consumers can consult their Web site to be informed of foods that pose the most serious threats to health, particularly for the most vulnerable groups (Fig. 9–7).

Figure 9–7 Fish market: How contaminated is the fish you eat? (Reprinted with permission from Institute of Medicine. (2003). The future of the public's health in the 21st century. Washington, DC: National Academies Press. Adapted from Dahlgren, G. & Whitehead, M. (1991). Policies and strategies to promote social equity in health. Stockholm (Mimeo): Institute for Future Studies.)

One specific area where nurses have been involved in education, advocacy, and policy efforts is with fish advisories. The EPA National listing of Fish Advisories reports almost 5,000 fish advisories representing 42% of the nation's lake acreage and 36% of the nation's total river miles (EPA, 2015a). Advisories warn consumers of contaminants (mercury, PCBs, chlordane, dioxins, and DDT). These contaminants persist in the environment, particularly in river and lake sediments where fish consume them from bottom-feeding organisms. Bioaccumulation refers to the process where toxins accumulate in greater concentration in an organism than the rate of elimination. Toxins can accumulate from direct exposure or from eating contaminated food products. Through biomagnifications, the toxins present at lower levels of the food chain are in greater concentration in those species further up the chain. Therefore, humans who eat contaminated fish are exposed to toxins at all levels across the food chain. Public health nurse and Georgetown University faculty member, Dr. Laura Anderko, has been involved with fish advisories for many years (2015). In collaboration with the EPA, she prepared the educational set of four modules on this topic: *Fish Facts for Health Professionals: Methylmercury Exposure, Fish Consumption, and Health Risks/Benefits*. This is available through the Web site (www.fish-facts.org).

Nurses who work with community agencies can use collaborative strategies to ensure

that the population served is protected from environmental hazards, learns how to advocate for a safer community, and identifies appropriate sources of information. The Right to Know legislation and use of Safety Data Sheets provide some assurance and can be helpful in teaching our clients how to better protect themselves as well. PHNs can direct community members to consult the EPA Web site to learn about their right to know. To locate local information, nurses and community members can visit the EPA Web site at www.epa.gov. One link connects to "your own community" and leads to *MyEnvironment* where consumers can learn more about the risks for one's own community, how to address specific pollution, and ensure safe drinking water. Nurses can teach their community partners how to access a consumer confidence report. Every public water system is required to provide information to consumers that identify any detected contaminants or factors that affect the water quality for those customers that they serve. Common contamination is microbial or from chemicals in fertilizers, and other contaminants, such as lead and arsenic, may also be present. This responsibility to provide the public with information about public water systems is mandated through the SDWA enacted in 1974 that established standards for safe drinking water. Individuals can access information from their own water supplier or can visit the EPA Web site (EPA, 2015q). In addition, PHNs can access for themselves and their community partners the EPA resource, *Water on Tap: What you Need to Know,* that is available in English, Chinese, and Spanish through the EPA Web site. This guide discusses not only the safety of public water systems but what individuals using well water can do to ensure the safety of their drinking water. Ways to conserve water use are addressed, as well as the various types of treatment devices such as filters that can be used at the point of entry or point of use for the water in one's home (EPA, 2015gg).

Global Environmental Health

Nurses must engage in strategies to protect human health in their communities through the core functions of public health: assessment, policy development, and assurance. To effectively do this, nurses must think globally in order to be effective locally. This means that considering global conditions of climate change and the effect upon human health is an important beginning (NIEHS, 2015b). However, broadening our perspectives to consider foods imported from countries around the world, toys made in other countries and used in the United States, and the manufacture of products in locations where the regulations for safety are not as stringent (or in some cases more stringent) as in the United States assists nurses in efforts to address environmental health knowledge and advocacy. Nurses who endorse "green nursing" by promoting more ecological and environmentally safe practices in their workplace are making an impact upon global environmental health. The United Nations Millennium Development Goals (MDGs) for 2015 (that are being updated as the Sustainability Development Goals) addressed a number of health issues that relate to the environment. See Chapter 16 on Global Health. McDermott-Levy, Leffers, and Huffling (2014) examine each of the eight MDGs from an environmental health perspective in order to illustrate the broad range of global environmental health issues. Some of the issues included concerns about nutrition, pesticide use, effects of climate change on agriculture, and impact of sanitation upon nutrition in relation to MDG 1: Eradicate extreme poverty and hunger. MDG 2: Achieving universal primary education is threatened by the fact that in most low-income countries, women, particularly young girls, spend long hours fetching water for home use. The lack of safe drinking water is a serious global health concern. Likewise, household energy use is a concern to women who bear the responsibility for food preparation and shelter for their children. This threatens the goals of gender equality and maternal health. With MDG 6: Combating HIV/AIDS, malaria, and other diseases, there are environmental health implications from the effects of climate change and vector-borne disease, as well as the use of pesticides for these vectors.

Although it is now illegal in most countries to dump waste into the ocean or to ship waste to less developed countries that have less stringent laws to protect their citizens from toxins, large quantities of toxic industrial waste, medical waste, toxic ash from incinerators, as well as the growing issue of e-waste from computers and other electronic products have found their way to ocean waters and poorer countries. In order to fully promote the health of populations, nurses must take personal action to reduce their use of products (particularly those with toxic chemicals), reuse as much as possible, and recycle (in safe processes) to decrease their personal environmental footprint. Nurses must also incorporate the environmental health knowledge and skills mandated by the ANA *Scope and Standards of Nursing Practice* into their nursing practice (ANA, 2015b).

SUMMARY

Environmental health is a discipline encompassing all of the elements of the environment that influence the health and well-being of its inhabitants. PHNs need to monitor and determine causal links between people and their environment with a concern as to how they may promote the health and well-being of both. An ecologic perspective of environmental health is essential for nurses to understand the human–environment relationship and how the health of one affects the health of the other. Prevention and strategic or long-range concerns are also important in considering environmental health, because what is done today may affect the health of future generations. Examples such as DES use in pregnancy and the effects on the children of those women are cautionary tales of the unintended consequences of toxic substances, even when used for beneficial purposes. The precautionary principle reminds us that absence of proof that an action, chemical, or material poses a threat to individuals and the environment is not proof of its safety.

Use of an "upstream" approach challenges the public health nurse to understand the social determinants of health and address system level factors that are at the root of health problems rather than looking solely at healthy lifestyle issues. The disproportionate impact of environmental hazards on low-income populations and people of color argue for the use of environmental justice to remedy those situations. The built environment can both negatively and positively influence the health of a community. Efforts made to promote sustainability, community cohesiveness, and healthy lifestyles can and are being successfully implemented across the county.

Both public and private sectors are involved in regulating, monitoring, and preventing environmental health problems. Health professionals, especially PHNs, and the general public should be aware of reliable sources of information so that best evidence can inform decisions. Utilizing the core functions for public health, the public health nurse recognizes the key role of assessment, assurance, and policy development to influence change in the health of individuals, families, communities, and the environment. The public health nurse should be a leader of the team of health professionals who promote and protect the reciprocal relationship between the environment and the public's health.

ACTIVITIES TO PROMOTE CRITICAL THINKING

Understanding Body Burden by Examining the Risks to Health From Personal Care Products

Many people lack awareness of their exposures to harmful chemicals in the environment. Children and adolescents are most vulnerable to exposures from personal care products because of their developmental stage. To gain a better understanding of common risks to health from commonly used personal care products, you will use the resources of the EWG.

1. Begin by watching the EWG video *10 Americans*. There is an 8-minute version available on YouTube. Then consider one specific area where humans are exposed to toxic chemicals: personal care products. Consider more than just cosmetics, and consider also soaps, toothpaste, and other products used several times a day for personal care.
2. Visit the EWG Web site http://www.ewg.org/. Select their *Skin Deep* database of commonly used products. Search for those you use frequently and identify the risks posed to your personal health.
3. Next, select a population group in the community that might be at risk (e.g., neonates, adolescents, elderly) and consider how you might educate that group about their body burden or exposures.

Environmental Protection Agency Activity

As a nursing student, it is important for you to know about common community hazards in order to educate the community members. Visit the EPA *My Environment* site and enter your home zip code or that of the community where you work. The link for this Web site is http://www.epa.gov/myenvironment/. There you will find headings for *MyAir*, *MyWater*, *MyHealth*, *MyEnergy*, *MyLand*, *MyEnvironmentReports*, and *MyCommunity*.

1. Look through these headings to identify the hazards in your community. What is the air quality? Are there particular industries, power plants, or high areas for auto emissions that affect health? What about water quality? How might you advise community members to learn about their water quality? Are there significant toxic waste sites? What types of exposures are there in the community?
2. Can you identify possible risks from climate change and severe weather events? What might be ways to ensure emergency preparedness for those most at risk?
3. Using the framework of this chapter and the core public health functions, select a strategy for each area: assessment, policy development, and assurance that is most appropriate for your community.

Air Quality Activity

Have you heard alerts on TV or radio, or seen Internet reports about unhealthy air quality? Do you know what toxic substances are in your community's air? How do these impact you and sensitive groups such as children and older adults? You can find out by examining the EPA's My Environment and AirNow Web sites (http://www.airnow.gov/). Other helpful sites may be found through the CDC, the EPA, and local air resources boards or agencies. Go on a computer scavenger hunt and see what you can find:

- Look around your city or neighborhood. What are the most common environmental hazards? Visit the EPA "My Environment" site. Look at the AQI and air facilities on the map on this site. Be sure to read about radon too. How might these impact the air you breathe? Find the AirNow Web site and enter your zip code. For your city or area, which three companies have the highest amounts of emissions? Are there any VOCs, metals, or polycyclic aromatic hydrocarbons listed for the top company?
- If you were an OHN, what safety measures would you want in place to respond to accidental exposures to these chemicals? What could you do for emergency first aid until assistance arrives?
- If you were a school nurse, what would be your concerns for the children's exposures to air pollution?
- If you were a home care nurse, what would be your concerns for the elderly patients you care for?

ACTIVITY TO PROMOTE CRITICAL THINKING II

How Safe Is Your Home and Hospital? Personal Care and Cleaning Products Activity

Most nursing students can relate to the number of chemicals that are used in hospital settings. Begin this exercise by visiting the ToxTown site http://toxtown.nlm.nih.gov/flash/city/flash.php and click on the hospital you see in the city view. Consider the types of exposures there. As you read in our student perspective from Anna, there are many chemicals used in homes and hospitals that carry environmental exposure risks. Many of these are personal care products or cleaning products. To gain a better understanding of common risks to health from commonly used personal care products you will use resources from the EWG and the DHHS Household Products Database.

1. Begin by watching the EWG (2012) video 10 Americans. There is a version available on YouTube at this link https://www.youtube.com/watch?v=0-kc3AIM_LU. Then consider one specific area where humans are exposed to toxic chemicals: personal care products. This includes not only cosmetics but also soaps, toothpaste, and other products used several times a day for personal care.
2. Visit the EWG Web site http://www.ewg.org/. Select their Skin Deep database of commonly used products. Search for those you use frequently and identify the risks posed to your personal health and that of your patients.
3. Visit the DHHS Web site for the Household Products Database http://householdproducts.nlm.nih.gov/index.htm and examine other common products.
4. Finally consider a population group in the community that might be at risk when hospitalized (neonates, adolescents, older adults) and consider how you might educate that group about their exposures.

ACTIVITY TO PROMOTE CRITICAL THINKING III

Environmental Protection Agency Activity

As a nursing student, it is important for you to know about common community hazards in order to educate community members. Visit the EPA's MyEnvironment Web site and enter you home zip code or that of the community where you work. The link for this site is http://www3.epa.gov/enviro/myenviro/. There you will find headings for MyMaps, MyAir, MyWater, MyEnergy, MyHealth, MyClimate, MyLand, MyEnvironmentReports, and MyCommunity.

1. Look through these headings to identify the hazards in your community. What is the air quality? Are there particular industries, power plants, or high areas for auto emissions that affect health? What about water quality? Are there significant toxic waste sites? What types of exposures are there in the community?
2. Can you identify possible risks from climate change and severe weather events? What might be ways to assure emergency preparedness for those most at risk?
3. Using the framework for this chapter, the core public health functions, select a strategy that is most appropriate for your community for each area: assessment, policy development, and assurance.

COMMUNITY HEALTH NURSING TOOLBOX

10 CHAPTER

Communication and Collaboration in the 21st Century: Informatics and Health Technology in Community Health Nursing

"Think like a wise man but communicate in the language of the people."
—William Butler Yeats (1865–1939)

"Technology gives us power, but it does not and cannot tell us how to use that power. Thanks to technology, we can instantly communicate across the world, but it still doesn't help us know what to say."
—Jonathan Sacks (1948–), British Rabbi and Philosopher

LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

- Identify the seven basic parts of the communication process.
- Describe five barriers to effective communication in community health nursing and how to deal with them.
- Summarize the key issues related to health literacy.
- Explain the stages of group process.
- Describe five characteristics of collaboration in community health.
- Discuss the value of contracting to both clients and public health nurses.
- Design a contract useful in community health nursing.
- Debate the pros and the cons of using electronic health records (EHRs).
- Describe the unique features of big data and areas of public health where it is most helpful.
- Explain the three main trends in mHealth and give a public health-related example of each.
- Identify a current example of the combination of data and GIS applications in public health.

Communication, collaboration, and contracting are primary tools for community health nurses. They form the basis for effective relationships that contribute both to the prevention of illness and to the protection and promotion of population health. Because of its relationship to health promotion and disease prevention and management, health literacy is a concept that is important to health care providers, especially those in public settings. For the nurse accustomed to communicating one-on-one with clients, communicating with community groups, along with a wide range of professionals and lay community workers, requires new skills. Group work is a key component of community health nursing, and effective application of group process skills will facilitate work with both task and support groups. Unlike ordinary social relationships, collaborative relationships are based on a team approach with shared responsibilities and mutual participation in establishing and carrying out goals. Effective professional collaboration can improve health outcomes and foster organizational commitment. The concept of contracting can further assist the collaborative process. Clients and health care professionals enter into a working agreement, or contract, tailored to address specific client needs.

Leveraging the power of health technology is one of the ways we can improve health for vulnerable and minority communities. The implementation and evaluation of technology innovations will help to address public health concerns. Health technology serves as a powerful equalizer for improving health education and access to care among vulnerable and minority populations by reaching people where they are and in whatever environment they live. This chapter examines these tools and discusses their integration into community health nursing practice.

COMMUNICATION IN COMMUNITY HEALTH NURSING

The importance of communication is often taken for granted because people spend most of their waking hours communicating through speaking, listening, reading, or writing. Yet, the quality of people's communication has far-reaching effects. In nursing, lack of effective communication can lead to misunderstanding, poor performance, interpersonal conflict, ineffective program development, medical mistakes, and many other undesirable outcomes. Therefore, to be successful nurses, we must use both our clinical skills and good communication skills (Arnold & Boggs, 2016).

Effective communication is vital to all areas of nursing but is considered to be a fundamental core competency needed in public health nursing practice. The Quad Council PHN Competencies (Swider, Krothe, Reyes, & Cravetz, 2013) includes communication skills as one of the eight essential core competencies. Communicating effectively, soliciting input from others, and listening to others in a nonjudgmental way are a few of the necessary skills highlighted in that document. Nurses working in community health must be skilled in effective communication to be able to maintain relationships with individual clients, family members and aggregate populations, members of the health care team, and community partners. Good communication skills will enable public health nurses to provide quality health care and health education; advocate effectively for clients, families, and populations; initiate public health policy; and implement programs designed to meet the needs of clients (Vertino, 2014). Ineffective communication is one of the major causes of preventable adverse events in acute care settings (James, 2013). In community health nursing, effective individual and group communication can improve patient outcomes, enhance professional collaboration, and foster organizational commitment.

Communication provides a two-way flow of information that nourishes professional–client and professional–professional relationships. It also establishes the base of information on which health planning decisions are made and programs developed. For communication to take place, clients and professionals need to send and receive messages. As participants in the communication process, community health nurses play both roles: sender and receiver. The nurse working with a group of abused women must learn to "read" the messages these women send. Similarly, as a member of a health planning team, the nurse must be able to elicit ideas as well as contribute to the planning process by speaking and acting in ways that promote information sharing.

Communication serves several functions in community health nursing. It provides information for decision making at all levels of community health. From the choice of goals for a small client support group to health policy affecting a population at risk, decisions are enhanced through effective communication. Communication functions as a motivator by clarifying information, so that consensus is reached and the people involved can move

forward with commitment to shared goals. Effective communication facilitates the expression of feelings and promotes closer working relationships. It also controls behavior by providing clear expectations and boundaries for group member actions.

The Communication Process

Communication in its simplest form is the sending and receiving of a message, a process by which one assigns and conveys meaning in an attempt to create shared understanding. This process incorporates the conventional aspects of communication—sender, receiver, message, channel, feedback, the encoding, and the decoding of the messages (Tonn, 2012). This seven-step process is described in Figure 10–1.

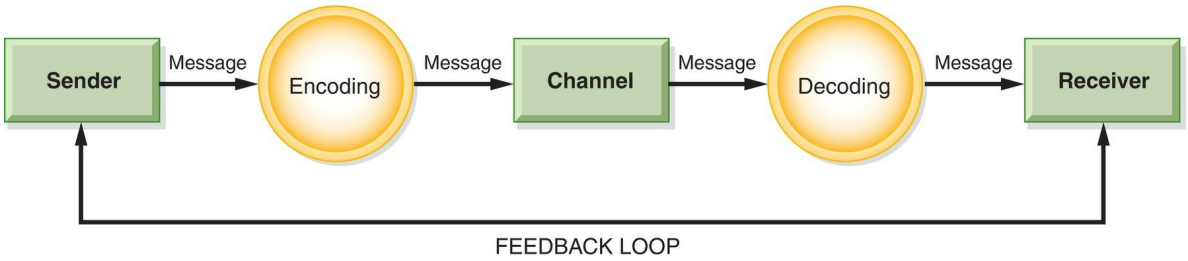

FIGURE 10–1 The communication process (the feedback loop).

It is often suggested that the message is the most important aspect of communication because without the message, there can be no communication. However, for effective communication to occur, we must take a closer look at the seven steps of the communication process. First, the sender must effectively encode the message for the receiver. To transmit the message, the sender must decide which specific signals or codes, such as language, words, gestures, and body language, to use. The degree of the sender's success in encoding a message is influenced by the sender's communication skills, knowledge about the topic, attitudes, and feelings related to the message.

The channel is the medium through which the sender conveys the message. The channel may be a written, spoken, or nonverbal expression, and communication channels may be formal, such as a written grant proposal, or informal, such as a face-to-face verbal statement. Other examples include e-mail messages, a written report to provide information, a written care plan, or a facial expression indicating confusion. Once the sender has conveyed a message through a channel, the receiver must translate (decode) the message into an understandable form. The receiver's ability to decode the message is influenced by knowledge of the topic, skills in reading and listening, and attitudes, beliefs, and sociocultural values.

Although communication has been exchanged, this does not mean that the exchange is meaningful. All communication involves perception and expectation. We interpret messages based upon prior experiences with either the sender/receiver or with others who have influenced our lives. The final part of the communication process, the feedback loop, allows both the sender and the receiver to check on the success of the transference of meaning and to renegotiate the message to allow for clarity and better understanding. Effective communication is seen only when the message sent is received and interpreted by

the receiver as intended (Borkowski, 2016).

Communication Barriers and Strategies to Overcome Them

Community health nurses should be aware of the barriers that block effective communication. Display 10–1 lists barriers that nurses working in community health may encounter.

DISPLAY 10.1 BARRIERS TO EFFECTIVE COMMUNICATION IN COMMUNITY HEALTH NURSING

Selective Perception

Receivers in the communication process interpret a message through their own perceptions, which are influenced by their own experience, interests, values, motivations, and expectations. They project this perceptual screen onto the communication process as they decode a message, leading to possible distortion or misinterpretation of the meaning from the sender's original intent. Nurses can overcome this barrier by using the feedback loop to ask clients or others involved to voice their understanding of the message. This provides an opportunity for clarification and correction of misunderstandings, which is an essential step in the communication process and helps to prevent miscommunication that can lead to mistakes.

Filtering

Filtering is described as manipulation of information by the sender in order to make it seem more favorable to the receiver. To gain favor with receivers, senders sometimes say what they believe receivers want to hear rather than the whole truth (Tuhovsky, 2015).

Clients sometimes use filtering during a needs assessment process, giving only partial or distorted information because they think this is what health professionals want to hear. Filtering can also affect PHNs. Cole (1990), in a classic work, notes that we have "filters" through which we view others—often influenced by culture, ethnicity, and socioeconomic class or even gender—and these can lead to miscommunication. Cole's premise is that people from different backgrounds actually view the world differently, thus confounding communication and leading to prejudice and stereotyping. PHNs should consider the communication style and preferences of the

people with whom they come in contact and avoid stereotyping (Tuhovsky, 2015). Another intent of filtering is to slant information. Prepared minutes from a meeting or a department's quarterly report can emphasize some points and omit or de-emphasize others, giving (sometimes unintentionally) false impressions that influence decision making.

Emotional Influence

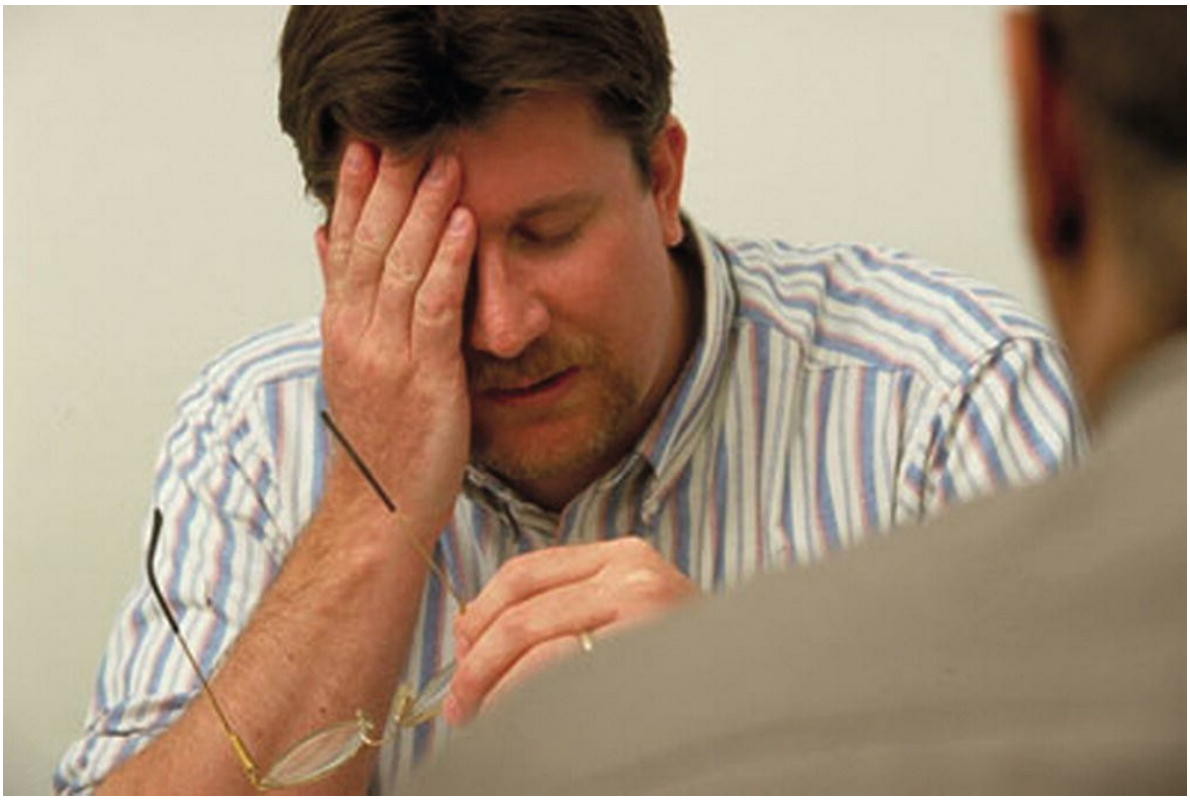
How a person feels at the time a message is sent or received influences the meaning. Senders can distort messages, and receivers can interpret messages incorrectly when emotions cloud their perception. Emotions can interfere with rational and objective reasoning, thus blocking communication. Nurses need to be aware of their own emotions as they send messages. To avoid misunderstandings, they also need to ascertain the emotional status of clients or health professionals with whom they are communicating. For example, it is important for PHNs to remain calm and unruffled when dealing with families in crisis. Family communication may be angry, blaming, and confrontational because of a child's serious health crisis, for instance. A PHN who responds with frustration, defensiveness, or anger only heightens the family's emotional reactions. A calm, firm, reassuring presence can go far in diffusing the situation and promoting clearer and more constructive communication. It is always helpful to be aware of the receiver's emotional status and help the receiver to identify it. You may say, "I sense that you are feeling upset about Joey's diagnosis. Are there any questions I can answer for you? How can I be helpful?"

Language Barriers

People interpret the meaning of words differently, depending on many variables, such as age, education, cultural background, and primary spoken language. An adolescent understands the terms dope and bad to mean that something is good or desirable, whereas an 80-year-old woman might understand the terms to mean drugs or marijuana and unacceptable or unpleasant, respectively. In the community health, nurses work with a wide range of clients and professionals whose disparate ages, education levels, and cultural backgrounds lead to different communication patterns.

Language of Nursing

The context of health care provides nurses with a unique vocabulary that may not be understood by clients, family, and community members. The use of scientific terminology or jargon by some health professionals can be confusing. For example, the terms critical pathways or case management approach may have little meaning to a community group. PHNs should be able to adjust their communication styles as appropriate; for instance, communication techniques would be different when educating a new mother on proper breast-feeding techniques than when discussing community health needs with the director of a community health department



(Tuhovsky, 2015).

Overcoming barriers to effective communication requires development of sound communication skills that include sending skills, receiving skills, and interpersonal skills.

Sending Skills

Sending skills enable nurses to transmit messages effectively. Through these skills, nurses convey information to clients and other persons. Two important considerations influence the clarity and effectiveness of message sending. First, the extent of the nurse's self-awareness affects communication. Does the nurse feel anxious, angry, tired, impatient, or concerned? Does the nurse find certain individuals irritating or offensive? What motives and interests prompt the communication? Second, the nurse's awareness of the receiver influences the sending of messages. What do clients or the professionals with whom the nurse is interacting want or need? Is the message suited to their cultural background and level of understanding? Does the message have significance for them? How are receivers responding as the nurse sends the message?

Two main channels are used to send messages: nonverbal and verbal. Nonverbal messages, those conveyed without words, constitute a large portion of the messages transmitted in normal communication. Nonverbal statements may enhance or discredit what someone says verbally and, thus, are even more important than the spoken words (Phutela, 2015). People send messages nonverbally in many ways. Nonverbal messages can be sent through personal appearance, dress, posture, facial expression, gestures, and physical distance between sender and receiver. Body language often speaks louder than words. Facial expressions can convey acceptance or rejection, interest or boredom, anger or patience, and fear or confidence. Gestures and bodily movements, such as clenched hands, crossed arms, tapping fingers, hands on hips, or a turned shoulder, can negatively affect communication. Eye contact or lack of it, tone of voice, and use of silence also send important nonverbal messages. A nurse's awareness that nonverbal messages may have different cultural meanings or social interpretations can save considerable misunderstanding.

Verbal messages are communicated ideas, attitudes, and feelings transmitted by speaking or writing. Effective sending skills depend on asking for feedback to make certain that receivers have understood the verbal message's intent. Nurses cannot always assume clients or other professionals completely understand the exact intent of their words. Communication is more effective if speakers avoid using jargon that is unfamiliar to clients. Like all occupations, nursing has its own vocabulary, or jargon, which may not be understood by clients and may make them feel inferior.

The basic rules for effective sending can be summarized in this manner:

1. Keep the message honest and uncomplicated.
2. Use as few words as possible to state it.
3. Ask for reactions (feedback) to make certain that the message is understood.

Receiving Skills

Receiving skills are as important to communication as sending skills. They involve not only listening to what people say but also observing their behavior and nonverbal cues. They enable nurses to receive accurate and complete messages. Effective receiving skills require attending to nonverbal as well as verbal messages and seeking feedback to understand their meaning.

If members of a seniors' exercise class agree to certain exercises but do not participate in them, they are sending a message. What message is their behavior sending? Were the proposed exercises too difficult? Did they misunderstand the nurse's instructions about how

to perform the exercises? Are they resisting in other areas of the program? The nurse's role is to clarify the intent of the message through effective communication skills.

An essential skill needed for receiving messages is active listening or reflective listening, which is considered to be the most useful and important listening skill. Active listening is the skill of assuming responsibility for and striving to understand the feelings and thoughts in a sender's message, thus giving importance to the person speaking (Karp, 2015). Understanding the message from the sender's perspective demands careful attention, which arises from a genuine interest in what the speaker has to say. Active listeners demonstrate their interest, often by remaining quiet when appropriate, sitting forward with arms relaxed, sustaining eye contact, nodding the head, and asking occasional questions for clarification (Heslip, 2015; Wolf, 2015). The content and feeling of the sender's message may be overwhelming at times, and the receiver can become preoccupied with formulating a response rather than listening actively so it is important to tune out distractions. Sometimes, it is helpful to let the speaker's words mentally repeat as your client speaks. At times, paraphrasing, or repeating back to the sender what the receiver heard, is helpful in clarifying the sender's meaning (Harmon, 2016). Summarizing your perceptions at the end of a home visit, for instance, helps to ensure that the client's communication has been accurately interpreted.

Active listening helps to communicate acceptance and increase trust, especially when the listener is empathetic and nonjudgmental. However, often we listen to our own personal beliefs and values when clients are speaking, and we make judgments about their messages. A critical response to the client's message by the nurse cuts off communication. Many nurses note that "a curtain drops"—a visible change of expression takes place—when the client *disengages* in response to a nurse's judgmental response. Refraining from making any negative judgments of the message or the way it is delivered will allow clients to be heard and acknowledged, which ultimately increases acceptance of suggestions (Karp, 2015).

Nurses also can listen actively by asking reflective questions that restate what clients or others have said to clarify the received meaning. Reflective questions have a twofold purpose: to show a sincere attempt to understand the sender's message and to demonstrate the importance of the message. An example of a reflective question follows:

Client states: "Quitting smoking is impossible."
The nurse asks: "Do you feel you can't quit smoking?"

By asking reflective questions, the nurse continues to clarify the messages clients send. You can reflect back to clients their:

- Account of the facts
- Thoughts and beliefs
- Feelings and emotions
- Wants, needs, and motivations

- Hopes and expectations

Active listening allows us to more accurately understand another person's viewpoint and helps to bring issues and concerns into the open where they can be more easily resolved. And if a misunderstanding has occurred, active listening will allow community health nurses to address any misunderstanding immediately (Canpolat, Kuzu, Yildirim, & Canpolat, 2015).

Interpersonal Skills

Effective communication in community health nursing also requires interpersonal skills. Three types of interpersonal skills build on sending and receiving skills, but go beyond the mere exchange of messages. They are showing respect, empathizing, and developing trust and rapport.

Showing Respect

Showing respect means conveying the attitude that clients and others have importance, dignity, and worth—a concept basic to nursing practice (Sabatino, Rocco, Stievano, & Alvaro, 2015). Respect can be expressed by treating clients' ideas and comments as valuable and worthy of attention, as well as demonstrating an interest in wanting to understand the situation from the other person's point of view. We show respect by the manner in which we address people—for instance, by using the courtesy titles of "Mr." or "Mrs." until it is determined how the client wants to be addressed. On a more subtle level, the tone of voice the nurse uses can show respect or make people feel inferior and insignificant. Nonverbal cues and active listening can indicate to clients that you are fully engaged and interested in their issues. Clients, community members, and other professionals all need to feel respected if they are to enter fully into the mutual exchange necessary for effective communication and optimal health care.

Empathizing

Empathy is a critical component of the communication process and is essential to the nursing process (Maruca, Díaz, Kuhnly, & Jeffries, 2015). The capacity to empathize communicates a sensitive awareness of another person's feelings, emotional state, and point of view. We show empathy by striving to put ourselves in our client's shoes—by reflecting their feelings and expressing the message in the receiver's language. This action allows us to convey the message, "This is the way it seems to me. Am I understanding that correctly?" The nurse should keep validating the speaker's true feelings to be certain that the message is being interpreted correctly. The nurse should use the same terms and, if possible, the same tone of voice as the other person did. For example, you should assume a serious manner if the speaker seems serious. Effective empathetic responses facilitate the development of mutual trust and a sense of shared understanding (Meyer-Junco, 2015).

Developing Trust and Rapport

Building trust and rapport with clients is usually the first goal for community health nurses, and the strongest tool a community health nurse can use in order to develop a trusting relationship is communication. Effective communication can aid in establishing a trusting relationship that is open, genuine, and demonstrates true concern for their clients (O'Hagan et al., 2014). Clients note that a trusting relationship is developed when the community health nurse shows respect and enhances dignity by being open, accepting, nonjudgmental, and showing empathy (Clancy, Gressnes, & Svensson, 2013). Clients appreciate nurses using a transparent process of communication; this includes being reliable, honest, and admitting when they don't have all of the answers (Elcock, 2014). However, power differences that may exist between the nurse and client may present difficulties in creating a trusting relationship. This is important to understand as clients and others will not express their true feelings if they do not fully trust the nurse (Rutherford, 2014). Many times, clients may say what they think the nurse wants to hear. They may agree to a plan of action simply because they do not want to displease the nurse or they may hide their true feelings because they think that the nurse is eager for a decision. Also, agreeing with others, especially with people who are in powerful positions and from more dominant cultures, is the polite and respectful thing to do in some cultures. The nurse who is unaware of this fact may mistakenly interpret the client's agreement as understanding, thus a "teachable moment" is lost.

Building a trusting relationship is a dynamic process essential in community health nursing. Trust can be nurtured through a consistent relationship with clients (Soares, 2016). Unexpected circumstances can occur and result in breaking your word (and trust) with a client, but it is important to acknowledge that breach and work more carefully to fulfill your obligations in order to rebuild trust (Rodwell & Ellershaw, in press). A trusting relationship can enable our clients to have the necessary strength needed to accomplish important lifestyle changes (see Evidence-Based Practice). Therefore, we need to promote trust in all relationships by:

- Committing to have knowledge and experience of the patient and situation.
- Clarifying expectations, anticipated behaviors, and boundaries of the nurse–client relationship
- Demonstrating consistency
- Being aware of attitudes and behaviors that do not promote trust (Dawson-Rose et al., in press; Kulbok, Thatcher, Park, & Meszaros, 2012)

EVIDENCE-BASED PRACTICE

Community Health Nurse–Client Communication

Early research on community health nurse–client communication revealed that this relationship supported self-confidence through the verbal communication patterns of information sharing/advising, negotiating, encouraging, calming, confirming, joking, listening, and silence (Vehvilamen-Julkunen, 1992). Newer research has verified the importance of establishing rapport and trust, understanding our clients, and describes the complex communication skills used by nurses with their clients. A review of studies conducted over a 30-year period revealed that preconditions for trust between nurses and patients exist. These included a level of preexisting trust due to past experiences with nurses and the health care system, the accessibility or availability of the nurse, the technical skill and bedside manner of the nurse, and the nurse's continual presence or service (Dinç & Gastmans, 2013). A trusting relationship was developed over time and was dynamic and changing; it is a reciprocal relationship and the nurse earns continued trust by meeting patient

expectations. Characteristics of the nurse that facilitate trust include being honest, sensitive, authentic, respectful, caring, accepting of the patient, encouraging, and being committed to giving good care. Barriers to trust include language barriers (e.g., jargon), not understanding the needs of the patient, being neglectful or not having adequate time or knowledge/skill, and conflicts involving power or time. Murray and McCrone (2015) noted similar findings in their integrative review of studies done over a 15-year period. Trust in health care providers and the system promotes more positive patient outcomes, better management of chronic diseases, and increased use of preventive health care. Mistrust leads to underuse of health care when needed, reduced adherence to treatment regiments, and may result in higher health care costs. The trust relationship is negotiated over time and becomes more stable as the patient feels respected and accepted and values the ethical and moral practice of the nurse. Motivational counseling is a PHN task, and preconditions needed for establishment of a trusting relationship during health counseling involve establishment of trust and rapport. Taking the time to get to know the patient as a person enhances the development of trust. Setting goals and contracting with patients, rather than taking control, supports continued trust. Their conceptual definition of promoting trust is "provider demonstration of interpersonal and technical competence, moral comportment and vigilance to support positive patient outcomes" (Murray & McCrone, 2015, p. 4).

Talk with your instructor and PHNs about these findings. Do they concur? How can you use this information to promote more effective trusting relationships with your clients?

Factors Influencing Communication

In a helping relationship, it is important for the public health nurse to demonstrate effective communication. Display 10–2 lists key components that assist in promoting a helping relationship.

DISPLAY 10.2 CHARACTERISTICS OF A HELPING RELATIONSHIP

In a helping relationship, it is important to promote:

- Openness, genuineness, trustworthiness, and self-awareness (ability to reflect on one's strengths and weaknesses)
- Sensitivity, acceptance, and concern for the client
- Respect for the client as an individual, which includes:
  - Encouraging client to take an active role in health care and to be included in all decisions and choices
  - Considering ethnic and cultural backgrounds
  - Considering family background, beliefs, and values
- Knowledge, self-confidence, creativity, compassion, and empathy
- Ability to problem solve and to confront or direct when necessary (Miller & Rollnick, 2013)

Effective communication is also strongly influenced by previous experiences and culture of both the nurse and the client. Previous experiences of both sender and receiver influence their perceptions and the meanings they attach to messages. For example, adolescents who are having difficulty with parents' authority may hear the nurse's suggestion to "learn more about sexually transmitted diseases" as an authoritarian command or effort to exert control. Requests for clarification help to verify that messages are being received as intended.

The respective cultures of sender and receiver influence both understanding and acceptance of messages. Communication between health care providers and clients who share the same culture and language background is often complex, but differences in culture, ethnicity, and linguistics pose even greater challenges in establishing a helping

relationship (see From the Case Files: Mr. Sanchez Needs an Interpreter).

From the Case Files I

Mr. Sanchez Needs an Interpreter

I am a student in community health nursing now, but I work as an extern at our small, local county hospital helping out in the emergency department (ED). A man came in one Saturday a month or so ago with a bad cut to his right hand from a push lawnmower—you know, the kind without a motor. Mr. Sanchez was trying to clean the grass from the blades and cut himself pretty badly. The ED doc asked him if he had received a tetanus shot recently, and he quickly nodded "yes." He spoke a little English, but I could tell that he was having some trouble understanding some of our questions. His friend, who brought him to the ED, did not speak English at all. We couldn't find an interpreter—they are always stretched so thin. None of us spoke Spanish. Anyway, he wasn't given a tetanus booster—we just cleaned his wound, closed it with stitches, bandaged it, and told him to keep it clean. He was given a prescription for an antibiotic medication. It was a busy night, and I didn't think about it much. A few weeks later, Mr. Sanchez was back in the hospital because his wound had gotten infected, and he had used a needle to drain some pus from his hand (he hadn't gotten the prescription filled because he had no insurance and no money due to being off work now because of his injury). Unfortunately, by poking around with the needle, he had provided a perfect, anaerobic place for tetanus to flourish. He now was in the ICU with full-blown tetanus. I have never seen anything like this! He was on a ventilator and had to be "paralyzed," so that we could get air into him. I had only read about opisthotonos—in which the body arches with only feet and head touching the bed because of a tetanic spasm—but now I was seeing it firsthand. This poor man was completely rigid, and we were trying to give him meds to relax him and permit the ventilator to work, but at the same time, we were working to keep his blood pressure from dropping too low from the meds. Mr. Sanchez spent 30 agonizing days in ICU—all because he nodded "yes" to the doc's question about the tetanus booster. With hindsight I think he probably just wanted to get out of the ED and didn't truly understand the question. A $5 tetanus booster could have prevented all of this misery and expense. (He had no insurance and was an undocumented alien, so the county paid the bill.) We should have used an interpreter, should have insisted on it, and should have waited until one was available. They are always in short supply—but I truly understand the importance of a translator now. I have some Spanish-speaking clients in my community health nursing rotation. I do my best to speak with them, and they are usually very welcoming and patient, but when I need to be sure that something is fully understood, I request that an interpreter accompany me on my home visits. I always remember Mr. Sanchez and what can happen when you don't use an interpreter.

Amy, age 24

In community health nursing, nurses often find themselves communicating cross-culturally (sometimes through an interpreter), which requires patience and constant effort to ensure accurate and inoffensive messages. For example, a nervous laugh, appropriate as an outlet in one culture, may appear rude and disrespectful to someone from another culture. Silence, which in Native American cultures indicates patience and thoughtfulness, may be interpreted as weakness or indifference to someone not familiar with these cultural practices. As culture is dynamic, community health nurses can never assume they know what is typical of another's culture; however, it has been shown that knowledge of someone's cultural background can aid in providing quality care within the cultural context of the client (Crawford, Candlin, & Roger, 2015; Savio & George, 2013). See Chapter 5.

Health Literacy and Health Outcomes

"Health literacy is the skills, knowledge, motivation and capacity of a person to access, understand, appraise and apply information to make effective decision about health and health care and take appropriate action" (Johnson, 2015, p. 21). Health literacy includes several tasks that relate to the ability to understand basic medical information, like how to take medicine, follow orders from the provider, access health care, and use health education from print and online sources (Rowlands, Berry, Protheroe, & Rudd, 2015). Comprehension of health information, either verbal or written, is important for clients in maintaining their health and the health of their families. However, many people lack the ability to read, understand, and act on health information presented to them on a regular basis. The *National Action Plan to Improve Health Literacy* addresses these issues and cites research showing that limited health literacy affects people of all races, incomes, ages, and educational levels, with the impact of limited health literacy disproportionately affecting minority and lower socioeconomic groups, and nearly 9 out of 10 adults have difficulty with using the health information that is routinely presented to them (USDHHS, 2010). Clear communication and understanding is important to health care outcomes; the interchange between health care provider and the patient is a vital part of health literacy (Nouri & Rudd, 2015). Cultural belief systems and styles of communication affect comprehension and responses to health information (National Network of Libraries of Medicine, 2013). The level of health literacy among rural heart failure patients has been shown to predict morbidity and mortality rates (Moser et al., 2015). It is important to be able to communicate with health care personnel and to fully comprehend instructions and information. (See Display 10–3 for further explanation.)

DISPLAY 10.3 HEALTH COMMUNICATION—ONE DISPARITY: LOW-LITERACY CLIENTS

Most poorly educated populations, those with the lowest literacy levels, have the highest mortality and morbidity. Changing demographics suggest that low literacy is an increasing problem among adults over age 65, certain racial and ethnic groups, recent refugee and immigrant populations, low-income populations, people with less than a high school degree or GED, nonnative speakers of English, and those living with chronic mental and/or physical health conditions (National Network of Libraries of Medicine, 2013; USDHHS, 2010). Yet it has been well documented

that most health information pamphlets, brochures, and other materials cannot be read or comprehended by low-literacy adults. Communication with these high-risk groups should be simplified and should include easy-to-read materials. At the same time, there is the danger of making the communication so simple that the reader feels insulted. Low literacy does not necessarily mean low intelligence. How does the nurse find the right balance?

The goal of communication is to achieve understanding. If clients are to understand health communication—whether the messages are spoken or written—they must be given ample opportunity to provide feedback. Before final printing and distribution, pamphlets and other written health information should be reviewed by members of the intended audience. Proposed users should comment on the readability and acceptability of both text and graphics. With spoken communication, nurses should regularly solicit feedback to make certain that messages are understood.

Low health literacy has a negative impact on a patient's health status and health outcomes. Research studies show that patients with limited reading skills are:

- Less likely to engage in health screenings and preventive action
- Less likely to have chronic disease under control
- More likely to be hospitalized
- More likely to report being in poor health
- More likely to die

Poor health literacy skills have been associated with poorer health status and increased health care costs and use of EDs as patients with low health literacy levels are less knowledgeable about their health conditions and are less likely to seek preventative care (Jihye, Namhee, & So Young, 2014; Wang et al., 2014). A systematic review of articles assessed health literacy rates for patients seeking care through hospital EDs found that a substantial portion of patients seen in EDs have limited health literacy and that older adults (≥65) with lower health literacy were more likely to use the ED as a primary source for care —leading to increased health care costs (Mantwill & Schulz, 2015). For children, low literacy skills in both the children and their caregivers have been tied to poor health outcomes. A systematic review of parent health literacy found that those parents with low literacy skills had worse health behaviors and had less knowledge about their child's condition and less likely to engage in behaviors to help improve their child's condition, thus leading to worse health outcomes for their children (Morrison, Myrvik, Brousseau, Hoffmann, & Stanley, 2013).

Health literacy is characterized as critical to health promotion and disease prevention; therefore, it is important to recognize that health literacy goes beyond the basic definitions of literacy and can include such things as cultural literacy and computer literacy, as well as scientific, media, and technological literacy (National Network of Libraries of Medicine,

2013; USDHHS, 2010). Vulnerable groups are most affected by low health literacy, and strengthening skills in this area can help address health disparities. For instance, the elderly, recent immigrants, migrants, ethnic minorities, and low levels of education and dominant language proficiency are those most often to be unable to effectively manage their health, gain service access, and understand information presented to them; they are also proportionately more likely to have chronic illnesses such as diabetes, heart disease, and other noncommunicable diseases (Kickbusch, Pelikan, Apfel, & Tsouros, 2013). Recognizing the factors that affect health literacy is important as we strive to improve health literacy because it "builds resilience" and improves the health of individuals and populations (p. 22). An individual who is health literate can

- Understand and complete self-care instructions, including complex daily medical regimens
- Plan and attain necessary lifestyle adjustments to improve their health
- Make positive, informed health-related decisions
- Know when and how to access necessary health care
- Address health issues in their community and society by sharing health-promoting activities with others (p. 23)

The USDHHS developed the National Action Plan to Improve Health Literacy based on the vision and principles that "(1) everyone has the right to health information that helps them make informed decisions and (2) health services are delivered in ways that are understandable and beneficial to health, longevity, and quality of life" (USDHHS, 2010, p. 16) (Display 10–4).

DISPLAY 10.4 THE NATIONAL ACTION PLAN TO IMPROVE HEALTH LITERACY

Vision for the Future

- An engaged and informed public that values health promotion, protection, and preparedness

The vision informing this plan is of a society that

- Provides everyone with access to accurate and accountable health information

- Delivers person-centered health information and services
- Supports lifelong learning and skills to promote good health

This vision depends on achieving the following seven goals:

1. Develop and disseminate health and safety information that is accurate, accessible, and actionable.
2. Promote changes in the health care system that improves health information, communication, informed decision making, and access to health services.
3. Incorporate accurate, standards-based, and developmentally appropriate health and science information and curricula in childcare and education through the university level.
4. Support and expand local efforts to provide adult education, English language instruction, and culturally and linguistically appropriate health information services in the community.
5. Build partnerships, develop guidance, and change policies.
6. Increase basic research and the development, implementation, and evaluation of practices and interventions to improve health literacy.
7. Increase the dissemination and use of evidenced-based health literacy practices and interventions.

From U.S. Department of Health and Human Services: Office of Disease Prevention and Promotion. (2010). National action plan to improve health literacy. Retrieved from http://www.health.gov/communication/HLActionPlan/pdf/Health_Literacy_Action_Plan.pdf

To be sure that these goals are being met, the improvement of health literacy and health communication for our population continues to be a priority in the *Healthy People 2020* goals (Display 10–5).

DISPLAY 10.5 HEALTH COMMUNICATION, HEALTH INFORMATION TECHNOLOGY, AND HEALTH LITERACY

Selected *Healthy People 2020* objectives related to health literacy or health communication are listed below:

Health Communication (HC) and Health Information Technology (HIT)

HC/HIT-1: Improve the health literacy of the population.

HC/HIT-2: Increase the proportion of persons who report that their health care providers have satisfactory communication skills.

HC/HIT-3: Increase the proportion of persons who report that their health care providers always involved them in decisions about their health care as much as they wanted.

HC/HIT-4: Increase the proportion of patients whose doctor recommends personalized health information resources to help them manage their health.

HC/HIT-5: Increase the proportion of persons who use electronic personal health management tools.

HC/HIT-6: Increase individuals' access to the Internet.

HC/HIT-7: Increase the proportion of adults who report having friends or family members whom they talk with about their health.

HC/HIT-8: Increase the proportion of quality, health-related Web sites.

HC/HIT-9: Increase the proportion of online health information seekers who report easily accessing health information.

HC/HIT-10: Increase the proportion of medical practices that use electronic health records.

HC/HIT-12: Increase the proportion of crisis and emergency risk messages intended to protect the public's health that demonstrate the use of best practices.

HC/HIT-13: Increase social marketing in health promotion and disease prevention.

U.S. Department of Health and Human Services (USDHHS). (2016). Healthy People 2020: Health communication and health information technology. Retrieved from https://www.healthypeople.gov/2020/topics-objectives/topic/health-communication-and-health-information-technology/objectives

Health communication not only encompasses the concept of health literacy but also incorporates health messages and campaigns, along with mass media and consumer health issues that are targeted to populations. Population health promotion is best achieved by health communication that uses multiple communication channels to reach individuals, families, and community members. Those mass media communication sources may include TV, radio, newspapers, Web sites, social media sites, smartphones/applications, text messaging, educational pamphlets, health care providers, nutrition, and medication labels. To manage disease and promote health, we must make sure our patients can understand the health information they see, hear, and read from multiple sources (Kickbusch et al., 2013). More information on these topics can be found in Chapter 11.

CONTRACTING IN COMMUNITY HEALTH NURSING

Contracting means negotiating a working agreement between two or more parties in which they come to a shared understanding and mutually consent to the purposes and terms of the transaction. Some kinds of contracts are familiar, such as when a buyer signs a contract agreeing to pay a certain amount over a specified period of time to purchase an automobile. Paying tuition for an education involves a form of contracting. Although no formal document is signed, students agree with an educational institution on a purpose (to obtain a degree), with the terms of the contract being regular tuition payments and regular learning opportunities over a planned period of time. For students in individual university courses, the syllabus is an informal contract. It spells out what is offered, what is expected, and what the outcomes may include. Sometimes, learning contracts are utilized within a course to further clarify roles and responsibilities, and students may "contract" for a grade —agree to do a specific number of assignments in exchange for a predetermined grade.

In contrast to legal contracts, which are written and legally binding, contracts in community health nursing can be either a verbal or written agreement that clients make with themselves, with family members, or with health care practitioners. This agreement commits clients to a set of behaviors, with the goal to improve adherence to a health promotion program or plan. Display 10–6 shows a contract used by community health nurses when counseling clients who desire to stop smoking. Contracts in a collaborative relationship or a nurse–client alliance may be flexible and changing and are based on mutual understanding and trust. The flexibility built into nurse–client contracting makes it a valuable tool for community health nurses.

DISPLAY 10.6 CLIENT SERVICE PLAN WITH CONTRACT

Madera County Public Health Department
Public Health Nursing: Client Individual Service Plan

Client Name: Angelica Luz-Smith
Client's Signature: _____
RN Case Manager: C. Rector, PHN
Start Date: 3/1/2017

Date: 3/1/2017 Strengths Identified: Angelica desires to improve the length and quality of life to be healthier to spend time with grandchildren Problems/Risks: Has smoked 1–2 packs per day for 20 years	Client Goal: ANGELICA will decrease to fewer than 10 cigarettes per day within the next 2 months. Contract agreement: Angelica will avoid temptations or situations associated with pleasurable aspects of smoking by: • Instead of smoking after meals, brush teeth or take a walk. • Limit social activities to where smoking is prohibited. • Find new activities that make smoking difficult such as swimming or bicycle riding. • Identify new activity to spend time on during work breaks (reading, crosswords, etc.). • Avoid alcoholic drinks. • Keep oral substitutes such as carrots, pickles, sugarless gum handy. • Take a yoga class to learn relaxation techniques. Angelica will explore community resources: • American Lung Association Program: Freedom from Smoking • California Smokers' Helpline: 1-800-NO-BUTTS	Case Manager: Teaching/Counseling/ Referral Case Manager will: • Promote positive expectations for success; encourage self-efficacy. • Prepare Angelica for relapse. • Assist in developing timeframe with goal ultimately to be that Angelica will stop smoking completely. • Partner with Angelica for evaluation, feedback, and revision of health plan as needed. • Provide resources for Freedom from Smoking and California Smoker's Helpline.	Follow-up/ Reassessment Date: 5/2017 Outcome/Evaluation Angelica will be smoking fewer than 10 cigarettes (1/2 pack) per day by 5/2017.

Adapted from Gulanik, M., & Myers, J. (2014). Nursing care plans: Diagnosis, interventions, and outcomes (8th ed.). Philadelphia, PA: Elsevier/Mosby.

The same format is followed with clients who are receiving home health care services. The contract that develops from the partnership between client and home health care nurse often is referred to as a critical pathway. It consists of the written plans for client care with a timetable. This represents a more formal type of contracting: it is typically a fiscally driven and agency-required tool designed to document standards and quality of care while reducing costs (see Chapters 12 and 32).

Characteristics of Contracting

The concept of contracting, as used in the collaborative relationship, incorporates four distinctive characteristics: partnership and mutuality, commitment, format, and negotiation.

Partnership and Mutuality

All aspects of contracting involve shared participation and agreement between team members; they become partners in the relationship. There is also mutuality to the nurse–client relationship: If we were to document nurse–client collaboration on a continuum, paternalism would be at one extreme and autonomy at the other. Mutuality becomes the midpoint balance or ideal of these two extreme positions (Duiveman & Bonner, 2012). For example, a parenting group of 15 couples requested community health nursing involvement. The group entered into a mutual partnership with the nurse and came to an agreement on what they needed and what the nurse could provide. Together, they developed goals, outlined methods to meet those goals, explored resources to help achieve them, defined the time limits for the contract, and outlined their separate responsibilities. The contract involved reciprocal negotiation and shared evaluation. A partnership with mutuality means that all parties are responsible for setting up and carrying out the terms of the agreement within a dynamic balance.

Commitment

Second, every contract implies a commitment. The involved parties make a decision that binds them to fulfilling the purpose of the contract (Hufford, Williams, Malec, & Cravotta, 2012). In community health collaboration, contracting does not mean making a binding agreement in the legal sense, but it is a pledge of trust and dedication. Accompanying that sense of dedication is a strong motivation to see the contract through to completion. All parties feel responsible for keeping promises; all want to achieve the intended outcomes. When the nurse and the parenting group identified their separate tasks, they committed themselves: "Yes, we will do thus and so."

Format

Format, the third distinctive feature of contracting, involves outlining the specific terms of the relationship. Clients and professionals gain a clear idea of the purpose of the relationship, their respective responsibilities, and the specific limits within which they will work. Expectations are clarified for all parties involved. The format of contracting provides the framework for collaboration. Once the terms of the contract have been spelled out, there is no question about what has to be done, who is to do it, or within what timeframe it is to be accomplished. This format helps to avoid the difficulty of terminating long-term relationships and shifts health care responsibilities from the professionals to the individual

or group. At times, having something in writing helps the client "legitimize" the nurse–client interaction.

Negotiation

Finally, contracting always involves negotiation. The nurse and other team members propose certain responsibilities and then ask whether the clients agree. The nurse might ask, "What do you feel you can do to achieve this goal?" A period of give-and-take then occurs in which ideas are discussed and conclusions and consensus are reached—no coercion should be involved. Team members may find over time that terms or goals on which they had agreed need modification. Perhaps clients have assumed more responsibility than they can realistically handle at this time and need to redefine their specific responsibilities. Perhaps the nurse feels a need to involve another professional in the collaborative process. The importance of effective interpersonal communication between clients and professionals to keep contracts updated is emphasized. Negotiation during contracting allows for changes that facilitate the ultimate achievement of goals. It provides built-in flexibility and encourages ongoing communication among all team members. Negotiation gives contracting a dynamic quality. Also, we need to remember that, although we may be experts in community health nursing and feel that we know best what is needed for our clients, they know more about their life circumstances and how health and illness impact them. Mutual respect and regard are necessary before effective contracting can take place. Duiveman and Bonner (2012) conducted a qualitative study of community health nurses contracting with clients and noted that negotiation was one of three themes that emerged, along with needs assessment and education toward self-care. Negotiation was used to develop the contract and to periodically change it as needed.

Value of Contracting

The value of contracting has been demonstrated in many settings and disciplines. Contracts have been used for many years in psychiatric and other nursing settings to promote client self-respect, problem-solving skills, autonomy, and motivation. Other disciplines, such as social work and counseling, have long used contracting as a tool in helping to enhance realistic planning and emphasize partnership (Hufford et al., 2012). For example, both nurses and social workers can utilize contracting to help a frustrated young mother develop a child safety plan. If a young mother feels that she may hit her child out of anger or frustration, a plan can be developed to identify a family member or friend who can be called in a time of crisis. This process identifies the potential problem and allows the mother to identify a resource that can help her in a time of need—ultimately keeping her baby safe (Kobayashi, Fukushima, Kitaoka, Shimizu, & Shimanouchi, 2015). Dieticians have used contracting to improve patient motivation and compliance with dietary interventions (Desroches et al., 2015). Educational contracts between students and instructors have proven valuable for facilitating learning. Negotiating with students to develop contracts gives them the opportunity to realize that what they want does matter, and it allows them to become more responsible for their own work and more enthusiastic about their education.

Public health nursing has used the concept of contracting for many years, developing partnerships with clients to address issues such as weight loss, exercise, and substance abuse. Without always labeling it contracting, these techniques have been used with clients who, for example, want to lose weight. In this case, the contract involves mutual agreement on certain exercise and eating patterns for clients and teaching and support responsibilities for the nurse. Often, it has a set time limit, such as 6 months, within which to achieve the intended weight loss. For chronically ill older adults, PHNs can help take a complex behavior and break it into manageable steps. For example, the idea of exercise may seem overwhelming to an older adult struggling with chronic health issues; however, contracting to walk at a moderate pace for 30 minutes three times a week may seem feasible. And, success in meeting the contract may aid in stimulating future efforts to increase exercise activities. In each case, a partnership is developed, with agreement about the partnership and the conditions under which it will be carried out. Nurses and clients are, in effect, contracting even though they may see it simply as setting goals with clients, and no written documentation is developed.

As more nurses seek to promote client autonomy and self-care, the wide applicability of contracting within nursing practice is recognized. PHNs may use contracting when implementing health promotion programs. Community health interventions where contracting may be helpful include stopping or reducing substance abuse, changing eating habits, increasing physical activity, improving diabetes care, and addressing depression and medication compliance. Display 10–7 is a simple contract that can be used by community health nurses and other providers when working with families to combat childhood obesity.

DISPLAY 10.7 RX FOR HEALTHIER LIVING

IDEAS FOR HEALTHIER LIVING

5	Eat at least 5 fruits and vegetables every day.
2	Limit screen time (e.g., TV, video games, computer) to 2 hours or less per day.
1	Get 1 hour or more of physical activity every day.
0	Drink fewer sugar-sweetened drinks. Try water and low-fat milk instead.

MY HEALTHY LIFE STYLE

- Eat ___ fruits and vegetables each day.
- Reduce screen time to ___ minutes per day.
- Get ___ minutes of physical activity each day.
- Reduce number of sugared drinks to ___ per day.

_____ Client's name/Signature
_____ Parent's/Caregiver Signature
_____ Provider's Signature
_____ Date

Adapted from Let's Move: America's move to raise a healthier generation of kids. (n.d.). Prescribe activity and healthy habits. Retrieved from http://www.letsmove.gov/prescribe-activity-and-healthy-habits

Common concepts of contracting in community health nursing:

1. Involves clients in promoting their own health
2. Motivates clients to perform necessary tasks
3. Focuses on clients' unique needs, regardless of aggregate size
4. Increases the possibility of achieving the health goals identified by collaborating team members
5. Enhances all team members' problem-solving skills
6. Fosters client participation in the decision-making process
7. Promotes clients' autonomy and self-esteem as they learn self-care
8. Makes nursing service more efficient and cost-effective (Duiveman & Bonner, 2012)

Contracting can also be done with groups or aggregates and with agencies (e.g., schools, businesses). For instance, a school district may want to contract with a public health agency to provide PHNs and health educators to address pregnancy prevention. The nurse working with the adolescents in the pregnancy prevention program may want to informally contract with them about sharing information gleaned in the small-group teaching exercises with their parents to encourage adolescent–parent communication.

Potential Problems with Contracting

Emphasis on contracting as a method rather than a concept can create problems. If a client has experienced contracts only in a business setting, it is possible to carry the stereotype of a cold, formal arrangement into the nursing practice setting. Some nurses fear that asking clients to negotiate a contract will place clients under stress, impede the development of trust, and negatively influence the relationship. Others have found that some clients prefer to have the nurse make decisions for them and are not ready to enter into any kind of negotiation. These problems in contracting can be overcome by understanding the true conception of contracting. Contracting is not a panacea. Some clients cannot fully participate in a collaborative relationship. Developmentally delayed clients and those with serious mental or cognitive impairments (e.g., mental illness, dementia) may be unable to fully participate in the nurse–client contract. Also, the use of contracting should not be used in place of developing a therapeutic relationship with clients. For example, when working with clients with suicidal ideations, practitioners may use contracting to address suicide prevention—developing a written agreement between the health care provider and the client stating that the client will refrain from suicidal behavior for a specified time period. However, it has been found that formal contracting in suicide prevention is often used in place of a therapeutic alliance and also can weaken an existing therapeutic relationship. Suicide prevention contracting should be done very carefully as it has the potential to produce negative outcomes when used in high-risk patients who are unlikely to be able to give informed consent (Wortzel, Matarazzo, & Homaifar, 2013).

Problems can arise when contracting with aggregates or agencies, as well. In the earlier example of contracting with a school district on pregnancy prevention, the community health nurse may need to take into account the culture of the school, as well as the community in general. If the school is concerned about teen pregnancy, but the community is against "sex education," it may be an unrealistic alliance. The community or agency culture may prevent real progress on this issue.

Principles of Contracting

Contracting applies the basic principles of adult education: self-direction, mutual negotiation, and mutual evaluation. It need not be a formal, written, or complex negotiation; it may be formal or informal, written or verbal, simple or detailed, and signed or unsigned by client and nurse. It should be adapted to the particular client's abilities to assess, plan, implement, and evaluate, which may vary greatly from situation to situation. The tool shown in Display 10–12 seeks input from the client. The client's goals are mutually set, and the goals are spelled out. Initial interventions are dated, as are follow-up and reassessment visits. In addition, there is a place for a continuing assessment of outcomes and for evaluation on future dates. Like all nursing tools, contracting enhances a client's health only if it is adapted to each particular set of client needs and abilities.

Contracting in Steps

Contracting follows a sequence of steps. As a working agreement, it depends on knowing what clients want, agreeing on goals, identifying methods to achieve these goals, knowing the resources that collaborating members bring to the relationship, using appropriate outside resources, setting limits, deciding on responsibilities, and providing for periodic reviews. Each of these tasks requires discussion among members of the contractual group. The tasks are incorporated into the contracting process and can be described in eight phases that follow the nursing process.

Assessment

1. *Explore needs*: Assess clients' health and needs: done by clients, nurse, and other relevant persons.

Nursing Diagnosis/Goal Setting

1. *Establish goals*: Discussion followed by agreement among contracting members on goals and objectives

Plan/Intervention

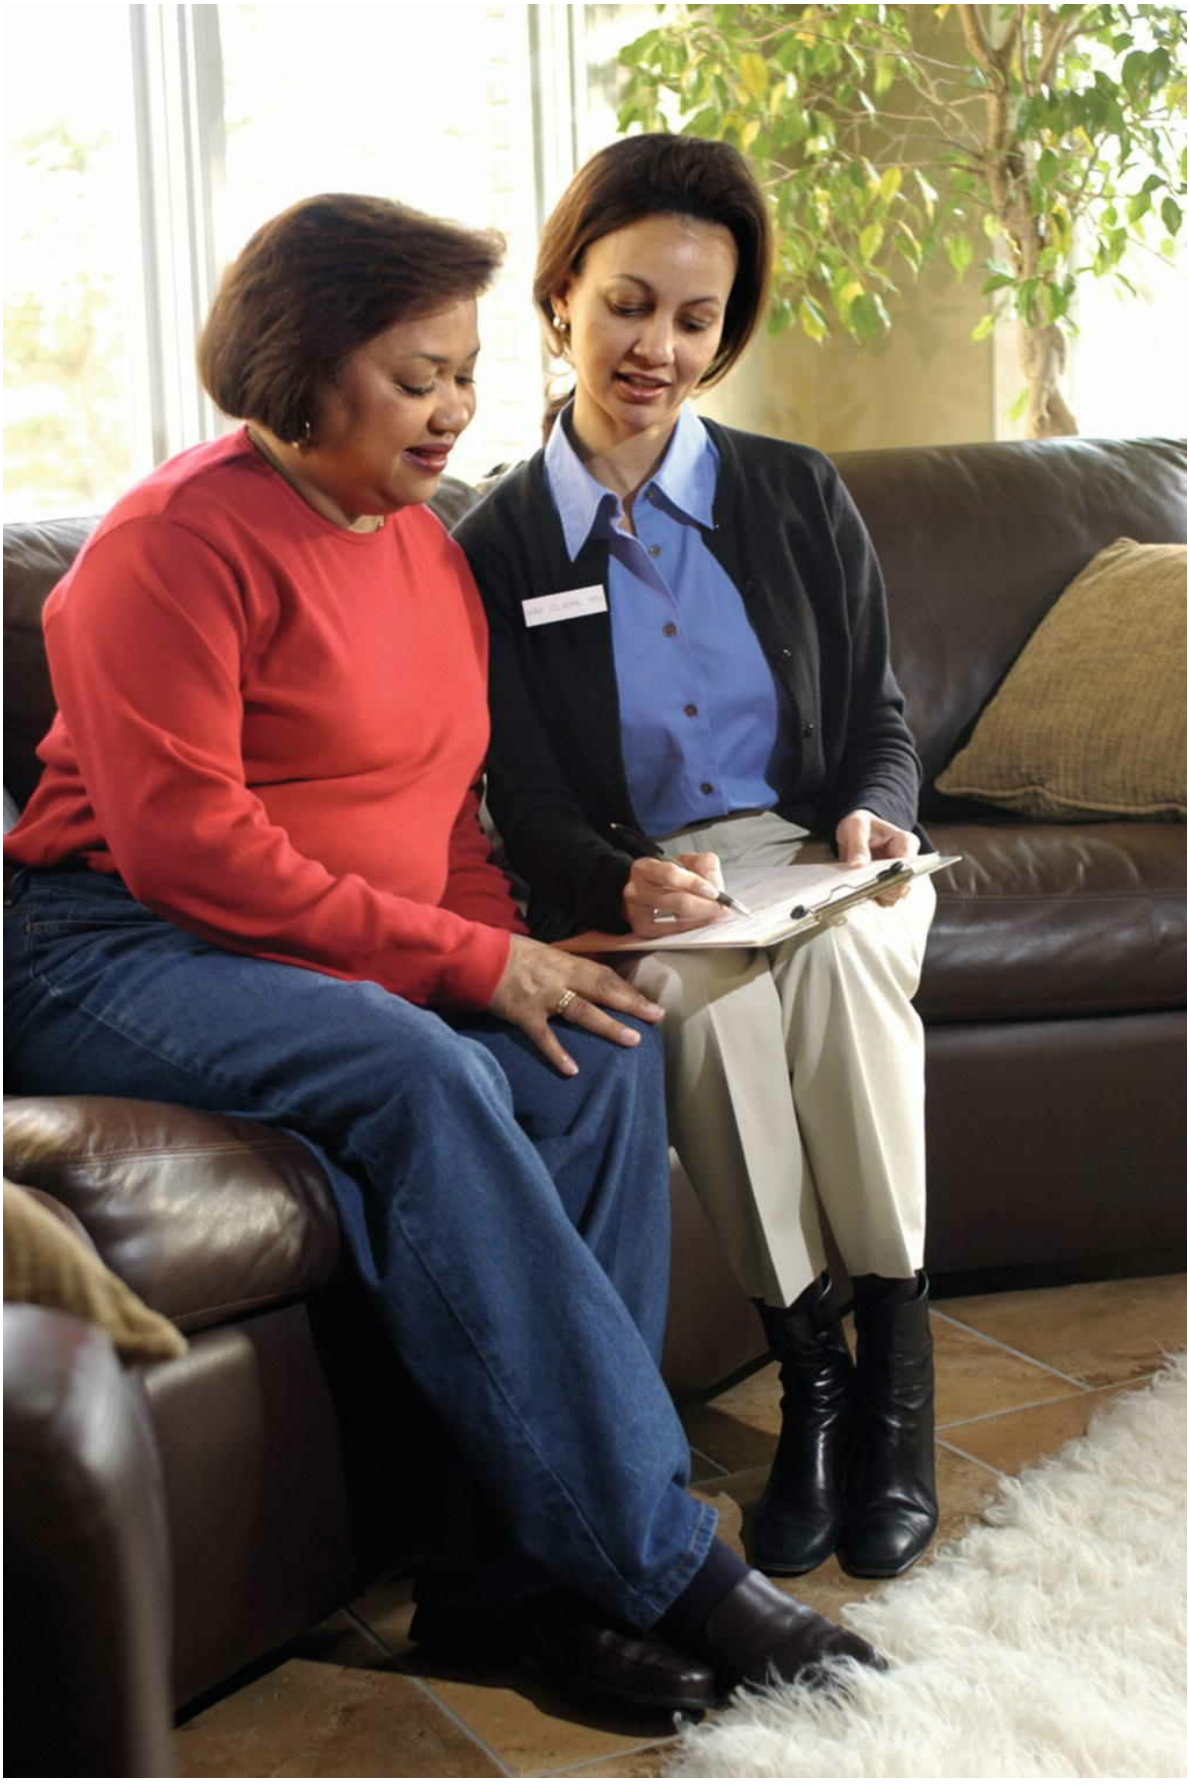
1. *Explore resources*: Define what each member has to offer (clarify PHN role) and can expect from the others; identify appropriate resources and agencies.
2. *Develop a plan*: Identify methods, activities, and a timeline for achieving the stated goals.
3. *Divide responsibilities*: Negotiate the activities for which each member will be responsible.
4. *Agree on time frame*: Setting limits for the contract in terms of length of time or number of meetings.

Evaluation

1. *Evaluation*: Formative and summative assessments of progress toward goals occur at agreed-on intervals.
2. *Renegotiation or termination*: Agree to modify, renegotiate, or terminate the contract.

As community health nurses use this process to negotiate a contract, they must adapt it to each situation. The sequence of phases may change, and some steps may overlap. Nevertheless, the basic elements remain important considerations for successful contracting (Fig. 10–2).

FIGURE 10–2 The concept and process of contracting. Contracting is based on four distinctive features, shown here as spokes that support a wheel. These features form the basis for a reciprocal relationship among clients, nurse, and other persons. This relationship is not static; it is a dynamic process that moves through phases, represented here as the outer rim of the wheel. The process moves forward, focused on meeting clients' needs, and enables the collaborating group to facilitate ultimate achievement of clients' goals.



Levels of Contracting

Community health nurses use contracts at levels ranging from formal to informal. The degree of formality depends on the demands of the situation. To fund a community health program for preventing child abuse, for example, a formal contract in the form of a written grant proposal may be needed. To conduct a wide-scale needs assessment of a homeless population, the services of an epidemiologist and statistician may require a formal contract to clarify roles and expectations, as well as fees. Formal contracting involves all parties negotiating a written contract by mutual agreement, signing the agreement, and sometimes having it witnessed or notarized. This level of contract has been used with mental health or substance-abusing clients, where the seriousness of the working agreement and the need to actively involve the client are important aspects of therapy.

Some situations best lend themselves to a modified and less formal use of contracting, in which the nursing plan becomes the written contract. For example, a school nurse forms a support group for pregnant adolescents. The nurse uses modified contracting by discussing with the girls the purpose of the group and the number of sessions needed and obtaining their agreement to attend all sessions.

Informal contracting involves some form of verbal agreement about relatively clear-cut purposes and tasks. A client group may agree to prioritize their list of needs, the nurse may agree to conduct health teaching sessions, the social worker may agree to obtain informational materials, and so on. Sometimes, nurses use contracting informally without realizing it. They conclude a session with clients by agreeing with them about the purpose and time of the next meeting. Conscious use of contracting, however, is a more effective way to provide structure for the relationship and foster client involvement, regardless of the level at which it is applied.

The level of contracting also may change during the development of communication and collaboration. Clients often need education about their options. Initially, they may have difficulty in identifying needs and making choices. The professional team can work to promote clients' self-confidence and help them assume increasing responsibility for their own health. Through these efforts, contracting becomes a consciously recognized part of the relationship, and clients become fully participating partners.

COMMUNICATING WITH GROUPS

An important aspect of communication in community health nursing involves working with groups of people. Community health nurses are regularly involved in committees, task forces, and other work-related groups; they also work with aggregates in small groups—often teaching and facilitating support groups. Group communication patterns can be complex, and interaction requires skill on the nurse's part to elicit feedback from all members and to generate a common understanding among the group's members. Because the relationships among group members can significantly influence the effectiveness of communication, community health nurses need to understand how to organize groups and how groups function and develop over time, as well as techniques for facilitating group support and decision making.

Group Development

Think about the first time you walked into a nursing classroom—you didn't know the teacher or any of the other students in your group. What were your feelings? What did you expect or need the teacher to do? How did your feelings and expectations about the students and teacher change by the end of the term? Changes in "group dynamics" over time are termed group process.

In 1977, Tuckman and Jenson were credited with identifying the five most commonly used stages of group development (Display 10–8). The first stage of their model is termed *forming*. In this stage, members feel awkward and hesitant, needing to be reassured and accepted. Members depend on the group leader or facilitator to help them develop mutual trust and give them structure and guidance (Carter & Mossholder, 2015). At this stage, the group leader's task is to help the members become oriented to each other and to the work or purpose at hand.

DISPLAY 10.8 STAGES OF GROUP DEVELOPMENT

Forming—Group dependent on facilitator; anxiety high, need safe environment, structure, and avoid too much self-disclosure; agree on guidelines for group work/behavior; orient to task or purpose of group.

Storming—Competition and conflict; need for structure; problem solving; need to draw out quiet members; continue to clarify group task or purpose.

Norming—Group now more cohesive and creative; acknowledge others' contributions; shared leadership; trust increases; work moves along more quickly.

Performing—Not reached by all groups; true interdependence—can work as group, or as individuals, and in subgroups; most productive; least reliant on facilitator.

Adjourning—The termination phase; conclusion of activities and resolution of relationships; formal acknowledgment of group work.

"Ice-breaker" activities, to introduce members to each other and move past the awkwardness and hesitancy, are often used at the first group meeting. Conflict and sensitive topics, or too much self-disclosure by leaders or group members, are avoided at this stage. Rather, it is important to set ground rules (e.g., no sharing personal information outside of

support group) and define the scope of work and timeline for completion. As group interaction is established in the first stage, task roles are the major focus with maintenance roles emerging in later stages (see Task, Maintenance, and Nonfunctional Roles in Group, Display 10–9).

DISPLAY 10.9 TASK, MAINTENANCE, AND NONFUNCTIONAL ROLES IN GROUPS

Task Roles: Required in selecting and carrying out group tasks.

Maintenance Roles: Required in strengthening and maintaining group relationships and activities.

Nonfunctional Roles: Roles that harm the group and its work—often self-oriented behavior.

Task Role Behaviors

Initiating Activity: Proposing solutions; suggesting new ideas, new definitions of the problem, and new approaches to the problem or new organization of material.

Seeking Information: Asking for clarification of suggestions; requesting additional information or facts.

Seeking Opinions: Looking for an expression of feeling about something from members; seeking clarification of values, suggestions, or ideas.

Giving Information: Offering facts or generalizations; relating one's own experiences to the group problem to illustrate a point.

Giving Opinions: Stating an opinion or belief concerning a suggestion or suggestions; particularly concerning its value rather than its factual basis.

Elaborating: Clarifying, giving examples or developing meanings, and trying to envision how a proposal might work if adopted.

Coordinating: Showing relationships among various ideas or suggestions, trying to pull ideas and suggestions together, trying to draw together activities of various subgroups or members.

Summarizing: Pulling together related ideas or suggestions; restating suggestions after the group has discussed them.

Maintenance Role Behaviors

Encouraging: Being friendly, warm, and responsive to others, praising others and their ideas, agreeing with and accepting contributions of others.

Gatekeeping: Trying to make it possible for another member to make a contribution to the group by saying "We haven't heard anything from Jim yet" or suggesting limited talking time for everyone, so that all will have a chance to be heard.

Standard Setting: Expressing standards for the group to use in choosing its content or procedures or in evaluating its decisions; reminding the group to avoid decisions that conflict with group standards.

Following: Going along with decisions of the group, thoughtfully accepting ideas of others, and serving as audience during group discussion.

Expressing Group Feelings: Summarizing what group feeling is sensed to be and describing reactions of the group to ideas or solutions.

Both Task and Maintenance Role Behaviors

Evaluating: Submitting group decisions or accomplishments to compare with group standards and measuring accomplishments against goals.

Diagnosing: Determining sources of difficulties, appropriate steps to take next, and analyzing the main block to progress.

Testing for Consensus: Tentatively asking for group opinions in order to find out whether the group is nearing consensus on a decision and sending up trial balloons to test group opinions.

Mediating: Harmonizing, conciliating differences in points of view, and suggesting compromise solutions.

Relieving Tension: Draining off negative feelings by jesting or pouring oil on troubled waters and putting a tense situation in a wider context.

Types of Nonfunctional Behaviors

Being Aggressive: Working for status by criticizing or blaming others, showing hostility toward the group or some individual, and deflating egos or status of others.

Blocking: Interfering with the progress of the group by going off on a tangent, citing personal experiences unrelated to the problem, arguing too much on a point, and rejecting ideas without consideration.

Self-confessing: Using the group as a sounding board and expressing personal, nongroup- oriented feelings or points of view.

Competing: Vying with others to produce the best idea, talk the most, play the most roles, and gain favor with the leader.

Seeking Sympathy: Trying to induce other group members to be sympathetic to one's problems or misfortunes, deploring one's own situation, or disparaging

one's own ideas to gain support.

Special Pleading: Introducing or supporting suggestions related to one's own pet concerns or philosophies and lobbying.

Horsing Around: Clowning, joking, mimicking, and disrupting the work of the group.

Seeking Recognition: Attempting to call attention to one's self by loud or excessive talking, extreme ideas, and unusual behavior.

Withdrawal: Acting indifferent or passive, using excessive formality, daydreaming, doodling, whispering to others, and wandering off the subject.

Adapted from Boyd, M. A. (2015). Psychiatric nursing: Contemporary practice (6th ed.). Philadelphia, PA: Wolters Kluwer.

Kirst-Ashman, K., & Hull, G. (2011). Understanding generalist practice (6th ed.). Belmont, CA: Cengage Learning.

The next stage is called *storming*, which is when the group begins to work together. In this stage, conflict and competition become more common as different agendas, ideas, and approaches begin to compete for attention. However, this period of role ambiguity is necessary to allow group members to identify roles and expectations and get a feel for how the group will work together. The storming stage can be difficult, but an effective group leader can guide group members in problem solving and setting goals. Modeling maintenance roles such as encouraging all group members to participate, asking for a quiet member to share an idea with the group, and summarizing group feelings is helpful in moving group members along in maintenance as well as task roles.

By the time group members begin to show signs of cohesiveness, they have moved on to the *norming* stage, and work begins to progress. Trust and openness are much more apparent, and there is a shared sense of "belonging" to the group. Creativity and shared ideas and opinions characterize this stage. Until this time, most groups function at the task level, but by this stage, maintenance activities are more apparent as members draw others in and constructively share feelings. The leader should continue to role model good maintenance behaviors to move the group along in its work.

The *performing* stage may not occur with all groups; it is characterized by the ability to work as a total group, in subgroups or independently. This stage is considered the most productive, as group members are motivated and able to handle the decision-making process in a competent and autonomous manner. A high level of team satisfaction is seen in this stage as members are now able to work together more smoothly and do not need a lot of direction from the facilitator.

When either work or support groups end, the final stage of development is termed *adjourning*. In adjourning, the emphasis is on wrapping up the project, and this results in a withdrawal from both task and relationship or maintenance activities. Group members often feel happy that they have accomplished their goal but are sad about the loss or

disbanding of the group. PHN group leaders can support the group as they prepare to disengage through a closure activity such as a small party or ceremony (Betts & Healy, 2015).

Group Functions in Decision Making

Groups, regardless of size, perform many functions. Four functions of particular relevance to group decision making include:

1. *Group members share information*. In public health nursing, groups often include clients, health professionals, and community members who share their experience and expertise to arrive at solutions and decisions. Something one member says may spur others to think of more creative solutions or share similar problems allowing group members to gain insight and develop trust (Kilpatrick, Lavoie-Tremblay, Ritchie, & Lamothe, 2014).
2. *Groups are heterogeneous and present diverse views* that enrich the number and types of alternatives in the problem-solving process. Group decisions are often better than individual ones because of the diversity of experiences and perspectives. However, group facilitators should promote open, prejudiced-free attitudes within the group to increase the positive benefits of diversity (Kilpatrick et al., 2014).
3. *Groups influence their members, thinking* by broadening their perspectives and presenting new ways of thinking about the issues. This allows group members to gain more insight in understanding the issue at hand (Hare, 2010). This influencing

function can improve the quality of group decision making and increase the likelihood of decisions that support positive outcomes (Kilpatrick et al., 2014).

4. *Groups progress toward consensus* or resolution by planning tasks that allow members to discuss a set of alternatives and arrive at solutions to meet established goals. Time pressures and desire for completion help to move this process along (Kilpatrick et al., 2014).

Techniques for Enhancing Group Decision Making

There are a variety of group decision-making techniques.

As a member of many decision-making groups in the community, the community health nurse can facilitate the process through certain techniques. Three strategies commonly used in community health settings include brainstorming, multivoting technique, and nominal group technique.

Brainstorming

Brainstorming is an idea-generating process that encourages group members to freely offer suggestions. When brainstorming, group members are asked to present ideas. They are encouraged to be creative and "think out of the box"; no idea is too bizarre or wild. Furthermore, no criticism or discussion is allowed until all ideas have been exhausted and recorded. This technique is helpful for generating creative possibilities and is most useful in

the early stages of decision making. Research has shown that brainstorming is considered to be the most widely used method of generating creative ideas, but is often less effective than nominal group techniques (Gobble, 2014).

Multivoting

Multivoting is a decision-making tool that enables members to prioritize a long list of ideas with minimal discussion and difficulty. Multivoting often follows brainstorming to narrow the list to a few items worthy of immediate attention. All of the ideas are listed on a flip chart and members are allowed to vote on one third of the total number of items. For example, if there are 60 items, members are given 20 stickers to place their "vote" beside their top priorities on the flip chart. Once everyone has voted, the stickers are tallied to arrive at a shorter list of priorities (Minnesota Department of Health, 2016).

Nominal Group Technique

Nominal group technique is a group decision-making method in which group members are asked to not speak to each other but instead are asked to write down their ideas, along with the advantages and disadvantages of the issue being addressed. After everyone has completed the task, the members' ideas are presented to the group, and discussion takes place so that the information can be categorized and prioritized (Baheiraei, Mirghafourvand, Mohammadi, Mohammad-Alizadeh, & Nedjat, 2013). Nominal group technique affords researchers a means of collecting data that are inclusive and respectful of participants' opinions, while allowing both shy and talkative members to join in the discussion.

Other Group Communication Techniques

Not all community health nursing work with groups involves group process and group decision making. Sometimes, community health nurses are asked to speak to groups of concerned citizens at public meetings to raise awareness of an issue (e.g., preparing for disasters) or provide information to parent-teacher groups (e.g., immunization compliance). Often, they are called upon to incorporate group-teaching methods to change behaviors (see Chapter 11 for more on health teaching). Group teaching can be an effective tool for many health care challenges such as for diabetes teaching and education (Aeyoung, De Gagne, Sunah, & Young-Oak, 2015; Kewming, D'Amore, & Mitchell, 2016).

Group or public education and communication occur routinely in public health nursing. However, it is even more critical during disasters and other public health emergencies. Consistent public messages, interagency communication, and providing education and guidance on disaster preparedness are essential communication techniques for the garnering trust and reducing anxieties (Humphreys & Thompson, 2014).

COLLABORATION AND PARTNERSHIPS IN COMMUNITY HEALTH NURSING

Effective interdisciplinary and interprofessional collaboration is essential in the health care system to achieve quality health care and assure successful outcomes (Morgan, Pullon, & McKinlay, 2015). The definition of collaboration implies working together for the greater good; however, a more detailed definition will help facilitate the development of collaboration into practice for community health nurses. In this context, collaboration means a purposeful interaction among nurses, clients, other professionals, and community members to develop strategies for improving the health of individuals, families, and communities (Mitchell et al., 2013).

Although collaboration is a complex dynamic process, there are really only two basic features of collaboration: (1) it has a goal, and (2) it involves several parties assisting one another to achieve that goal. The overriding purpose or goal of collaboration in community health practice is to benefit the health of the public. Therefore, many players must work together (e.g., agencies, professionals, clients, lay health workers) to effectively achieve that goal. Partners will be able to meet their goals more effectively if the collaborative process promotes an atmosphere of mutual trust and respect, maintains open and honest communication, and accepts the roles and skills of the participating partners (Mitchell et al., 2013).

Asset-based community development (ABCD) is a methodology that starts with community assets and strengths including local persons, community associations and networks, natural resources, and institutions as a means of working with residents to create sustainable communities. Rather than a needs-focused approach, ABCD starts with identifying the types of skills and resources in the community and then consults with the community members on improvements they would like to make (Nel, 2015). Similarly, community-based participatory research (CBPR) involves community members in the entire research process from identifying a topic of importance to the community through implementation and dissemination (Kulbok et al., 2012; Pavlish & Pharris, 2012). See more on CPBR in Chapter 4. Involving stakeholders in planning and implementing programs and research increases their buy-in and the likelihood of success.

Key principles for establishing partnerships and collaboration with communities and interprofessional team members include:

- Think “outside the box” when looking for partners or collaborators.
- Plans are guides toward a goal; stay flexible.
- Partners must be part of the planning; continuously widen the circle of participants.
- When adding new partners, be prepared to replan.
- Maintain different levels of collaboration (different team members have more resources, come in later to the project, or leave the project earlier).

- Use consensus-building techniques that are creative and visual.
- Establish a shared vision; then share the plans and leadership (Bryant, 2014; Nel, 2015; Ng, Fraser, Goding, Paroissien, & Ryan, 2013).

To meet the needs of aggregate populations, public health nursing practice draws on the expertise and assistance of numerous individuals. The list of team members can include health planners, policy makers, epidemiologists, biostatisticians, community citizens, demographers, environmentalists, educators, politicians, housing experts, safety professionals, and industrial hygienists in addition to nurses, physicians, social workers, dieticians, psychologists, physical therapists, dentists, and other professionals involved in health services. All partners should be encouraged and allowed to utilize their skills and knowledge to optimize outcomes (Bryant, 2014; Kulbok et al., 2012).

Depending on the need to be addressed, community health nurses may work with many people on a single project or on multiple endeavors; it is important to remember to involve the most important team players. Therefore, representatives from the identified client population should always be included as key members of the collaborative process. For example, to address the increasing prevalence of childhood obesity and adolescent metabolic syndrome, research is beginning to show promise beyond just family-based programs to involve school-based interventions (IOM, 2012). Therefore, overweight and obese adolescents and their parents should be included in the process of designing and implementing school-based nutritional and physical activity interventions. By including members of the identified population, potential barriers, such as having few healthy food and drink choices at school, lack of consistent opportunities for exercise, and poor understanding about how to maintain weight loss, can be addressed. In a CBPR study about developing weight management lesson plans and audiovisual aids for a school-based health center intervention in New Mexico, researchers sought advice on adolescents' definition of health and motivation for weight loss, as well as how to best provide culturally and developmentally appropriate interventions and aids, along with incorporation of Internet activities and resources so that their program was attractive to a population of largely Hispanic, Black, and American Indian teens. Outcomes after participating in the intervention revealed significant improvement in BMI percentile and waist circumference compared to a control group (Sussman et al., 2013). Another example involves developing a culturally based intervention program to address HIV/AIDS among Latino youth, and the collaborative process including members of the targeted population while also including HIV prevention and treatment providers, HIV case management agencies, funding partners, and community members. By involving the appropriate interdisciplinary members, effective community health programs can be designed and implemented (Salerno, Delaney, Swartwout, & Tsui-Sui, 2015). Chapter 4 has more information on CBPR. Display 10–10 presents a case study illustrating the concept of community collaboration.

DISPLAY 10.10 COMMUNITY COLLABORATION

Case Study: Community Health Improvement Partnership

Problem #1:

The proportion of people who are uninsured in the United States is problematic. In the state of Florida, 2010 data from the Census Bureau indicates that one in four Floridians under the age of 65 lack health insurance that puts Florida third on the list of states with the highest percentage of uninsured. For the total population, 22.5% were uninsured. This high percentage of uninsured residents in Florida affects all Floridians through higher medical costs, insurance premiums, and taxes. The health insurance crisis in Florida puts all communities at risk. Floridians without health insurance are more likely to be sicker as access to care is late or not at all, thus impacting quality of life greatly. In Sarasota County, Florida, 38% of uninsured residents report that they delayed or did not get needed medical care when sick, with 12% reporting their health care status as fair or poor.

What can a community do to address the number of uninsured individuals in their neighborhoods? In Sarasota County, community leaders believed that a community is only as strong as its weakest member and that finding ways to expand coverage and increase access to affordable care for the uninsured was vital to the health of their entire county. The Community Health Improvement Partnership (CHIP) in Sarasota County brought together a dynamic collaboration of individuals, community leaders, not-for-profit organizations, and hospitals that are dedicated to improving the physical, mental, social, and environmental health of all citizens in Sarasota County. Community Health Action Teams (CHATs), comprising community volunteers and organizational partners, were formed in several areas of the county to focus on improving the health of a specific community. CHATs identified and studied health issues and then took action to tackle priority issues. For example, the North Port CHAT helped bring additional health care and transportation services to its community and also promoted youth activities and efforts to reduce substance abuse.

The Health Provocateur Project is another example of CHIP's initiatives. This initiative convened major stakeholders of the local health care system, including hospital chief executive officers (CEOs) and health department administrators on a

quarterly basis to discuss and act on local issues. A team of collaborators from 12 hospitals and health departments created Sarasota Healthcare Access, a model system of care to improve services to the uninsured. Using a large-scale systems approach, the goals of this initiative included:

- Creating a formal system of the exchange of patient health information, data, and information on program/providers services
- Developing a universal referral system
- Utilizing existing capacity of providers to increase the number of residents who are enrolled in primary care and oral health service programs
- Providing case management services for uninsured clients with identified medical conditions to reduce unnecessary emergency room visits and hospital readmissions
- Enhancing access to low-cost medication
- Increasing community awareness of available health care resources for the uninsured

Effective collaboration in Sarasota County has led to the creation of a coordinated system of care that moved Sarasota County one step closer to improving the quality of life for all its residents.

Problem #2:

In 2013, data indicated that obesity were the most pressing challenge, and a new action plan was developed. The main components of that plan included the following:

- Development of a consistent message that promoted healthy weight.
- Applying EBP protocols to assess current weight of individuals.
- Developing a standard template for a healthy weight plan.
- Building capacity to meet the needs of the obese population (prevention, assessment, treatment, follow-up).
- Implementing interventions to improve environments that promoted healthy weight.
- School nurses, school nutrition programs, and parents were engaged to promote healthier eating in schools, and day care providers were also contacted. Worksite wellness collaborative and CHAT teams worked to improve healthy food access in the community.

Once the new assessment processes and healthy weight templates were in place, a pilot program showed early improvements in BMI.

Case Study Analysis Questions

Directions: Explore the CHIP Web site (http://www.chip4health.org) to learn more about this initiative and help answer the following questions:

1. What characteristics of collaborative partnerships are evident in this case study? Provide examples.
2. How are community members engaged in the CHIP initiatives? What is the role of CHAT teams in both problems?
3. What barriers to communication would you anticipate in working with CHIP teams?
4. Provide examples of three task and maintenance roles that the public health nurse can use to facilitate effective communication during CHIP and Health Provocateur Project meetings.
5. Discuss the stages of group development that you would expect the CHAT team to experience. What interventions can the community health nurse employ to help the CHAT move to the performing stage?
6. The hospitals and health departments in the Health Provocateur Project are a mix of government, for-profit, and not-for-profit organizations. What are the benefits and challenges of these entities working together?
7. What barriers to collaboration would you expect in the Health Provocateur Project? In the Obesity Project? What communication interventions could the public health nurse use to address the barriers?

In the Levels of Prevention display, the levels of prevention pyramid are utilized to provide a framework of the collaborative process in community health nursing. One of the objectives seen in *Healthy People 2020* is Environmental Health objective HP2020-13: Eliminate elevated blood lead levels in children (U.S. Department of Health and Human Services [USDHHS], 2014). To achieve this objective, community health nurses need to be able to collaborate effectively with community partners in the design and implementation of health programs that address this very significant issue. However, the same nurses may work directly with individuals and families to educate them on the importance of having their children tested for elevated lead blood levels, and once a child is identified with an elevated lead blood level, the nurse may collaborate with individual clients to understand the importance of medical treatment for their child.

Culture and Collaborative Services

Culture is a set of shared understandings related to knowledge, attitudes, and behaviors that give meaning to an experience. In public health nursing, clients and providers are often separated by their own distinct set of understandings or culture. Therefore, clients' cultural background, experience in collaboration and partnership building, perspectives, and expressions of need provide important information for the planning and delivery of services (Display 10–11). PHNs, by being aware of one's own culture and the difference between their culture and their clients', will be able to participate in cultural exchanges with clients that will promote stronger alliances, allowing them to develop greater understanding, acceptance, and commitment to more fully use the health programs designed for their benefit (Tucker et al., 2014). See Chapter 5 for more on culture in community health nursing.

DISPLAY 10.11 CROSS-CULTURAL GUIDELINES

1. Community health nurses should strive to ensure all population members receive care and services that are respectful and sensitive to their client's cultural beliefs and practices.
2. Be aware of your own belief system and values; understand and acknowledge that cultural differences may exist.
3. Develop a basic understanding and knowledge of other cultures, but do not use generalizations about other cultures to stereotype or oversimplify your ideas to another person or group. Remember there are differences within each cultural group that are influenced by individual characteristics and geographical location; therefore, never assume you understand what a person from another culture thinks or feels.
4. Demonstrate a genuine interest in the client's personal circumstances and seek to establish trust. Suspend judgments and respect the opinion of others.
5. Be aware of power imbalances and the effect on communication. Identify members who are accorded higher status and authority in family or group and respect the status hierarchy. Respect gender and age differences.
6. Do not assume that there is only one way (yours) to communicate. Keep working on ways to improve your cross-cultural communication skills. For example, avoid using jargon or slang that may not be understood cross-

culturally. Use very clear and simple English.

7. Unspoken communication can be powerful; be aware and use appropriate body language.
8. Practice active listening. Try to put yourself in the other person's shoes, especially when another person's ideas or perceptions are different from your own. Be willing to step outside your comfort zone.
9. Do not assume that just because clients say they understand the information that they really do. Clarify questions and statements. Seek feedback by reframing the question in a different form to ensure understanding.
10. Apologize for cultural mistakes. Admit your own limitations and state willingness to learn from others. Show appreciation for the opportunity to learn from others.
11. Easily understood information and services should be delivered in the preferred language of the population served. Whenever possible, utilize interpreters who are trained in culturally competent care, and if possible, avoid using family members or friends to interpret. Look directly at the client, not the interpreter, when speaking.
12. Practice—we get better at cross-cultural collaboration when we practice it.

Adapted from Eubanks, R. L., McFarland, M. R., Mixer, S. J., Munoz, C., Pacquiao, D. F., & Wenger, A. F. (2010). Chapter 4: Cross-cultural communication. Journal of Transcultural Nursing, 22(Suppl 1), 137S–150S.

Rowe, J., & Paterson, J. (2010). Culturally competent communication with refugees. Home Health Care Management Practice, 22(5), 334–338.

Characteristics of Collaborative Partnerships in Community Health Nursing

To explore the meaning of collaboration in the context of community health nursing, this section examines five characteristics that distinguish collaboration from other types of interaction: shared goals, mutual participation, maximized resources, clear responsibilities, and set boundaries.

Levels of Prevention Pyramid Applied to Children's Health and the Environment: Collaborative Opportunities for Community Health Nurses at All Three Levels of Prevention

SITUATION: High lead blood levels were identified in a community

GOAL: Using the three levels of prevention:

- Programs and policies will be developed to prevent childhood lead poisoning.
- Children will be screened for elevated blood levels.
- Lead-poisoned infants and children will receive appropriate medical care and environmental follow-up.

TERTIARY PREVENTION (REDUCE THE MORBIDITY RELATED TO LEAD EXPOSURE OR POISONING)	
Prevent Death and Further Disability	**Interventions**
• Restore child to healthful state. • Restore the environment to a healthful state.	• Medical treatment as indicated; may include chelation therapy • Removal of child from environment • Aggressive environmental remediation
SECONDARY PREVENTION (MINIMIZE ABSORPTION OF LEAD AND ELIMINATE CHRONIC EXPOSURE)	
Early Diagnosis	**Prompt Treatment**
Surveillance and screening activities for early detection, treatment, and referral for management of environmental lead exposure	Identification of children with elevated blood lead levels Routine maintenance and repair of homes in high-risk communities
PRIMARY PREVENTION (REMOVE LEAD FROM THE ENVIRONMENT SO THAT EXPOSURE CANNOT OCCUR)	
Health Promotion and Education	**Health Protection**
• Identify high-risk areas, populations, and activities associated with housing-based lead exposure. • Use local data and expertise to expand resources and motivate action for primary prevention. • Develop strategies and ensure the creation of lead-safe housing. • Collaborative partnerships in communities to provide educational programs to increase knowledge of lead safety in at-risk populations • Evaluate and redesign current prevention programs to achieve primary prevention while ensuring adequate secondary interventions.	• Use surveillance, demographic, and housing data to identify high-risk geographic areas • Identify high-risk families who could benefit from immediate assessment and services to reduce lead exposure. • Educate community partners on the cost of inaction to the community and affected families; highlight risk disparities. • Incorporate lead hazard screening into home visits by community health nurses. • Assure current programs are meeting the community's needs or readjust priorities.

Adapted from Centers for Disease Control and Prevention (CDC) (2015a).

Shared Goals

First, collaboration in community health nursing is goal directed. The nurse, clients, and others involved in the collaborative effort or partnership recognize specific reasons for entering into the relationship. For example, a lumber company with 150 employees seeks to develop a wellness program. The community health nurse, company employee representatives, a safety expert, an industrial hygienist, a health educator, an exercise therapist, a nutritionist, and a psychologist might work together to develop specific physical and mental health goals. The team enters into the collaborative relationship with broad needs or purposes to be met and specific objectives to accomplish.

Mutual Participation

Second, in community health nursing, collaboration involves mutual participation; all team members contribute and are mutually benefited (Petri, 2010). Collaboration involves a reciprocal exchange, in which individual team players discuss their intended involvement and contribution, and it is important for all members of a team to feel equally valued—no hierarchies should exist (Davis & Travers Gustafson, 2015). The lumber company representatives may outline assessed areas of need, such as back-strengthening exercises to facilitate lifting and reduce strain. The professionals, including the nurse involved in the collaboration, will offer their own specific ideas and expertise to design the wellness

program. In interdisciplinary teams, physicians, nurses, lay community health workers, clients, outside agency personnel, and others must be able to effectively share ideas and frustrations on an equal, reciprocal basis.

Maximized Use of Resources

A third characteristic of collaboration is that it maximizes the use of community assets (Majee, Goodman, Vetter-Smith, & Canfield, 2016). That is, the collaborative partnership is designed to draw on the expertise of those who are most knowledgeable and in the best positions to influence a favorable outcome. If the lumber company team has identified a need for health education materials, the nurse and other members of the collaborating team may explore health education resources through the local health department and within their own professions. In this age of dwindling resources, it is now common for public health agencies to seek additional funding assistance from other agencies to support new community health programs or to provide educational information or interventions. Acute care hospitals and public health agencies may align over common interests (e.g., influenza, diabetes, and other lifestyle diseases). Outside funding agencies, both government and nonprofit, are increasingly looking for proof of effective collaboration and coalition building before approving grant or government funding. Being able to demonstrate fiscal responsibility and evidence-based outcomes will assist community health nurses in sustaining health promotion efforts on a long-term basis, and this may be facilitated by collaborative partnerships.

Clear Responsibilities

Fourth, the collaborating team members work in partnership and assume clearly defined responsibilities. As in a football team, each member in the partnership plays a specific role with related tasks. The nurse may play a case management or group-leadership role, whereas others assume roles appropriate to their areas of expertise. Effective collaboration clearly designates what each member will do to accomplish the identified goals. The nurse, for example, might coordinate the planning effort for the lumber company wellness program and work with the health educator to develop classes on various topics. The psychologist might advise on a chemical dependency program, and the industrial hygienist would provide assistance with safety measures. Each member of the team develops an understanding of individual responsibilities based on realistic and honest expectations. This understanding comes through effective communication. The collaborating partners explore necessary resources, assess their capabilities, and determine their willingness to assume tasks.

Boundaries

Fifth, collaboration in community health practice has set boundaries, with a beginning and an end, that fall within the goals of the partnership. An important part of defining collaboration is determining the conditions under which it occurs and when it will be terminated. The temporal boundaries sometimes are determined by progress toward the

goal, sometimes by the number of team member contacts and often by setting a time limit (Browning, Torain, & Patterson, 2016). The collaborating group might target 6 months as a completion date for the lumber company wellness program and establish a timeline with designated activities to reach the goal. Once the purpose for the collaboration has been accomplished, the group as a formal entity can be terminated.

In some settings, the partnership may desire to continue to work on other, mutually agreed upon activities. If so, the process begins again with different goals. Some partnerships are ongoing. For example, a university with a department of nursing might use a neighborhood community center for clinical experiences for their students. The community center has needs that may include health assessments and in-home health teaching among community members, flu shots given at the center for elders without transportation, or health education classes for the adults in an English-as-a-Second-Language (ESL) class or for preschoolers in a Head Start program. The center and the university work in partnership so that, each semester, ongoing services are provided by the nursing students and coordinated by a faculty member or graduate nursing student in collaboration with the community center staff. Each partner wins. The students receive a rich educational experience, and the neighborhood center gets services they would otherwise do without. Within such a model, there are opportunities for students and volunteers. Students from other educational disciplines—social work, theater arts, physical therapy, early elementary education, and other areas—can be integrated into a center that serves people of all ages. Professionals (e.g., dentists, pediatricians) who are willing to volunteer (e.g., one-half or 1 day per week) enhance the services provided, as can lay volunteers, who can read to the children, answer the telephone, or participate in fund raising. When people collaborate and work together in partnership, a great number of possibilities exist.

Fostering Client Participation

This chapter has stressed that communication and collaboration are based on mutual participation. The extent of clients' involvement in that participation varies, however, depending on their readiness and ability to participate (Albarran, Heilemann, & Koniak-Griffin, 2014). The client's level of wellness at the time of the initial professional–client encounter directly influences participation. Some people are not physically or emotionally healthy enough to assume an active role in the relationship. Women recently discharged from the hospital after a mastectomy, for example, have many physical and emotional adjustments with which to cope. Their families, too, must expend additional energies to provide needed support and to cope with the temporary loss of the woman's usual role in the family. They may find it difficult to engage actively in identifying their needs and goals at the start of the collaborative process. The nurse may have to take a stronger initial leadership role; however, the goals of collaboration are not abandoned. Gradually, as the client's wellness level improves or the client's family becomes more involved, the nurse can encourage more active participation. Developmentally disabled clients, or others who are cognitively impaired, may not have the full capacity for true collaboration, but a collaborative team can work together with them in designing an effective plan.

Engaging clients in a collaborative process may be difficult at times. Clients with lower literacy skills or from low-income levels or minority or different cultural backgrounds may need extensive encouragement to actively participate in a collaborative relationship. Sometimes, a client's previous experience with health personnel limits participation in collaboration; clients who were not previously encouraged to participate in decision making by physicians, nurses, or other professionals may follow the pattern of a passive role and may not feel that they can truly collaborate. Unless the nurse persists in efforts to reduce the dependence of clients, the relationship can fall short of therapeutic goals (Dawson-Rose et al., 2016; Kulbok et al., 2012).

The nurse's own view of collaboration also influences the degree of client participation. Nurses who are accustomed to relating to clients in an adult-to-child manner restrict client involvement. If nurses see their position as more informed, and the client's position as one of complete ignorance and need, a paternalistic relationship may develop. All clients have resources on which to build, and the community health nurse should help clients to discover these resources and use them to enhance collaboration and attain health goals.

Structure of Collaborative Relationships

Like group process, collaboration among agencies or groups of people may occur in stages (Display 10–12). During this process, the work of identifying and meeting the client's needs takes place. Because most collaborative and partner relationships are bound by time, the structure involves several phases: (1) a beginning phase when the team relationship is just being established; (2) a middle, working phase; and (3) a termination phase when the relationship or project ends.

DISPLAY 10.12 STAGES OF COLLABORATION

Competition: Competing backgrounds, ideas, and motivations and a search to find shared values, goals, and ethical principles.

Networking/Communication: Sharing information promotes development of trust and role clarity and reduces miscommunication caused by stereotypical views of other disciplines, professions, or entities.

Cooperation/Coordination: More sharing of resources, less duplication, and formal communication through structure and agreements and more mutual respect.

Coordination/Partnership: Becoming more invested in the success of all partners, better able to manage and share resources, and full support of agencies involved.

Coalition: Shared leadership and decision making; resources benefit all members; sufficient power and authority to work collectively.

Collaboration: Shared mission and vision, open and trusting communication, strong relationships, sense of belonging, and shared accomplishments and goals.

Institute of Medicine. (2016). Collaboration between health care and public health. Washington, DC: National Academies Press.

Northern Illinois University. (n.d.). Stages of collaboration. Retrieved from http://www.niu.edu/rcrportal/collabresearch/stages/stages.html

The first phase is a period of establishing and defining the team relationship. All of the team members, including clients, are getting to know each other; they seek to establish

communication patterns and develop trust. In this phase, they identify the clients'/projects' needs and determine the goals toward which they will work.

The second phase occurs when team members start working together to accomplish desired goals. Their work may include assessment and planning as well as implementation and evaluation. The cycle of the nursing process is repeated as needed during this working phase until goals are satisfactorily accomplished.

The third or termination phase occurs when the need for team members to work together has ended. When team members have grown close in the relationship, termination can be difficult. Termination should never occur abruptly or without participation. It often requires careful advance preparation to make certain that all parties understand when and why it is taking place. Termination helps to ensure a clear-cut end to the collaborative relationship. For example, a nurse, physician, social worker, psychologist, and nutritionist collaborated with a refugee group for almost 1 year. As the group's multiple needs declined, the professionals began to taper off their assistance. Two months before the relationship was ended, termination of the group was discussed. At first, client group members were frightened at the loss of group support, but slowly they took ownership and control, and with their newly acquired skills, they assumed more responsibility for their health needs.

Barriers to Effective Collaboration

Communication barriers and miscommunication can inhibit effective collaboration. This is sometimes caused by misconceptions on the part of team members regarding the professional knowledge and motives of other team members. Stereotypes and the perception of unequal power and authority granted to certain disciplines can sabotage the effectiveness of communication and true collaboration. Apprehension about sharing information with the team, inflexibility and uneasiness with the more fluid boundaries required in collaboration, and a failure to develop a common purpose and goals are all barriers for effective teamwork and collaboration. It is essential that team members share information about their respective disciplines and backgrounds, as well as personal expectations related to collaborative efforts that includes their perspective on what they see as the goal of the process (Shaw, Mitchell, & Del Fabbro, 2015). Organizational or structural factors, such as inadequate time, lack of resources, and lack of agency support are also cited as barriers to effective collaboration (Al Sayah, Szafran, Robertson, Bell, & Williams, 2014).

Conflict is inevitable when dealing with groups of diverse individuals, but how potential anger, resentment, and mistrust are handled is the key to getting beyond conflict (Soares Lopes, Meira Albino, de Menezes, & Muniz Ribeiro, 2015). Open, honest communication must prevail. One strategy to handle conflict is to introduce "carefronting"—described as a method of addressing and resolving conflict by confronting others in a caring, responsible, yet self-asserting manner. This method involves honest communication that sends the message that both parties in the situation should be treated with respect. Using "I" messages ensures that all parties in the conflict matter and that you care enough to negotiate differences so that common goals can be met. It is more fruitful to focus on the issue or problem at hand in a safe environment where all members can voice their opinions openly and not on personal determinations of who is right or wrong (Klinkhamer, 2015).

HEALTH TECHNOLOGY

Health technology provides many opportunities for public health nurses to reach clients.

Health technology/informatics utilizes processes, procedures theories, and concepts from information and computer science, health sciences, and social sciences. Nurses use the tools of information technology (IT) to support delivery of care and improve the health status of all. Health data, information, wisdom, and knowledge can be collected, stored, processed, and communicated. Nurses and other health professionals, administrators, policy and decision makers, as well as consumers, and clients/patients can use IT, hardware, and software (Nelson & Staggers, 2014).

Early Use of Computers in Health care

The successful application of innovative developments in the computer and information sciences to complex problems in health care promoted the birth of a new distinct specialty, health care informatics. This specialty is usually thought to have begun in the 1950s with the beginning use of computers in health care, as noted in a classic article by Dezelic (2007). Connie Settlemeyer created an example of early nursing informatics applications. Connie, while a graduate student at University of Pittsburg in the late 1960s, designed a mainframe-based computer-assisted instruction for teaching nursing students how to chart using a common problem-oriented format. The application was used to teach nursing at the University of Pittsburg throughout the 1970s (Nelson & Staggers, 2014). In the 1960s, El Camino hospital, conveniently located in Silicon Valley, collaborated with Lockheed to install the first computer-aided medical information system, which was known as MIS. Also in the 1960s, Dr. Lawrence Weed at the University of Vermont developed a system to reorganize and automate patient medical records. Weed's work was ultimately the basis for the Mayo health system medical record (Health Technology Review, n.d.). Information systems began to be installed by a number of hospitals to manage inventory and business data. El Camino hospital currently describes itself as a cutting-edge medical technology ecosystem (El Camino Hospital, 2016).

In the 1970s, order entry and results reporting were some of the first hospital information systems. In this decade, computer use was confined to specialty areas such as hemodynamic monitoring in intensive care and procedure areas. Libraries also began the switch to computerized databases, which helped to expand accessibility to medical information. This allowed for access to conference proceedings and journals allowing the knowledge specific to a specialty to become organized and readily available (Health Technology Review, n.d.).

Electronic Health Records Today

Electronic health records (EHRs) are, at their simplest, digital (computerized) versions of patients' paper charts. The contemporary EHR is a complex piece of software with multiple functions and capabilities. It enables a health care provider to record patient progress in free text, place prescription orders, receive decision-support alerts and reminders, order laboratory tests, receive and review results electronically, message patients or fellow providers, and perform a variety of other documentation and clinical tasks. Most nurses practicing today complete charting electronically, either exclusively or at least some of the time. Most U.S. hospitals and health care systems are using a form of EHRs currently. The Centers for Medicare and Medicaid Services (CMS) incentivized hospitals and health care systems to move to EHRs. The American Recovery and Reinvestment Act, signed in 2009 by President Obama, included the Health Information Technology for Economic and Clinical Health Act (HITECH). The CMS were directed through HITECH to motivate eligible providers to begin using EHRs, rather than paper. Financial incentives to health care systems were offered beginning in 2011, and penalties for not using EHRs began in 2015. CMS promoted the adoption of EHRs into three "meaningful use" stages (Duffy, 2015, para. 2). Stage 1 involves data capture and sharing. Stage 2 is about advancing clinical processes, whereas the third stage covers improved outcomes (Duffy, 2015).

By May 2013, about 80% of hospitals were using EHRs (Wu, 2014). The long-term goal of the federal EHR incentive program is to improve the quality and safety of health care. Adoption of EHRs was done with the best intentions in reaction to the mandates, but sometimes without adequate planning and or training. One of the most significant problems encountered is discrete EHR systems within departments in the same hospital or system. Chosen EHR systems may meet the needs of a specific clinical area but may not interact with other EHR systems used in other clinical areas in the same facility. Health care systems may have multiple ways to register patients that do not feed into each other. This leads to frustration on the part of nurses and other clinicians, as well as clients or patients.

One of the most beneficial advantages of using EHRs is the ability to enter data once and reuse them multiple times. This capability reduces redundancy and can reduce errors by providing the history from previous encounters. When an individual is readmitted, the previous data can be reviewed and update with the goal of decreasing charting time and improving continuity of care. Sensmeier (2015) suggests that nurses, as knowledge workers, can use EHR's clinical data to:

- Optimize workflow and support decision making.
- Tell the patient's story.
- Collaborate to foster knowledge translation.
- Leverage analytics to extract actionable knowledge.
- Use sharable, comparable data.

- Build evidence out of nursing practice.

The use of EHRs in public health has followed a slower progression than in hospitals. Reporting (e.g., communicable disease, immunizations) has moved from paper to unidirectional electronic reporting in many areas. Only a few states have capability for bidirectional data exchange between EHRs and immunization monitoring systems. A report of stage 1 implementation noted that 40% of eligible health care providers have submitted data on immunizations to public health agencies. A total of 54% of hospitals have submitted data to immunization registries, and 15% have electronically transferred lab results to public health agencies (Wu, 2014). A program, BioSense 2.0, collects data on ED visits and hospitalizations from multiple sources and works with local and state public health departments to determine the health of local communities (Wu, 2014). Public health agencies may also work with Health Information Exchanges (HIEs) in order to connect with local health care providers, hospitals, pharmacies, and laboratories in sharing health-related information; HIEs have the potential to provide real-time surveillance (e.g., location tracking of high-risk clients during emergencies, syndrome surveillance). Agencies may also find EHRs helpful in areas such as epidemiology, large-scale planning and budgets, and with grant writing (Birkhead, Klompas, & Shah, 2015; Tomines, Readhead, Readhead, & Teutsch, 2013). For example, an agency may search for specific characteristics and target vulnerable populations to best determine more effective planning and targeted interventions (e.g., clients with specific chronic diseases, current smokers). Individuals may also gain access to their own health information, and this is especially helpful in the case of immunization records (Wu, 2014).

Big Data

The McKinsey Global Institute defines big data as "datasets whose sizes are beyond the ability of typical database software tools to capture, store, manage and analyze" (Maynika et al., 2011, p. 1). Garcia (2015, p. 53) shared, "broadly speaking, big data refers to a large complex data set that can be analyzed to reveal patterns, trends, and associations, related to human behavior and interactions." The "big" in big data is not solely related to size, but it suggests the use of new statistical tools and the need for massive and/or multiple computers to process the data. Big data today may be considered ordinary or small in the future (Garcia, 2015).

Nurses in all settings add to big data through sharable and comparable documentation in the EHR (Garcia, 2015). The health care industry historically has generated large amounts of data, through record keeping, compliance and regulatory requirements, and patient care. EHRs lead to large amounts of electronic data. With mandatory EHR requirements and the potential to improve the quality of health care delivery meanwhile reducing costs, these massive quantities of data ("big data") can support a wide range of medical and health care functions, including clinical decision support, disease surveillance, and population health management, as well as many others (Raghupathi & Raghupathi, 2014). The use of big data makes it easier to drill down (or view more detailed information), drill up (or see data in an aggregate view), as well as "slicing-and-dicing" (or combining different data variables) than when using more traditional forms of data collection and analysis (Tomines et al., 2013, para. 12).

A goal of EHR documentation is capturing health and care data in structured ways that help build a foundation for accurate, reliable, clinically meaningful measurement across systems and settings of care. Big data are the core of that documentation, all of data entered in EHRs and more. The consistent and reliable use of data elements will allow information to be collected once and reused for multiple purposes (Sensmeier, 2015). As discussed, if EHR systems are not integrated (e.g., if they do not work together and talk to teach other), the task is much more challenging.

EHRs and health care systems are not the only source of big data. Medical data generated by computers and smartphones that gather information from wearable sensors and imaging devices are also included. In other words, a huge amount of data are being gathered (Sensmeier, 2015). Garcia (2015) asks nurses to imagine a future where infectious disease can be rapidly linked to exposures and vaccination patterns to prevent the spread of illness. We also need to imagine a future where patient acuity is calculated from nursing documentation, workloads adjusted, and health care–related infections reduced by the utilization of big data-driven evidence-based protocols.

Mobile Health (mHealth)

The rapid expansion of mobile technology provides an opportunity for nurses and other clinicians to improve health and health care through forms of interactive mobile health (mHealth), referred to as mHealth services. mHealth includes the use of wireless technologies, such as smartphones, tablets, and notebooks for improving health. Mobile technology use in health care is evolving beyond the initial use as direct communication between nurses/clinicians and clients with one-way monitoring. mHealth offers great opportunities for improving global health, safety, and preparedness. The potential of mobile technology's impact on sharing health information and collecting disease/health data is tremendous due to its portability, affordability, and availability; it also has the potential to save billions of dollars in health care costs (Grant, 2013). The potential of mHealth will be further established as patients' experiences with technology and clinical/psychosocial outcomes are evaluated (Park, Howie-Esquivel, Whooley, & Dracup, 2014).

Three current mHealth trends have been identified by the U.S. Department of Health and Human Services (USDHHS, 2014). The trends include mHealth technology that is interactive, integrated, and multimedia. Interactive strategies enable "two-way flow of information that engages patients more actively" in their health management. Integrative strategies use multiple "self-management applications to share health information between patients and providers through text messages, centralized web-based" tracking and management programs, and mobile monitoring (such as glucose monitoring). Multimedia use "games and quizzes" to communicate preventive messages and motivate behavior change (USDHHS, 2014, p. 5).

mHealth is extending health care to underserved areas. Technology puts health care providers in a position to change how health care is delivered, the quality of the patient experience, and the cost of health care. Advantages include management of chronic disease, empowering the elderly and expectant mothers, reminding people to take medication, serving underserved areas, and improving health outcomes and medical system efficiency.

Big differentials exist between developed and developing nations. Africa has lowest rate of mHealth adoption, whereas North America, South America, and Southeast Asia showed the highest adoption levels. A number of countries have initiatives in the pilot stage or have informal activities that are underway. Chronic disease management is the greatest need in many areas. Remote monitoring devices enable individuals with long-term health alterations to manage their illness with clinician consultation (USDHHS, 2014). This keeps them out of doctor's offices for routine care and thereby helps to reduce health care costs. Real-time management is especially important in the case of chronic diseases. More research is required to link mobile technology to health outcomes. See From the Case Files: Monitoring a Cholera Outbreak Using Cell phones.

From the Case Files II

Monitoring a Cholera Outbreak Using Cell phones

Cholera outbreaks in the African country of Rawanda sickened hundreds of people over a 2-year period. Nathan Eagle, an engineer and adjunct professor of epidemiology at Harvard University, wondered if tracking the location of individuals using cell phone data might indicate an early sign of an outbreak. For instance, if he tracked 100 individuals within a specific radius and noted that their movements slowed suddenly, it might indicate that there was a new outbreak. He had used mHealth earlier in assisting a small African hospital to prevent shortages of blood by using text messaging to alert the main blood bank early before the blood shortages became an emergency. So, he was familiar with cell phone use in Africa.

For the cholera outbreak, he used the cell phone service providers' call data records to track individuals' movements. When combining that data with public health records, he then had "big data" to use in testing his hypothesis. As luck would have it, as his experiment got started, the roads began to wash out during a flood, and people stopped moving around because they could no longer travel the roadways. However, he still found the data useful because cholera outbreaks often occur approximately 2 weeks following a flood.

Using cell phones in the developing world is a promising approach, as about 90% of the worldwide population has wireless coverage, and around 65% of cell phone subscribers live in areas of the developing world (Harvard University, 2012).

Mobile Phones

Approximately 91% Americans own a mobile phone, and 64% of those are smartphones (Pew Research Center, 2016). Most people keep mobile phones close by, and check them several times throughout the day. Konok, Gigler, Bereczky, and Miklósi (2016) reported that people are extremely attached to their mobile phones, and most were kept within arm's reach. Mobile phone use is highest among individuals who use cell phones as their primary methods of communication. Mobile phone technologies offer promising opportunities for nurses working in the community setting (Christofferson, Hamlett-Berry, & Augustson, 2015; Lin et al., 2015).

Nearly two thirds (63%) of cell phone owners now use their phone to go online, according to the Pew Research Center's *Internet & American Life Project* (Duggan & Smith, 2013), and because 91% of all Americans own a cell phone, 57% of all American adults are cell Internet users. This is an 8% increase from the 55% of cell owners who did so at a similar point in 2012, and a twofold increase over the 31% who did so in 2009. See Table 10–1.

Table 10–1 Demographics of Cell and Smartphone Owners, 2014

	Have a Cell Phone
All Adults	90%
Men	93%
Women	88%
Race/Ethnicity	
Hispanic	92%
White and Black	90% each
Age Group	
18–29 years	98%
30–49 years	97%
50–64; 65 and over	88%; 74%
Household Income	
$50,000–$74,999	99%
$75,000 +	98%
$30,000–$49,999	90%
Under $30,000/yr.	84%
Level of Education	
College/some college	93% each
High school or less	87%
Type of Community	
Suburban	92%
Rural and urban	88% each

Adapted from Pew Research Center. (2016). Cell phone and smartphone ownership demographics. Retrieved from http://www.pewinternet.org/data-trend/mobile/cell-phone-and-smartphone-ownership-demographics/

Sixty-seven percent of cell owners find themselves checking their phone for messages, alerts, or calls—even when they don't notice their phone ringing or vibrating. Forty-four percent

of cell owners have slept with their phone next to their bed because they wanted to make sure they didn't miss any calls, text messages, or other updates during the night. Twenty nine percent of cell owners describe their cell phone as something they can't imagine doing without (Duggan, 2013). See Table 10–2 for cell phone activities.

Table 10–2 Americans' Cell Phone Activities

81%	Sending or receiving text messages
60%	Use it to access the Internet
52%	Sending or receiving e-mails
50%	Use it to download apps
49%	Use it to get recommendations, directions, or for other location-based services and information
48%	Listening to music
21%	Use it for video calls or chats
8%	Use it to share location or to "check-in"

Adapted from Duggan, M. (2013, September 19). Cell phone activities 2013. Retrieved from http://pewinternet.org/Reports/2013/Cell-Activities.aspx

Connected health offers the patient the opportunity to feel constantly linked to the health delivery system and offers the system a just-in-time messaging opportunity that can be motivating, educational, and caring. A disadvantage is that mobile or cellular phones are frequently less reliable than landlines, with users citing spotty service, dropped calls, and text messages delayed or lost in cyberspace. To use this network for essential health care communication, improvements are needed (Kvedar, Nesbitt, Kvedar, & Darkins, 2011). Connected health offers the patient the opportunity to feel constantly connected to the health delivery system and offers the system a just-in-time messaging opportunity that can be motivating, educational, and caring (Health Information and Management Systems Society, 2016).

Text messages are the initial, simplest, and most common type of mobile data service and are becoming a vital tool for the delivery of health information and engaging users to improve their health (AHRQ, 2014; CDC, 2015b). Text messaging is a way of connecting

quickly with a large population (Nelson, Joos, & Wolf, 2013). Global penetration of mobile text messages approaches 100% worldwide and is a widely recognized communication method in most societies (Kannisto, Koivunen, & Välimäki, 2014). Mobile phones are the most commonly used type of technology globally and have the potential to positively influence health-related behavioral change and self-management of both acute and chronic conditions (Park, Howie-Esquivel, & Dracup, 2014). The use of text messaging has been advocated for people living with HIV as a means of improving health quality and preventing complications (Coomes et al., 2012). Kannisto et al. (2014) conducted a systematic literature review of studies on text message reminders. Although the evidence for text messaging application recommendations is still limited, 77% (46 out of 60) of the studies showed improved outcomes with a text messaging intervention. The outcome measures included adherence to medication or treatment, appointment attendance, appointment nonattendance, and patient satisfaction. Park, Howie-Esquival, and Dracup (2014) conducted a systematic review of text messaging and medication adherence and reported that 62% of studies revealed that text messaging was efficacious in improving medication adherence. Given the widespread use of mobile phone text message reminders among different patient groups, it may have the potential to improve adherence to medication and attendance at clinical appointments globally.

Text messaging is simple, low cost, and ubiquitous. It continues to increase as a form of communication. As noted earlier, mobile phones are often kept close to people, checked several times throughout the day. Cole-Lewis and Kershaw found that people had their phones in the room with them 90% of the time, and 50% of the time they were within arm's reach (2010). Text messaging is considered more private and less intrusive than a phone call. Pictures, video, and text can be sent. Text messaging allows for automatic contact with groups of clients without the sender having send an individual message to each intended recipient. Response may be real time or at the leisure of the recipient. Text messages are less expensive than phone calls and less prone to spam than e-mail. Texts may be stored and revisited, and all languages are supported (Hebda & Czar, 2013). However, health literacy and cultural appropriateness for diverse populations must be considered when using text messages (USDHHS, 2014).

Reminder and educational text messages have the ability to be disseminated widely and broadly, reaching mass number of recipients quickly and inexpensively (Militello, Kelley, & Melnyk, 2012). Tailored, user-friendly interventions delivered by mobile phone may be a better fit with many individuals' lifestyles than traditional treatment and an attractive option for both clinicians and patients or clients. Mobile phones have a broad range of users, diverse functions, and the ability to intercede in "real time." Text messaging can overcome barriers of time and access to reach even high-risk populations (Militello et al., 2012).

Much research in public health has found that it is possible to use text messages to help deliver health-related information and to help people manage disease (e.g., diabetes) and make better health decisions such as smoking less and exercising more. Text message

interventions promote healthy lifestyle behaviors, have become widely integrated into routine daily life, and are simple, low cost, and nonlabor intensive. Use of text messaging to deliver information about more sensitive topics, such as sexual health and reducing risky behaviors, seems promising. Opt in features, which allow choice for the recipient, can also be used (Militello et al., 2012).

Text messaging can deliver tailored, convenient, and regular reminders to assist clients with medication regimes as described with cardiac medications (Park, Howie-Esquivel, Chung, & Dracup, 2014) and those with human immunodeficiency virus (Sharma & Agarwal, 2012). For instance, daily text messages including medication reminders and education were sent for 6 weeks to adolescents and adults with atopic dermatitis. Significant improvements were noted in treatment adherence, self-care behaviors, skin severity, and quality of life (Pena-Robichaux, Kvedar, & Watson, 2010). Another study looked at acceptability of text messaging as an intervention with a cohort of African Americans who had uncontrolled hypertension (Buis, Artinian, Schwiebert, Yarandi, & Levy, 2015).

Timely administration of immunizations is a high priority in public health nursing practice. Kharbanda, Stockwell, Fox, and Rickert (2009) found that immunization reminders delivered by text message were preferred over mail or phone reminders. A later study found that parents' choice to enroll in a text message reminder-recall programs effectively promoted on-time receipt of subsequent HPV vaccine doses (Kharbanda et al., 2011). Stockwell et al. (2012) report that text messaging was effective in encouraging a change in behavior that led to higher rates of influenza vaccination. See examples of text messaging interventions and research in Table 10–3.

Table 10–3 Selected Examples of Text Messaging Interventions and Research

Innovation	Description
Text Messages to Parents Increase Influenza Immunization Rate for Low-Income, Minority Children	A series of automated text messages to predominantly low-income, Latino parents about influenza and the importance of influenza vaccines leads to a small but meaningful increase in the percentage of children vaccinated
Sexual Health Clinics Provide Most Test Results via Text Message, Leading to Faster Diagnosis and Treatment, Greater Capacity to Serve Patients	Sexual health clinics communicate most test results via text message, leading to faster diagnosis and treatment and greater clinic capacity for handling new cases.
Weekly Text Messaging Service Enhances Access to Local Clinics and Accurate Information on Sexual Health for Teens and Young Adults	Weekly text messaging service for teens and young adults enhances access to sexual health information and services and generates positive changes in behavior and knowledge.
Low-Income, Rural HIV/AIDS Patients Receive Regular Text Messages, Leading to Higher Quality of Life and Greater Engagement in Care	Low-income, African American, rural HIV patients receive regular self-written text message reminders that encourage them to regularly access HIV/AIDS primary care, leading to greater retention in care and enhanced quality of life.
Daily Text Messages and Nurse Follow-up Improve Self-Management Behaviors in Patients with Diabetes, Leading to Better Glycemic Control and Lower Costs.	Daily, automated text messages combined with nurse follow-up improved self-management behaviors among patients with diabetes, leading to significant improvements in glycemic control, fewer doctor visits, lower costs, and high patient satisfaction.
Texting Service Enhances Minority Youth Access to HIV/AIDS Information and Testing. A statewide text messaging service provides minority youth and young adults in Illinois with accurate information on HIV/AIDS and connects them to free HIV testing and related services.	A statewide text messaging service provides minority youth and young adults in Illinois with accurate information on HIV/AIDS and connects them to free HIV testing and related services.
Monthly Text Messages Increase Compliance With Recommended Blood Glucose Testing in Medicaid Managed Care Enrollees With Diabetes.	A Medicaid managed care organization uses cell phone text messaging to remind members with type 2 diabetes to get regular blood glucose testing, leading to a significant increase in the percentage of members receiving tests on a regular basis.
Regular Reminders via Text Message Increase Adherence to Medication Regimen, Significantly Reduce Risk of Organ Rejection in Pediatric Liver Transplant Patients	Regular reminders via text message enhance adherence to medication regimens and reduce risk of organ rejection in pediatric liver transplant patients.
Text Messaging Program Increases Awareness and Concern About Sexually Transmitted Diseases Among At-Risk Youth, Particularly African Americans.	SexInfo provided free basic information and referrals for in-person health consultations to at-risk youth in San Francisco via an opt-in text messaging service.
Weekly Text Messaging Service Enhances Access to Local Clinics and Accurate Information on Sexual Health for Teens and Young Adults.	Weekly text messaging service for teens and young adults enhances access to sexual health information and services and generates positive changes in behavior and knowledge.
Public Health Nurses Provide Case Management to Low-Income Women With Chronic Conditions, Leading to Improved Mental Health and Functional Status.	Public health nurses provide case management services to women with one or more chronic conditions who receive Temporary Assistance for Needy Families, leading to enhanced access to mental health services, fewer depressive symptoms, and improved functional status. Nurses used text messaging as necessary to ensure health-related needs were met.

Selected from Agency for Health Care Quality & Research (AHRQ). (n.d.). Innovations exchange: Search innovations. Retrieved from https://innovations.ahrq.gov/search/innovations/Text%20Messaging?page=1

Text messages may be used for simple reminders to have blood pressure checked or to notify individuals about an upcoming appointment or to pick up prescriptions (Nelson et al., 2013). Buchholz, Wilbur, Ingram, and Fogg (2013) conducted a systematic review of research studies on adult physical activity and a text messaging intervention. They concluded that a small group of researchers have studied text messaging as a method to promote physical activity, but that those studies show improvement in physical activity outcomes.

Text messaging is used globally to communicate, motivate individuals to engage in

healthy or healthier behaviors, deliver public health messages, and alert populations about available resources or disasters. Nurses and other clinicians use of texting may be to assist patients and caregivers with management of chronic conditions and disease prevention. Text messaging provides a venue to deliver information to hard-to-reach populations and the opportunity to have a positive influence on health knowledge, behaviors, and clinical outcomes (USDHHS, 2014). See Display 10–13.
