The fluctuations in both the heart rate and blood pressure tend to follow the changes in the newborn's behavioral state. An increase in activity, such as wakefulness, movement, or crying, corresponds to an increase in heart rate and blood pressure. In contrast, the compromised newborn demonstrates markedly less physiologic variability overall. Tachycardia may be found with volume depletion, cardiorespiratory disease, drug withdrawal, and hyperthyroidism. Bradycardia is often associated with apnea and is often seen with hypoxia.

Blood Volume

The blood volume of the newborn depends on the amount of blood transferred from the placenta at birth. It is usually estimated to be 80 to 85 mL/kg of body weight in the term infant (Blackburn, 2007). However, the volume may vary as much as 25% to 40%, depending on when clamping of the umbilical cord occurs. Early (before 30 to 40 seconds) or late (after 3 minutes) clamping of the umbilical cord changes circulatory dynamics during transition. Recent studies show the benefits of delayed cord clamping as improving the newborn's cardiopulmonary adaptation, preventing childhood anemia without increasing hypervolemia-related risks, increasing blood pressure, improving oxygen transport, and increasing red blood cell flow. Although a tailored approach is required in the case of cord clamping, the balance of available data suggests that delayed cord clamping should be the method of choice (Levy & Blickstein, 2006; Mercer et al., 2007). Further research is needed to explain the relationship among oxygen transport, red blood cell volume, and initiation of breathing, thereby indicating whether early or delayed cord clamping is beneficial.

Blood Components

Fetal red blood cells are large, but few in number. After birth, the red cell count gradually increases as the cell size decreases, because they live in an environment with much higher PO_2. A newborn's red cells have a life span of 80 to 100 days, compared to 120 days in adults.

Hemoglobin initially declines as a result of a decrease in neonatal red cell mass (physiologic anemia of infancy). Leukocytosis (elevated white blood cells) is present as a result of birth trauma soon after birth. The newborn's platelet count and aggregation ability are the same as adults.

The newborn's hematologic values are affected by the site of the blood sample (capillary blood has higher levels of hemoglobin and hematocrit compared with venous blood), placental transfusion (delayed cord clamping and normal shift of plasma to extravascular spaces, which causes higher levels of hemoglobin and hematocrit), and gestational age (increased age is associated with increased numbers of red cells and hemoglobin) (Blackburn, 2007). Table 17.2 lists normal newborn blood values.

Respiratory System Adaptations

The first breath of life is a gasp that generates an increase in transpulmonary pressure and results in diaphragmatic descent. Hypercapnia, hypoxia, and acidosis resulting from normal labor become stimuli for initiating respirations. Inspiration of air and expansion of the lungs allow for an increase in tidal volume (amount of air brought into the lungs). Surfactant is a surface tension-reducing lipoprotein found in the newborn's lungs that prevents alveolar collapse at the end of expiration and loss of lung volume. It lines the alveoli to enhance aeration of gas-free lungs, thus reducing surface tension and lowering the pressure required to open the alveoli. Normal lung function is dependent upon surfactant, which permits a decrease in

TABLE 17.2 NORMAL NEWBORN BLOOD VALUES

Lab Data	Normal Range
Hemoglobin	17–20 g/dL
Hematocrit	52%–63%
Platelets	100,000–300,000/μL
Red blood cells	5.1–5.8 (1,000,000/μL)
White blood cells	10–30,000/mm^3

surface tension at end-expiration (to prevent atelectasis) and an increase in surface tension during lung expansion (to facilitate elastic recoil on inspiration). Surfactant provides the lung stability needed for gas exchange. The newborn's first breath, in conjunction with surfactant, overcomes the surface forces to permit aeration of the lungs. The chest wall of the newborn is floppy because of the high cartilage content and poorly developed musculature. Thus, accessory muscles to help in breathing are ineffective.

One of the most crucial adaptations that the newborn makes at birth is adjusting from a fluid-filled intrauterine environment to a gaseous extrauterine environment. During fetal life, the lungs are expanded with an ultrafiltrate of the amniotic fluid. During and after birth, this fluid must be removed and replaced with air. Passage through the birth canal allows intermittent compression of the thorax, which helps eliminate the fluid in the lungs. Pulmonary capillaries and the lymphatics remove the remaining fluid.

If fluid is removed too slowly or incompletely (e.g., with decreased thoracic squeezing during birth or diminished respiratory effort), transient tachypnea (respiratory rate above 60 bpm) of the newborn occurs. Examples of situations involving decreased thoracic compression and diminished respiratory effort include cesarean birth and sedation in newborns (Kenner & Lott, 2007).

▶ *Take* NOTE!

A baby born by cesarean delivery does not have the same benefit of the birth canal squeeze as does the newborn born by vaginal delivery. Closely observe the respirations of the newborn after cesarean delivery.

Lungs

Before the newborn's lungs can maintain respiratory function, the following events must occur:

- Initiation of respiratory movement
- Expansion of the lungs
- Establishment of functional residual capacity (ability to retain some air in the lungs on expiration)
- Increased pulmonary blood flow
- Redistribution of cardiac output (McLenan, 2007)

Initial breathing is probably the result of a reflex triggered by pressure changes, noise, light, chilling, compression of the fetal chest during delivery, and high carbon dioxide and low oxygen concentrations of the newborn's blood. Many theories address the initiation of respiration in the newborn, but most are based on speculation from observations rather than on empirical research (Wheeler & McCaffrey, 2007). Research continues to search for answers to these questions.

Respirations

After respirations are established in the newborn, they are shallow and irregular, ranging from 30 to 60 breaths per minute, with short periods of apnea (less than 15 seconds). The newborn's respiratory rate varies according to his or her activity; the more active the newborn, the higher the respiratory rate, on average. Signs of respiratory distress to observe for include cyanosis, tachypnea, expiratory grunting, sternal retractions, and nasal flaring. Respirations should not be labored, and the chest movements should be symmetric. In some cases, **periodic breathing** may occur, which is the cessation of breathing that lasts 5 to 10 seconds without changes in color or heart rate (Arenson & Drake, 2007). Periodic breathing may be observed in newborns within the first few days of life and requires close monitoring.

▶ *Take* NOTE!

Apneic periods lasting more than 15 seconds with cyanosis and heart rate changes require further evaluation (Kenner & Lott, 2007).

Body Temperature Regulation

Newborns are dependent on their environment for the maintenance of body temperature, much more so immediately after birth than later in life. One of the most important elements in a newborn's survival is obtaining a stable body temperature to promote an optimal transition to extrauterine life. On average, a newborn's temperature ranges from 36.5° to37.5°C (97.9° to 99.7°F).

Thermoregulation is the process of maintaining the balance between heat loss and heat production. It is a critical physiologic function that is closely related to the transition and survival of the newborn. An appropriate thermal environment is essential for maintaining a normal body temperature. Compared with adults, newborns tolerate a narrower range of environmental temperatures and are extremely vulnerable to both under- and overheating. Nurses play a key role in providing an appropriate environment to help newborns maintain thermal stability.

▶ *Consider* THIS!

When I look down at my little miracle of life in my arms, I can't help but beam with pride at this great accomplishment. She seems so vulnerable and defenseless, and yet is equipped with everything she needs to survive at birth. When the nurse brought my daughter in for the first time after birth, I wanted to see and feel every part of her. Much to my dismay, she was

(continued)

Consider THIS! *(continued)*

wrapped up like a mummy in a blanket and she had a pink knit cap on her head. I asked the nurse why all the babies had to look like they were bound for the North Pole with all these layers on. Wasn't she aware it was summertime and probably at least 80 degrees outside?

The nurse explained that newborns lose body heat easily and need to be kept warm until their temperature stabilizes. Even though I wanted to get up close and personal with my baby, I decided to keep the pink polar bear outfit on her.

Thoughts: Newborns may be born with "everything they need to survive" on the outside, but they still experience temperature instability and lose heat through radiation, evaporation, convection, and conduction. Because the newborn's head is the largest body part, a great deal of heat can be lost if a cap is not kept on the head. What guidance can be given to this mother before discharge to stabilize her daughter's temperature while at home? What simple examples can be used to demonstrate your point?

Heat Loss

Newborns have several characteristics that predispose them to heat loss:

- Thin skin with blood vessels close to the surface
- Lack of shivering ability to produce heat involuntarily
- Limited stores of metabolic substrates (glucose, glycogen, fat)
- Limited use of voluntary muscle activity or movement to produce heat
- Large body surface area relative to body weight
- Lack of subcutaneous fat, which provides insulation
- Little ability to conserve heat by changing posture (fetal position)
- No ability to adjust their own clothing or blankets to achieve warmth
- Inability to communicate that they are too cold or too warm

Every newborn struggles to maintain body temperature from the moment of birth, when the newborn's wet body is exposed to the much cooler environment of the birthing room. The amniotic fluid covering the newborn cools as it evaporates rapidly in the low humidity and air-conditioning of the room. The newborn's temperature may decrease 3 to 5 degrees within minutes after leaving the warmth of the mother's uterus (99.6°F) (Mercer et al., 2007).

The transfer of heat depends on the temperature of the environment, air speed, and water vapor pressure or humidity. Heat exchange between the environment and the newborn involves the same mechanisms as those with any physical object and its environment. These mechanisms are conduction, convection, evaporation, and radiation. Prevention of heat loss is a key nursing intervention (Fig. 17.2).

Conduction

Conduction involves the transfer of heat from one object to another when the two objects are in direct contact with each other. Conduction refers to heat fluctuation between the newborn's body surface when in contact with other solid surfaces, such as a cold mattress, scale, or circumcision restraining board. Heat loss by conduction can also occur when touching a newborn with cold hands or when the newborn has direct contact with a colder object such as a metal scale. Using a warmed cloth diaper or blanket to cover any cold surface touching a newborn directly helps to prevent heat loss through conduction.

Convection

Convection involves the flow of heat from the body surface to cooler surrounding air or to air circulating over a body surface. An example of convection-related heat loss would be a cool breeze that flows over the newborn. To prevent heat loss by this mechanism, keep the newborn out of direct cool drafts (open doors, windows, fans, air conditioners) in the environment, work inside an isolette as much as possible and minimize opening portholes that allow cold air to flow inside, and warm any oxygen or humidified air that comes in contact with the newborn. Using clothing and blankets in isolettes is an effective means of reducing the newborn's exposed surface area and providing external insulation. Also, transporting the newborn to the nursery in a warmed isolette, rather than carrying him or her, helps to maintain warmth and reduce exposure to the cool air.

Evaporation

Evaporation involves the loss of heat when a liquid is converted to a vapor. Evaporative loss may be insensible (such as from skin and respiration) or sensible (such as from sweating). Insensible loss occurs, but the individual isn't aware of it. Sensible loss is objective and can be noticed. It depends on air speed and the absolute humidity of the air. For example, when the baby is born, the body is covered with amniotic fluid. The fluid evaporates into the air, leading to heat loss. Heat loss via evaporation also occurs when bathing a newborn. Drying newborns immediately after birth with warmed blankets and placing a cap on their head will help to prevent heat loss through evaporation. In addition, drying the newborn after bathing will help prevent heat loss through evaporation. Promptly changing wet linens, clothes, or diapers will also reduce heat loss and prevent chilling.

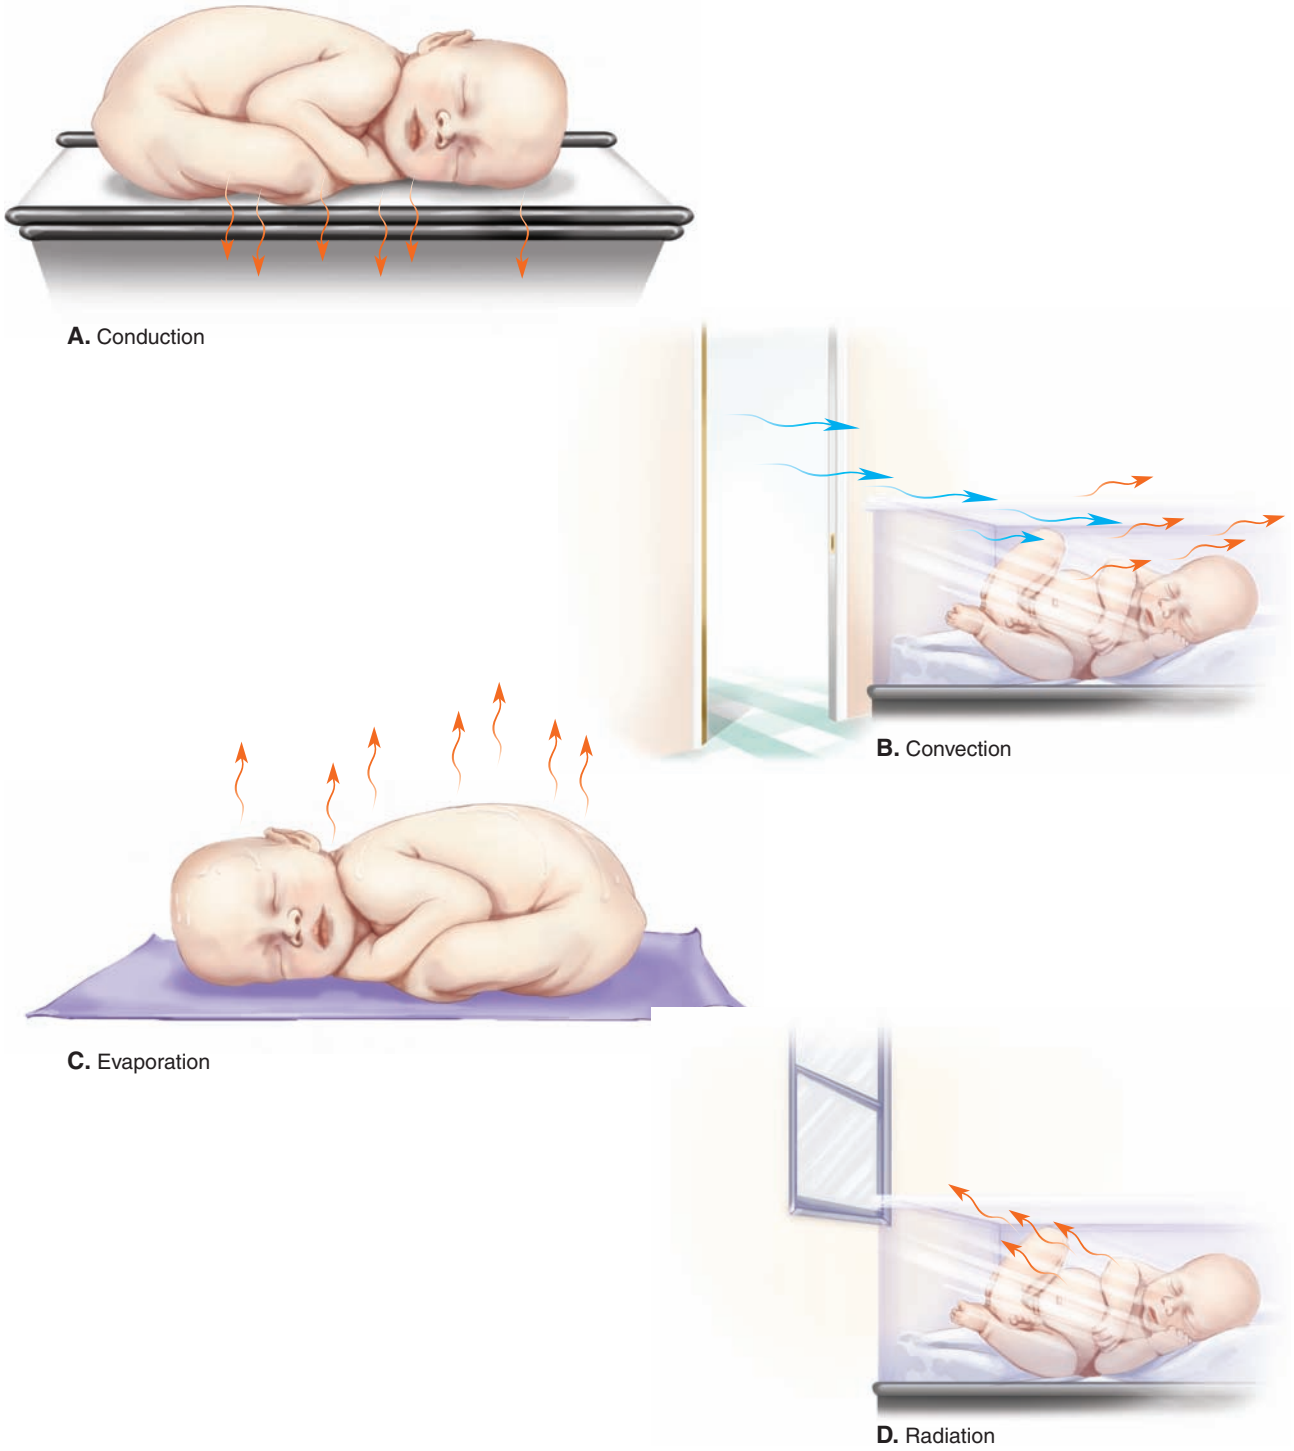

FIGURE 17.2 The four mechanisms of heat loss in the newborn. (**A**) Conduction. (**B**) Convection. (**C**) Evaporation. (**D**) Radiation.

Radiation

Radiation involves loss of body heat to cooler, solid surfaces in close proximity but not in direct contact with the newborn. The amount of heat loss depends on the size of the cold surface area, the surface temperature of the body, as well as the temperature of the receiving surface area. For example, when a newborn is placed in a single-wall isolette next to a cold window, heat loss from radiation occurs. Newborns will become cold even though they are in a heated isolette. To reduce heat loss by radiation, keep cribs and isolettes away from outside walls, cold windows, and air conditioners. Also, using radiant

warmers for transporting newborns and when performing procedures that may expose the newborn to the cooler environment will help reduce heat loss.

A warmed transporter is an enclosed isolette on wheels. A radiant warmer is an open bed with a radiant heat source above. This type of environment allows health care professionals to reach the newborn to carry out procedures and treatments (see Evidence-Based Practice 17.1).

Overheating

The newborn is also prone to overheating. Limited insulation and limited sweating ability can predispose any newborn to overheating. Control of body temperature is achieved via a complex negative feedback system that creates a balance between heat production, heat gain, and heat loss. The primary heat regulator is located in the hypothalamus and the central nervous system. The immaturity of the newborn's central nervous system makes it difficult to create and maintain this balance. Therefore, the newborn can become overheated easily. For example, an isolette that is too warm or one that is left too close to a sunny window may lead to hyperthermia. Although heat production can substantially increase in response to a cool environment, basal metabolic rate and the resultant heat produced cannot be reduced. Overheating increases fluid loss, the respiratory rate, and the metabolic rate considerably.

Thermoregulation

Thermoregulation, the balance between heat loss and heat production, is related to the newborn's rate of metabolism and oxygen consumption. The newborn attempts to conserve heat and increase heat production in the following ways: increasing the metabolic rate, increasing muscular activity through movement, increasing peripheral vasoconstriction, and assuming a fetal position to hold in heat and minimize exposed body surface area.

An environment in which body temperature is maintained without an increase in metabolic rate or oxygen use is called a **neutral thermal environment (NTE)**. Within an NTE, the rates of oxygen consumption and metabolism are minimal, and internal body temperature is maintained because of thermal balance. It promotes growth and stability and minimizes heat (energy) and water loss (McLenan, 2007). Because newborns have difficulty maintaining their body heat through shivering or other mechanisms, they need a higher environmental temperature to maintain an NTE. If the environmental temperature decreases, the newborn responds by consuming more oxygen. The respiratory rate increases (tachypnea) in re-

EVIDENCE-BASED PRACTICE 17.1
Radiant Warmers Versus Incubators for Regulating Body Temperature in Newborns

● Study

Providing a thermoneutral environment is an essential component of the immediate and longer-term care of newborn. The methods currently used include incubators and open-care systems, with or without modifications such as heat shields and plastic wrap. The system used must allow ready access to the infant while minimizing alterations in the immediate environment.

This study was performed to assess the effects of radiant warmers versus incubators on neonatal fluid and electrolyte balance, morbidity, and mortality. Eight studies were included in this review.

▲ Findings

Compared with incubators, radiant warmers caused a statistically significant increase in insensible water loss and a trend toward increased oxygen consumption that was not statistically significant. Due to small numbers, effects on important clinical outcomes could not be adequately assessed. A comparison of radiant warmers with heat shields versus incubators without heat shields showed a trend for increased insensible water loss in the radiant warmer group, but the difference was not statistically significant. No difference was shown in terms of oxygen consumption.

Further randomized controlled trials are required to assess the effects of radiant warmers versus incubators in neonatal care on important short- and long-term outcomes.

■ Nursing Implications

Preventing cold stress in newborns is essential in assisting them to make the physiologic transition to extrauterine life. This study compared two heat sources but failed to reach a clear consensus as to which was better. Nurses can apply these results in caring for newborns by making sure that fluid intake is sufficient to make up for insensible water loss when the baby is under either heat source. In addition, they can assist in future research about heat sources that support thermoregulation in the newborn.

Flenady, V. J., & Woodgate, P. G. (2007). Radiant warmers versus incubators for regulating body temperature in newborn infants. *Cochrane Database of Systematic Reviews,* 00075320-100000000-00251, Issue 4, 2007.

sponse to the increased need for oxygen. As a result, the newborn's metabolic rate increases.

The newborn's primary method of heat production is through nonshivering thermogenesis, a process in which brown fat (adipose tissue) is oxidized in response to cold exposure. Brown fat is a special kind of highly vascular fat found only in newborns. The brown coloring is derived from the fat's rich supply of blood vessels and nerve endings. These fat deposits, which are capable of intense metabolic activity—and thus generate a great deal of heat—are found between the scapulae, at the nape of the neck, in the mediastinum, and in areas surrounding the kidneys and adrenal glands. Brown fat makes up about 2% to 6% of body weight in the full-term newborn (Blackburn, 2007). When the newborn experiences a cold environment, the release of norepinephrine increases, which in turn stimulates brown fat metabolism by the breakdown of triglycerides. Cardiac output increases, increasing blood flow through the brown fat tissue. Subsequently, this blood becomes warmed as a result of the increased metabolic activity of the brown fat.

Newborns can experience heat loss through all four mechanisms, ultimately resulting in cold stress. **Cold stress** is excessive heat loss that requires a newborn to use compensatory mechanisms (such as nonshivering thermogenesis and tachypnea) to maintain core body temperature (Cinar & Filiz, 2006). The consequences of cold stress can be quite severe. As the body temperature decreases, the newborn becomes less active, lethargic, hypotonic, and weaker. All newborns are at risk for cold stress, particularly within the first 12 hours of life. However, preterm newborns are at the greatest risk for cold stress and experience more profound effects than full-term newborns because they have less fat stores, poorer vasomotor responses, and less insulation to cope with a hypothermic event.

Cold stress in the newborn can lead to the following problems if not reversed: depleted brown fat stores, increased oxygen needs, respiratory distress, increased glucose consumption leading to hypoglycemia, metabolic acidosis, jaundice, hypoxia, and decreased surfactant production (McLenan, 2007).

▶ *Take* NOTE!

Nurses must be aware of the thermoregulatory needs of the newborn and must ensure that these needs are met to provide the newborn with the best start possible.

To minimize the effects of cold stress and maintain an NTE, the following interventions are helpful:

- Prewarming blankets and hats to reduce heat loss through conduction
- Keeping the infant transporter (warmed isolette) fully charged and heated at all times
- Drying the newborn completely after birth to prevent heat loss from evaporation
- Encouraging skin-to-skin contact with the mother if the newborn is stable
- Promoting early breastfeeding to provide fuels for nonshivering thermogenesis
- Using heated and humidified oxygen
- Always using radiant warmers and double-wall isolettes to prevent heat loss from radiation
- Deferring bathing until the newborn is medically stable, and using a radiant heat source while bathing (Fig. 17.3)
- Avoiding the placement of a skin temperature probe over a bony area or one with brown fat, because it does not give an accurate assessment of the whole body temperature (most temperature probes are placed over the liver when the newborn is supine or side-lying)

Hepatic System Function

At birth, the newborn's liver assumes the functions that the placenta handled during fetal life. These functions include

FIGURE 17.3 Bathing a newborn under a radiant warmer to prevent heat loss.

iron storage, carbohydrate metabolism, blood coagulation, and conjugation of bilirubin.

Iron Storage

As red blood cells are destroyed after birth, the iron is released and is stored by the liver until new red cells need to be produced. Newborn iron stores are determined by total body hemoglobin content and length of gestation. At birth, the term newborn has iron stores sufficient to last approximately 4 to 6 months (Garfunkel, Kaczorowski, & Christy, 2007).

Carbohydrate Metabolism

When the placenta is lost at birth, the maternal glucose supply is cut off. Initially, the newborn's serum glucose levels decline. Usually, a term newborn's blood glucose level is 70% to 80% of the maternal blood glucose level (Kenner & Lott, 2007).

Glucose is the main source of energy for the first several hours after birth. With the newborn's increased energy needs after birth, the liver releases glucose from glycogen stores for the first 24 hours. Initiating feedings helps to stabilize the newborn's blood glucose levels. Typically a newborn's blood glucose levels are assessed using a heel stick sample of blood on admission to the nursery and again at approximately 4 hours of age.

Bilirubin Conjugation

The liver is also responsible for the conjugation of bilirubin—a yellow to orange bile pigment produced by the breakdown of red blood cells. In utero, elimination of bilirubin in the blood is handled by the placenta and the mother's liver. However, once the cord is cut, the newborn must now assume this function.

Bilirubin normally circulates in plasma, is taken up by liver cells, and is changed to a water-soluble pigment that is excreted in the bile. This conjugated form of bilirubin is excreted from liver cells as a constituent of bile.

The principal source of bilirubin in the newborn is the hemolysis of erythrocytes. This is a normal occurrence after birth, when fewer red blood cells are needed to maintain extrauterine life.

When red blood cells die after approximately 80 days of life, the heme in their hemoglobin is converted to bilirubin. Bilirubin is released in an unconjugated form called indirect bilirubin, which is fat-soluble. Enzymes, proteins, and different cells in the reticuloendothelial system and liver process the unconjugated bilirubin into conjugated bilirubin or direct bilirubin. This form is water-soluble and now enters the gastrointestinal system via the bile and is eventually excreted through feces. The kidneys also excrete a small amount.

Newborns produce bilirubin at a rate of approximately 6 to 8 mg/kg/day. This is more than twice the production rate in adults, primarily because of relative polycythemia and increased red blood cell turnover. Bilirubin production typically declines to the adult level within 10 to 14 days after birth (Maisels, 2006). In addition, the metabolic pathways of the liver are relatively immature and thus cannot conjugate bilirubin as quickly as needed.

Failure of the liver cells to break down and excrete bilirubin can cause an increased amount of bilirubin in the bloodstream, leading to jaundice (Stokowski, 2006). Bilirubin is toxic to the body and must be excreted. Blood tests ordered to determine bilirubin levels measure bilirubin in the serum. Total bilirubin is a combination of indirect (unconjugated) and direct (conjugated) bilirubin.

When unconjugated bilirubin pigment is deposited in the skin and mucous membranes, jaundice typically results. **Jaundice**, also known as icterus, refers to the yellowing of the skin, sclera, and mucous membranes that results from increased bilirubin blood levels. Visible jaundice as a result of increased blood bilirubin levels occurs in more than half of all healthy newborns. Even in healthy term newborns, extremely elevated blood levels of bilirubin during the first week of life can cause kernicterus, a permanent and devastating form of brain damage (W. R. Hansen, 2007).

Common risk factors for the development of jaundice include fetal–maternal blood group incompatibility, prematurity, breastfeeding, drugs (such as diazepam [Valium], oxytocin [Pitocin], sulfisoxazole/erythromycin [Pediazole], and chloramphenicol [Chloromycetin]), maternal gestational diabetes, infrequent feedings, male gender, trauma during birth resulting in cephalhematoma, cutaneous bruising, polycythemia, previous sibling with hyperbilirubinemia, infections such as TORCH (toxoplasmosis, other viruses, rubella, cytomegalovirus, herpes simplex viruses), and ethnicity such as Asian or Native American (W. R. Hansen, 2007).

The causes of newborn jaundice can be classified into three groups based on the mechanism of accumulation:

1. Bilirubin overproduction, such as from blood incompatibility (Rh or ABO), drugs, trauma at birth, polycythemia, delayed cord clamping, and breast milk jaundice
2. Decreased bilirubin conjugation, as seen in physiologic jaundice, hypothyroidism, and breastfeeding
3. Impaired bilirubin excretion, as seen in biliary obstruction (biliary atresia, gallstones, neoplasm), sepsis, chromosomal abnormality (Turner syndrome, trisomy 18 and 21), and drugs (aspirin, acetaminophen, sulfa, alcohol, steroids, antibiotics) (Stokowski, 2006)

Jaundice in the newborn is discussed in more detail in Chapter 24.

Gastrointestinal System Adaptations

The full-term newborn has the capacity to swallow, digest, metabolize, and absorb food taken in soon after birth. At birth, the pH of the stomach contents is mildly

acidic, reflecting the pH of the amniotic fluid. The once-sterile gut changes rapidly, depending on what feeding is received.

Mucosal Barrier Protection

An important adaptation of the gastrointestinal system is the development of a mucosal barrier to prevent the penetration of harmful substances (bacteria, toxins, and antigens) present within the intestinal lumen. At birth, the newborn must be prepared to deal with bacterial colonization of the gut. Colonization is dependent on oral intake. It usually occurs within 24 hours of age and is required for the production of vitamin K (Kenner & Lott, 2007). If harmful substances are allowed to penetrate the mucosal epithelial barrier under pathologic conditions, they can cause inflammatory and allergic reactions (Blackburn, 2007).

▶ *Take* NOTE!

Human breast milk provides a passive mechanism to protect the newborn against the dangers of a deficient intestinal defense system. It contains antibodies, viable leukocytes, and many other substances that can interfere with bacterial colonization and prevent harmful penetration.

Stomach and Digestion

The stomach of the newborn has a capacity ranging from 30 to 90 mL, with a variable emptying time of 2 to 4 hours. The cardiac sphincter and nervous control of the stomach is immature, which may lead to uncoordinated peristaltic activity and frequent regurgitation. Immaturity of the pharyngoesophageal sphincter and absence of lower esophageal peristaltic waves also contribute to the reflux of gastric contents. Avoiding overfeeding and stimulating frequent burping may minimize regurgitation. Most digestive enzymes are available at birth, allowing newborns to digest simple carbohydrates and protein. However, they have limited ability to digest complex carbohydrates and fats, because amylase and lipase levels are low at birth. As a result, newborns excrete a fair amount of lipids, resulting in fatty stools.

Adequate digestion and absorption are essential for newborn growth and development. Normally, term newborns lose 5% to 10% of their birthweight as a result of insufficient caloric intake within the first week after birth, shifting of intracellular water to extracellular space, and insensible water loss. To gain weight, the term newborn requires an intake of 108 kcal/kg/day from birth to 6 months of age (Begany & Mascarenhas, 2007).

Bowel Elimination

The frequency, consistency, and type of stool passed by newborns vary widely. The evolution of a stool pattern begins with a newborn's first stool, which is meconium. **Meconium** is composed of amniotic fluid, shed mucosal cells, intestinal secretions, and blood. It is greenish black, has a tarry consistency, and is usually passed within 12 to 24 hours of birth. The first meconium stool passed is sterile, but this changes rapidly with ingestion of bacteria through feedings. After feedings are initiated, a transitional stool develops, which is greenish brown to yellowish brown, thinner in consistency, and seedy in appearance.

▶ *Take* NOTE!

Newborns who are fed early pass stools sooner, which helps to reduce bilirubin buildup.

The last development in the stool pattern is the milk stool. The characteristics differ in breast-fed and formula-fed newborns. The stools of the breast-fed newborn are yellow-gold, loose and stringy to pasty in consistency, and typically sour-smelling. The stools of the formula-fed newborn vary depending on the type of formula ingested. They may be yellow, yellow-green, or greenish and loose, pasty, or formed in consistency, and they have an unpleasant odor.

Renal System Changes

The majority of term newborns void immediately after birth, indicating adequate renal function. Although the newborn's kidneys can produce urine, they are limited in their ability to concentrate it until about 3 months of age, when the kidneys mature. Until that time, a newborn voids frequently and the urine has a low specific gravity (1.001 to 1.020). About six to eight voidings daily is average for most newborns; this indicates adequate fluid intake (Arenson & Drake, 2007).

The renal cortex is relatively underdeveloped at birth and does not reach maturity until 12 to 18 months of age. At birth, the glomerular filtration rate (GFR) is approximately 30% of normal adult values, reaching approximately 50% of normal adult values by the 10th day of life and full adult values by the first year of life (Blackburn, 2007). The low GFR and the limited excretion and conservation capability of the kidney affect the newborn's ability to excrete salt, water loads, and drugs.

▶ *Take* NOTE!

The possibility of fluid overload is increased in newborns; keep this in mind when administering intravenous therapy to a newborn.

Immune System Adaptations

Essential to the newborn's survival is the ability to respond effectively to hostile environmental forces. The newborn's immune system begins working early in gestation, but many of the responses do not function adequately during the early neonatal period. The intrauterine environment usually protects the fetus from harmful microorganisms and the need for defensive immunologic responses. With exposure to a wide variety of microorganisms at birth, the newborn must develop a balance between its host defenses and the hostile environmental organisms to ensure a safe transition to the outside world.

Responses of the immune system serve three purposes: defense (protection from invading organisms), homeostasis (elimination of worn-out host cells), and surveillance (recognition and removal of enemy cells). The newborn's immune system response involves recognition of the pathogen or other foreign material, followed by activation of mechanisms to react against and eliminate it. All immune responses primarily involve leukocytes (white blood cells).

The immune system's responses can be divided into two categories: natural and acquired immunity. These mechanisms are interrelated and interdependent; both are required for immunocompetency.

Natural Immunity

Natural immunity includes responses or mechanisms that do not require previous exposure to the microorganism or antigen to operate efficiently. Physical barriers (such as intact skin and mucous membranes), chemical barriers (such as gastric acids and digestive enzymes), and resident nonpathologic organisms make up the newborn's natural immune system. Natural immunity involves the most basic host defense responses: ingestion and killing of microorganisms by phagocytic cells.

Acquired Immunity

Acquired immunity involves two primary processes: (1) the development of circulating antibodies or immunoglobulins capable of targeting specific invading agents (antigens) for destruction and (2) formation of activated lymphocytes designed to destroy foreign invaders. Acquired immunity is absent until after the first invasion by a foreign organism or toxin.

Immunoglobulins are subdivided into five classes: IgA, IgD, IgE, IgG, and IgM. The newborn depends largely on three immunoglobulins for defense mechanisms: IgG, IgA, and IgM.

IgG is the major immunoglobulin and the most abundant, making up about 80% of all circulating antibodies (Blackburn, 2007). It is found in serum and interstitial fluid. It is the only class able to cross the placenta, with active placental transfer beginning at approximately 20 to 22 weeks' gestation. IgG produces antibodies against bacteria, bacterial toxins, and viral agents.

IgA is the second most abundant immunoglobulin in the serum. IgA does not cross the placenta, and maximum levels are reached during childhood. This immunoglobulin is believed to protect mucous membranes from viruses and bacteria. IgA is predominantly found in the gastrointestinal and respiratory tracts, tears, saliva, colostrum, and breast milk.

▶ *Take* NOTE!

A major source of IgA is human breast milk, so breastfeeding is believed to have significant immunologic advantages over formula feeding (Blackburn, 2007).

IgM is found in blood and lymph fluid and is the first immunoglobulin to respond to infection. It does not cross the placenta, and levels are generally low at birth unless there is a congenital intrauterine infection. IgM offers a major source of protection from blood-borne infections. The predominant antibodies formed during neonatal or intrauterine infection are of this class.

Integumentary System Adaptations

The most important function of the skin is to provide a protective barrier between the body and the environment. It limits the loss of water, prevents absorption of harmful agents, protects thermoregulation and fat storage, and protects against physical trauma. The epidermal barrier begins to develop during mid-gestation and is fully formed by about 32 weeks' gestation. Although the neonatal epidermis is similar to the adult epidermis in thickness and lipid composition, skin development is not complete at birth (Hale, 2007). Although the basic structure is the same as that of an adult, the less mature the newborn, the less mature the skin functions. Fewer fibrils connect the dermis and epidermis in the newborn compared with the adult. Also in a newborn, the risk of injury producing a break in the skin from tape, monitors, and handling is greater than for an adult. In addition, sweat glands are present at birth, but full adult functioning is not present until the second or third year of life (Blackburn, 2007). Exposure to air after birth accelerates epidermal development in all newborns (Hale, 2007).

Newborns vary greatly in appearance. Many of the variations are temporary and reflect the physiologic adaptations that the newborn is experiencing. Skin coloring varies, depending on the newborn's age, race or ethnic group, temperature, and whether he or she is crying. Skin color changes with both the environment and health sta-

tus. At birth, the newborn's skin is dark red to purple. As the newborn begins to breathe air, the skin color changes to red. This redness normally begins to fade the first day.

Neurologic System Adaptations

The nervous system consists of the brain, spinal cord, 12 cranial nerves, and a variety of spinal nerves that come from the spinal cord. Neurologic development follows cephalocaudal (head to toe) and proximal–distal (center to outside) patterns. Myelin develops early on in sensory impulse transmitters. Thus, the newborn has an acute sense of hearing, smell, and taste. The newborn's sensory capabilities include:

- Hearing—well developed at birth, responds to noise by turning to sound
- Taste—ability to distinguish between sweet and sour by 72 hours old
- Smell—ability to distinguish between mother's breast milk and breast milk from others
- Touch—sensitivity to pain, responds to tactile stimuli
- Vision—ability to focus on objects only in close proximity (7–12 inches away); tracks objects in midline or beyond (90 inches); this is the least mature sense at birth (McLenan, 2007)

Remember Maria, the new mother who is worried that her daughter can't see? What might the new mother notice about her daughter's behavior? What might be the new mother's expectations?

Successful adaptations demonstrated by the respiratory, circulatory, thermoregulatory, and musculoskeletal systems indirectly indicate the central nervous system's successful transition from fetal to extrauterine life, because it plays a major role in all these adaptations. In the newborn, congenital reflexes are the hallmarks of maturity of the central nervous system, viability, and adaptation to extrauterine life.

The presence and strength of a reflex is an important indication of neurologic development and function. A **reflex** is an involuntary muscular response to a sensory stimulus. It is built into the nervous system and does not need the intervention of conscious thought to take effect (Arenson & Drake, 2007). Many neonatal reflexes disappear with maturation, although some remain throughout adulthood.

The arcs of these reflexes end at different levels of the spine and brain stem, reflecting the function of the cranial nerves and motor systems. The way newborns blink, move their limbs, focus on a caretaker's face, turn toward sound, suck, swallow, and respond to the environment are all indications of their neurologic abilities. Congenital defects within the central nervous system are frequently not overt but may be revealed in abnormalities in tone, posture, or behavior (Kenner & Lott, 2007). Damage to the nervous system (birth trauma, perinatal hypoxia) during the birthing process can cause delays in the normal growth, development, and functioning of the newborn. Early identification may help to identify the cause and to start early intervention to decrease long-term complications or permanent sequelae.

Newborn reflexes are assessed to evaluate neurologic function and development. Absent or abnormal reflexes in a newborn, persistence of a reflex past the age when it is normally lost, or redevelopment of an infantile reflex in an older child or adult may indicate neurologic pathology. (See Chapter 18 for a description of newborn reflex assessment.)

The Healthy Start nurse explained to Maria that all newborns are born with some degree of myopia (can't see distances) and that 20/20 vision isn't generally achieved until 2 years of age. What developmental information should the nurse discuss with Maria?

Behavioral Adaptations

In addition to adapting physiologically, the newborn also adapts behaviorally. All newborns progress through a specific pattern of events after birth, regardless of their gestational age or the type of birth they experienced.

Behavioral Patterns

The newborn usually demonstrates a predictable pattern of behavior during the first several hours after birth, characterized by two periods of reactivity separated by a sleep phase. Behavioral adaptation is a defined progression of events triggered by stimuli from the extrauterine environment after birth.

First Period of Reactivity

The first period of reactivity begins at birth and lasts for 30 minutes. The newborn is alert and moving and may appear hungry. This period is characterized by myoclonic movements of the eyes, spontaneous Moro reflexes, sucking motions, chewing, rooting, and fine tremors of the extremities (Dabrowski, 2007). Respiration and heart rate are elevated but gradually begin to slow as the next period begins.

This period of alertness allows parents to interact with their newborn and to enjoy close contact with their new baby (Fig. 17.4). The appearance of sucking and rooting behaviors provides a good opportunity for initiating breastfeeding. Many newborns latch on the nipple and suck well at this first experience.

FIGURE 17.4 The first period of reactivity is an optimal time for interaction.

FIGURE 17.5 Newborn during the second period of reactivity. Note the newborn's wide-eyed interest.

Period of Deceased Responsiveness

At 30 to 120 minutes of age, the newborn enters the second stage of transition—that of sleep or a decrease in activity. This phase is referred to as a period of decreased responsiveness. Movements are less jerky and less frequent. Heart and respiratory rates decline as the newborn enters the sleep phase. The muscles become relaxed, and responsiveness to outside stimuli diminishes. During this phase, it is difficult to arouse or interact with the newborn. No interest in sucking is shown. This quiet time can be used for both mother and newborn to remain close and rest together after labor and the birthing experience.

Second Period of Reactivity

The second period of reactivity begins as the newborn awakens and shows an interest in environmental stimuli. This period lasts 2 to 8 hours in the normal newborn (Vandenberg, 2007). Heart and respiratory rates increase. Peristalsis also increases. Thus, it is not uncommon for the newborn to pass meconium during this period. In addition, motor activity and muscle tone increase in conjunction with an increase in muscular coordination (Fig. 17.5).

Interaction between the mother and the newborn during this second period of reactivity is encouraged if the mother has rested and desires it. This period also provides a good opportunity for the parents to examine their newborn and ask questions.

▶ *Take* NOTE!

Teaching about feeding, positioning for feeding, and diaper-changing techniques can be reinforced during this time.

Newborn Behavioral Responses

Newborns demonstrate several predictable responses when interacting with their environment. How they react to the world around them is termed a **neurobehavioral response**. It comprises predictable periods that are probably triggered by external stimuli.

Expected newborn behaviors include orientation, habituation, motor maturity, self-quieting ability, and social behaviors. Any deviation in behavioral responses requires further assessment, because it may indicate a complex neurobehavioral problem.

Orientation

The response of newborns to stimuli is called orientation. They become more alert when they sense a new stimulus in their environment. Orientation reflects newborns' response to auditory and visual stimuli, demonstrated by their movement of head and eyes to focus on that stimulus. Newborns prefer the human face and bright shiny objects. As the face or object comes into their line of vision, newborns respond by staring at the object intently. Newborns use this sensory capacity to become familiar with people and objects in their surroundings.

Remember Maria, who was concerned about her newborn daughter's vision? She told the nurse that her daughter didn't show any interest in her pastel-colored homemade mobile she had hung across the room from her crib. What suggestions can the nurse make to Maria regarding the placement of the mobile and the types and colors of objects used to promote orientation in her newborn daughter?

Habituation

Habituation is the newborn's ability to process and respond to visual and auditory stimuli—that is, how well

and appropriately he or she responds to the environment. Habituation is the ability to block out external stimuli after the newborn has become accustomed to the activity. During the first 24 hours after birth, newborns should increase their ability to habituate to environmental stimuli and sleep. Habituation provides a useful indicator of their neurobehavioral intactness.

Motor Maturity

Motor maturity depends on gestational age and involves evaluation of posture, tone, coordination, and movements. These activities enable newborns to control and coordinate movement. When stimulated, newborns with good motor organization demonstrate movements that are rhythmic and spontaneous. Bringing the hand up to the mouth is an example of good motor organization. As newborns adapt to their new environment, smoother movements should be observed. Such motor behavior is a good indicator of the newborn's ability to respond and adapt accordingly—that is, process stimuli appropriately by the central nervous system.

Self-Quieting Ability

Self-quieting ability refers to newborns' ability to quiet and comfort themselves. Newborns vary in their ability to console themselves or to be consoled. "Consolability" is how newborns are able to change from the crying state to an active alert, quiet alert, drowsy, or sleep state. They console themselves by hand-to-mouth movements and sucking, alerting to external stimuli and motor activity (Arenson & Drake, 2007). Assisting parents to identify consoling behaviors to quiet their newborn if the newborn is not able to self-quiet is important. These behaviors include rocking, holding, gently patting, and softly singing to them.

Social Behaviors

Social behaviors include cuddling and snuggling into the arms of the parent when the newborn is held. Usually newborns are very sensitive to being touched, cuddled, and held. Cuddliness is very important to parents, because they frequently gauge their ability to care for their newborn by the newborn's acceptance or positive response to their actions. This can be assessed by the degree to which the newborn nestles into the contours of the holder's arms. Most newborns cuddle, but some will resist. Assisting parents to assume comforting behaviors (e.g., by cooing while holding their newborn) and praising them for their efforts can help foster cuddling behaviors.

Key Concepts

- The neonatal period is defined as the first 28 days of life. As the newborn adapts to life after birth, numerous physiologic changes occur.
- At birth, the cardiopulmonary system must switch from fetal to neonatal circulation and from placental to pulmonary gas exchange.
- One of the most crucial adaptations that the newborn makes at birth is the adjustment of a fluid medium exchange from the placenta to the lungs and that of a gaseous environment.
- Neonatal RBCs have a life span of 80 to 100 days in comparison with the adult RBC life span of 120 days, which causes several adjustment problems.
- Thermoregulation is the maintenance of balance between heat loss and heat production. It is a critical physiologic function that is closely related to the transition and survival of the newborn.
- The newborn's primary method of heat production is through nonshivering thermogenesis, a process in which brown fat (adipose tissue) is oxidized in response to cold exposure. Brown fat is a special kind of highly vascular fat found only in newborns.
- Heat loss in the newborn is the result of four mechanisms: conduction, convection, evaporation, and radiation.
- Responses of the immune system serve three purposes: defense (protection from invading organisms), homeostasis (elimination of worn-out host cells), and surveillance (recognition and removal of enemy cells).
- In the newborn, congenital reflexes are the hallmarks of maturity of the central nervous system, viability, and adaptation to extrauterine life.
- The newborn usually demonstrates a predictable pattern of behavior during the first several hours after birth, characterized by two periods of reactivity separated by a sleep phase.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. When assessing the term newborn, the following are observed: newborn is alert, heart and respiratory rates have stabilized, and meconium has been passed. The nurse determines that the newborn is exhibiting behaviors indicating:
   a. Initial period of reactivity
   b. Second period of reactivity
   c. Decreased responsiveness period
   d. Period of sleep
2. When caring for a newborn, the nurse ensures that the doors of the nursery are closed and minimizes opening of the isolette portholes to prevent heat loss via which mechanism?
   a. Conduction
   b. Evaporation
   c. Convection
   d. Radiation
3. After teaching a group of nursing students about thermoregulation and appropriate measures to prevent heat loss by evaporation, which of the following student behaviors would indicate successful teaching?
   a. Transporting the newborn in an isolette
   b. Maintaining a warm room temperature
   c. Placing the newborn on a warmed surface
   d. Drying the newborn immediately after birth
4. After birth, the nurse would expect which fetal structure to close as a result of increases in the pressure gradients on the left side of the heart?
   a. Foramen ovale
   b. Ductus arteriosus
   c. Ductus venosus
   d. Umbilical vein
5. Which of the following newborns could be described as breathing normally?
   a. Newborn A is breathing deeply, with a regular rhythm, at a rate of 20 bpm
   b. Newborn B is breathing diaphragmatically with sternal retractions, at a rate of 70 bpm
   c. Newborn C is breathing shallowly, with 40-second periods of apnea and cyanosis
   d. Newborn D is breathing shallowly, at a rate of 36 bpm, with short periods of apnea
6. When assessing a term newborn (6 hours old), the nurse auscultates bowel sounds and documents recent passing of meconium. These findings would indicate:
   a. Abnormal gastrointestinal newborn transition and need to be reported
   b. An intestinal anomaly that needs immediate surgery
   c. A patent anus with no bowel obstruction and normal peristalsis
   d. A malabsorption syndrome resulting in fatty stools

CRITICAL THINKING EXERCISES

1. As the nurse manager, you have been orienting a new nurse in the nursery for the past few weeks. Although she has been demonstrating adequacy with most procedures, today you observe her bathing several newborns without covering them, weighing them on the scale without a cover, leaving the storage door open with the transporter nearby, and leaving the newborns' head covers and blankets off after showing them to family members through the nursery observation window.
   a. What is your impression of this behavior?
   b. What principles concerning thermoregulation need to be reinforced?
   c. How will you evaluate whether your instructions have been effective?
2. The most important adaptations for the newborn to make after birth are to establish respirations, make cardiovascular adjustments, and establish thermoregulation. Nursing care focuses on monitoring and supporting adjustments to extrauterine adaptation. Write appropriate nursing intervention to help achieve the following newborn adaptations:
   a. Respiratory adaptation
   b. Safety, including prevention of infection
   c. Thermoregulation

Study Activities

1. While in the nursery clinical setting, identify the period of behavioral reactivity (first, inactivity, or second period) for two newborns born at different times. Share your findings in post-conference that clinical day.
2. Obtain a set of vital signs (temperature, pulse, respiration) of a newborn on admission to the nursery. Repeat this procedure and compare changes in the values several hours later. Discuss what changes in the vital signs you would expect during this transitional period.
3. Find two websites about transition to extrauterine life that can be shared with other nursing students as well as nursery nurses. Critique the information presented in terms of how accurate and current it is.
4. The most common mechanism of heat loss in the newborn is _____.

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Define the key terms.
2. Discuss the assessments performed during the immediate newborn period.
3. Select interventions that meet the immediate needs of the term newborn.
4. List the components of a typical physical examination of a newborn.
5. Identify common variations that can be noted during a newborn's physical examination.
6. List common concerns in the newborn and appropriate interventions.
7. Compare the importance of the newborn screening tests.
8. Explain common interventions that are appropriate during the early newborn period.
9. Discuss the nurse's role in meeting the newborn's nutritional needs.
10. Outline discharge planning content and education needed for the family with a newborn.

Kelly, a 16-year-old first-time mother, calls the hospital maternity unit 3 days after being discharged home. She tells the nurse that her newborn son "looks like a canary" and "isn't nursing well." She wonders what is wrong.

Wow

You can send a more powerful message with your actions and behavior than with words alone.

Immediately after the birth of a newborn, all parents are faced with the task of learning and understanding as much as possible about caring for this new family member, even if the parents already have other children. In their new or expanded role as parents, they will face many demands and challenges. For most, this is a wonderful, exciting time filled with many discoveries and much information.

Parents learn as they watch the nurse interacting with their newborn. Nurses play a major role in teaching parents about normal newborn characteristics and about ways to foster optimal growth and development. This role is even more important today because of limited hospital stays.

The newborn has come from a dark, small, enclosed space in the mother's uterus into the bright, cold extrauterine environment. Nurses can easily forget that they are caring for a small human being who is experiencing his or her first taste of human interaction outside the uterus. The newborn period is an extremely important one, and two National Health Goals have been developed to address this critical period.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of mothers who breast-feed their babies during the early postpartum period from a baseline of 64% to 75%.	• Will emphasize the importance of breast milk as the most complete form of nutrition for infants • Will help to promote infant health, growth, immunity, and development throughout the newborn and infant periods • Will help to foster early detection and prompt treatment for conditions, thereby lessening the incidence of illness, disability, and death associated with these conditions and their overall effects on the newborn, infant, and family
Increase the proportion of mothers who breast-feed at 6 months from a baseline of 29% to 50%.	
Increase the proportion of mothers who breast-feed at 1 year from a baseline of 16% to 25%.	
Ensure appropriate newborn bloodspot screening, newborn hearing screening, follow-up testing, and referral services.	
Ensure that all newborns are screened at birth for conditions mandated by their state-sponsored newborn screening programs.	
Ensure that follow-up diagnostic testing for screening positives is performed within an appropriate time period.	

Source: U.S. DHHS, 2000.

It is also easy to overlook the intensity with which parents and visitors observe the actions of nurses as they care for the new family member. Nurses need to serve as a model for giving nurturing care to newborns.

This chapter provides information about assessment and interventions in the period immediately following the birth of a newborn and during the early newborn period.

Nursing Management During the Immediate Newborn Period

The period of transition from intrauterine to extrauterine life occurs during the first several hours after birth. During this time, the newborn is undergoing numerous adaptations, many of which are occurring simultaneously (see Chap. 17 for more information on the newborn's adaptation). The neonate's temperature, respiration, and cardiovascular dynamics stabilize during this period. Close observation of the newborn's status is essential. Careful examination of the newborn at birth can detect anomalies, birth injuries, and disorders that can compromise adaptation to extrauterine life. Problems that occur during this critical time can have a lifelong impact.

Assessment

The initial newborn assessment is completed in the birthing area to determine whether the newborn is stable enough to stay with the parents or whether resuscitation or immediate interventions are necessary. A second assessment is done within the first 2 to 4 hours, when the newborn is admitted to the nursery. A third assessment is completed before discharge. The purpose of these assessments is to determine whether the baby is normal, to provide information to the parents, and to identify apparent physical abnormalities (Arenson & Drake, 2007).

During the initial newborn assessment, look for signs that might indicate a problem, including:

- Nasal flaring
- Chest retractions
- Grunting on exhalation
- Labored breathing
- Generalized cyanosis
- Abnormal breath sounds: rhonchi, crackles (rales), wheezing, stridor
- Abnormal respiratory rates (tachypnea, more than 60 breaths/minute; bradypnea, less than 25 breaths/minute)
- Flaccid body posture
- Abnormal heart rates (tachycardia, more than 160 bpm; bradycardia, less than 100 bpm)
- Abnormal newborn size: small or large for gestational age

If any of these findings are noted, medical intervention may be necessary.

Apgar Scoring

The **Apgar score**, introduced in 1952 by Dr. Virginia Apgar, is used to evaluate newborns at 1 minute and 5 minutes after birth. An additional Apgar assessment is done at 10 minutes if the 5-minute score is less than 7 points (Keenan, 2006). Assessment of the newborn at 1 minute provides data about the newborn's initial adaptation to extrauterine life. Assessment at 5 minutes provides a clearer indication of the newborn's overall central nervous system status.

Five parameters are assessed with Apgar scoring. A quick way to remember the parameters of Apgar scoring is as follows:

- A = appearance (color)
- P = pulse (heart rate)
- G = grimace (reflex irritability)
- A = activity (muscle tone)
- R = respiratory (respiratory effort)

Each parameter is assigned a score ranging from 0 to 2 points. A score of 0 points indicates an absent or poor response; a score of 2 points indicates a normal response (Table 18.1). A normal newborn's score should be 8 to 10 points. The higher the score, the better the condition of the newborn. If the Apgar score is 8 points or higher, no intervention is needed other than supporting normal respiratory efforts and maintaining thermoregulation. Scores of 4 to 7 points signify moderate difficulty and scores of 0 to 3 points represent severe distress in adjusting to extrauterine life. The Apgar score is influenced by the presence of infection, congenital anomalies, physiologic immaturity, maternal sedation via medications, and neuromuscular disorders (Keenan, 2006).

When the newborn experiences physiologic depression, the Apgar score characteristics disappear in a predictable manner: first the pink coloration is lost, next the respiratory effort, and then the tone, followed by reflex irritability and finally heart rate (Kenner & Lott, 2007).

▶ *Take* NOTE!

Although Apgar scoring is done at 1 and 5 minutes, it also can be used as a guide during the immediate newborn period to evaluate the newborn's status for any changes because it focuses on critical parameters that must be assessed throughout the early transition period.

Length and Weight

Parents are eager to know their newborn's length and weight. These measurements are taken soon after birth. A disposable tape measure or a built-in measurement board located on the side of the scale can be used. Length is measured from the head of the newborn to the heel with the newborn unclothed (Fig. 18.1). Because of the flexed position of the newborn after birth, place the newborn in a supine position and extend the leg completely when measuring the length. The expected length of a full-term newborn is usually 48 to 53 cm (19 to 21 inches). Molding can affect measurement (Dillon, 2007).

TABLE 18.1 APGAR SCORING FOR NEWBORNS

Parameter (Assessment Technique)	0 Point	1 Point	2 Points
Heart rate (auscultation of apical heart rate for 1 full minute)	Absent	Slow (<100 bpm)	>100 bpm
Respiratory effort (observation of the volume and vigor of the newborn's cry; auscultation of depth and rate of respirations)	Apneic	Slow, irregular, shallow	Regular respirations (usually 30–60 breaths/minute), strong, good cry
Muscle tone (observation of extent of flexion in the newborn's extremities and newborn's resistance when the extremities are pulled away from the body)	Limp, flaccid	Some flexion, limited resistance to extension	Tight flexion, good resistance to extension with quick return to flexed position after extension
Reflex irritability (flicking of the soles of the feet or suctioning of the nose with a bulb syringe)	No response	Grimace or frown when irritated	Sneeze, cough, or vigorous cry
Skin color (inspection of trunk and extremities with the appropriate color for ethnicity appearing within minutes after birth)	Cyanotic or pale	Appropriate body color; blue extremities (acrocyanosis)	Completely appropriate color (pink on both trunk and extremities)

FIGURE 18.1 Measuring a newborn's length. (**A**) The nurse extends the newborn's leg and marks the pad at the heel. (**B**) The nurse measures from the newborn's head to the heel mark.

Most often, newborns are weighed using a digital scale that reads the weight in grams. Typically, the term newborn weighs 2,700 to 4,000 g (6 to 9 lb; Fig. 18.2). Birthweights less than 10% or more than 90% on a growth chart are outside the normal range and need further investigation. Weights taken at later times are compared with previous weights and are documented with regard to gain or loss on a nursing flow sheet. Newborns typically lose approximately 10% of their initial birth weight by 3 to 4 days of age secondary to loss of meconium, extracellular fluid, and limited food intake. This weight loss is usually regained by the 10th day of life (Kliegman et al., 2007).

FIGURE 18.2 Weighing a newborn. Note how the nurse guards the newborn from above to prevent injury.

Newborns can be classified by their birthweight regardless of their gestational age (AAP, 2007a) as follows:

- Low birthweight: <2,500 g (<5.5 lb)
- Very low birthweight: <1,500 g (<3.5 lb)
- Extremely low birthweight: <1,000 g (<2.5 lb)

Vital Signs

Heart rate and respiratory rate are assessed immediately after birth with Apgar scoring. Heart rate, obtained by taking an apical pulse for 1 full minute, typically is 120 to 160 bpm. Newborns' respirations are assessed when they are quiet or sleeping. Place a stethoscope on the right side of the chest and count the breaths for 1 full minute to identify any irregularities. The newborn respiratory rate is 30 to 60 breaths/minute with symmetric chest movement. Heart and respiratory rates are assessed every 30 minutes until stable for 2 hours after birth. Once stable, the heart rate and respiratory rates are checked every 8 hours (Kenner & Lott, 2007).

Axillary temperature is typically assessed not immediately after birth but on admission to the nursery or when the initial newborn assessment is carried out (e.g., the LDR room). The normal axillary temperature for a term newborn is 36.5° to 37.5°C (97.9° to 99.7°F). Rectal temperatures are no longer taken because of the risk of perforation (Blackburn, 2007). The thermometer or temperature probe is held in the midaxillary space according to manufacturer's directions and hospital protocol. Temperature is reassessed every 30 minutes until it has been stable for 2 hours, then every 8 hours until discharge (Kliegman et al., 2007).

Blood pressure is not usually assessed as part of a normal newborn examination unless there is a clinical indication or low Apgar scores. If assessed, an oscillometer (Dinamap) is used. The typical range is 50 to 75 mmHg

TABLE 18.2 NEWBORN VITAL SIGNS

Newborn Vital Signs	Ranges of values
Temperature	36.5° to 37.5°C (97.9° to 99.7°F)
Heart rate (pulse) to 180 during crying	120 to 160 bpm; can increase
Respirations	30 to 60 breaths/minute at rest; will increase with crying
Blood pressure	50 to 75 mmHg systolic, 30 to 45 mmHg diastolic

(systolic) and 30 to 45 mmHg (diastolic). Crying, moving, and late clamping of the umbilical cord will increase systolic pressure (Dillon, 2007).

Typical values for newborn vital signs are provided in Table 18.2.

Gestational Age Assessment

To determine a newborn's **gestational age** (the stage of maturity), physical signs and neurologic characteristics are assessed. Typically, gestational age is determined by using a tool such as the Dubowitz/Ballard or New Ballard Score system (Fig. 18.3). This scoring system provides an objective estimate of gestational age by scoring the specific parameters of physical and neuromuscular maturity. Points are given for each assessment parameter, with a low score of –1 point or –2 points for extreme immaturity to 4 or 5 points for postmaturity. The scores from each section are added together to correspond to a specific gestational age in weeks.

The physical maturity section of the examination is done during the first 2 hours after birth. The physical maturity assessment section of the Ballard examination evaluates physical characteristics that appear different at different stages depending on a newborn's gestational maturity. Newborns who are physically mature have higher scores than those who are not. The areas assessed on the physical maturity examination include:

- Skin texture—typically ranges from sticky and transparent to smooth, with varying degrees of peeling and cracking, to parchment-like or leathery with significant cracking and wrinkling
- Lanugo—soft downy hair on the newborn's body, which is absent in preterm newborns, appears with maturity, and then disappears again with postmaturity
- Plantar creases—creases on the soles of the feet, which range from absent to covering the entire foot, depending on maturity (the greater the number of creases, the greater the newborn's maturity)
- Breast tissue—the thickness and size of breast tissue and areola (the darkened ring around each nipple), which range from being imperceptible to full and budding
- Eyes and ears—eyelids can be fused or open and ear cartilage and stiffness determine the degree of maturity (the greater the amount of ear cartilage with stiffness, the greater the newborn's maturity)
- Genitals—in males, evidence of testicular descent and appearance of scrotum (which can range from smooth to covered with rugae) determine maturity; in females, appearance and size of clitoris and labia determine maturity (a prominent clitoris with flat labia suggests prematurity, whereas a clitoris covered by labia suggests greater maturity)

The neuromuscular maturity section typically is completed within 24 hours after birth. Six activities or maneuvers that the newborn performs with various body parts are evaluated to determine the newborn's degree of maturity:

1. Posture—How does the newborn hold his or her extremities in relation to the trunk? The greater the degree of flexion, the greater the maturity. For example, extension of arms and legs is scored as 0 point and full flexion of arms and legs is scored as 4 points.
2. Square window—How far can the newborn's hands be flexed toward the wrist? The angle is measured and scored from more than 90 degrees to 0 degrees to determine the maturity rating. As the angle decreases, the newborn's maturity increases. For example, an angle of more than 90 degrees is scored as –1 point and an angle of 0 degrees is scored as 4 points.
3. Arm recoil—How far do the newborn's arms "spring back" to a flexed position? This measure evaluates the degree of arm flexion and the strength of recoil. The reaction of the arm is then scored from 0 to 4 points based on the degree of flexion as the arms are returned to their normal flexed position. The higher the points assigned, the greater the neuromuscular maturity (for example, recoil less than a 90-degree angle is scored as 4 points).
4. Popliteal angle—How far will the newborn's knees extend? The angle created when the knee is extended is measured. An angle less than 90 degrees indicates greater maturity. For example, an angle of 180 degrees is scored as –1 point and an angle of less than 90 degrees is scored as 5 points.
5. Scarf sign—How far can the elbows be moved across the newborn's chest? An elbow that does not reach midline indicates greater maturity. For example, if the elbow reaches or nears the level of the opposite shoulder, this is scored as –1 point; if the elbow does not cross the proximate axillary line, it is scored as 4 points.
6. Heel to ear—How close can the newborn's feet be moved to the ears? This maneuver assesses hip flexibility: the lesser the flexibility, the greater the newborn's maturity. The heel-to-ear assessment is scored in the same manner as the scarf sign.

FIGURE 18.3 Gestational age assessment tool. (Ballard, J. L., Khoury, J. C., Wedig, K., et al. [1991]. New Ballard Score, expanded to include extremely premature infants. *Journal of Pediatrics, 119*[3], 417–423.)

After the scoring is completed, the 12 scores are totaled and then compared with standardized values to determine the appropriate gestational age in weeks. Scores range from very low in preterm newborns to very high for mature and postmature newborns.

Typically newborns are also classified according to gestational age as:

- Preterm or premature—born before 37 weeks' gestation, regardless of birthweight
- Term—born between 38 and 42 weeks' gestation
- Postterm or postdates—born after completion of week 42 of gestation
- Postmature—born after 42 weeks and demonstrating signs of placental aging

Using the information about gestational age and then considering birthweight, newborns can also be classified as follows:

- Small for gestational age (SGA)—weight less than the 10th percentile on standard growth charts (usually <5.5 lb)
- Appropriate for gestational age (AGA)—weight between 10th and 90th percentiles
- Large for gestational age (LGA)—weight more than the 90th percentile on standard growth charts (usually >9 lb)

Chapter 23 describes these variations in birthweight and gestational age in greater detail.

▶ *Take* NOTE!

Gestational age assessment is important because it allows the nurse to plot growth parameters and to anticipate problems related to prematurity, postmaturity, and growth abnormalities.

Nursing Interventions

During the immediate newborn period, care focuses on helping the newborn to make the transition to extrauterine life. The nursing interventions include maintaining airway patency, ensuring proper identification, administering prescribed medications, and maintaining thermoregulation.

Maintaining Airway Patency

Immediately after birth, a newborn is suctioned to remove fluids and mucus from the mouth and nose. Typically, the newborn's mouth is suctioned first with a bulb syringe to remove debris and then the nose is suctioned. Suctioning in this manner helps to prevent aspiration of fluid into the lungs by an unexpected gasp.

When suctioning a newborn with a bulb syringe, compress the bulb before placing it into the oral or nasal cavity. Release bulb compression slowly, making sure the tip is placed away from the mucous membranes to draw up the excess secretions. Remove the bulb syringe from the mouth or nose, and then, while holding the bulb syringe tip over an emesis basin lined with paper towel or tissue, compress the bulb to expel the secretions. Repeat the procedure several times until all secretions are removed.

▶ *Take* NOTE!

Always keep a bulb syringe near the newborn in case he or she develops sudden choking or a blockage in the nose.

Ensuring Proper Identification

Before the newborn and family leave the birthing area, be sure that agency policy about identification is followed. Typically, the mother and newborn, and possibly the father, receive matching identification bracelets. The newborn commonly receives two ID bracelets, one on a wrist and one on an ankle. The mother receives a matching one, usually on her wrist. The ID bands usually state name, gender, date and time of birth, and identification number. The same identification number is on the bracelets of all the family members.

These ID bracelets provide for the safety of the newborn and must be secured before the mother and newborn leave the birthing area. The ID bracelets are checked by all nurses to validate that the correct newborn is brought to the right mother if they are separated for any period of time (Fig. 18.4). They also serve as the official newborn identification and are checked before initiating any procedure on that newborn and on discharge from the unit (AAP, 2007). Taking the newborn's picture within 2 hours after birth with a color camera or color video/digital image also helps prevent mix-ups and abduction. Some facilities use electronic devices that sound an alarm if the newborn is removed from the area.

Newborns' footprints may also be taken, using a form that includes the mother's fingerprint, name, and date and time of the birth. Some states require footprints of the newborn, although many studies point out that birthing room staff members do not take consistently legible footprints suitable for identification purposes (Kenner & Lott, 2007). Many states have stopped requiring newborn footprints, and thus other means of identification are needed, such as collecting cord blood at the time of birth for DNA testing and live scans to capture digital forensic-quality prints that are suitable for identification purposes (Cohen, 2007).

Administering Prescribed Medications

During the immediate newborn period, two medications are commonly ordered: vitamin K and eye prophylaxis with

FIGURE 18.4 The nurse checks the newborn's identification band against the mother's.

either erythromycin or tetracycline ophthalmic ointment (Drug Guide 18.1).

Vitamin K

Vitamin K, a fat-soluble vitamin, promotes blood clotting by increasing the synthesis of prothrombin by the liver. A deficiency of this vitamin would delay clotting and might lead to hemorrhage.

Generally, the bacteria of the intestine produce vitamin K in adequate quantities. However, the newborn's bowel is sterile, so vitamin K is not produced in the intestine until after microorganisms are introduced, such as with the first feeding. Usually it takes about a week for the newborn to produce enough vitamin K to prevent vitamin K deficiency bleeding (Wasee, 2006).

The efficacy of vitamin K in preventing early vitamin K deficiency bleeding is firmly established and has been the standard of care since the AAP recommended it in the early 1960s. They recommend that vitamin K be administered to all newborns soon after birth in a single intramuscular dose of 0.5 to 1 mg (AAP, 2007) (Fig. 18.5). They suggest that additional research is needed to validate the efficacy and safety of oral forms of vitamin K, which have been used in many parts of the world but currently are not recommended in the United States.

FIGURE 18.5 The nurse administers vitamin K IM to the newborn.

Eye Prophylaxis

All newborns in the United States, whether delivered vaginally or by cesarean birth, must receive an instillation of a prophylactic agent in their eyes within an hour or two of birth. This is mandated in all 50 states to prevent **ophthalmia neonatorum**, which can cause neonatal blindness (CDC, 2007). Ophthalmia neonatorum is a hyperacute purulent conjunctivitis occurring during the first 10 days of life. It is usually contracted during birth when the baby comes in contact with infected vaginal discharge of the mother (CDC, 2007). Most often both eyelids become swollen and red with purulent discharge.

Prophylactic agents that are currently recommended include erythromycin 0.5% ophthalmic ointment or tetracycline 1% ophthalmic ointment in a single application. Silver nitrate solution was formerly used but has little efficacy in preventing chlamydial eye disease (CDC, 2007).

Regardless of which agent is used, instillation should be done as soon as possible after birth (Fig. 18.6). If

DRUG GUIDE 18.1 DRUGS FOR THE NEWBORN

Drug	Action/Indication	Nursing Implications
Phytonadione (vitamin K [Aqua-MEPHYTON, Konakion, Mephyton])	Provides the newborn with vitamin K (necessary for production of adequate clotting factors II, VII, IX, and X by the liver) during the first week of birth until newborn can manufacture it Prevents vitamin K deficiency bleeding (VKDB) of the newborn	• Administer within 1 to 2 hours after birth. • Give as an IM injection at a 90-degree angle into the middle third of the vastus lateralis muscle. • Use a 25-gauge, 5/8-in needle for injection. • Hold the leg firmly and inject medication slowly after aspirating. • Adhere to standard precautions. • Assess for bleeding at injection site after administration.
Erythromycin ophthalmic ointment 0.5% or tetracycline ophthalmic ointment 1%	Provides bactericidal and bacteriostatic actions to prevent *Neisseria gonorrhoeae* and *Chlamydia trachomatis* conjunctivitis Prevents ophthalmia neonatorum	• Be alert for chemical conjunctivitis for 1–2 days. • Wear gloves, and open eyes by placing thumb and finger above and below the eye. • Gently squeeze the tube or ampoule to apply medication into the conjunctival sac from the inner canthus to the outer canthus of each eye. • Do not touch the tip to the eye. • Close the eye to make sure the medication permeates. • Wipe off excess ointment after 1 minute.

FIGURE 18.6 The nurse administers eye prophylaxis.

instillation is delayed to allow visualization and bonding, the nursery staff should make sure the agent is administered when the newborn reaches the nursery for observation and assessment.

Inform all parents about the eye treatment, including why it is recommended, what problems may arise if the treatment is not given, and possible adverse effects of the treatment.

▶ ***Take*** *NOTE!*

Parents have the right to refuse this treatment, but if they received adequate teaching about the treatment and understand its importance, they usually will consent to it.

Maintaining Thermoregulation

Newborns have trouble regulating their temperature, especially during the first few hours after birth (see Chap. 17 for a complete discussion). Therefore, maintaining body temperature is crucial.

Assess body temperature frequently during the immediate newborn period. The baby's temperature should be taken every 30 minutes for the first 2 hours or until the temperature has stabilized, and then every 8 hours until discharge (AAP, 2007).

Commonly a thermistor probe (automatic sensor) is attached to the newborn to record body temperature on a monitoring device. The probe is taped to the newborn's abdomen, usually in the right upper quadrant, which allows for position changes without having to readjust the probe. The other end of the thermistor probe is inserted into the radiant heat control panel. Temperature parameters are set on an alarm system connected to the heat panel that will sound if the newborn's temperature falls out of the set range. Check the probe connection periodically to make sure that it remains secure. Remember the potential for heat loss in newborns, and perform all nursing interventions in a way that minimizes heat loss and prevents hypothermia.

Axillary temperatures can also be used to assess the newborn's body temperature. At one time, rectal thermometers were routinely used to monitor body temperature, but their use is no longer recommended because of the risk of traumatizing the rectal lining (Blackburn, 2007). A newborn's temperature typically is maintained at 36.5° to 37.5°C (97.7° to 99.7°F) (Kenner & Lott, 2007).

Nursing interventions to help maintain body temperature include:

- Dry the newborn immediately after birth to prevent heat loss through evaporation.
- Wrap the baby in warmed blankets to reduce heat loss via convection.
- Use a warmed cover on the scale to weigh the unclothed newborn.
- Warm stethoscopes and hands before examining the baby or providing care.
- Avoid placing newborns in drafts or near air vents to prevent heat loss through convection.
- Delay the initial bath until the baby's temperature has stabilized to prevent heat loss through evaporation.
- Avoid placing cribs near cold outer walls to prevent heat loss through radiation.
- Put a cap on the newborn's head after it is thoroughly dried after birth.
- Place the newborn under a temperature-controlled radiant warmer (Fig. 18.7).

Nursing Management During the Early Newborn Period

The early newborn period is a time of great adjustment for both the mother and the newborn, both of whom are adapting to many physiologic and psychological changes. In the past, mothers and newborns remained in the health care facility while these dramatic changes were taking place, with nurses and doctors readily available. However, today shorter hospital stays are the norm, and new mothers can easily be overwhelmed by having to go through all of these changes in such a short time: the woman gives birth, experiences marked physiologic and psychological changes, and must adapt to her newborn and learn the skills needed to care for herself and the baby, all within 24 to 48 hours.

The nurse's role is to assist the mother and her newborn through this dramatic transition period. The newborn needs continued health assessment, and the mother needs to be taught to care for the new baby. At discharge, the new mother may panic and feel insecure about her role as primary caretaker. Nurses play a major role in promoting the newborn's transition by providing ongoing assessment and

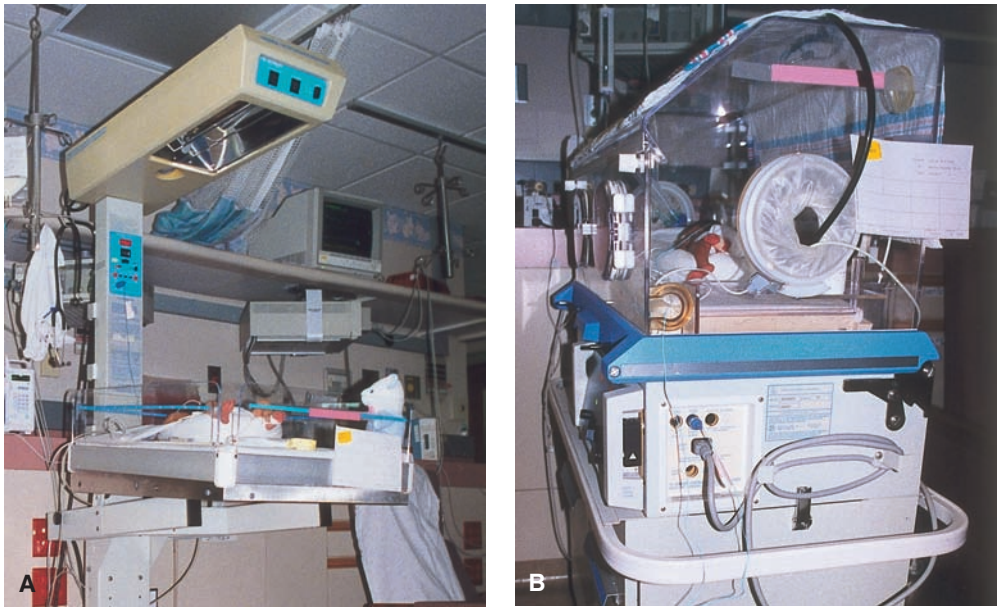

FIGURE 18.7 Maintaining thermoregulation. (**A**) Radiant warmer. (**B**) Isolette.

care and in promoting the woman's confidence by serving as a role model and teaching about proper newborn care.

Assessment

The newborn requires ongoing assessment after leaving the birthing area to ensure that his or her transition to extrauterine life is progressing without problems. The nurse uses the data gathered during the initial assessment as a baseline for comparison.

Perinatal History

Pertinent maternal and fetal data are vital to formulate a plan of care for the mother and her newborn. Historical information is obtained from the medical record and from interviewing the mother. Review the maternal history because it provides pertinent information, such as the presence of certain risk factors that could affect the newborn. Keep in mind that a comprehensive maternal history may not be available, especially if the mother has had limited or no prenatal care.

Historical information usually includes the following:

- Mother's name, medical record number, blood type, serology result, rubella and hepatitis status, and history of substance abuse
- Other maternal tests that are relevant to the newborn and care, such as HIV and group B streptococcus status
- Intrapartum maternal antibiotic therapy (type, dose, and duration)
- Maternal illness that can affect the pregnancy, evidence of chorioamnionitis, maternal use of medications such as steroids
- Prenatal care, including timing of first visit and subsequent visits
- Risk for blood group incompatibility, including Rh status and blood type
- Fetal distress or any nonreassuring fetal heart rate patterns during labor
- Known inherited conditions such as sickle cell anemia and phenylketonuria (PKU)
- Birthweights of previous live-born children, along with identification of any newborn problems
- Social history, including tobacco, alcohol, and recreational drug use
- History of depression or domestic violence
- Cultural factors, including primary language and educational level
- Pregnancy complications associated with abnormal fetal growth, fetal anomalies, or abnormal results from tests of fetal well-being
- Information on the progress of labor, birth, labor complications, duration of ruptured membranes, and presence of meconium in the amniotic fluid
- Medications given during labor, at birth, and immediately after birth
- Time and method of delivery, including presentation and the use of forceps or a vacuum extractor
- Status of the newborn at birth, including Apgar scores at 1 and 5 minutes, the need for suctioning, weight, gestational age, vital signs, and umbilical cord status
- Medications administered to the newborn
- Postbirth maternal information, including placental findings, positive cultures, and presence of fever

Newborn Physical Examination

The initial newborn physical examination, which may demonstrate subtle differences related to the newborn's age, is carried out within the first 24 hours after birth. For example, a newborn who is 30 minutes old has not yet

completed the normal transition from intrauterine to extrauterine life, and thus variability may exist in vital signs and in respiratory, neurologic, gastrointestinal, skin, and cardiovascular systems. Therefore, a comprehensive examination should be delayed until after the newborn has completed the transition.

In a quiet newborn, begin the examination with the least invasive and noxious elements of the examination (auscultation of heart and lungs). Then examine the areas most likely to irritate the newborn (e.g., examining the hips and eliciting the Moro reflex). A general visual assessment provides an enormous amount of information about the well-being of a newborn. Initial observation gives an impression of a healthy (stable) versus an ill newborn and a term versus a preterm newborn.

A typical physical examination of a newborn includes a general survey of skin color, posture, state of alertness, head size, overall behavioral state, respiratory status, gender, and any obvious congenital anomalies. Check the overall appearance for anything unusual. Then complete the examination in a systematic fashion.

Remember Kelly, who called the home health nurse and said her newborn son "looks like a canary"? What additional information is needed about the baby? What might be causing his yellow color?

Anthropometric Measurements

Shortly after birth, after the gender of the child is revealed, most parents want to know the "vital statistics" of their newborn—length and weight—to report to their family and friends. Additional measurements, including head and chest circumference, are also taken and recorded. Abdominal measurements are not routinely obtained unless there is a suspicion of pathology that causes abdominal distention. The newborn's progress from that point on will be validated based on these early measurements. These measurements will be compared with future serial measurements to determine growth patterns, which are plotted on growth charts to evaluate normalcy. Therefore, accuracy is key.

Length

The average length of most newborns is 50 cm (20 in), but it can range from 45 to 55 cm (18 to 22 in). Measure length with the unclothed newborn lying on a warmed blanket placed on a flat surface with the knees held in an extended position. Then run a tape measure down the length of the newborn—from the head to the soles of the feet—and record this measurement in the newborn's record (see Fig. 18.1).

Weight

At birth the average newborn weighs 3,400 g (7.5 lb), but normal birthweights can range from 2,500 to 4,000 g (5 lb, 8 oz to 8 lb, 14 oz). Newborns are weighed immediately after birth and then daily. Newborns usually lose up to 10% of their birthweight within the first few days of life, but regain it in approximately 10 days. Newborns are weighed on admission to the nursery or are taken to a digital scale to be weighed and returned to the mother's room.

First, balance the scale if it is not balanced. Place a warmed protective cloth or paper as a barrier on the scale to prevent heat loss by conduction; recalibrate the scale to zero after applying the barrier. Next, place the unclothed newborn in the center of the scale. Keep a hand above the newborn for safety (see Fig. 18.2).

Weight is affected by racial origin, maternal age, size of the parents, maternal nutrition, and placental perfusion (Lawrence, 2006). Weight should be correlated with gestational age. A newborn who weighs more than normal might be LGA or an infant of a diabetic mother (IDM); a newborn who weighs less than normal might be SGA or preterm or might have a genetic syndrome. It is important to identify the cause for the deviation in size and to monitor the newborn for complications common to that etiology.

Head Circumference

The average newborn head circumference is 32 to 38 cm (13 to 15 in). Measure the circumference at the head's widest diameter (the occipitofrontal circumference). Wrap a flexible or paper measuring tape snugly around the newborn's head and record the measurement (Fig. 18.8A).

▶ Take NOTE!

Head circumference may need to be remeasured at a later time if the shape of the head is altered from birth.

The head circumference should be approximately one fourth of the newborn's length (Lawrence, 2006). A small head might indicate microcephaly caused by rubella, toxoplasmosis, or SGA status; an enlarged head might indicate hydrocephalus or increased intracranial pressure. Both need to be documented and reported for further investigation.

Chest Circumference

The average chest circumference is 30 to 36 cm (12 to 14 in). It is generally equal to or about 2 to 3 cm less than the head circumference (Burns et al., 2009). Place a flexible or paper tape measure around the unclothed newborn's chest at the nipple line without pulling it taut (see Fig. 18.8B).

▶ Take NOTE!

The head and chest circumferences are usually equal by about 1 year of age.

FIGURE 18.8 (**A**) Measuring head circumference. (**B**) Measuring chest circumference.

Vital Signs

In the newborn, temperature, pulse, and respirations are monitored frequently and compared with baseline data obtained immediately after birth. Generally, vital signs (excluding blood pressure) are taken:

- On admission to the nursery or in the LDR room after the parents are allowed to hold and bond with the newborn
- Once every 30 minutes until the newborn has been stable for 2 hours
- Then once every 4 to 8 hours until discharge (AAP, 2007)

Blood pressure is not routinely assessed in a normal newborn unless the baby's clinical condition warrants it. This schedule can change depending on the baby's health status.

Obtain a newborn's temperature by placing an electronic temperature probe in the midaxillary area or by monitoring the electronic thermistor probe that has been taped to the abdominal skin (applied when the newborn was placed under a radiant heat source).

Monitor the newborn's temperature hourly for changes until it stabilizes. On average, a newborn's temperature is 36.5° to 37.5°C (97.9° to 99.7°F). If the temperature is higher, adjust the environment, such as removing some clothing or blankets. If the temperature is lower, check the radiant warmer setting or add a warmed blanket. Report any abnormalities to the primary health care provider if simple adjustments to the environment do not change the baby's temperature.

Obtain an apical pulse by placing the stethoscope over the fourth intercostal space on the chest. Listen for a full minute, noting rate, rhythm, and abnormal sounds such as murmurs. In the typical newborn, the heart rate is 120 to 160 bpm, with wide fluctuations with activity and sleep. Sinus arrhythmia is a normal finding. Murmurs detected during the newborn period do not necessarily indicate congenital heart disease, but they need to be assessed frequently over the next several months to see if they persist.

Also palpate the apical, femoral, and brachial pulses for presence and equality (Fig. 18.9). Report any abnormalities to the primary health care provider for evaluation.

Assess respirations by observing the rise and fall of the chest for 1 full minute. Respirations should be symmetric, slightly irregular, shallow, and unlabored at a rate of 30 to 60 breaths/minute. The newborn's respirations are predominantly diaphragmatic, but they are synchronous with abdominal movements. Also auscultate breath sounds. Note any abnormalities, such as tachypnea, bradypnea, grunting, gasping, periods of apnea lasting longer than 20 seconds, asymmetry or decreased chest expansion, abnormal breath sounds (rhonchi, crackles), or sternal retractions. Some variations might exist early after birth, but if the abnormal pattern persists, notify the primary health care provider.

Skin

Observe the overall appearance of the skin, including color, texture, turgor, and integrity. The newborn's skin should be smooth and flexible, and the color should be consistent with genetic background.

FIGURE 18.9 Assessing the newborn's vital signs. (**A**) Assessing the apical pulse. (**B**) Palpating the femoral pulse. (**C**) Palpating the brachial pulse.

Skin Condition and Color

Check skin turgor by pinching a small area of skin over the chest or abdomen and note how quickly it returns to its original position. In a well-hydrated newborn, the skin should return to its normal position immediately. Skin that remains "tented" after being pinched indicates dehydration. A small amount of lanugo (fine downy hair) may be observed over the shoulders and on the sides of the face and upper back. There may be some cracking and peeling of the skin. The skin should be warm to the touch and intact.

The newborn's skin often appears blotchy or mottled, especially in the extremities. Persistent cyanosis of fingers, hands, toes, and feet with mottled blue or red discoloration and coldness is called **acrocyanosis**. It may be seen in newborns during the first few weeks of life in response to exposure to cold. Acrocyanosis is normal and intermittent.

Newborn Skin Variations

While assessing the skin, note any rashes, ecchymoses or petechiae, nevi, or dark pigmentation. Skin lesions can be congenital or transient; they may be a result of infection or may result from the mode of birth. If any are present, observe the anatomic location, arrangement, type, and color. Bruising may result from the use of devices such as a vacuum extractor during delivery. Petechiae may be the result of pressure on the skin during the birth process. Forceps marks may be observed over the cheeks and ears. A small puncture mark may be seen if internal fetal scalp electrode monitoring was used during labor.

Common skin variations include vernix caseosa, stork bites or salmon patches, milia, Mongolian spots, erythema toxicum, harlequin sign, nevus flammeus, and nevus vasculosus (Fig. 18.10).

Vernix caseosa is a thick white substance that protects the skin of the fetus. It is formed by secretions from the fetus's oil glands and is found during the first 2 or 3 days after birth in body creases and the hair. It does not need to be removed because it will be absorbed into the skin.

Stork bites or salmon patches are superficial vascular areas found on the nape of the neck, on the eyelids, and between the eyes and upper lip (see Fig. 18.10A). The name comes from the marks on the back of the neck where, as myth goes, a stork may have picked up the baby. They are caused by a concentration of immature blood vessels and are most visible when the newborn is crying. They are considered a normal variant, and most fade and disappear completely within the first year.

Milia are unopened sebaceous glands frequently found on a newborn's nose. They may also appear on the chin and forehead (see Fig. 18.10B). They form from oil glands and disappear on their own within 2 to 4 weeks. When they occur in a newborn's mouth and gums, they are termed **Epstein's pearls**. They occur in approximately 60% of newborns (AAP, 2007b).

Mongolian spots are blue or purple splotches that appear on the lower back and buttocks of newborns (see Fig. 18.10C). They tend to occur in African-American, Asian, and Indian newborns but can occur in dark-skinned newborns of all races. The spots are caused by a concentration of pigmented cells and usually disappear within the first 4 years of life (Kliegman et al., 2007).

Erythema toxicum (newborn rash) is a benign, idiopathic, generalized, transient rash that occurs in up to 70% of all newborns during the first week of life. It consists of small papules or pustules on the skin resembling flea bites. The rash is common on the face, chest, and back (see Fig. 18.10D). One of the chief characteristics

FIGURE 18.10 Common skin variations. (**A**) Stork bite. (**B**) Milia. (**C**) Mongolian spots. (**D**) Erythema toxicum. (**E**) Nevus flammeus (port-wine stain). (**F**) Strawberry hemangioma.

of this rash is its lack of pattern. It is caused by the newborn's eosinophils reacting to the environment as the immune system matures (AAP, 2007b). It does not require any treatment and disappears in a few days.

Harlequin sign refers to the dilation of blood vessels on only one side of the body, giving the newborn the appearance of wearing a clown suit. It gives a distinct midline demarcation, which is described as pale on the nondependent side and red on the opposite, dependent side. It results from immature autoregulation of blood flow and is commonly seen in low-birthweight newborns when there is a positional change (Dillon, 2007). It is transient, lasting as long as 20 minutes, and no intervention is needed.

Nevus flammeus, also called a port wine stain, commonly appears on the newborn's face or other body areas (see Fig. 18.10E). It is a capillary angioma located directly below the dermis. It is flat with sharp demarcations

and is purple–red. This skin lesion is made up of mature capillaries that are congested and dilated. It ranges in size from a few millimeters to large, occasionally involving as much as half the body surface. Although it does not grow in area or size, it is permanent and will not fade. Port wine stains may be associated with structural malformations, bony or muscular overgrowth, and certain cancers. Recent studies have noted an association between port wine birthmarks and childhood cancer, so newborns with these lesions should be monitored with periodic eye examinations, neurologic imaging, and extremity measurements (Johnson et al., 2007). Pulsed dye laser surgery has been used to remove larger lesions with some success (AAP, 2007b).

Nevus vasculosus, also called a strawberry mark or strawberry hemangioma, is a benign capillary hemangioma in the dermal and subdermal layers. It is raised, rough, dark red, and sharply demarcated (see Fig. 18.10F). It is commonly found in the head region within a few weeks after birth and can increase in size or number. Commonly seen in premature infants weighing less than 1,500 g (Kenner & Lott, 2007), these hemangiomas tend to resolve by age 3 without any treatment.

Head

Head size varies with age, gender, and ethnicity and has a general correlation with body size. Inspect a newborn's head from all angles. The head should appear symmetric and round. As many as 90% of the congenital malformations present at birth are visible on the head and neck, so careful assessment is very important (AAP, 2007a).

The newborn has two fontanels at the juncture of the cranial bones. The anterior fontanel is diamond-shaped and closes by 18 to 24 months. Typically it measures 4 to 6 cm at the largest diameter (bone to bone). The posterior one is triangular, smaller than the anterior fontanel (usually fingertip size or 0.5 to 1 cm), and closes by 6 to 12 weeks. Palpate both fontanels, which should be soft, flat, and open. Then palpate the skull. It should feel smooth and fused, except at the area of the fontanels. Also assess the size of the head and the anterior and posterior fontanels, and compare them with appropriate standards.

Variations in Head Size and Appearance

During inspection and palpation, be alert for common variations that may cause asymmetry. These include caput succedaneum, cephalhematoma, and molding.

Molding is the elongated shaping of the fetal head to accommodate passage through the birth canal (Fig. 18.11). It occurs with a vaginal birth from a vertex position in which elongation of the fetal head occurs with prominence of the occiput and overriding sagittal suture line. It typically resolves within a week after birth without intervention.

Caput succedaneum describes localized edema on the scalp that occurs from the pressure of the birth process. It is commonly observed after prolonged labor. Clinically, it appears as a poorly demarcated soft tissue swelling that crosses suture lines. Pitting edema and overlying petechiae and ecchymosis are noted (Fig. 18.12A). The swelling will gradually dissipate in about 3 days without any treatment. Newborns who were delivered via vacuum extraction usually have a caput in the area where the cup was used.

FIGURE 18.11 Molding in a newborn's head.

Cephalhematoma is a localized effusion of blood beneath the periosteum of the skull. This condition is due to disruption of the vessels during birth. It occurs after prolonged labor and use of obstetric interventions such as low forceps or vacuum extraction. The clinical features include a well-demarcated, often fluctuant swelling with no overlying skin discoloration. The swelling does not cross suture lines and is firmer to the touch than an edematous area (see Fig. 18.12B). Cephalhematoma usually appears on the second or third day after birth and disappears within weeks or months (Simonson et al., 2007).

Common Abnormalities in Head or Fontanel Size

Common abnormalities in head or fontanel size that may indicate a problem include:

- Microcephaly—a head circumference more than 2 standard deviations below average or less than 10% of normal parameters for gestational age, caused by failure of brain development (Cohen, 2007). It can be familial, with autosomal dominant or recessive inheritance, and it may be associated with infections (cytomegalovirus) and syndromes such as trisomy 13 and 18, and fetal alcohol syndrome (Kenner & Lott, 2007).

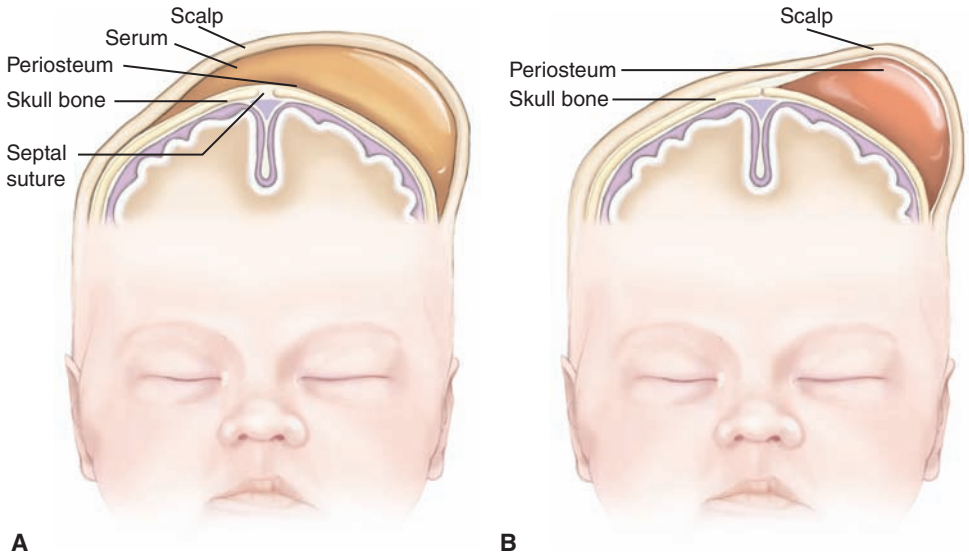

FIGURE 18.12 (**A**) Caput succedaneum involves the collection of serous fluid and often crosses the suture line. (**B**) Cephalhematoma involves the collection of blood and does not cross the suture line.

- Macrocephaly—a head circumference more than 90% of normal, typically related to hydrocephalus (Dillon, 2007). It is often familial (with autosomal dominant inheritance) and can be either an isolated anomaly or a manifestation of other anomalies, including hydrocephalus and skeletal disorders (achondroplasia).
- Large fontanels—more than 6 cm in the anterior diameter bone to bone or more than a 1-cm diameter in the posterior fontanel; possibly associated with malnutrition, hydrocephaly, congenital hypothyroidism, trisomies 13, 18, and 21, and various bone disorders such as osteogenesis imperfecta
- Small or closed fontanels—smaller-than-normal anterior and posterior diameters or fontanels that are closed at birth; associated with microcephaly or premature synostosis (union of two bones by osseous material) (Blackburn, 2007)

Face

Observe the newborn's face for fullness and symmetry. The face should have full cheeks and should be symmetric when the baby is resting and crying. If forceps were used during birth, the newborn may have bruising and reddened areas over both cheeks and parietal bones secondary to the pressure of the forceps blades. Reassure the parents that this resolves without treatment, and point out improvement each day.

Problems with the face can also involve facial nerve paralysis caused by trauma from the use of forceps. Paralysis is usually apparent on the first or second day of life. Typically, the newborn will demonstrate asymmetry of the face with the inability to close the eye and move the lips on the affected side. Newborns with facial nerve paralysis have difficulty making a seal around the nipple, and consequently milk or formula drools from the paralyzed side of the mouth. Most facial nerve palsies resolve spontaneously within days, although full recovery may require weeks to months. Attempt to determine the cause from the newborn's history.

Nose

Inspect the nose for size, symmetry, position, and lesions. The newborn's nose is small and narrow. The nose should have a midline placement, patent nares, and an intact septum. The nostrils should be of equal size and should be patent. A slight mucus discharge may be present, but there should be no actual drainage. The newborn is a preferential nose breather and will use sneezing to clear the nose if needed. The newborn can smell after the nasal passages are cleared of amniotic fluid and mucus (AAP, 2007a).

Mouth

Inspect the newborn's mouth, lips, and interior structures. The lips should be intact with symmetric movement and positioned in the midline; there should not be any lesions. Inspect the lips for pink color, moisture, and cracking. The lips should encircle the examiner's finger to form a vacuum. Variations involving the lip might include cleft upper lip (separation extending up to the nose) or thin upper lip associated with fetal alcohol syndrome.

Assess the inside of the mouth for alignment of the mandible, intact soft and hard palate, sucking pads inside the cheeks, a midline uvula, a free-moving tongue, and working gag, swallow, and sucking reflexes. The mucous membranes lining the oral cavity should be pink and moist, with minimal saliva present.

Normal variations might include Epstein's pearls (small, white epidermal cysts on the gums and hard palate

that disappear in weeks), erupted precocious teeth that may need to be removed to prevent aspiration, and thrush (white plaque inside the mouth caused by exposure to *Candida albicans* during birth), which cannot be wiped away with a cotton-tipped applicator.

Eyes

Inspect the external eye structures, including the eyelids, lashes, conjunctiva, sclera, iris, and pupils, for position, color, size, and movement. There may be marked edema of the eyelids and subconjunctival hemorrhages due to pressure during birth. The eyes should be clear and symmetrically placed. Test the blink reflex by bringing an object close to the eye; the newborn should respond quickly by blinking. Also test the newborn's pupillary reflex: pupils should be equal, round, and reactive to light bilaterally. Assess the newborn's gaze: he or she should be able to track objects to the midline. Movement may be uncoordinated during the first few weeks of life. Many newborns have transient strabismus (deviation or wandering of eyes independently) and searching nystagmus (involuntary repetitive eye movement), which is caused by immature muscular control. These are normal for the first 3 to 6 months of age.

Examine the internal eye structures. A red reflex (luminous red appearance seen on the retina) should be seen bilaterally on retinoscopy. The red reflex normally shows no dullness or irregularities.

Chemical conjunctivitis commonly occurs within 24 hours of instillation of eye prophylaxis after birth. There is lid edema with sterile discharge from both eyes. Usually it resolves within 48 hours without treatment.

Ears

Inspect the ears for size, shape, skin condition, placement, amount of cartilage, and patency of the auditory canal. The ears should be soft and pliable and should recoil quickly and easily when folded and released. Ears should be aligned with the outer canthi of the eyes. Low-set ears are characteristic of many syndromes and genetic abnormalities, such as trisomy 13 and 18, and internal organ abnormalities involving the renal system.

An otoscopic examination is not typically done because the newborn's ear canals are filled with amniotic fluid and vernix caseosa, which would make visualization of the tympanic membrane difficult.

Newborn hearing screening is required by law in most states (discussed later in the chapter). Hearing loss is the most common birth defect in the United States: One in 1,000 newborns is profoundly deaf and 2 to 3 in 1,000 have partial hearing loss (Wrightson, 2007). Delays in identification and intervention may affect the child's cognitive, verbal, behavioral, and emotional development. Screening at birth has reduced the age at which newborns with hearing loss are identified and has improved early intervention rates dramatically (AAP, 2007b). Prior to universal newborn screening, children were usually older than 2 years before significant congenital hearing loss was detected; by this time it had already affected their speech and language skills (USPSTF, 2006).

Causes of hearing loss can be conductive, sensorineural, or central. Risk factors for congenital hearing loss include cytomegalovirus infection and preterm birth necessitating a stay in the neonatal intensive care unit.

To assess for hearing ability generally, observe the newborn's response to noises and conversations. The newborn typically turns toward these noises and startles with loud ones.

Neck

Inspect the newborn's neck for movement and ability to support the head. The newborn's neck will appear almost nonexistent because it is so short. Creases are usually noted. The neck should move freely in all directions and should be capable of holding the head in a midline position. The newborn should have enough head control to be able to hold it up briefly without support. Report any deviations such as restricted neck movement or absence of head control.

Also inspect the clavicles, which should be straight and intact. The clavicles are the bones mostly commonly broken in infants, especially large ones. In most cases, the fractured clavicle is asymptomatic, but decreased or absent movement and pain or tenderness on movement of the arm on the affected side may be noted (Kenner & Lott, 2007). Treatment involves immobilization and minimizing pain.

Chest

Inspect the newborn's chest for size, shape, and symmetry. The newborn's chest should be round, symmetric, and 2 to 3 cm smaller than the head circumference. The xiphoid process may be prominent at birth, but it usually becomes less apparent when adipose tissue accumulates. Nipples may be engorged and may secrete a white discharge. This discharge, which occurs in both boys and girls, is a result of exposure to high levels of maternal estrogen while in utero. This enlargement and milky discharge usually dissipates within a few weeks. Some newborns may have extra nipples, called supernumerary nipples. They are typically small, raised, pigmented areas vertical to the main nipple line, 5 to 6 cm below the normal nipple (AAP, 2007a). They tend to be familial and do not contain glandular tissue. Reassure parents that these extra small nipples are harmless.

The newborn chest is usually barrel-shaped with equal anteroposterior and lateral diameters, and symmetric. Auscultate the lungs bilaterally for equal breath sounds. Normal breath sounds should be heard, with little difference between inspiration and expiration. Fine crackles can be heard on inspiration soon after birth as a result of clearing amniotic fluid from the lungs. Diminished breath sounds might indicate atelectasis, effusion, or poor respiratory effort (Dillon, 2007).

Listen to the heart when the newborn is quiet or sleeping. S1 and S2 heart sounds are accentuated at birth. The point of maximal impulse (PMI) is a lateral to midclavicular line located at the fourth intercostal space. A displaced PMI may indicate tension pneumothorax or cardiomegaly. Murmurs are often heard and are usually benign, but if present after the first 12 hours of life should be evaluated to rule out a cardiac disorder (Kliegman et al., 2007).

Abdomen

Inspect the abdomen for shape and movement. Typically the newborn's abdomen is protuberant but not distended. This contour is a result of the immaturity of the abdominal muscles. Abdominal movements are synchronous with respirations because newborns are, at times, abdominal breathers.

Auscultate bowel sounds in all four quadrants and then palpate the abdomen for consistency, masses, and tenderness. Perform auscultation and palpation systematically in a clockwise fashion until all four quadrants have been assessed. Palpate gently to feel the liver, the kidneys, and any masses. The liver is normally palpable 1 to 3 cm below the costal margin in the midclavicular line. The kidneys are 1 to 2 cm above and to both sides of the umbilicus. Normal findings would include bowel sounds in all four quadrants and no masses or tenderness on palpation. Absent or hyperactive bowel sounds might indicate an intestinal obstruction. Abdominal distention might indicate ascites, obstruction, infection, masses, or an enlarged abdominal organ (Cohen, 2007).

Inspect the umbilical cord area for the correct amount of blood vessels (two arteries and one vein). The umbilical vein is larger than the two umbilical arteries. Evidence of only a single umbilical artery is associated with renal and gastrointestinal anomalies. Also inspect the umbilical area for signs of bleeding, infection, granuloma, or abnormal communication with the intra-abdominal organs (Walsh, 2007).

Genitalia

Inspect the penis and scrotum in the male. In the circumcised male newborn, the glans should be smooth, with the meatus centered at the tip of the penis. It will appear reddened until it heals. For the uncircumcised male, the foreskin should cover the glans. Check the position of the urinary meatus: it should be in the midline at the glans tip. If it is on the ventral surface of the penis, hypospadias is present; if it is on the dorsal surface of the penis, it is termed epispadias. In either case, circumcision should be avoided until further evaluation.

Inspect the scrotum for size, symmetry, color, presence of rugae, and location of testes. The scrotum usually appears relatively large and should be pink in white neonates and dark brown in neonates of color. Rugae should be well formed and should cover the scrotal sac. There should not be bulging, edema, or discoloration (Fig. 18.13A).

FIGURE 18.13 Newborn genitalia. (**A**) Male genitalia. Note the darkened color of the scrotum. (**B**) Female genitalia.

Palpate the scrotum for evidence of the testes, which should be in the scrotal sac. The testes should feel firm and smooth and should be of equal size on both sides of the scrotal sac in the term newborn. Undescended testes (cryptorchidism) might be palpated in the inguinal canal in preterm infants; they can be unilateral or bilateral. If the testes are not palpable within the scrotal sac, further investigation is needed.

In the female newborn, inspect the external genitalia. The urethral meatus is located below the clitoris in the midline (Dillon, 2007). In contrast to the male genitalia, the female genitalia will be engorged: the labia majora and minora may both be edematous. The labia majora is large and covers the labia minora. The clitoris is large and the hymen is thick. These findings are due to the maternal hormones estrogen and progesterone (see Fig. 18.13B). A vaginal discharge composed of mucus mixed with blood may also be present during the first few weeks of life. This discharge, called **pseudomenstruation**, requires no treatment. Explain this phenomenon to the parents.

Variations in female newborns may include a labial bulge, which might indicate an inguinal hernia; ambiguous genitalia; a rectovaginal fistula with feces present in the vagina; and an imperforate hymen.

Inspect the anus in both male and female newborns for position and patency. Passage of meconium indicates patency. If meconium is not passed, a lubricated rectal thermometer can be inserted or a digital examination can be performed to determine patency. Abnormal findings would include anal fissures or fistulas and no meconium passed within 24 hours after birth.

Extremities and Back

Inspect the newborn's upper extremities for appearance and movement. Inspect the hands for shape, number, and position of fingers and presence of palmar creases. The newborn's arms and hands should be symmetric and should move through range of motion without hesitation. Observe for spontaneous movement of the extremities. Each hand should have five digits. Note any extra digits (polydactyly) or fusing of two or more digits (syndactyly). Most newborns have three palmar creases on the hand. A single palmar crease, called a simian line, is frequently associated with Down syndrome.

A brachial plexus injury can occur during a difficult birth involving shoulder dystocia. Erb's palsy is an injury resulting from damage to the upper plexus during labor and birth. The affected arm hangs limp alongside the body, and the affected shoulder and arm are adducted, extended, and internally rotated with a pronated wrist. The Moro reflex is absent on the affected side in brachial palsy. Complete recovery may take 3 to 6 months (Adegbehingbe et al., 2007).

Assess the lower extremities in the same manner. They should of equal length, with symmetric skin folds. Inspect the feet for clubfoot (a turning-inward position), which is secondary to intrauterine positioning. This may be positional or structural. Perform the Ortolani and Barlow maneuvers to identify congenital hip dislocation, commonly termed developmental dysplasia of the hip (DDH). Nursing Procedure 18.1 highlights the steps for performing these maneuvers.

Inspect the back. The spine should appear straight and flat and should be easily flexed when the baby is held in a prone position. Observe for the presence of a tuft of

Nursing Procedure 18.1

PERFORMING ORTOLANI AND BARLOW MANEUVERS

Purpose: To Detect Congenital Developmental Dysplasia of the Hip

Ortolani Maneuver

1. Place the newborn in the supine position and flex the hips and knees to 90 degrees at the hip.
2. Grasp the inner aspect of the thighs and abduct the hips (usually to approximately 180 degrees) while applying upward pressure.

A

3. Listen for any sounds during the maneuver. There should be no "cluck" or "click" heard when the legs are abducted. Such a sound indicates the femoral head hitting the acetabulum as the head re-enters the area. This suggests developmental hip dysplasia.

Barlow Maneuver

1. With the newborn still lying supine and grasping the inner aspect of the thighs (as just mentioned), adduct the thighs while applying outward and downward pressure to the thighs.

B

2. Feel for the femoral head slipping out of the acetabulum; also listen for a click (Dillon, 2007).

hair, a pilonidal dimple in the midline, a cyst, or a mass along the spine. These abnormal findings should be documented and reported to the primary health care provider.

Table 18.3 summarizes the newborn assessment.

Neurologic Status

Assess the newborn's state of alertness, posture, muscle tone, and reflexes.

Newborn Alertness, Posture, and Muscle Tone

The newborn should be alert and not persistently lethargic. The normal posture is hips abducted and partially flexed, with knees flexed. Arms are adducted and flexed at the elbow. Fists are often clenched, with fingers covering the thumb.

To assess for muscle tone, support the newborn with one hand under the chest. Observe how the neck muscles hold the head. The neck extensors should be able to hold the head in line briefly. There should be only slight head lag when pulling the newborn from a supine position to a sitting one.

Newborn Reflexes

Assess the newborn's reflexes to evaluate neurologic function and development. Absent or abnormal reflexes in a newborn, persistence of a reflex past the age when the reflex is normally lost, or return of an infantile reflex in an older child or adult may indicate neurologic pathology (Table 18.4). Reflexes commonly assessed in the newborn include sucking, Moro, stepping, tonic neck, root-

TABLE 18.3 NEWBORN ASSESSMENT SUMMARY

Assessment	Usual Findings	Variations and Common Problems
Anthropometric measurements	Head circumference: 33–37 cm (13–14 in) Chest circumference: 30–33 cm (12–13 in) Weight: 2,500–4,000 g (5.5–8.5 lb) Length: 45–55 cm (19–21 in)	SGA, LGA, preterm, postterm
Vital signs	Temperature: 36.5°–37.5°C (97°–99°F) Apical pulse: 120–160 bpm Respirations: 30–60 breaths/minute	
Skin	Normal: smooth, flexible, good skin turgor, warm	Jaundice, acrocyanosis, milia, Mongolian spots, stork bites
Head	Normal: varies with age, gender, ethnicity	Microcephaly, macrocephaly, enlarged fontanels
Face	Normal: full cheeks, facial features symmetric	Facial nerve paralysis, nevus flammeus, nevus vasculosus
Nose	Normal: small, placement in the midline and narrow, ability to smell	Malformation or blockage
Mouth	Normal: aligned in midline, symmetric, intact soft and hard palate	Epstein's pearls, erupted precocious teeth, thrush
Neck	Normal: short, creased, moves freely, baby holds head in midline	Restricted movement, clavicular fractures
Eyes	Normal: clear and symmetrically placed on face	Chemical conjunctivitis, subconjunctival hemorrhages
Ears	Normal: soft and pliable with quick recoil when folded and released	Low-set ears, hearing loss
Chest	Normal: round, symmetric, smaller than head	Nipple engorgement, whitish discharge
Abdomen	Normal: protuberant contour, soft, three vessels in umbilical cord	Distended, only two vessels in umbilical cord
Genitals	Normal male: smooth glans, meatus centered at tip of penis Normal female: swollen female genitals as a result of maternal estrogen	Edematous scrotum in males, vaginal discharge in females
Extremities and spine	Normal: extremities symmetric with free movement	Congenital hip dislocation; tuft or dimple on spine

TABLE 18.4 NEWBORN REFLEXES: APPEARANCE AND DISAPPEARANCE

Reflex	Appearance	Disappearance
Blinking	Newborn	Persists into adulthood
Moro	Newborn	3–6 mo
Grasp	Newborn	3–4 mo
Stepping	Birth	1–2 mo
Tonic neck	Newborn	3–4 mo
Sneeze	Newborn	Persists into adulthood
Rooting	Birth	4–6 mo
Gag reflex	Newborn	Persists into adulthood
Cough reflex	Newborn	Persists into adulthood
Babinski sign	Newborn	12 mo

ing, Babinski, and palmar grasp reflex. Spinal reflexes tested include truncal incurvation (Galant reflex) and anocutaneous reflex (anal wink).

The sucking reflex is elicited by gently stimulating the newborn's lips by touching them. The newborn will typically open the mouth and begin a sucking motion. Placing a gloved finger in the newborn's mouth will also elicit a sucking motion (Fig. 18.14A).

The Moro reflex, also called the embrace reflex, occurs when the neonate is startled. To elicit this reflex, place the newborn on his or her back. Support the upper body weight of the supine newborn by the arms, using a lifting motion, without lifting the newborn off the surface. Then release the arms suddenly. The newborn will throw the arms outward and flex the knees; the arms then return to the chest. The fingers also spread to form a C. The newborn initially appears startled and then relaxes to a normal resting position (see Fig. 18.14B).

Assess the stepping reflex by holding the newborn upright and inclined forward with the soles of the feet touching a flat surface. The baby should make a stepping motion or walking, alternating flexion and extension with the soles of the feet (see Fig. 18.14C).

The tonic neck reflex resembles the stance of a fencer and is often called the fencing reflex. Test this reflex by having the newborn lie on the back. Turn the baby's head to one side. The arm toward which the baby is facing should extend straight away from the body with the hand partially open, whereas the arm on the side away from the face is flexed and the fist is clenched tightly. Reversing the direction to which the face is turned reverses the position (see Fig. 18.14D).

Elicit the rooting reflex by stroking the newborn's cheek. The newborn should turn toward the side that was stroked and should begin to make sucking movements (see Fig. 18.14E).

The Babinski reflex should be present at birth and disappears at approximately 1 year of age. It is elicited by stroking the lateral sole of the newborn's foot from the heel toward and across the ball of the foot. The toes should fan out. A diminished response indicates a neurologic problem and needs follow-up (see Fig. 18.14F).

The newborn exhibits two grasp reflexes: palmar grasp and plantar grasp. Elicit the palmar grasp reflex by placing a finger on the newborn's open palm. The baby's hand will close around the finger. Attempting to remove the finger causes the grip to tighten. Newborns have strong

FIGURE 18.14 Newborn reflexes. (**A**) Sucking reflex. (**B**) Moro reflex. *(continued)*

FIGURE 18.14 (continued) (**C**) Stepping reflex. (**D**) Tonic neck reflex. (**E**) Rooting reflex. (**F**) Babinski reflex. *(continued)*

FIGURE 18.14 (continued) (**G**) Palmar grasp. (**H**) Plantar grasp.

grasps and can almost be lifted from a flat surface if both hands are used. The grasp should be equal bilaterally (see Fig. 18.14G).

The plantar grasp is similar to the palmar grasp. Place a finger just below the newborn's toes. The toes typically curl over the finger (see Fig. 18.14H).

Blinking, sneezing, gagging, and coughing are all protective reflexes and are elicited when an object or light is brought close to the eye (blinking), something irritating is swallowed or a bulb syringe is used for suctioning (gagging and coughing), or an irritant is brought close to the nose (sneezing).

The truncal incurvation reflex (Galant reflex) is present at birth and disappears in a few days to 4 weeks. With the newborn in a prone position or held in ventral suspension, apply firm pressure and run a finger down either side of the spine. This stroking will cause the pelvis to flex toward the stimulated side. This indicates T2–S1 innervation. Lack of response indicates a neurologic or spinal cord problem.

The anocutaneous reflex (anal wink) is elicited by stimulating the perianal skin close to the anus. The external sphincter will constrict (wink) immediately with stimulation. This indicates S4–5 innervation (Kenner & Lott, 2007).

Nursing Interventions

Developing confidence to care for their newborn is challenging for most couples. It takes time and patience and a great deal of instruction provided by the nurse. "Showing and telling" parents about their newborn and all the procedures (e.g., feeding, bathing, changing, handling) involved in daily care are key nursing interventions.

Providing General Newborn Care

Generally, newborn care involves bathing and hygiene, diaper care, cord care, circumcision care, use of appropriate clothing, environmental safety measures, and prevention of infection. Nurses should teach these skills to parents and should serve as role models for appropriate and consistent interaction with newborns. Demonstrating respect for the newborn and family helps foster a positive atmosphere to promote the newborn's growth and development.

Bathing and Hygiene

Immediately after birth, drying the newborn and removing blood may minimize the risk of infection caused by hepatitis B, herpesvirus, and HIV, but the specific benefits of this practice remain unclear. Until the newborn has been thoroughly bathed, standard precautions should be used when handling the newborn.

Newborns are bathed primarily for aesthetic reasons, and bathing is postponed until thermal and cardiorespiratory stability is ensured. Traditional reasons why nurses bathe the newborn are so they can conduct a physical assessment, reduce the effect of hypothermia, and allow the mother to rest (Cohen, 2007). However, recent research suggests that nurses do not need to give the newborn an initial bath to reduce heat loss; rather, the parents could be given this opportunity, supported by nurses. A study found that the amount of heat loss was similar in newborns bathed by parents versus newborns who were bathed by nurses (Walsh, 2007).

Wear gloves, because of potential exposure to maternal blood on the newborn, and perform the bath quickly, drying the baby thoroughly to prevent heat loss by evaporation. Move from the "cleanest" area (the eyes) to the most soiled area (the diaper area) to prevent cross-contamination.

Use plain warm water on the face and eyes, adding a mild soap (e.g., Dove) to cleanse the remainder of the body. Instruct the parents to wash the face and neck gently after each feeding to prevent rashes and to prevent the odor that can develop when milk accumulates in the neck creases.

Wash the hair using running water so that the scalp can be thoroughly rinsed. A mild shampoo or soap can be used. Wash both fontanel areas. Frequently parents avoid these "soft spots" because they fear that they will "hurt the baby's brain" if they rub too hard. Reassure parents that there is a strong membrane providing protection. Urge the parents to clean and rinse these areas well. If the anterior fontanel is not rinsed well after shampooing, cradle cap (dry flakes on the scalp) can develop. In Figure 18.15, the nurse is showing the father how to bathe his newborn.

After bathing, place the newborn under the radiant warmer and wrap him or her securely in blankets to prevent chilling. Check the baby's temperature within an hour to make sure it is within normal limits. If it is low, place the newborn under a radiant heat source again.

The literature suggests that tub bathing for the first bath, as opposed to sponge bathing, can be done without significantly lowering the newborn's temperature or increasing rates of cord infection in healthy term newborns (AAP, 2007c).

After the initial bath, the newborn may not receive another full one during the stay in the birthing unit. The diaper area will be cleansed at each diaper change, and any milk spilled will be cleaned. Clear water and a mild soap are appropriate to cleanse the diaper area. The use of lotions, baby oil, and powders is not encouraged because oils and lotions can lead to skin irritation and can cause rashes. Powders should not be used because they can be inhaled, causing respiratory distress. If the parents want to use oils and lotions, have them apply a small amount onto their hand first, away from the newborn; this warms the lotion. Then the parents should apply the lotion or oil sparingly.

Instruct parents that a bath two or three times weekly is sufficient for the first year; more frequent bathing may dry the skin. Parents should not fully immerse the newborn into water until the umbilical cord area is healed—up to 2 weeks after birth. Encourage parents to give the infant a sponge bath until the umbilical cord falls off and the navel area is healed completely. If the newborn has been circumcised, advise parents to wait until that area has also healed (usually 1 to 2 weeks). Until then, clean the penis with mild soap and water and apply a small amount of Vaseline to the tip to prevent the diaper from adhering to the penis. Instruct parents to apply the diaper loosely and place the newly circumcised male infant on his side or back to prevent pressure and irritation on the penis.

Encourage the parents to gather all items needed before starting the bath: a soft, clean washcloth; two cotton balls to clean the eyes; mild, unscented soap and shampoo; towels or blankets; a tub or basin with warm water; a clean diaper; and a change of clothes. Other guidelines for bathing newborns are given in Teaching Guidelines 18.1.

FIGURE 18.15 The nurse demonstrates bathing a newborn while the father watches.

Elimination and Diaper Area Care

Newborn elimination patterns are highly individualized. Usually the urine is light amber in color. Soaking 6 to 12 diapers a day indicates adequate hydration. Stools can

TEACHING GUIDELINES 18.1

Bathing a Newborn

- Select a warm room with a flat surface at a comfortable working height.
- Before the bath, gather all supplies needed so they will be within reach.
- Never leave the newborn alone or unattended at any time during the bath.
- Undress the newborn down to shirt and diaper.
- Always support the newborn's head and neck when moving or positioning him or her.
- Place a blanket or towel underneath the newborn for warmth and comfort.
- In this order, progressing from the cleanest to the dirtiest areas:
  - Wipe eyes with plain water, using either cotton balls or a washcloth. Wipe from the inner corner of the eyes to the outer with separate wipes.
  - Wash the rest of the face, including ears, with plain water.
  - Using baby shampoo, gently wash the hair and rinse with water.
  - Pay special attention to body creases, and dry thoroughly.
  - Wash extremities, trunk, and back. Wash, rinse, dry, cover.
  - Wash diaper area last, using soap and water, and dry; observe for rash.
- Put on a clean diaper and clean clothes after the bath.

change in color, texture, and frequency without signaling a problem. Meconium is passed for the first 48 hours after birth; the stools appear thick, tarry, sticky, and dark green. Transitional stools (thin, brown to green, less sticky than meconium) typically appear by day 3 after initiation of feeding. The stool characteristics after transitional stool depend on whether the newborn is breast-fed or bottle-fed. Breast-fed newborns typically pass mustard-colored, soft stool with a seedy consistency; formula-fed newborns pass yellow to brown, formed stool with a pasty consistency. As long as the newborn seems content, is eating normally, and shows no signs of illness, minor changes in bowel movements should not be a concern.

The newborn needs to be checked frequently to see whether a diaper change is needed, especially after feeding. Adhere to standard precautions when providing diaper area care. Instruct parents to keep the top edge of the diaper below the umbilical cord area to prevent irritation and to allow air to help dry the cord.

Meconium can be difficult to remove from the skin. Use plain water or special cleansing wipes if necessary to clean the area. Teach parents how to clean the diaper area properly and how to prevent skin irritation. Encourage them to avoid products such as powder and fragranced items, which could be irritating.

Discuss the pros and cons of using cloth diapers versus disposable diapers so that the parents can make informed decisions. Regardless of the type of diapers used, up to 10 diapers a day, or about 70 a week, will be needed.

Additional information about diapering might include:

- Before diapering, make sure all supplies are within reach, including clean diaper, cleaning agent or wipes, and ointment.
- Lay the newborn on a changing table and remove the dirty diaper.
- Use water and mild soap or wipes to gently wipe the genital area clean; wipe from front to back for girls to avoid urinary tract infections.
- Wash your hands thoroughly before and after changing diapers.

While performing diaper area care, parents should observe the area closely for irritation or rash. Tips for preventing or healing a diaper rash include:

- Change diapers frequently, especially after bowel movements.
- Apply a "barrier" cream, such as A & D ointment, after cleaning with mild soap and water.
- Use dye- and fragrance-free detergents to wash cloth diapers.
- Avoid the use of plastic pants, because they tend to hold in moisture.
- Expose the newborn's bottom to air several times a day.
- Place the newborn's buttocks in warm water after he or she had a diaper on all night.

▶ *Take* NOTE!

Advise parents that a rash that persists for more than 3 days may be fungal in origin and may require additional treatment. Encourage the parents to notify the health care provider.

Cord Care

The umbilical cord begins drying within hours after birth and is shriveled and blackened by the second or third day. Within 7 to 10 days, it sloughs off and the umbilicus heals. During this transition, frequent assessments of the area are necessary to detect any bleeding or signs of infection. Cord bleeding is abnormal and may occur if the cord clamp is loosened. Any cord drainage is also abnormal and is generally caused by infection, which requires immediate treatment.

To protect the cord area during each diaper change, apply the appropriate agent (e.g., triple dye, alcohol, or an antimicrobial agent), according to facility policy, to the cord stump to prevent any ascending infections. Single-use agents for cleaning are recommended to prevent cross-contamination with other newborns. Expect to remove the cord clamp approximately 24 hours after birth by using a cord-cutting clamp. However, if the cord is still moist, keep the clamp in place and ensure a referral to home health care so that the home care nurse can remove it after discharge. Always adhere to agency policies regarding cord care; changes in policy may be necessary based on new research findings.

Many parents avoid contact with the cord site to make sure they don't "bother" it. Teach them how to care for the cord site when they go home to prevent complications (Teaching Guidelines 18.2).

Circumcision Care

Circumcision is the surgical removal of all or part of the foreskin (prepuce) of the penis (AAP, 2007c). This has been traditionally done for hygiene and medical reasons and is the oldest known religious rite. In the Jewish faith, circumcision is a ritual that is performed by a *mohel* (ordained circumciser) on the eighth day after birth if possible. The circumcision is followed by a religious ceremony during which the newborn is named.

There are three commonly used methods of circumcision: the Gomco clamp, the Plastibell device, and the Mogen clamp. During the circumcision procedure, part of the foreskin is removed by clamping and cutting with a scalpel (Gomco or Mogen clamp) or by using a Plastibell. The Plastibell is fitted over the glans, and the excess foreskin is pulled over the plastic ring. A suture is tied around the rim to apply pressure to the blood vessels, creating hemostasis. The excess foreskin is cut away. The plastic rim remains in place until healing occurs.

TEACHING GUIDELINES 18.2

Umbilical Cord Care

- Observe for bleeding, redness, drainage, or foul odor from the cord stump and report it to your newborn's primary care provider immediately.
- Avoid tub baths until the cord has fallen off and the area has healed.
- Expose the cord stump to the air as much as possible throughout the day.
- Fold diapers below the level of the cord to prevent contamination of the site and to promote air-drying of the cord.
- Observe the cord stump, which will change color from yellow to brown to black. This is normal.
- Never pull the cord or attempt to loosen it; it will fall off naturally.

The plastic ring typically loosens and falls off in approximately 1 week (Kenner & Lott, 2007) (Fig. 18.16).

The debate over routine newborn circumcision continues in the United States. For many years, the purported benefits and harms of circumcision have been debated in the medical literature and society at large, with no clear consensus to date. Despite the controversy, circumcision is the most common surgical procedure performed on newborns, and almost two thirds of American male newborns are circumcised (Cunningham et al., 2005).

A policy statement by the AAP indicates that newborn circumcision has potential disadvantages and risks as well as medical benefits and advantages. Risks to the newborn include infection, hemorrhage, skin dehiscence, adhesions, urethral fistula, and pain. Benefits to the newborn include the following:

- Urinary tract infections are slightly less common in circumcised boys; however, rates are low in both circumcised and uncircumcised boys and are easily treated without long-term sequelae.
- Sexually transmitted infections are less common in circumcised males, but the risk is believed to be related more to behavioral factors than to circumcision status. However, circumcised males have a 50% lower risk of acquiring HIV infection (Ridings & Amaya, 2007).
- There appears to be a slightly lower rate of penile cancer in circumcised males; however, penile cancer is rare and risk factors such as genital warts, infection with human papillomavirus (HPV), multiple sex partners, and cigarette smoking seem to play a much larger role in causing penile cancer than circumcision status (Kliegman et al., 2007).

The new AAP recommendations state that if parents decide to circumcise their newborn, pain relief must be provided. Research has found that newborns circumcised without analgesia experience pain and stress, indicated by changes in heart rate, blood pressure, oxygen saturation, and cortisol levels (Ridings & Amaya, 2007). Analgesic methods may include EMLA cream (a topical mixture of local anesthetics), a dorsal penile nerve block with buffered lidocaine, acetaminophen, a sucrose pacifier, and swaddling (Cunningham et al., 2005).

The AAP recommends that parents be given accurate and unbiased information about the risks and benefits of circumcision. As with other newborn procedures, research continues. Nurses must keep informed about current medical research to allow parents to make informed decisions. The absence of compelling medical evidence in favor of or against newborn circumcision makes informed consent of parents of paramount importance. The circumcision discussion involves cultural, religious, medical, and emotional considerations. Nurses may have difficulty remaining unbiased and unemotional as they present the facts to parents. Circumcision is a very personal decision for parents, and the nurse's major responsibility is to inform the parents of the risks and benefits of the pro-

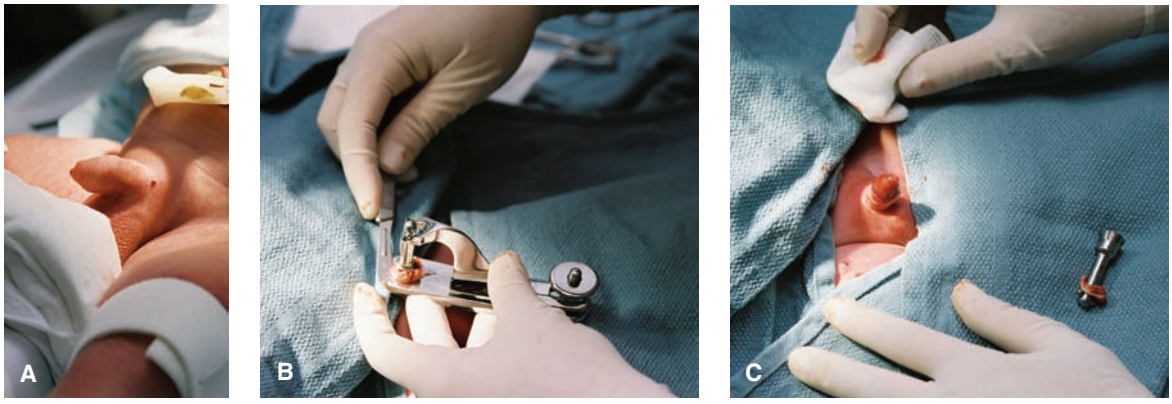

FIGURE 18.16 Circumcision. (**A**) Before the procedure. (**B**) Clamp applied and foreskin removed. (**C**) Appearance after circumcision.

cedure and to address concerns so that the parents can reach a fully informed decision.

▶ *Take* NOTE!

The decision to circumcise the male newborn is often a social one, with the strongest factor being whether the newborn's father is himself circumcised (AAP, 2007).

Immediately after circumcision, the tip of the penis is usually covered with petroleum jelly-coated gauze to keep the wound from sticking to the diaper. Continued care of this site includes:

- Assess for bleeding every 30 minutes for at least 2 hours.
- Document the first voiding to evaluate for urinary obstruction or edema.
- Squeeze soapy water over the area daily and then rinse with warm water. Pat dry.
- Apply a small amount of petroleum jelly with every diaper change if the Plastibell was used; clean with mild soap and water if other techniques were used.
- Fasten the diaper loosely over the penis and avoiding placing the newborn on his abdomen to prevent friction.

If a Plastibell has been used, it will fall off by itself in about a week. Inform parents of this and advise them not to pull it off sooner. Also instruct the parents to check daily for any foul-smelling drainage, bleeding, or unusual swelling.

If the newborn is uncircumcised, wash the penis with mild soap and water after each diaper change and do not force the foreskin back; it will retract normally over time.

Safety

Newborns are completely dependent on those around them to ensure their safety. Their safety must be ensured while in the health care facility and after they are discharged. Parental education is key, especially as the newborn grows and develops and begins to respond to and explore his or her surroundings (Teaching Guidelines 18.3).

Environmental Safety

People who enter a health care facility for treatment expect to be safe there until they return home, but ensuring a safe environment can be a daunting challenge to a health care facility.

Consider this scenario: A woman dressed in nurse's clothing entered the hospital room of a new mother soon after she had given birth. This "nurse" told the mother she needed to take her newborn to the nursery to have him weighed. Sometime later, a staff nurse making her routine rounds realized something was wrong when she saw that the newborn's bassinet in the mother's room was empty and the mother was sound asleep in her bed. The staff nurse called security immediately because she suspected that a newborn abduction had taken place.

This is a typical abduction scenario that is repeated many times throughout the United States each year. In **infant abduction**, someone who is not a family member takes a child less than 1 year old (Cohen, 2007). Infant abductions are traumatic for the parents, the community, and the health care facility. The facility may also face huge financial liability if a lawsuit is filed by the parents.

Abductions typically occur during the day and are usually carried out by women who are not criminally sophisticated. Many of these women experienced a pregnancy loss in the past; they are often emotionally immature and compulsive, with low self-esteem. Most female abductors can play the role of a hospital employee convincingly (Healthcare Risk Management, 2007).

Health care agencies are challenged to prevent infant abduction by instituting sound security practices and

TEACHING GUIDELINES 18.3

General Newborn Safety

- Have emergency telephone numbers readily available, such as those for emergency medical assistance and the poison control center.
- Keep small or sharp objects out of reach to prevent them from being aspirated.
- Put safety plugs in wall sockets within the child's reach to prevent electrocution.
- Do not leave the infant alone in any room without a portable intercom on.
- Always supervise the newborn in the tub: a newborn can drown in 2 inches of water.
- Make sure the crib or changing table is sturdy, without any loose hardware, and is painted with lead-free paint.
- Avoid placing the crib or changing table near blinds or curtain cords.
- Provide a smoke-free environment for all infants.
- Place all infants on their backs to sleep to prevent sudden infant death syndrome.
- To prevent falls, do not leave the newborn alone on any elevated surface.
- Use sun shields on strollers and hats to avoid overexposing the newborn to the sun.
- To prevent infection, thoroughly wash your hands before preparing formula.
- Thoroughly investigate any infant care facility before using it.

Source: AAP, 2007b.

systems (AWHONN Lifelines, 2007). Such measures include the following:

- All newborns must be transported in cribs and not carried.
- Nurses must respond immediately to any security alarm that sounds on the unit.
- Newborns must never be unattended at any time, especially in hallways.
- All staff must wear appropriate identification at all times.
- Scrubs should not be worn by nursing staff on the postpartum unit.
- Personnel should be wary of visitors who do not seem to be visiting a specific mother.
- The electronic security system should be checked to make sure it works.
- Proper functioning and placement of any electronic sensors used on newborns should be ensured.
- Parents should be taught what infant abduction is; why infant security is important; the schedule of nursery, feeding, and visiting hours; rules about visitor access; the facility's security policies and procedures; what parents can do to protect their infant in the hospital; which staff members are allowed to handle the newborn; and what a proper ID looks like.

Providing a safe and secure environment is a shared responsibility of the facility, staff, and parents. Preventing abductions requires everyone to learn and follow the rules and policies.

Car Safety

Every state requires the use of car seats for infants and children, because motor vehicle accidents are still the leading cause of unintentional injury and death in children under age 5 (AAP, 2007d). In more than half of these deaths, the child was unrestrained.

Despite evidence that the use of car seats can reduce the morbidity and mortality of motor vehicle crashes, parents who lack knowledge about them may underuse or misuse them (AAP, 2007d). Make sure that both parents understand the importance of safely transporting their newborn in a federally approved safety car seat every time the infant rides in a car. Do not release any newborn unless the parents have a car seat in place for their newborn's ride home (Fig. 18.17). If they cannot afford one, many community organizations will provide one for them. According to the AAP, no one car seat is considered to be the "safest" or the "best," but rather consistent and proper use is the key to preventing injuries and deaths. Instruct parents in the following:

- Select a car seat that is appropriate for the child's size and weight.
- Use the car seat correctly, every time the child is in the car.
- Use rear-facing car seats for infants until they are at least 1 year old and weigh 20 lb.

FIGURE 18.17 Newborn in a properly secured car seat.

- Make sure the harness (most seats have a three- to five-point harness) is in the slots at or below the shoulders.

Infection Prevention

The nurse plays a major role in preventing infection in the newborn environment. Ways to control infection are as follows:

- Minimize exposure of newborns to organisms.
- Wash your hands before and after providing care, and insist that all personnel wash their hands before handling any newborn.
- Do not allow ill staff or visitors to visit or handle newborns.
- Monitoring the umbilical cord stump and circumcision site for signs of infection.
- Providing eye prophylaxis by instilling prescribed medication soon after birth.
- Educate parents about appropriate home measures that will prevent infections, such as practicing good hand washing before and after diaper changes, keeping the newborn well hydrated, avoiding bringing the infant into crowds (which may expose him or her to colds and flu viruses), observing for early signs of infection (fever, vomiting, loss of appetite, lethargy, labored breathing, green watery stools, drainage from umbilical cord site or eyes), and keeping pediatrician appointments for routine immunizations.

Promoting Sleep

Although many parents feel their newborns need them every minute of the day, babies actually need to sleep much of the day initially. Usually newborns sleep up to 15 hours daily. They sleep for 2 to 4 hours at a time but do not sleep through the night because their stomach capacity is too small to go long periods without nourishment.

▶ *Take* NOTE!

All newborns develop their own sleep patterns and cycles, but it may take several months before the newborn sleeps through the night.

Parents should place the newborn on his or her back to sleep. To prevent suffocation, all fluffy bedding, quilts, sheepskins, stuffed animals, and pillows should be removed from the crib.

Parents should be informed that the practice of "co-sleeping" (sharing a bed) is not safe: for example, infants who sleep in adult beds are up to 40 times more likely to suffocate than those who sleep in cribs (Buswell & Spatz 2007). Suffocation can occur when the infant gets entangled in bedding or caught under pillows, or slips between the bed and the wall or the headboard and mattress. The parent may accidentally roll against or on top of the baby. The safest place for a newborn to sleep is in a crib, without any movable objects close by.

Teach parents to avoid other unsafe conditions, such as placing the newborn in the prone position, using a crib that does not meet federal safety guidelines, allowing window cords to hang loose and in close proximity to the crib, or setting the room temperature too high (can cause overheating) (Adler, Hyderi, & Hamilton, 2006).

Enhancing Bonding

Encourage and enhance parent–newborn interaction by involving both parents with the baby and demonstrating appropriate nurturing behaviors:

- Say "hello" and introduce yourself to the newborn.
- Ask the parents permission to care for and hold their newborn. This helps parents to realize that they are responsible for their child and reminds nurses of their role.
- Show parents the power of a soothing voice to calm the newborn.
- Provide care to the newborn in the least stressful way.
- Demonstrate ways to wake the newborn up gently to feed better.
- Tell parents what you are doing, why you are doing it, and how they can duplicate what you are doing at home.
- Offer the opportunity for parents to perform care while you observe them. Support their efforts to soothe the newborn throughout the care process.
- Help parents to interpret the communication cues the newborn uses.
- Point out the efforts the newborn is making to connect with the parents (e.g., alerting to the familiar voice, following the parents while they are speaking, quieting when held securely).

One of the most pleasurable aspects of newborn care is being close to them. Bonding begins soon after birth when parents cradle their newborn and gently stroke him or her with their fingers. Provide parents with opportunities for "skin-to-skin" contact with the newborn, holding the baby against their own skin when feeding or cradling. Many newborns respond very positively to gentle massage. If necessary, recommend books and videos that cover the subject.

For newborns, crying is their only way to communicate that something is wrong. Try to find out the reason why: Is the diaper wet? Is the room too hot or too cold? Is the baby uncomfortable (e.g., diaper rash or tight clothing)? Suggest the following ways in which parents can soothe an upset newborn:

- Try feeding or burping to relieve air or stomach gas.
- Lightly rub the newborn's back and speak softly to him or her.
- Gently sway side to side, or rock back and forth in a rocking chair.
- Talk with the newborn while making eye contact.
- Take the newborn for a walk in a stroller or carriage to get fresh air.
- Change the baby's position from back to side or vice versa.
- Try singing, reciting poetry and nursery rhymes, or reading to the baby.
- Turn on a musical mobile above the newborn's head.
- Give more physical contact by walking, rocking, or patting the newborn.
- Swaddle the newborn to provide a sense of security and comfort. To do this:
  - Spread out a receiving blanket, with one corner folded slightly.
  - Lay the newborn face up with head at the folded corner.
  - Wrap the left corner over the baby's body and tuck it beneath the baby.
  - Bring the bottom corner over the baby's feet.
  - Wrap the right corner around the baby, leaving only the head exposed.

Assisting With Screening Tests

Screening newborns for problems is important because some potentially life-threatening metabolic diseases may not be obvious at birth. Newborn screening tests that are required in most states before discharge are used to check for certain genetic and inborn errors of metabolism and hearing. Early identification and initiation of treatment can prevent significant complications and can minimize the negative effects of untreated disease.

Genetic and Inborn Errors of Metabolism Screening

Although each state mandates which conditions must be tested, the most common screening tests are for PKU, hypothyroidism, galactosemia, and sickle cell disease (Table 18.5).

TABLE 18.5 SELECTED CONDITIONS SCREENED FOR IN THE NEWBORN

Condition	Description	Clinical Picture/ Effect If Not Treated	Treatment	Timing of Screening
PKU	Autosomal recessive inherited deficiency in one of the enzymes necessary for the metabolism of phenylalanine to tyrosine—essential amino acids found in most foods	Irritability, vomiting of protein feedings, and a musty odor to the skin or body secretions of the newborn; if not treated, mental and motor retardation, seizures, microcephaly, and poor growth and development	Lifetime diet of foods low in phenylalanine (low protein) and monitoring of blood levels (Lawson, 2007); special newborn formulas available: Phenex and Lofenalac	Universally screened for in the United States; testing is done 24–48 hours after protein feeding (PKU)
Congenital hypothyroidism	Deficiency of thyroid hormone necessary for normal brain growth, calorie metabolism, and development; may result from maternal hypothyroidism	Increased risk in newborns with birthweight <2,000 g or >4,500 g, and those of Hispanic and Asian ethnic groups; feeding problems, growth and breathing problems; if not treated, irreversible brain damage and mental retardation	Lifelong thyroid replacement therapy (Dudek, 2006)	Testing (measures thyroxin [T4] and TSH) is done between days 4 and 6 of life.
Galactosemia	Absence of the enzyme needed for the conversion of the milk sugar galactose to glucose	Poor weight gain, vomiting, jaundice, mood changes, loss of eyesight, seizures, and mental retardation; if untreated, galactose buildup causing permanent damage to the brain, eyes, and liver, and eventually death	Eliminate milk from diet; substitute soy milk	First test done on discharge from the hospital with a follow-up test within 1 month
Sickle cell anemia	Recessively inherited abnormality in hemoglobin structure, most commonly found in African-American newborns	Anemia developing shortly after birth; increased risk for infection, growth restriction, vaso-occlusive crisis	Maintenance of hydration and hemodilution, rest, electrolyte replacement, pain management, blood replacement, and antibiotics	Bloodspot obtained at same time of other newborn screening tests or prior to 3 months of age

The trend toward early discharge of newborns can affect the timing of screening and the accuracy of some test results. For example, the newborn needs to ingest enough breast milk or formula to elevate phenylalanine levels for the screening test to identify PKU accurately, so newborn screening for PKU testing should not be performed before 24 hours of age.

Screening tests for genetic and inborn errors of metabolism require a few drops of blood taken from the newborn's heel (Fig. 18.18). These tests are usually per-

FIGURE 18.18 Screening for PKU. (**A**) Performing a heel stick. (**B**) Applying the blood specimen to the card for screening.

formed shortly before discharge. Newborns who are discharged before 24 hours of age need to have repeat tests done within a week in an outpatient facility.

Be aware of which conditions your state regularly screens for at birth to ensure that the parents are taught about the tests and the importance of early treatment. Also be familiar with the optimal time frame for screening and conditions that could affect the results. Ensure that a satisfactory specimen has been obtained at the appropriate time and that circumstances that could cause false results have been minimized. Send out specimens and completed forms within 24 hours of collection to the appropriate laboratory (Kenner & Lott, 2007).

Hearing Screening

Hearing loss is the most common birth disorder in the United States: approximately three to five newborns out of every 1,000 have some degree of hearing loss. Unlike a physical deformity, hearing loss is not clinically detectable at birth and thus remains difficult to assess (Wrightson, 2007). Factors associated with an increased risk of hearing loss include:

- Family history of childhood sensory hearing loss
- Congenital infections such as cytomegalovirus, rubella, toxoplasmosis, herpes
- Craniofacial anomalies involving the pinna or ear canal
- Low birthweight (less than 1,500 g)
- Postnatal infections such as bacterial meningitis
- Head trauma
- Hyperbilirubinemia requiring an exchange transfusion
- Exposure to ototoxic drugs, especially aminoglycosides
- Perinatal asphyxia (USPSTF, 2006)

Delays in identification and intervention may affect the child's language development, academic performance, and cognitive development. Detection before 3 months greatly improves outcomes. Because of this, auditory screening programs for all newborns are recommended by the AAP and are mandated by law in over 30 states. Screening only infants with risk factors is not enough, because as many as 50% of infants born with hearing loss have no known risk factors (AAP, 2007b). Early identification and intervention can prevent severe psychosocial, educational, and language development delays.

The current goals of *Healthy People 2010* (see the Healthy People 2010 display earlier in this chapter) are to screen all infants by 1 month of age, confirm hearing loss with an audiologic examination by 3 months of age, and treat with comprehensive early intervention services before 6 months of age (USDHHS, Volume II, Objective 16-20).

All newborns should be screened prior to discharge to ensure that any newborn with a hearing loss is not missed. Those with suspected hearing loss should be referred for follow-up assessment (Box 18.1 discusses screening methods). In addition, nurses should ensure that testing is accurate to facilitate early diagnosis and intervention services and to optimize the newborn's developmental potential.

BOX 18.1 Newborn Hearing Screening Methods

A newborn's hearing can be screened in one of two ways: otoacoustic emission (OAE) or automated auditory brain stem response (ABR). In OAE, an earphone is placed in the infant's ear canal and the sounds produced by the newborn's inner ear are measured in response to certain tones or clicks presented through the earphone. Preset parameters in the equipment decide whether the OAEs are sufficient for the newborn to pass or whether a referral is necessary for further evaluation.

In ABR, an earphone is placed in the ear canal or an earmuff is placed over the newborn's ear, and a soft, rapid tapping noise is presented. Electrodes placed around the newborn's head, neck, and shoulders record neural activity from the infant's brain stem in response to the tapping noises. The ABR tests how well the ear and the nerves leading to the brain work. Like OAEs, automated ABR screening is sensitive to more than mild degrees of hearing loss, but a "pass" does not guarantee normal hearing.

EVIDENCE-BASED PRACTICE 18.1
Universal Neonatal Hearing Screening Versus Selective Screening as Part of the Management of Childhood Deafness

● Study
The principal factors that determine how deafness affects a child's development are the degree of hearing impairment and the age at which it is diagnosed. A number of factors are thought to increase the risk of hearing impairment, such as low birthweight, prematurity, and perinatal hypoxia and jaundice. The high incidence of deafness in children without risk factors and the introduction of simple new screening tests with high sensitivity and specificity have led many prestigious bodies to recommend universal early detection programs for deafness rather than screening that targets high-risk groups. A study was performed to compare the long-term effectiveness of a universal neonatal screening and early treatment program for hearing impairment versus screening and treatment of high-risk neonates only.

▲ Findings
This review found no randomized trials that compared the long-term results of these screening programs. Controlled trials and before-and-after studies are needed to address this issue.

■ Nursing Implications
Although additional research is needed, nurses should encourage all parents to have their newborns screened. The AAP recommends hearing screening for all newborns so that early interventions can be provided to prevent speech, language, and cognitive development impairments. This information should be stressed during discharge planning activities and follow-up tests if warranted.

Puig, T., Municio, A., & Medà, C. (2006). Universal neonatal hearing screening versus selective screening as part of the management of childhood deafness. *Cochrane Database of Systematic Reviews* 2006, Issue 2. Art. No.: CD003731. DOI: 10.1002/14651858.CD003731.pub2

Dealing With Common Concerns
During the newborn period of transition, certain conditions can develop that require intervention. These conditions, although not typically life-threatening, can be a source of anxiety for the parents. Common concerns include transient tachypnea of the newborn, physiologic jaundice, and hypoglycemia.

Transient Tachypnea of the Newborn
Transient tachypnea of the newborn appears soon after birth. It is accompanied by retractions, expiratory grunting, or cyanosis and is relieved by low-dose oxygen therapy. Mild or moderate respiratory distress typically is present at birth or within 6 hours of birth. This condition usually resolves within 3 days.

Transient tachypnea of the newborn occurs when the fetal liquid in the lungs is removed slowly or incompletely. This can be due to the lack of thoracic squeezing that occurs during a cesarean birth, or diminished respiratory effort if the mother received central nervous system depressant medication. Prolonged labor, macrosomia of the fetus, and maternal asthma also have been associated with this condition (Asenjo, 2007).

Nursing interventions include providing supportive care (giving oxygen, ensuring warmth, observing respiratory status frequently, and allowing time for the pulmonary capillaries and the lymphatics to remove the remaining fluid). The clinical course is relatively benign, but any newborn respiratory issue can be very frightening to the parents. Provide a thorough explanation and reassure them that the condition will resolve over time.

Physiologic Jaundice
Physiologic jaundice is very common in newborns, with the majority demonstrating yellowish skin, mucous membranes, and sclera within the first 3 days of life. In any given year, approximately 60% of the newborns in the United States will experience clinical jaundice (Deshpande & Ramer, 2007). Jaundice is the visible manifestation of hyperbilirubinemia. It typically results from the deposition of unconjugated bilirubin pigment in the skin and mucous membranes.

Factors that contribute to the development of physiologic jaundice in the newborn include an increased bilirubin load because of relative polycythemia, a shortened erythrocyte life span (80 days compared with the adult 120 days), and immature hepatic uptake and conjugation processes (Deshpande & Ramer, 2007). Normally the liver removes bilirubin from the blood and changes it to a form in which it can be excreted. As the red blood cell breakdown continues at a fast pace, the newborn's liver cannot keep up with bilirubin removal. Thus, bilirubin accumulates in the blood, causing a yellowish discoloration on the skin.

The AAP has recently released guidelines for the prevention and management of hyperbilirubinemia in newborns. These include:

- Promotion and support of successful breast-feeding practices to make sure the newborn is well hydrated and stooling frequently to promote elimination of bilirubin
- Completion of a systematic assessment before discharge for the risk of severe hyperbilirubinemia

- Early and focused follow-up based on the risk assessment
- When indicated, treatment of newborns with phototherapy or exchange transfusion to prevent kernicterus (AAP, 2006b)

Assess for jaundice in all newborns by pressing gently with a fingertip on the bridge of the nose, sternum, or forehead. If jaundice is present, the blanched area will appear yellow before the capillary refill (Kenner & Lott, 2007).

Measures that parents can take to reduce the risk of jaundice include exposing the newborn to natural sunlight for short periods of time throughout the day to help oxidize the bilirubin deposits on the skin, provide breastfeeding on demand to promote elimination of bilirubin through urine and stooling, and avoiding glucose water supplementation, which hinders elimination.

If or when the levels of unconjugated serum bilirubin increase and do not return to normal levels with increased hydration, phototherapy is used. The serum level of bilirubin at which phototherapy is initiated is a matter of clinical judgment by the physician, but it is often begun when bilirubin levels reach 12 to 15 mg/dL in the first 48 hours of life in a term newborn (Arenson & Drake, 2007). **Phototherapy** involves exposing the newborn to ultraviolet light, which converts unconjugated bilirubin into products that can be excreted through feces and urine.

▶ *Take* NOTE!

Exposure of newborns to sunlight represents the first documented use of phototherapy in the medical literature. Sister J. Ward, a charge nurse in Essex, England, in 1956 recognized that when jaundiced newborns were exposed to the sun they became less yellow. This observation changed the entire treatment of jaundice in newborns (Maisels, 2006).

Phototherapy reduces bilirubin levels in the blood by breaking down unconjugated bilirubin into colorless compounds. These compounds can then be excreted in the bile. Phototherapy aims to curtail the increase in bilirubin blood levels, thereby preventing kernicterus, a condition in which unconjugated bilirubin enters the brain. If not treated, kernicterus can lead to brain damage and death.

During the past several decades, phototherapy has generally been administered with either banks of fluorescent lights or spotlights. Factors that determine the dose of phototherapy include spectrum of light emitted, irradiance of light source, design of light unit, surface area of newborn exposed to the light, and distance of the newborn from the light source (Cohen, 2006). For phototherapy to be effective, the rays must penetrate as much of the skin as possible. Thus, the newborn must be naked and turned frequently to ensure maximum exposure of the skin. Several side effects of standard phototherapy have been identified: frequent loose stools, increased insensible water loss, transient rash, and potential retinal damage if the newborn's eyes are not covered sufficiently.

Recently, fiberoptic pads (Biliblanket or Bilivest) have been developed that can be wrapped around the newborn or on which the newborn can lie. The light is delivered from a tungsten–halogen bulb through a fiberoptic cable and is emitted from the sides and ends of the fibers inside a plastic pad (Cohen, 2006). These products work on the premise that phototherapy can be improved by delivering higher-intensity therapeutic light to decrease bilirubin levels. The pads do not produce appreciable heat like the banks of lights or spotlights do, so insensible water loss is not increased. Eye patches also are not needed; thus, parents can feed and hold their newborns continuously to promote bonding.

When caring for newborns receiving phototherapy for jaundice, nurses must do the following:

- Closely monitor body temperature and fluid and electrolyte balance.
- Observe skin integrity (as a result of exposure to diarrhea and phototherapy lights).
- Provide eye protection to prevent corneal injury related to phototherapy exposure.
- Encourage parents to participate in their newborn's care to prevent parent–infant separation.

See Chapter 24 for a more detailed discussion of hyperbilirubinemia.

The home health nurse made a postpartum visit to Kelly to assess the situation. Kelly's son was slightly jaundiced when the home health nurse pressed gently over his sternum, but Kelly said he was nursing better compared with the previous 2 days. What home suggestions can the nurse make to Kelly to reduce the jaundice? What specific education about physiologic jaundice is needed?

Hypoglycemia

Hypoglycemia affects as many as 40% of all full-term newborns (Kenner & Lott, 2007). It is defined as a blood glucose level of less than 35 mg/dL or a plasma concentration of less than 40 mg/dL (Kenner & Lott, 2007). In newborns, blood glucose levels fall to a low point during the first few hours of life because the source of maternal glucose is removed when the placenta is expelled. This period of transition is usually smooth, but certain newborns are at greater risk for hypoglycemia: infants of diabetic mothers, preterm newborns, and newborns with IUGR, inadequate caloric intake, sepsis, asphyxia, hypothermia, polycythemia, glycogen storage disorders, and endocrine deficiencies (Kliegman et al., 2007).

Most newborns experience transient hypoglycemia and are asymptomatic. The symptoms, when present, are nonspecific and include jitteriness, lethargy, cyanosis, apnea, seizures, high-pitched or weak cry, and poor feeding. If hypoglycemia is prolonged or is left untreated, serious, long-term adverse neurologic sequelae such as learning disabilities and mental retardation can occur (Cohen, 2007). Subsequently, early diagnosis and appropriate intervention are essential for all newborns.

Nursing care of the hypoglycemic newborn includes monitoring for signs of hypoglycemia or identifying high-risk newborns prone to this disorder based on their perinatal history, physical examination, body measurements, and gestational age. Check the blood glucose level of all newborns within the first few hours after birth and every 4 hours thereafter. More frequent monitoring and early feeding may be necessary for newborns considered to be high risk. Prevent hypoglycemia in newborns at risk by initiating early feedings with breast milk or formula. If hypoglycemia persists despite feeding, notify the primary health care provider for orders such as intravenous therapy with dextrose solutions. Anticipate hypoglycemia in certain high-risk newborns and begin assessments immediately on nursery admission.

Promoting Nutrition

Several physiologic changes dictate the type and method of feeding throughout the newborn's first year. Some of these changes include the following:

- Stomach capacity is limited to about 90 mL at birth. The emptying time is short (2 to 3 hours) and peristalsis is rapid. Therefore, small, frequent feedings are needed at first, with amounts progressively increasing with maturity.
- The immune system is immature at birth, so the baby is at a high risk for food allergies during the first 4 to 6 months of life. Introducing solid foods prior to this time increases the risk of developing food allergies.
- Pancreatic enzymes and bile to assist in digestion of fat and starch are in limited supply until about 3 to 6 months of age. Infants cannot digest cereal prior to this time.
- The kidneys are immature and unable to concentrate urine until about 4 to 6 weeks of age. Excess protein and mineral intake can place a strain on kidney function and can lead to dehydration. Infants need to consume more water per unit of body weight than adults do as a result of their high body weight from water.
- Immature muscular control at birth changes over time to assist in the feeding process by improving head and neck control, hand–eye coordination, swallowing, and ability to sit, grasp, and chew. At about 4 to 6 months, inborn reflexes disappear, head control develops, and the infant can sit to be fed, making spoon-feeding possible (Dudek, 2006).

Newborn Nutritional Needs

As newborns grow, their energy and nutrient requirements change to meet their body's changing needs. During infancy, energy, protein, vitamin, and mineral requirements per pound of body weight are higher than at any other time of life. These high levels are needed to fuel the rapid growth and development during this stage of life. Generally, an infant's birthweight doubles in the first 4 to 6 months of life and triples within the first year (Dillon, 2007).

A newborn's caloric needs range from 80 to 120 cal/kg body weight. For the first 3 months, the infant needs 110 cal/kg/day; this decreases to 100 cal/kg/day from 3 to 6 months (Begany & Mascarenhas, 2007). Breast milk and formulas contain approximately 20 cal/oz, so the caloric needs of young infants can be met if several feedings are given throughout the day.

Fluid requirements for the newborn and infant range from 100 to 150 mL/kg daily. This requirement can be met through breast or bottle feedings. Additional water supplementation is not necessary. Adequate carbohydrates, fats, protein, and vitamins are achieved through consumption of breast milk or formula. The AAP recommends that bottle-fed infants be given iron supplementation, because iron levels are low in all types of formula milk. This can be achieved by giving iron-fortified formula from birth. The breast-fed infant draws on iron reserves for the first 6 months and then needs iron-rich foods or supplementation added at 6 months of age. The AAP (2007c) also has recommended that all infants (breast- and bottle-fed) receive a daily supplement of vitamin D starting within the first 2 months of life to prevent rickets and vitamin D deficiency. It is also recommended that fluoride supplementation be given to infants not receiving fluoridated water after the age of 6 months (AAP, 2007c).

Supporting the Choice of Feeding Method

Parents typically decide about the method of feeding well before the infant is born. Prenatal and childbirth classes present information about breast-feeding versus bottle feeding and allow the parents to make up their minds about which method is best for them. Various factors can influence their decision, including socioeconomic status, culture, employment, social support available, level of education, range of care interventions provided during pregnancy, childbirth, and the early postpartum period, and especially partner support (Pryor & Huggins, 2007). Nurses can provide evidence-based information to assist the couple in making their decision. Regardless of which method is chosen, the nurse needs to respect and support the couple.

Feeding the Newborn

The newborn can be fed at any time during the transition period if assessments are normal and a desire is demonstrated. Before the newborn can be fed, determine his or her ability to suck and swallow. Clear any mucus in the

nares or mouth with a bulb syringe before initiating feeding. Auscultate bowel sounds, check for abdominal distention, and inspect the anus for patency. If these parameters are within normal limits, newborn feeding may be started. Most newborns are on demand feeding schedules and are allowed to feed when they awaken. When they go home, mothers are encouraged to feed their newborns every 2 to 4 hours during the day and only when the newborn awakens during the night for the first few days after birth.

Parents often have many questions about feeding. Generally, newborns should be fed on demand whenever they seem hungry. Most newborns will give clues about their hunger status by crying, placing their fingers or fist in their mouth, rooting around, and sucking.

Newborns differ in their feeding needs and preferences, but most breast-fed ones need to be fed every 2 to 3 hours, nursing for 10 to 20 minutes on each breast. The length of feedings is up to the mother and newborn. Encourage the mother to respond to cues from her infant and not feed according to a standard or preset schedule.

Formula-fed newborns usually feed every 3 to 4 hours, finishing a bottle in 30 minutes or less. Bottle-fed infants consume about 2 to 4 fluid ounces at first and double their intake within a few weeks of age (Begany & Mascarenhas, 2007). If the newborn seems satisfied, wets 6 to 10 diapers daily, produces several stools a day, sleeps well, and is gaining weight regularly, then he or she is probably receiving sufficient breast milk or formula.

Newborns swallow air during feedings, which causes discomfort and fussiness. Parents can prevent this by burping them frequently throughout the feeding. Tips about burping include:

- Hold the newborn upright with his or her head on the parent's shoulder (Fig. 18.19A).
- Support the head and neck while the parent gently pats or rubs the newborn's back (Fig.18.19B).
- Have the newborn sit on the parent's lap, while supporting the baby's chest and head. Gently rub the newborn's back with the other hand.
- Lay the newborn on the parent's lap with the baby's back facing up.
- Support the newborn's head in the crook of the parent's arm and gently pat or rub the back.

▶ *Take* NOTE!

It is the upright position, not the strength of the patting or rubbing, that allows the newborn to release air accumulated in the stomach.

Stress to parents that feeding time is more than an opportunity to get nutrients into their newborn; it is also a time for closeness and sharing. Feedings are as much for the baby's emotional pleasure as his or her physical well-being. Encourage parents to maintain eye contact with the newborn during the feeding, hold him or her comfortably close to them, and talk softly during the feeding to promote closeness and security.

FIGURE 18.19 The nurse demonstrates holding the newborn upright over the shoulder (**A**) and sitting the newborn upright, supporting the neck and chin (**B**).

Breast-Feeding

There is consensus in the medical community that breast-feeding is optimal for all newborns. The AAP and the American Dietetic Association recommend breast-feeding exclusively for the first 6 months of life, continuing it in conjunction with other food at least until the newborn's first birthday (AAP, 2007c). Box 18.2 highlights the advantages of breast-feeding for the mother and newborn.

Mothers should continue to breast-feed during mild illnesses such as colds or the flu. However, in the United States mothers with HIV are advised not to breast-feed.

The composition of breast milk changes over time from colostrum, to transitional milk, and finally to mature milk. Colostrum is a thick, yellowish substance secreted during the first few days after birth. It is high in protein, minerals, and fat-soluble vitamins. It is rich in immunoglobulins (IgA), which help protect the newborn's gastrointestinal tract against infections. It is a natural laxative that helps rid the intestinal tract of meconium quickly (Pryor & Huggins, 2007).

BOX 18.2 Advantages of Breast-Feeding

Advantages for the Newborn

- Contributes to the development of a strong immune system
- Stimulates growth of positive bacteria in digestive tract
- Reduces incidence of stomach upset, diarrhea, and colic
- Begins the immunization process at birth by providing passive immunity
- Promotes optimal mother–infant bonding
- Reduces risk of newborn constipation
- Promotes greater developmental gains in preterm infants (AAP, 2006a, 2006b)
- Provides easily tolerated and digestible formula that is sterile, at proper temperature, and readily available with no artificial colorings, flavorings, or preservatives
- Is less likely to result in overfeeding, leading to obesity (AAP, 2006a, 2006b)
- Promotes better tooth and jaw development as a result of sucking hard
- Provides protection against food allergies
- Is associated with avoidance of type 1 diabetes and heart disease

Advantages for the Mother

- Can facilitate postpartum weight loss
- Stimulates uterine contractions to control bleeding
- Promotes uterine involution as a result of release of oxytocin
- Lowers risk of breast cancer and osteoporosis
- Affords some protection against conception, although it is not a reliable contraceptive method (Pryor & Huggins, 2007)

Transitional milk occurs between colostrum and mature milk and contains all the nutrients in colostrum, but it is thinner and less yellow than colostrum. This transitional milk is replaced by true or mature milk around day 10 after birth. Mature milk appears bluish and is not as thick as colostrum. It provides 20 cal/oz and contains:

- Protein—Although the content is lower than formula, it is ideal to support growth and development for the newborn. The majority of protein is whey, which is easy to digest.
- Fat—Approximately 58% of total calories are fat, but they are easy to digest. Essential fatty acid content is high, as is the level of cholesterol, which helps develop enzyme systems capable of handling cholesterol later in life.
- Carbohydrate—Approximately 35% to 40% of total calories are in the form of lactose, which stimulates the growth of natural defense bacteria in the gastrointestinal system and promotes calcium absorption.
- Water—Water, the major nutrient in breast milk, makes up 85% to 95% of the total volume. Total milk volume varies with the age of the infant and demand.
- Minerals—Breast milk contains calcium, phosphorus, chlorine, potassium, and sodium, with trace amounts of iron, copper, and manganese. Iron absorption is about 50%, compared with about 4% for iron-fortified formulas.
- Vitamins—All vitamins are present in breast milk; vitamin D is the lowest in amount. Debate about the need for vitamin D supplementation is ongoing.
- Enzymes—Lipase and amylase are found in breast milk to assist with digestion (Dudek, 2006).

Breast-Feeding Assistance

Breast-feeding can be initiated immediately after birth. If the newborn is healthy and stable, wipe the newborn from head to toe with a dry cloth and place him or her skin-to-skin on the mother's abdomen. Then cover the newborn and mother with another warmed blanket to hold in the warmth. Immediate mother–newborn contact takes advantage of the newborn's natural alertness after a vaginal birth and fosters bonding. This immediate contact also reduces maternal bleeding and stabilizes the newborn's temperature, blood glucose level, and respiratory rate (AAP, 2007c).

Left alone on the mother's abdomen, a healthy newborn scoots upward, pushing with the feet, pulling with the arms, and bobbing the head until finding and latching on to the mother's nipple. A newborn's sense of smell is highly developed, which also helps in finding the nipple. As the newborn moves to the nipple, the mother produces high levels of oxytocin, which contracts the uterus, thereby minimizing bleeding. Oxytocin also causes the breasts to release colostrum when the newborn sucks on the nipple. Colostrum is rich in antibodies and thus provides the newborn with her "first immunization" against infection.

Keys to successful breast-feeding include:

- Initiating breast-feeding within the first hour of life if the newborn is stable
- Following the newborn's feeding schedule—8 to 12 times in 24 hours
- Providing unrestricted periods of breast-feeding
- Offering no supplement unless medically indicated
- Having a lactation consultant observe a feeding session
- Avoiding artificial nipples and pacifiers except during a painful procedure
- Feeding from both breasts over each 24-hour period
- Watching for indicators of sufficient intake from infant:
  - Six to ten wet diapers daily
  - Waking up hungry 8 to 12 times in 24 hours
  - Acting content and falling asleep after feeding
- Keeping the newborn with the mother throughout the hospital stay

Help position the newborn so that latching-on is effective and is not painful for the mother. Placing pillows or a folded blanket under the mother's head may help, or rolling her to one side and tucking the newborn next to her. Assess both the mother and newborn during this initial session to determine needs for assistance and education. One tool used frequently in this assessment is the LATCH scoring tool (Table 18.6). The higher the score, the less nursing intervention is needed by the mother and baby.

Breast-Feeding Positioning

The mother and infant must be in comfortable positions to ensure breast-feeding success. The four most common positions for breast-feeding are the football, cradle, across-the-lap, and side-lying holds. Each mother, on experimentation, can decide which positions feel most comfortable for her (Fig. 18.20).

In the football hold, the mother holds the infant's back and shoulders in her palm and tucks the infant under her arm. Remind the mother to keep the infant's ear, shoulder, and hip in a straight line. The mother supports the breast with her hand and brings it to the infant's lips to latch on. She continues to support the breast until the infant begins to nurse. This position allows the mother to see the infant's mouth as she guides her infant to the nipple. This is a good choice for mothers who have had a cesarean birth because it avoids pressure on the incision.

The cradling position is the one most commonly used. The mother holds the baby in the crook of her arm, with the infant facing the mother. The mother supports the breast with her opposite hand.

In the across-the-lap position, the mother places a pillow across her lap, with the infant facing the mother. The mother supports the infant's back and shoulders with her palm and supports her breast from underneath. After the infant is in position, the infant is pulled forward to latch on.

In the side-lying position, the mother lies on her side with a pillow supporting her back and another pillow supporting the newborn in the front. To start, the mother props herself up on an elbow and supports the newborn with that arm, while holding her breast with the opposite hand. Once nursing is started, the mother lies down in a comfortable position.

To promote latching-on, instruct the mother to make a C or a V with her fingers. In the C hold, the mother places her thumb well above the areola and the other four fingers

TABLE 18.6 THE LATCH SCORING TOOL

Parameters	0 Point	1 Point	2 Points
L: Latch	Sleepy infant, no sustained latch achieved	Must hold nipple in infant's mouth to sustain latch and suck; must stimulate infant to continue to suck	Grasps nipple; tongue down; rhythmic sucking
A: Audible swallowing	None	A few observed with stimulation	Spontaneous and intermittent both <24 hours old and afterward
T: type of nipple	Inverted (drawn inward into breast tissue)	Flat (not protruding)	Everted or protruding out after stimulation
C: comfort of nipple	Engorged, cracked bleeding; severe discomfort	Filling; reddened, small blisters or bruises; mild to moderate discomfort	Soft, nontender
H: hold (positioning)	Nurse must hold infant to breast	Minimal assistance; help with positioning, then mother takes over	No assistance needed by nurse

Sources: AAP (2006a, 2006b, 2007); Pryor & Huggins (2007).

FIGURE 18.20 Breast-feeding positions.

below the areola and under the breast. In the V hold, the mother places her index finger above the areola and her other three fingers below the areola and under the breast. Either method can be used as long as the mother's hand is well away from the nipple so the infant can latch on.

Breast-Feeding Education

Breast-feeding is not an innate skill in human mothers. Almost all women have the potential to breast-feed successfully, but many fail because of inadequate knowledge. Nursing Care Plan 18.1 gives typical nursing diagnoses, outcomes, and interventions. For many mothers and newborns, breast-feeding goes smoothly from the start, but for others it is a struggle. Nurses can help throughout the experience by demonstrating techniques and offering encouragement and praise for success. Nurse should emphasize that the key to successful breast-feeding is correct positioning and latching-on.

Teaching by nurses has been shown to have a significant effect on both the ability to breast-feed successfully and the duration of lactation (Dudek, 2006). During the first few breast-feeding sessions, mothers want to know how often they should be nursing, whether breast-feeding is going well, if the newborn is getting enough nourishment, and what problems may ensue and how to cope with them. Education for the breast-feeding mother is highlighted in Teaching Guidelines 18.4.

Remember Kelly, who was concerned about jaundice in her newborn son? At her son's 2-week well-baby checkup at the clinic, his bilirubin level came back within normal limits. Kelly still felt he was not getting enough to eat and stated that she might switch to formula-feeding her son. What information can the nurse present to promote and reinforce breast-feeding? Should the nurse make a referral to the lactation consultant?

Breast Milk Storage and Expression

If the breast-feeding mother becomes separated from the newborn for any reason (e.g., work, travel, illness), she needs instruction on how to express and store milk safely. Expressing milk can be done manually (hand compression of breast) or by using a breast pump. Manual or hand pumps are inexpensive and can be used by mothers who occasionally need an extra bottle if they are going out. Electric breast pumps are used for mothers who experience a lengthy separation from their infants and need to pump their breasts regularly (Fig. 18.21).

To ensure the safety of expressed breast milk, instruct the mother in the following:

- Wash your hands before expressing milk or handling breast milk.
- Use clean containers to store expressed milk.
- Use sealed and chilled milk within 24 hours.
- Discard any milk that has been refrigerated more than 72 hours.
- Use any frozen expressed milk within 3 months.
- Do not use microwave ovens to warm chilled milk.
- Discard any used milk; never refreeze it.
- Store milk in quantities to be used for each feeding (2 to 4 oz).
- Thaw milk in warm water before using (AAP, 2007b).

Nursing Care Plan 18.1

OVERVIEW OF THE MOTHER AND NEWBORN HAVING DIFFICULTY WITH BREAST-FEEDING

Baby boy James, weight 7 lb, 4 oz, was born a few hours ago. His mother, Jane, is a 19-year-old gravida 1, para 1. His Apgar scores were 9 points at both 1 and 5 minutes. Labor and birth were unremarkable, and James was admitted to the nursery for assessment. After stabilization, James was brought to his mother, who had said she wished to breast-feed. The postpartum nurse assisted Jane with positioning and latching-on and left the room for a few minutes. On returning, Jane was upset, James was crying, and Jane stated she wanted a bottle of formula to feed him since she didn't have milk and her nipples hurt.

Assessment reveals a young, inexperienced mother placed in an uncomfortable situation with limited knowledge of breast-feeding. Anxiety from the mother transferred to James, resulting in crying. The mother, apprehensive about breast-feeding, needs additional help.

NURSING DIAGNOSIS: Knowledge deficit related to breast-feeding skills

Outcome Identification and Evaluation

Mother will demonstrate understanding of breast-feeding skills as evidenced by use of correct positioning and technique, and verbalization of appropriate information related to breast-feeding.

Interventions: Providing Education

- Instruct mother on proper positioning for breast-feeding; suggest use of football hold, side-lying position, modified cradle, and across-the-lap position to ensure comfort and *to promote ease in breast-feeding.*
- Review breast anatomy and milk letdown reflex *to enhance mother's understanding of lactation.*
- Observe newborn's ability to suck and latch on to the nipple *to assess whether newborn has adequate ability.*
- Monitor sucking and newborn swallowing for several minutes *to ensure adequate latching on and to assess intake.*
- Reinforce nipple care with water and exposure to air *to maintain nipple integrity.*

NURSING DIAGNOSIS: Anxiety related to breast-feeding ability and irritable, crying newborn

Outcome Identification and Evaluation

Mother will verbalize increased comfort with breast-feeding as evidenced by positive statements related to breast-feeding and verbalization of desire to continue to breast-feed newborn.

Interventions: Reducing Anxiety

- Ensure that the environment is calm and soothing without distractions *to promote maternal and newborn relaxation.*
- Show mother correct latching-on technique *to promote breast-feeding.*
- Assist in calming newborn by holding and talking *to ensure that the newborn is relaxed prior to latching on.*
- Reassure mother she can be successful at breast-feeding *to enhance her self-esteem and confidence.*
- Encourage frequent trials and attempts *to enhance confidence.*
- Encourage the mother to verbalize her anxiety/fears *to reduce anxiety.*

NURSING DIAGNOSIS: Pain related to breast-feeding and incorrect latching-on technique

Outcome Identification and Evaluation

Mother will experience a decrease in pain during breast-feeding as evidenced by statements of less nipple pain.

Interventions: Reducing Pain

- Suggest several alternate positions for breast-feeding *to increase comfort.*
- Demonstrate how to break suction before removing infant from breast *to minimize trauma to nipple.*
- Inspect nipple area *to promote early identification of trauma.*
- Reinforce correct latching-on technique *to prevent nipple trauma.*
- Administer pain medication if indicated *to relieve pain.*
- Instruct about nipple care between feedings *to maintain nipple integrity.*

TEACHING GUIDELINES 18.4

Breast-Feeding

- Set aside a quiet place where you can be relaxed and won't be disturbed. Relaxation promotes milk letdown.
- Sit in a comfortable chair or rocking chair or lie on a bed. Try to make each feeding calm, quiet, and leisurely. Avoid distractions.
- Listen to soothing music and sip a nutritious drink during feedings.
- Initially, nurse the newborn every few hours to stimulate milk production. Remember that the supply of milk is equal to the demand—the more sucking, the more milk.
- Watch for signals from the infant to indicate that he or she is hungry, such as:
  - Nuzzling against the mother's breasts
  - Demonstrating the rooting reflex by making sucking motions
  - Placing fist or hands in mouth to suck on
  - Crying and squirming
  - Smacking of the lips
- Stimulate the rooting reflex by touching the newborn's cheek to initiate sucking.
- Look for signs indicating that the newborn has latched on correctly: wide-open mouth with the nipple and much of the areola in the mouth, lips rolled outward, and tongue over lower gum, visible jaw movement drawing milk out, rhythmic sucking with an audible swallowing (soft "ka" or "ah" sound indicates the infant is swallowing milk).
- Hold the newborn closely, facing the breast, with the newborn's ear, shoulder, and hip in direct alignment.
- Nurse the infant on demand, not on a rigid schedule. Feed every 2 to 3 hours within a 24-hour period for a total of 8 to 12 feedings.
- Alternate the breast you offer first; identify with a safety pin on bra.
- Vary your position for each feeding to empty breasts and reduce soreness.
- Look for signs that the newborn is getting enough milk:
  - At least six wet diapers and two to five loose yellow stools daily
  - Steady weight gain after the first week of age
  - Pale-yellow urine, not deep yellow or orange
  - Sleeping well, yet looks alert and healthy when awake (AAP, 2007a)
- Wake up the newborn if he or she has nursed less than 5 minutes by unwrapping him or her.
- Before removing the baby from the breast, break the infant's suction by inserting a finger.
- Burp the infant to release air when changing breasts and at the end of the breast-feeding session.
- Avoid supplemental formula feedings to prevent "nipple confusion" (Pryor & Huggins, 2007)
- Do not take drugs or medications unless approved by the health care provider.
- Avoid drinking alcohol or caffeinated drinks because they pass through milk.
- Do not smoke while breast-feeding; it increases the risk of sudden infant death syndrome.
- Always wash your hands before expressing or handling milk to store.
- Wear nursing bras and clothes that are easy to undo.

Common Breast-Feeding Concerns

Breast-feeding women may experience problems such as cracked nipples, engorgement, or mastitis. Breast-feeding should not be painful for the mother. If she has sore, cracked nipples, the first step is to find the cause. Incorrect positioning or latching-on, removing the infant from the breast without first breaking the suction, or wearing a bra that is too tight can cause cracked or sore nipples. Cracked nipples can increase the risk of mastitis because a break in the skin may allow *Staphylococcus aureus* or other organisms to enter the body.

Sore nipples usually are caused by improper infant attachment, which traumatizes the tissue. The nurse should review techniques for proper positioning and latching-on. Recommend the following to the mother:

- Use only water, not soap, to clean the nipples to prevent dryness.
- Express some milk before feeding to stimulate the milk ejection reflex.
- Avoid using breast pads with plastic liners, and change pads when they are wet.
- Wear a comfortable bra that is not too tight.
- Apply a few drops of breast milk to the nipples after feeding.
- Rotate positions when feeding the infant to promote complete breast emptying.
- Leave the nursing bra flaps down after feeding to allow nipples to air-dry.
- Inspect the nipples daily for redness or cracks (Arenson & Drake, 2007).

To ease nipple pain and trauma, reinforce appropriate latching-on and remind the woman about the need to break the suction at the breast before removing the newborn from the breast. Additional measures may include

FIGURE 18.21 Hand-held breast pump.

applying cold compresses over the area and massaging breast milk onto the nipple after feeding.

Engorgement may occur as the milk comes in around day 3 or 4 after birth of the newborn. Explain to the mother that engorgement, though uncomfortable, is self-limited and will resolve as the newborn continues to nurse. The mother should continue to nurse during engorgement to avoid a plugged milk duct, which could lead to mastitis. Provide the following tips for relieving engorgement:

- Take warm to hot showers to encourage milk release.
- Express some milk manually before breast-feeding.
- Wear a supportive nursing bra 24 hours a day to provide support.
- Feed the newborn in a variety of positions—sitting up and then lying down.
- Massage the breasts from under the axillary area down toward the nipple.
- Increase the frequency of feedings.
- Apply warm compresses to the breasts prior to nursing.
- Stay relaxed while breast-feeding.
- Use a breast pump if nursing or manual expression is not effective.
- Remember that this condition is temporary and resolves quickly.

Mastitis, or inflammation of the breast, causes flu-like symptoms, chills, fever, and malaise. These symptoms may occur before the development of soreness, aching, swelling, and redness in the breast (usually the upper outer quadrant). This condition usually occurs in just one breast when a milk duct becomes blocked, causing inflammation, or through a cracked or damaged nipple, allowing bacteria to infect a portion of the breast. Treatment consists of rest, warm compresses, antibiotics, breast support, and continued breast-feeding (the infection will not pass into the breast milk). Explain to the mother that it is important to keep the milk flowing in the infected breast, whether it is through nursing or manual expression or with a breast pump.

Formula Feeding

Despite the general acknowledgment that breast-feeding is the most desirable means of feeding infants, about 40% of mothers choose formula feeding and need education about this procedure. Formula-fed infants grow more rapidly than breast-fed infants not only in weight but also in length (Begany & Mascarenhas, 2007).

Formula feeding requires more than just opening, pouring, and feeding. Parents need information about the types of formula available, preparation and storage of formula, equipment, feeding positions, and the amount to feed their newborn. The mother also needs to know how to prevent lactation (see Chap. 16 for more information).

Commercially prepared formulas are regulated by the Food and Drug Administration (FDA) and are manufactured by Meade Johnson (Enfamil) or Ross Laboratories (Similac) in the United States. Normal full-term infants usually receive conventional cow's milk-based formula, but this decision is made by the health care provider. If the infant shows signs of a reaction or lactose intolerance, a switch to another formula type is recommended. The general recommendation is for all infants to receive iron-fortified formula until the age of 1 year. The latest generation of infant formulas includes some fortification with docosahexaenoic acid (DHA) and arachidonic acid (ARA), two natural components of breast milk. Researchers have found that formulas with DHA and ARA can enhance visual and cognitive development in children (Lawson, 2007).

Commercial formulas come in three forms: powder, concentrate, and easy to feed or ready to use. All are similar in terms of nutritional content but differ in expense. Powdered formula is the least expensive, with concentrated formula the next most expensive. Both must be mixed with water before using. Ready-to-feed formula is the most expensive; it can be opened and poured into a bottle and fed directly to the infant.

Parents need information about the equipment needed for formula feeding. Basic supplies are 4 to 6 4-oz bottles, 8 to 10 8-oz bottles, 8 to 10 nipple units, a bottle brush, and a nipple brush. A key area of instruction is assessing for flow of formula through the nipple and checking for any nipple damage. When the bottle is filled and turned upside down, the flow from the nipple should be approximately one drop per second. If the parents are using bottles with disposable bags, instruct them to make sure they have a tight-fitting nipple to prevent leaks. Frequent observation of the flow rate from the nipple and the condition of the nipple will prevent choking and aspiration

associated with too fast a rate of delivery. Ask the parents to fill a bottle with formula and then turn it upside down and observe the rate at which the formula drips from the bottle. If it is too fast (more than one drop/second), then the nipple should be replaced.

Correct formula preparation is critical to the newborn's health and development. Mistakes in dilution may result if the parents do not understand how to prepare the formula or make measurement errors. The safety of the water supply should be considered. If well water is used, parents should sterilize the water by boiling it or should use bottled water. Many health care providers still recommend that all water used in formula preparation be brought to a rolling boil for 1 to 2 minutes and should be cooled to room temperature before use.

Opened cans of ready-made or concentrated formula should be covered and refrigerated after being prepared for the day (24 hours). Instruct parents to discard any unused portions after 48 hours.

▶ *Take* NOTE!

Any formula left in the bottle after feeding should also be discarded, because the infant's saliva has been mixed with it.

To warm refrigerated formula, advise the parents to place the bottle in a pan of hot water and test the temperature by letting a few drops fall on the inside of the wrist. If it is comfortably warm to the mother, it is the correct temperature.

Formula-Feeding Assistance

The process of feeding a newborn formula from a bottle should mirror breast-feeding as closely as possible. Although nutrition is important, so are the emotional and interactive components of feeding. Encourage parents to cuddle their newborn closely and position him or her so that the head is in a comfortable position, not too far back or turned, which makes swallowing difficult. Also urge parents to communicate with their newborn during the feedings by talking and singing to him or her.

Although it may seem that bottle feeding is not a difficult task, many new parents find it awkward. At first glance, holding an infant and a bottle appears simple enough, but both the position of the baby and the angle of the bottle must be correct.

Formula-Feeding Positions

Advise mothers to feed their newborns in a relaxed and quiet setting to create a sense of calm for themselves and the baby. Make sure that comfort is a priority for both mother and newborn. The mother can sit in a comfortable chair, using a pillow to support the arm in which she is holding the baby. The mother can cradle the newborn in a semi-upright position, supporting the newborn's head in the crook of her arm. Holding the newborn close during feeding provides stimulation and helps prevent choking. Holding the newborn's head raised slightly will help prevent formula from washing backward into the eustachian tubes in the ears, which can lead to an ear infection.

Formula-Feeding Education

Parents require teaching about the correct preparation and storage of formula as well as the techniques for feeding. See Teaching Guidelines 18.5.

Proper positioning makes bottle feeding easier and more enjoyable for both mother and newborn. As in breast-feeding, frequent burping is key. Advise the parents to hold the bottle so that formula fills the nipple, thus allowing less air to enter. Infants get fussy when they swallow air during feedings and need to be relieved of it every 2 to 3 oz.

TEACHING GUIDELINES 18.5

Formula-Feeding

- Wash your hands with soap and water before preparing formula.
- Mix the formula and water amounts exactly as the label specifies.
- Always hold the newborn and bottle during feedings; never prop the bottle.
- Never freeze formula or warm it in the microwave.
- Place refrigerated formula in a pan of hot water for a few minutes to warm.
- Test the temperature of the formula by shaking a few drops on the wrist.
- Hold the bottle like a pencil, keeping it tipped to prevent air from entering. Position the bottle so that the nipple remains filled with milk.
- Burp the infant after every few ounces to allow air swallowed to escape.
- Move the nipple around in the infant's mouth to stimulate sucking.
- Always keep a bulb syringe close by to use if choking occurs.
- Avoid putting the infant to bed with a bottle to prevent "baby bottle tooth decay."
- Feed the newborn approximately every 3 to 4 hours.
- Use an iron-fortified formula for the first year.
- Prepare enough formula for the next 24 hours.
- Check nipples regularly and discard any that are sticky, cracked, or leaking.
- Store unmixed, open liquid formula in the refrigerator for up to 48 hours.
- Throw away any formula left in the bottle after each feeding.

Emphasize to parents that an electrolyte imbalance can occur in infants who are fed formula that has been incorrectly mixed. Hypernatremia can result from formula that is mixed too thickly; the high concentration of sodium is too much for the baby's immature kidneys to handle. As a result, sodium is excreted along with water, leading to dehydration. Mixing the formula with too much water in an effort to save money can lead to failure to thrive and lack of weight gain (AAP, 2007b).

Weaning and Introduction of Solid Foods

Eventually, breast-feeding or formula feeding ends. Weaning involves the transition from breast to bottle, from breast or bottle to cup, or from liquids to solids. Weaning from breast-feeding to cup has several advantages over weaning to a bottle because it eliminates the step of weaning first to a bottle and then to a cup. Another advantage is that the bottle does not become a security object for the infant.

Weaning can be done because the mother is returning to work and cannot keep breast-feeding, or because the infant is losing interest in breast-feeding and showing signs of independence. There is no "right" time to wean; it depends on the desires of the mother and infant. Weaning represents a significant change in the way the mother and infant interact, and each mother must decide for herself when she and her infant are ready to take that step. Either one can start the weaning process, but usually it occurs between 6 months and 1 year of age.

To begin weaning from the breast, instruct mothers to substitute breast-feeding with a cup or bottle. Often the midday feeding is the easiest feeding to replace. A trainer cup with two handles and a snap-on lid with a spout is appropriate and minimizes spilling. Because weaning is a gradual process, it may take months. Instruct parents to proceed slowly and let the infant's willingness and interest guide them.

Weaning from the bottle to the cup also needs to be timed appropriately for mother and infant. Typically, the night bottle is the last to be given up, with cup drinking substituted throughout the day. Slowly diluting the formula with water over a week can help in this process; the final result is an all-water bottle. To prevent the baby from sucking on the bottle during the night, remove it from the crib after the infant falls asleep.

When infants double their birthweight and weigh at least 13 lb, it is time to consider introducing solid foods. Readiness cues include:

- Consumption of 32 oz of formula or breast milk daily (estimated)
- Ability to sit up with minimal support and turn head away to indicate fullness
- Reduction of protrusion reflex so cereal can be propelled to back of throat
- Demonstration of interest in food others around them are eating
- Ability to open mouth automatically when food approaches it

When introducing solid foods, certain principles apply:

- Only one new single-ingredient food (e.g., rice cereal or carrots) should be introduced at a time to watch for allergies.
- Infants should be allowed to set the pace regarding how much they wish to eat.
- New foods should not be introduced more frequently than every 3 to 5 days.
- Fruits are added after cereals; then vegetables and meats are introduced; eggs are introduced last.
- A relaxed, unhurried, calm atmosphere for meals is important.
- A variety of foods are provided to ensure a balanced diet.
- Infants should never be force-fed (Lawson, 2007).

Nurses can promote good feeding practices by actively listening to new mothers, helping them clarify their feelings and discussing solutions. A warm, sincere manner and tone of voice will put an anxious mother at ease. Giving accurate information, making suggestions, and presenting options will enable the mother to decide what is best for her and her infant. Nurses should be sensitive to the individual, family, and economic and cultural differences among mothers before offering suggestions for feeding practices that may not be appropriate.

Preparing for Discharge

Preparing the parents for discharge is an essential task for the nurse. Because of today's shorter hospital stays, the nurse must identify the major teaching topics that need to be covered. Nurses should assess the parents' baseline knowledge and learning needs and plan how to meet them. Using the following principles fosters a learner-centered approach:

- Make the environment conducive to learning. Encourage the parents to feel comfortable during this intense time by using support and praise.
- Allow the parents to provide input about the content and the process of learning. What do they want and need to learn?
- Build the parents' self-esteem by confirming that their responses to the entire birthing process and aftercare are legitimate, and others have felt the same way.
- Ensure that what the parents learn is relevant to their day-to-day home situation.
- Encourage responsibility by reinforcing that their emotional and physical responses are within the normal range.
- Respect cultural beliefs and practices that are important to the family by taking into account their heritage and health beliefs regarding newborn care. Examples include placing a bellyband over the newborn's navel

(Hispanics and African-Americans), delaying naming the newborn (Asian-Americans and Haitians), and delaying breast-feeding (Native Americans; they regard colostrum as "bad") (Bowers, 2007).

While in the hospital, women have ready access to support and hands-on instruction regarding feeding and newborn care. When the new mother is discharged, this close supervision and support by nurses should not end abruptly. Providing the new parents with the phone number of the mother–baby unit will help them through this stressful transitional period. Giving the new family information and offering backup support via the telephone will increase parenting success.

▸ *Consider* THIS!

I have always prided myself on being very organized and in control in most situations, but survival at home after childbirth wasn't one of them. I left the hospital 24 hours after giving birth to my son because my doctor said I could. The postpartum nurse encouraged me to stay longer, but wanting to be in control and sleeping in my own bed again won out. I thought my baby would be sleeping while I sent out birth announcements to my friends and family—wrong! What happened instead was my son didn't sleep as I imagined and my nipples became sore after breast-feeding every few hours. I was weary and tired and wanted to sleep, but I couldn't. Somehow I thought I would be getting a full night's sleep because I was up throughout the day, but that was a fantasy too. At 2 o'clock in the morning when you are up feeding your baby, you feel you are the only one in the world up at that time and feel very much alone. My feelings of being organized and in control all the time have changed dramatically since I left the hospital. I have learned to yield to the important needs of my son and derive satisfaction from being able to bring comfort to him and to let go of my control.

Thoughts: It is interesting to see how a newborn changed this woman's need to organize and control her environment. What "tips of survival" could the nurse offer this woman to help in her transition to home with her newborn? How can friends and family help when women arrive home from the hospital with their newborns?

Ensuring Follow-Up Care

Most newborns are scheduled for their first health follow-up appointment within 2 to 4 days after discharge so they can have additional laboratory work done as part of the newborn screening series, especially if they were discharged within 48 hours. After this first visit, the typical schedule of health care visits is as follows: 2 to 4 weeks of age; 2, 4, and 6 months of age for checkups and vaccines; 9 months of age for a checkup; 12 months for a checkup and tuberculosis testing; 15 and 18 months for checkups and vaccines; and 2 years of age for a checkup. These appointments provide an opportunity for parents to ask questions and receive anticipatory guidance as their newborn grows and develops.

In addition to encouraging parents to keep follow-up appointments, advise parents to call their health care provider if they notice signs of illness in their newborn. They should know which over-the-counter medicines should be kept on hand. Review the following warning signs of illness with parents:

- Temperature of 38.3°C (101°F) or higher
- Forceful, persistent vomiting, not just spitting up
- Refusal to take feedings
- Two or more green, watery diarrheal stools
- Infrequent wet diapers and change in bowel movements from normal pattern
- Lethargy or excessive sleepiness
- Inconsolable crying and extreme fussiness
- Abdominal distention
- Difficult or labored breathing

Providing Immunization Information

Parents also need instructions about immunizations for their newborn. **Immunization** is the process of rendering an individual immune or of becoming immune to certain communicable diseases (AAP, 2007). The purpose of the immune system is to identify unknown (non-self) substances in the body and develop a defense against these invaders. Disease prevention by immunization is a public health priority and is one of the leading health indicators as part of *Healthy People 2010.* Despite many advances in vaccine delivery, the goal of universal immunization has not been reached (AAP, 2007). Nurses can help to meet this national goal by educating new parents about the importance of disease prevention through immunizations.

Immunity can be provided either passively or actively. Passive immunity is protection transferred via already formed antibodies from one person to another. Passive immunity includes transplacental passage of antibodies from a mother to her newborn, immunity passed through breast milk, and immunity from immunoglobulins. Passive immunity provides limited protection and decreases over a period of weeks or months (Blackburn, 2007). Active immunity is protection produced by an individual's own immune system. It can be obtained by having the actual disease or by receiving a vaccine that produces an immunologic response by that person's body. Active immunity may be lifelong either way.

Young infants and children are susceptible to various illnesses because their immune systems are not yet mature. Many of these illnesses can be prevented by following the recommended schedule of childhood immunizations; Figure 18.22 shows the 2008 Childhood Immunization

Recommended Immunization Schedule for Persons Aged 0–6 Years—UNITED STATES • 2008

For those who fall behind or start late, see the catch-up schedule

Vaccine ▼ Age ▶	Birth	1 month	2 months	4 months	6 months	12 months	15 months	18 months	19–23 months	2–3 years	4–6 years
Hepatitis B[1]	HepB	HepB		see footnote 1	HepB						
Rotavirus[2]			Rota	Rota	Rota						
Diphtheria, Tetanus, Pertussis[3]			DTaP	DTaP	DTaP	see footnote 3	DTaP				DTaP
Haemophilus influenzae type b[4]			Hib	Hib	*Hib*[4]	Hib					
Pneumococcal[5]			PCV	PCV	PCV	PCV				PPV	
Inactivated Poliovirus			IPV	IPV	IPV						IPV
Influenza[6]					Influenza (Yearly)						
Measles, Mumps, Rubella[7]						MMR					MMR
Varicella[8]						Varicella					Varicella
Hepatitis A[9]						HepA (2 doses)				HepA Series	
Meningococcal[10]										MCV4	

Range of recommended ages

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2007, for children aged 0 through 6 years. Additional information is available at **www.cdc.gov/vaccines/recs/schedules**. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including for **high-risk conditions: http://www.cdc.gov/vaccines/pubs/ACIP-list.htm**. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at **www.vaers.hhs.gov** or by telephone, **800-822-7967**.

1. Hepatitis B vaccine (HepB). *(Minimum age: birth)*

At birth:

- Administer monovalent HepB to all newborns prior to hospital discharge.
- If mother is hepatitis B surface antigen (HBsAg) positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine the HBsAg status as soon as possible and if HBsAg positive, administer HBIG (no later than age 1 week).
- If mother is HBsAg negative, the birth dose can be delayed, in rare cases, with a provider's order and a copy of the mother's negative HBsAg laboratory report in the infant's medical record.

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1–2 months. The final dose should be administered no earlier than age 24 weeks. Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of at least 3 doses of a licensed HepB series, at age 9–18 months (generally at the next well-child visit).

4-month dose:

- It is permissible to administer 4 doses of HepB when combination vaccines are administered after the birth dose. If monovalent HepB is used for doses after the birth dose, a dose at age 4 months is not needed.

2. Rotavirus vaccine (Rota). *(Minimum age: 6 weeks)*

- Administer the first dose at age 6–12 weeks.
- Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks. Do not administer any dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP). *(Minimum age: 6 weeks)*

- The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4–6 years.

4. *Haemophilus influenzae* type b conjugate vaccine (Hib). *(Minimum age: 6 weeks)*

- If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required.
- TriHIBit® (DTaP/Hib) combination products should not be used for primary immunization but can be used as boosters following any Hib vaccine in children age 12 months or older.

5. Pneumococcal vaccine. *(Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPV])*

- Administer one dose of PCV to all healthy children aged 24–59 months having any incomplete schedule.
- Administer PPV to children aged 2 years and older with underlying medical conditions.

6. Influenza vaccine. *(Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])*

- Administer annually to children aged 6–59 months and to all eligible close contacts of children aged 0–59 months.
- Administer annually to children 5 years of age and older with certain risk factors, to other persons (including household members) in close contact with persons in groups at higher risk, and to any child whose parents request vaccination.
- For healthy persons (those who do not have underlying medical conditions that predispose them to influenza complications) ages 2–49 years, either LAIV or TIV may be used.
- Children receiving TIV should receive 0.25 mL if age 6–35 months or 0.5 mL if age 3 years or older.
- Administer 2 doses (separated by 4 weeks or longer) to children younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time last season but only received one dose.

7. Measles, mumps, and rubella vaccine (MMR). *(Minimum age: 12 months)*

- Administer the second dose of MMR at age 4–6 years. MMR may be administered before age 4–6 years, provided 4 weeks or more have elapsed since the first dose.

8. Varicella vaccine. *(Minimum age: 12 months)*

- Administer second dose at age 4–6 years; may be administered 3 months or more after first dose.
- Do not repeat second dose if administered 28 days or more after first dose.

9. Hepatitis A vaccine (HepA). *(Minimum age: 12 months)*

- Administer to all children aged 1 year (i.e., aged 12–23 months). Administer the 2 doses in the series at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children.

10. Meningococcal vaccine. *(Minimum age: 2 years for meningococcal conjugate vaccine (MCV4) and for meningococcal polysaccharide vaccine (MPSV4))*

- Administer MCV4 to children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. MPSV4 is also acceptable.
- Administer MCV4 to persons who received MPSV4 3 or more years previously and remain at increased risk for meningococcal disease.

FIGURE 18.22 Recommended childhood immunization schedule.

Schedule. Readers can view the latest CDC immunization schedule by visiting www.cdc.gov/nip. The schedule for immunizations should be reviewed with parents, stressing the importance of continued follow-up health care to preserve their infant's health.

The newborn's first immunization (hepatitis B) is received in the hospital soon after birth. The first dose can also be given by age 2 months if the mother is HbsAg negative. If the mother is HbsAg positive, then the newborn should receive hepatitis B vaccine and hepatitis B immunoglobulin within 12 hours of birth (Cunningham et al., 2005).

Education for the parents should include the risks and benefits for each vaccine and possible adverse effects. Federal law requires a consent form to be signed before administering a vaccine. Parents have the right to refuse immunizations based on their religious beliefs and can sign a waiver noting their decision. The nurse administering the vaccine must document the date and time it was given, name and manufacturer, lot number and expiration date of the vaccine given, site and route of administration, and the name and title of the nurse who administered the vaccine.

Key Concepts

- The period of transition from intrauterine to extrauterine life occurs during the first several hours after birth. It is a time of stabilization for the newborn's temperature, respiration, and cardiovascular dynamics.
- The newborn's bowel is sterile at birth. It usually takes about a week for the newborn to produce vitamin K in sufficient quantities to prevent VKDB.
- It is recommended that all newborns in the United States receive an instillation of a prophylactic agent (erythromycin or tetracycline ophthalmic ointment) in their eyes within an hour or two of being born.
- Nursing measures to maintain newborns' body temperature include drying them immediately after birth to prevent heat loss through evaporation, wrapping them in prewarmed blankets, putting a hat on their head, and placing them under a temperature-controlled radiant warmer.
- The specific components of a typical newborn examination include a general survey of skin color, posture, state of alertness, head size, overall behavioral state, respiratory status, gender, and any obvious congenital anomalies.
- Gestational age assessment is pertinent because it allows the nurse to plot growth parameters and to anticipate potential problems related to prematurity/postmaturity and growth abnormalities such as SGA/LGA.
- After the newborn has passed the transitional period and stabilized, the nurse needs to complete ongoing assessments, vital signs, weight and measurements, cord care, hygiene measures, newborn screening tests, and various other tasks until the newborn is discharged home from the birthing unit.
- Important topics about which to educate parents include environmental safety, newborn characteristics, feeding and bathing, circumcision and cord care, sleep and elimination patterns of newborns, safe infant car seats, holding/positioning, and follow-up care.
- Newborn screening tests consist of hearing and certain genetic and inborn errors of metabolism tests required in most states for newborns before discharge from the birth facility.
- The AAP and the American Dietetic Association recommend breast-feeding exclusively for the first 6 months of life and that it continue along with other food at least until the first birthday.
- Parents who choose not to breast-feed need to know what types of formula are available, preparation and storage of formula, equipment, feeding positions, and how much to feed their infant.
- Common problems associated with the newborn include transient tachypnea, physiologic jaundice, and hypoglycemia.
- Transient tachypnea of the newborn appears soon after birth; is accompanied by retractions, expiratory grunting, or cyanosis; and is relieved by low-dose oxygen.
- Physiologic jaundice is a very common condition in newborns, with the majority demonstrating yellowish skin, mucous membranes, and sclera within the first 3 days of life. Newborns undergoing phototherapy in the treatment of jaundice require close monitoring of their body temperature, fluid, and electrolyte balance; observation of skin integrity; eye protection; and parental participation in their care.
- The newborn with hypoglycemia requires close monitoring for signs and symptoms of hypoglycemia if present. In addition, newborns at high risk need to be identified based on their perinatal history, physical examination, body measurements, and gestational age. Blood glucose levels of all newborns are checked within the first few hours after birth and every 4 hours thereafter.
- The schedule for immunizations should be reviewed with parents, stressing the importance of continual follow-up health care to preserve their infant's health.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. At birth, a newborn's assessment reveals the following: heart rate of 140 bpm, loud crying, some flexion of extremities, crying when bulb syringe is introduced into the nares, and a pink body with blue extremities. The nurse would document the newborn's Apgar score as:
   a. 5 points
   b. 6 points
   c. 7 points
   d. 8 points
2. The nurse is explaining phototherapy to the parents of a newborn. The nurse would include which of the following as the purpose?
   a. Increase surfactant levels
   b. Stabilize the newborn's temperature
   c. Destroy Rh-negative antibodies
   d. Oxidize bilirubin on the skin
3. The nurse administers a single dose of vitamin K intramuscularly to a newborn after birth to promote:
   a. Conjugation of bilirubin
   b. Blood clotting
   c. Foreman ovale closure
   d. Digestion of complex proteins
4. A prophylactic agent is instilled in both eyes of all newborns to prevent which of the following conditions?
   a. Gonorrhea and chlamydia
   b. Thrush and Enterobacter
   c. *Staphylococcus* and syphilis
   d. Hepatitis B and herpes
5. The AAP recommends that all newborns be placed on their backs to sleep to reduce the risk of:
   a. Respiratory distress syndrome
   b. Bottle mouth syndrome
   c. Sudden infant death syndrome
   d. GI regurgitation syndrome
6. Which of the following immunizations is received by newborns before hospital discharge?
   a. Pneumococcus
   b. Varicella
   c. Hepatitis A
   d. Hepatitis B
7. Which condition would be missed if newborns are screened before they have tolerated protein feedings for at least 48 hours?
   a. Hypothyroidism
   b. Cystic fibrosis
   c. Phenylketonuria
   d. Sickle cell disease

CRITICAL THINKING EXERCISES

1. Linda Scott, an African-American mother who delivered her first baby and is on the mother–baby unit, calls the nursery nurse into her room and expresses concern about how her daughter looks. Ms. Scott tells the nurse that her baby's head looks like a "banana" and is mushy to the touch, and she has "white spots" all over her nose. In addition, there appear to be "big bluish bruises" all over her baby's buttocks. She wants to know what is wrong with her baby and whether these problems will go away.
   a. How should the nurse respond to Ms. Scott's questions?
   b. What additional newborn instruction might be appropriate at this time?
   c. What reassurance can be given to Ms. Scott regarding her daughter's appearance?
2. At approximately 12:30 a.m. on a Friday, a woman enters a hospital through a busy emergency room. She is wearing a white uniform and a lab coat with a stethoscope around her neck. She identifies herself as a new nurse coming back to check on something she had left on the unit on an earlier shift. She enters a postpartum client's room containing the mother's newborn, pushes the open crib down a hallway, and escapes through an exit. The security cameras aren't working. The infant isn't discovered missing until the 2 a.m. check by the nurse.

a. What impact does an infant abduction have on the family and the hospital?

b. What security measure was the weak link in the chain of security?

c. What can hospitals do to prevent infant abduction?

STUDY ACTIVITIES

1. Interview a new mother on the postpartum unit on her second day about the changes she has noticed in her newborn's appearance and behavior within the past 24 hours. Discuss your interview findings at post conference.
2. Demonstrate a newborn bath to a new mother in her room, using the principle of bathing from the cleanest to the dirtiest body part. Discuss the questions asked by the mother and her reaction to the demonstration in post conference.
3. Go to the La Leche League website (www.lalecheleague.org). Review the information it provides on breast-feeding. How helpful would it be to a new mother?
4. Debate the risks and benefits of neonatal circumcision within your nursing group at post conference. Did either side present a stronger position? What is your opinion, and why?

CHAPTER 19

Nursing Management of Pregnancy at Risk: Pregnancy-Related Complications

KEY TERMS

abortion
abruptio placentae
ectopic pregnancy
gestational hypertension
gestational trophoblastic disease (GTD)
high-risk pregnancy
hyperemesis gravidarum
multiple gestation
oligohydramnios
polyhydramnios
placenta previa
premature rupture of membranes (PROM)
preterm premature rupture of membranes (PPROM)

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Define the term "high-risk pregnancy."
2. Explain common factors that might place a pregnancy at high risk.
3. Identify the causes of vaginal bleeding during early and late pregnancy.
4. Outline nursing assessment and management for the pregnant woman experiencing vaginal bleeding.
5. Develop a plan of care for the woman experiencing preeclampsia, eclampsia, and HELLP syndrome.
6. Explain the pathophysiology of polyhydramnios and subsequent management.
7. Select factors in a woman's prenatal history that place her at risk for premature rupture of membranes (PROM).
8. Formulate a teaching plan for maintaining the health of pregnant women experiencing a high-risk pregnancy.

Helen, a 35-year-old G5 P4, presented to the labor and birth suite with severe abdominal pain. She reports that the pain began suddenly about an hour ago while she was resting. She has had two prior cesarean births and thus far has had an uneventful past 32 weeks. Helen appears distressed and is moaning. What additional assessments do you need to care for Helen? What might be your immediate nursing action?

Wow

Detours and bumps along the road of life can be managed, but many cannot be entirely cured.

Most people view pregnancy as a natural process with a positive outcome—the birth of a healthy newborn. Unfortunately, conditions can occur that may result in negative outcomes for the fetus, mother, or both. A **high-risk pregnancy** is one in which a condition exists that jeopardizes the health of the mother, her fetus, or both. The condition may result from the pregnancy, or it may be a condition that was present before the woman became pregnant.

Approximately one in four pregnant women is considered to be at high risk or diagnosed with complications (Jung & Erogul, 2007). Women who are considered to be at high risk have a higher morbidity and mortality compared with mothers in the general population. The risk status of a woman and her fetus can change during the pregnancy, with a number of problems occurring during labor, birth, or afterward, even in women without any known previous antepartal risk. Examples of high-risk conditions include gestational diabetes and ectopic pregnancy. These conditions are specifically addressed in *Healthy People 2010*. Early identification of the woman at risk is essential to ensure that appropriate interventions are instituted promptly, increasing the opportunity to change the course of events and provide a positive outcome.

The term "risk" may mean different things to different groups. For example, health care professionals may focus on the disease processes and treatments to prevent complications. Nurses may focus on nursing care and on the psychosocial impact on the woman and her family. Insurance companies may concentrate on the economic issues related to the high-risk status. The woman's attention may be focused on her own needs and those of her family. Together, working as a collaborative team, the ultimate goal of care is to ensure the best possible outcome for the woman, her fetus, and her family.

Risk assessment begins at the first antepartal visit and continues with each subsequent visit because factors may be identified in later visits that were not apparent during earlier visits. For example, as the nurse and client develop a trusting relationship, previously unidentified or unsuspected factors (such as drug abuse or intimate partner violence) may be revealed. Through education and support, the nurse can encourage the client to inform her health care provider of these concerns, and necessary interventions or referrals can be made.

Various factors must be considered when determining a woman's risk for adverse pregnancy outcomes (Britt, Eden, & Evans, 2006), and a comprehensive approach to high-risk pregnancy is needed. For example, prenatal stress and distress have been shown to have significant consequences for the mother, child, and family (Price et al., 2007). Risks are grouped into broad categories based on threats to health and pregnancy outcome. Current categories of risk are biophysical, psychosocial, sociodemographic, and environmental (Gilbert, 2007) (Box 19.1).

This chapter describes the major conditions directly related to the pregnancy that can complicate a pregnancy, possibly affecting maternal and fetal outcomes. These include bleeding during pregnancy (spontaneous abortion, ectopic pregnancy, gestational trophoblastic disease, cervical insufficiency, placenta previa, and abruptio placentae), hyperemesis gravidarum, gestational hypertension, HELLP syndrome, gestational diabetes, blood incompatibility, amniotic fluid imbalances (hydramnios and oligohydramnios), multiple gestation, and premature rupture of membranes. Chapter 20 addresses preexisting conditions that can complicate a woman's pregnancy as well as populations that are considered to be at high risk.

HEALTHY PEOPLE 2010

Objective	Significance
Decrease the proportion of pregnant women with gestational diabetes	• Will help to promote proper prepregnant and pregnancy glycemic control; foster careful perinatal obstetric monitoring, thereby helping to reduce perinatal death and congenital abnormalities • Will help to reinforce the importance of good nutrition during pregnancy as paramount in increasing better pregnancy outcomes
Reduce ectopic pregnancies	• Will help to focus attention on the need for initiating prenatal care early and for continued monitoring throughout pregnancy, thus helping to decrease maternal mortality related to ectopic pregnancies through early detection

Source: U.S. DHHS, 2000.

Bleeding During Pregnancy

Bleeding at any time during pregnancy is potentially life-threatening. Bleeding can occur early or late in the pregnancy and may result from numerous conditions. Conditions commonly associated with early bleeding (first half of pregnancy) include spontaneous abortion, ectopic pregnancy, gestational trophoblastic disease, and conditions associated with midtrimester bleeding, such as cervical insufficiency. Conditions associated with late bleeding include placenta previa and abruptio placentae, which usually occur after the 20th week of gestation.

BOX 19.1 Factors Placing a Woman at Risk During Pregnancy

Biophysical Factors
- Genetic conditions
- Chromosomal abnormalities
- Multiple pregnancy
- Defective genes
- Inherited disorders
- ABO incompatibility
- Large fetal size
- Medical and obstetric conditions
- Preterm labor and birth
- Cardiovascular disease
- Chronic hypertension
- Incompetent cervix
- Placental abnormalities
- Infection
- Diabetes
- Maternal collagen diseases
- Pregnancy-induced hypertension
- Asthma
- Postterm pregnancy
- Hemoglobinopathies
- Nutritional status
- Inadequate dietary intake
- Food fads
- Excessive food intake
- Under- or overweight status
- Hematocrit value less than 33%
- Eating disorder

Psychosocial Factors
- Smoking
- Caffeine
- Alcohol
- Drugs
- Inadequate support system
- Situational crisis
- History of violence
- Emotional distress
- Unsafe cultural practices

Sociodemographic Factors
- Poverty status
- Lack of prenatal care
- Age younger than 15 years or older than 35 years
- Parity—all first pregnancies and more than five pregnancies
- Marital status—increased risk for unmarried
- Accessibility to health care
- Ethnicity—increased risk in nonwhite women

Environmental Factors
- Infections
- Radiation
- Pesticides
- Illicit drugs
- Industrial pollutants
- Second-hand cigarette smoke
- Personal stress (Gilbert, 2007; Blackburn, 2007)

Source: Blackburn, 2007; Gilbert, 2007.

SPONTANEOUS ABORTION

An **abortion** is the loss of an early pregnancy, usually before week 20 of gestation. Abortion can be spontaneous or induced. A spontaneous abortion refers to the loss of a fetus resulting from natural causes—that is, not elective or therapeutically induced by a procedure. The term *miscarriage* is often used by nonmedical people to denote an abortion that has occurred spontaneously. A miscarriage can occur during early pregnancy, and many women who miscarry may not even be aware that they are pregnant. About 80% of spontaneous abortions occur within the first trimester.

The overall rate for spontaneous abortion in the United States is reported to be 15% to 20% of recognized pregnancies in the United States. However, with the development of highly sensitive assays for human chorionic gonadotropin (hCG) levels that detect pregnancies prior to the expected next menses, the incidence of pregnancy loss increases significantly—to about 60% to 70% (Puscheck & Pradhan, 2007).

Pathophysiology

The causes of spontaneous abortion are varied and often unknown. The most common cause for first-trimester abortions is fetal genetic abnormalities, usually unrelated to the mother. Those occurring during the second trimester are more likely related to maternal conditions, such as incompetent cervix, congenital or acquired anomaly of the uterine cavity, hypothyroidism, diabetes mellitus, chronic nephritis, use of crack cocaine, inherited and acquired thrombophilias, lupus, and acute infection such as rubella virus, cytomegalovirus, herpes simplex virus, bacterial vaginosis, and toxoplasmosis (Simpson, 2007).

Nursing Assessment

When a pregnant woman calls and reports vaginal bleeding, she must be seen as soon as possible by a health care professional to ascertain the etiology. Varying degrees of vaginal bleeding, low back pain, abdominal cramping, and passage of products of conception tissue may be reported.

Ask the woman about the color of the vaginal bleeding (bright red is significant) and the amount—for example, question her about the frequency with which she is changing her peripads (saturation of one peripad hourly is significant) and the passage of any clots or tissue. Instruct her to save any tissue or clots passed and bring them with her to the health care facility. Also, obtain a description of any other signs and symptoms the woman may be experiencing, along with a description of their severity and duration. It is important to remain calm and listen to the woman's description.

When the woman arrives at the health care facility, assess her vital signs and observe the amount, color, and characteristics of the bleeding. Ask her to rate her current pain level, using an appropriate pain assessment tool. Also, evaluate the amount and intensity of the woman's abdominal cramping or contractions, and assess the woman's level of understanding about what is happening to her. A thorough assessment helps in determining the type of spontaneous abortion, such as threatened abortion, inevitable abortion, incomplete abortion, complete abortion, missed abortion, and habitual abortion, that the woman may be experiencing (Table 19.1).

Nursing Management

Nursing management of the woman with a spontaneous abortion focuses on providing continued monitoring and psychological support, for the family is experiencing acute loss and grief. An important component of this support is reassuring the woman that spontaneous abortions usually result from an abnormality and that her actions did not cause the abortion.

Providing Continued Monitoring

Continued monitoring and ongoing assessments are essential for the woman experiencing a spontaneous abortion. Monitor the amount of vaginal bleeding through pad counts and observe for passage of products of conception tissue. Assess the woman's pain and provide appropriate pain management to address the cramping discomfort.

Assist in preparing the woman for procedures and treatments such as surgery to evacuate the uterus or medications such as misoprostol or PGE2. If the woman is Rh negative and not sensitized, expect to administer RhoGAM within 72 hours after the abortion is complete. Drug Guide 19.1 gives more information about these medications.

Providing Support

A woman's emotional reaction may vary depending on her desire for this pregnancy and her available support network. Provide both physical and emotional support. In addition, prepare the woman and her family for the assessment process, and answer their questions about what is happening.

Explaining some of the causes of spontaneous abortions can help the woman to understand what is happening and may allay her fears and guilt that she did something to cause this pregnancy loss. Most women experience an acute sense of loss and go through a grieving process with a spontaneous abortion. Providing sensitive listening, counseling, and anticipatory guidance to the woman and her family will allow them to verbalize their feelings and ask questions about future pregnancies.

The grieving period may last as long as 2 years after a pregnancy loss, with each person grieving in his or her own way. Encourage friends and family to be supportive but give the couple space and time to work through their loss. Referral to a community support group for parents who have experienced a miscarriage can be very helpful during this grief process.

ECTOPIC PREGNANCY

An **ectopic pregnancy** is any pregnancy in which the fertilized ovum implants outside the uterine cavity. Ectopic pregnancies occur in from 1 in every 40 to 1 in every 100 pregnancies in the United States (March of Dimes, 2007). Their incidence has increased dramatically in the past few decades as a result of improved diagnostic techniques, such as more sensitive beta-hCG assays and the availability of transvaginal ultrasound (Silver, 2007).

With an ectopic pregnancy, rupture and hemorrhage may occur due to the growth of the embryo. A ruptured ectopic pregnancy is a medical emergency. It is a potentially life-threatening condition and involves pregnancy loss. It is the leading cause of maternal mortality in the first trimester and accounts for 10% to 15% of all pregnancy-related deaths (Lipscomb, 2007).

Pathophysiology

Normally, the fertilized ovum implants in the uterus. With an ectopic pregnancy, the ovum implants outside the uterus. The most common site for implantation is the fallopian tubes, but some ova may implant in the cornua of the uterus, the ovary, the cervix, or the abdominal cavity (Fig. 19.1) (Sepilian & Wood, 2007). None of these anatomic sites can accommodate placental attachment or a growing embryo.

Ectopic pregnancies usually result from conditions that obstruct or slow the passage of the fertilized ovum through the fallopian tube to the uterus. This may be a physical blockage in the tube, or failure of the tubal epithelium to move the zygote (the cell formed after the egg is fertilized) down the tube into the uterus. In the general population, most cases are the result of tubal scarring secondary to pelvic inflammatory disease. Organisms such

TABLE 19.1 CATEGORIES OF ABORTION

Category	Assessment Findings	Diagnosis	Therapeutic Management
Threatened abortion	Vaginal bleeding (often slight) early in a pregnancy No cervical dilation or change in cervical consistency Mild abdominal cramping Closed cervical os No passage of fetal tissue	Vaginal ultrasound to confirm if sac is empty Declining maternal serum hCG and progesterone levels to provide additional information about viability of pregnancy	Conservative supportive treatment Possible reduction in activity in conjunction with nutritious diet and adequate hydration
Inevitable abortion	Vaginal bleeding (greater than that associated with threatened abortion) Rupture of membranes Cervical dilation Strong abdominal cramping Possible passage of products of conception	Ultrasound and hCG levels to indicate pregnancy loss	Vacuum curettage if products of conception are not passed, to reduce risk of excessive bleeding and infection Prostaglandin analogs such as misoprostol to empty uterus of retained tissue (only used if fragments are not completely passed)
Incomplete abortion (passage of some of the products of conception)	Intense abdominal cramping Heavy vaginal bleeding Cervical dilation	Ultrasound confirmation that products of conception still in uterus	Client stabilization Evacuation of uterus via dilation and curettage (D&C) or prostaglandin analog
Complete abortion (passage of all products of conception)	History of vaginal bleeding and abdominal pain Passage of tissue with subsequent decrease in pain and significant decrease in vaginal bleeding	Ultrasound demonstrating an empty uterus	No medical or surgical intervention necessary Follow-up appointment to discuss family planning
Missed abortion (nonviable embryo retained in utero for at least 6 weeks)	Absent uterine contractions Irregular spotting Possible progression to inevitable abortion	Ultrasound to identify products of conception in uterus	Evacuation of uterus (if inevitable abortion does not occur): suction curettage during first trimester, dilation and evacuation during second trimester Induction of labor with intravaginal PGE2 suppository to empty uterus without surgical intervention
Habitual abortion	History of three or more consecutive spontaneous abortions Not carrying the pregnancy to viability or term	Validation via client's history	Identification and treatment of underlying cause (possible causes such as genetic or chromosomal abnormalities, reproductive tract abnormalities, chronic diseases or immunologic problems) Cervical cerclage in second trimester if incompetent cervix is the cause

DRUG GUIDE 19.1 MEDICATIONS USED WITH SPONTANEOUS ABORTIONS

Medication	Action/Indications	Nursing Implications
Misoprostol (Cytotec)	Stimulates uterine contractions to terminate a pregnancy; to evacuate the uterus after abortion to ensure passage of all the products of conception	• Monitor for side effects such as diarrhea, abdominal pain, nausea, vomiting, dyspepsia. • Assess vaginal bleeding and report any increased bleeding, pain, or fever. • Monitor for signs and symptoms of shock, such as tachycardia, hypotension, and anxiety.
Mifepristone (RU-486)	Acts as progesterone antagonist, allowing prostaglandins to stimulate uterine contractions; causes the endometrium to slough; may be followed by administration of misoprostol within 48 hours	• Monitor for headache, vomiting, diarrhea, and heavy bleeding. • Anticipate administration of antiemetic prior to use to reduce nausea and vomiting. • Encourage client to use acetaminophen to reduce discomfort from cramping.
PGE2, dinoprostone (Cervidil, Prepidil Gel, Prostin E2)	Stimulates uterine contractions, causing expulsion of uterine contents; to expel uterine contents in fetal death or missed abortion during second trimester, or to efface and dilate the cervix in pregnancy at term	• Bring gel to room temperature before administering. • Avoid contact with skin. • Use sterile technique to administer. • Keep client supine 30 minutes after administering. • Document time of insertion and dosing intervals. • Remove insert with retrieval system after 12 hours or at the onset of labor. • Explain purpose and expected response to client.
Rh(D) immunoglobulin (Gamulin, HydroRho-D, RhoGAM)	Suppresses immune response of nonsensitized Rh-negative patients who are exposed to Rh-positive blood; to prevent isoimmunization in Rh-negative women exposed to Rh-positive blood after abortions, miscarriages, and pregnancies	• Administer intramuscularly in deltoid area. • Give only MICRhoGAM for abortions and miscarriages <12 weeks unless fetus or father is Rh negative (unless patient is Rh positive, Rh antibodies are present). • Educate woman that she will need this after subsequent deliveries if newborns are Rh positive; also check lab study results prior to administering the drug.

as *Neisseria gonorrhoeae* and *Chlamydia trachomatis* preferentially attack the fallopian tubes, producing silent infections. A recent study reported a twofold increased risk for ectopic pregnancy in women with a history of a chlamydia infection (Bakken, Skjeldestad, & Nordbo, 2007). Even with early treatment, tubal damage can occur.

Therapeutic Management

The therapeutic management of ectopic pregnancy depends on whether the tube is intact or has ruptured. Historically, the treatment of ectopic pregnancy was limited to surgery, but medical therapy is currently available.

If the fallopian tube is still intact, medical management becomes an option. To be eligible for medical therapy, the client must be hemodynamically stable, with no signs of active bleeding in the peritoneal cavity, and the mass (which must measure less than 4 cm as determined by ultrasound) must be unruptured (Lipscomb, 2007). The potential advantages include avoidance of surgery, the preservation of tubal patency and function, and a lower cost. Methotrexate, prostaglandins, misoprostol, and actinomycin have all been used in the medical (nonsurgical) management of ectopic pregnancy, with a reported success rate of approximately 90% (Lipscomb, 2007).

Methotrexate, the agent most commonly used, is a folic acid antagonist that inhibits cell division in the developing embryo. It typically has been used as a chemotherapeutic agent in the treatment of leukemias, lymphomas, and carcinomas. It has been shown to produce results similar to that for surgical therapy in terms of high success rate, low complication rate, and good reproductive potential (Vitthala, Cheema, & Misra, 2007). Adverse effects associated with methotrexate include nausea, vomiting, stomatitis, diarrhea, gastric upset, increased abdominal pain, and dizziness. Prior to receiving the single-dose intramuscular injection to treat unruptured pregnancies, the woman needs to be counseled on the risks, benefits, adverse effects, and the possibility of failure of medical therapy, which would result in tubal rupture, necessitating surgery (Selway, 2006). The woman

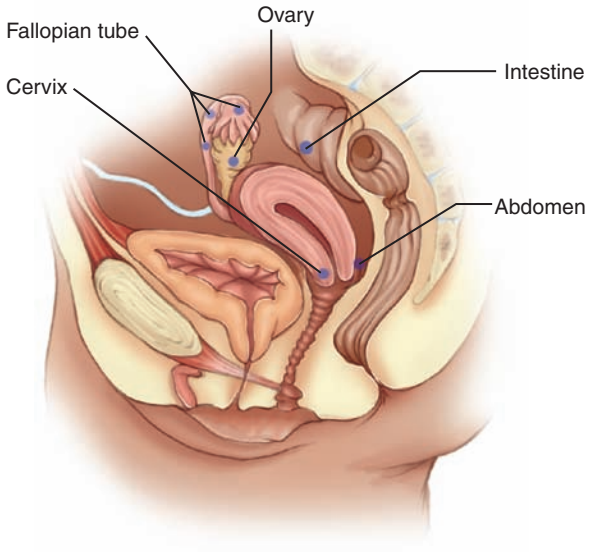

FIGURE 19.1 Possible sites for implantation with an ectopic pregnancy.

is then instructed to return weekly for follow-up laboratory studies for the next several weeks until beta-hCG titers decrease.

Surgical management for the unruptured fallopian tube might involve a linear salpingostomy to preserve the tube—an important consideration for the woman wanting to preserve her future fertility.

With a ruptured ectopic pregnancy, surgery is necessary as a result of possible uncontrolled hemorrhage. A laparotomy with a removal of the tube (salpingectomy) may be necessary. With earlier diagnosis and medical management, the focus has changed from preventing maternal death to facilitating rapid recovery and preserving fertility.

Regardless of the treatment approach (medical or surgical), the woman's beta-hCG level is monitored until it is undetectable to ensure that any residual trophoblastic tissue that forms the placenta is gone. Also, all Rh-negative unsensitized clients are given Rh immunoglobulin to prevent isoimmunization in future pregnancies.

Nursing Assessment

Nursing assessment focuses on determining the existence of an ectopic pregnancy and whether or not it has ruptured.

Health History and Physical Examination

Assess the client thoroughly for signs and symptoms that may suggest an ectopic pregnancy. The onset of signs and symptoms varies, but they usually begin at about the seventh or eighth week of gestation. A missed menstrual period, adnexal fullness, and tenderness may indicate an unruptured tubal pregnancy. As the tube stretches, the pain

EVIDENCE-BASED PRACTICE 19.1
Ectopic Pregnancy: Selecting the Best Intervention

● Study

The incidence of ectopic pregnancy, which involves implantation of the fertilized ovum outside the uterine cavity, has increased over the past several decades due to advances in diagnostic methods. The most common site for implantation is in the fallopian tube (thus the name tubal pregnancy). If left untreated, tubal rupture and hemorrhage can occur. At one time, surgery was the only available treatment option. However, treatment today may involve expectant care, medication therapy, or surgery (laparoscopic or open approach). Questions have arisen as to the effectiveness and safety of these treatments.

A study was conducted to evaluate the effectiveness of major types of treatment for ectopic pregnancy. Data were collected from 35 randomized controlled trials that compared the treatments for ectopic pregnancies.

▲ Findings

The open approach to surgery was significantly more effective in removing the ectopic pregnancy than the laparoscopic approach, but the laparoscopic approach was more cost-effective. Medication therapy involving fixed multiple doses of methotrexate was effective in women who had low pregnancy hormone levels without any evidence of bleeding. Expectant management was less successful than drug therapy, but the information on this treatment option was inadequate.

■ Nursing Implications

This study identified three important treatment options available to a woman with an ectopic pregnancy. Nurses can use this information in their practice as a basis for formulating a teaching plan about treatment options. Nurses can use the information from this study when reviewing the health care provider's recommendations for treatment. As a result, women can make a more informed decision. Nurses also can advocate for medication therapy for women who have low pregnancy hormone levels and no bleeding.

Hajenius, P. J., Mol, F., Mol, B. W. J., Bossuyt, P. M. M., Ankum, W. M., & van der Veen, F. (2007). Interventions for tubal ectopic pregnancy. *Cochrane Database of Systematic Reviews* 2007. Issue 1. Art. No.: CD000324.DOI: 10.1002/14651858.CD000324.pub2.

increases. Pain may be unilateral, bilateral, or diffuse over the abdomen.

▶ *Take* NOTE!

The hallmark of ectopic pregnancy is abdominal pain with spotting within 6 to 8 weeks after a missed menstrual period. Although this is the classic triad, all three of these signs and symptoms occur in only about 50% of cases. Many women have symptoms typical of early pregnancy, such as breast tenderness, nausea, fatigue, shoulder pain, and low back pain.

In addition, review the client's history for possible contributing factors. These may include:

- Previous ectopic pregnancy
- History of sexually transmitted infections (STIs)
- Fallopian tube scarring from pelvic inflammatory disease
- In utero exposure to diethylstilbestrol
- Endometriosis
- Previous tubal or pelvic surgery
- Infertility and infertility treatments, including use of fertility drugs
- Uterine abnormalities such as fibroids
- Presence of intrauterine contraception
- Use of progestin-only mini-pill (slows ovum transport)
- Postpartum or post-abortion infection
- Increasing age (older than 35 years)
- Cigarette smoking (Brown-Guttovz, 2006)

If rupture or hemorrhage occurs before treatment begins, symptoms may worsen and include severe, sharp, and sudden pain in the lower abdomen as the tube tears open and the embryo is expelled into the pelvic cavity; feelings of faintness; referred pain to the shoulder area, indicating bleeding into the abdomen, caused by phrenic nerve irritation; hypotension; marked abdominal tenderness with distention; and hypovolemic shock.

Laboratory and Diagnostic Testing

The use of transvaginal ultrasound to visualize the misplaced pregnancy and low levels of serum beta-hCG assist in diagnosing an ectopic pregnancy. The ultrasound determines whether the pregnancy is intrauterine, assesses the size of the uterus, and provides evidence of fetal viability. The visualization of an adnexal mass and the absence of an intrauterine gestational sac are diagnostic of ectopic pregnancy (Condous, 2006). In a normal intrauterine pregnancy, beta-hCG levels typically double every 2 to 4 days until peak values are reached 60 to 90 days after conception. Concentrations of hCG decrease after 10 to 11 weeks and reach a plateau at low levels by 100 to 130 days (Blackburn, 2007). Therefore, low beta-hCG levels are suggestive of an ectopic pregnancy or impending abortion. Additional tests may be done to rule out other conditions such as spontaneous abortion, ruptured ovarian cyst, appendicitis, and salpingitis.

Nursing Management

Nursing management for the woman with an ectopic pregnancy focuses on preparing the woman for treatment, providing support, and providing education about preventive measures.

Preparing the Woman for Treatment

Administer analgesics as ordered to promote comfort and relieve discomfort from abdominal pain. Although the intensity of the pain can vary, women often report a great deal of pain. If the woman is treated medically, explain the medication that will be used and what she can expect. Also review signs and symptoms of possible adverse effects. If treatment will occur on an outpatient basis, outline the signs and symptoms of ectopic rupture (severe, sharp, stabbing, unilateral abdominal pain; vertigo/fainting; hypotension; and increased pulse) and advise the woman to seek medical help immediately if they occur.

If surgery is needed, close assessment and monitoring of the client's vital signs, bleeding (peritoneal or vaginal), and pain status are critical to identify hypovolemic shock, which may occur with tubal rupture. Prepare the client physiologically and psychologically for surgery or any procedure. Provide a clear explanation of the expected outcome. Astute vigilance and early referral will help reduce short- and long-term morbidity.

Providing Emotional Support

The woman with an ectopic pregnancy requires support throughout diagnosis, treatment, and aftercare. A woman's psychological reaction to an ectopic pregnancy is unpredictable. However, it is important to recognize she has experienced a pregnancy loss in addition to undergoing treatment for a potentially life-threatening condition. The woman may find it difficult to comprehend what has happened to her because events occur so quickly. In the woman's mind, she had just started a pregnancy and now it has ended abruptly. Help her to make this experience "more real" by encouraging her and her family to express their feelings and concerns openly, and validating that this is a loss of pregnancy and it is okay to grieve over the loss.

Provide emotional support, spiritual care, client education, and information about community support groups available (such as Resolve through Sharing) as the client grieves for the loss of her unborn child and comes to terms with the medical complications of the situation. Acknowledge the client's pregnancy and allow her to discuss her feelings about what the pregnancy means. Also, stress the need for follow-up blood testing for several weeks to monitor hCG titers until they return to zero, indicating

resolution of the ectopic pregnancy. Ask about her feelings and concerns about her future fertility, and provide teaching about the need to use contraceptives for at least three menstrual cycles to allow her reproductive tract to heal and the tissue to be repaired. Include the woman's partner in this discussion to make sure both parties understand what has happened, what intervention is needed, and what the future holds regarding childbearing.

Educating the Client

Preventing ectopic pregnancies through screening and client education is essential. Many can be prevented by avoiding conditions that might cause scarring of the fallopian tubes. In addition, a contributing factor to the development of ectopic pregnancy is a previous ectopic pregnancy. Therefore, educating the woman is crucial.

Prevention education may include the following:

- Reduce risk factors such as sexual intercourse with multiple partners or intercourse without a condom.
- Avoid contracting STIs that lead to pelvic inflammatory disease (PID).
- Obtain early diagnosis and adequate treatment of STIs.
- Avoid the use of intrauterine contraceptive methods to reduce the risk of repeat ascending infections, which can be responsible for tubal scarring.
- Use condoms to decrease the risk of infections that cause tubal scarring.
- Seek prenatal care early to confirm the location of pregnancy.

GESTATIONAL TROPHOBLASTIC DISEASE (GTD)

Gestational trophoblastic disease (GTD) comprises a spectrum of neoplastic disorders that originate in the placenta. Gestational tissue is present, but the pregnancy is not viable. The incidence is about 1 in 1,000 pregnancies in the United States; in Asian countries, the rate is as much as 15 times higher (Moore & Ware, 2007). The two most common types of GTD are hydatidiform mole (partial and complete) and choriocarcinoma.

Pathophysiology

Hydatidiform mole is a benign neoplasm of the chorion in which the chorionic villi degenerate and become transparent vesicles containing clear, viscid fluid. Hydatiform mole is classified as complete or partial, distinguished by differences in clinical presentation, pathology, genetics, and epidemiology (Garner et al., 2007). The complete mole contains no fetal tissue and develops from an "empty egg," which is fertilized by a normal sperm (the paternal chromosomes replicate, resulting in 46 all-paternal chromosomes). The embryo is not viable and dies. No circulation is established, and no embryonic tissue is found. The complete mole is associated with the development of choriocarcinoma. The partial mole has a triploid karyotype (69 chromosomes), because two sperm have provided a double contribution by fertilizing the ovum (Fig. 19.2).

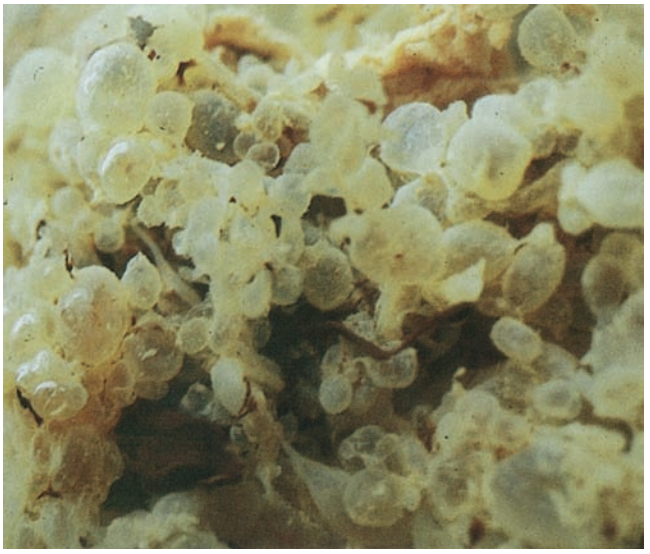

FIGURE 19.2 Complete hydatiform mole. The chorionic villi degenerate and become filled with a viscid fluid, forming transparent vesicles.

▸ *Consider THIS!*

We had lived across the dorm hall from each other during nursing school but really didn't get to know each other except for a casual hello in passing. When we graduated, Rose went to work in the emergency room and I in OB. We saw each other occasionally in the employee cafeteria, but a quick hello was all that we usually exchanged. I heard she married one of the paramedics who worked in the ER and was soon pregnant. I finally got to say more than hello when she was admitted to the OB unit bleeding during her fourth month of pregnancy. What was discovered was gestational trophoblastic disease and not a normal pregnancy. I remember holding her in my arms as she wept. She was told she had a complete molar pregnancy after surgery, and she would need extensive follow-up for the next year. I lost track of her that summer as my life became busier. Around Thanksgiving time, I heard she had died from choriocarcinoma. I attended her funeral, finally, to get the time to say a final hello and good-bye, but this time with sadness and tears.

Thoughts: Rose was only 26 years old when she succumbed to this very virulent cancer. I think back

(continued)

Consider THIS! *(continued)*

and realize I missed knowing this brave young woman and wished that I had taken the time to say more than hello. Could her outcome have been different? Why wasn't it recognized earlier? Did she not follow up after her diagnosis? I can only speculate regarding the whom, what, and where. She lived a short but purposeful life, and hopefully continued research will change other women's outcomes in the future.

The exact cause of molar pregnancy is unknown, but researchers are looking into a genetic basis. Studies have revealed some remarkable features about molar pregnancies, including:

- Ability to invade into the wall of the uterus
- Tendency to recur in subsequent pregnancies
- Possible development into choriocarcinoma, a virulent cancer with metastasis to other organs
- Influence of nutritional factors, such as protein deficiency
- Tendency to affect older women more often than younger women

Having a molar pregnancy (partial or complete) results in the loss of the pregnancy and the possibility of developing choriocarcinoma, a chorionic malignancy from the trophoblastic tissue. The most frequent sites of metastases are the lungs, lower genital tract, brain, liver, kidney and gastrointestinal tract (Hernandez, 2007).

Therapeutic Management

Treatment consists of immediate evacuation of the uterine contents as soon as the diagnosis is made and long-term follow-up of the client to detect any remaining trophoblastic tissue that might become malignant. Dilation and suction curettage (D&C) are used to empty the uterus. The tissue obtained is sent to the laboratory for analysis to evaluate for choriocarcinoma. Serial levels of hCG are used to detect residual trophoblastic tissue for 1 year. If any tissue remains, hCG levels will not regress. In 80% of women with a benign hydatidiform mole, serum hCG titers steadily drop to normal within 8 to 12 weeks after evacuation of the molar pregnancy. In the other 20% of women with a malignant hydatidiform mole, serum hCG levels begin to rise (Hernandez, 2007).

Due to the increased risk for cancer, the client is advised to receive extensive follow-up therapy for the next 12 months. The follow-up protocol may include:

- Baseline hCG level, chest radiograph, and pelvic ultrasound
- Weekly serum hCG level until it drops to zero and remains at that level for 3 consecutive weeks, then monthly for 6 months, then every 2 months for the remainder of the year
- Chest radiograph every 6 months to detect pulmonary metastasis
- Regular pelvic examinations to assess uterine and ovarian regression
- Systemic assessments for symptoms indicative of lung, brain, liver, or vaginal metastasis
- Strong recommendation to avoid pregnancy for 1 year because the pregnancy can interfere with the monitoring of hCG levels
- Use of a reliable contraceptive for at least 1 year (Gilbert, 2007)

Nursing Assessment

The nurse plays a crucial role in identifying and bringing this condition to the attention of the health care provider based on sound knowledge of the typical clinical manifestations and through astute antepartal assessments.

Clinical manifestations of GTD are very similar to those of spontaneous abortion at about 12 weeks of pregnancy. Assess the woman for potential clinical manifestations at each antepartal visit. Be alert for the following:

- Report of early signs of pregnancy, such as amenorrhea, breast tenderness, fatigue
- Brownish vaginal bleeding/spotting
- Anemia
- Severe morning sickness (due to high hCG levels)
- Fluid retention and swelling
- Uterine size larger than expected for pregnancy dates
- Extremely high hCG levels present; no single value considered diagnostic
- Early development of preeclampsia (usually not present until after 24 weeks)
- Absence of fetal heart rate or fetal activity
- Expulsion of grapelike vesicles (possible in some women)

The diagnosis is made by high hCG levels and the characteristic appearance of the vesicular molar pattern in the uterus via transvaginal ultrasound.

Nursing Management

Nursing management of the woman with GTD focuses on preparing her for a D&C, providing emotional support to deal with the loss and potential risks, and educating her about the risk that cancer may develop after a molar pregnancy and the strict adherence needed with the follow-up program. The woman must understand the need for the continued follow-up care regimen to improve her chances of future pregnancies and to ensure her continued quality of life.

Preparing the Client

Upon diagnosis, the client will need an immediate evacuation of the uterus. Perform preoperative care, preparing the client physically and psychologically for the procedure.

Providing Emotional Support

To aid the client and her family in coping with the loss of the pregnancy and the possibility of a cancer diagnosis, use the following interventions:

- Listen to their concerns and fears.
- Allow them time to grieve for the pregnancy loss.
- Acknowledge their loss and sad feelings (say you are sorry for their loss).
- Encourage them to express their grief; allow them to cry.
- Provide them with as much factual information as possible to help them make sense of what is happening.
- Enlist support from additional family and friends as appropriate and with the client's permission.

Educating the Client

After GTD is diagnosed, teach the client about the condition and appropriate interventions that may be necessary to save her life. Explain each phase of treatment accurately and provide support for the woman and her family as they go through the grieving process.

As with any facet of health care, be aware of the latest research and new therapies. Inform the client about her follow-up care, which will probably involve close clinical surveillance for approximately 1 year, and reinforce its importance in monitoring the client's condition. Tell the client that serial serum beta-hCG levels are used to detect residual trophoblastic tissue. Continued high or increasing hCG titers are abnormal and need further evaluation.

Inform the client about the possible use of chemotherapy, such as methotrexate, which may be started as prophylaxis. Strongly urge the client to use a reliable contraceptive to prevent pregnancy for 1 year, as a pregnancy would interfere with tracking the serial beta-hCG levels used to identify a potential malignancy. Stress the need for the client to cooperate and adhere to the plan of therapy throughout this year-long follow-up.

CERVICAL INSUFFICIENCY

Cervical insufficiency, also called premature dilatation of the cervix, describes a weak, structurally defective cervix that spontaneously dilates in the absence of contractions in the second trimester, resulting in the loss of the pregnancy. The incidence of cervical insufficiency is less than 1%; estimates range from 1 in 500 to 1 in 2,000 pregnancies, accounting for approximately 20% to 25% of midtrimester losses (Fox & Chervenak, 2008).

Pathophysiology

The exact mechanism contributing to cervical insufficiency is not known. The incompetent cervix may have less elastin, less collagen, and greater amounts of smooth muscle than the normal cervix (Evans, 2007). Several theories have been proposed that focus on damage to the cervix as a key component.

Cervical insufficiency is likely to be the clinical endpoint of many pathologic processes, such as congenital cervical hypoplasia, in utero diethylstilbestrol (DES) exposure that caused cervical hypoplasia, trauma to the cervix (conization, amputation, obstetric laceration, or forced cervical dilatation [may occur during elective pregnancy termination]). Other conditions such as previous precipitous birth, a prolonged second stage of labor, or increased uterine volume (multiple gestation, hydramnios) are associated with cervical insufficiency (Vyas et al., 2006). However, the exact etiology of cervical insufficiency is not known.

Cervical length also has been associated with cervical insufficiency and subsequently preterm birth. Recent studies have examined the association between a short cervical length and the risk of preterm birth. Some have demonstrated a continuum of risk between a shorter cervix on ultrasound and a higher risk of preterm birth, leading to the hypothetical argument that women with a short cervix on ultrasound might benefit from cervical cerclage, but there have been conflicting results (Lotgering, 2007; Vidaeff & Ramin, 2007).

Therapeutic Management

Cervical insufficiency may be treated in a variety of ways: bed rest; pelvic rest; avoidance of heavy lifting; or surgically, via a procedure of a cervical cerclage in the second trimester. Cervical cerclage involves using a heavy purse-string suture to secure and reinforce the internal os of the cervix (Fig. 19.3).

According to the American College of Obstetricians & Gynecologists (ACOG) (2003), if a short cervix is identified at or after 20 weeks and no infection (chorioamnionitis) is present, the decision to proceed with cerclage should be made with caution. There have been limited numbers of well-designed randomized studies to support its efficacy. Suture displacement, rupture of membranes, and chorioamnionitis are the most common complications associated with cerclage placement, and their incidence varies widely in relation to the timing and indications for

FIGURE 19.3 Cervical cerclage.

the cerclage (Ressel, 2004). The optimal timing for cerclage removal is unclear, according to ACOG (2003).

Nursing Assessment

Nursing assessment focuses on obtaining a thorough history to determine any risk factors that might have a bearing on this pregnancy—previous cervical trauma, preterm labor, fetal loss in the second trimester, or previous surgeries or procedures involving the cervix. History may reveal a previous loss of pregnancy around 20 weeks.

Also be alert for complaints of vaginal discharge or pelvic pressure. Commonly with cervical insufficiency the woman will report a pink-tinged vaginal discharge or an increase in pelvic pressure. Cervical dilation also occurs. If this continues, rupture of the membranes, release of amniotic fluid, and uterine contractions occur, subsequently resulting in delivery of the fetus, often before it is viable.

▶ *Take* NOTE!

The diagnosis of cervical insufficiency remains difficult in many circumstances. The cornerstone of diagnosis is a history of midtrimester pregnancy loss associated with painless cervical dilatation without evidence of uterine activity.

Transvaginal ultrasound typically is done around 20 weeks' gestation to determine cervical length and evaluate for shortening. Cervical shortening occurs from the internal os outward and can be viewed on ultrasound as funneling. The amount of funneling can be determined by dividing funnel length by cervical length. The most common time at which a short cervix or funneling develops is 18 to 22 weeks, so ultrasound screening should be performed during this interval (Fox & Chervenak, 2008). A cervical length less than 25 mm is abnormal between 14 weeks and 24 weeks and may increase the risk of preterm labor.

Expect the woman (particularly a woman with pelvic pressure, backache, or increased mucoid discharge) to undergo serial transvaginal ultrasound evaluations every few days to avoid missing rapid changes in cervical dilation or until the trend in cervical length can be characterized (Bernasko et al., 2006).

Nursing Management

Nursing management focuses on monitoring the woman very closely for signs of preterm labor: backache, increase in vaginal discharge, rupture of membranes, and uterine contractions. Provide emotional support and education to allay the couple's anxiety about the well-being of their fetus. Provide preoperative care and teaching as indicated if the woman will be undergoing cerclage. Teach the client and her family about the signs and symptoms of preterm labor and the need to report any changes immediately. Also reinforce the need for activity restrictions (if appropriate) and continued regular follow-up. Continuing surveillance throughout the pregnancy is important to promote a positive outcome for the family.

PLACENTA PREVIA

Placenta previa is a bleeding condition that occurs during the last two trimesters of pregnancy. In placenta previa (literally, "afterbirth first"), the placenta implants over the cervical os. It may cause serious morbidity and mortality to the fetus and mother. It complicates approximately 5 of 1,000 births or 1 in every 200 pregnancies and is associated with potentially serious consequences from hemorrhage, abruption (separation) of the placenta, or emergency cesarean birth (Joy & Lyon, 2007).

Pathophysiology

The exact cause of placenta previa is unknown. It is initiated by implantation of the embryo in the lower uterus. With placental attachment and growth, the cervical os may become covered by the developing placenta. Placental vascularization is defective, allowing the placenta to attach directly to the myometrium (accreta), invade the myometrium (increta), or penetrate the myometrium (percreta).

Placenta previa is generally classified according to the degree of coverage or proximity to the internal os, as follows (Fig. 19.4):

- Total placenta previa: the internal cervical os is completely covered by the placenta
- Partial placenta previa: the internal os is partially covered by the placenta
- Marginal placenta previa: the placenta is at the margin or edge of the internal os
- Low-lying placenta previa: the placenta is implanted in the lower uterine segment and is near the internal os but does not reach it

Therapeutic Management

Therapeutic management depends on the extent of bleeding, the amount of placenta over the cervical os, whether the fetus is developed enough to survive outside the uterus, the position of the fetus, the mother's parity, and the presence or absence of labor (Zeltzer, 2007).

If the mother and fetus are both stable, therapeutic management may involve expectant ("wait-and-see") care. This care can be carried out at home or on an antepartal unit in the health care facility. If there is no active bleeding and the client has readily available access to reliable

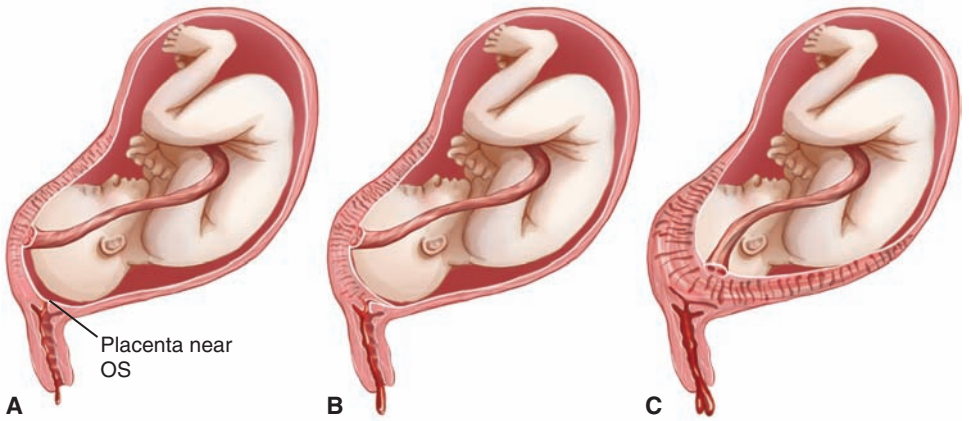

FIGURE 19.4 Classification of placenta previa. (**A**) Marginal. (**B**) Partial. (**C**) Complete.

transportation, can maintain bed rest at home, and can comprehend instructions, expectant care at home is appropriate. However, if the client requires continuous care and monitoring and cannot meet the home care requirements, the antepartal unit is the best environment.

Nursing Assessment

Nursing assessment involves a thorough history, including possible risk factors, and physical examination. Evaluate the client closely for these risk factors:

- Advancing maternal age (more than 35 years)
- Previous cesarean birth
- Multiparity
- Uterine insult or injury
- Cocaine use
- Prior placenta previa
- Infertility treatment
- Asian ethnic background (incidence is increased in Asian cultural groups)
- Multiple gestations
- Previous induced surgical abortion
- Smoking
- Previous myomectomy to remove fibroids
- Smoking (Ko & Yoon, 2007)

Health History and Physical Examination

Ask the client if she has any problems associated with bleeding, now or in the recent past. The classical clinical presentation is painless, bright-red vaginal bleeding occurring during the second or third trimester. The initial bleeding usually is not profuse and it ceases spontaneously, only to recur again. The first episode of bleeding occurs (on average) at 27 to 32 weeks' gestation. The bleeding is thought to arise secondary to the thinning of the lower uterine segment in preparation for the onset of labor. When the bleeding occurs at the implantation site in the lower uterus, the uterus cannot contract adequately and stop the flow of blood from the open vessels. Typically with normal placental implantation in the upper uterus, minor disruptive placental attachment is not a problem, because there is a larger volume of myometrial tissue able to contract and constrict bleeding vessels.

Assess the client for uterine contractions, which may or may not occur with the bleeding. Palpate the uterus; typically it is soft and nontender on examination. Auscultate the fetal heart rate; it commonly is within normal parameters. Fetal distress is usually absent but may occur when cord problems arise, such as umbilical cord prolapse or cord compression, or when the client has experienced blood loss to the extent that maternal shock or placental abruption has occurred (Oppenheimer, 2007).

Laboratory and Diagnostic Testing

To validate the position of the placenta, a transvaginal ultrasound is done. In addition, magnetic resonance imaging may be ordered when preparing for delivery because it allows identification of placenta accreta (placenta abnormally adherent to the myometrium), increta (placenta accreta with penetration of the myometrium), or percreta (placenta accreta with invasion of the myometrium to the peritoneal covering, causing rupture of the uterus) in addition to placenta previa. These placental abnormalities, although rare, carry a very high morbidity and mortality rate, possibly necessitating a hysterectomy at delivery.

Nursing Management

Whether the care setting is in the client's home or in the health care facility, the nurse focuses on monitoring the maternal–fetal status, including assessing for signs and symptoms of vaginal bleeding and fetal distress, and providing support and education to the client and her family, including what events and diagnostic studies are being performed. For the majority of women, a cesarean birth will be planned. Nursing Care Plan 19.1 discusses the nursing process for the woman with placenta previa.

Nursing Care Plan 19.1

OVERVIEW OF THE WOMAN WITH PLACENTA PREVIA

Sandy, a 39-year-old G5, P4, multigravida client at 32 weeks' gestation, was admitted to the labor and birth suite with sudden vaginal bleeding. Sandy had no further active bleeding and did not complain of any abdominal discomfort or tenderness. She did complain of occasional "tightening" in her stomach. Her abdomen palpated soft. Fetal heart rates were in the 140s with accelerations with movement. She was placed on bed rest with bathroom privileges. Ultrasound identified a low-lying placenta with a viable, normal-growth fetus. She was diagnosed with placenta previa and admitted for observation and surveillance of fetal well-being. Her history revealed two previous cesarean births, smoking half a pack of cigarettes per day, and endometritis infection after birth of her last newborn. Additional assessment findings included painless, bright-red vaginal bleeding with initial bleeding ceasing spontaneously; irregular, mild, and sporadic uterine contractions; fetal heart rate and maternal vital signs within normal range; fetus in transverse lie; anxiety related to the outcome of pregnancy; and expression of feelings of helplessness.

NURSING DIAGNOSIS: Ineffective tissue perfusion (fetal and maternal) related to blood loss

Outcome Identification and Evaluation

Client will maintain adequate tissue perfusion as evidenced by stable vital signs, decreased blood loss, few or no uterine contractions, normal fetal heart rate patterns and variability, and positive fetal movement

Interventions: Maintaining Adequate Tissue Perfusion

- Establish IV access *to allow for administration of fluids, blood, and medications as necessary.*
- Obtain type and cross-match for at least 2 U blood products *to ensure availability should bleeding continue.*
- Obtain specimens as ordered for blood studies, such as CBC and clotting studies *to establish a baseline and use for future comparison.*
- Monitor output *to evaluate adequacy of renal perfusion.*
- Administer IV fluid replacement therapy as ordered *to maintain blood pressure and blood volume.*
- Palpate for abdominal tenderness and rigidity *to determine bleeding and evidence of uterine contractions.*
- Institute bed rest *to reduce oxygen demands.*
- Assess for rupture of membranes *to evaluate for possible onset of labor.*
- Avoid vaginal examinations *to prevent further bleeding episodes.*
- Complete an Rh titer *to identify need for RhoGAM.*
- Avoid nipple stimulation *to prevent uterine contractions.*
- Continuously monitor for contractions or PROM *to allow for prompt intervention.*
- Administer tocolytic agents as ordered *to stall preterm labor.*
- Monitor vital signs frequently *to identify possible hypovolemia and infection.*
- Assess frequently for active vaginal bleeding *to minimize risk of hemorrhage.*
- Continuously monitor fetal heart rate with electronic fetal monitor *to evaluate fetal status.*
- Assist with fetal surveillance tests as ordered *to aid in determining fetal well-being.*
- Observe for abnormal fetal heart rate patterns, such as loss of variability, decelerations, tachycardia, *to identify fetal distress.*
- Position patient in side-lying position with wedge for support *to maximize placental perfusion.*
- Assess fetal movement *to evaluate for possible fetal hypoxia.*
- Teach woman to monitor fetal movement *to evaluate well-being.*
- Administer oxygen as ordered *to increase oxygenation to mother and fetus.*

Nursing Care Plan 19.1 (continued)

NURSING DIAGNOSIS: Anxiety related to threats to self and fetus

Outcome Identification and Evaluation

Client will experience a decrease in anxiety as evidenced by verbal reports of less anxiety, use of effective coping measures, and calm demeanor

Interventions: Minimizing Anxiety

- Provide factual information about diagnosis and treatment, and explain interventions and the rationale behind them *to provide client with understanding of her condition.*
- Answer questions about health status honestly *to establish a trusting relationship.*
- Speak calmly to patient and family members *to minimize environmental stress.*
- Encourage the use of past effective techniques for coping *to promote relaxation and feelings of control.*
- Acknowledge and facilitate the woman's spiritual needs *to promote effective coping.*
- Involve the woman and family in the decision-making process *to foster self-confidence and control over situation.*
- Maintain a presence during stressful periods *to allay anxiety.*
- Use the sense of touch if appropriate *to convey caring and concern.*
- Encourage talking as a means *to release tension.*

Monitoring Maternal–Fetal Status

Assess the degree of vaginal bleeding; inspect the perineal area for blood that may be pooled underneath the woman. Estimate and document the amount of bleeding. Perform a peripad count on an ongoing basis, making sure to report any changes in amount or frequency to the health care provider. If the woman is experiencing active bleeding, prepare for blood typing and cross-matching in the event a blood transfusion is needed.

▶ ***Take*** NOTE!

Avoid doing vaginal examinations in the woman with placenta previa. They may disrupt the placenta and cause hemorrhage.

Monitor maternal vital signs and uterine contractility frequently for changes. Have the client rate her level of pain using an appropriate pain rating scale.

Assess fetal heart rates via Doppler or electronic monitoring to detect fetal distress. Monitor the woman's cardiopulmonary status, reporting any difficulties in respirations, changes in skin color, or complaints of difficulty breathing. Have oxygen equipment readily available should fetal or maternal distress develop. Encourage the client to lie on her side to enhance placental perfusion.

If the woman has an intravenous (IV) line inserted, inspect the IV site frequently. Alternately, anticipate the insertion of an intermittent IV access device such as a saline lock, which can be used if quick access is needed for fluid restoration and infusion of blood products. Obtain laboratory tests as ordered, including complete blood count (CBC), coagulation studies, and Rh status if appropriate.

Administer pharmacologic agents as necessary. Give Rh immunoglobulin if the client is Rh negative at 28 weeks' gestation. Monitor tocolytic medication if prevention of preterm labor is needed.

Providing Support and Education

Determine the woman's level of understanding about placenta previa and the associated procedures and treatment plan. Doing so is important to prevent confusion and gain her cooperation. Provide information about the condition and make sure that all information related is consistent with information from the primary care provider. Explain all assessments and treatment measures as needed. Act as a client advocate in obtaining information for the family.

Teach the woman how to perform and record daily fetal movement. This action serves two purposes. One, it provides valuable information about the fetus. Two, it is an activity that the client can participate in, thereby fostering some feeling of control over the situation.

If the woman will require prolonged hospitalization or home bed rest, assess the physical and emotional impact that this may have on her. Evaluate her coping mechanisms to help determine how well she will be able to adjust to and cooperate with the treatment plan. Allow the client to verbalize her feelings and fears and provide emotional support. Also, provide opportunities for distraction—educational videos, arts and crafts, computer games, reading books—and evaluate the client's response.

In addition to the emotional impact of prolonged bed rest, thoroughly assess the woman's skin to prevent skin breakdown and to help alleviate her discomfort secondary to limited physical activity. Instruct the woman in appropriate skin care measures. Encourage her to eat a balanced diet with adequate fluid intake to ensure adequate nutrition

and hydration and prevent complications associated with urinary and bowel elimination secondary to bed rest.

Teach the client and family about any signs and symptoms that should be reported immediately. In addition, prepare the woman for the possibility of a cesarean birth. The woman must notify her health care provider about any bleeding episodes or backaches (may indicate preterm labor contractions) and must adhere to the prescribed bed rest regimen. To ensure compliance and a positive outcome, she needs to be aware of the purpose of all of the observations that need to be made.

ABRUPTIO PLACENTAE

Abruptio placentae is the separation of a normally located placenta after the 20th week of gestation and prior to birth that leads to hemorrhage. It is a significant cause of third-trimester bleeding, with a high mortality rate. It occurs in about 1% of all pregnancies throughout the world (Gaufberg, 2007), or 1 in 120 pregnancies. The overall fetal mortality rate for placental abruption is 20% to 40%, depending on the extent of the abruption. Maternal mortality is approximately 6% in abruptio placentae and is related to cesarean birth and/or hemorrhage/coagulopathy (Deering & Satin, 2007).

Pathophysiology

The etiology of this condition is unknown; however, it has been proposed that abruption starts with degenerative changes in the small maternal arterioles, resulting in thrombosis, degeneration of the decidua, and possible rupture of a vessel. Bleeding from the vessel forms a retroplacental clot. The bleeding causes increased pressure behind the placenta and results in separation (Collins, 2007).

Fetal blood supply is compromised and fetal distress develops in proportion to the degree of placental separation. This is caused by the insult of the abruption itself and by issues related to prematurity when early birth is required to alleviate maternal or fetal distress.

Abruptio placentae is classified according to the extent of separation and the amount of blood loss from the maternal circulation. Classifications include:

- Mild (grade 1): minimal bleeding (less than 500 mL), marginal separation (10% to 20%), tender uterus, no coagulopathy, no signs of shock, no fetal distress
- Moderate (grade 2): moderate bleeding (1,000 to 1,500 mL), moderate separation (20% to 50%), continuous abdominal pain, mild shock
- Severe (grade 3): absent to moderate bleeding (more than 1,500 mL), severe separation (more than 50%), profound shock, agonizing abdominal pain, and development of disseminated intravascular coagulopathy (DIC) (Gilbert, 2007)

Abruptio placentae also may be classified as partial or complete, depending on the degree of separation. Alternately, it can be classified as concealed or apparent, by the type of bleeding (Fig. 19.5).

Remember Helen, the pregnant woman with severe abdominal pain? Electronic fetal monitoring revealed uterine hypertonicity with absent fetal heart sounds. Palpation of her abdomen revealed rigidity and extreme tenderness in all four quadrants. Her vital signs were as follows—temperature, afebrile; pulse 94; respirations 22; blood pressure 130/90 mm Hg. What might you suspect as the cause of Helen's abdominal pain? What course of action would you anticipate for Helen?

Therapeutic Management

Treatment of abruptio placentae is designed to assess, control, and restore the amount of blood lost; to provide a positive outcome for both mother and newborn; and to prevent coagulation disorders, such as DIC (Box 19.2). Emergency measures include starting two large-bore IV lines with normal saline or lactated Ringer's solution to combat hypovolemia, obtaining blood specimens for evaluating hemodynamic status values and for typing and cross-matching, and frequently monitoring fetal and maternal well-being. After the severity of abruption is determined and appropriate blood and fluid replacement is given, cesarean birth is done immediately if fetal distress is evident. If the fetus is not in distress, close monitoring continues, with delivery planned at the earliest signs of fetal distress. Because of the possibility of fetal blood loss through the placenta, a neonatal intensive care team should be available during the birth process to assess and treat the newborn immediately for shock, blood loss, and hypoxia.

If the woman develops DIC, treatment focuses on determining the underlying cause of DIC and correcting it. Replacement therapy of the coagulation factors is achieved by transfusion of fresh-frozen plasma along with cryoprecipitate to maintain the circulating volume and provide oxygen to the cells of the body. Anticoagulant therapy (low-molecular-weight heparin), packed red cells, platelet concentrates, antithrombin concentrates, and nonclotting protein-containing volume expanders, such as plasma protein fraction or albumin, are also used to combat this serious condition (Bick, 2007). Prompt identification and early intervention are essential for a woman with acute DIC associated with abruptio placentae to treat DIC and possibly save her life.

Nursing Assessment

Abruptio placentae is a medical emergency. The nurse plays a critical role in assessing the pregnant woman presenting with abdominal pain and/or experiencing vaginal bleeding, especially in a concealed hemorrhage, in which

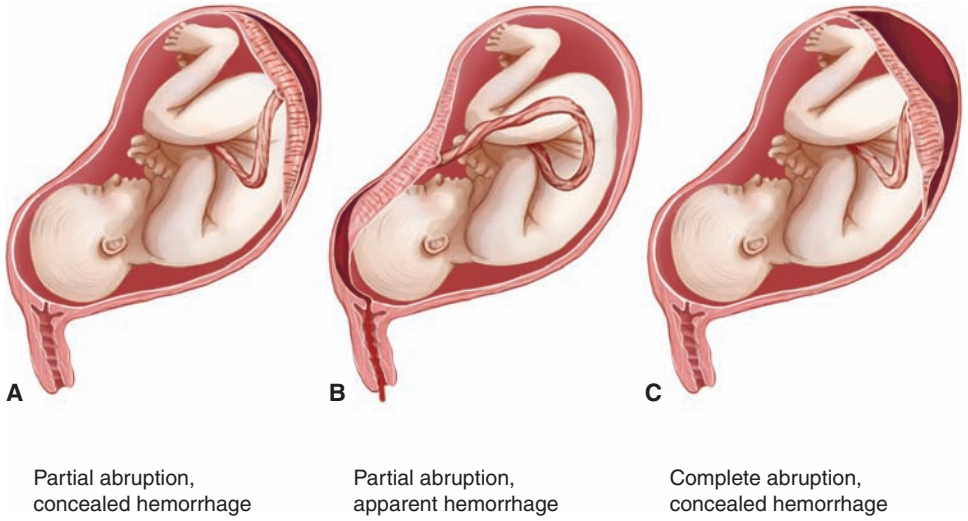

FIGURE 19.5 Classifications of abruptio placentae. (**A**) Partial abruption with concealed hemorrhage. (**B**) Partial abruption with apparent hemorrhage. (**C**) Complete abruption with concealed hemorrhage.

the extent of bleeding is not recognized. Rapid assessment is essential to ensure prompt, effective interventions to prevent maternal and fetal morbidity and mortality. Comparison Chart 19.1 compares placenta previa with abruptio placentae.

BOX 19.2 Disseminated Intravascular Coagulation (DIC)

DIC is a bleeding disorder characterized by an abnormal reduction in the elements involved in blood clotting resulting from their widespread intravascular clotting (Gilbert, 2007). This disorder can occur secondary to abruptio placentae.

Simply put, the clinical and pathologic manifestations of DIC can be described as a loss of balance between the clot-forming activity of thrombin and the clot-lysing activity of plasmin. Therefore, too much thrombin tips the balance toward the prothrombic state and the client develops clots. Alternately, too much clot lysis (fibrinolysis) results from plasmin formation and the client hemorrhages. Small clots form throughout the body, and eventually the blood-clotting factors are used up, rendering them unavailable to form clots at sites of tissue injury. Clot-dissolving mechanisms are also increased, which result in bleeding (possibly severe).

DIC can be stimulated by many factors, including sepsis, malignancy, and obstetric conditions such as placental abruption, missed abortion or retained dead fetus, amniotic fluid embolism, and eclampsia.

Laboratory studies that assist in the diagnosis include:

- Decreased fibrinogen and platelets
- Prolonged PT and aPTT
- Positive D-dimer tests and fibrin (split) degradation products (objective evidence of the simultaneous formation of thrombin and plasmin) (Furlong & Furlong, 2007)

Health History and Physical Examination

Begin the health history by assessing the woman for risk factors that may predispose her to abruptio placentae, such as maternal smoking, advanced maternal age (over 35 years old), poor nutrition, multiple gestation, excessive intrauterine pressure caused by hydramnios, hypertension, severe trauma (e.g., auto accident, intimate partner violence), cocaine use, alcohol ingestion, and multiparity (Norwitz & Schorge, 2006; Zeltzer, 2007). Ask the woman about her previous pregnancies to determine if she has experienced a prior abruption. In addition, be alert for other notable risk factors, such as male fetal gender, chorioamnionitis, prolonged premature ruptured membranes (more than 24 hours), oligohydramnios, preeclampsia, and low socioeconomic status (Deering & Satin, 2007).

Assess the woman for bleeding. As the placenta separates from the uterus, hemorrhage ensues. It can be apparent, appearing as vaginal bleeding, or it can be concealed. Vaginal bleeding is present in 80% of women diagnosed with abruptio placentae and may be significant enough to jeopardize both maternal and fetal health within a short time frame. The remaining 20% of abruptions are associated with a concealed hemorrhage and the absence of vaginal bleeding. Monitor the woman's level of consciousness, noting any signs or symptoms that may suggest shock.

▶ *Take* NOTE!

Vital signs can be within normal range, even with significant blood loss, because a pregnant woman can lose up to 40% of her total blood volume without showing signs of shock (Gilbert, 2007).

Assess the woman for complaints of pain, including the type, onset, and location. Ask if she has had any contractions. Palpate the abdomen, noting any contractions,

COMPARISON CHART 19.1 PLACENTA PREVIA VERSUS ABRUPTIO PLACENTAE

Manifestation	Placenta Previa	Abruptio Placentae
Onset	Insidious	Sudden
Type of bleeding	Always visible; slight, then more profuse	Can be concealed or visible
Blood description	Bright red	Dark
Discomfort/Pain	None (painless)	Constant; uterine tenderness on palpation
Uterine tone	Soft and relaxed	Firm to rigid
Fetal heart rate	Usually in normal range	Fetal distress or absent
Fetal presentation	May be breech or transverse lie; engagement is absent	No relationship

uterine tenderness, tenseness, or rigidity. Ask if she has noticed any changes in fetal movement and activity. Decreased fetal movement may be the presenting complaint, resulting from fetal jeopardy or fetal death (Oyelese & Ananth, 2006). Assess fetal heart rate and continue to monitor it electronically.

▶ ***Take*** *NOTE!*

Classic manifestations of abruptio placentae include painful, dark-red vaginal bleeding (port wine color) because the bleeding comes from the clot that was formed behind the placenta; "knife-like" abdominal pain; uterine tenderness; contractions; and decreased fetal movement. Rapid assessment is essential to ensure prompt, effective interventions to prevent maternal and fetal morbidity and mortality.

Laboratory and Diagnostic Testing

Laboratory and diagnostic tests may be helpful in diagnosing the condition and guiding management. These studies may include:

- CBC—determines the current hemodynamic status; however, it is not reliable for estimating acute blood loss
- Fibrinogen levels—typically are increased in pregnancy (hyperfibrinogenemia); thus, a moderate dip in fibrinogen levels might suggest coagulopathy (DIC) and, if profuse bleeding occurs, the clotting cascade might be compromised
- Prothrombin time (PT)/activated partial thromboplastin time (aPTT)—determines the client's coagulation status, especially if surgery is planned
- Type and cross-match—determines blood type if a transfusion is needed
- Kleihauer–Betke test—detects fetal red blood cells in the maternal circulation, determines the degree of fetal–maternal hemorrhage, and helps calculate the appropriate dosage of RhoGAM to give to Rh-negative clients
- Nonstress test—demonstrates findings of fetal jeopardy manifested by late decelerations or bradycardia
- Biophysical profile—aids in evaluating clients with chronic abruption; a low score (less than 6 points) suggests possible fetal compromise (Collins, 2007)

Ultrasound is not useful for making a definitive diagnosis because the clot is sonographically visible in less than 50% of the cases (Zeltzer, 2007).

Nursing Management

Nursing management of the woman with abruptio placentae warrants immediate care to provide the best outcome for both mother and fetus.

Ensuring Adequate Tissue Perfusion

Upon arrival to the facility, place the woman on strict bed rest and in a left lateral position to prevent pressure on the vena cava. This position provides uninterrupted perfusion to the fetus. Expect to administer oxygen therapy via nasal cannula to ensure adequate tissue perfusion. Monitor oxygen saturation levels via pulse oximetry to evaluate the effectiveness of interventions.

Obtain maternal vital signs frequently, as often as every 15 minutes as indicated, depending on the woman's status and amount of blood loss. Observe for changes in vital signs suggesting hypovolemic shock and report them immediately. Also expect to insert an indwelling urinary (Foley) catheter to assess hourly urine output and initiate an IV infusion for fluid replacement using a large-bore catheter.

Assess fundal height for changes. An increase in size would indicate bleeding. Monitor the amount and characteristics of any vaginal bleeding as frequently as every 15 to 30 minutes. Be alert for signs and symptoms of DIC, such as bleeding gums, tachycardia, oozing from the IV insertion site, and petechiae, and administer blood products as ordered if DIC occurs.

Institute continuous electronic fetal monitoring. Assess uterine contractions and report any increased uterine

tenseness or rigidity. Also observe the tracing for tetanic uterine contractions or changes in fetal heart rate patterns suggesting fetal compromise.

Providing Support and Education

A woman diagnosed with abruptio placentae may be filled with a sense of heightened anxiety and apprehension, for her own health as well as that of her fetus. Communicate empathy and understanding of the client's experience, and provide emotional support throughout this frightening time. Remain with the couple, acknowledge their emotions and fears, and address their spiritual and cultural needs. Answer their questions about the status of their fetus openly and honestly, being sure to explain indicators of fetal well-being. Provide information about the various diagnostic tests, treatments, and procedures that may be done, including the possible need for a cesarean birth.

Depending on the client's status, extent of bleeding, and length of gestation, the fetus may not survive. If the fetus does survive, he or she most likely will require neonatal intensive care. Assist the client and family to deal with the loss or with the birth of a newborn in the neonatal intensive care unit.

Although abruptio placentae is not a preventable condition, client education is important to help reduce the risk for a recurrence of this condition. Encourage the woman to avoid drinking, smoking, or using drugs during pregnancy. Urge her to seek early and continuous prenatal care and to receive prompt health care if any signs and symptoms occur in future pregnancies.

Think back to Helen, the pregnant woman described at the beginning of the chapter. She was diagnosed with abruptio placentae and was prepared for an emergency cesarean birth. On exploration, there was almost a 75% abruption, with approximately 800 mL of concealed blood between the uterus and the placenta. In addition, she lost an additional 500 mL during surgery. What in Helen's history may have placed her at increased risk for abruption? What assessments and interventions would be essential during her postpartum recovery secondary to her large blood loss? What psychosocial interventions would be necessary due to her fetal loss?

Hyperemesis Gravidarum

At least 80% of women experience nausea and vomiting during their pregnancy (Lane, 2007). The term *morning sickness* is often used to describe this condition when symptoms are relatively mild. Such symptoms usually disappear after the first trimester. This mild form mostly affects the quality of life of the woman and her family, whereas the severe form—hyperemesis gravidarum—results in dehydration, electrolyte imbalance, and the need for hospitalization (Wilcox & Edelman, 2007).

Unlike morning sickness, **hyperemesis gravidarum** is a complication of pregnancy characterized by persistent, uncontrollable nausea and vomiting that persists beyond the 20th week of pregnancy, causing weight loss of more than 5% of prepregnancy body weight, dehydration, metabolic acidosis from starvation, alkalosis from loss of hydrochloric acid, and hypokalemia (Lamondy, 2007).

Hyperemesis is estimated to occur in approximately 5 per 1,000 pregnancies. The prevalence increases in molar pregnancies and multiple gestations. Its peak incidence occurs between 8 and 12 weeks of pregnancy, and it usually resolves by week 16 (Ogunyemi, 2007).

▶ *Take* NOTE!

Every pregnant woman needs to be instructed to report any episodes of severe nausea and vomiting or episodes that extend beyond the first trimester.

Pathophysiology

Although the exact cause of nausea and vomiting is unknown, its effects—decreased placental blood flow, decreased maternal blood flow, and acidosis—can threaten the health of the mother and fetus. Dehydration can also lead to preterm labor (Lane, 2007). Numerous theories abound, but few studies have produced scientific evidence to identify the etiology of this condition. It is likely that multiple factors contribute to it.

Elevated levels of hCG are present in all pregnant women during early pregnancy, usually declining after 12 weeks. This corresponds to the usual duration of morning sickness. In hyperemesis gravidarum, the hCG levels are often higher and extend beyond the first trimester. Symptoms exacerbate the disease. Decreased fluid intake and prolonged vomiting cause dehydration; dehydration increases the serum concentration of hCG, which in turn exacerbates the nausea and vomiting—a vicious cycle. A few other theories that have been proposed to explain its etiology include:

- Endocrine theory—high levels of hCG and estrogen during pregnancy
- Metabolic theory—vitamin B6 deficiency
- Psychological theory—psychological stress increases the symptoms

Therapeutic Management

Conservative management in the home is the first line of treatment for the woman with hyperemesis gravidarum. This usually focuses on dietary and lifestyle changes.

If conservative management fails to alleviate the client's symptoms and nausea and vomiting continue,

hospitalization is necessary to reverse the effects of severe nausea and vomiting.

On admission to the hospital, blood tests are ordered to assess the severity of the client's dehydration, electrolyte imbalance, ketosis, and malnutrition. Parenteral fluids and drugs are ordered to rehydrate the woman and reduce the symptoms. The first choice for fluid replacement is generally 5% dextrose in lactated Ringer's solution with vitamins (pyridoxine [B6]) and electrolytes added. Oral food and fluids are withheld for the first 24 to 36 hours to allow the GI tract to rest. Antiemetics may be administered rectally or intravenously to control the nausea and vomiting initially because the woman is considered NPO. Once her condition stabilizes and she is allowed oral intake, medications may be administered orally.

If the client does not improve after several days of bed rest, "gut rest," IV fluids, and antiemetics, total parenteral nutrition or feeding through a percutaneous endoscopic gastrostomy tube is instituted to prevent malnutrition.

The FDA has not approved any drugs for the treatment of nausea and vomiting in pregnancy, but the risk of administration must be balanced against the sequelae of prolonged starvation and dehydration. Finding a drug that works for any given client is largely a matter of trial and error. If one drug is ineffective, another class of drugs with a different mechanism of action may help. Promethazine (Phenergan) and prochlorperazine (Compazine) are among the older preparations usually tried first. If they fail to relieve symptoms, newer drugs such as ondansetron (Zofran) may be tried. Most drugs are given parenterally or rectally (Lane, 2007) (Drug Guide 19.2).

Few women receive complete relief of symptoms from any one therapy. Complementary and alternative medicine therapies appeal to many to help supplement traditional ones. Some popular therapies include acupressure, massage, therapeutic touch, ginger, and the wearing of Sea-bands to prevent nausea and vomiting. Recent research has reported a positive effect of using acupressure over the Neiguan point on the wrist by Sea-bands to control nausea and vomiting associated with pregnancy (Lane, 2007).

Nursing Assessment

Nursing assessment of the woman with hyperemesis gravidarum requires a thorough history and physical examination to identify signs and symptoms associated with this disorder. The client is extremely uncomfortable. She may experience many hours of lost work productivity and sleep, and hyperemesis may damage family relationships. If hyperemesis progresses untreated, it may cause neurologic disturbances, renal damage, retinal hemorrhage, or death (Lane, 2007). Laboratory and diagnostic tests aid in determining the severity of the disorder.

Health History and Physical Examination

Begin the history by asking the client about the onset, duration, and course of her nausea and vomiting. Ask her about any medications or treatments she used and how effective they were in relieving her nausea and vomiting. Obtain a diet history from the client, including a dietary

DRUG GUIDE 19.2 MEDICATIONS USED FOR HYPEREMESIS GRAVIDARUM

Medication	Action/Indications	Nursing Implications
Promethazine (Phenergan)	Diminishes vestibular stimulation and acts on the chemoreceptor trigger zone (CTZ) Symptomatic relief of nausea and vomiting, and motion sickness	Be alert for urinary retention, dizziness, hypotension, and involuntary movements. Institute safety measures to prevent injury secondary to sedative effects Offer hard candy and frequent rinsing of mouth for dryness.
Prochlorperazine (Compazine)	Acts centrally to inhibit dopamine receptors in the CTZ and peripherally to block vagus nerve stimulation in the GI tract Controls severe nausea and vomiting	Be alert for abnormal movements and for neuroleptic malignant syndrome such as seizures, hyper-/hypotension, tachycardia, and dyspnea. Assess mental status, intake/output Caution patient not to drive as a result of drowsiness or dizziness Advise to change position slowly to minimize effects of orthostatic hypotension.
Odansetron (Zofran)	Blocks serotonin peripherally, centrally, and in the small intestine Prevents nausea and vomiting	Monitor for possible side effects such as diarrhea, constipation, abdominal pain, headache, dizziness, drowsiness, and fatigue. Monitor liver function studies as ordered.

Sources: Hodgson & Kizior, 2007; Lilley et al., 2007.

recall for the past week. Note the client's knowledge of nutrition and need for appropriate nutritional intake. Be alert for patterns that may contribute to or trigger her distress. Also ask about any complaints of ptyalism (excessive salivation), anorexia, indigestion, and abdominal pain or distention. Ask if she has noticed any blood or mucus in her stool.

Review the client's history for possible risk factors, such as young age, nausea and vomiting with previous pregnancy, history of intolerance of oral contraceptives, nulliparity, trophoblastic disease, multiple gestation, emotional or psychological stress, gastroesophageal reflux disease, primigravida status, obesity, hyperthyroidism, and *Helicobacter pylori* seropositivity (Ogunyemi, 2007). Weigh the client and compare this weight to her weight before she began experiencing symptoms and to her prepregnancy weight to estimate the degree of loss. With hyperemesis, weight loss usually exceeds 5% of body mass.

Inspect the mucous membranes for dryness and check skin turgor for evidence of fluid loss and dehydration. Assess blood pressure for changes, such as hypotension, that may suggest a fluid volume deficit. Also note any complaints of weakness, fatigue, activity intolerance, dizziness, or sleep disturbances.

Assess the client's perception of the situation. Note any evidence of depression, anxiety, irritability, mood changes, and decreased ability to concentrate, which can add to her emotional distress (Lamondy, 2007). Determine the woman's support systems that are available for help.

Laboratory and Diagnostic Testing

The results of laboratory and diagnostic tests may provide clues to the severity or etiology of the disorder: These may include:

- Liver enzymes—elevations of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) are usually present
- CBC—elevated levels of red blood cells and hematocrit, indicating dehydration
- Urine ketones—positive when the body breaks down fat to provide energy in the absence of inadequate intake
- Blood urea nitrogen (BUN)—increased in the presence of salt and water depletion
- Urine specific gravity—greater than 1.025, possibly indicating concentrated urine linked to inadequate fluid intake or excessive fluid loss
- Serum electrolytes—decreased levels of potassium, sodium, and chloride resulting from excessive vomiting and loss of hydrochloric acid in stomach
- Ultrasound—evaluation for molar pregnancy or multiple gestation (Wilcox & Edelman, 2007)

Nursing Management

Nursing management for the client with hyperemesis gravidarum focuses on promoting comfort by controlling the client's nausea and vomiting and promoting adequate nutrition. In addition, the nurse plays a major role in supporting and educating the client and her family.

Promoting Comfort and Nutrition

During the initial period, expect to withhold all oral food and fluids, maintaining NPO status to allow the GI tract to rest. In addition, administer prescribed antiemetics to relieve the nausea and vomiting and IV fluids to replace fluid losses. Monitor the rate of infusion to prevent overload and assess the IV insertion site to prevent infiltration or infection. Also administer electrolyte replacement therapy as ordered to correct any imbalances, and periodically check serum electrolyte levels to evaluate the effectiveness of therapy.

Provide physical comfort measures such as hygiene measures and oral care. Pay special attention to the environment, making sure to keep the area free of pungent odors. As the client's nausea and vomiting subside, gradually introduce oral fluids and foods in small amounts. Monitor intake and output and assess the client's tolerance to the increase in intake.

Providing Support and Education

Women with hyperemesis gravidarum commonly are fatigued physically and emotionally. Many are exhausted, frustrated, and anxious. Offer reassurance that all interventions are directed toward promoting positive pregnancy outcomes for both the woman and her fetus. Providing information about the expected plan of care may help to alleviate the client's anxiety. Listen to her concerns and feelings, answering all questions honestly. Educate the woman and her family about the condition and its treatment options (Teaching Guidelines 19.1). Teach the client about therapeutic lifestyle changes, such as avoiding stressors and fatigue that may trigger nausea and vomiting. Offer ongoing support and encouragement and promote active participation in care decisions, thereby empowering the client and her family. Attempting to provide the client with a sense of control may help her overcome the feeling that she has lost control. If necessary, refer the client to a spiritual advisor or counseling. Also suggest possible local or national support groups that the client may contact for additional information.

Arrange for possible home care follow-up for the client and reinforce discharge instructions to promote understanding. Collaborate with community resources to ensure continuity of care.

Gestational Hypertension

Gestational hypertension is characterized by hypertension without proteinuria after 20 weeks of gestation and a return of the blood pressure to normal postpartum. Previously, gestational hypertension was known as pregnancy-induced hypertension or toxemia of pregnancy, but these terms are no longer used. Gestational hypertension is clin-

TEACHING GUIDELINES 19.1

Teaching to Minimize Nausea and Vomiting

- Avoid noxious stimuli—such as strong flavors, perfumes, or strong odors such as frying bacon—that might trigger nausea and vomiting.
- Avoid tight waistbands to minimize pressure on abdomen.
- Eat small, frequent meals throughout the day—six small meals.
- Separate fluids from solids by consuming fluids in between meals.
- Avoid lying down or reclining for at least 2 hours after eating.
- Use high-protein supplement drinks.
- Avoid foods high in fat.
- Increase your intake of carbonated beverages.
- Increase your exposure to fresh air to improve symptoms.
- Eat when you are hungry, regardless of normal mealtimes.
- Drink herbal teas containing peppermint or ginger.
- Avoid fatigue and learn how to mange stress in life.
- Schedule daily rest periods to avoid becoming overtired.
- Eat foods that settle the stomach, such as dry crackers, toast, or soda.

ically characterized by a blood pressure of 140/90 mm Hg or more on two occasions at least 6 hours apart (Gibson & Carson, 2007). Gestational hypertension can be differentiated from chronic hypertension, which appears before the 20th week of gestation; or hypertension before the current pregnancy, which continues after the woman gives birth.

Gestational hypertension is the second leading cause of maternal death in the United States after thromboembolism, accounting for almost 15% of such deaths, and the most common complication reported during pregnancy. Hypertension complicates 12% to 20% of pregnancies and the rate has increased steadily, approximately 30% to 40% since 1990, for all ages, races, and ethnic groups. The highest rates are in women younger than 20 or older than 40 (Weismiller, 2007).

ACOG (2007a) and the National High Blood Pressure Education Program (2000) have identified a classification system for hypertensive disorders. Hypertension may be a preexisting condition (chronic hypertension) or it may present for the first time during pregnancy (gestational hypertension). Regardless of its onset, hypertension jeopardizes the well-being of the mother as well as the fetus.

The classification of hypertensive disorders in pregnancy currently consists of four categories:

- Gestational hypertension: blood pressure elevation (140/90 mm Hg) identified after midpregnancy without proteinuria
- Chronic hypertension: hypertension prior to the pregnancy or diagnosed before week 20 of gestation
- Transient hypertension: hypertension without preeclampsia at the time of birth, during labor, or within 24 hours postpartum; resolution within 12 weeks postpartum to normotensive blood pressure levels
- Chronic hypertension with preeclampsia: chronic hypertension with new proteinuria or exacerbation of previously controlled blood pressure, or proteinuria, thrombocytopenia, or elevated liver enzymes (ACOG, 2007; Blackburn, 2007).

Gestational hypertension can be classified as preeclampsia or eclampsia. Each is associated with specific criteria. Preeclampsia is further categorized as mild or severe. Comparison Chart 19.2 highlights these classifications.

Pathophysiology

Gestational hypertension remains an enigma. The condition can be devastating to both the mother and fetus, and yet the etiology still remains a mystery to medical science despite decades of research. Many theories exist, but none have truly explained the widespread pathologic changes that result in pulmonary edema, oliguria, seizures, thrombocytopenia, and abnormal liver enzymes (Podymow & August, 2007). Despite the results of several research studies, the use of aspirin or supplementation with calcium, magnesium, zinc, or antioxidant therapy (vitamin C and E), salt restriction, diuretic therapy, or fish oils has not proved to prevent this destructive condition.

The underlying mechanisms involved with this disorder are vasospasm and hypoperfusion. In addition, endothelial injury occurs, leading to platelet adherence, fibrin deposition, and the presence of schistocytes (fragment of an erythrocyte).

Generalized vasospasm results in elevation of blood pressure and reduced blood flow to the brain, liver, kidneys, placenta, and lungs. Decreased liver perfusion leads to impaired liver function and subcapsular hemorrhage. This is demonstrated by epigastric pain and elevated liver enzymes in the maternal serum. Decreased brain perfusion leads to small cerebral hemorrhages and symptoms of arterial vasospasm such as headaches, visual disturbances, blurred vision, and hyperactive deep tendon reflexes (DTRs). A thromboxane/prostacyclin imbalance leads to increased thromboxane (potent vasoconstrictor and stimulator of platelet aggregation) and decreased prostacyclin (potent vasodilator and inhibitor of platelet aggregation), which contribute to the hypertensive state. Decreased kidney perfusion reduces the glomerular filtra-

COMPARISON CHART 19.2 PREECLAMPSIA VERSUS ECLAMPSIA

	Mild Preeclampsia	Severe Preeclampsia	Eclampsia
Blood pressure	>140/90 mm Hg after 20 weeks' gestation	>160/110 mm Hg	Same as severe preeclampsia
Proteinuria	300 mg/24 h or greater than 1+ protein on a random dipstick urine sample	>500 mg/24 hours; greater than 3+ on random dipstick urine sample	Marked proteinuria
Seizures/coma	No	No	Yes
Hyperreflexia	No	Yes	Yes
Other signs and symptoms	Mild facial or hand edema Weight gain	Headache Oliguria Blurred vision, scotomata (blind spots) Pulmonary edema Thrombocytopenia (platelet count <100,000 platelets/mm^3) Cerebral disturbances Epigastric or RUQ pain HELLP	Severe headache Generalized edema RUQ or epigastric pain Visual disturbances Cerebral hemorrhage Renal failure HELLP

tion rate (GFR), resulting in decreased urine output and increased serum levels of sodium, BUN, uric acid, and creatinine, further increasing extracellular fluid and edema. Increased capillary permeability in the kidneys allows albumin to escape, which reduces plasma colloid osmotic pressure and moves more fluid into extracellular spaces; this leads to pulmonary edema and generalized edema. Poor placental perfusion resulting from prolonged vasoconstriction helps to contribute to intrauterine growth restriction, premature separation of the placenta (abruptio placentae), persistent fetal hypoxia, and acidosis. In addition, hemoconcentration (resulting from decreased intravascular volume) causes increased blood viscosity and elevated hematocrit (ACOG, 2007a).

Therapeutic Management

Management of the woman with gestational hypertension varies depending on the severity of her condition and its effects on the fetus. Typically the woman is managed conservatively if she is experiencing mild symptoms. However, if the condition progresses, management becomes more aggressive.

Management for Mild Preeclampsia

Conservative strategies for mild preeclampsia are used if the woman exhibits no signs of renal or hepatic dysfunction or coagulopathy. A woman with mild elevations in blood pressure may be placed on bed rest at home. She is encouraged to rest as much as possible in the lateral recumbent position to improve uteroplacental blood flow, reduce her blood pressure, and promote diuresis. In addition, antepartal visits and diagnostic testing—such as CBC, clotting studies, liver enzymes, and platelet levels—increase in frequency. The woman will be asked to monitor her blood pressure daily (every 4 to 6 hours while awake) and report any increased readings; she will also measure the amount of protein found in urine using a dipstick and will weigh herself for any weight gain. Daily fetal movement counts also are implemented. If there is any decrease in movement, the woman needs to be evaluated by her health care provider that day. A balanced, nutritional diet with no sodium restriction is advised. In addition, she is encouraged to drink six to eight 8-oz glasses of water daily.

If home management fails to reduce the blood pressure, admission to the hospital is warranted and the treatment strategy is individualized based on the severity of the condition and the gestational age at the time of diagnosis. During the hospitalization, the woman with mild preeclampsia is monitored closely for signs and symptoms of severe preeclampsia or impending eclampsia (e.g., persistent headache, hyperreflexia). Blood pressure measurements are frequently recorded along with daily weights to detect excessive weight gain resulting from edema. Fetal surveillance is instituted in the form of daily fetal movement counts, nonstress testing, and serial ultrasounds to evaluate fetal growth and amniotic fluid volume to confirm fetal well-being. Expectant management usually continues until the pregnancy reaches term, fetal lung maturity is documented, or complications develop that warrant immediate birth (Mundy, 2006).

Prevention of disease progression is the focus of treatment during labor. Blood pressure is monitored frequently and a quiet environment is important to minimize the risk of stimulation and to promote rest. IV magnesium sulfate is infused to prevent any seizure activity, along with

antihypertensives if blood pressure values begin to rise. Calcium gluconate is kept at the bedside in case the magnesium level becomes toxic. Continued close monitoring of neurologic status is warranted to detect any signs or symptoms of hypoxemia, impending seizure activity, or increased intracranial pressure. An indwelling urinary (Foley) catheter usually is inserted to allow for accurate measurement of urine output.

Management for Severe Preeclampsia

Severe preeclampsia may develop suddenly and bring with it high blood pressure of more than 160/110 mmHg, proteinuria of more than 5 g in 24 hours, oliguria of less than 400 mL in 24 hours, cerebral and visual symptoms, and rapid weight gain. This clinical picture signals severe preeclampsia, and immediate hospitalization is needed.

Treatment is highly individualized and based on disease severity and fetal age. Birth of the infant is the only cure, because preeclampsia depends on the presence of trophoblastic tissue. Therefore, the exact age of the fetus is assessed to determine viability.

Severe preeclampsia is treated aggressively because hypertension poses a serious threat to mother and fetus. The goal of care is to stabilize the mother–fetus dyad and prepare for birth. Therapy focuses on controlling hypertension, preventing seizures, preventing long-term morbidity, and preventing maternal, fetal, or newborn death (Weismiller, 2007). Intense maternal and fetal surveillance starts when the mother enters the hospital and continues throughout her stay.

The woman in labor with severe preeclampsia typically receives oxytocin to stimulate uterine contractions and magnesium sulfate to prevent seizure activity. Oxytocin and magnesium sulfate can be given simultaneously via infusion pumps to ensure both are administered at the prescribed rate. The client is evaluated closely for magnesium toxicity. If at all possible, a vaginal delivery is preferable to a cesarean birth. PGE2 gel may be used to ripen the cervix. A cesarean birth may be performed if the client is seriously ill. A pediatrician/neonatologist must be available in the birthing room to care for the newborn. A newborn whose mother received high doses of magnesium sulfate needs to be monitored for respiratory depression, hypocalcemia, and hypotonia (Blackburn, 2007).

Management of Eclampsia

In the woman who develops an eclamptic seizure, the convulsive activity begins with facial twitching, followed by generalized muscle rigidity. Respirations cease for the duration of the seizure, resulting from muscle spasms, thus compromising fetal oxygenation. Coma usually follows the seizure activity, with respiration resuming. Eclamptic seizures are life-threatening emergencies and require immediate treatment to decrease maternal morbidity and mortality.

As with any seizure, the initial management is to clear the airway and administer adequate oxygen. Positioning the woman on her left side and protecting her from injury during the seizure are key. Suction equipment must be readily available to remove secretions from her mouth after the seizure is over. IV fluids are administered after the seizure at a rate to replace urine output and additional insensible losses. Fetal heart rate is monitored closely. Magnesium sulfate is administered IV to prevent further seizures. Hypertension is controlled with antihypertensive medications. After the seizures are controlled, the woman's stability is assessed and birth via induction or cesarean birth is performed (Blincoe, 2007).

If the woman's condition remains stable, she will be transferred to the postpartum unit for care. If she becomes unstable after giving birth, she may be transferred to the critical care unit for closer observation.

Nursing Assessment

Preventing complications related to hypertension during pregnancy requires the use of assessment, advocacy, and counseling skills. Assessment begins with the accurate measurement of the client's blood pressure at each encounter. In addition, nurses need to assess for subjective complaints that may indicate progression of the disease—visual changes, severe headaches, unusual bleeding or bruising, or epigastric pain (Blincoe, 2007). The significant signs of gestational hypertension—proteinuria and hypertension—occur without the woman's awareness. Unfortunately, by the time symptoms are noticed, gestational hypertension can be severe.

▶ *Take* NOTE!

The absolute blood pressure (value that validates elevation) of 140/90 mmHg should be obtained on two occasions 6 hours apart to be diagnostic of gestational hypertension. Proteinuria is defined as 300 mg or more of urinary protein per 24 hours or more than 1+ protein by chemical reagent strip or dipstick of at least two random urine samples collected at least 6 hours apart with no evidence of UTI (ACOG, 2007a).

Health History and Physical Examination

Take a thorough history during the first antepartal visit to identify whether the woman is at risk for preeclampsia. Risk factors include:

- Primigravida status
- Chromosomal abnormalities
- Structural congenital anomalies
- Multifetal pregnancy
- History of preeclampsia in a previous pregnancy
- Excessive placental tissue, as is seen in women with GTD

- Chronic stress
- Family history of preeclampsia (mother or sister)
- Lower socioeconomic group
- History of diabetes, hypertension, or renal disease
- Poor nutrition
- African-American ethnicity
- Age extremes (younger than 20 or older than 40)
- Obesity (Weismiller, 2007)

In addition, complete a nutritional assessment that includes the woman's usual intake of protein, calcium, daily calories, and fluids.

Women at risk for preeclampsia require more frequent prenatal visits throughout their pregnancy, and they require teaching about problems so that they can report them promptly.

Blood pressure must be measured carefully and consistently. Obtain all measurements with the woman in the same position (blood pressure is highest in the sitting position and lowest in the side-lying position) and by using the same technique (automated vs. manual). This standardization in position and technique will yield the most accurate readings (Weismiller, 2007).

Obtain the client's weight (noting gain since last visit), and assess for amount and location of edema. Asking questions such as, "Do your rings still fit on your fingers?" or "Is your face puffy when you get up in the morning?" will help to determine whether fluid retention is present or if the woman's status has changed since her last visit.

▶ *Take* NOTE!

Although edema is not a cardinal sign of preeclampsia, weight should be monitored frequently to identify sudden gains in a short time span. Current research relies less on the classic triad of symptoms (hypertension, proteinuria, and edema or weight gain) and more on decreased organ perfusion, endothelial dysfunction (capillary leaking and proteinuria), and elevated blood pressure as key indicators (Gibson & Carson, 2007).

If edema is present, assess the distribution, degree, and pitting. Document your findings and identify whether the edema is dependent or pitting. Dependent edema is present on the lower half of the body if the client is ambulatory, where hydrostatic pressure is greatest. It is usually observed in the feet and ankles or in the sacral area if the client is on bed rest.

Pitting edema is edema that leaves a small depression or pit after finger pressure is applied to a swollen area (Gibson & Carson, 2007). Record the depth of pitting demonstrated when pressure is applied. Although subjective, the following is used to record relative degrees:

- 1+ pitting edema = 2-mm depression into skin; disappears rapidly
- 2+ pitting edema = 4-mm skin depression; disappears in 10 to 15 seconds
- 3+ pitting edema = 6-mm depression into skin; lasts more than 1 minute
- 4+ pitting edema = 8-mm depression into skin; lasts 2 to 3 minutes

At every antepartal visit, assess the fetal heart rate with a Doppler device. Also check a clean-catch urine specimen for protein using a dipstick.

Laboratory and Diagnostic Testing

Various laboratory tests may be performed to evaluate the woman's status. Typically these include a CBC, serum electrolytes, BUN, creatinine, and hepatic enzyme levels. Urine specimens are checked for protein; if levels are 1-2+ or greater, a 24-hour urine collection is completed.

Nursing Management

Nursing management of the woman with gestational hypertension focuses on close monitoring of blood pressure and ongoing assessment for evidence of disease progression. Throughout the client's pregnancy, fetal surveillance is key.

Intervening With Preeclampsia

The woman with mild preeclampsia requires frequent monitoring to detect changes because preeclampsia can progress rapidly. Instruct all women in the signs and symptoms of preeclampsia and urge them to contact their health care professional for immediate evaluation should any occur.

Typically women with mild preeclampsia can be managed at home if they have a good understanding of the disease process, are stable, have no abnormal laboratory test results, and demonstrate good fetal movement (Teaching Guidelines 19.2). The home care nurse makes frequent visits and follow-up phone calls to assess the woman's condition, to assist with scheduling periodic evaluations of the fetus (such as nonstress tests), and to evaluate any changes that might suggest a worsening of the woman's condition.

Early detection and management of mild preeclampsia is associated with the greatest success in reducing progression of this condition. As long as the client carries out the guidelines of care as outlined by the health care provider and she remains stable, home care can continue to maintain the pregnancy until the fetus is mature. If disease progression occurs, hospitalization is required.

Intervening With Severe Preeclampsia

The woman with severe preeclampsia requires hospitalization. Maintain the client on complete bed rest in the left lateral lying position. Ensure that the room is dark

TEACHING GUIDELINES 19.2

Teaching for the Woman With Mild Preeclampsia

- Rest in a quiet environment to prevent cerebral disturbances.
- Drink 8 to 10 glasses of water daily.
- Consume a balanced, high-protein diet including high-fiber foods.
- Obtain intermittent bed rest to improve circulation to the heart and uterus.
- Limit your physical activity to promote urination and subsequent decrease in blood pressure.
- Enlist the aid of your family so that you can obtain appropriate rest time.
- Perform self-monitoring as instructed, including
  - Taking your own blood pressure twice daily
  - Checking and recording weight daily
  - Performing urine dipstick twice daily
  - Recording the number of fetal kicks daily
- Contact the home health nurse if any of the following occurs:
  - Increase in blood pressure
  - Protein present in urine
  - Gain of more than 1 lb in 1 week
  - Burning or frequency when urinating
  - Decrease in fetal activity or movement
  - Headache (forehead or posterior neck region)
  - Dizziness or visual disturbances
  - Increase in swelling in hands, feet, legs, and face
  - Stomach pain, excessive heartburn, or epigastric pain
  - Decreased or infrequent urination
  - Contractions or low back pain
  - Easy or excessive bruising
  - Sudden onset of abdominal pain
  - Nausea and vomiting

and quiet to reduce stimulation. Give sedatives as ordered to encourage quiet bed rest. The client is at risk for seizures if the condition progresses. Therefore, institute and maintain seizure precautions, such as padding the side rails and having oxygen, suction equipment, and call light readily available to protect the client from injury.

▶ ***Take*** NOTE!

Preeclampsia increases the risk of placental abruption, preterm birth, intrauterine growth restriction, and fetal distress during childbirth. Be prepared!

Closely monitor the client's blood pressure. Administer antihypertensives as ordered to reduce blood pressure (Drug Guide 19.3). Assess the client's vision and level of consciousness. Report any changes and any complaints of headache or visual disturbances. Offer a high-protein diet with 8 to 10 glasses of water daily. Monitor the client's intake and output every hour and administer fluid and electrolyte replacements as ordered. Assess the woman for signs and symptoms of pulmonary edema, such as crackles and wheezing heard on auscultation, dyspnea, decreased oxygen saturation levels, cough, neck vein distention, anxiety, and restlessness (Blincoe, 2007).

To achieve a safe outcome for the fetus, prepare the woman for possible testing to evaluate fetal status as preeclampsia progresses. These may include the nonstress test, serial ultrasounds to track fetal growth, amniocentesis to determine fetal lung maturity, Doppler velocimetry to screen for fetal compromise, and biophysical profile to evaluate ongoing fetal well-being (Jung & Erogul, 2007).

Other laboratory tests may be performed to monitor the disease process and to determine if it is progressing into HELLP syndrome. These include liver enzymes such as lactic dehydrogenase (LDH), ALT, and AST; chemistry panel, such as creatinine, BUN, uric acid, and glucose; CBC, including platelet count; coagulation studies, such as PT, PTT, fibrinogen, and bleeding time; and a 24-hour urine collection for protein and creatinine clearance.

Administer parenteral magnesium sulfate as ordered to prevent seizures. Assess deep tendon reflexes (DTRs) to evaluate the effectiveness of therapy. Clients with preeclampsia commonly present with hyperreflexia. Severe preeclampsia causes changes in the cortex, which disrupts the equilibrium of impulses between the cerebral cortex and the spinal cord. Brisk reflexes (hyperreflexia) are the result of an irritable cortex and indicate central nervous system involvement (Warden & Euerle, 2007).

Diminished or absent reflexes occur when the client develops magnesium toxicity. Because magnesium is a potent neuromuscular blockade, the afferent and efferent nerve pathways do not relay messages properly and hyporeflexia develops. Common sites used to assess DTRs are biceps reflex, triceps reflex, patellar reflex, Achilles reflex, and plantar reflex. Nursing Procedure 19.1 highlights the steps for assessing the patellar reflex.

The National Institute of Neurological Disorders and Stroke (NINDS), a division of the National Institutes of Health, published a scale in the early 1990s that, although subjective, is used widely today. It grades reflexes from 0 to 4+. Grades 2+ and 3+ are considered normal, whereas grades 0 and 4 may indicate pathology (Table 19.2). Because these are subjective assessments, to improve communication of reflex results, condensed descriptor categories such as absent, average, brisk, or clonus should be used rather than numeric codes (Gilbert, 2007).

Clonus is the presence of rhythmic involuntary contractions, most often at the foot or ankle. Sustained clonus

DRUG GUIDE 19.3 MEDICATIONS USED WITH PREECLAMPSIA AND ECLAMPSIA

Medication	Action/Indications	Nursing Implications
Magnesium sulfate	Blockage of neuromuscular transmission, vasodilation Prevention and treatment of eclamptic seizures.	Administer IV loading dose of 4–6 g over 30 minutes, continue maintenance infusion of 2–4 g/hour as ordered. Monitor serum magnesium levels closely. Assess DTRs and check for ankle clonus. Have calcium gluconate readily available in case of toxicity. Monitor for signs and symptoms of toxicity, such as flushing, sweating, hypotension, and cardiac and central nervous system depression.
Hydralazine hydrochloride (Apresoline)	Vascular smooth muscle relaxant, thus improving perfusion to renal, uterine, and cerebral areas Reduction in blood pressure	Administer 5–10 mg by slow IV bolus every 20 minutes. Use parenteral form immediately after opening ampule. Withdraw drug slowly to prevent possible rebound hypertension. Monitor for adverse effects such as palpitations, headache, tachycardia, anorexia, nausea, vomiting, and diarrhea.
Labetalol hydrochloride (Normodyne)	Alpha 1 and beta blocker Reduction in blood pressure	Be aware that drug lowers blood pressure without decreasing maternal heart rate or cardiac output. Administer IV bolus dose of 10–20 mg and then administer IV infusion of 2 mg/minute until desired blood pressure value achieved. Monitor for possible adverse effects such as gastric pain, flatulence, constipation, dizziness, vertigo, and fatigue.
Nifedipine (Procardia)	Calcium channel blocker/dilation of coronary arteries, arterioles, and peripheral arterioles Reduction in blood pressure, stoppage of preterm labor	Administer 10 mg orally for three doses and then every 4–8 hours. Monitor for possible adverse effects such as dizziness, peripheral edema, angina, diarrhea, nasal congestions, cough.
Sodium nitroprusside	Rapid vasodilation (arterial and venous) Severe hypertension requiring rapid reduction in blood pressure	Administer via continuous IV infusion with dose titrated according to blood pressure levels. Wrap IV infusion solution in foil or opaque material to protect from light. Monitor for possible adverse effects, such as apprehension, restlessness, retrosternal pressure, palpitations, diaphoresis, abdominal pain.
Furosemide (Lasix)	Diuretic action, inhibiting the reabsorption of sodium and chloride from the ascending loop of Henle Pulmonary edema (used only if condition is present)	Administer via slow IV bolus at a dose of 10–40 mg over 1–2 minutes. Monitor urine output hourly. Assess for possible adverse effects such as dizziness, vertigo, orthostatic hypotension, anorexia, vomiting, electrolyte imbalances, muscle cramps, and muscle spasms.

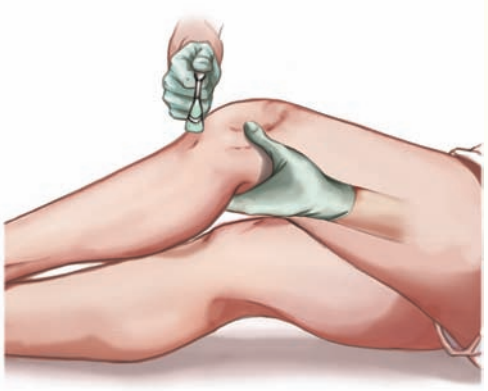
Sources: Hodgson & Kizior, 2007; Lilley et al., 2007.

Nursing Procedure 19.1

ASSESSING THE PATELLAR REFLEX

Purpose: To Evaluate for Nervous System Irritability Related to Preeclampsia

1. Place the woman in the supine position (or sitting upright with the legs dangling freely over the side of the bed or examination table).
2. If lying supine, have the woman flex her knee slightly.
3. Place a hand under the knee to support the leg and locate the patellar tendon. It should be midline just below the knee cap.
4. Using a reflex hammer or the side of your hand, strike the area of the patellar tendon firmly and quickly.
5. Note the movement of the leg and foot. A patellar reflex occurs when the leg and foot move (documented as 2+).
6. Repeat the procedure on the opposite leg.



Nursing Procedure 19.2

TESTING FOR ANKLE CLONUS

Purpose: To Evaluate for Nervous System Irritability Related to Preeclampsia

1. Place the woman in the supine position.
2. Have the client slightly bend her knee and place a hand under the knee to support it.
3. Dorsiflex the foot briskly and then quickly release it.
4. Watch for the foot to rebound smoothly against your hand. If the movement is smooth without any rapid contractions of the ankle or calf muscle, then clonus is not present; if the movement is jerky and rapid, clonus is present.
5. Repeat on the opposite side.

confirms central nervous system involvement. Nursing Procedure 19.2 highlights the steps when testing for ankle clonus.

With magnesium sulfate administration, the client is at risk for magnesium toxicity. Closely assess the client for signs of toxicity, which include a respiratory rate of less than 12 breaths per minute, absence of deep tendon reflexes, and a decrease in urinary output, below 30 mL per hour. Also monitor serum magnesium levels. Although exact levels may vary among agencies, serum magnesium levels ranging from 4 to 7 mEq/L are considered therapeutic, whereas levels more than 8 mEq/dL are generally considered toxic. As levels increase, the woman is at risk for severe problems:

- 10 mEq/L: possible loss of DTRs
- 15 mEq/L: possible respiratory depression
- 25 mEq/L: possible cardiac arrest (Podymow & August, 2007)

If signs and symptoms of magnesium toxicity develop, expect to administer calcium gluconate as the antidote.

Throughout the client's stay, closely monitor her for signs and symptoms of labor. Perform continuous electronic fetal monitoring to assess fetal well-being. Note trends in baseline rate and presence or absence of accelerations or decelerations. Also observe for signs of fetal distress and report them immediately. Administer glucocorticoid treatment as ordered to enhance fetal lung maturity and prepare for labor induction if the mother's condition warrants.

TABLE 19.2 GRADING DEEP TENDON REFLEXES

Description of Finding	Grade
Reflex absent, no response detected	0
Hypoactive response, diminished	1
Reflex in lower half of normal range	2
Reflex in upper half of normal range	3
Hyperactive, brisk, clonus present	4

Sources: Arenson & Drake, 2007; Weber, 2007.

Keep the client and family informed of the woman's condition and educate them about the course of treatment. Provide emotional support for the client and family. Severe preeclampsia is very frightening for the client and her family, and most expectant mothers are very anxious about their own health as well as that of the fetus. To allay anxiety, use light touch to comfort and reassure her that the necessary actions are being taken. Actively listening to her concerns and fears and communicating them to the health care provider is important in keeping lines of communication open. Offering praise for small accomplishments can provide positive reinforcement for behaviors that should be continued.

Intervening for Eclampsia

The onset of seizure activity identifies eclampsia. Typically, eclamptic seizures are generalized and start with facial twitching. The body then becomes rigid, in a state of tonic muscular contraction. The clonic phase of the seizure involves alternating contraction and relaxation of all body muscles. Respirations stop during seizure activity and resume shortly after it ends. Client safety is the primary concern during eclamptic seizures. If possible, turn the client to her side and remain with her. Make sure that the side rails are up and padded. Dim the lights and keep the room quiet.

Document the time and sequence of events as soon as possible. After the seizure activity has ceased, suction the nasopharynx as necessary and administer oxygen. Continue the magnesium sulfate infusion to prevent further seizures. Ensure continuous electronic fetal monitoring, evaluating fetal status for changes. Also assess the client for uterine contractions. After the client is stabilized, prepare her for the birthing process as soon as possible to reduce the risk of perinatal mortality.

Providing Follow-Up Care

After delivery of the newborn, continue to monitor the client for signs and symptoms of preeclampsia/eclampsia for at least 48 hours. Expect to continue to administer magnesium sulfate infusion for 24 hours to prevent seizure activity, and monitor serum magnesium levels for toxicity.

Assess vital signs at least every 4 hours, along with routine postpartum assessments—fundus, lochia, breasts, bladder, bowels, and emotional state attention when performing the fundal assessment and assessing lochia. Monitor urine output closely. Diuresis is a positive sign that, along with a decrease in proteinuria, signals resolution of the disease.

HELLP

HELLP is an acronym for hemolysis, elevated liver enzymes, and low platelets. HELLP syndrome occurs in about 20% of pregnant women diagnosed with severe preeclampsia. Although it has been reported as early as 17 weeks' gestation, most of the time it is diagnosed between 22 and 36 weeks' gestation (White, 2006). HELLP syndrome leads to an increased maternal risk for developing liver hematoma or rupture, stroke, cardiac arrest, seizure, pulmonary edema, DIC, subendocardial hemorrhage, adult respiratory distress syndrome, renal damage, sepsis, hypoxic encephalopathy, and maternal or fetal death (White, 2006).

Pathophysiology

The hemolysis that occurs is termed microangiopathic hemolytic anemia. It is thought to happen when red blood cells become fragmented as they pass through small, damaged blood vessels. Elevated liver enzymes are the result of reduced blood flow to the liver secondary to obstruction from fibrin deposits. Hyperbilirubinemia and jaundice result from liver impairment. Low platelets result from vascular damage, the result of vasospasm, and platelets aggregate at sites of damage, resulting in thrombocytopenia in multiple sites (Basama & Granger, 2007).

Therapeutic Management

The treatment for HELLP syndrome is based on the severity of the disease, the gestational age of the fetus, and the condition of the mother and fetus. The client should be admitted or transferred to a tertiary center with a neonatal intensive care unit. Additional treatments include magnesium sulfate, antihypertensives, and correction of the coagulopathies that accompany HELLP syndrome. After this syndrome is diagnosed and the woman's condition is stable, birth of the infant is indicated.

Magnesium sulfate is used prophylactically to prevent seizures. Antihypertensives such as hydralazine or labetalol are given to control blood pressure. Blood component therapy—such as fresh-frozen plasma, packed red cells, or platelets—is transfused to address the microangiopathic hemolytic anemia. Birth may be delayed up to 96 hours so that betamethasone or dexamethasone can be given to stimulate lung maturation in the preterm fetus.

Nursing Assessment

Nursing assessment of the woman with HELLP is similar to that for the woman with severe preeclampsia. Be alert for complaints of nausea (with or without vomiting), malaise, epigastric or right upper quadrant pain, and demonstrable edema. Perform systematic assessments frequently, as indicated by the woman's condition and response to therapy.

A diagnosis of HELLP syndrome is made based on laboratory test results, including:

- Low hematocrit that is not explained by any blood loss
- Elevated LDH (liver impairment)
- Elevated AST (liver impairment)
- Elevated ALT (liver impairment)

- Elevated BUN
- Elevated bilirubin level
- Elevated uric acid and creatinine levels (renal involvement)
- Low platelet count (less than 100,000 cells/mm^3)

Nursing Management

Nursing management of the woman diagnosed with HELLP syndrome is the same as that for the woman with severe preeclampsia. Closely monitor the client for changes and provide ongoing support throughout this experience.

Gestational Diabetes

Gestational diabetes is a condition involving glucose intolerance that occurs during pregnancy. It is discussed in greater detail in Chapter 20.

Blood Incompatibility

Blood incompatibility most commonly involves blood type or the Rh factor. Blood type incompatibility, also known as ABO incompatibility, is not as severe a condition as Rh incompatibility. ABO incompatibility rarely causes significant hemolysis, and antepartum treatment is not warranted. Rh sensitization occurs in approximately 1 in 1,000 births to Rh-negative women (Salem, 2007).

According to the CDC (2007), Rh disease affected 16,000 newborns in the United States annually before RhoGAM administration was used to prevent it. Despite prevention measures, there still are approximately 4,000 infants annually affected with Rh disease.

Pathophysiology

Hemolysis associated with ABO incompatibility is limited to type O mothers with fetuses who have type A or B blood. In mothers with type A and B blood, naturally occurring antibodies are of IgM class, which do not cross the placenta, whereas in type O mothers, the antibodies are predominantly IgG in nature. Because A and B antigens are widely expressed in a variety of tissues besides red blood cells, only a small portion of antibodies crossing the placenta are available to bind to fetal red cells. In addition, fetal red cells appear to have less surface expression of A or B antigen, resulting in few reactive sites—hence the low incidence of significant hemolysis in affected neonates.

With ABO incompatibility, usually the mother is blood type O, with anti-A and anti-B antibodies in her serum; the infant is blood type A, B, or AB. The incompatibility arises as a result of the interaction of antibodies present in maternal serum and the antigen sites on the fetal red cells.

Rh incompatibility is a condition that develops when a woman with Rh-negative blood type is exposed to Rh-positive blood cells and subsequently develops circulating titers of Rh antibodies. Individuals with Rh-positive blood type have the D antigen present on their red cells, whereas individuals with an Rh-negative blood type do not. The presence or absence of the Rh antigen on the red blood cell membrane is genetically controlled.

In the United States, 15% of the population lack the Rh surface antigen on the erythrocyte and are considered Rh negative. The vast majority (85%) of individuals are considered Rh positive (Alan, 2007).

Rh incompatibility most commonly arises with exposure of an Rh-negative mother to Rh-positive fetal blood during pregnancy or birth, during which time erythrocytes from the fetal circulation leak into the maternal circulation. After a significant exposure, alloimmunization or sensitization occurs. As a result, maternal antibodies are produced against the foreign Rh antigen.

Theoretically, fetal and maternal blood does not mix during pregnancy. In reality, however, small placental accidents (transplacental bleeds secondary to minor separation), abortions, ectopic pregnancy, abdominal trauma, trophoblastic disease, amniocentesis, placenta previa, and abruptio placentae allow fetal blood to enter the maternal circulation and initiate the production of antibodies to destroy Rh-positive blood. The amount of fetal blood necessary to produce Rh incompatibility varies. In one study, less than 1 mL of Rh-positive blood was shown to result in sensitization of women who are Rh negative (Salem, 2007).

Once sensitized, it takes approximately a month for Rh antibodies in the maternal circulation to cross over into the fetal circulation. In 90% of cases, sensitization occurs during delivery (Blackburn, 2007). Thus, most firstborn infants with Rh-positive blood type are not affected because the short period from first exposure of Rh-positive fetal erythrocytes to the birth of the infant is insufficient to produce a significant maternal IgG antibody response.

The risk and severity of alloimmune response increase with each subsequent pregnancy involving a fetus with Rh-positive blood. A second pregnancy with an Rh-positive fetus often produces a mildly anemic infant, whereas succeeding pregnancies produce infants with more serious hemolytic anemia.

Nursing Assessment

At the first prenatal visit, determine the woman's blood type and Rh status. Also obtain a thorough health history, noting any reports of previous events involving hemorrhage to delineate the risk for prior sensitization. When the client's history reveals an Rh-negative mother who may be pregnant with an Rh-positive fetus, prepare the client for an antibody screen (indirect Coombs test) to determine whether she has developed isoimmunity to the Rh antigen. This test detects unexpected circulating antibodies in a woman's serum that could be harmful to the fetus (Gilbert, 2007).

Nursing Management

If the indirect Coombs test is negative (meaning no antibodies are present), then the woman is a candidate for RhoGAM. If the test is positive, RhoGAM is of no value because isoimmunization has occurred. In this case, the fetus is carefully monitored for hemolytic disease.

The incidence of isoimmunization has declined dramatically as a result of prenatal and postnatal RhoGAM administration after any event in which blood transfer may occur. The standard dose is 300 µg, which is effective for 30 mL of fetal blood. Rh immunoglobulin helps to destroy any fetal cells in the maternal circulation before sensitization occurs, thus inhibiting maternal antibody production. This provides temporary passive immunity, thereby preventing maternal sensitization.

The current recommendation is that every Rh-negative nonimmunized woman receives RhoGAM at 28 weeks' gestation and again within 72 hours after giving birth. Other indications for RhoGAM include:

- Ectopic pregnancy
- Chorionic villus sampling
- Amniocentesis
- Prenatal hemorrhage
- Molar pregnancy
- Maternal trauma
- Percutaneous umbilical sampling
- Therapeutic or spontaneous abortion
- Fetal death
- Fetal surgery (Blackburn, 2007)

Despite the availability of RhoGAM and laboratory tests to identify women and newborns at risk, isoimmunization remains a serious clinical reality that continues to contribute to perinatal and neonatal mortality. Nurses, as client advocates, are in a unique position to make sure test results are brought to the health care provider's attention so appropriate interventions can be initiated. In addition, nurses must stay abreast of current literature and research regarding isoimmunization and its management. Stress to all women that early prenatal care can help identify and prevent this condition. Since Rh incompatibility is preventable with the use of RhoGAM, prevention remains the best treatment. Nurses can make a tremendous impact to ensure positive outcomes for the greatest possible number of pregnancies through education.

Amniotic Fluid Imbalances

Amniotic fluid develops from several maternal and fetal structures, including the amnion, chorion, maternal blood, fetal lungs, GI tract, kidneys, and skin. Any alteration in one or more of the various sources will alter the amount of amniotic fluid. Polyhydramnios and oligohydramnios are two imbalances associated with amniotic fluid.

POLYHYDRAMNIOS

Polyhydramnios, also called hydramnios, is a condition in which there is too much amniotic fluid (more than 2,000 mL) surrounding the fetus between 32 and 36 weeks. It occurs in approximately 3% of all pregnancies and is associated with fetal anomalies of development (Rajiah & Banerjee, 2007). It is associated with poor fetal outcomes because of the increased incidence of preterm births, fetal malpresentation, and cord prolapse.

There are several causes of polyhydramnios. Generally, too much fluid is being produced, there is a problem with the fluid being taken up, or both. It can be associated with maternal disease and fetal anomalies, but it can also be idiopathic in nature.

Therapeutic Management

Treatment may include close monitoring and frequent follow-up visits with the health care provider if the hydramnios is mild to moderate. In severe cases in which the woman is in pain and experiencing shortness of breath, an amniocentesis or artificial rupture of the membranes is done to reduce the fluid and the pressure. Removal of fluid by amniocentesis is only transiently effective. A noninvasive treatment may involve the use of a prostaglandin synthesis inhibitor (indomethacin) to decrease amniotic fluid volume by decreasing fetal urinary output, but this may cause premature closure of the fetal ductus arteriosus (Boyd & Carter, 2007).

Nursing Assessment

Begin the assessment with a thorough history, being alert to risk factors such as maternal diabetes or multiple gestation. Review the maternal history for information about possible fetal anomalies, including fetal esophageal or intestinal atresia, neural tube defects, chromosomal deviations, fetal hydrops, central nervous system or cardiovascular anomalies, and hydrocephaly.

Determine the gestational age of the fetus and measure the woman's fundal height. With hydramnios, there is a discrepancy between fundal height and gestational age, or a rapid growth of the uterus is noted. Assess the woman for complaints of discomfort in her abdomen, such as being severely stretched and tight. Also note any reports of uterine contractions, which may result from overstretching of the uterus. Assess for shortness of breath resulting from pressure on her diaphragm and inspect her lower extremities for edema, which results from increased pressure on the vena cava.

Palpate the abdomen and obtain fetal heart rate. Often the fetal parts and heart rate are difficult to obtain because of the excess fluid present.

Prepare the woman for possible diagnostic testing to evaluate for the presence of possible fetal anomalies. An ultrasound usually is done to measure the pockets of

amniotic fluid to estimate the total volume. In some cases, ultrasound also is helpful in finding the etiology of polyhydramnios, such as multiple pregnancy or a fetal structural anomaly.

Nursing Management

Nursing management of the woman with polyhydramnios focuses on ongoing assessment and monitoring for symptoms of abdominal pain, dyspnea, uterine contractions, and edema of the lower extremities. Explain to the woman and her family that this condition can cause her uterus to become overdistended and may lead to preterm labor and preterm rupture of membranes. Outline the signs and symptoms of both conditions and instruct the woman to contact her health care provider if they do occur. If a therapeutic amniocentesis is performed, assist the health care provider and monitor maternal and fetal status throughout for any changes.

OLIGOHYDRAMNIOS

Oligohydramnios is a decreased amount of amniotic fluid (less than 500 mL) between 32 weeks and 36 weeks' gestation. It occurs in 5% to 8% of all pregnancies. Oligohydramnios may result from any condition that prevents the fetus from making urine or blocks it from going into the amniotic sac.

This condition puts the fetus at an increased risk of perinatal morbidity and mortality (Blackburn, 2007). Reduction in amniotic fluid reduces the ability of the fetus to move freely without risk of cord compression, which increases the risk for fetal death and intrapartal hypoxia.

Therapeutic Management

The woman with oligohydramnios can be managed on an outpatient basis with serial ultrasounds and fetal surveillance through nonstress testing and biophysical profiles. As long as fetal well-being is demonstrated with frequent testing, no intervention is necessary. If fetal well-being is compromised, however, birth is planned along with amnioinfusion (the transvaginal infusion of crystalloid fluid to compensate for the lost amniotic fluid). The fluid is introduced into the uterus through an intrauterine pressure catheter. The infusion is administered in a controlled fashion to prevent overdistention of the uterus. Amnioinfusion is thought to improve abnormal fetal heart rate patterns, decrease cesarean births, and possibly minimize the risk of neonatal meconium aspiration syndrome (Norwitz & Schorge, 2006).

Nursing Assessment

Review the maternal history for factors associated with oligohydramnios, including:

- Uteroplacental insufficiency
- Premature rupture of membranes prior to labor onset
- Hypertension of pregnancy
- Maternal diabetes
- Intrauterine growth restriction
- Postterm pregnancy
- Fetal renal agenesis
- Polycystic kidneys
- Urinary tract obstructions

Assess the client for complaints of fluid leaking from the vagina. Leaking of amniotic fluid from the vagina occurs with rupture of the amniotic sac. Leaking in conjunction with a uterus that is small for expected dates of gestation also suggests oligohydramnios. Unfortunately, the woman may not present with any symptoms. Typically, the reduced volume of amniotic fluid is identified on ultrasound.

Nursing Management

Nursing management of the woman with oligohydramnios involves continuous monitoring of fetal well-being during nonstress testing or during labor and birth by identifying nonreassuring patterns on the fetal monitor. Variable decelerations indicating cord compression are common. Changing the woman's position might be therapeutic in altering this fetal heart rate pattern. After the birth, evaluate the newborn for signs of postmaturity, congenital anomalies, and respiratory difficulty.

Assist with amnioinfusion as indicated and continue to assess the woman's vital signs, contraction status, and fetal heart rate throughout the procedure. Provide comfort measures such as changing the bed linens and the woman's bed clothes frequently because of the constant leakage of fluid from the vagina. Also provide frequent perineal care during the infusion.

Multiple Gestation

Multiple gestation is defined as more than one fetus being born to a pregnant woman. This includes twins, triplets, and higher-order multiples such as quadruplets on up. In the past two decades, the number of multiple gestations in the United States has jumped dramatically because of the widespread use of fertility drugs, older women having babies, and assisted reproductive technologies to treat infertility. About one third of live births from assisted reproductive technology result in more than one infant, and twins represent 85% of those multiple-birth children (Grainger, Frazier, & Rowland, 2006). In the United States, the overall prevalence of twins is approximately 12 per 1,000, and two thirds are dizygotic (Zach & Pramanik, 2007). The increasing number of multiple gestations is a concern because women who are expecting more than one infant are at high risk for preterm labor, hydramnios, hyperemesis gravidarum, anemia, preeclamp-

sia, and antepartum hemorrhage. Fetal/newborn risks or complications include prematurity, respiratory distress syndrome, birth asphyxia/perinatal depression, congenital anomalies (central nervous system, cardiovascular, and GI defects), twin-to-twin transfusion syndrome (transfusion of blood from one twin [i.e., donor] to the other twin [i.e., recipient]), intrauterine growth restriction, and becoming conjoined twins (Zach & Pramanik, 2007).

The two types of twins are monozygotic and dizygotic (Fig. 19.6). Monozygotic twins develop when a single, fertilized ovum splits during the first 2 weeks after conception. Monozygotic twins also are called identical twins. Two sperm fertilizing two ova produce dizygotic twins, which are called fraternal twins. Separate amnions, chorions, and placentas are formed in dizygotic twins. Triplets can be monozygotic, dizygotic, or trizygotic.

Therapeutic Management

When a multiple gestation is confirmed, the woman is followed with serial ultrasounds to assess fetal growth patterns and development. Biophysical profiles along with nonstress tests are ordered to determine fetal well-being. Many women are hospitalized in late pregnancy to prevent preterm labor and receive closer surveillance. During the intrapartum period the woman is closely monitored, with a perinatal team available to assist after birth. Operative delivery is frequently needed due to fetal malpresentation.

Nursing Assessment

Obtain a health history and physical examination. Be alert for complaints of fatigue and severe nausea and vomiting. Assess the woman's abdomen and fundal height. Typically with a multiple gestation the uterus is larger than expected based on the estimated date of birth. Laboratory test results may reveal anemia. Prepare the woman for ultrasound, which typically confirms the diagnosis of a multiple gestation.

Nursing Management

During the prenatal period, care focuses on providing education and support for the woman in areas of nutrition, increased rest periods, and close observation for pregnancy complications—anemia, excessive weight gain, proteinuria, edema, vaginal bleeding, and hypertension. Instruct the woman to be alert for and report immediately any signs and symptoms of preterm labor—contractions, uterine cramping, low back ache, increase in vaginal discharge, loss of mucus plug, pelvic pain, and pressure.

With the onset of labor, expect to monitor fetal heart rates continuously. Prepare the woman for an ultrasound to assess the presentation of each fetus to determine the best delivery approach. Ensure that extra nursing staff and the perinatal team are available for any birth or newborn complications.

After the babies are born, closely assess the woman for hemorrhage by frequently assessing uterine involution. Palpate the uterine fundus and monitor the amount and characteristics of lochia.

Throughout the entire pregnancy, birth, and hospital stay, inform and support the woman and her family. Encourage them to ask questions and verbalize any fears and concerns.

Premature Rupture of Membranes

Premature rupture of membranes (**PROM**) is the rupture of the bag of waters before the onset of true labor. There are a number of associated conditions and complications, such as infection, prolapsed cord, abruptio placentae, and preterm labor. This is the single most common diagnosis associated with preterm births (Gilbert, 2007).

PROM occurs in approximately 12% of all births (ACOG, 2007b). If prolonged (greater than 24 hours), the woman's risk for infection (chorioamnionitis, endometritis, sepsis, and neonatal infections) increases and

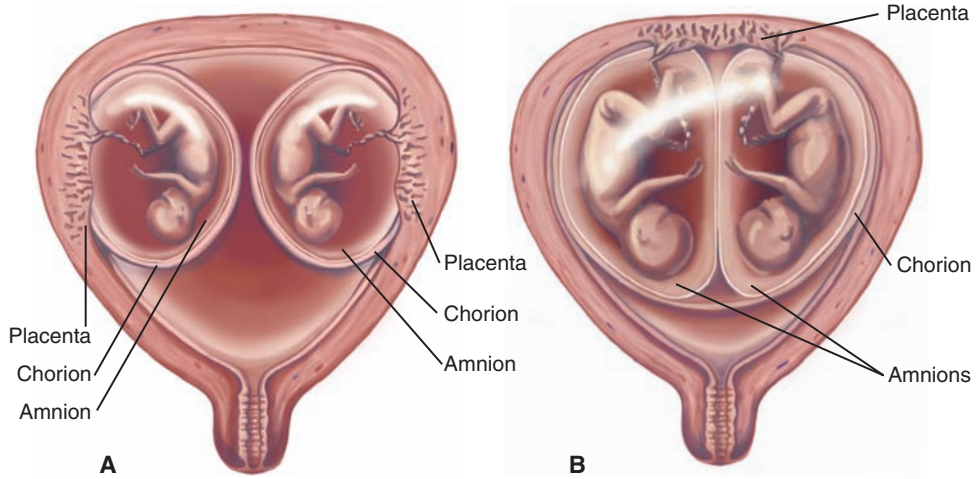


FIGURE 19.6 Multiple gestation with twins. (**A**) Dizygotic twins, where each fetus has its own placenta, amnion, and chorion. (**B**) Monozygotic twins, where the fetuses share one placenta, two amnions, and one chorion.

this risk continues to increase as the duration of rupture time increases. The time interval from rupture of membranes to the onset of regular contractions is termed the latent period.

The terminology pertaining to PROM can be confusing. PROM is rupture of the membranes prior to the onset of labor and is used appropriately when referring to a woman who is beyond 37 weeks' gestation, has presented with spontaneous rupture of the membranes, and is not in labor. Related terms include **preterm premature rupture of membranes** (**PPROM**), which is defined as rupture of membranes prior to the onset of labor in a woman who is *less* than 37 weeks of gestation. Perinatal risks associated with PPROM may stem from immaturity, including respiratory distress syndrome, intraventricular hemorrhage, patent ductus arteriosus, and necrotizing enterocolitis.

The exact cause of PROM is not known. In many cases, PROM occurs spontaneously.

Therapeutic Management

Treatment of PROM typically depends on the gestational age. Under no circumstances is an unsterile digital cervical examination done until the woman enters active labor, to minimize infection exposure. If the fetal lungs are mature, induction of labor is initiated. PROM is not a lone indicator for surgical birth. If the fetal lungs are immature, expectant management is carried out with adequate hydration, reduced physical activity, pelvic rest, and close observation for possible infection, such as with frequent monitoring of vital signs and laboratory test results (e.g., the white blood cell count). Corticosteroids may be given to enhance fetal lung maturity if lungs are immature, although this remains controversial. Recent studies have shown clear benefits of antibiotics to decrease neonatal morbidity associated with PPROM (ACOG, 2007b).

Nursing Assessment

Nursing assessment focuses on obtaining a complete health history and performing a physical examination to determine maternal and fetal status. An accurate assessment of the gestational age and knowledge of the maternal, fetal, and neonatal risks are essential to appropriate evaluation, counseling, and management of women with PROM and PPROM.

Health History and Physical Examination

Review the maternal history for risk factors such as infection, increased uterine size (hydramnios, macrosomia, multifetal gestation), uterine and fetal anomalies, lower socioeconomic status, STIs, cervical insufficiency, vaginal bleeding, and cigarette smoking during pregnancy. Ask about any history or current symptoms of UTI (frequency, urgency, dysuria, or flank pain) or pelvic or vaginal infection (pain or vaginal discharge).

Assess for signs and symptoms of labor, such as cramping, pelvic pressure, or back pain. Also assess her vital signs, noting any signs indicative of infection such as fever and elevated white blood cell count (more than 18,000 cells/mm^3) (Jazayeri & Galan, 2007).

Institute continuous electronic fetal heart rate monitoring to evaluate fetal well-being. Conduct a vaginal examination to ascertain the cervical status in PROM. If PPROM exists, a sterile speculum examination (where the examiner inspects the cervix but does not palpate it) is done rather than a digital cervical examination because it may diminish latency (period of time from rupture of membranes to birth) and increase newborn morbidity (Cunningham et al., 2005).

Observe the characteristics of the amniotic fluid. Note any evidence of meconium, or a foul odor. When meconium is present in the amniotic fluid, it typically indicates fetal distress related to hypoxia. Meconium stains the fluid yellow to greenish brown, depending on the amount present. A foul odor of amniotic fluid indicates infection. Also observe the amount of fluid. A decreased amount of amniotic fluid reduces the cushioning effect, thereby making cord compression a possibility. Key assessments are summarized in Box 19.3.

Laboratory and Diagnostic Testing

To diagnose PROM or PPROM, several procedures may be used: the Nitrazine test, fern test, or ultrasound. After the insertion of a sterile speculum, a sample of the fluid

BOX 19.3 Key Assessments With Premature Rupture of Membranes

For the woman with PROM, the following assessments are essential:

- Determining the date, time, and duration of membrane rupture by client interview
- Ascertaining gestational age of the fetus based on date of mother's LMP, fundal height, and ultrasound dating
- Questioning the woman about possible history of or recent UTI or vaginal infection that might have contributed to PROM
- Assessing for any associated labor symptoms, such as back pain or pelvic pressure
- Assisting with or performing diagnostic tests to validate leakage of fluid, such as Nitrazine test, "ferning" on slide, and ultrasound
- Continually assessing for signs of infection including
  - Elevation of maternal temperature and pulse rate
  - Abdominal/uterine tenderness
  - Fetal tachycardia more than 160 bpm
  - Elevated white blood cell count and C-reactive protein
  - Cloudy, foul-smelling amniotic fluid

in the vaginal area is obtained. With a Nitrazine test, pH of the fluid is tested; amniotic fluid is more basic (7.0) than normal vaginal secretions (4.5). Nitrazine paper turns blue in the presence of amniotic fluid. However, false-positive results can occur if blood, urine, semen, or antiseptic chemicals are also present; all will increase the pH.

For the fern test, a sample of vaginal fluid is place on a slide to be viewed directly under a microscope. Amniotic fluid will develop a fern-like pattern when it dries because of sodium chloride crystallization. If both of these tests are inconclusive, a transvaginal ultrasound can also be used to determine whether membranes have ruptured by demonstrating a decreased amount of amniotic fluid (oligohydramnios) in the uterus (Jazayeri & Galan, 2007).

Other laboratory and diagnostic tests that may be used include:

- Urinalysis and urine culture for UTI or asymptomatic bacteriuria
- Cervical test or culture for chlamydia or gonorrhea
- Vaginal culture for bacterial vaginosis and trichomoniasis
- Vaginal introital/rectal culture for group B streptococcus

Nursing Management

Nursing management for the woman with PROM or PPROM focuses on preventing infection and identifying uterine contractions. The risk for infection is great because of the break in the amniotic fluid membrane and its close proximity to vaginal bacteria. Therefore, monitor maternal vital signs closely. Be alert for a temperature elevation or an increase in pulse, which could indicate infection. Also monitor the fetal heart rate continuously, reporting any fetal tachycardia (which could indicate a maternal infection) or variable decelerations (suggesting cord compression). If variable decelerations are present, anticipate amnioinfusion based on agency policy. Evaluate the results of laboratory tests such as a CBC. An elevation in white blood cells would suggest infection. Administer antibiotics if ordered.

Encourage the woman and her partner to verbalize their feelings and concerns. Educate them about the purpose of the protective membranes and the implications of early rupture. Keep them informed about planned interventions, including potential complications and required therapy. As appropriate, prepare the woman for induction or augmentation of labor as appropriate if she is near term.

If labor doesn't start within 48 hours, the woman with PPROM may be discharged home on expectant management, which may include:

- Antibiotics if cervicovaginal cultures are positive
- Activity restrictions
- Education about signs and symptoms of infection and when to call with problems or concerns (Teaching Guidelines 19.3)

TEACHING GUIDELINES 19.3

Teaching for the Woman With PPROM

- Monitor your baby's activity by performing fetal kick counts daily.
- Check your temperature daily and report any temperature increases to your health care provider.
- Watch for signs related to the beginning of labor. Report any tightening of the abdomen or contractions.
- Avoid any touching or manipulating of your breasts, which could stimulate labor.
- Do not insert anything into your vagina or vaginal area.
- Maintain any specific activity restrictions as recommended.
- Wash your hands thoroughly after using the bathroom and make sure to wipe from front to back each time.
- Keep your perineal area clean and dry.
- Take your antibiotics as directed if your health care provider has prescribed them.
- Call your health care provider with changes in your condition, including fever, uterine tenderness, feeling like your heart is racing, and foul-smelling vaginal discharge.

- Frequent fetal testing for well-being
- Ultrasound every 3 to 4 weeks to assess amniotic fluid levels
- Possible corticosteroid treatment depending on gestational age
- Daily kick counts to assess fetal well-being

Key Concepts

- Identifying risk factors early on and ongoing throughout the pregnancy is important to ensure the best outcome for every pregnancy. Risk assessment should start with the first prenatal visit and continue with subsequent visits.
- The three most common causes of hemorrhage early in pregnancy (first half of pregnancy) are spontaneous abortion, ectopic pregnancy, and GTD.
- Ectopic pregnancies occur in about 1 in 50 pregnancies and have increased dramatically during the past few decades.
- Having a molar pregnancy results in the loss of the pregnancy and the possibility of developing choriocarcinoma, a chronic malignancy from the trophoblastic tissue.
- The classic clinical picture presentation for placenta previa is painless, bright-red vaginal bleeding occurring during the third trimester.

- Treatment of abruptio placentae is designed to assess, control, and restore the amount of blood lost; to provide a positive outcome for both mother and infant; and to prevent coagulation disorders.
- DIC can be described in simplest terms as a loss of balance between the clot-forming activity of thrombin and the clot-lysing activity of plasmin.
- Hyperemesis gravidarum is a complication of pregnancy characterized by persistent, uncontrollable nausea and vomiting before the 20th week of gestation.
- Gestational hypertension is the leading cause of maternal death in the United States and the most common complication reported during pregnancy.
- HELLP is an acronym for hemolysis, elevated liver enzymes, and low platelets.
- Rh incompatibility is a condition that develops when a woman of Rh-negative blood type is exposed to Rh-positive fetal blood cells and subsequently develops circulating titers of Rh antibodies.
- Hydramnios occurs in approximately 3 to 4% of all pregnancies and is associated with fetal anomalies of development.
- Nursing care related to the woman with oligohydramnios involves continuous monitoring of fetal well-being during nonstress testing or during labor and birth by identifying nonreassuring patterns on the fetal monitor.
- The increasing number of multiple gestations is a concern because women who are expecting more than one infant are at high risk for preterm labor, hydramnios, hyperemesis gravidarum, anemia, preeclampsia, and antepartum hemorrhage.
- Nursing care related to PROM centers on infection prevention and identification of preterm labor contractions.
- Early identification of preterm labor would allow for appropriate interventions that may prolong the pregnancy, such as transferring the woman to a facility with a neonatal intensive care unit for prenatal care, administering glucocorticoids to the mother to promote fetal lung maturity, and giving appropriate antibiotics to treat infections to arrest the labor process.
- It is essential that nurses teach all pregnant women how to detect the early symptoms of preterm labor and what to do if they experience contractions or cramping that does not go away.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. A woman diagnosed with preeclampsia is to receive magnesium sulfate. The rationale for this drug is to:
   a. Reduce CNS irritability to prevent seizures
   b. Provide supplementation of an important mineral she needs
   c. Prevent constipation during and after the birthing process
   d. Decrease musculoskeletal tone to augment labor
2. A woman is suspected of having abruptio placentae. Which of the following would the nurse expect to assess as a classic symptom?
   a. Painless, bright-red bleeding
   b. "Knife-like" abdominal pain
   c. Excessive nausea and vomiting
   d. Hypertension and headache
3. RhoGAM is given to Rh-negative women to prevent maternal sensitization. In addition to pregnancy, Rh-negative women would also receive this medication after which of the following?
   a. Therapeutic or spontaneous abortion
   b. Head injury from a car accident
   c. Blood transfusion after a hemorrhage
   d. Unsuccessful artificial insemination procedure
4. After teaching a woman about hyperemesis gravidarum and how it differs from the typical nausea and vomiting of pregnancy, which statement by the woman indicates that the teaching was successful?
   a. "I can expect the nausea to last through my second trimester."
   b. "I should drink fluids with my meals instead of in between them."
   c. "I need to avoid strong odors, perfumes, or flavors."
   d. "I should lie down after I eat for about 2 hours."
5. A pregnant woman, approximately 12 weeks' gestation, comes to the emergency department after calling her health care provider's office and reporting moderate vaginal bleeding. Assessment reveals cervical dilation and moderately strong abdominal cramps. She reports that she has passed some tissue with the bleeding. The nurse interprets these findings to suggest which of the following?
   a. Threatened abortion
   b. Inevitable abortion
   c. Incomplete abortion
   d. Missed abortion

CRITICAL THINKING EXERCISES

1. Suzanne, a 16-year-old primigravida, presents to the maternity clinic complaining of continual nausea and vomiting for the past 3 days. She states she is approximately 15 weeks pregnant and has been unable to hold anything down or take any fluids in without throwing up for the past 3 days. She reports she is dizzy and weak. On examination, Suzanne appears pale and anxious. Her mucous membranes are dry, skin turgor is poor, and her lips are dry and cracked.
   a. What is your impression of this condition?
   b. What risk factors does Suzanne have?
   c. What intervention is appropriate for this woman?
2. Gloria is an obese 39-year-old primigravida of African-American descent who is diagnosed with gestational hypertension. Her history reveals that her sister developed preeclampsia during her pregnancy. When describing her diet to the nurse, Gloria mentions that she tends to eat a lot of fast food.
   a. What risk factors does Gloria have that increase her risk for gestational hypertension?
   b. When assessing Gloria, what assessment findings would lead the nurse to suspect that Gloria has developed severe preeclampsia?

STUDY ACTIVITIES

1. Ask a community health maternity nurse how the signs and symptoms of gestational hypertension (including preeclampsia and eclampsia) are taught, and how effective efforts have been to reduce the incidence in the area.
2. Find a website designed to help parents who have suffered a pregnancy loss secondary to a spontaneous abortion. What is its audience level? Is the information up to date?
3. A pregnancy in which the blastocyst implants outside the uterus is an _____ pregnancy.
4. The most serious complication of hydatidiform mole is the development of _____ afterward.
5. Discuss various activities a woman with a multiple gestation could engage in to help pass the time when ordered to be on bed rest at home for 2 months.

CHAPTER 20

Nursing Management of the Pregnancy at Risk: Selected Health Conditions and Vulnerable Populations

KEY TERMS

acquired immunodeficiency syndrome (AIDS)
adolescence
anemia
fetal alcohol spectrum disorder (FASD)
gestational diabetes mellitus
glycosylated hemoglobin (HbA1C) level
human immunodeficiency virus (HIV)
impaired fasting glucose
impaired glucose tolerance
neonatal abstinence syndrome
perinatal drug abuse
pica
pregestational diabetes
teratogen
type 1 diabetes
type 2 diabetes

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify at least two conditions present before pregnancy that can have a negative effect on a pregnancy.
2. Explain how a condition present before pregnancy can affect the woman physiologically and psychologically when she becomes pregnant.
3. Differentiate the nursing assessment and management for a pregnant woman with diabetes from that of a pregnant woman without diabetes.
4. Explore how congenital and acquired heart conditions can affect a woman's pregnancy.
5. Describe the nursing assessment and management of a pregnant woman with cardiovascular disorders and respiratory conditions.
6. Differentiate among the types of anemia affecting pregnant women in terms of prevention and management.
7. Describe the most common infections that can jeopardize a pregnancy, and propose possible preventive strategies.
8. Explain the nurse's role in the prevention and management of adolescent pregnancy.

Rose, a thin 16-year-old appearing very pregnant, came into the clinic wheezing and having difficulty catching her breath. She had missed several previous prenatal visits but arrived at the clinic today in distress. Rose has a history of asthma since she was 5 years old. How might Rose's current condition affect her pregnancy? Is this picture typical of the pregnant asthmatic?

Wow

As the sun sets each day, nurses should make sure they have done something for others, and should try to be understanding even under the most difficult of conditions.

LEARNING OBJECTIVES (continued)

9. Identify the impact of pregnancy on a woman over the age of 35.
10. Develop a plan of care for the pregnant woman who is HIV positive.
11. Examine the effects of substance abuse during pregnancy.

Pregnancy and childbirth are exciting yet complex facets within the continuum of women's health. Ideally the pregnant woman is free of any conditions that can affect a pregnancy, but in reality many women enter pregnancy with a multitude of health-related or psychosocial issues that can have a negative impact on the outcome.

Many pregnant women express the wish, "I hope my baby is born healthy." Nurses can play a major role in helping this become a reality by educating women before they become pregnant. Conditions such as diabetes, cardiac and respiratory disorders, anemias, and specific infections frequently can be controlled through close prenatal management so that their impact on pregnancy is minimized. Nurses can provide pregnancy-prevention strategies when counseling teenagers. Meeting the developmental needs of pregnant adolescents is a challenge. Finally, lifestyle choices can place many women at risk during pregnancy, and nurses need to remain nonjudgmental in working with these special populations. Lifestyle choices such as use of alcohol, nicotine, and illicit substances during pregnancy are addressed in a National Health goal.

Chapter 19 described pregnancy-related conditions that place the woman at risk. This chapter addresses common conditions that can have a negative impact on the pregnancy and special populations at risk, outlining appropriate nursing assessment and management for each condition or situation. The unique skills of nurses, in conjunction with the other members of the health care team, can increase the potential for a positive outcome in many high-risk pregnancies.

HEALTHY PEOPLE 2010

Objective	Significance
Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women Increase in reported abstinence in the past month from substances by pregnant women Alcohol from a baseline of 86% to 94% Binge drinking from a baseline of 99% to 100% Cigarette smoking from abaseline of 87% to 99% Illicit drugs from a baseline of 98% to 100%	Will help to focus attention on measures for reducing substance exposure and use, thereby minimizing the effects of these substances on the fetus and newborn

USDHHS, 2000.

Diabetes Mellitus

Diabetes mellitus is a chronic disease characterized by a relative lack of insulin or absence of the hormone, which is necessary for glucose metabolism. The chronic hyperglycemia of diabetes is associated with long-term damage, dysfunction, and failure of the eyes, kidneys, nerves, heart, and blood vessels. The prevalence of diabetes in the United States is increasing at an alarming rate, already reaching epidemic proportions. A contributing factor to these increasing rates is the incidence of obesity. Diabetes is a common endocrine disorder, affecting up to 14% of all pregnancies (American Diabetes Association [ADA], 2007a).

Diabetes commonly is classified based on disease etiology (ADA, 2007a). These groups include:

- **Type 1 diabetes**: absolute insulin deficiency (due to an autoimmune process); usually appears before the age of 30 years; approximately 10% of those diagnosed have type 1 diabetes
- **Type 2 diabetes**: insulin resistance or deficiency (related to obesity, sedentary lifestyle); diagnosed primarily in adults older than 30 years of age but is now being seen in children; accounts for 90% of all diagnosed cases.
- **Impaired fasting glucose** and **impaired glucose tolerance**: characterized by hyperglycemia at a level lower than what qualifies as a diagnosis of diabetes (fasting blood glucose level between 100 and 125 mg/dL; blood glucose level between 140 and 199 mg/dL after a 2-hour glucose tolerance test, respectively); symptoms of diabetes are absent; newborns are at risk for being large for gestational age (LGA)
- **Gestational diabetes mellitus**: glucose intolerance with its onset during pregnancy or first detected in pregnancy

During pregnancy, diabetes typically is categorized into two groups: **pregestational diabetes** (alteration in carbohydrate metabolism identified before conception), which includes women with type 1 or type 2 disease; and gestational diabetes, which develops during pregnancy.

Pregestational diabetes complicates 0.2% to 0.3% of all pregnancies and affects more than 15,000 women annually. Gestational diabetes occurs in approximately 8% of all pregnant women, and those rates are higher among women of color. It is associated with either neonatal complications such as macrosomia, hypoglycemia, and birth trauma or maternal complications such as preeclampsia and cesarean birth. Gestational diabetes complicates more than 200,000 pregnancies annually in the United States and accounts for 90% of diabetic pregnancies (ADA, 2007a).

Before the discovery of insulin in 1922, most women with diabetes were infertile or experienced spontaneous abortion (March of Dimes, 2007b). Over the past several decades, great strides have been made in improving the outcomes of pregnancy in women with diabetes, but this chronic metabolic disorder remains a high-risk condition during pregnancy. A favorable outcome requires commitment on the woman's part to comply with frequent prenatal visits, dietary restrictions, self-monitoring of blood glucose levels, frequent laboratory tests, intensive fetal surveillance, and perhaps hospitalization.

Pathophysiology

With diabetes, there is a deficiency of or resistance to insulin. This alteration interferes with the body's ability to obtain essential nutrients for fuel and storage. If a pregnant woman has pregestational diabetes or develops gestational diabetes, the profound metabolic alterations that occur during pregnancy and that are necessary to support the growth and development of fetus can be affected.

▸ *Consider THIS!*

Scott and I had been busy all day setting up the new crib and nursery, and we finally sat down to rest. I was due any day, and we had been putting this off until we had a long weekend to complete the task. I was excited to think about all the frilly pinks that decorated her room. I was sure that my new daughter would love it as much as I loved her already. A few days later I barely noticed any fetal movement, but I thought that she must be as tired as I was by this point.

That night I went into labor and kept looking at the worried faces of the nurses and the midwife in attendance. I had been diagnosed with gestational diabetes a few months ago and had tried to follow the instructions regarding diet and exercise, but old habits are hard to change when you are 38 years old. I was finally told after a short time in the labor unit that they couldn't pick up a fetal heartbeat and an ultrasound was to be done—still no heartbeat was detected. Scott and I were finally told that our daughter was a stillborn. All I could think about was that she would never get to see all the pink colors in the nursery. . .

Maternal metabolism is directed toward supplying adequate nutrition for the fetus. In pregnancy, placental hormones cause insulin resistance at a level that tends to parallel the growth of the fetoplacental unit. As the placenta grows, more placental hormones are secreted. Human placental lactogen (hPL) and growth hormone (somatotropin) increase in direct correlation with the growth of placental tissue, rising throughout the last 20 weeks of pregnancy and causing insulin resistance. Subsequently, insulin secretion increases to overcome the resistance of these two hormones. In the nondiabetic pregnant woman, the pancreas can respond to the demands for increased insulin production to maintain normal glucose levels throughout the pregnancy (Cypryk et al., 2007). However, the woman with glucose intolerance or diabetes during pregnancy cannot cope with changes in metabolism resulting from insufficient insulin to meet the needs during gestation.

Over the course of pregnancy, insulin resistance changes. It peaks in the last trimester to provide more nutrients to the fetus. The insulin resistance typically results in postprandial hyperglycemia, although some women also have an elevated fasting blood glucose level (Homko & Reece, 2006). With this increased demand on the pancreas in late pregnancy, women with diabetes or glucose intolerance cannot accommodate the increased insulin demand; glucose levels rise as a result of insulin deficiency, leading to hyperglycemia. Subsequently, the mother and her fetus can experience major problems (Table 20.1).

Therapeutic Management

Preconception counseling is key for the woman with pregestational diabetes (the alteration in carbohydrate metabolism is identified before conception) to ensure that her disease state is stable. The goals of preconception care are to:

- Integrate the woman into the management of her diabetes
- Achieve the lowest glycosylated hemoglobin A1C test results without excessive hypoglycemia
- Ensure effective contraception until stable glycemia is achieved
- Identify and evaluate long-term diabetic complications such as retinopathy, nephropathy, neuropathy, cardiovascular disease, and hypertension (ADA, 2007b)

Excellent control of blood glucose, as evidenced by normal fasting blood glucose levels and a **glycosylated hemoglobin (HbA1C) level** (a measurement of the average glucose levels over the past 100 to 120 days), is crucial to achieve the best pregnancy outcome. A glycosylated hemoglobin level of less than 7% indicates good control; a value of more than 8% indicates poor control and warrants intervention (ADA, 2007b).

Preconception counseling also is important in helping to reduce the risk of congenital malformation. The most common malformations associated with diabetes occur in the renal, cardiac, skeletal, and central nervous systems. Since these defects occur by the eighth week of gestation, preconception counseling is critical. The rate

TABLE 20.1 DIABETES AND PREGNANCY: EFFECTS ON THE MOTHER AND FETUS

Effects on the Mother	Effects on the Fetus/Neonate
• Polyhydramnios due to fetal diuresis caused by hyperglycemia • Gestational hypertension of unknown etiology • Ketoacidosis due to uncontrolled hyperglycemia • Preterm labor secondary to premature membrane rupture • Stillbirth in pregnancies complicated by ketoacidosis and poor glucose control • Hypoglycemia as glucose is diverted to the fetus (occurring in first trimester) • Urinary tract infections resulting from excess glucose in the urine (glucosuria), which promotes bacterial growth • Chronic monilial vaginitis due to glucosuria, which promotes growth of yeast • Difficult labor, cesarean birth, postpartum hemorrhage secondary to an overdistended uterus to accommodate a macrosomic infant	• Cord prolapse secondary to polyhydramnios and abnormal fetal presentation • Congenital anomaly due to hyperglycemia in the first trimester (cardiac problems, neural tube defects, skeletal deformities, and genitourinary problems) • Macrosomia resulting from hyperinsulinemia stimulated by fetal hyperglycemia • Birth trauma due to increased size of fetus, which complicates the birthing process (shoulder dystocia) • Preterm birth secondary to hydramnios and an aging placenta, which places the fetus in jeopardy if the pregnancy continues • Fetal asphyxia secondary to fetal hyperglycemia and hyperinsulinemia • Intrauterine growth restriction (IUGR) secondary to maternal vascular impairment and decreased placental perfusion, which restricts growth • Perinatal death due to poor placental perfusion and hypoxia • Respiratory distress syndrome (RDS) resulting from poor surfactant production secondary to hyperinsulinemia inhibiting the production of phospholipids, which make up surfactant • Polycythemia due to excessive red blood cell (RBC) production in response to hypoxia • Hyperbilirubinemia due to excessive RBC breakdown from hypoxia and an immature liver unable to break down bilirubin • Neonatal hypoglycemia resulting from ongoing hyperinsulinemia after the placenta is removed • Subsequent childhood obesity and carbohydrate intolerance

Sources: March of Dimes, 2007b; Gilbert, 2007; Blackburn, 2007.

of congenital anomalies in women with pregestational diabetes can be reduced if excellent glycemic control is achieved at the time of conception (Varughese et al., 2007). This information needs to be stressed with all diabetic women contemplating a pregnancy.

In addition, the woman with pregestational diabetes needs to be evaluated for complications of diabetes. This evaluation should be part of baseline screening and continuing assessment during pregnancy.

Therapeutic management for the woman with gestational diabetes mellitus (defined as glucose intolerance with its onset during pregnancy or first detected during pregnancy) focuses on tight glucose control. The ADA (2007b) recommends maintaining a fasting blood glucose level below 95 mg/dL, with postprandial levels below 140 mg/dL and 2-hour postprandial levels below 120 mg/dL. In comparison, for pregnant women without diabetes, near-normal glucose values include a fasting value between 60 to 90 mg/dL, a 1-hour postprandial value of 100 to 120 mg/dL, and a 2-hour postprandial value of 60 to 120 mg/dL. Such tight control has been advocated because it is associated with a reduction in macrosomia (Scollan-Koliopoulos, Guadagno, & Walker, 2006).

Women with diabetes need comprehensive prenatal care. The primary goals of care are to maintain glycemic control and minimize the risks of the disease on the fetus. Key aspects of treatment include nutritional management, insulin regimens, and close maternal and fetal surveillance.

Nutritional management focuses on maintaining balanced glucose levels and providing enough energy and nutrients for the pregnant woman, while avoiding ketosis, and minimizing the risk of hypoglycemia in women treated with insulin (Edelstein & Herbold, 2007). Women who receive dietary instruction and follow it have been shown to have a better pregnancy outcome than those who don't receive dietary advice (Henriksen, 2006). For the woman with gestational diabetes, nutritional management may be all that is necessary.

Insulin, which doesn't cross the placenta, historically has been the medication of choice for treating hyperglycemia in pregnancy. Recent studies have examined the use of oral hypoglycemic medications in pregnancy. Several studies have used glyburide (Diabeta) with promising results. When oral agents are prescribed, additional treatment with insulin may be necessary as the pregnancy advances (Scollan-Koliopoulos, Guadagno, & Walker, 2006). More research is indicated to establish the drug's safety and efficacy in managing diabetes in pregnancy before it can be considered an evidence-based practice (Homko & Reece, 2006; Rochon et al., 2006).

The ADA recommends that women diagnosed with gestational diabetes by a 3-hour glucose tolerance test re-

ceive nutritional counseling from a registered dietitian. The ADA also recommends insulin therapy if diet is unsuccessful in achieving a fasting glucose level below 105 mg/dL, a 1-hour postprandial level below 155 mg/dL, or 2-hour postprandial level below 130 mg/dL (ADA, 2007b).

The American College of Obstetricians and Gynecologists (ACOG) recommends the use of diet or insulin to achieve a 1-hour postprandial blood glucose level of 130 mg/dL. Both ADA and ACOG believe that further studies are needed to establish the safety of oral antidiabetic agents. Glycemic control—regardless of whether it involves diet, insulin, or oral agents—leads to fewer cases of shoulder dystocia, hyperbilirubinemia requiring phototherapy, nerve palsy, bone fracture, large for gestational age status, and fetal macrosomia (ADA, 2008).

Insulin remains the medication of choice for glycemic control in pregnant and lactating women with any type of diabetes (Ekpebegh et al., 2007). Generally, insulin doses are reduced in the first trimester to prevent hypoglycemia resulting from increased insulin sensitivity as well as from nausea and vomiting. Newer short-acting insulins such as lispo (Humalog) and aspart (Novolog), which do not cross the placenta, may help reduce postprandial hyperglycemia, episodes of hypoglycemia between meals (Hackley, Kriebs, & Rousseau, 2007). Target fasting glucose values of 60 to 90 mg/dL and 1-hour postprandial values less than 120 mg/dL are necessary to provide good glycemic control and good pregnancy outcomes (Frieden & Chan, 2007). Changes in diet and activity level add to the need for changes in insulin dosages throughout pregnancy.

Insulin regimens vary, and controversy remains over the best strategy for insulin delivery in pregnancy. Many health care providers use a split-dose therapy (⅔ of the daily dose in the morning and the remaining ⅓ in the evening). Others advocate the use of an insulin pump to deliver a continuous subcutaneous insulin infusion. Regardless of which protocol is used, frequent blood glucose measurements are necessary, and the insulin dosage is adjusted on the basis of daily glucose levels.

EVIDENCE-BASED PRACTICE 20.1
Selecting Methods of Insulin Administration for Pregnant Women With Diabetes

● Study

A woman who has diabetes and becomes pregnant is at risk for various problems, both for herself and her fetus. The goal during pregnancy is to maintain optimal glucose control. For these women, insulin is the mainstay of treatment. Unfortunately blood glucose levels are not static and insulin requirements change throughout pregnancy.

Insulin typically is administered subcutaneously, commonly in multiple doses throughout the day. However, it also may be administered via a continuous subcutaneous infusion. The question arises as to which method of insulin administration affords the best control of blood glucose levels. The belief is that the continuous infusions would provide better blood glucose control and thus reduce the risks of problems for the mother and fetus.

A study was conducted comparing the effects of continuous subcutaneous insulin infusions with multiple daily doses of insulin therapy. The study involved a search of randomized controlled trials comparing these two methods of administration and their effect on neonatal birthweight, perinatal mortality, fetal anomalies, and maternal hypo- and hyperglycemia. Two studies consisting of 60 women were reviewed and a meta-analysis was performed.

▲ Findings

Women receiving continuous insulin infusions experienced an increase in birthweight of their infants compared to mothers receiving multiple daily doses of insulin. However, the researchers did not identify this difference as clinically significant. The researchers found no significant differences in perinatal mortality, fetal anomalies, or maternal hypo- and hyperglycemia between the two groups. The researchers attributed this to the small number of trials reviewed and the limited sample size of participants in the study. They concluded that there was insufficient evidence to support one method being better than the other. The researchers recommended additional research using a more vigorous approach and larger samples of women.

■ Nursing Implications

This study, although inconclusive, does underscore the need for glucose control in women with pregestational diabetes. Nurses need to be aware of these findings so that they can integrate knowledge of adequate blood glucose control when teaching pregnant women with diabetes about its potential effects, regardless of the method for insulin administration. Nurses also need to be cognizant of the various methods for insulin administration so that they can incorporate the information from this study to provide individualized care to the pregnant woman with diabetes, thereby promoting the best possible outcomes for the mother and her fetus.

Farrar, D., Tuffnell, D. J., & West, J. Continuous subcutaneous insulin infusion versus multiple daily injections of insulin for pregnant women with diabetes. *Cochrane Database of Systematic Reviews* 2007. Issue 3. Art. No.: CD005542.DOI: 10.1002/14651858.CD005542.pub2.

Close maternal and fetal surveillance is also essential. Frequent laboratory tests are done during pregnancy to monitor the woman's status and glucose control. Fetal surveillance via diagnostic testing aids in evaluating fetal well-being and assisting in determining the best time for birth.

For the laboring woman with diabetes, intravenous saline is given and blood glucose levels are monitored every 1 to 2 hours. Glucose levels are maintained below 110 mg/dL throughout labor to reduce the likelihood of neonatal hypoglycemia. If necessary, an infusion of regular insulin may be given to maintain this level (ADA, 2007b). If the woman was receiving insulin during her pregnancy, adjustments in dosage may be necessary after birth since glucose diversion across the placenta to supply the growing fetus is no longer present and insulin resistance is now removed. Frequently, the woman with gestational diabetes can remain controlled through diet and weight management; the woman with type 1 diabetes usually returns to prepregnant levels of insulin administration (Modder, 2008).

Nursing Assessment

Nursing assessment begins at the first prenatal visit. A thorough history and physical examination in conjunction with specific laboratory and diagnostic testing aids in developing an individualized plan of care for the woman with diabetes.

Health History and Physical Examination

For the woman with pregestational diabetes, obtain a thorough history of the preexisting diabetic condition. Ask about her duration of disease, management of glucose levels (insulin injections, insulin pump, or oral hypoglycemic agents), dietary adjustments, presence of vascular complications and current vascular status, current insulin regimen, and technique used for glucose testing. Review any information that she may have received as part of her preconception counseling and measures that were implemented during this time.

Be knowledgeable about the woman's nutritional requirements and assess the adequacy and pattern of her dietary intake. Assess her blood glucose self-monitoring in terms of technique, frequency, and her ability to adjust the insulin dose based on the changing patterns. Ask about the frequency of episodes of hypoglycemia or hyperglycemia to ascertain the woman's ability to recognize and treat them. Continue to assess her for signs and symptoms of hypo- and hyperglycemia.

During antepartum visits, assess the client's knowledge about her disease, including the signs and symptoms of hypoglycemia, hyperglycemia, and diabetic ketoacidosis, insulin administration techniques, and the impact of pregnancy on her chronic condition. If possible have the woman demonstrate her technique for blood glucose monitoring and insulin administration if appropriate. Although the client may have had diabetes for some time, do not assume that she has a firm knowledge base about her disease process or management of it (Fig. 20.1).

Assess the woman's risk for gestational diabetes at the first prenatal visit. The ADA (2007b) recommends assessing all women for risk factors and then determining the need for additional testing in the high-risk group only. Factors that place a woman at high risk include:

- Previous infant with congenital anomaly (skeletal, renal, central nervous system, cardiac)
- History of gestational diabetes or hydramnios in a previous pregnancy
- Family history of diabetes
- Age 35 or older
- Previous infant weighing more than 9 pounds (4,000 g)
- Previous unexplained fetal demise or neonatal death
- Maternal obesity (Body Mass Index [BMI] > 30)
- Hypertension
- Hispanic, Native American, or African-American ethnicity
- Recurrent monilia infections that don't respond to treatment
- Signs and symptoms of glucose intolerance (polyuria, polyphagia, polydipsia, fatigue)
- Presence of glycosuria or proteinuria (Hackley, Kriebs, & Rousseau, 2007)

Women with clinical characteristics consistent with a high risk for gestational diabetes should undergo glucose testing as soon as feasible.

Provide close ongoing assessment throughout the antepartal period. Women with gestational diabetes mellitus are at increased risk for preeclampsia and glucose control-related complications such as hypoglycemia, hyperglycemia, and ketoacidosis. Gestational diabetes of any severity increases the risk of fetal macrosomia. It is also associated with an increased frequency of maternal hypertensive disorders and operative births. This may be the result of fetal growth disorders (ADA, 2007b).

FIGURE 20.1 The nurse is demonstrating the technique for self-blood glucose monitoring with a pregnant client.

Even though gestational diabetes is diagnosed during pregnancy, the woman may have had glucose intolerance before the pregnancy. Therefore, monitor the woman closely for signs and symptoms of possible complications.

Also assess the woman's psychosocial adaptation to her condition. This assessment is critical to gain her cooperation for a change in regimen or the addition of a new regimen throughout pregnancy. Identify her support systems and note any financial constraints, as she will need more intense monitoring and frequent fetal surveillance.

Laboratory and Diagnostic Testing

The results of laboratory and diagnostic tests provide valuable information about maternal and fetal well-being. Women with pregestational diabetes and those discovered to have gestational diabetes require ongoing maternal and fetal surveillance to promote the best outcome.

Screening

ACOG and ADA currently recommend a risk analysis of all pregnant women at their first prenatal visit and additional screening of all high-risk pregnant women again at 24 to 28 weeks, or earlier if risk factors are present. If the initial screening risk assessment is low, additional screening may not be necessary. Pregnant women who fulfill all of the following criteria need not be screened:

- No history of glucose intolerance
- Less than 25 years old
- Normal body weight
- No family history (first-degree relative) of diabetes
- No history of poor obstetric outcome
- Not from an ethnic/racial group with a high prevalence of diabetes (ADA, 2007b)

If the initial risk assessment is high, rescreening should take place between 24 and 28 weeks. A woman with abnormal early results may have had diabetes before the pregnancy, and her fetus is a great risk for congenital anomalies. An elevated glycosylated hemoglobin supports the likelihood of gestational diabetes (D'Arrigo, 2007).

There is little consensus regarding the appropriate screening method. Typically, screening is based on a 50-g 1-hour glucose challenge test, usually performed between week 24 and 28 of gestation (ADA, 2007b). A 50-g oral glucose load is given, without regard to the timing or content of the last meal. Blood glucose is measured 1 hour later; a level above 140 mg/dL is abnormal. If the result is abnormal, a 3-hour glucose tolerance test is done. Normal values are:

- Fasting blood glucose level: less than 105 mg/dL
- At 1 hour: less than 190 mg/dL
- At 2 hours: less than 165 mg/dL
- At 3 hours: less than 145 mg/dL

A diagnosis of gestational diabetes can be made only after an abnormal result is obtained on the glucose tolerance test. Two or more abnormal values confirm a diagnosis of gestational diabetes (ADA, 2007a).

Surveillance

Maternal surveillance may include the following:

- Urine check for protein (may indicate the need for further evaluation for preeclampsia) and for nitrates and leukocyte esterase (may indicate a urinary tract infection)
- Urine check for ketones (may indicate the need for evaluation of eating habits)
- Kidney function evaluation every trimester for creatinine clearance and protein levels
- Eye examination in the first trimester to evaluate the retina for vascular changes
- HbA1c every 4 to 6 weeks to monitor glucose trends (Hackley, Kriebs, & Rousseau, 2007)

Fetal surveillance may include ultrasound to provide information about fetal growth, activity, and amniotic fluid volume and to validate gestational age. Alpha-fetoprotein levels may be obtained to detect congenital anomalies such as an open neural tube or ventral wall defects of omphalocele or gastroschisis, and a fetal echocardiogram may be necessary to rule out cardiac anomalies. A biophysical profile helps to monitor fetal well-being and uteroplacental profusion, and nonstress tests commonly are performed weekly after 28 weeks' gestation to evaluate fetal well-being. As the pregnancy progresses, an amniocentesis may be done to determine the lecithin/sphingomyelin (L/S) ratio and the presence of phosphatidyl glycerol (PG) to evaluate whether the fetal lung is mature enough for birth (Frieden & Chan, 2007).

Nursing Management

The ideal outcome of every pregnancy is a healthy newborn and mother. Nurses can be pivotal in realizing this positive outcome for women with pregestational or gestational diabetes by implementing measures to minimize risks and complications. Since the woman with diabetes is considered to be at high risk, antepartal visits occur more frequently (every 2 weeks up to 28 weeks and then twice a week until birth), providing the nurse with numerous opportunities for ongoing assessment, education, and counseling (Nursing Care Plan 20.1).

Promoting Optimal Glucose Control

At each visit, review the mother's blood glucose levels, including any laboratory tests and self-monitoring results. Reinforce with the woman the need to perform blood glucose monitoring (usually four times a day, before meals and at bedtime) and to keep a record of the results. If appropriate, obtain a fingerstick blood glucose level to evaluate the accuracy of self-monitoring results. Also assess the woman's techniques for monitoring blood glucose levels and for administering insulin if ordered, and offer support and guidance. If the woman is receiving insulin

Nursing Care Plan 20.1

OVERVIEW OF THE PREGNANT WOMAN WITH TYPE 1 DIABETES

Donna, a 30-year-old woman with type 1 diabetes, presents to the maternity clinic for preconception care. She has been a diabetic for 8 years and takes insulin twice daily by injection. She does blood glucose self-monitoring four times daily. She reports that her disease is fairly well controlled, but "I'm worried about how my diabetes will affect a pregnancy and my baby. Will I need to make changes in my routine? Will my baby be normal?" She reports that she recently had a foot infection and needed to go to the emergency room because it led to an episode of ketoacidosis. She states that her last glycosylated hemoglobin A1c test results were abnormal.

NURSING DIAGNOSIS: Deficient knowledge related to type 1 diabetes, blood glucose control, and effects of condition on pregnancy as evidenced by questions about effect on pregnancy, possible changes in regimen, and pregnancy outcome

Outcome Identification and Evaluation

Client will demonstrate increased knowledge of type 1 diabetes and effects on pregnancy *as evidenced by proper techniques for blood glucose monitoring and insulin administration, ability to modify insulin doses and dietary intake to achieve control, and verbalization of need for glycemic control prior to pregnancy, with blood glucose levels remaining within normal range.*

Interventions: Providing Client Teaching

- Assess client's knowledge of diabetes and pregnancy *to establish a baseline from which to develop an individualized teaching plan.*
- Review the underlying problems associated with diabetes and how pregnancy affects glucose control *to provide client with a firm knowledge base for decision making.*
- Review signs and symptoms of hypoglycemia and hyperglycemia and prevention and management measures *to ensure client can deal with them should they occur.*
- Provide written materials describing diabetes and care needed for control *to provide opportunity for client's review and promote retention of learning.*
- Observe client administering insulin and self-glucose testing for technique and offer suggestions for improvement if needed *to ensure adequate self-care ability.*
- Discuss proper foot care *to prevent future infections.*
- Teach home treatment for symptomatic hypoglycemia *to minimize risk to client and fetus.*
- Outline acute and chronic diabetic complications *to reinforce the importance of glucose control.*
- Discuss use of contraceptives until blood glucose levels can be optimized before conception occurs *to promote best possible health status before conception.*
- Explain the rationale for good glucose control and the importance of achieving excellent glycemic control before pregnancy *to promote a positive pregnancy outcome.*
- Review self-care practices (blood glucose monitoring and frequency of testing; insulin administration; adjustment of insulin dosages based on blood glucose levels) *to foster independence in self-care and feelings of control over the situation.*
- Refer client for dietary counseling *to ensure optimal diet for glycemic control.*
- Outline obstetric management and fetal surveillance needed for pregnancy *to provide client with information on what to expect.*
- Discuss strategies for maintaining optimal glycemic control during pregnancy *to minimize risks to client and fetus.*

Nursing Care Plan 20.1 (continued)

NURSING DIAGNOSIS: Anxiety related to future pregnancy and its outcome secondary to underlying diabetes as evidenced by questions about her condition's effect on the baby and baby being normal

Outcome Identification and Evaluation

Client will openly express her feelings related to her diabetes and pregnancy *as evidenced by statements of feeling better about her pre-existing condition and pregnancy outlook, and statements of understanding related to future childbearing by linking good glucose control with positive outcomes for both herself and offspring.*

Interventions: Minimizing Anxiety

- Review the need for a physical examination *to evaluate for any effects of diabetes on the client's health status.*
- Explain the rationale for assessing client's blood pressure, vision, and peripheral pulses at each visit *to provide information related to possible effects of diabetes on health status.*
- Identify any alterations in present diabetic condition that need intervention *to aid in minimizing risks that may increase client's anxiety level.*
- Review potential effects of diabetes on pregnancy *to promote client understanding of risks and ways to control or minimize them.*
- Encourage active participation in decision making and planning pregnancy *to promote feelings of control over the situation and foster self-confidence.*
- Discuss feelings about future childbearing and managing pregnancy *to help reduce anxiety related to uncertainties.*
- Encourage client to ask questions or voice concerns *to help decrease anxiety related to the unknown.*
- Emphasize the use of frequent and continued surveillance of client and fetal status during pregnancy *to reduce the risk of complications and aid in alleviating anxieties related to the unknown.*
- Provide positive reinforcement for healthy behaviors and actions *to foster continued use and enhancement of self-esteem.*

therapy, assist with any changes needed if glucose levels are not controlled.

Obtain a urine specimen and check for glucose, protein, and ketones. Ask the woman if she has had any episodes of hypoglycemia and what she did to alleviate them.

Discuss dietary measures related to blood glucose control (Fig. 20.2). In addition, recommend the following:

- Avoid weight loss and dieting during pregnancy.
- Ensure that food intake is adequate to prevent ketone formation and promote weight gain.
- Eat three meals a day plus three snacks to promote glycemic control.
  - –40% of calories from good-quality complex carbohydrates
  - –35% of calories from protein sources
  - –25% of calories from unsaturated fats (ADA, 2007b)

▶ *Take* NOTE!

Nutrient requirements and recommendations for weight gain for the pregnant woman with diabetes are the same as those for the pregnant nondiabetic woman.

If necessary, arrange for consultation with a dietitian or nutritionist to individualize the dietary plan. Also encourage the women to participate in an exercise program that includes at least three sessions lasting longer than 15 minutes per week. Exercise may lessen the need for insulin or dosage adjustments.

When caring for the laboring woman with pregestational or gestational diabetes, adjust the intravenous flow rate and the rate of supplemental regular insulin based on

FIGURE 20.2 The pregnant client eating a nutritious meal to ensure adequate glucose control.

the blood glucose levels as ordered. Monitor blood glucose levels every 1 to 2 hours or more frequently if necessary. Keep a syringe with 50% dextrose solution available at the bedside to treat profound hypoglycemia. Monitor fetal heart rate patterns throughout labor to detect nonreassuring patterns. Assess maternal vital signs every hour, in addition to assessing the woman's urinary output with an indwelling catheter. If a cesarean birth is scheduled, monitor the woman's blood glucose levels hourly and administer short-acting insulin or glucose based on the blood glucose levels as ordered.

After birth, monitor blood glucose levels every 2 to 4 hours and continue intravenous fluid administration as ordered. Encourage breastfeeding to assist in maintaining good glucose control. For the woman with pregestational diabetes and type 1 or 2 diabetes, expect insulin needs to decrease rapidly after birth: they may be reduced by half of the antepartum dose as meals are started (Hackley, Kriebs, & Rousseau, 2007). Some women may return to their prepregnancy insulin dosage.

The therapy plan after childbirth is individualized for each woman. If recommended dietary modifications are carried out along with weight loss, the woman with gestational diabetes may return to her normal glucose levels. This is also true for the woman with pregestational diabetes, except that she will return to her prepregnancy insulin administration levels. This provides the nurse with a wonderful opportunity to reinforce healthy lifestyle interventions on the postpartum unit. Nurses can also become involved with community-based education to continue to offer their expertise.

Preventing Complications

Assess the woman closely for signs and symptoms of complications at each visit. Anticipate possible complications and plan appropriate interventions or referrals. Check the woman's blood pressure for changes and evaluate for proteinuria when obtaining a urine specimen. These might suggest the development of preeclampsia. Measure fundal height and review gestational age. Note any discrepancies between fundal height and gestational age or a sudden increase in uterine growth. These may suggest hydramnios.

Encourage the woman to perform daily fetal movement counts to monitor fetal well-being. Tell her specifically when she should notify her health care provider. Also prepare the woman for the need for frequent laboratory and diagnostic testing to evaluate fetal status. Assist with serial ultrasounds to monitor fetal growth and with nonstress tests and biophysical profiles to assess fetal well-being.

Providing Client Education and Counseling

The pregnant woman with diabetes requires counseling and education about the need for strict glucose monitoring, diet and exercise, and signs and symptoms of complications. Encourage the client and her family to make any lifestyle changes needed to optimize the pregnancy outcome. Providing dietary education and lifestyle advice that extends beyond pregnancy may lower the risk that the woman will have gestational diabetes in subsequent pregnancies as well as type 2 diabetes (Scollan-Koliopoulos, Guadagno, & Walker, 2006). At each visit stress the importance of performing blood glucose screening and documenting the results. With proper instruction, the client and her family will be able to cope with all the changes in her body during pregnancy (Teaching Guidelines 20.1).

Review discussions about the timing of birth and the rationale. Counsel the client about the possibility of cesarean birth for an LGA infant, or inform the woman who will be giving birth vaginally about the possible need for augmentation with oxytocin (Pitocin).

▶ *Take* NOTE!

In the woman with well-controlled diabetes, birth is typically not induced before term unless there are complications, such as preeclampsia or fetal compromise. An early delivery date might be set for the woman with poorly controlled diabetes who is having complications.

Instruct the client about the benefits of breastfeeding related to blood glucose control. Breastfeeding helps to normalize blood glucose levels. Therefore, encourage the woman to breastfeed her newborn. Also teach the woman receiving insulin for her diabetes that her insulin needs after birth will drastically decrease. Inform her that she will need a repeat glucose challenge test at a postpartum visit (ADA, 2007b).

For the woman with gestational diabetes, the focus is on lifestyle education. Women with gestational diabetes have a greater than 50% increased risk of developing type 2 diabetes (ADA, 2007a). Inform the woman that screening most likely will be done at the postpartum follow-up appointment in 6 weeks. Women with normal results at that visit typically are screened every 3 years thereafter (ADA, 2007a). Teach her how to maintain an optimal weight to reduce her risk of developing diabetes. If necessary, refer the woman to a dietitian to help outline a balanced nutritious diet.

Cardiovascular Disorders

Every minute, an American woman dies of cardiovascular disease (American Heart Association [AHA], 2007). Cardiovascular disease is the leading cause of death for men and women in the United States. It kills nearly 500,000 women each year. Despite the prominent reduction in cardiovascular mortality among men, the rate has not declined for women. Cardiovascular disease has killed more women then men since 1984 (AHA, 2007). In addition to being the number-one killer of women, at

TEACHING GUIDELINES 20.1

Teaching for the Pregnant Woman With Diabetes

- Be sure to keep your appointments for frequent prenatal visits and tests for fetal well-being.
- Perform blood glucose self-monitoring as directed, usually before each meal and at bedtime. Keep a record of your results and call your healthcare provider with any levels outside the established range. Bring your results to each prenatal visit.
- Perform daily "fetal kick counts." Document them and report any decrease in activity.
- Drink 8 to 10 8-ounce glasses of water each day to prevent bladder infections and maintain hydration.
- Wear proper, well-fitted footwear when walking to prevent injury.
- Engage in a regular exercise program such as walking to aid in glucose control, but avoid exercising in temperature extremes.
- Consider breastfeeding your infant to lower your blood glucose levels.
- If you are taking insulin:
  - Administer the correct dose of insulin at the correct time every day.
  - Eat breakfast within 30 minutes after injecting regular insulin to prevent a reaction.
  - Plan meals at a fixed time and snacks to prevent extremes in glucose levels.
- Avoid simple sugars (cake, candy, cookies), which raise blood glucose levels.
- Know the signs and symptoms of hypoglycemia and treatment needed:
  - Sweating, tremors, cold, clammy skin, headache
  - Feeling hungry, blurred vision, disorientation, irritability
  - Treatment: Drink 8 ounces of milk and eat two crackers or glucose tablets
- Carry "glucose boosters" (such as Life Savers) to prevent hypoglycemia.
- Know the signs and symptoms of hyperglycemia and treatment needed:
  - Dry mouth, frequent urination, excessive thirst, rapid breathing
  - Feeling tired, flushed, hot skin, headache, drowsiness
  - Treatment: Notify health care provider, since hospitalization may be needed
- Wear a diabetic identification bracelet at all times.
- Wash your hands frequently to prevent infections.
- Report any signs and symptoms of illness, infection, and dehydration to your health care provider, because these can affect blood glucose control.

the time of diagnosis women have both a poorer overall prognosis and a higher risk of death than men diagnosed with heart disease (Peddicord, 2005). More women die of heart disease, stroke, and other cardiovascular diseases than men, yet many women do not realize they are at risk. These diseases kill more women each year than the next five causes of death combined (AHA, 2007).

Approximately 3% of pregnant women have cardiac disease, which is responsible for 10% to 25% of maternal deaths (Cunningham et al., 2005). The prevalence of cardiac disease is increasing as a result of lifestyle patterns, including cigarette smoking, diabetes, and stress. As women are delaying childbearing, the incidence of cardiac disease in pregnancy will continue to increase. Rheumatic heart disease used to represent the majority of cardiac conditions during pregnancy, but congenital heart disease now constitutes nearly half of all cases of heart disease encountered during pregnancy. Classic symptoms of heart disease mimic common symptoms of late pregnancy, such as palpitations, shortness of breath with exertion, and occasional chest pain. Few women with heart disease die during pregnancy, but they are at risk for other complications, such as heart failure, arrhythmias, and stroke. Their offspring are also at risk of complications, such as premature birth, low birthweight for gestational age, respiratory distress syndrome, intraventricular hemorrhage, and death (Abdin, 2006).

CONGENITAL AND ACQUIRED HEART DISEASE

Congenital heart disease often involves structural defects that are present at birth but may not be discovered at that time (Table 20.2). Until recently women with congenital heart disease didn't live long enough to bear children. Today, due to new surgical techniques to correct these defects, many of these women can complete a successful pregnancy at relatively low risk when appropriate counseling and optimal care are provided. Increasing numbers of women with complex congenital heart disease are reaching childbearing age. Complications such as growth restriction and preterm and premature birth and fetal and neonatal mortality are more common among children of women with congenital heart disease. The risk of complications is determined by the severity of the cardiac lesion, the presence of cyanosis, the maternal functional class, and the use of anticoagulation (Karamermer & Roos-Hesselink, 2007).

Women with certain congenital conditions should avoid pregnancy. These include uncorrected tetralogy of Fallot or transposition of the great arteries, and Eisenmenger's syndrome, a defect with both cyanosis and pulmonary hypertension (Karamermer & Roos-Hesselink, 2007).

TABLE 20.2 SELECTED HEART CONDITIONS AFFECTING PREGNANCY

Condition	Description	Management
Tetralogy of Fallot	Congenital defect involving four structural anomalies: obstruction to pulmonary flow; ventricular septal defect (abnormal opening between the right and left ventricles); dextroposition of the aorta (aortic opening overriding the septum and receiving blood from both ventricles); and right ventricular hypertrophy (increase in volume of the myocardium of the right ventricle) (O'Toole, 2005)	Hospitalization and bed rest possible after the 20th week with hemodynamic monitoring via a pulmonary artery catheter to monitor volume status Oxygen therapy may be necessary during labor and birth.
Atrial septal defect (ASD)	Congenital heart defect involving a communication or opening between the atria with left-to-right shunting due to greater left-sided pressure Arrhythmias present in some women	Treatment with atrioventricular nodal blocking agents, and at times with electrical cardioversion (Gilbert & Harmon, 2006)
Ventricular septal defect (VSD)	Congenital heart defect involving an opening in the ventricular septum, permitting blood flow from the left to the right ventricle. Complications include arrhythmias, heart failure, and pulmonary hypertension (McMahon, 2007).	Rest with limited activity if symptomatic
Patent ductus arteriosus	Abnormal persistence of an open lumen in the ductus arteriosus between the aorta and the pulmonary artery after birth; results in increased pulmonary blood flow and redistribution of flow to other organs (Hermes-DeSantis & Clyman, 2006)	Surgical ligation of the open ductus during infancy; subsequent problems minimal after surgical correction
Mitral valve prolapse	Very common in the general population, occurring most often in younger women Leaflets of the mitral valve prolapse into the left atrium during ventricular contraction. The most common cause of mitral valve regurgitation if present during pregnancy (Wooley & Boudoulas, 2007) Usually improvement in mitral valve function due to increased blood volume and decreased systemic vascular resistance of pregnancy; most women are able to tolerate pregnancy well.	Most women are asymptomatic; diagnosis is made incidentally. Occasional palpations, chest pain, or arrhythmias in some women, possibly requiring beta-blockers Usually no special precautions are necessary during pregnancy.
Mitral valve stenosis	Most common chronic rheumatic valvular lesion in pregnancy Causes obstruction of blood flow from the atria to the ventricle, thereby decreasing ventricular filling and causing a fixed cardiac output Resultant pulmonary edema, pulmonary hypertension, and right ventricular failure (Barker et al., 2006) Most pregnant women with this condition can be managed medically.	General symptomatic improvement with medical management involving diuretics, beta-blockers, and anticoagulant therapy Activity restriction, reduction in sodium, and potentially bed rest if condition severe

(continued)

TABLE 20.2 SELECTED HEART CONDITIONS AFFECTING PREGNANCY (continued)

Condition	Description	Management
Aortic stenosis	Narrowing of the opening of the aortic valve, leading to an obstruction to left ventricular ejection (Balentine & Eisenhart, 2008). Women with mild disease can tolerate hypervolemia of pregnancy; with progressive narrowing of the opening, cardiac output becomes fixed. Diagnosis can be confirmed with echocardiography. Most women can be managed with medical therapy, bed rest, and close monitoring.	Diagnosis confirmed with echocardiography Pharmacologic treatment with beta-blockers and/or antiarrhythmic agents to reduce risk of heart failure and/or dysrhythmias Bed rest/limited activity and close monitoring
Peripartum cardiomyopathy	Rare congestive cardiomyopathy that may arise during pregnancy. Multiparity, age, multiple fetuses, hypertension, an infectious agent, autoimmune disease, or cocaine use may contribute to its presence (Mooney, 2007). Development of heart failure in the last month of pregnancy or within 5 months of giving birth without any preexisting heart disease or any identifiable cause	Preload reduction with diuretic therapy Afterload reduction with vasodilators Improvement in contractility with inotropic agents Nonpharmacologic approaches include salt restriction and daily exercise such as walking or biking. The question of whether another pregnancy should be attempted is controversial due to the high risk of repeat complications.
Myocardial infarction	Rare during pregnancy but incidence is expected to increase as older women are becoming pregnant and the risk factors for coronary artery disease become more prevalent Factors contributing to MI include family history, stress, smoking, age, obesity, multiple fetuses, hypercholesterolemia, and cocaine use (Gibson & Carson, 2007). Increased plasma volume and cardiac output during pregnancy increase the cardiac workload as well as the myocardial oxygen demands; imbalance in supply and demand may contribute to myocardial ischemia.	Usual treatment modalities for any acute MI along with consideration for the fetus Anticoagulant therapy, rest, and lifestyle changes to preserve the health of both parties

Sources: Balentine & Eisenhart, 2008; Gibson & Carson, 2007; McMahon, 2007; Mooney, 2007; O'Toole, 2005.

Acquired heart disease is typically rheumatic in origin (see Table 20.2). The incidence of rheumatic heart disease has declined dramatically in the past several decades because of prompt identification of streptococcal throat infections and treatment with antibiotics. When the heart is involved, valvular lesions such as mitral stenosis, prolapse, or aortic stenosis are common.

Many women are postponing childbearing until the fourth or fifth decade of life. With advancing maternal age, underlying medical conditions such as hypertension, diabetes, and hypercholesterolemia contributing to ischemic heart disease become more common and increase the incidence of acquired heart disease complicating pregnancy. Coronary artery disease and myocardial infarction may result.

A woman's ability to function during the pregnancy is often more important than the actual diagnosis of the cardiac condition. The following is a functional classification

system developed by the Criteria Committee of the New York Heart Association (1994) based on past and present disability and physical signs:

- Class I: asymptomatic with no limitation of physical activity
- Class II: symptomatic (dyspnea, chest pain) with increased activity
- Class III: symptomatic (fatigue, palpitations) with normal activity
- Class IV: symptomatic at rest or with any physical activity

The classification may change as the pregnancy progresses and the woman's body must cope with the increasing stress on the cardiovascular system resulting from the numerous physiologic changes taking place. Typically, a woman with class I or II cardiac disease can go through a pregnancy without major complications. A woman with class III disease usually has to maintain bed rest during pregnancy. A woman with class IV disease should avoid pregnancy (McCann, 2007). Women with cardiac disease may benefit from preconception counseling so that they know the risks before deciding to become pregnant.

Maternal mortality varies directly with the functional class at pregnancy onset. ACOG has adopted a three-tiered classification according to the risk of death during pregnancy (Box 20.1).

BOX 20.1 Classification of Maternal Mortality Risk

Group I (minimal risk) has a mortality rate of 1% and comprises women with:
- Patent ductus arteriosus
- Tetralogy of Fallot, corrected
- Atrial septal defect
- Ventricular septal defect
- Mitral stenosis, class I and II

Group II (moderate risk) has a mortality rate of 5% to 15% and comprises women with:
- Tetralogy of Fallot, uncorrected
- Mitral stenosis with atrial fibrillation
- Aortic stenosis, class III and IV
- Aortic coarctation without valvular involvement
- Artificial valve replacement

Group III (major risk) has a 25% to 50% mortality rate and comprises women with:
- Pulmonary hypertension
- Complicated aortic coarctation
- Previous myocardial infarction

Sources: Gilbert & Harmon, 2006; Gilbert, 2007; Blackburn, 2007.

Pathophysiology

Numerous hemodynamic changes occur in all pregnant women. These normal physiologic changes can overstress the woman's cardiovascular system, increasing her risk for problems. Increased cardiac workload and greater myocardial oxygen demand during pregnancy place the woman's cardiovascular system at high risk for morbidity and mortality.

▶ *Take* NOTE!

Uterine blood flow increases by at least 1 liter per minute, requiring the body to produce more blood during pregnancy. This results in a 25% increase in red blood cells, a 50% expansion of plasma volume during pregnancy, and an overall hemodilution. In addition, the increase in total red blood cellular volume includes an increase in clotting factors and platelets, defining the hypercoagulable state of pregnancy (Dobbenga-Rhodes & Prive, 2006). These changes start as early as the second month of gestation.

Similarly, cardiac output increases steadily during pregnancy by 30% to 50% over prepregnancy levels: stroke volume increases 20% to 30% from prepregnant levels, and the maternal heart rate increases by 10 to 20 beats per minute. The increase is due to both the expansion in blood volume and the augmentation of stroke volume and heart rate. Other hemodynamic changes associated with pregnancy include a decrease in both the systemic vascular resistance and pulmonary vascular resistance, thereby lowering the systolic and diastolic blood pressure. In addition, the hypercoagulability associated with pregnancy might increase the risk of arterial thrombosis and embolization. These normal physiologic changes are important for a successful adaptation to pregnancy but create unique physiologic challenges for the woman with cardiac disease (Comparison Chart 20.1).

Therapeutic Management

Ideally, a woman with a history of congenital or acquired heart disease should consult her health care provider before becoming pregnant and should undergo a risk assessment. This risk assessment must consider the woman's functional capacity, exercise tolerance, degree of cyanosis, medication needs, and history of arrhythmias. Data needed for risk assessment can be acquired from a thorough cardiovascular history and examination, a 12-lead electrocardiogram (ECG), and evaluation of oxygen saturation levels by pulse oximetry. The impact of heart disease on a woman's childbearing potential needs to be clearly explained, and information on how pregnancy may affect her and the fetus is important. This allows women to make an informed choice

COMPARISON CHART 20.1 CARDIOVASCULAR CHANGES: PREPREGNANCY VS PREGNANCY

Measurement	Prepregnancy	Pregnancy
Heart rate	72 (±10 bpm)	+10–20%
Cardiac output	4.3 (±0.9 L/min)	+30% to 50%
Blood volume	5 L	+20% to 50%
Stroke volume	73.3 (±9 mL)	+30%
Systemic vascular resistance	1,530 (±520 dyne/cm/sec)	–20%
Oxygen consumption	250 mL/minute	+20–30%

Sources: Blincoe, 2007; Blackburn, 2007; Harvey, 2007.

whether they wish to accept the risks associated with pregnancy. When possible, any surgical procedures, such as valve replacement, should be done before pregnancy to improve fetal and maternal outcomes (Uebing et al., 2006).

If the woman presents for care after she has become pregnant, prenatal counseling focuses on the impact of the hemodynamic changes of pregnancy, the signs and symptoms of cardiac compromise, and dietary and lifestyle changes needed. More frequent prenatal visits (every 2 weeks until the last month and then weekly) are usually needed to ensure the health and safety of the mother and fetus.

Nursing Assessment

Frequent and thorough assessments are crucial during the antepartum period to ensure early detection of and prompt intervention for problems. Assess the woman's vital signs, noting any changes. Auscultate the apical heart rate and heart sounds, being especially alert for abnormalities, including irregularities in rhythm or murmurs. Check the client's weight and compare to baseline and weights obtained on previous visits. Report any weight gain outside recommended parameters. Inspect the extremities for edema and note any pitting.

Question the woman about fetal activity, and ask if she has noticed any changes. Report any changes such as a decrease in fetal movements. Ask the woman about any symptoms of preterm labor, such as low back pain, uterine contractions, and increased pelvic pressure and vaginal discharge, and report them immediately. Assess the fetal heart rate and review serial ultrasound results to monitor fetal growth.

Assess the client's lifestyle and her ability to cope with the changes of pregnancy and its effect on her cardiac status and ability to function. Evaluate the client's understanding of her condition and what restrictions and lifestyle changes may be needed to provide the best outcome for her and her fetus. A healthy infant and mother at the end of pregnancy is the ultimate goal. As the client's pregnancy advances, expect her functional class to be revised based on her level of disability. Suggest realistic modifications.

The nurse plays a major role in recognizing the signs and symptoms of cardiac decompensation. Decompensation refers to the heart's inability to maintain adequate circulation. As a result, tissue perfusion in the mother and the fetus is impaired. The pregnant woman is most vulnerable for this complication from 28 to 32 weeks of gestation and in the first 48 hours postpartum (Witcher & Harvey, 2006). Assess the woman for the following signs and symptoms:

- Shortness of breath on exertion, dyspnea
- Cyanosis of lips and nail beds
- Swelling of face, hands, and feet
- Jugular vein engorgement
- Rapid respirations
- Abnormal heartbeats, reports of heart racing or palpitations
- Chest pain with effort or emotion
- Syncope with exertion
- Increasing fatigue
- Moist, frequent cough

▶ ***Take*** *NOTE!*

Assessing the pregnant woman with heart disease for cardiac decompensation is vital because the mother's hemodynamic status determines the health of the fetus.

Nursing Management

Nursing management of the pregnant woman with heart disease focuses on assisting with measures to stabilize the mother's hemodynamic status, because a decrease in maternal blood pressure or volume will cause blood to be shunted away from the uterus, thus reducing placental perfusion. Pregnant women with cardiac disease also need assistance in reducing risks that would lead to complications or further cardiac compromise. Therefore, education and counseling are critical. Collaboration between the cardiologist, obstetrician, perinatologist, and nurse is needed to promote the best possible outcome.

Encourage the woman to continue taking her cardiac medications as prescribed. Review the indications, actions, and potential side effects of the medications. Reinforce the importance of frequent antepartal visits and close medical supervision throughout the pregnancy.

Discuss the need to conserve energy. Help the client to prioritize household chores and childcare to allow rest periods. Encourage the client to rest in the side-lying position, which enhances placental perfusion.

Encourage the client to eat nutritious foods and consume a high-fiber diet to prevent straining and constipation. Discuss limiting sodium intake if indicated to reduce fluid retention. Contact a dietitian to assist the woman in planning nutritionally appropriate meals.

Assist the woman in preparing for diagnostic tests to evaluate fetal well-being. Describe the tests that may be done, such as ECG and echocardiogram, and explain the need for serial nonstress testing, usually beginning at approximately 32 weeks.

Instruct the woman in how to monitor fetal activity and movements. Urge her to do this daily and report any changes in activity immediately.

Although the morbidity and mortality rates of pregnant women with cardiac disease have decreased greatly, congestive heart failure, cardiac arrhythmia, thromboembolism, angina, hypoxemia, and infective endocarditis can occur (Witcher & Harvey, 2006). Explain the signs and symptoms of these complications and review the sign and symptoms of cardiac decompensation, encouraging the woman to notify her health care provider if any occur.

Provide support and encouragement throughout the antepartal period. Assess the support systems available to the client and her family, and encourage her to use them. If necessary, assist with referrals to community services for additional support.

During labor, anticipate the need for invasive hemodynamic monitoring, and make sure the woman has been prepared for this beforehand. Monitor her fluid volume carefully to prevent overload. Anticipate the use of epidural anesthesia if a vaginal birth is planned. After birth, assess the client for fluid overload as peripheral fluids mobilize. This fluid shift from the periphery to the central circulation taxes the heart, and signs of heart failure such as cough, progressive dyspnea, edema, palpitations, and crackles in the lung bases may ensue before postpartum diuresis begins. Because hemodynamics do not return to baseline for several days after childbirth, women at intermediate or high risk require monitoring for at least 48 hours postpartum (Barker et al., 2006).

CHRONIC HYPERTENSION

Chronic hypertension exists when the woman has high blood pressure before pregnancy or before the 20th week of gestation, or when hypertension persists for more than 12 weeks postpartum. The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC, 2003) has classified blood pressure as follows:

- Normal: systolic less than 120 mmHg, diastolic less than 80 mmHg
- Prehypertension: systolic 120 to 139 mmHg, diastolic 80 to 89 mmHg
- Mild hypertension: systolic 140 to 159 mmHg, diastolic 90 to 99 mmHg
- Severe hypertension: systolic 160 mm Hg or higher, diastolic 100 mm Hg or higher

Chronic hypertension occurs in up to 22% of women of childbearing age, with the prevalence varying according to age, race, and BMI. It complicates at least 5% of pregnancies, with 1 in 4 women developing preeclampsia during pregnancy (Blincoe, 2007). Chronic hypertension is typically seen in older, obese women with glucose intolerance. The most common complication is preeclampsia, which is seen in approximately 25% of women who enter the pregnancy with hypertension (Podymow & August, 2007; Tihtonen et al., 2007). (See Chapter 19 for more information about preeclampsia.)

Therapeutic Management

Preconception counseling is important in fostering positive outcomes. Typically, it involves lifestyle changes such as diet, exercise, weight loss, and smoking cessation.

Treatment for women with chronic hypertension focuses on maintaining normal blood pressure, preventing superimposed preeclampsia/eclampsia, and ensuring normal fetal development. Once the woman is pregnant, antihypertensive agents are typically reserved for severe hypertension (150 to 160 mmHg/100 to 110 mmHg). Methyldopa (Aldomet) is commonly prescribed because of its safety record during pregnancy. This slow-acting antihypertensive agent helps to improve uterine perfusion. Other antihypertensive agents that can be used include labetalol (Transdate), atenolol (Tenorium), and nifedipine (Procardia) (Gibson & Carson, 2007).

Lifestyle changes are needed and should continue throughout gestation. The woman with chronic hypertension will be seen more frequently (every 2 weeks until 28 weeks and then weekly until birth) to monitor her blood pressure and to assess for any signs of preeclampsia. At approximately 24 weeks' gestation, the woman will be instructed to document fetal movement. At this same time, serial ultrasounds will be ordered to monitor fetal growth and amniotic fluid volume. Additional tests will be included if the client's status changes.

Nursing Assessment

Nursing assessment of the woman with chronic hypertension involves a thorough history and physical examination. Review the woman's history closely for risk factors. The

pathogenesis of hypertension is multifactorial and includes many modifiable risk factors such as smoking, obesity, caffeine intake, excessive alcohol intake, excessive salt intake, and use of nonsteroidal anti-inflammatory drugs. Also be alert for nonmodifiable risk factors such as increasing age and African-American race (Sharp, 2006). Ask if the woman has received any preconceptual counseling and what measures have been used to prevent or control hypertension.

Assess the woman's vital signs, in particular her blood pressure. Evaluate her blood pressure in all three positions (sitting, lying, and standing) and note any major differences in the readings. Assess her for orthostatic hypertension when she changes her position from sitting to standing. Document your findings.

Ask the woman if she monitors her blood pressure at home; if so, inquire about the typical readings. Ask the woman if she uses any medications for blood pressure control, including the drug, dosage, and frequency of administration, as well as any side effects. Ask the woman about lifestyle modifications that she has used to address any modifiable risk factors, and their effectiveness.

Hypertension during pregnancy decreases uteroplacental perfusion. Therefore, fetal well-being must be assessed and closely monitored. Anticipate serial ultrasounds to assess fetal growth and amniotic fluid volume. Question the woman about fetal movement and evaluate her report of daily "kick counts." Assess fetal heart rate at every visit.

Nursing Management

Preconception counseling is the ideal time to discuss lifestyle changes to prevent or control hypertension. One area to cover during this visit would be the Dietary Approaches to Stop Hypertension (DASH) diet, which contains an adequate intake of potassium, magnesium, and calcium. Sodium is usually limited to 2.4 g. Suggest aerobic exercise, although the woman should cease it once the pregnancy is confirmed. Encourage smoking cessation and avoidance of alcohol. If the woman is overweight, encourage her to lose weight before becoming pregnant, not during the pregnancy (Dudek, 2006). Stressing the positive benefits of a healthy lifestyle might help motivate the woman to make the modifications and change unhealthy habits.

Assist the woman in scheduling appointments for antepartum visits every 2 weeks until 28 weeks' gestation and then weekly. Prepare the woman for frequent fetal assessments. Explaining the rationale for the need to monitor fetal growth is important to gain the woman's cooperation. Carefully monitor the woman for signs and symptoms of abruptio placentae (abdominal pain, rigid abdomen, vaginal bleeding), as well as superimposed preeclampsia (elevation in blood pressure, weight gain, edema, proteinuria). Alerting the woman to these risks allows early identification and prompt intervention.

Stress the importance of daily periods of rest (1 hour) in the left lateral recumbent position to maximize placental perfusion. Encourage women with chronic hypertension to use home blood pressure monitoring devices. Urge the woman to report any elevations. As necessary, instruct the woman and her family how to take and record a daily blood pressure, and reinforce the need for her to take her medications as prescribed to control her blood pressure and to ensure the well-being of her unborn child. Praising her for her efforts at each prenatal visit may motivate her to continue the regimen throughout her pregnancy.

The close monitoring of the woman with chronic hypertension continues during labor and birth and during the postpartum period to prevent or identify the onset of preeclampsia. Accurate and frequent blood pressure readings and careful administration of antihypertensive medications, if prescribed, are essential components of care. Stressing the need for continued medical supervision after childbirth is vital to motivate the woman to maintain or initiate lifestyle changes and dietary habits and stay compliant with her medication regimen.

Respiratory Conditions

During pregnancy, the respiratory system is affected by hormonal changes, mechanical changes, and prior respiratory conditions. These changes can cause a woman with a history of compromised respiration to decompensate during pregnancy. While upper respiratory infections are typically self-limiting, chronic respiratory conditions, such as asthma or tuberculosis, can have a negative effect on the growing fetus when alterations in oxygenation occur in the mother. The outcome of pregnancy in a woman with a respiratory condition depends on the severity of the oxygen alteration as well as the degree and duration of hypoxia on the fetus.

ASTHMA

Asthma affects approximately 1% to 4% of pregnancies. It affects 20 million Americans and is one of the most common and potentially serious medical conditions to complicate pregnancy (Arenson & Drake, 2007). Maternal asthma is associated with an increased risk of infant death, preeclampsia, intrauterine growth retardation (IUGR), preterm birth, and low birthweight. These risks are linked to the severity of asthma: more severe asthma increases the risk (National Asthma Education Prevention Program [NAEPP], 2007).

Remember Rose, the pregnant teenager with asthma in acute distress described at the beginning of the chapter? What therapies might be offered to control her symptoms? Should she be treated differently than someone who is not pregnant? Why or why not?

Pathophysiology

Asthma, an allergic-type inflammatory response of the respiratory tract to various stimuli, is also known as reactive airway disease because the bronchioles constrict in response to allergens, irritants, and infections. In addition to bronchoconstriction, inflammation of the airways produces thick mucus that further limits the movement of air and makes breathing difficult.

The normal physiologic changes of pregnancy affect the respiratory system. While the respiratory rate does not change, hyperventilation increases at term by 48% due to high progesterone levels. Diaphragmatic elevation and a decrease in functional lung residual capacity occur late in pregnancy, which may reduce the woman's ability to inspire deeply to take in more oxygen. Oxygen consumption and the metabolic rate both increase, placing additional stress on the woman's respiratory system (American Academy of Allergy, Asthma, and Immunology [AAAAI], 2007).

Both the woman and her fetus are at risk if asthma is not well managed during pregnancy. When a pregnant woman has trouble breathing, her fetus also has trouble getting the oxygen it needs for adequate growth and development. Severe persistent asthma has been linked to the development of maternal hypertension, preeclampsia, placenta previa, uterine hemorrhage, and oligohydramnios. Women whose asthma is poorly controlled during pregnancy are at increased risk of preterm birth, low birthweight, and stillbirth (Hackley, Kriebs, & Rousseau, 2007).

The severity of the condition improves in one third of pregnant women, remains unchanged in one third, and worsens in one third (Hackley, Kriebs, & Rousseau, 2007). However, the effect of pregnancy on asthma is unpredictable. The greatest increase in asthma attacks usually occurs between 24 and 36 weeks' gestation; flare-ups are rare during the last 4 weeks of pregnancy and during labor (AAAAI, 2007).

Therapeutic Management

Asthma should be treated as aggressively in pregnant women as in nonpregnant women because the benefits of averting an asthma attack outweigh the risks of medications. The goals of treatment are to prevent hospitalization, emergency room visits, work loss, and chronic disability. NAEPP recommends three specific drugs to be used during pregnancy to control asthma:

- Budesonide (inhaled-corticosteroid)
- Albuterol (short-acting beta2 agonist)
- Salmeterol (long-acting beta2 agonist)

Oral corticosteroids are not recommended for the treatment of asthma during pregnancy, but they can be used to treat severe asthma attacks during pregnancy (AAAAI, 2007).

Nursing Assessment

Obtain a thorough history of the disease, including the woman's usual therapy and control measures. Question the woman about asthma triggers and strategies used to reduce exposure to them (Box 20.2). Review the client's medication therapy regimen.

Auscultate the lungs and assess respiratory and heart rates. Include the rate, rhythm, and depth of respirations; skin color; blood pressure and pulse rate; and signs of fatigue. Patients with an acute asthma attack often present with wheezing, chest tightness, tachypnea, nonproductive coughing, shortness of breath, and dyspnea. Lung auscultation findings might include diffuse wheezes and rhonchi, bronchovesicular sounds, and a more prominent expiratory phase of respiration compared to the inspiratory phase (More, 2007). If the pregnancy is far enough along, the fetal heart rate is measured and routine prenatal assessments (weight, blood pressure, fundal height, urine for protein) are completed.

Laboratory studies usually include a complete blood count with differential (to assess the degree of nonspecific inflammation and identify anemia) and pulmonary function tests (to assess the severity of an attack and to provide a baseline to evaluate the client's response to treatment).

Nursing Management

Nursing management focuses on client education about the condition and the skills necessary to manage it: self-monitoring, correct use of inhalers, identifying and limiting exposure to asthma triggers, and following a long-term plan for managing asthma and for promptly handling signs and symptoms of worsening asthma. Client education fosters adherence to the treatment regimen, thereby promoting an optimal environment for fetal growth and development.

Ensure that the woman understands drug actions and interactions, the uses and potential abuses of asthma

BOX 20.2 Common Asthma Triggers

- Smoke and chemical irritants
- Air pollution
- Dust mites
- Animal dander
- Seasonal changes with pollen, molds, and spores
- Upper respiratory infections
- Esophageal reflux
- Medications, such as aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs)
- Exercise
- Cold air
- Emotional stress

Sources: AAAAI, 2007; Little & Sinert, 2008; Gilbert, 2007.

medications, and the signs and symptoms that require medical evaluation. Reviewing potential perinatal complications with the woman is helpful in motivating her to adhere to the prescribed regimen. At each antepartum visit, reassess the efficacy of the treatment plan to determine whether adjustments are needed.

Taking control of asthma in pregnancy is the responsibility of the client along with her health care team. Providing the client with the knowledge and tools to monitor her condition, control triggers and her environment (Teaching Guidelines 20.2), and use medications to prevent acute exacerbations assist the client in taking control. Facilitating a partnership with the woman will improve perinatal outcomes.

When teaching the pregnant woman with asthma, cover the following topics:

- Signs and symptoms of asthma progression and exacerbation
- Importance and safety of medication to the fetus and to herself
- Warning signs that indicate the need to contact the health care provider
- Potential harm to the fetus and to herself by undertreatment or delay in seeking help
- Prevention and avoidance of known triggers
- Home use of metered-dose inhalers
- Adverse effects of medications

During labor, monitor the client's oxygenation saturation by pulse oximetry and provide pain management through epidural analgesia to reduce stress, which may trigger an acute attack. Continuously monitor the fetus for distress during labor and assess fetal heart rate patterns for hypoxia. Assess the newborn for signs and symptoms of hypoxia.

TEACHING GUIDELINES 20.2

Teaching to Control Environmental Triggers

- Remove any carpeting in the house, especially the bedroom, to reduce dust mites.
- Use allergen-proof encasing on the mattress, box spring, and pillows.
- Wash all bedding in hot water.
- Remove dust collectors in house, such as stuffed animals, books, knick-knacks.
- Avoid pets in the house to reduce exposure to pet dander.
- Use a high-efficiency particulate air-filtering system in the bedroom.
- Do not smoke, and avoid places where you can be exposed to passive cigarette smoke from others.
- Stay indoors and use air conditioning when the pollen or mold count is high or air quality is poor.
- Wear a covering over your nose and mouth when going outside in the cold weather.
- Avoid exposure to persons with colds, flu, or viruses.

Take NOTE!

Successful asthma management can reduce adverse perinatal outcomes: preeclampsia, preterm birth, and low birthweight.

Rose, the pregnant teenager described earlier, is concerned about passing her asthma on to her baby. What should the nurse discuss with her? What questions should the nurse ask to help in identifying triggers in Rose's environment to prevent future asthma attacks?

TUBERCULOSIS

Tuberculosis (TB) is a disease that has been around for years but never seems to go away completely. Globally, TB is second only to HIV/AIDS as a cause of illness and death in adults, accounting for over 9 million cases of active disease and 2 million deaths each year. Someone in the world is newly infected with TB every second. Overall, one third of the world's population is currently infected with TB (World Health Organization [WHO], 2007). Although it is not prevalent in the United States, a resurgence was noted starting in the mid-1980s secondary to the AIDS epidemic and immigration. Left undiagnosed and untreated, each person with active TB will infect on average between 10 and 15 people each year (WHO, 2007). With the large numbers of immigrants coming to the United States, all nurses must be skilled in screening for and managing this condition.

A person becomes infected by inhaling the infectious organism, *Mycobacterium tuberculosis,* which is carried on a droplet nuclei and spread by airborne transmission. The lung is the major site of involvement, but the lymph glands, meninges, bones, joints, and kidneys can become infected. Women can remain asymptomatic for long periods of time as the organism may lie dormant. Pregnant women with untreated TB are more likely to have preeclampsia, miscarriage, preterm labor, an underweight infant, an infant with a low Apgar score, and perinatal death (Bothamley, 2006). The newborn is at risk of postnatally acquired TB if the mother still has active TB at the time of birth. Therefore, prenatal diagnosis and effective treatment of the mother are essential.

Therapeutic Management

Therapeutic management of TB during pregnancy is essentially the same as that for the general population. Medications are the cornerstone of treatment to prevent infection from progressing. The medical therapy for pregnant women is a combination of medications such as isoniazid, rifampin, and ethambutol, taken daily for up to 9 months. These anti-TB agents appear to have minimal teratogenic risks and may be started as soon as the diagnosis of TB is made. However, extensive research has not been done to determine the definitive safety of these drugs (Herchline & Amorosa, 2007).

Nursing Assessment

Review the woman's history for risk factors such as immunocompromised status, recent immigration status, homelessness or overcrowded living conditions, and injectable drug use. Women emigrating from developing countries such as Latin America, Asia, the Indian subcontinent, Eastern Europe, Russia, China, Mexico, Haiti, and Africa with high rates of TB also are at risk.

At antepartum visits, be alert for clinical manifestations of TB, including fatigue, fever or night sweats, nonproductive cough, slow weight loss, anemia, hemoptysis, and anorexia (Noyes & Popay, 2007). If TB is suspected or the woman is at risk for developing TB, anticipate screening with purified protein derivative (PPD) administered by intradermal injection. If the client has been exposed to TB, a reddened induration will appear within 72 hours. If the test is positive, anticipate a follow-up chest x-ray with lead shielding over the abdomen and sputum cultures to confirm the diagnosis.

Nursing Management

Compliance with the multidrug therapy is critical to protect the woman and her fetus from progression of TB. Provide education about the disease process, the mode of transmission, prevention, potential complications, and the importance of adhering to the treatment regimen.

Stressing the importance of health-promotion activities throughout the pregnancy is important. Some suggestions might include avoiding crowded living conditions, avoiding sick people, maintaining adequate hydration, eating a nutritious, well-balanced diet, keeping all prenatal appointments to evaluate fetal growth and well-being, and getting plenty of fresh air by going outside frequently. Determining the woman's understanding of her condition and treatment plan is important for compliance. A language interpreter may be needed to validate and reinforce her understanding if she does not speak English.

Breastfeeding is not contraindicated during the medication regimen and should in fact be encouraged. Management of the newborn of a mother with TB involves preventing transmission by teaching the parents not to cough, sneeze, or talk directly into the newborn's face. Nurses need to stay current about new therapies and screening techniques to treat this centuries-old disease.

Hematologic Conditions

Anemia, a reduction in red blood cell volume, is measured by hematocrit (Hct) or a decrease in the concentration of hemoglobin (Hgb) in the peripheral blood. This results in reduced capacity of the blood to carry oxygen to the vital organs of the mother and fetus. Anemia is a sign of an underlying problem but does not indicate its origin.

IRON DEFICIENCY ANEMIA

Iron deficiency anemia affects one in four pregnancies and is usually related to an inadequate dietary intake of iron (McCann, 2007). It is a very common state in pregnant women. Anemia during the early part of pregnancy can increase the likelihood of preterm birth, low birthweight, and perinatal mortality (Blackburn, 2007). With significant maternal iron depletion, the fetus will attempt to store iron, but at the cost to the mother. Anemia at term increases the perinatal risk for both the mother and newborn. The risks of hemorrhage (impaired platelet function) and infection during and after birth also are increased.

Therapeutic Management

The goals of treatment for iron deficiency anemia in pregnancy are to eliminate symptoms, correct the deficiency, and replenish iron stores. The CDC recommends routine iron supplementation for all pregnant women at a low dose of 30 mg/day beginning at the first prenatal visit. Attempting to meet maternal iron requirements solely through diet in the face of diminished iron stores is difficult.

Nursing Assessment

Review the mother's history for factors that may contribute to the development of iron deficiency anemia, including poor nutrition, hemolysis, **pica** (consuming non-food substances), multiple gestation, limited intervals between pregnancies, and blood loss. Assess the woman's dietary intake as well as the quantity and timing of ingestion of substances that interfere with iron absorption, such as tea, coffee, chocolate, and high-fiber foods. Ask the woman if she has fatigue, weakness, malaise, anorexia, or increased susceptibility to infection, such as frequent colds. Inspect the skin and mucous membranes, noting any pallor. Obtain vital signs and report any tachycardia.

Prepare the woman for laboratory testing. Laboratory tests usually reveal low Hgb (<11 g/dL), low Hct (<35%), low serum iron (<30 ug/dL), microcytic and hypochromic cells, and low serum ferritin (<100 mg/dL).

▶ *Take* NOTE!

Hemoglobin and hematocrit decrease normally during pregnancy in response to an increase in blood plasma in comparison to red blood cells. This hemodilution can lead to physiologic anemia of pregnancy, which is expected in the second trimester of pregnancy. This hemodilution phenomenon should not be confused with an iron deficiency anemia, in which the Hgb would be below 11 g/100 mL and Hct below 35%.

Nursing Management

Nursing management of the woman with iron deficiency anemia focuses on encouraging compliance with drug therapy and providing dietary instruction about the intake of foods high in iron. Although iron constitutes a minimal percentage of the body's total weight, it has several major roles: it assists in the transport of oxygen and carbon dioxide throughout the body, it aids in the production of red blood cells, and it plays a role in the body's immune response.

Stress the importance of taking the prenatal vitamin and iron supplement consistently. Encourage the woman to take the iron supplement with vitamin C-containing fluids such as orange juice, which will promote absorption, rather than milk, which can inhibit iron absorption. Taking iron on an empty stomach improves its absorption, but many women cannot tolerate the gastrointestinal discomfort it causes. In such cases, advise the woman to take it with meals. Instruct the woman about adverse effects, which are predominantly gastrointestinal and include gastric discomfort, nausea, vomiting, anorexia, diarrhea, metallic taste, and constipation. Suggest that the woman take the iron supplement with meals and increase her intake of fiber and fluids to help overcome the most common side effects.

Provide dietary counseling. Recommend foods high in iron, such as dried fruits, whole grains, green leafy vegetables, meats, peanut butter, and iron-fortified cereals (Dudek, 2006). Anticipate the need for a referral to a dietitian. Teaching Guidelines 20.3 highlights instructions for the pregnant woman with iron deficiency anemia.

TEACHING GUIDELINES 20.3

Teaching for the Woman With Iron Deficiency Anemia

- Take your prenatal vitamin daily; if you miss a dose, take it as soon as you remember.
- For best absorption, take iron supplement between meals.
- Avoid taking iron supplement with coffee, tea, chocolate, and high-fiber food.
- Eat foods rich in iron, such as:
  - Meats, green leafy vegetables, legumes, dried fruits, whole grains
  - Peanut butter, bean dip, whole-wheat fortified breads and cereals
- For best iron absorption from foods, consume the food along with a food high in vitamin C.
- Increase your exercise, fluids, and high-fiber foods to reduce constipation.
- Plan frequent rest periods during the day.

THALASSEMIA

Thalassemia is a group of hereditary anemias in which synthesis of one or both chains of the hemoglobin molecule (alpha and beta) is defective. A low Hgb and a microcytic, hypochromic anemia result. The prevalence and severity of thalassemia depend on the woman's racial background: persons of Mediterranean, Asian, Italian, or Greek heritage and African-Americans are most frequently affected. Beta-thalassemia is the most common form found in the United States (Curran & Poggi, 2007).

Thalassemia occurs in two forms: alpha-thalassemia and beta-thalassemia. Alpha-thalassemia (minor), the heterozygous form, results from the inheritance of one abnormal gene from either parent, placing the offspring in a carrier trait state. These women have little or no hematologic disease and are clinically asymptomatic (silent carrier state). Beta-thalassemia (major) is the form involving inheritance of the gene from both parents. Beta-thalassemia major can be very severe. Genetic counseling might be necessary when decisions about childbearing are being made.

Thalassemia minor has little effect on the pregnancy, although the woman will have mild, persistent anemia. This anemia does not respond to iron therapy, and iron supplements should not be prescribed. Women with thalassemia major do not usually become pregnant because of lifelong severe hemolysis, anemia, and premature death (Hackley, Kriebs, & Rousseau, 2007).

Management of thalassemia during pregnancy depends on the severity of the disease. Identification and screening are important to plan care. The woman's ethnic background, medical history, and blood studies are analyzed. If the woman is determined to be a carrier, screening of the father of the child is indicated. Knowledge of the carrier state of each parent provides the genetic counselor with knowledge about the risk that the fetus will be a carrier or will have the disease (Curran & Poggi, 2007).

Mild anemia may be present, and instructions to rest and avoid infections are helpful. Nurses should provide supportive care and expectant management throughout the pregnancy.

SICKLE CELL ANEMIA

Sickle cell anemia is an autosomal recessive inherited condition that results from a defective hemoglobin molecule (hemoglobin S). It is found most commonly in African-Americans, Southeast Asians, and Middle Eastern populations. About 1 in 10 African-Americans are carriers of the trait, while approximately 3 in 800 are affected with the disease (McCann, 2007). People with only one gene for the trait (heterozygous) will have sickle cell trait without obvious symptoms of the disease and with little effect on the pregnancy.

Pathophysiology

In the human body, the hemoglobin molecule serves as the oxygen-carrying component of the red blood cells. Most people have several types of circulating hemoglobin (HbA and HbA2) that make up the majority of their circulatory system. In sickle cell disease, the abnormal hemoglobin S (HbS) replaces HbA and HbA2. This abnormal hemoglobin (HbS) becomes sickle-shaped as a result of any stress or trauma such as infection, fever, acidosis, dehydration, physical exertion, excessive cold exposure, or hypoxia. Significant anemia results. (See Chapter 46 for more information about sickle cell disease.)

Sickle cell anemia during pregnancy is associated with more severe anemia and frequent vaso-occlusive crises, with increased maternal and perinatal morbidity and mortality. In pregnant women with sickle cell anemia, complications can occur at any time during gestation, labor and birth, or postpartum. This is believed to be secondary to hormonal modifications, hypercoagulable state, and increased susceptibility to infection. Microvascular sickling in the placental circulation is associated with miscarriages, placental abruption, preeclampsia, preterm labor, intrauterine growth restriction, and low birthweight (Elsayegh & Shapiro, 2007).

Therapeutic Management

Ideally, women with hemoglobinopathies are screened before conception and are made aware of the risks of sickle cell anemia to themselves and to the fetus. A blood hemoglobin electrophoresis is done for all women from high-risk ancestry at their first prenatal visit to determine the types and percentages of hemoglobin present. This information should help them in making reproductive decisions.

Treatment depends on the health status of the woman. During pregnancy, only supportive therapy is used: blood transfusions for severe anemia, analgesics for pain, and antibiotics for infection.

Nursing Assessment

Assess the woman for signs and symptoms of sickle cell anemia. Ask the woman if she has anorexia, dyspnea, or malaise. Inspect the color of the skin and mucous membranes, noting any pallor. Be alert for indicators of sickle cell crisis, including severe abdominal pain, muscle spasms, leg pains, joint pain, fever, stiff neck, nausea and vomiting, and seizures (McCann, 2007).

Nursing Management

Clients require emotional support, education, and follow-up care to deal with this chronic condition, which can have a great impact on the woman and her family. Monitor vital signs, fetal heart rate, weight gain, and fetal growth. Assess hydration status at each visit and urge the client to drink 8 to 10 glasses of fluid daily to prevent dehydration. Teach the client about the need to avoid infections (including meticulous handwashing), cigarette smoking, alcohol consumption, and temperature extremes.

Assist the woman in scheduling frequent fetal well-being assessments, such as biophysical profiles, nonstress tests, and contraction stress tests, and monitor laboratory test results for changes. Throughout the antepartal period, be alert for early signs and symptoms of crisis.

During labor, encourage rest and provide pain management. Oxygen supplementation is typically used throughout labor, along with intravenous fluids to maintain hydration. The fetal heart rate is monitored closely. After giving birth, the woman is fitted with antiembolism stockings to prevent blood clot formation. Before discharge from the facility after birth of the newborn, discuss family planning options.

Infections

A wide variety of infections can affect the progression of pregnancy, possibly having a negative impact on the outcome. The effect of the infection depends on the timing and severity of the infection and the body systems involved. Common viral infections include cytomegalovirus (CMV), rubella, herpes simplex, hepatitis B, varicella, parvovirus B19, and several sexually transmitted infections (Table 20.3). Toxoplasmosis and group B streptococcus are common nonviral infections. Only the most common infections will be discussed here.

CYTOMEGALOVIRUS

Cytomegalovirus (CMV) is the most common congenital and perinatal viral infection in the world, possibly affecting up to 3% of all newborns (Ross, Jones, & Lynch,

TABLE 20.3 SEXUALLY TRANSMITTED INFECTIONS AFFECTING PREGNANCY

Infection/Organism	Effect on Pregnancy and Fetus/Newborn	Implications
Syphilis (*Treponema pallidum*)	Maternal infection increases risk of premature labor and birth. Newborn may be born with congenital syphilis—jaundice, rhinitis, anemia, IUGR, and CNS involvement.	All pregnant women should be screened for this STI and treated with benzathine penicillin G 2.4 million units IM to prevent placental transmission.
Gonorrhea (*Neisseria gonorrhoeae*)	Majority of women are asymptomatic. It causes ophthalmia neonatorum in the newborn from birth through infected birth canal.	All pregnant women should be screened at first prenatal visit, with repeat screening in the third trimester. All newborns receive mandatory eye prophylaxis with tetracycline or erythromycin within the first hour of life. Mother is treated with ceftriaxone (Rocephin) 125 mg IM in single dose before going home.
Chlamydia (*Chlamydia trachomatis*)	Majority of women are asymptomatic. Infection is associated with infertility and ectopic pregnancy, spontaneous abortions, preterm labor, premature rupture of membranes, low birthweight, stillbirth, and neonatal mortality. Infection is transmitted to newborn through vaginal birth. Neonate may develop conjunctivitis or pneumonia.	All pregnant women should be screened at first prenatal visit and treated with erythromycin.
Human papillomavirus (HPV)	Infection causes warts in the anogenital area, known as condylomata acuminata. These warts may grow large enough to block a vaginal birth. Fetal exposure to HPV during birth is associated with laryngeal papillomas.	Warts are treated with trichlorocetic acid, liquid nitrogen, or laser therapy under colposcopy. A quadrivalent HPV vaccine (Gardasil) against the viral types most likely to cause cervical cancer (types 16 and 18) and genital warts (types 6 and 11) has been licensed in the United States for girls and women 9 to 26 years old. The vaccine is 95% to 100% effective (Zimmerman, 2007). It is hoped that this vaccine will reduce the number of HPV-positive pregnant women in the future.
Trichomonas (*Trichomonas vaginalis*)	Infection produces itching and burning, dysuria, strawberry patches on cervix, and vaginal discharge. Infection is associated with premature rupture of membranes and preterm birth.	Treatment is with a single 2-g dose of metronidazole (Flagyl).

Sources: CDC STD Treatment Guidelines, 2006; Moore & Saybold, 2007.

2006). Pregnant women acquire active disease primarily from sexual contact, blood transfusions, kissing, and contact with children in daycare centers. The virus can be found in virtually all body fluids. Prevalence rates in women in the United States range from 50% to 85% (Hoerst & Samson, 2007). The incidence of primary CMV infection in pregnant women in the United States ranges from 1% to 3% (Hoerst & Samson, 2007). CMV infection during pregnancy may result in abortion, stillbirth, low birthweight, IUGR, microcephaly, deafness, blindness, mental retardation, jaundice, or congenital or neonatal infection. The first or primary infection, if it occurs during pregnancy, is the most dangerous to the fetus: the fetus has a 40% to 50% chance of being infected.

Most women are asymptomatic and don't know they have been exposed to CMV. Symptoms of CMV in the fetus and newborn, known as cytomegalovirus inclusion disease (CID), include hepatomegaly, thrombocytopenia, IUGR, jaundice, microcephaly, hearing loss, chorioretinitis, and mental retardation (Hoerst & Samson, 2007). Since there is no therapy that prevents or treats CMV infections, nurses are responsible for educating and supporting childbearing-age women at risk for CMV infection. Stressing the importance of good handwashing and use of sound hygiene practices can help to reduce transmission of the virus.

RUBELLA

Rubella, commonly called German measles, is spread by droplets or through direct contact with a contaminated object. The risk of a pregnant woman transmitting this virus through the placenta to her fetus increases with earlier exposure to the virus. When infection occurs within the first month after conception, 50% of fetuses show signs of infection; in the second month following conception, 25% of fetuses will be infected; and in the third month, 10% of fetuses will be affected (Santis et al., 2006).

Education for primary prevention is key. Ideally, all women have been vaccinated and have adequate immunity against rubella. However, all women are still screened at their first prenatal visit to determine their status. A rubella antibody titer 1:8 or greater proves evidence of immunity. Women who are not immune should be vaccinated during the immediate postpartum period so they will be immune before becoming pregnant again (CDC, 2007c). Nurses need to check the rubella immune status of all new mothers and should make sure all mothers with a titer of less than 1:8 are immunized prior to discharge after birth of the newborn.

HERPES SIMPLEX VIRUS

Approximately 50 million people are infected with genital herpes in the United States, and 500,000 new cases are diagnosed annually. Despite strategies designed to prevent perinatal transmission, the number of cases of newborn herpes simplex virus (HSV) infection continues to rise, mirroring the rising prevalence of genital herpes infection in women of childbearing age (Fischer, 2007).

HSV is a DNA virus with two subtypes: HSV-1 and HSV-2. HSV-1 infections were traditionally associated with oral lesions (fever blisters), whereas HSV-2 infections occurred in the genital region. Currently, either type can be found in either location (Fischer, 2007).

Infection occurs by direct contact of the skin or mucous membranes with an active lesion through such activities as kissing, sexual (vaginal, oral, anal) contact, or routine skin-to-skin contact. HSV is associated with infections of the genital tract that when acquired during pregnancy can result in severe systemic symptoms in the mother and significant morbidity and mortality in the newborn (Baker, 2007). Once the virus enters the body, it never leaves.

Infants born to mothers with a primary HSV infection have a 30% to 50% risk of acquiring the infection via perinatal transmission near or during birth. Recurrent genital herpes simplex infections carry a 1% to 3% risk of neonatal infection if the recurrence occurs around the time of vaginal birth (Xu et al., 2007).

The greatest risk of transmission is when the mother develops a primary infection near term and it is not recognized. Most neonatal infections are acquired at or around the time of birth through either ascending infection after ruptured membranes or contact with the virus at the time of birth. The method and timing of birth in a woman with genital herpes are controversial. The CDC recommends that in the absence of active lesions, a vaginal birth is acceptable, but if the woman has active herpetic lesions near or at term, a cesarean birth should be planned (CDC, 2008).

Management for the woman with genital herpes during pregnancy involves caring for her as well as reducing the risk of newborn herpes. Since the majority of newborn herpes cases result from perinatal transmission of the virus during vaginal birth, and because transmission can result in severe neurologic impairment or death, treatment of the mother with an antiviral agent such as acyclovir must be started as soon as the culture comes back positive. Universal screening for herpes is not economically sound, so nurses need to remain knowledgeable about current practice to provide accurate and sensitive care to all women.

HEPATITIS B VIRUS

Hepatitis B virus (HBV) is one of the most prevalent chronic diseases in the world. HBV can be transmitted through contaminated blood, illicit drug use, and sexual contact. The virus is 100 times more infectious than HIV and, unlike HIV, it can live outside the body in dried blood for more than a week (Hoerst & Samson, 2007).

Sexual transmission accounts for most adult HBV infections in the United States. Acutely infected women develop hepatitis with anorexia, nausea, vomiting, fever, abdominal pain, and jaundice. In women with acute hepatitis B, vertical transmission occurs in approximately 10% of newborns when infection occurs in the first trimester and in 80% to 90% of newborns when acute infection oc-

curs in the third trimester. Without intervention, 70% to 90% of infants born to women who are positive for hepatitis B will have chronic hepatitis B by 6 months of age (Kripke, 2007).

In addition, hepatitis B infection during pregnancy is associated with an increased risk of preterm birth, low birthweight, and neonatal death. Newborns infected with HBV are likely to become chronic carriers of the virus, becoming reservoirs for continued infection in the population (CDC, 2007e). The fetus is at particular risk during birth because of the possible contact with contaminated blood at this time.

Nursing Assessment

Review the woman's history for factors placing her at high risk:

- History of sexually transmitted infections
- Household contacts with HBV-infected persons
- Employment as a health care worker
- Abuse of intravenous drugs
- Sex worker (prostitute)
- Foreign born
- Multiple sexual partners
- Chinese, Southeast Asian, or African heritage
- Sexual partners who are HBV infected (CDC, 2007e)

At the first prenatal visit, all pregnant women should be screened for hepatitis B surface antigen (HbsAg) via blood studies. Expect to repeat this screening later in pregnancy for women in high-risk groups (Hoerst & Samson, 2007).

Nursing Management

If a woman tests positive for HBV, expect to administer HBV immune globulin (HBIG, Hep-B-Gammagee). The newborn receives HBV vaccine (Recombivax-HB, Engerix-B) within 12 hours of birth. The second and third doses of the vaccine are given at 1 month and 6 months of age (CDC, 2007e). The CDC recommends routine vaccination of all newborns.

Women who are HbsAg-negative may be vaccinated safely during pregnancy. No current research supports the use of surgical births to reduce vertical transmission of HBV. Breastfeeding by mothers with chronic HBV infection does not increase the risk of viral transmission to their newborns (Pyrsopoulos & Reddy, 2007).

Client education related to prevention of HBV is essential. Teach the woman about safer sex practices, good handwashing techniques, and the use of standard precautions (Teaching Guidelines 20.4). Protection can be afforded with the highly effective hepatitis B vaccine.

Permanent remission of the disease even with treatment rarely occurs. Therefore, therapy is directed at long-term suppression of viral replication and prevention of end-stage liver disease. Urge the woman to consume a high-protein diet and avoid fatigue. A healthy lifestyle can help delay disease progression. Initiate an open discussion about the modes of transmission and use of condoms to prevent spread.

TEACHING GUIDELINES 20.4

Teaching to Prevent Hepatitis B Virus

- Abstain from alcohol.
- Avoid intravenous drug exposure or sharing of needles.
- Encourage all household contacts and sexual partners to be vaccinated.
- Receive immediate treatment for any sexually transmitted infection.
- Know that your newborn will receive the hepatitis B vaccine soon after birth.
- Use good handwashing techniques at all times.
- Avoid contact with blood or body fluids.
- Use barrier methods such as condoms during sexual intercourse.
- Avoid sharing any personal items, such as razors, toothbrushes, or eating utensils.

VARICELLA ZOSTER VIRUS

Varicella zoster virus (VZV), a member of the herpesvirus family, is the virus that causes both varicella (chickenpox) and herpes zoster (shingles). Pregnant women are at risk for developing varicella when they come in close contact with children who have active infection. Maternal varicella can be transmitted to the fetus through the placenta, leading to congenital varicella syndrome, if the mother is infected during the first half of pregnancy, via an ascending infection during birth, or by direct contact with infectious lesions, leading to infection after birth. Varicella occurs in approximately 1 to 7 of 10,000 pregnancies (Anderson & Safdar, 2007).

Congenital varicella syndrome can occur in newborns of mothers infected during early pregnancy. It is characterized by low birthweight, skin lesions in a dermatomal distribution, spontaneous abortion, chorioretinitis, cataracts, cutaneous scarring, limb hypoplasia, microcephaly, ocular abnormalities, mental retardation, and early death (Laartz & Gompf, 2007).

Preconception counseling is important for preventing this condition. A major component of counseling involves determining the woman's varicella immunity. The vaccine is administered if needed. Provide education to women who work in occupations that increase the risk of

exposure to the virus, such as daycare workers, teachers of young children, and staff caring for children in institutional settings.

Varicella during pregnancy can be associated with severe illnesses for both the mother and her newborn. If contracted in the first half of pregnancy, some pregnant women are at risk for developing varicella pneumonia, which may put them at risk of life-threatening ventilatory compromise and death (Sauerbrei & Wutzler, 2007). If the mother develops varicella rashes close to her due date, generalized neonatal varicella leading to death in about 20% of cases can be expected (Gardella & Brown, 2007). Maternal infection is preventable by preconception vaccination.

PARVOVIRUS B19

Parvovirus B19 infection occurs worldwide. The incidence of acute B19 infection in pregnancy is about 3% (Malee, 2007). Parvovirus B19 is a common, self-limiting benign childhood virus that causes erythema infectiosum, also known as fifth disease (referring to its "fifth place" in a list of common childhood infections). Approximately 50% to 65% of women of reproductive age have developed immunity to parvovirus B19 (Broliden, Tolfvenstam, & Norbeck, 2006).

Pathophysiology

The infection is spread transplacentally, by the oropharyngeal route in casual contact, and through infected blood. Infection of the fetus occurs through transplacental passage of the virus. Acute infection in pregnancy can cause B19 infection in the fetus, leading to nonimmune fetal hydrops secondary to severe anemia or fetal loss, depending on the gestational age at the time of infection. The risk to the fetus is greatest when the woman is exposed and infected within the first 20 weeks of gestation. In addition to hydrops, other fetal effects of parvovirus include spontaneous abortion, congenital anomalies (central nervous system, craniofacial, and eye), and long-term effects such as hepatic insufficiency, myocarditis, and learning disabilities (Cunningham & Rennels, 2006).

Therapeutic Management

Generally, diagnosis of parvovirus is based on clinical symptoms and serologic antibody testing for parvovirus immunoglobulin G and parvovirus immunoglobulin M (IgM). Parvovirus B19 infection is followed by lifelong immunity, which is shown by positive serum B19 IgG. Pregnant women who have been exposed to or who develop symptoms of parvovirus B19 require assessment to determine whether they are susceptible to infection (nonimmune). If the woman is immune, she can be reassured that she will not develop infection and that the virus will not adversely affect her pregnancy. If she is nonimmune, then referral to a perinatologist is recommended and counseling regarding the risks of fetal transmission, fetal loss, and hydrops is necessary. Knowledge of how best to manage it during pregnancy lags behind our understanding of the potential adverse consequences.

Intrauterine B19 infection is a cause of fetal anemia, hydrops, and demise, and perhaps also of congenital anomalies. The best strategy for surveillance of the infected pregnant woman is serial ultrasounds for detection of hydropic changes and fetal anemia, and treatment for severe fetal anemia. Serial ultrasounds are advocated because the rates of fetal death and complications peak 4 to 6 weeks after exposure, but they can occur as late as 3 months following onset of symptoms (Elbaz et al., 2007).

The infected newborn is assessed for any anomaly and followed for up to 6 years to identify any sequelae (Cunningham & Rennels, 2006).

Nursing Assessment

Review the mother's history for any risk factors. Schoolteachers, daycare workers, and women living with school-aged children are at highest risk for being seropositive for parvovirus B19, especially if a recent outbreak has occurred in those settings. Also assess the woman for specific signs and symptoms. The characteristic rash starts on the face with a "slapped-cheeks" appearance and is followed by a generalized maculopapular rash. Fever, arthralgia, and generalized malaise are usually present in the mother. Prepare the mother for antibody testing.

Nursing Management

Prevention is the best strategy. Stress the need for handwashing after handling children; cleaning toys and surfaces that children have been in contact with; and avoiding the sharing of food and drinks. Screening for parvovirus B19 during early pregnancy may help in early diagnosis, but the cost-effectiveness of a national screening program has not been accepted to date. The nurse can provide information regarding risk factors and potential complications if exposed and support the parent's decision.

GROUP B STREPTOCOCCUS

Group B streptococcus (GBS) is a naturally occurring bacterium found in 10% to 35% of healthy adults. Women who test positive for the GBS bacteria are considered carriers. Carrier status is transient and doesn't indicate illness. Approximately 25% of pregnant women carry GBS in the rectum or vagina, thus introducing the risk of colonization of the fetus during birth. GBS affects about 1 in every 2,000 newborns in the United States

(March of Dimes, 2007d). Approximately 1 out of every 100 to 200 newborns born to mothers who carry GBS will develop signs and symptoms of GBS disease. Although GBS is rarely serious in adults, it can be life-threatening to newborns. GBS is the most common cause of sepsis and meningitis in newborns and is a frequent cause of newborn pneumonia (Moos, 2006). Newborns with early-onset (within a week after birth) GBS infections may have pneumonia or sepsis, whereas late-onset (after the first week) infections often manifest with meningitis (CDC, 2007b).

Genital tract colonization poses the most threat to the newborn because of exposure during birth and to the mother because of ascending infection after the membranes rupture. GBS colonization in the mother is thought to cause chorioamnionitis, endometritis, and postpartum wound infection.

Therapeutic Management

Antibiotic therapy usually is effective in treating women with GBS infections of the urinary tract or uterus, or chorioamnionitis without any sequelae. According to the 2002 CDC guidelines, all pregnant women should be screened for GBS at 35 to 37 weeks' gestation. Vaginal and rectal specimens are cultured for the presence of the bacterium. If positive, the woman should be treated with intravenous antibiotics during labor.

Penicillin G is the treatment of choice for GBS infection because of its narrow spectrum. Alternative antibiotics can be prescribed for clients with a penicillin allergy. The drug is usually administered intravenously at least 4 hours before birth so that it can reach adequate levels in the serum and amniotic fluid to reduce the risk of newborn colonization. Close monitoring is required during the administration of intravenous antibiotics because severe allergic reactions can occur rapidly.

Nursing Assessment

Review the woman's prenatal history, asking about any previous infection. Determine if the woman's membranes have ruptured and the time of rupture. Rupture of amniotic membranes greater than 18 hours increases the risk for infection. Monitor the mother's vital signs, reporting any maternal fever greater than 100.4°F. Assess the woman for other risk factors for perinatal transmission of GBS, including previous colonization with GBS, low socioeconomic status, African-American race, age less than 20 years, positive colonization at 35 to 37 weeks' gestation, GBS in urine sample, previous birth of GBS-positive newborn, preterm birth, and use of invasive obstetric procedures (March of Dimes, 2007d). Document this information to help prevent vertical transmission to the newborn.

Many women with GBS infection are asymptomatic, but they may have urinary tract infections, uterine infections, and chorioamnionitis.

Nursing Management

Nurses play major roles as educators and advocates for all women and newborns to reduce the incidence of GBS infections. Ensure that pregnant women between 35 and 37 weeks' gestation are screened for GBS infection during a prenatal visit. Record the results and notify the birth attendant if the woman has tested positive for GBS. During labor, be prepared to administer intravenous antibiotics to all women who are GBS positive.

TOXOPLASMOSIS

Toxoplasmosis is a relatively widespread parasitic infection caused by a one-celled organism, *Toxoplasma gondii.* When a pregnant woman is exposed to this protozoan, the infection can pose serious risks to her fetus. Between 1 in 1,000 and 8,000 newborns are born infected with toxoplasmosis in the United States (Hokelek & Safdar, 2006). It is transferred by hand to mouth after touching cat feces while changing the cat litter box or through gardening in contaminated soil. Consuming undercooked meat, such as pork, lamb, or venison, can also transmit this organism.

A pregnant woman who contracts toxoplasmosis for the first time has approximately a 40% chance of passing the infection to her fetus (March of Dimes, 2007e). Although the woman typically remains asymptomatic, transmission to her fetus can occur throughout pregnancy. A fetus that contracts congenital toxoplasmosis typically has a low birthweight, enlarged liver and spleen, chorioretinitis, jaundice, neurologic damage, and anemia (Peyron et al., 2006).

Treatment of the woman during pregnancy to reduce the risk of congenital infection is a combination of pyrimethamine and sulfadiazine. Treatment with sulfonamides during pregnancy has been shown to reduce the risk of congenital infection.

Prevention is the key to managing this infection. Nurses play a key role in educating the woman about measures to prevent toxoplasmosis (Teaching Guidelines 20.5).

Vulnerable Populations

Every year there are an estimated 220 million pregnancies worldwide, with about 6 million of them in the United States (Alan Guttmacher Institute, 2007). Each pregnancy runs the risk of an adverse outcome for the mother and the baby, but risks are dramatically increased for certain vulnerable populations: adolescents, women over the age of 35, women who are HIV positive, and women who abuse substances. While risks cannot be totally eliminated once pregnancy has begun, they can be reduced through appropriate and timely interventions.

TEACHING GUIDELINES 20.5

Teaching to Prevent Toxoplasmosis

- Avoid eating raw or undercooked meat, especially lamb or pork. Cook all meat to an internal temperature of 160°F throughout.
- Clean cutting boards, work surfaces, and utensils with hot soapy water after contact with raw meat or unwashed fruits and vegetables.
- Peel or thoroughly wash all raw fruits and vegetables before eating them.
- Wash hands thoroughly with warm water and soap after handling raw meat.
- Avoid feeding the cat raw or undercooked meats.
- Avoid emptying or cleaning the cat's litter box. Have someone else do it daily.
- Keep the cat indoors to prevent it from hunting and eating birds or rodents.
- Avoid uncooked eggs and unpasteurized milk.
- Wear gardening gloves when in contact with outdoor soil.
- Avoid contact with children's sandboxes, because cats can use them as litter boxes.

Every woman's experience with pregnancy is unique and personal. The circumstances each one faces and what pregnancy means to her involve emotions and experiences that belong solely to her. Many women in these special population groups go through this experience in confusion and isolation, feeling desperately in need of help but not knowing where to go. Although all pregnant women experience these emotions to a certain extent, but they are heightened in women who have numerous psychosocial issues. Pregnancy is a stressful time. Pregnant women face wide-ranging changes in their lives, relationships, and bodies as they move toward parenthood. These changes can be challenging for a woman without any additional stresses but are even more so in the face of age extremes, illness, or substance abuse.

Skilled nursing interventions are essential to promote the best outcome for the client and her baby. Timely support and appropriate interventions during the perinatal period can have long-standing implications for the mother and her newborn, ultimately with the goal of stability and integration of the family as a unit.

PREGNANT ADOLESCENT

Adolescence lasts from the onset of puberty to the cessation of physical growth, roughly from 11 to 19 years of age. Adolescents vacillate between being children and being adults. They need to adjust to the physiologic changes their bodies are undergoing and establish a sexual identity during this time. They search for personal identity and desire freedom and independence of thought and action. However, they continue to have a strong dependence on their parents (O'Toole, 2005).

Each year in the United States, approximately 1 million adolescents, or 10% of girls between the ages of 15 to 19 years, become pregnant. These pregnancies, which account for 11% of all births, are typically unintended and occur outside of marriage (Alan Guttmacher Institute, 2006). In addition, about half of all teen pregnancies occur within 6 months of first having sexual intercourse. Of girls who become pregnant, one in six will have a repeat pregnancy within 1 year. Most of these girls are unmarried, and many are not ready for the emotional, psychological, and financial responsibilities of parenthood (March of Dimes, 2007a). Adolescent pregnancy is further complicated by the adolescent's lack of financial resources: the income of teen mothers is half that of women who have given birth in their 20s (March of Dimes, 2007a).

Although the incidence of teenage pregnancy has steadily declined since the early 1990s, it continues to be higher in the United States than in any other industrialized country (Alan Guttmacher Institute, 2006). Even this reduced incidence represents what is considered an unacceptably high level of pregnancy in an age group that is likely to suffer the social consequences of early pregnancy most. Subsequently, adolescent pregnancy is considered a major health problem and is addressed in Healthy People 2010.

Impact of Pregnancy in Adolescence

Adolescents are a unique group with special needs related to their stage of development. Adolescent pregnancy can be an emotionally charged situation, laden with ethical dilemmas and decisions. Topics such as abstinence, safer sex, abortion, and the decision to have a child are sensitive issues.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce pregnancy among adolescent females from a baseline of 68 pregnancies per 1,000 adolescent girls to 43 pregnancies per 1,000 adolescent girls	Will help to foster a continued decline in adolescent pregnancy rates by focusing on interventions related to pregnancy prevention, including safe sex practices and teaching about the complications associated with adolescent pregnancy

USDHHS, 2000.

Adolescent pregnancy is an area when a nurse's moral convictions may influence the care that he or she provides to clients. Nurses need to examine their own beliefs about teen sexuality to identify personal assumptions. Putting aside one's moral convictions may be difficult, but it is necessary when working with pregnant adolescents. To be effective, health care providers must be able to communicate with adolescents in a manner they can understand and respect them as individuals.

Developmental Issues

An adolescent must accomplish certain developmental tasks to advance to the next stage of maturity. These developmental tasks include:

- Seeking economic and social stability
- Developing a personal value system
- Building meaningful relationships with others (Fig. 20.3)
- Becoming comfortable with their changing bodies
- Working to become independent from their parents
- Learning to verbalize conceptually (Zarrett & Eccles, 2006)

Adolescents have special needs when working to accomplish their developmental tasks and making a smooth transition to young adulthood. One of the biggest areas of need is sexual health. Adolescents commonly lack the information, skills, and services necessary to make informed choices related to their sexual and reproductive health. Developmentally, adolescents are trying to figure out who they are and how they fit into society. As adolescents mature, their parents become less influential and peers become more influential. Peer pressure can lead adolescents to participate in sexual activity, as can the typical adolescent's belief that "it won't happen to me" (Box 20.3).

As a result, unplanned pregnancies occur. Work on the developmental tasks of adolescence, especially identity, can be interrupted as the adolescent attempts to integrate the tasks of pregnancy, bonding, and preparing to care for another with the tasks of developing self-identity and independence. A pregnant adolescent must try to meet her own needs along with those of her fetus. The process of learning how to separate from the parents while learning how to bond and attach to a newborn brings conflict and stress. A pregnancy can exacerbate an adolescent's feeling of loss of control (Secco et al., 2007).

FIGURE 20.3 Adolescent girls sharing time together.

BOX 20.3 Possible Factors Contributing to Adolescent Pregnancy

- Early menarche
- Peer pressure to become sexually active
- Sexual or other abuse as a child
- Lack of accurate contraceptive information
- Fear of telling parents about sexual activity
- Feelings of invulnerability
- Poverty (85% of births occur in poor families)
- Culture or ethnicity (high incidence in Hispanic and African-American girls)
- Unprotected sex
- Low self-esteem and inability to negotiate
- Lack of appropriate role models
- Strong need for someone to love
- Drug use, truancy from school, or other behavioral problems
- Wish to escape a bad home situation
- Early dating without supervision

Sources: March of Dimes, 2008; Langille, 2007.

Health and Social Issues

Adolescent pregnancy has a negative impact in terms of both health and social consequences. For example, seven out of ten adolescents will drop out of school. More than 75% will receive public assistance within 5 years of having their first child. In addition, children of adolescent mothers are at greater risk of preterm birth, low birthweight, child abuse, neglect, poverty, and death (As-Sanie, Gantt, & Rosenthal, 2004). The younger the adolescent is at the time of the first pregnancy, the more likely it is that she will have another pregnancy during her teens (Holub et al., 2007).

The psychosocial risks associated with early childbearing often have an even greater impact on mothers, families, and society than the obstetric or medical risks (Zeck et al., 2007). Pregnant adolescents experience higher rates of domestic violence and substance abuse. Those experiencing abuse are more likely to abuse substances, receive inadequate prenatal care, and have lower pregnancy weight compared with those who are not (Magill & Wilcox, 2007). Moreover, substance abuse (cigarettes, alcohol, or illicit drugs) can contribute to low birthweight, IUGR, preterm births, newborn addiction, and sepsis (March of Dimes, 2007a).

Although early childbearing (12 to 19 years of age) occurs in all socioeconomic groups, it is more prevalent among poor women and those from minority backgrounds, who face more obstetric and newborn risks than their more affluent counterparts (March of Dimes, 2007a). Poverty often contributes to delayed prenatal care and medical complications related to poor nutrition, such as anemia.

The financial burden of adolescent pregnancy is high and costs taxpayers an estimated $7 billion to $15 billion annually in the United States (Alan Guttmacher Institute, 2007). Much of the expense stems from Medicaid, food stamps, state health department maternity clinics, Aid to Families and Children, and direct payments to health care providers. However, this amount does not address the costs to society in terms of the loss of human resources and the far-reaching intergenerational effects of adolescent parenting.

For some adolescents, pregnancy may be seen as a hopeless situation: a grim story of poverty and lost dreams, of being trapped in a life that was never wanted. Health-related behaviors, such as smoking, diet, sexual behavior, and help-seeking behaviors, that are developed during adolescence often endure into later life (Goodman et al., 2007). The consequences associated with an adolescent's less-than-optimal health status at this age due to pregnancy can ultimately affect her long-term health and that of her children.

However, some adolescents can create a happy, stable life for themselves and their children by facing their challenges and working hard to beat the odds.

Recall Rose, the pregnant teenager with asthma. What issues would be important for the nurse to discuss with her related to her pregnancy, her asthma, and her age?

Nursing Assessment

Assessment of the pregnant adolescent is the same as that for any pregnant woman. However, when dealing with pregnant teens, the nurse also needs to ask:

- How does the girl see herself in the future?
- Are realistic role models available to her?
- How much does she know about child development?
- What financial resources are available to her?
- Does she work? Does she go to school?
- What emotional support is available to her?
- Can she resolve conflicts and manage anger?
- What does she know about health and nutrition for herself and her child?
- Will she need help dealing with the challenges of the new parenting role?
- Does she need information about community resources?

Having an honest regard for adolescents requires getting to know them and being able to appreciate the important aspects of their life. Doing so forms a basis for the nurse's clinical judgment and promotes care that takes into account the concerns and practical circumstances of the teen and her family. Skillful practice includes knowing how and when to advise a teen and when to listen and refrain from giving advice. Giving advice can be misinterpreted as "preaching," and the adolescent will probably ignore the information. The nurse must be perceptive, flexible, and sensitive and must work to establish a therapeutic relationship.

Nursing Management

For adolescents, as for all women, pregnancy can be a physically, emotionally, and socially stressful time. The pregnancy is often both the result of and cause of social problems and stressors that can be overwhelming to them. Nurses must support adolescents during the transition from childhood into adulthood, which is complicated by their emergence into motherhood. Assist the adolescent in identifying family and friends who want to be involved and provide support throughout the pregnancy.

Help the adolescent identify the options for this pregnancy, such as abortion, self-parenting of the child, temporary foster care for the baby or herself, or placement of the child for adoption. Explore with the adolescent why she became pregnant. Becoming aware of why she decided to have a child is necessary to help with the development of the adolescent and her ability to parent. Identify barriers to seeking prenatal care, such as lack of transportation, too many problems at home, financial concerns, the long wait for an appointment, and lack of sensitivity on the part of the health care system. Encourage the girl to set goals and work toward them. Assist her in returning to school and furthering her education. As appropriate, initiate a referral for career or job counseling.

Stress that the girl's physical well-being is important for both her and her developing fetus, which depends on her for its own health-related needs. Assist with arrangements for care, including stress management and self-care.

Having a healthy newborn eases the transition to motherhood somewhat, rather than having to deal with the added stress of caring for an unhealthy baby (Secco et al., 2007). Monitor weight gain, sleep and rest patterns, and nutritional status to promote positive outcomes for both. Stress the importance of attending prenatal education classes. Provide appropriate teaching based on the adolescent's developmental level and emphasize the importance of continued prenatal and follow-up care. Monitor maternal and fetal well-being throughout pregnancy and labor (Fig. 20.4).

FIGURE 20.4 A pregnant adolescent receiving care during labor.

Nurses can also play a major role in preventing adolescent pregnancies, perhaps by volunteering to talk to teen groups. Box 20.4 highlights the key areas for teaching adolescents about pregnancy prevention.

Tackling the many issues surrounding adolescent pregnancy is difficult. Making connections with clients is crucial regardless of how complex their situation is. The future challenges nurses to find solutions to teenage pregnancies. Nurses must take proactive positions while working with adolescents, parents, schools, and communities to reduce the problems associated with early childbearing.

BOX 20.4 Topics for Teaching Adolescents to Prevent Pregnancy

- High-risk behaviors that lead to pregnancy
- Involvement in programs such as Free Teens, Teen Advisors, or Postponing Sexual Involvement
- Planning and goal setting to visualize their futures in terms of career, college, travel, and education
- Choice of abstinence or taking a step back to become a "second-time virgin"
- Discussions about sexuality with a wiser adult—someone they respect can help put things in perspective
- Protection against sexually transmitted infections and pregnancy if they choose to remain sexually active
- Critical observation and review of peers and friends to make sure they are creating the right atmosphere for friendship
- Empowerment to make choices that will shape their life for years to come, including getting control of their own lives now
- Appropriate use of recreational time, such as sports, drama, volunteer work, music, jobs, church activities, and school clubs

THE PREGNANT WOMAN OVER AGE 35

The term "elderly primip" is used to describe women ages 35 or older who are pregnant for the first time. A few decades ago, a woman having a baby after the age of 35 probably was giving birth to the last of several children, but today she may be having her first. With advances in technology and the tendency of women to seek career advancement prior to childbearing, the dramatic increase in women having first pregnancies after the age of 35 will likely continue.

Impact of Pregnancy on the Older Woman

Whether childbearing is delayed by choice or by chance, starting a family at age 35 is different and not without risks. Women in this age group may already have chronic health conditions that may put the pregnancy at risk. In addition, numerous studies have shown that increasing maternal age is a risk factor for infertility and spontaneous abortions, gestational diabetes, chronic hypertension, preeclampsia, preterm labor and birth, multiple pregnancy, genetic disorders and chromosomal abnormalities, placenta previa, IUGR, low Apgar scores, and surgical births (Hilton, 2006). However, even though increased age implies increased complications, most women today who become pregnant after age 35 have healthy pregnancies and healthy newborns (March of Dimes, 2007c).

Nursing Assessment

Nursing assessment of the pregnant woman over age 35 is the same as that for any pregnant woman. For a woman of this age, a preconception visit is important to identify chronic health problems that might affect the pregnancy and also to address lifestyle issues that may take time to modify. Encourage the older woman to plan for the pregnancy by seeing her health care provider before getting pregnant to discuss preexisting medical conditions, medications, and lifestyle choices. Assess the woman for risk factors such as cigarette smoking, poor nutrition, overweight or underweight, alcohol use, or illicit drug use.

A preconception visit also provides the opportunity to educate the woman about risk factors and provide information on how to modify her lifestyle habits to improve the pregnancy outcome. Assist the woman with lifestyle changes so that she can begin pregnancy in an optimal state of health. For example, if the woman is overweight, educate her about weight loss so that she can start the pregnancy at a healthy weight. If the woman smokes, encourage smoking cessation to reduce the effects of nicotine on herself and her fetus.

Prepare the woman for laboratory and diagnostic testing to establish a baseline for future comparisons. The

risk of having a baby with Down syndrome increases with age, especially over age 35. Amniocentesis is routinely offered to all older women to allow the early detection of numerous chromosomal abnormalities, including Down syndrome. Additionally, a quadruple blood test screen (alpha fetoprotein [AFP], human chorionic gonadotropin [hCG], unconjugated estriol [UE], and inhibin A [placental hormone]) drawn between 15 and 20 weeks of pregnancy can be helpful in screening for Down syndrome and neural tube defects.

Nursing Management

During routine prenatal visits, the nurse can play a key role in promoting a healthy pregnancy. Consider social, genetic, and environmental factors that are unique to the older pregnant women and prepare to address these factors when providing care. Although research has shown increases in preterm labor and births, low-birthweight newborns, and operative interventions for older women, many carry their pregnancies to term without incident (Tough et al., 2007).

Assess the woman's knowledge about risk factors and measures to reduce them. Educate her about measures to promote a positive outcome. Encourage her to get early and regular prenatal care. Advise her to eat a variety of nutritious foods, especially fortified cereals, enriched grain products, and fresh fruits and vegetables, and drink at least six to eight glasses of water daily and to take the prescribed vitamin containing 400 micrograms of folic acid daily. Also stress the need for her to avoid alcohol intake during pregnancy, avoid exposure to second-hand smoke, and take no drugs unless they are prescribed. Provide continued surveillance of the mother and fetus throughout the pregnancy.

WOMEN WHO ARE HIV POSITIVE

Human immunodeficiency virus (HIV) is a retrovirus that is transmitted by blood and body fluids. The number of people living with HIV infection in 2006 was estimated at nearly 40 million, including approximately 20 million women of childbearing age and 2.5 million children, most of whom acquired HIV from mother-to-child transmission (CDC, 2007a).

Despite the revolutionary strides that have been made in treatment and detection and recent clinical advances and cautious optimism associated with combination therapies and vaccines, the number of individuals who are HIV positive continues to climb worldwide. Intensive efforts notwithstanding, there still remains no real "cure" on the horizon (Lampe, 2006).

Historically, HIV/AIDS was associated with the male homosexual community and intravenous drug users, but currently the prevalence of HIV/AIDS is now increasing more rapidly among women than men. Women are the fastest-growing segment of persons becoming infected with HIV; transmission in women occurs most frequently from sexual contact (64%) and from intravenous drug use (33%) (CDC, 2007a). Most women, a large number of whom are mothers, have acquired the disease through heterosexual contact. The risk of acquiring HIV through heterosexual contact is greater for women due to exposure to the higher viral concentration in semen. In addition, sexual intercourse may cause breaks in the vaginal lining, increasing the chances that the virus will enter the woman's body. Fifty percent of all the HIV/AIDS cases worldwide occur in women. AIDS is the third leading cause of death among all U.S. women aged 25 to 44 years and the leading cause of death among African-American women in this age group (CDC, 2007a).

Pathophysiology

The three recognized modes of HIV transmission are unprotected sexual intercourse with an infected partner, contact with infected blood or blood products, and perinatal transmission.

▶ ***Take*** NOTE!

HIV is not transmitted by doorknobs, faucets, toilets, dirty dishes, mosquitoes, wet towels, coughing or sneezing, shaking hands, or being hugged or by any other indirect method.

The virus attacks the T4 cells, decreases the CD4 cell count, and disables the immune system. The HIV condition can progress to a severe immunosuppressed state termed **acquired immunodeficiency syndrome (AIDS)**. AIDS is a progressive, debilitating disease that suppresses cellular immunity, predisposing the infected person to opportunistic infections and malignancies. The CDC defines AIDS as an HIV-infected person with a specific opportunistic infection or a CD4 count of less than 200. Eventually, death occurs. The time from infection with HIV to development of AIDS is a median of 11 years but varies depending on whether the patient is taking current antiretroviral therapy (Johnsen, 2007). Research indicates that pregnancy does not accelerate the progression of HIV to AIDS or death (Cressey & Lallemant, 2007).

Once infected with HIV, the woman develops antibodies that can be detected with the enzyme-linked immunosorbent assay (ELISA) and confirmed with the Western blot test. Antibodies develop within 6 to 12 weeks

after exposure, although this latent period is much longer in some women. Table 20.4 highlights the four stages of HIV infection according to the CDC (2007a).

Impact of HIV on Pregnancy

When a woman who is infected with HIV becomes pregnant, the risks to herself, her fetus, and the newborn are great. The risks are compounded by problems such as drug abuse, lack of access to prenatal care, poverty, poor nutrition, and high-risk behaviors such as unsafe sex practices and multiple sex partners, which can predispose the woman to additional sexually transmitted infections such as herpes, syphilis, or human papillomavirus (HPV). Additional risk factors to assess for include women who exchange sex for money or drugs or have sex partners who do; women whose past or present sex partners were HIV infected; and women who had a blood transfusion between 1978 and 1985 (U.S. Preventive Services Task Force [USPSTF], 2006b). Subsequently, pregnant women who are HIV positive are at risk for preterm delivery, premature rupture of membranes, intrapartal or postpartum hemorrhage, postpartum infection, poor wound healing, and genitourinary tract infections (CDC, 2007a).

Perinatal transmission of HIV (from the mother to the fetus or child) also can occur. However, such cases have decreased in the past several years in the United States, primarily due to the use of zidovudine (ZDV) therapy in pregnant women infected with HIV. This has not been the case in poor countries without similar resources. The Joint United Nations programs on HIV/AIDS (UNAIDS) estimates that over 600,000 new infections due to mother-to-child transmission occur annually. This number is expected to increase rapidly as the prevalence rises in Southeast Asia (Johnsen, 2007). Perinatal transmission rates are as high as 35% when there is no intervention (antiretroviral therapy) and below 5% when antiretroviral treatment and appropriate care are available.

With perinatal transmission, approximately 25% to 50% of children manifest AIDS within the first year of life, and about 80% have clinical symptoms of the disease within 3 to 5 years (Johnsen, 2007). Breastfeeding is a major contributing factor for mother-to-child transmission, and the infected mother must be informed about this (Dao et al., 2007). The U.S. Public Health Service recommends that women who are HIV positive should avoid breastfeeding to prevent HIV transmission to the newborn. Given the devastating effects of HIV infection on children, preventing its transmission is critical (Lampe, 2006).

In addition to perinatal transmission, the fetus and newborn also are at risk for prematurity, IUGR, low birthweight, and infection. Prompt treatment with antiretroviral medications for the HIV-infected infant may slow the progression of the disease.

Therapeutic Management

Women who are seropositive for HIV require counseling about the risk of perinatal transmission and the potential for obstetric complications. The risk of perinatal transmission directly correlates with the viral load (Johnsen, 2007). A discussion of the options on continuing the pregnancy, medication therapy, risks, perinatal outcomes, and treatment is warranted. Women who elect to continue with the pregnancy should be treated with antiretroviral therapy regardless of their CD4 count or viral load.

Drug therapy is the mainstay of treatment for pregnant women infected with HIV. The standard treatment is

TABLE 20.4 STAGES OF HIV INFECTION OUTLINED BY THE CDC

Stages	Description	Clinical Picture
I	Acute infection	Early stage with pervasive viral production Flu-like symptoms 2–4 weeks after exposure Signs and symptoms: weight loss, low-grade fever, fatigue, sore throat, night sweats, and myalgia
II	Asymptomatic infection	Viral replication continues within lymphatics Usually free of symptoms; lymphadenopathy
III	Persistent generalized lymphadenopathy	Possibly remaining in this stage for years; AIDS develops in most within 7–10 years Opportunistic infections occur
IV	End-stage disease (AIDS)	Severe immune deficiency High viral load and low CD4 counts Signs and symptoms: bacterial, viral, or fungal opportunistic infections, fever, wasting syndrome, fatigue, neoplasms, and cognitive changes

oral antiretroviral drugs given twice daily from 14 weeks' gestation until giving birth, intravenous administration during labor, and oral syrup for the newborn in the first 6 weeks of life (Hackley, Kriebs, & Rousseau, 2007). The goal of therapy is to reduce the viral load as much as possible, which reduces the risk of transmission to the fetus.

Decisions about the birthing method to be used are made on an individual basis based on several factors involving the woman's health. Some reports suggest that cesarean birth may reduce the risk of HIV infection (Johnsen, 2007). Efforts to reduce instrumentation, such as avoiding the use of an episiotomy, fetal scalp electrodes, and fetal scalp sampling, will reduce the newborn's exposure to bodily fluids.

With appropriate therapies, the prognosis for pregnant women with HIV infection has improved significantly. In addition, the newborns of women with HIV infection who have received treatment usually do not become infected. Unfortunately, therapy is complicated and medications are expensive. Moreover, the medications are associated with numerous adverse effects and possible toxic reactions. These therapies offer a dual purpose: reduce the likelihood of mother-to-infant transmission and provide optimal suppression of the viral load in the mother. The core goal of all medical therapy is to bring the client's viral load to an undetectable level, thus minimizing the risk of transmission to the fetus and newborn.

Nursing Assessment

Nursing assessment begins with a thorough history and physical examination. In addition, the woman is offered screening for HIV antibodies.

Health History and Physical Examination

Review the woman's history for risk factors, such as unsafe sex practices, multiple sex partners, and injectable drug use. Also have the woman complete a risk assessment survey. In addition, question the woman about any flu-like symptoms such as a low-grade fever, fatigue, sore throat, night sweats, diarrhea, cough, skin lesions, or muscle pain.

Perform a complete physical examination. Obtain the woman's weight and determine if she has lost weight recently. Assess for signs and symptoms of sexually transmitted infections (STIs), such as vulvovaginal candidiasis, bacterial vaginosis, HSV, chancroid, CMV, or chlamydia because of the increased risk for STIs.

▶ *Take* NOTE!

Women who request an HIV test despite reporting no individual risk factors should be considered at risk, since many are not likely to disclose their high-risk behaviors.

Laboratory and Diagnostic Testing

The U.S. Public Health Service recommends that all pregnant women be offered HIV antibody testing, regardless of their risk of infection, and that testing be done during the initial prenatal evaluation (Lampe, 2006). Testing is essential because treatments are available that can reduce the likelihood of perinatal transmission and maintain the health of the woman.

▶ *Take* NOTE!

Screening only women who are identified as high risk based on their histories is inadequate due to the prolonged latency period that can exist after exposure. Also, research indicating that treatment with antiretroviral agents could reduce vertical transmission from the infected mother to the newborn has dramatically increased the importance of HIV antibody screening in pregnancy.

Offer all women who are pregnant or planning a pregnancy HIV testing using ELISA. Prepare the woman with a reactive screening test for an additional test, such as the Western blot or an immunofluorescence assay. The Western blot is the confirmatory diagnostic test. A positive antibody test confirmed by a supplemental test indicates that the woman has been infected with HIV and can pass it on to others. HIV antibodies are detectable in at least 95% of women within 3 months after infection (Cressey & Lallemant, 2007).

In addition to the usual screening tests done in normal pregnancy, additional testing for STIs may be necessary. Women infected with HIV have high rates of STIs, especially HPV, vulvovaginal candidiasis, bacterial vaginosis, syphilis, HSV, chancroid, CMV, gonorrhea, chlamydia, and hepatitis B (Hackley, Kriebs, & Rousseau, 2007).

Nursing Management

Women infected with HIV should have comprehensive prenatal care, which starts with pretest and posttest counseling. In pretest counseling, the client completes a risk assessment survey and the nurse explains the meaning of positive versus negative test results, obtains informed consent for HIV testing, and educates the woman on how to prevent HIV infection by changing lifestyle behaviors if needed. Posttest counseling includes informing the client of the test results, reviewing the meaning of the results again, and reinforcing safer sex guidelines. All pretest and posttest counseling should be documented in the client's chart.

Educating the Client

Pregnant clients are dealing with many issues at their first prenatal visit. The confirmation of pregnancy may be ac-

companied by feelings of joy, anxiety, depression, or other emotions. Simultaneously, the client is given many pamphlets and receives advice and counseling about many important health issues (e.g., nutrition, prenatal development, appointment schedules). This health teaching may be done while the woman feels excited, tired, and anxious. To expect women to understand detailed explanations of a complex disease entity (HIV/AIDS) too may be unrealistic. Determine the client's readiness for this discussion.

Identify the client's individual needs for teaching, emotional support, and physical care. Approach education and counseling of HIV-positive pregnant women in a caring, sensitive manner. Address the following information:

- Infection control issues at home
- Safer sex precautions
- Stages of the HIV disease process and treatment for each stage
- Symptoms of opportunistic infections
- Preventive drug therapies for her unborn infant
- Avoidance of breastfeeding
- Referrals to community support, counseling, and financial aid
- Client's support system and potential caretaker
- Importance of continual prenatal care
- Need for a well-balanced diet
- Measures to reduce exposure to infections

Be knowledgeable about HIV infection and how HIV is transmitted and share this knowledge with all women. Nurses also can work to influence legislators, public health officials, and the entire health establishment toward policies to address the HIV epidemic. Research toward treatment and cure is tremendously important, but the major key to prevention of the spread of the virus is education. Nurses play a major role in this education.

Supporting the Client

Be aware of the psychosocial sequelae of HIV/AIDS. A diagnosis of HIV can put a woman into an emotional tailspin, where she is worried about her own health and that of her unborn infant. She may experience grief, fear, or anxiety about the future of her children. Along with the medications that are so important to her health maintenance, address the woman's mental health needs, family dynamics, capacity to work, and social concerns and provide appropriate support and guidance.

Be aware of your personal beliefs and attitudes toward women who are HIV positive or have AIDS. Incorporate this awareness in your actions as you help the woman face the reality of the diagnosis and treatment options. Empathy, understanding, caring, and assistance are key to helping the client and her family.

Preparing for Labor, Birth, and Afterward

Current evidence suggests that cesarean birth performed before the onset of labor and before the rupture of membranes significantly reduces the rate of perinatal transmission. ACOG recommends that HIV-positive women be offered elective cesarean birth to reduce the rate of transmission beyond that which may be achieved through antiretroviral therapy. They further suggest that operative births be performed at 38 weeks' gestation and that amniocentesis be avoided to prevent contamination of the amniotic fluid with maternal blood. Decisions concerning the method of delivery should be based on the woman's viral load, the duration of ruptured membranes, the progress of labor, and other pertinent clinical factors (USPHSTF, 2006b).

Prepare the woman physically and emotionally for the possibility of cesarean birth and assist as necessary. Ensure that she understands the rationale for the surgical birth.

After the birth of the newborn, the motivation for taking antiretroviral medications may be lower, thus affecting the woman's compliance with therapy. Encourage the woman to continue therapy for her own sake as well as that of the newborn. Nurses can make a difference in helping women to adhere to their complex drug regimens.

Reinforce family planning methods during this time, incorporating a realistic view of her disease status. The use of oral contraceptives with concurrent use of condoms is recommended (Lampe, 2006). Advise the woman that breastfeeding is not recommended. Instruct the HIV-positive woman in self-care measures, including the proper method for disposing of perineal pads to reduce the risk of exposing others to infected body fluids. Finally, teach the HIV-positive woman the signs and symptoms of infection in newborns and infants, encouraging her to report any to the health care provider.

▶ *Take* NOTE!

When providing direct care, ***ALWAYS*** *follow standard precautions.*

THE PREGNANT WOMAN WITH SUBSTANCE ABUSE

Perinatal drug abuse is the use of alcohol and other drugs by pregnant women. The incidence of substance abuse during pregnancy is highly variable because most pregnant women are reluctant to reveal the extent of their use. The National Institute on Drug Abuse estimates that 6% of the women in the United States have used illicit drugs while pregnant. These include cocaine, marijuana, heroin, and psychotherapeutic drugs that were not prescribed by a health care professional. More than 18% used alcohol and 21% smoked cigarettes during their pregnancy (National Institute on Drug Abuse [NIDA], 2007a).

Impact of Substance Abuse on Pregnancy

The use of drugs, legal or not, increases the risk of medical complications in the mother and poor birth outcomes in the newborn. The placenta acts as an active transport mechanism, not as a barrier, and substances pass from a mother to her fetus through the placenta. Thus, the fetus as well as the mother experiences substance use, abuse, and addiction. Additionally, fetal vulnerability to drugs is much greater because the fetus has not developed the enzymatic system needed to metabolize drugs (Hackley, Kriebs, & Rousseau, 2007).

A woman who claims to have taken no drugs while pregnant may be unaware that substances such as hair dye, diet cola, paint, or over-the-counter (OTC) medications for colds or headaches are still considered drugs. Thus, it is very difficult to get a true picture of the real use of drugs by pregnant women.

Many drugs are considered to have a teratogenic effect on growing fetuses. A **teratogen** is any environmental substance that can cause physical defects in the developing embryo and fetus. Pregnant women with substance abuse commonly present with polysubstance abuse, which is likely to be more damaging than the use of any single substance. Thus, it is inherently difficult to ascribe a specific perinatal effect to any one substance (Rassool & Villar-Luis, 2006).

Effects of Addiction

Addiction is a multifaceted process that is affected by environmental, psychological, family, and physical factors. Women who use drugs, alcohol, or tobacco come from all socioeconomic backgrounds, cultures, and lifestyles. Factors associated with substance abuse during a pregnancy may include low self-esteem, inadequate support systems, low self-expectations, high levels of anxiety, socioeconomic barriers, involvement in abusive relationships, chaotic familial and social systems, and a history of psychiatric illness or depression. Women often become substance abusers to relieve their anxieties, depression, and feelings of worthlessness (Jones, 2006).

Societal attitudes regarding women and substance abuse may prohibit them from admitting the problem and seeking treatment. Society sanctions women for failing to live up to expectations of how a pregnant woman "should" behave, thereby possibly driving them further away from the treatment they so desperately need. For many reasons, pregnant women who abuse substances feel unwelcome in prenatal clinics or medical settings. Often they seek prenatal care late or not at all. They may fear being shamed or reported to legal or child protection authorities. A nonjudgmental atmosphere and unbiased teaching to all pregnant women regardless of their lifestyle is crucial. A caring, concerned manner is critical to help these women feel safe and respond honestly to assessment questions.

Pregnancy can be a motivator for some who want to try treatment. The goal of therapy is to help the client deal with pregnancy by developing a trusting relationship. Providing a full spectrum of medical, social, and emotional care is needed.

Effects of Commonly Abused Substances

Substance abuse during pregnancy, particularly in the first trimester, has a negative effect on the health of the mother and the growth and development of the fetus. The fetus experiences the same systemic effects as the mother, but often more severely. The fetus cannot metabolize drugs as efficiently as the expectant mother and will experience the effects long after the drugs have left the women's system. Substance abuse during pregnancy is associated with preterm labor, abortion, IUGR, abruptio placentae, low birthweight, neurobehavioral abnormalities, and long-term childhood developmental consequences (Rassool & Villar-Luis, 2006). Table 20.5 summarizes the effects of selected drugs during pregnancy.

TABLE 20.5 EFFECTS OF SELECTED DRUGS ON PREGNANCY

Substance	Effect on Pregnancy
Alcohol	Spontaneous abortion, inadequate weight gain, IUGR, fetal alcohol spectrum disorder, the leading cause of mental retardation
Caffeine	Vasoconstriction and mild diuresis in mother; fetal stimulation, but teratogenic effects not documented via research
Nicotine	Vasoconstriction, reduced uteroplacental blood flow, decreased birthweight, abortion, prematurity, abruptio placentae, fetal demise
Cocaine	Vasoconstriction, gestational hypertension, abruptio placentae, abortion, "snow baby syndrome," CNS defects, IUGR
Marijuana	Anemia, inadequate weight gain, "amotivational syndrome," hyperactive startle reflex, newborn tremors, prematurity, IUGR
Narcotics	Maternal and fetal withdrawal, abruptio placentae, preterm labor, premature rupture of membranes, perinatal asphyxia, newborn sepsis and death, intellectual impairment, malnutrition
Sedatives	CNS depression, newborn withdrawal, maternal seizures in labor, newborn abstinence syndrome, delayed lung maturity

Sources: CDC, 2007d; Gilbert & Harmon, 2006; Jones, 2006.

Alcohol

Alcohol abuse is a major public health issue in the United States. Alcohol is a teratogen, a substance known to be toxic to human development. Approximately 10% of pregnant women report alcohol consumption (CDC, 2007d). Theoretically, no mother would give a glass of wine, beer, or hard liquor to her newborn, but when she drinks, her embryo or fetus is exposed to the same blood alcohol concentration as she is. The teratogenic effects of heavy maternal drinking have been recognized since 1973, when fetal alcohol syndrome was first described. Fetal alcohol syndrome is now a classification under the broader term of **fetal alcohol spectrum disorder (FASD)**; this disorder includes the full range of birth defects, such as structural anomalies and behavioral and neurocognitive disabilities caused by prenatal exposure to alcohol (Green, 2007). The incidence of FASD in the United States is estimated to be one or two cases per 1,000 live births (National Organization on Fetal Alcohol Syndrome [NoFAS], 2007). It is the leading cause of mental retardation (CDC, 2007d).

Not every woman who drinks during pregnancy will give birth to an affected child. Based on the best research available, the following is known about alcohol consumption during pregnancy:

- Intake increases the risk of alcohol-related birth defects, including growth deficiencies, facial abnormalities, central nervous system impairment, behavioral disorders, and intellectual development.
- No amount of alcohol consumption is considered safe during pregnancy.
- Damage to the fetus can occur at any stage of pregnancy, even before a woman knows she is pregnant.
- Cognitive defects and behavioral problems resulting from prenatal exposure are lifelong.
- Alcohol-related birth defects are completely preventable (U.S. Department of Health and Human Services [USDHHS], 2007).

Risk factors for giving birth to an alcohol-affected newborn include maternal age, socioeconomic status, ethnicity, genetic factors, poor nutrition, depression, family disorganization, unplanned pregnancy, and late prenatal care (Hackley, Kriebs, & Rousseau, 2007). Identification of risk factors strongly associated with alcohol-related birth outcomes could help identify high-risk pregnancies requiring intervention.

Characteristics of FASD include craniofacial dysmorphia (thin upper lip, small head circumference, and small eyes), IUGR, microcephaly, and congenital anomalies such as limb abnormalities and cardiac defects. Long-term sequelae include postnatal growth restriction, attention deficits, delayed reaction time, and poor scholastic performance (NoFAS, 2007). The complex neurobehavioral problems typically manifest themselves insidiously. Children with prenatal alcohol exposure struggle with cognitive, academic, social, emotional, and behavioral challenges.

BOX 20.5 Common Cognitive and Behavioral Problems Associated With FASD

- Attention-deficit/hyperactivity disorder (ADHD)
- Inability to foresee consequences
- Inability to learn from previous experience
- Lack of organization
- Learning difficulties
- Poor abstract thinking
- Poor impulse control
- Speech and language problems
- Poor judgment

These challenges reduce the child's ability to learn and function successfully in many structured environments (Green, 2007). Common cognitive and behavioral problems are listed in Box 20.5, and Figure 20.5 illustrates the characteristic facial features. See Chapter 24 for a more detailed discussion of the newborn with FASD.

One of the biggest challenges in determining the true prevalence of FASD is how to recognize the syndrome, which depends in part on the age and physical features of the person being assessed. Difficulty in identifying alcohol abuse is due to the client's denial of alcohol use, unwillingness to report alcohol consumption, underreporting, and limited ability to recollect the frequency, quantity, and type of alcohol consumed. This makes it difficult to identify women who are drinking during pregnancy, institute preventive measures, or refer them for treatment.

Women who drink excessively while pregnant are at high risk for giving birth to children with birth defects. To prevent these defects, women should stop drinking during

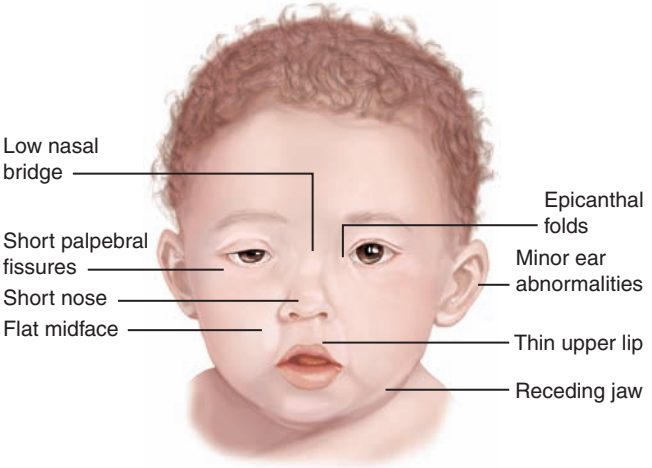

FIGURE 20.5 Typical facial characteristics of a newborn with FASD.

all phases of a pregnancy. Unfortunately, many women continue to drink during their pregnancy despite warnings from professionals.

Currently, it is not known whether there is a minimal amount of alcohol safe to drink during pregnancy; an occasional glass of wine might be harmless or might not be. Therefore, eliminating alcohol consumption during pregnancy is the ultimate goal to prevent FASD. Most women know they shouldn't drink during pregnancy, but the "window of vulnerability"—the time lag between conception and the discovery of pregnancy—may put substantial numbers of children at risk. Additionally, traditional alcohol-screening questionnaires, such as the Michigan Alcoholism Screening Test (MAST) and the CAGE Questionnaire, are not sensitive enough to detect low levels of alcohol consumption among women.

Several challenges remain in preventing birth defects due to alcohol consumption:

- Ways to improve clinical recognition of high-risk women who drink alcohol
- Ways to intervene more effectively to modify drinking behaviors
- In utero approaches to prevent or minimize fetal injury
- Strategies to address the neurodevelopmental problems of children affected by maternal alcohol ingestion

Caffeine

Caffeine, a CNS stimulant, is present in varying amounts in such common products as coffee, tea, colas, and chocolate. It is also in cold remedies and analgesics. Birth defects have not been linked to caffeine consumption, but maternal coffee consumption decreases iron absorption and may increase the risk of anemia during pregnancy. The FDA recommends that pregnant women eliminate or limit their consumption of caffeine to less than 300 mg/day, or the equivalent of three cups of coffee or cola (Hoffman & Brown, 2006).

Nicotine

Nicotine, found in cigarettes, is another substance that is harmful to the pregnant women and her fetus. Nicotine, which causes vasoconstriction, transfers across the placenta and reduces blood flow to the fetus, contributing to fetal hypoxia. When compared with alcohol, marijuana, and other illicit drug use, tobacco use is less likely to decline as the pregnancy progresses (Wang, 2007). Smoking is associated with adverse pregnancy outcomes. However, these adverse outcomes can be avoided if the woman stops smoking before becoming pregnant.

Smoking increases the risk of spontaneous abortion, preterm labor and birth, maternal hypertension, placenta previa, and abruptio placentae. The perinatal death rate among infants of smoking mothers is 20% to 35% higher (Raatikainen, Huurinainen, & Heinonen, 2007).

Smoking has also been considered an important risk factor for low birthweight, sudden infant death syndrome (SIDS), and cognitive deficits, especially in language, reading, and vocabulary, as well as poorer performances on tests of reasoning and memory. Researchers have also reported behavior problems, such as increased activity, inattention, impulsivity, opposition, and aggression (Wang, 2007).

Women who smoke during the pregnancy also continue to smoke after giving birth, and thus the infant will be exposed to nicotine after birth. This environmental or passive exposure affects the child's development and increases the risk of childhood respiratory disorders.

Cocaine

Cocaine use is second only to marijuana in women who abuse drugs during pregnancy. The incidence of cocaine exposure in utero is 1 to 10 per 1,000 live births (Weekes & Lee, 2006).

Cocaine is a psychoactive drug derived from the leaves of the coca plant, which grows in the Andes Mountains of Peru, Ecuador, and Bolivia. The freebase form, called "crack" because of the cracking or popping noise made in its preparation, is less expensive, easily made, and smokable. Cocaine is a powerful vasoconstrictor. When sniffed into the mucous membranes of the nose, it produces an intense "rush" that some have compared to an orgasmic experience. Smoked crack is absorbed rapidly by the pulmonary vasculature and reaches the brain's circulation in 6 to 8 seconds (NIDA, 2007b).

Cocaine use produces vasoconstriction, tachycardia, and hypertension in both the mother and the fetus (Weekes & Lee, 2006). Uteroplacental insufficiency may result from reduced blood flow and placental perfusion. Chronic use can result in low birthweight, the most common effect of cocaine use in pregnancy (NIDA, 2007b).

Studies suggest that perinatal cocaine use increases the risk of preterm labor, abortion, abruptio placentae, IUGR, intrauterine fetal distress and demise, seizures, withdrawal, and cerebral infarcts. Cocaine may increase the risk of uterine rupture and congenital anomalies (NIDA, 2007b). Fetal anomalies associated with cocaine use in early pregnancy involve neurologic problems such as neural tube defects and microcephaly; cardiovascular anomalies such as congenital heart defects; genitourinary conditions such as prune belly syndrome, hydronephrosis, and ambiguous genitalia; and gastrointestinal system problems such as necrotizing enterocolitis (Jones, 2006). Some infants exposed to cocaine in utero show increased irritability and are difficult to calm and soothe to sleep.

Marijuana

Marijuana is the most commonly used illicit drug in America, with over 90 million people having tried it at least once. It is often called pot, reefer, herb, widow, hash, grass, weed, Mary Jane, or MJ (NIDA, 2007c). Marijuana is a preparation of the leaves and flowering tops of *Cannabis*

sativa, the hemp plant, which contains a number of pharmacologically active agents. Tetrahydrocannabinol (THC) is the most active ingredient of marijuana. With heavy smoking, THC narrows the bronchi and bronchioles and produces inflammation of the mucous membranes. Smoking marijuana causes tachycardia and a reduction in blood pressure, resulting in orthostatic hypotension.

The effects of marijuana smoking on pregnancy are not yet fully understood because there are very few studies on its long-term effects on child development. One can speculate that the effects of marijuana on the immature nervous system may be subtle and not detected until more complex functions are required, usually in a formal educational setting. There is some evidence that marijuana increases the risk of spontaneous abortion and preterm delivery (Barros et al., 2006). Although marijuana is not considered teratogenic, many newborns display altered responses to visual stimuli, increased tremulousness, and a high-pitched cry, which might indicate CNS insults (Wang, 2007). A strong correlation exists between the use of marijuana and the use of alcohol and cigarettes.

Opiates and Narcotics

Opiates and narcotics include opium, heroin (known as horse, junk, smack, downtown), morphine, codeine, hydromorphone (Dilaudid; little D), oxycodone (Percodan, perkies), meperidine (Demerol, demise), and methadone (meth, dollies). These drugs are central nervous system depressants that soothe and lull. They may be used medically for pain, but all have a high potential for abuse. Most cause an intense addiction in both mother and newborn.

Narcotic dependence is particularly problematic in pregnant women. It leads to medical, nutritional, and social neglect by the woman due to the long-term risks of physical dependence, malnutrition, compromised immunity, hepatitis, and fatal overdose (Alexander et al., 2007). Taking opiates or narcotics during pregnancy places the woman at increased risk for preterm labor, IUGR, and preeclampsia (Wang, 2007).

Heroin is the most common illicitly used opioid. It is derived from the seeds of the poppy plant and can be sniffed, smoked, or injected. It crosses the placenta via simple diffusion within 1 hour of maternal consumption (Dodge, Brady, & Maguire, 2007). Use of heroin during pregnancy is believed to affect the developing brain of the fetus and may cause behavioral abnormalities in childhood (Alexander et al., 2007).

The most common harmful effect of heroin and other narcotics on newborns is withdrawal, or **neonatal abstinence syndrome** (see Chapter 24). This collection of symptoms may include irritability, hypertonicity, a high-pitched cry, vomiting, diarrhea, respiratory distress, disturbed sleeping, sneezing, diaphoresis, fever, poor sucking, tremors, and seizures (Ebner et al., 2007).

Withdrawal from opiates during pregnancy is extremely dangerous for the fetus, so a prescribed oral methadone maintenance program combined with psychotherapy is recommended for the pregnant woman. This closely supervised treatment program reduces withdrawal symptoms in the newborn, reduces drug cravings, and blocks the euphoric effects of narcotic drugs in order to reduce illicit drug use. Methadone maintenance provides a steady state of opiate levels, thus reducing the risk of withdrawal to the fetus and exposure to HIV and other STIs because the mother is no longer injecting drugs. However, methadone has the same withdrawal consequences for women and newborns as heroin does (Burns et al., 2007).

Sedatives

Sedatives relax the central nervous system and are used medically for inducing relaxation and sleep, relieving tension, and treating seizures. Sedatives easily cross the placenta and can cause birth defects and behavioral problems. Infants born to mothers who abuse sedatives during pregnancy may be physically dependent on the drugs themselves and are more prone to respiratory problems, feeding difficulties, disturbed sleep, sweating, irritability, and fever (Alexander et al., 2007).

Methamphetamines

Methamphetamine use among pregnant women has increased rapidly in the United States. This highly addictive stimulant is commonly known as speed, meth, or chalk. In its smoked form, it is often referred to as ice, crystal, crank, and glass. It is a white, odorless, bitter-tasting powder that was developed from its parent drug, amphetamine, and was used originally in nasal decongestants and bronchial inhalers. The maternal effects include increased energy and alertness, an intense rush, decreased appetite, tachycardia, and tachypnea. Chronic use can lead to psychosis, including paranoia, hallucinations, memory loss, and aggressive or violent behavior (Derlet & Albertson, 2006). Few studies have been done on the effects of methamphetamine abuse during pregnancy, but the few done indicate an increased risk for preterm births, placental abruption, fetal growth restriction, and congenital anomalies (NIDA, 2007d). These findings are hard to interpret, however, due to small sample size and polydrug use of the participants.

Nursing Assessment

Complete a thorough history and physical examination to evaluate a client for substance use and abuse. Substance abuse screening in pregnancy is done to detect the use of any substance known or suspected to exert a deleterious effect on the client or her fetus. Routinely ask about substance abuse with all women of childbearing age, inform them of the risks involved, and advise them

against continuing. Screening questionnaires are helpful in identifying potential users, may reduce the stigma of asking clients about substance abuse, and result in a more accurate and consistent evaluation. The questions in Box 20.6 may be helpful in assessing a client who is at risk for substance abuse during pregnancy. Using "accepting" terminology may encourage the woman to give honest answers without fear of reproach.

A urine toxicology screen may also be helpful in determining drug use, although a urine screen identifies only recent or heavy use of drugs. The length of time a drug is present in urine is as follows:

- Cocaine: 24 to 48 hours in an adult, 72 to 96 hours in an infant
- Heroin: 24 hours in an adult, 24 to 48 hours in an infant
- Marijuana: 1 week to 1 month in an adult, up to a month or longer in an infant
- Methadone: up to 10 days in an infant (Wang, 2007)

Nursing Management

If the woman's drug screen is positive, use this as an opportunity to discuss prenatal exposure to substances that may be harmful. The discussion may lead the nurse to refer the client for a diagnostic assessment or identify an intervention such as counseling that may be helpful. Being nonjudgmental is a key to success; a client is more apt to trust and reveal patterns of abuse if the nurse does not judge her and her lifestyle choices.

A positive drug screen in a newborn warrants an investigation by the state protection agency. In the interim, institute measures to reduce stress and stimuli to promote the newborn's comfort (see Chapter 24 for a more in-depth discussion).

Be proactive, supportive, and accepting when caring for the client. Assure women with substance abuse problems that sharing information of a confidential nature with health care providers will not render them liable to criminal prosecution. Provide counseling and education, emphasizing the following:

- Effects of substance exposure on the fetus
- Interventions to improve mother–child attachment and improve parenting
- Psychosocial support if treatment is needed to reduce substance abuse
- Referral to outreach programs to improve access to treatment facilities
- Hazardous legal substances to avoid during pregnancy
- Follow-up of children born to substance-dependent mothers
- Dietary counseling to improve the pregnancy outcome for both mother and child
- Drug screening to identify all drugs a client is using
- More frequent prenatal visits to monitor fetal well-being
- Maternal and fetal benefits of remaining drug-free
- Cultural sensitivity
- Coping skills, support systems, and vocational assistance

Substance abuse is a complex problem that requires sensitivity to each woman's unique situation and contributing factors. Be sure to address individual psychological and sociocultural factors to help the woman to regain control of her life. Treatment must combine different approaches and provide ongoing support for women learning to live drug-free. Developing personal strengths, such as communication skills and assertiveness, and self-confidence will help the woman in resisting the drug use. Encourage the use of appropriate coping skills. Enhancing self-esteem also helps provides a foundation to avoid drugs.

BOX 20.6 Sample Questions for Assessing Substance Use

- Have you ever used recreational drugs? If so, when and what?
- Have you ever taken a prescription drug other than as intended?
- What are your feelings about drug use during pregnancy?
- How often do you smoke cigarettes? How many per day?
- How often do you drink alcohol?

If the assessment reveals substance use, obtain additional information by using the RAFFT questions, which are a sensitive screening instrument for identifying substance abuse (Weekes & Lee, 2006):

R: Do you drink or take drugs to **R**elax, improve your self-image, or fit in?
A: Do you ever drink or take drugs while **A**lone?
F: Do you have any close **F**riends who drink or take drugs?
F: Does a close **F**amily member have a problem with alcohol or drugs?
T: Have you ever gotten in **T**rouble from drinking or taking drugs?

Key Concepts

- Preconception counseling for the woman with diabetes is helpful in promoting blood glucose control to prevent congenital anomalies.
- The classification system for diabetes commonly used is based on disease etiology and not pharmacology management; the classification includes type 1 diabetes, type 2 diabetes, gestational diabetes, and impaired fasting glucose and impaired glucose tolerance.
- A functional classification for heart disease during pregnancy is based on past and present disability: class I,

asymptomatic with no limitation of physical activity; class II, symptomatic (dyspnea, chest pain) with increased activity; class III, symptomatic (fatigue, palpitation) with normal activity; and class IV, symptomatic at rest or with any physical activity.

- Chronic hypertension exists when the woman has a blood pressure of 140/90 mm Hg or higher before pregnancy or before the 20th week of gestation or when hypertension persists for more than 12 weeks postpartum.
- Successful management of asthma in pregnancy involves elimination of environmental triggers, drug therapy, and client education.
- Ideally, women with hematologic conditions are screened before conception and are made aware of the risks to themselves and to a pregnancy.
- A wide variety of infections, such as rubella, herpes simplex, hepatitis B, varicella, parvovirus B19, and many sexually transmitted infections can affect the pregnancy, having a negative impact on its outcome.
- The younger the adolescent is at the time of the first pregnancy, the more likely it is that she will have another pregnancy during her teens. About 1 million teenagers between the ages of 15 and 19 become pregnant each year; about half give birth and keep their infants.
- The nurse's role in caring for the pregnant adolescent is to assist her in identifying the options for this pregnancy, including abortion, self-parenting of the child, temporary foster care for the baby or herself, or placement for adoption.
- The prevalence of HIV/AIDS is increasing more rapidly among women then men: half of all the HIV/AIDS cases worldwide now occur in women. There are only three recognized modes of HIV transmission: unprotected sexual intercourse with an infected partner, contact with infected blood or blood products, and perinatal transmission. Breastfeeding is a major contributing factor in mother-to-child transmission of HIV.
- Cases of perinatal AIDS have decreased in the past several years in the United States, primarily because of the use of zidovudine (ZDV) therapy in pregnant women with HIV. The U.S. Public Health Service recommends that all pregnant women should be offered HIV antibody testing regardless of their risk of infection, and that testing should be done during the initial prenatal evaluation.
- Pregnant women with substance abuse problems commonly abuse several substance, making it difficult to ascribe a specific perinatal effect to any one substance. Societal attitudes regarding pregnant women and substance abuse may prohibit them from admitting the problem and seeking treatment.
- Substance abuse during pregnancy is associated with preterm labor, abortion, low birthweight, CNS and fetal anomalies, and long-term childhood developmental consequences.
- Fetal alcohol spectrum disorder is a lifelong yet completely preventable set of physical, mental, and neurobehavioral birth defects; it is the leading cause of mental retardation in the United States.
- Nursing management for the woman with substance abuse focuses on screening and preventing substance abuse to reduce the high incidence of obstetric and medical complications as well as the morbidity and mortality among passively addicted newborns.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. Which of the following would the nurse include when teaching a pregnant woman about the pathophysiologic mechanisms associated with gestational diabetes?
   a. Pregnancy fosters the development of carbohydrate cravings.
   b. There is progressive resistance to the effects of insulin.
   c. Hypoinsulinemia develops early in the first trimester.
   d. Glucose levels decrease to accommodate fetal growth.
2. When providing prenatal education to a pregnant woman with asthma, which of the following would be important for the nurse to do?
   a. Explain that she should avoid steroids during her pregnancy.
   b. Demonstrate how to assess her blood glucose levels.
   c. Teach correct administration of subcutaneous bronchodilators.
   d. Ensure she seeks treatment for any acute exacerbation.
3. Which of the following conditions would most likely cause a pregnant woman with type 1 diabetes the greatest difficulty during her pregnancy?
   a. Placenta previa
   b. Hyperemesis gravidarum
   c. Abruptio placentae
   d. Rh incompatibility
4. Women who drink alcohol during pregnancy:
   a. Often produce more alcohol dehydrogenase
   b. Usually become intoxicated faster than before
   c. Can give birth to an infant with fetal alcohol spectrum disorder
   d. Gain fewer pounds throughout the gestation
5. When explaining to a pregnant woman about HIV infection and transmission, which of the following would the nurse include?
   a. It primarily occurs when there is a large viral load in the blood.
   b. HIV is most commonly transmitted via sexual contact.
   c. It affects the majority of infants of mothers with HIV infection.
   d. Nurses are most frequently affected due to needle sticks.

CRITICAL THINKING EXERCISES

1. A client at 26 weeks' gestation came to the clinic to follow up on her previous 1-hour glucose screening. Her results had come back outside the accepted screening range, and a 3-hour glucose tolerance test (GTT) had been ordered. It resulted in three abnormal values, confirming a diagnosis of gestational diabetes. As the nurse in the prenatal clinic you are seeing her for the first time.
   a. What additional information will you need to provide care for her?
   b. What education will she need to address this new diagnosis?
   c. How will you evaluate the effectiveness of your interventions?
2. A 14-year-old girl comes to the public health clinic with her mother. The mother tells you that her daughter has been "out messing around and has gotten herself pregnant." The girl is crying quietly in the corner and avoids eye contact with you. The mother reports that her daughter "must be following in my footsteps" because she became pregnant when she was only 15 years old. The client's mother goes back out into the waiting room and leaves the client with you.
   a. What is your first approach with the client to gain her trust?
   b. List the client's educational needs during this pregnancy.
   c. What prevention strategies are needed to prevent a second pregnancy?
3. Linda, a 27-year-old G3P2, is admitted to the labor and birth suite because of preterm rupture of membranes at an estimated 35 weeks' gestation. She has received no prenatal care and reports this was an unplanned pregnancy. Linda appears distracted and very thin. She reports that her two previous children have been in foster care since birth because the child welfare authorities "didn't think I was an adequate mother." She denies any recent use of alcohol or

drugs, but you smell alcohol on her breath. She has a spontaneous vaginal birth a few hours later, producing a 4-lb baby boy with Apgar scores of 8 at 1 minute and 9 at 5 minutes.

a. What aspects of this woman's history may lead the nurse to suspect that this infant may be at risk for fetal alcohol spectrum disorder?

b. What additional screening or laboratory tests might validate your suspicion?

c. What physical and neurodevelopmental deficits might present later in life if the infant has fetal alcohol spectrum disorder?

Study Activities

1. In the maternity clinic or hospital setting, interview a pregnant woman with a preexisting medical condition (e.g., diabetes, asthma, sickle cell anemia) and find out how this condition affects her life and this pregnancy, especially her lifestyle choices.
2. You have a close friend who has a problem with alcohol but denies it. She now admits to you that she thinks she is pregnant because she missed her period. What specific information and advice should you give her concerning alcohol use during pregnancy?
3. Should marijuana be legalized in the United States? What impact might your view (pro or con) have on pregnant women and their offspring?
4. Outline a discussion you might have with an HIV-positive pregnant woman who doesn't see the need to take antiretroviral agents to prevent perinatal transmission.
5. The nurse is preparing a teaching session about breastfeeding for a group of pregnant women who have various infections listed below. The nurse would include women with which of the following conditions? Select all that apply.

   a. Hepatitis B

   b. Parvovirus B19

   c. Herpesvirus type 2

   d. HIV-positive status

   e. Cytomegalovirus

   f. Varicella-zoster virus

CHAPTER 21

Nursing Management of Labor and Birth at Risk

KEY TERMS

amnioinfusion
cesarean birth
dystocia
forceps
hypertonic uterine dysfunction
hypotonic uterine dysfunction
labor induction
macrosomia
postterm pregnancy
precipitous labor
preterm labor
shoulder dystocia
tocolytic
umbilical cord prolapse
vacuum extractor
vaginal birth after cesarean (VBAC)

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Define dystocia.
2. Identify the four major abnormalities or problems associated with dysfunctional labor patterns, giving examples of each problem.
3. Describe the nursing management for the woman with dysfunctional labor experiencing a problem with the powers, passenger, passageway, and psyche.
4. Develop a plan of care for the woman experiencing preterm labor.
5. Discuss the nursing assessment and management of the woman experiencing a postterm pregnancy.
6. Explain four obstetric emergencies that can complicate labor and birth, including appropriate management for each.
7. Compare and contrast the nursing management for the woman undergoing labor induction or augmentation, forceps- and vacuum-assisted birth.
8. Summarize the plan of care for a woman who is to undergo a cesarean birth.
9. Discuss the key areas to be addressed when caring for a woman who is to undergo vaginal birth after cesarean (VBAC).

Jennifer, a 29 year-old G1P0, is at 41 weeks' gestation. Her health care provider has recommended that she come in for induction. She is very anxious about doing this since she has heard "horror stories" about the "hard painful contractions" that can result. What can the nurse do to calm her fears?

Wow

In face of a crisis or a potentially bad outcome, add a mixture of warmth and serenity to your technical abilities.

Most women describe pregnancy as an exciting time in their life, but the development of an unexpected problem can suddenly change this description dramatically. Consider the woman who has had a problem-free pregnancy and then suddenly develops a condition during labor, changing a routine situation into a possible crisis. Many complications occur with little or no warning and present challenges for the perinatal health care team as well as the family. The nurse plays a major role in identifying the problem quickly and coordinating immediate intervention, ultimately achieving a positive outcome.

National Health Goals address maternal and newborn outcomes involving complications of labor and birth and cesarean birth (USDHHS, 2000). These goals are highlighted in Healthy People 2010 21.1.

This chapter will address several conditions occurring during labor and birth that may increase the risk of an adverse outcome for the mother and fetus. It also describes birth-related procedures that may be necessary for the woman who develops a condition that increases her risk or that may be needed to reduce the woman's risk for developing a condition, thus promoting optimal maternal and fetal outcomes. Nursing management of the woman and her family focuses on professional support and compassionate care.

Dystocia

Dystocia, defined as abnormal or difficult labor, can be influenced by a vast number of maternal and fetal factors. Dystocia is said to exist when the progress of labor deviates from normal; it is characterized by a slow and abnormal progression of labor. It occurs in approximately 8% to 11% of all labors and is the leading indicator for primary cesarean birth in the United States (Joy & Lyon, 2007).

To characterize a labor as abnormal, a basic understanding of normal labor is essential. Normal labor starts with regular uterine contractions that are strong enough to result in cervical effacement and dilation. Early in labor, uterine contractions are irregular and cervical effacement and dilation occur gradually. When cervical dilation reaches 4 cm and uterine contractions become more powerful, the active phase of labor begins. It is usually during the active phase that dystocia becomes apparent. Because dystocia cannot be predicted or diagnosed with certainty, the term "failure to progress" is often used. This term includes lack of progressive cervical dilation, lack of descent of the fetal head, or both. An adequate trial of labor is needed to declare with confidence that dystocia or "failure to progress" exists.

Early identification of and prompt interventions for dystocia are essential to minimize risk to the woman and fetus. According to American College of Obstetrics and Gynecology (ACOG, 2003a), factors associated with an increased risk for dystocia include epidural analgesia, excessive analgesia, multiple gestation, hydramnios, maternal exhaustion, ineffective maternal pushing technique, occiput posterior position, longer first stage of labor, nulliparity, short maternal stature (less than 5 feet tall), fetal birth weight (more than 8.8 lb), shoulder dystocia, abnormal fetal presentation or position (breech), fetal anomalies (hydrocephalus), maternal age older than 35 years, gestational age more than 41 weeks, chorioamnionitis, ineffective uterine contractions, and high fetal station at complete cervical dilation.

Dystocia can result from problems or abnormalities involving the expulsive forces (known as the "powers"); presentation, position, and fetal development (the "passenger"); the maternal bony pelvis or birth canal (the "passageway"); and maternal stress (the "psyche"). Table 21.1 summarizes the diagnosis, therapeutic management, and nursing management of the common problems associated with dystocia.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce maternal illness and complications due to pregnancy Reduce maternal complications during hospitalized labor and delivery from a baseline of 31.2/100 deliveries to a target of 24/100 deliveries Reduce cesarean births among low-risk (full term, singleton, vertex presentation) women Reduce the number of cesarean births in women giving birth for the first time from a baseline of 18% to 15% Reduce the number of cesarean births in women with prior cesarean birth from 72% to 63%	• Will help to focus attention on the need for close antepartum surveillance and identification of risk factors for maternal illness and complications, particularly those most likely to be associated with maternal death • Will help to promote development of specific guidelines for trials of labor and labor management, continual labor support, and practice patterns, while helping to ensure positive maternal and newborn outcomes

USDHHS, 2000.

PROBLEMS WITH THE POWERS

When the expulsive forces of the uterus become dysfunctional, the uterus may either never fully relax (hypertonic contractions), placing the fetus in jeopardy, or relax too much (hypotonic contractions), causing ineffective contractions. Still another dysfunction can occur when the uterus contracts so frequently and with such intensity that a very rapid birth will take place (precipitous labor).

(text continues on page 643)

TABLE 21.1 DIAGNOSIS AND MANAGEMENT OF COMMON PROBLEMS ASSOCIATED WITH DYSTOCIA

	Description	Diagnosis	Therapeutic Management	Nursing Management
Problems with the powers				
Hypertonic uterine dysfunction	Occurring in the latent phase of the first stage of labor (cervical dilation of <4 cm); uncoordinated. Force of contraction typically in the midsection of uterus at the junction of the active upper and passive lower segments of the uterus rather than in the fundus. Loss of downward pressure to push the presenting part against the cervix (Gilbert & Harmon, 2007). Woman commonly becomes discouraged due to lack of progress; also has increased pain secondary to uterine anoxia.	Characteristic hypertonicity of the contractions and the lack of labor progress	Therapeutic rest with the use of sedatives to promote relaxation and stop the abnormal activity of the uterus. Identification and intervention of any contributing factors. Ruling out abruptio placentae (also associated with high resting tone and persistent pain). Onset of a normal labor pattern occurs in many women after a 4- to 6-hour rest period (Gilbert, 2007).	Institute bed rest and sedation to promote relaxation and reduce pain. Assist with measures to rule out fetopelvic disproportion and fetal malpresentation. Evaluate fetal tolerance to labor pattern, such as monitoring of FHR patterns. Assess for signs of maternal infection. Promote adequate hydration through IV therapy. Provide pain management via epidural or IV analgesics. Assist with amniotomy to augment labor. Explain to woman and family about dysfunctional pattern. Plan for operative birth if normal labor pattern is not achieved.
Hypotonic uterine dysfunction	Often termed secondary uterine inertia because the labor begins normally and then the frequency and intensity of contractions decrease (Joy & Lyon, 2007). Possible contributing factors: overdistended uterus with multifetal pregnancy or large single fetus, too much pain medicine given too early in labor, fetal malposition, and regional anesthesia (Bonilla & Forouzan, 2007).	Evaluation of the woman's labor to confirm that she is having hypotonic active labor rather than a long latent phase. Evaluation of maternal pelvis and fetal presentation and position to ensure that they are not contributing to the prolonged labor without noticeable progress.	Identification of possible cause of inefficient uterine action (a malpositioned fetus, a too small maternal pelvis, overdistention of the uterus with fluid or a macrosomic fetus). Rupture of amniotic sac (amniotomy) if all causes ruled out. Possible augmentation with oxytocin (Pitocin) to stimulate effective uterine contractions. Cesarean birth if amniotomy and augmentation ineffective.	Administer oxytocin as ordered once fetopelvic disproportion is ruled out. Assist with amniotomy if membranes are intact. Provide continuous electronic fetal monitoring. Monitor vital signs, contractions, and cervix continually. Assess for signs of maternal and fetal infection. Explain to woman and family about dysfunctional pattern. Plan for surgical birth if normal labor pattern is not achieved or fetal distress occurs.

Precipitous labor	Abrupt onset of higher-intensity contractions occurring in a shorter period of time instead of the more gradual increase in frequency, duration, and intensity that typifies most spontaneous labors	Identification based on the rapidity of progress through the stages of labor	Vaginal delivery if maternal pelvis is adequate	Closely monitor woman with previous history. Anticipate use of scheduled induction to control labor rate. Administer pharmacologic agents, such as tocolytics, to slow labor. Stay in constant attendance to monitor progress.
Problems with the passenger				
Persistent occiput posterior position	Engagement of fetal head in the left or right occipitotransverse position with the occiput rotating posteriorly rather than into the more favorable occiput anterior position (fetus born facing upward instead of the normal downward position) (Bonilla & Forouzan, 2007). Labor usually much longer and more uncomfortable (causing increased back pain during labor) if fetus remains in this position. Possible extensive caput succedaneum and molding from the sustained occiput posterior position.	Leopold maneuvers and vaginal examination to determine position of fetal head in conjunction with the mother's complaints of severe back pain (back of fetal head pressing on mother's sacrum and coccyx).	Labor to proceed, preparing the woman for a long labor (spontaneous resolution possible). Comfort measures and maternal positioning to help promote fetal head rotation.	Assess for complaints of intense back pain in first stage of labor. Anticipate possible use of forceps to rotate to anterior position at birth or manual rotation to anterior position at end of second stage. Assess for prolonged second stage of labor with arrest of descent (common with this malposition). Encourage maternal position changes to promote fetal head rotation: hands and knees and rocking pelvis back and forth; side-lying position; side lunges during contractions; sitting, kneeling, or standing while leaning forward; squatting position to give birth and enlarge pelvic outlet. Prepare for possible cesarean birth if rotation is not achieved. Administer agents as ordered for pain relief (effective pain relief crucial to help the woman to tolerate the back discomfort). Apply low back counterpressure during contractions to ease the discomfort. Use other

TABLE 21.1 DIAGNOSIS AND MANAGEMENT OF COMMON PROBLEMS ASSOCIATED WITH DYSTOCIA (continued)

	Description	Diagnosis	Therapeutic Management	Nursing Management
				helpful measures to attempt to rotate the fetal head, including lateral abdominal stroking in the direction that the fetal head should rotate; assisting the client into a hands-and-knees position (all fours); and squatting, pelvic rocking, stair climbing, assuming a side-lying position toward the side that the fetus should rotate, and side lunges (WHO, 2007). Provide measures to reduce anxiety. Continuously reinforce the woman's progress. Teach woman about measures to facilitate fetal head rotation.
Face and brow presentation	Face presentation with complete extension of the fetal head. Brow presentation: fetal head between full extension and full flexion so that the largest fetal skull diameter presents to the pelvis.	Diagnosis only once labor is well established via vaginal examination; palpation of facial features as the presenting part rather than the fetal head	Vaginal birth possible with face presentation with an adequate maternal pelvis and fetal head rotation; cesarean birth if head rotates backward. Cesarean birth for brow presentation unless head flexes.	Assist with evaluating for feto-pelvic disproportion. Anticipate cesarean birth if vertex position is not achieved. Explain fetal malposition to the woman and her partner. Provide close observation for any signs of fetal hypoxia, as evidenced by late decelerations on the fetal monitor.
Breech presentation	Fetal buttocks, or breech, presenting first rather than the head. 1. Frank breech: buttock as the presenting part, with hips flexed and legs and knees extended upward 2. Complete breech (or full breech): buttock as presenting part, with hips flexed and knees flexed in a "cannonball" position	Vaginal examination to determine breech presentation. Ideally, ultrasound to confirm a clinically suspected presentation and to identify any fetal anomalies.	The optimal method of birth is controversial: cesarean birth by some providers unless the fetus is small and the mother has a large pelvis; vaginal birth by others with each occurrence treated individually and labor monitored very closely.	Assess for associated conditions such as placenta previa, hydramnios, fetal anomalies, and multiple gestation. Arrange for ultrasound to confirm fetal presentation. Assist with external cephalic version possible after 36 weeks and administer tocolytics to assist with external cephalic version.

	3. Footling or incomplete breech: One or two feet as the presenting part, with one or both hips extended		Regardless of the birth method selected, the risk for trauma is high. Breech vaginal births are not recommended by ACOG and come with a higher risk to the mother and infant than a planned surgical birth (ACOG, 2001). Vaginal delivery: fetus allowed to spontaneously deliver up to the umbilicus; then maneuvers to assist in the delivery of the remainder of the body, arms, and head; fetal membranes left intact as long as possible to act as a dilating wedge and to prevent cord prolapse; anesthesiologist and pediatrician present. Caesarean birth; Use of external cephalic version to reduce the chance of breech presentation at birth; attempted after the 36th week of gestation but before the start of labor (some fetuses spontaneously turn to a cephalic presentation on their own toward term, and some will return to the breech presentation if external cephalic version is attempted too early [Fischer, 2007]); variable success rates, with risk for fractured bones, ruptured viscera, abruptio placentae, fetomaternal hemorrhage, and umbilical cord	Anticipate trial labor for 4 to 6 hours to evaluate progress if version is unsuccessful. Plan for cesarean birth if no progress is seen or fetal distress occurs. After external cephalic version, administer RhoGAM to the Rh-negative woman to prevent a sensitization reaction if trauma has occurred and the potential for mixing of blood exists (Gilbert, 2007).

(continued)

TABLE 21.1 DIAGNOSIS AND MANAGEMENT OF COMMON PROBLEMS ASSOCIATED WITH DYSTOCIA (continued)

	Description	Diagnosis	Therapeutic Management	Nursing Management
			entanglement (Fischer, 2007). Tocolytic drugs to relax the uterus, as well as other methods, to facilitate external cephalic version at term (Jenis, 2007). Individual evaluation of each woman for all factors before any interventions are initiated.	
Shoulder dystocia	Delivery of fetal head with neck not appearing; retraction of chin against the perineum; shoulders remaining wedged behind the mother's pubic bone, causing a difficult birth with potential for injury to both mother and baby. If shoulders still above the brim at this stage, no advancement. Newborn's chest trapped within the vaginal vault; chest unable to expand with respiration (although nose and mouth are outside). Risk of umbilical cord compression between the fetal body and the maternal pelvis.	Emergency, often unexpected complication. Diagnosis made when newborn's head delivers without delivery of neck and remaining body structures. Primary risk factors, including suspected infant macrosomia (weight >4,500 g), maternal diabetes mellitus, excessive maternal weight gain, abnormal maternal pelvic anatomy, maternal obesity, postdates pregnancy, short stature, a history of previous shoulder dystocia, and use of epidural analgesia (Gurewitsch et al., 2006).	If anticipated, preparatory tasks instituted: alerting of key personnel; education of woman and family regarding steps to be taken in the event of a difficult birth; emptying of woman's bladder to allow additional room for possible maneuvers needed for the birth. McRobert's maneuver. Suprapubic pressure (not fundal) (see Fig. 21.1). Combination of maneuvers effective in more than 50% of cases of shoulder dystocia (Abenhaim et al., 2007). Newborn resuscitation team readily available.	Intervene immediately due to cord compression. Perform McRobert's maneuver and application of suprapubic pressure. Assist with positioning the woman in squatting position, hands-and-knees position, or lateral recumbent position for birth to free shoulder. Anticipate cesarean birth if no success in dislodging shoulders. Clear room of unnecessary clutter to make room for additional personnel and equipment (Anderson, 2007). After the birth, assess newborn for crepitus, deformity, Erb's palsy, or bruising, which might suggest neurologic damage or a fracture (Arenson & Drake, 2007).
Multiple gestation	More than one fetus, leading to uterine overdistention and possibly resulting in hypotonic contractions and abnormal presentations of the fetuses. Fetal hypoxia during labor a significant threat due to placenta providing oxygen and nutrients to more than one fetus.	Nearly all multiples are now diagnosed early by ultrasound. Most women go into labor before 37 weeks.	Admission to facility with specialized care unit if woman goes into labor. Spontaneous progression of labor if woman has no complicating factors and first fetus is in longitudinal lie. Separate monitoring of each fetal heart rate during labor and birth.	Assess for hypotonic labor pattern due to overdistention. Evaluate for fetal presentation, maternal pelvic size, and gestational age to determine mode of delivery. Ensure presence of neonatal team for birth of multiples. Anticipate need for cesarean birth, which is common in multiple gestations.

			After birth of first fetus, clamping of cord and lie of the second twin assessed. Possible external cephalic version necessary to assist in providing a longitudinal lie. Second and subsequent fetuses at greater risk for birth-related complications, such as umbilical cord prolapse, malpresentation, and abruptio placentae (Zach & Pramanik, 2007). Cesarean birth if risk factors high.	
Excessive fetal size and abnormalities	Macrosomia leading to feto-pelvic disproportion (fetus unable to fit through the maternal pelvis to be born vaginally). Reduced contraction strength due to overdistention by large fetus leading to a prolonged labor and the potential for birth injury and trauma. Fetal abnormalities possibly interfering with fetal descent, leading to prolonged labor and difficult birth.	A diagnosis of fetal macrosomia can be confirmed by measuring the birthweight after birth. Suspicion of macrosomia based on the findings of an ultrasound examination before onset of labor (if suspected due to conditions such as maternal diabetes or obesity, estimation of fetal weight via ultrasound). Leopold's maneuvers to estimate fetal weight and position on admission to labor and birth unit.	Scheduled cesarean birth if diagnosis is made before the onset of labor to reduce the risk of injury to both the newborn and the mother. If identified by Leopold's maneuvers, possible trial of labor to evaluate progress; however, providers usually opt to proceed with a cesarean birth in a primigravida with a macrosomic fetus (Catalano, 2007).	Assess for inability of fetus to descend. Anticipate need for vacuum and forceps-assisted births (common). Plan for cesarean birth if maternal parameters are inadequate to give birth to large fetus.
Problems with the passageway	Contraction of one or more of the three planes of the pelvis. Poorer prognosis for vaginal birth in women with android and platypelloid types of pelvis. Contracted pelvis involving reduction in one or more of the pelvic diameters interfering with progress	Shortest A-P diameter <10 cm or greatest transverse diameter <12 cm. (Approximation of A-P diameter via measurement of diagonal conjugate, which in the contracted pelvis is <11.5 cm). X-ray pelvimetry to determine the smallest A-P diameter	Focus on allowing natural forces of labor contractions to push the largest diameter (biparietal) of the fetal head beyond the obstruction or narrow passage. Possible forceps and vacuum extraction to assist navigation through this passageway.	Assess for poor contractions, slow dilation, prolonged labor. Evaluate bowel and bladder status to reduce soft tissue obstruction and allow increased pelvic space. Anticipate trial of labor; if no labor progression after an adequate trial, plan for cesarean birth.

(continued)

TABLE 21.1 DIAGNOSIS AND MANAGEMENT OF COMMON PROBLEMS ASSOCIATED WITH DYSTOCIA (continued)

	Description	Diagnosis	Therapeutic Management	Nursing Management
	of labor: inlet, midpelvis, and outlet contracture. Obstruction in the birth canal, such as placenta previa that partially or completely obstructs the internal os of the cervix, fibroids in the lower uterine segment, a full bladder or rectum, an edematous cervix caused by premature bearing-down efforts, and human papillomavirus (HPV) warts.	through which the fetal head must pass. Interischial tuberous diameter of <8 cm possibly compromising outlet contracture (outlet and midpelvic contractures frequently occur together).		
Problems with the psyche	Release of stress-related hormones (catecholamines, cortisol, epinephrine, beta-endorphin), which act on smooth muscle (uterus) and reduce uterine contractility. Excessive release of catecholamines and other stress-related hormones not therapeutic. Release also results in decreased uteroplacental perfusion and increased risk for poor newborn adjustment (Gilbert, 2007).	Ruling out of other possible causes of dystocia	Treatment dependent on woman's responses such as anxiety, fear, anger, frustration, or denial (highly variable due to woman's understanding of the condition itself, past experiences, previous coping mechanisms, and the amount of family and nursing support received). Appropriate medical or surgical interventions depending on the underlying condition.	Provide comfortable environment—dim lighting, music. Encourage partner to participate. Provide pain management to reduce anxiety and stress. Ensure continuous presence of staff to allay anxiety. Provide frequent updates concerning fetal status and progress. Provide ongoing encouragement to minimize the woman's stress and help her to cope with labor and to promote a positive, timely outcome. Assist in relaxation and comfort measures to help her body work more effectively with the forces of labor. Engage the woman in conversation about her emotional well-being; offer anticipatory guidance and reassurance to increase her self-esteem and ability to cope, decrease frustration, and encourage cooperation.

Hypertonic uterine dysfunction occurs when the uterus never fully relaxes between contractions. Subsequently, contractions are erratic and poorly coordinated because more than one uterine pacemaker is sending signals for contraction. Placental perfusion becomes compromised, thereby reducing oxygen to the fetus. These hypertonic contractions exhaust the mother, who is experiencing frequent, intense, and painful contractions with little progression. This dysfunctional pattern occurs in early labor and affects nulliparous women more than multiparous women (Cheng & Caughey, 2007).

Hypotonic uterine dysfunction occurs during active labor (dilation more than 4 cm) when contractions become poor in quality and lack sufficient intensity to dilate and efface the cervix. The major risk with this complication is hemorrhage after giving birth because the uterus cannot contract effectively to compress blood vessels.

Precipitous labor is one that is completed in less than 3 hours. Women experiencing precipitous labor typically have soft perineal tissues that stretch readily, permitting the fetus to pass through the pelvis quickly and easily. Maternal complications are rare if the maternal pelvis is adequate and the soft tissues yield to a fast fetal descent. Potential fetal complications may include head trauma, such as intracranial hemorrhage or nerve damage, and hypoxia due to the rapid progression of labor (Sharf et al., 2007).

PROBLEMS WITH THE PASSENGER

Any presentation other than occiput anterior or a slight variation of the fetal position or size increases the probability of dystocia. These variations can affect the contractions or fetal descent through the maternal pelvis. Common problems involving the fetus include occiput posterior position, breech presentation, multifetal pregnancy, excessive size (macrosomia) as it relates to cephalopelvic disproportion (CPD), and structural anomalies.

Persistent occiput posterior is the most common malposition, occurring in about 15% of laboring women. The reasons for this malposition are often unclear. This position presents slightly larger diameters to the maternal pelvis, thus slowing fetal descent. A fetal head that is poorly flexed may be responsible. In addition, poor uterine contractions may not push the fetal head down into the pelvic floor to the extent that the fetal occiput sinks into it rather than being pushed to rotate in an anterior direction.

Face and brow presentations are rare and are associated with fetal abnormalities (anencephaly), pelvic contractures, high parity, placenta previa, hydramnios, low birthweight, or a large fetus (WHO, 2007).

Breech presentation, which occurs in 3% to 4% of labors, is frequently associated with multifetal pregnancies, grand multiparity (more than five births), advanced maternal age, placenta previa, hydramnios, preterm births, and fetal anomalies such as hydrocephaly (Lee, El-Sayed, & Gould, 2007). In a persistent breech presentation, an increased frequency of prolapsed cord, placenta previa, low birthweight from preterm birth, fetal or uterine anomalies, and perinatal morbidity and mortality from a difficult birth may occur (Cunningham et al., 2005). Perinatal mortality is increased two- to four-fold with a breech presentation, regardless of the mode of delivery (Lee, El-Sayed, & Gould, 2007).

Shoulder dystocia is defined as the obstruction of fetal descent and birth by the axis of the fetal shoulders after the fetal head has been delivered. The incidence of shoulder dystocia is increasing due to increasing birthweight, with reports of it in up to 2% of vaginal births. It is one of the most anxiety-provoking emergencies encountered in labor. Failure of the shoulders to deliver spontaneously places both the woman and the fetus at risk for injury. Postpartum hemorrhage, secondary to uterine atony or vaginal lacerations, is the major complication to the mother. Transient Erb's or Duchenne's brachial plexus palsies and clavicular or humeral fractures are the most common fetal injuries encountered with shoulder dystocia (WHO, 2007). Newborns experiencing shoulder dystocia typically have greater shoulder-to-head and chest-to-head disproportions compared with those delivered without dystocia (Cunningham et al., 2005). Prompt recognition and appropriate management, such as with McRobert's maneuver or suprapubic pressure, can reduce the severity of injuries to the mother and newborn (Fig. 21.1).

Take NOTE!

Prompt recognition and appropriate management of shoulder dystocia can reduce the severity of injuries to the mother and infant. Immediately assess the infant for signs of trauma such as a fractured clavicle, Erb's palsy, or neonatal asphyxia. Assess the mother for excessive vaginal bleeding and blood in the urine from bladder trauma.

Multiple gestation refers to twins, triplets, or more infants within a single pregnancy (Box 21.1). The incidence is increasing, primarily as a result of infertility treatment (both ovarian stimulation and in vitro fertilization) and an increased number of women giving birth at older ages (March of Dimes, 2007b). The incidence of twins is approximately 1 in 30 conceptions, with about two thirds of them due to the fertilization of two ova (dizygotic or fraternal) and about one third occurring from the splitting of one fertilized ovum (monozygotic or identical twins). One in approximately 8,100 pregnancies results in triplets (March of Dimes, 2007b). The most

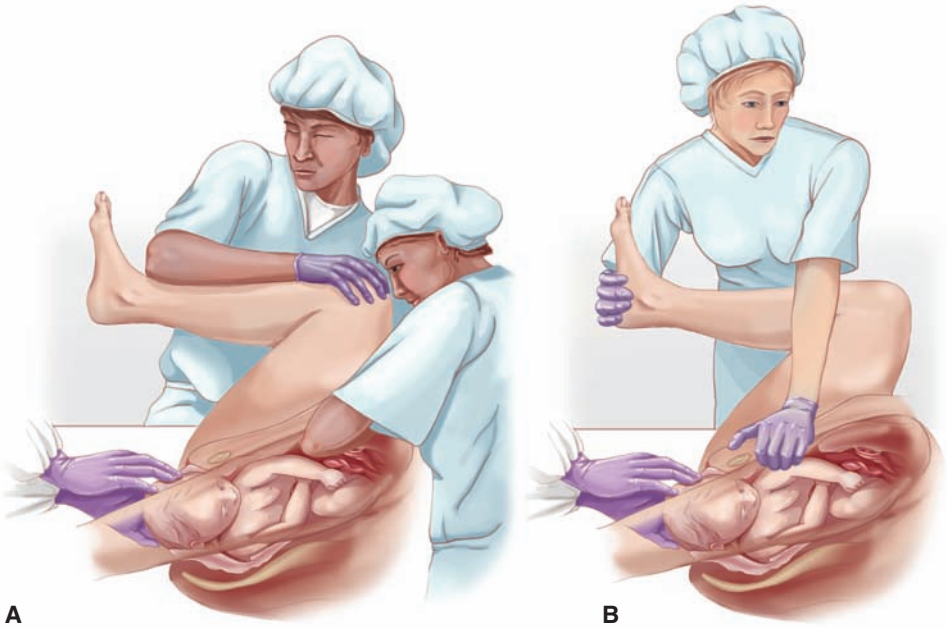

FIGURE 21.1 Maneuvers to relieve shoulder dystocia. (**A**) McRobert's maneuver. The mother's thighs are flexed and abducted as much as possible to straighten the pelvic curve. (**B**) Suprapubic pressure. Pressure is applied just above the pubic bone, pushing the fetal anterior shoulder downward to displace it from above the mother's symphysis pubis. The newborn's head is depressed toward the mother's anus while suprapubic pressure is applied.

BOX 21.1 Multiple Gestation

As the name implies, multiple gestation involves more than one fetus. These fetuses can result from fertilization of a single ovum or multiple ova. Twin pregnancies that are single-ovum conceptions (monozygotic twins) share one chorion (membrane closest to the uterus), and each twin has his or her own amnion (membrane surrounding the amniotic fluid). One fertilized ovum splits into two separate individuals who are said to be natural clones. They have separate amniotic sacs and placentas, are identical in appearance, and are always the same gender. Twin pregnancies that are multiple-ova conceptions (dizygotic twins) result from two ova fertilized by two sperm. Genetically, dizygotic twins are as alike (or unlike) as any other pair or siblings.

The fetuses of a twin gestation, whether monozygotic or dizygotic, are slightly "squashed" because two fetuses develop in a space usually occupied by one. This compression is reflected in the slowing of weight gain in both twins compared to that for singletons (Zach & Pramanik, 2007).

Multiple births other than twins can be of the identical type, the fraternal type, or combinations of the two. Triplets can occur from the division of one zygote into two, with one dividing again, producing identical triplets, or they can come from two zygotes, one dividing into a set of identical twins, and the second zygote developing as a single fraternal sibling, or from three separate zygotes. Triplets are said to occur once in 7,000 births and quadruplets once in 660,000 births (March of Dimes, 2007b). In recent years, fertility drugs used to induce ovulation have resulted in a greater frequency of quadruplets, quintuplets, sextuplets, and even octuplets.

common maternal complication is postpartum hemorrhage resulting from uterine atony.

Excessive fetal size and abnormalities can also contribute to labor and birth dysfunctions. **Macrosomia**, in which a newborn weighs 4,000 to 4,500 g (8.13 to 9.15 lb) or more at birth, complicates approximately 10% of all pregnancies (Jazayeri & Contreras, 2007). Fetal abnormalities may include hydrocephalus, ascites, or a large mass on the neck or head. Complications associated with dystocia related to excessive fetal size and anomalies include an increased risk for postpartum hemorrhage, dysfunctional labor, fetopelvic disproportion, soft tissue laceration during vaginal birth, fetal injuries or fractures, and asphyxia (Joy & Lyon, 2007).

PROBLEMS WITH THE PASSAGEWAY

Problems with the passageway (pelvis and birth canal) are related to a contraction of one or more of the three planes of the maternal pelvis: inlet, midpelvis, and outlet. The female pelvis can be classified into four types based on the shape of the pelvic inlet, which is bounded anteriorly by the posterior border of the symphysis pubis, posteriorly by the sacral promontory, and laterally by the linea terminalis. The four basic types are gynecoid, anthropoid, android, and platypelloid (see Chapter 12 for additional information). Contraction of the midpelvis is more common than inlet contraction and typically causes an arrest of fetal descent. Obstructions in the maternal birth canal, such as swelling of the soft maternal tissue and cervix, termed soft tissue dystocia, also can hamper fetal

descent and impede labor progression outside the maternal bony pelvis.

PROBLEMS WITH THE PSYCHE

Many women experience an array of emotions during labor, which may include fear, anxiety, helplessness, being alone, and weariness. These emotions can lead to psychological stress, which indirectly can cause dystocia.

Nursing Assessment

Begin the assessment by reviewing the client's history to look for risk factors for dystocia. Include in the assessment the mother's frame of mind to identify fear, anxiety, stress, lack of support, and pain, which can interfere with uterine contractions and impede labor progress. Helping the woman to relax will promote normal labor progress.

Assess the woman's vital signs. Note any elevation in temperature (might suggest an infection) or changes in heart rate or blood pressure (might signal hypovolemia). Evaluate the uterine contractions for frequency and intensity. Question the woman about any changes in her contraction pattern, such as a decrease or increase in frequency or intensity, and report these. Assess fetal heart rate and pattern, reporting any abnormal patterns immediately.

Assess fetal position via Leopold's maneuvers to identify any deviations in presentation or position, and report any deviations. Assist with or perform a vaginal examination to determine cervical dilation, effacement, and engagement of the fetal presenting part. Evaluate for evidence of membrane rupture. Report any malodorous fluid.

Nursing Management

Nursing management of the woman with dystocia, regardless of the etiology, requires patience. The nurse should provide physical and emotional support to the client and her family. The final outcome of any labor depends on the size and shape of the maternal pelvis, the quality of the uterine contractions, and the size, presentation, and position of the fetus. Thus, dystocia is diagnosed not at the start of labor but rather after it has progressed for a time.

Promoting the Progress of Labor

The nurse plays a major role in determining the progress of labor. Continue to assess the woman, frequently monitoring cervical dilation and effacement, uterine contractions, and fetal descent, and document that all assessed parameters are progressing. Evaluate progress in active labor by using the simple rule of 1 cm/hour for cervical dilation. When the woman's membranes rupture, if they have not already ruptured, observe for visible cord prolapse.

▶ *Take* NOTE!

If a dysfunctional labor occurs, contractions will slow or fail to advance in frequency, duration, or intensity; the cervix will fail to respond to uterine contractions by dilating and effacing; and the fetus will fail to descend.

Throughout labor, assess the woman's fluid balance status. Check skin turgor and mucous membranes. Monitor intake and output. Also monitor the client's bladder for distention at least every 2 hours and encourage her to empty her bladder often. In addition, monitor her bowel status. A full bladder or rectum can impede descent.

Continue to monitor fetal well-being. If the fetus is in the breech position, be especially observant for visible cord prolapse and note any variable decelerations in heart rate. If either occurs, report it immediately.

Be prepared to administer a labor stimulant such as oxytocin (Pitocin) if ordered to treat hypotonic labor contractions. Anticipate the need to assist with manipulations if shoulder dystocia is diagnosed. Prepare the woman and her family for the possibility of a cesarean birth if labor does not progress.

Providing Physical and Emotional Comfort

Employ physical comfort measures to promote relaxation and reduce stress. Offer blankets for warmth and a backrub, if the client wishes, to reduce muscle tension. Provide an environment conducive to rest so the woman can conserve her energy. Lower the lights and reduce external noise by closing the hallway door. Offer a warm shower to promote relaxation (if not contraindicated). Use pillows to support the woman in a comfortable position, changing her position every 30 minutes to reduce tension and to enhance uterine activity and efficiency. Offer her fluids/food as appropriate to moisten her mouth and replenish her energy (Fig. 21.2).

Assist with providing counterpressure along with backrubs if the fetus is in the occiput posterior position. Encourage the woman to assume different positions to promote fetal rotation. Upright positions are helpful in facilitating fetal rotation and descent. Also encourage the woman to visualize the descent and birth of the fetus.

Assess the woman's level of pain and degree of distress. Administer analgesics as ordered or according to the facility's protocol.

Evaluate the mother's level of fatigue throughout labor, such as verbal expressions of feeling exhausted, inability to cope in early labor, or inability to rest or calm down between contractions. Praise the woman and her partner for their efforts. Provide empathetic listening to increase the client's coping ability, and remain with the client to demonstrate caring.

FIGURE 21.2 The nurse applies a cool, moist washcloth to the client's forehead and offers her ice chips to combat thirst and provide comfort for the woman experiencing dystocia.

Promoting Empowerment

Educate the client and family about dysfunctional labor and its causes and therapies. Explain therapeutic interventions that may be needed to assist with the labor process. Encourage the client and her partner to participate in decision making about interventions.

Assist the woman and partner in expressing their fears and anxieties. Provide encouragement to help them to maintain control. Support the client and her partner in their coping efforts. Keep the woman and her partner informed of progress and advocate for them.

Preterm Labor

Preterm labor is defined as the occurrence of regular uterine contractions accompanied by cervical effacement and dilation before the end of the 37th week of gestation. If not halted, it leads to preterm birth.

Preterm births remain one of the biggest contributors to perinatal morbidity and mortality in the world. According to the March of Dimes (2007c, 2007d, 2007e), about 12% of births (one in eight infants) in the United States are premature.

Preterm birth is one of the most common obstetric complications, and its sequelae have a profound effect on the survival and health of the newborn. The rate of preterm births in the United States has increased 35% in the past 20 years. Preterm births account for 75% of neurodevelopmental disorders and other serious morbidities, as well as behavioral and social problems. They account for 85% of all perinatal morbidity and mortality. In addition, up to $30 billion is spent on maternal and infant care related to prematurity (March of Dimes, 2007c). Infants born prematurely also are at risk for serious sequelae such as respiratory distress syndrome, infections, congenital heart defects, thermoregulation problems that can lead to acidosis and weight loss, intraventricular hemorrhage, feeding difficulties resulting from diminished stomach capacity and an underdeveloped suck reflex, and neurologic disorders related to hypoxia and trauma at birth (Gray, 2006). Although great strides have been made in neonatal intensive care, prematurity remains the leading cause of death within the first month of life and is the second leading cause of all infant deaths (March of Dimes, 2007c).

The exact cause of preterm labor is not known. Currently, prevention is the goal.

Therapeutic Management

Predicting the risk of preterm labor is valuable only if there is an available intervention that is likely to improve the situation. According to ACOG, many factors must be considered before selecting an intervention. Many factors influence the decision to intervene when women present with symptoms of preterm labor, including the probability of progressive labor, gestational age, and the risks of treatment. ACOG (2003b) recommends the following as guidelines:

- There are no clear first-line **tocolytic** drugs (drugs that promote uterine relaxation by interfering with uterine contractions) to manage preterm labor. Clinical circumstances and the health care provider's preference should dictate treatment.
- Antibiotics do not appear to prolong gestation and should be reserved for group B streptococcal prophylaxis in women in whom birth is imminent.
- Tocolytic drugs may prolong pregnancy for 2 to 7 days; during this time, steroids can be given to improve fetal lung maturity and the woman can be transported to a tertiary care center.

Despite these recommendations, health care providers continue to prescribe pharmacologic treatment for preterm labor at home and in the hospital setting. This treatment often includes oral or intravenous tocolytics and varying degrees of activity restriction (Fig. 21.3). Antibiotics may also be prescribed to treat presumed or confirmed infections. Steroids may be given to enhance fetal lung maturity between 24 weeks and 34 weeks' gestation.

Tocolytic Therapy

The decision to stop preterm labor is individualized based on risk factors, extent of cervical dilation, membrane status, fetal gestational age, and presence or absence of infection. Tocolytic therapy is most likely ordered if preterm

FIGURE 21.3 The mother with preterm labor resting in bed at home.

labor occurs before the 34th week of gestation in an attempt to delay birth and thereby to reduce the severity of respiratory distress syndrome and other complications associated with prematurity. Tocolytic therapy does not typically prevent preterm birth, but it may delay it. It is contraindicated for abruptio placentae, acute fetal distress or death, eclampsia or severe preeclampsia, active vaginal bleeding, dilation of more than 6 cm, chorioamnionitis, and maternal hemodynamic instability (Griffin, 2007).

Medications most commonly used for tocolysis include magnesium sulfate (which reduces the muscle's ability to contract), terbutaline (Brethine, a beta-adrenergic), indomethacin (Indocin, a prostaglandin synthetase inhibitor), and nifedipine (Procardia, a calcium channel blocker). These drugs are used "off label": this means they are effective for this purpose but have not been officially tested and developed for this purpose by the FDA (Tan et al., 2006). All these medications have serious side effects, and the woman needs close supervision when they are being administered (Drug Guide 21.1).

Corticosteroids

Corticosteroids given to the mother in preterm labor can help prevent or reduce the frequency and severity of respiratory distress syndrome in premature infants delivered between 24 weeks and 34 weeks' gestation. The beneficial effects of corticosteroids on fetal lung maturation have been reported within 48 hours of initial administration (Blackburn, 2007). These drugs require at least 24 hours to become effective, so timely administration is crucial.

Nursing Assessment

The preterm birth rate cannot be reduced until there are ways to predict the risk for preterm birth. Because the etiology is often multifactorial, an individualized approach is needed.

Health History and Physical Examination

The signs of preterm labor are subtle and may be overlooked by the client as well as the health care professional. Obtain a thorough health history and be alert for risk factors associated with preterm labor and birth (Box 21.2).

Frequently, women are unaware that uterine contractions, effacement, and dilation are occurring, thus making early intervention ineffective in arresting preterm labor and preventing the birth of a premature newborn. Ask the woman about any complaints, being alert for the subtle symptoms of preterm labor, which may include:

- Change or increase in vaginal discharge
- Pelvic pressure (pushing-down sensation)
- Low, dull backache
- Menstrual-like cramps
- Heaviness or aching in the thighs
- Uterine contractions, with or without pain
- Intestinal cramping, with or without diarrhea (Gilbert, 2007; Gray, 2006)

Assess the pattern of the contractions: the contractions must be persistent, such that four contractions occur every 20 minutes or eight contractions occur in 1 hour. Evaluate cervical dilation and effacement: cervical effacement is 80% or greater and cervical dilation is greater than 1 cm (AAP & ACOG, 2003). On examination, engagement of the fetal presenting part will be noted.

Laboratory and Diagnostic Testing

Commonly used diagnostic testing for preterm labor risk assessment includes a complete blood count to detect infection, which may be a contributing factor to preterm labor; urinalysis to detect bacteria and nitrites, which are indicative of a urinary tract infection; and an amniotic fluid analysis to determine fetal lung maturity and the presence of subclinical chorioamnionitis.

Four other tests may be used for preterm labor prediction: fetal fibronectin testing, cervical length evaluation by transvaginal ultrasound, salivary estriol, and home monitoring of uterine activity to recognize preterm contractions. Fetal fibronectin and cervical length examinations have a high negative predictive value and are thus better at predicting which pregnant women are unlikely to have a preterm birth as opposed to predicting those who will (Grimes-Dennis & Berghella, 2007).

Fetal Fibronectin

Fetal fibronectin, a glycoprotein produced by the chorion, is found at the junction of the chorion and decidua (fetal membranes and uterus). It is present in cervicovaginal fluid prior to delivery, regardless of gestational age. It is not found in vaginal secretions unless there has been a disruption between the chorion and decidua. The test is a useful marker for impending membrane rupture within 7 to 14 days if the level increases to greater than 0.05 ug/mL. Conversely, if fetal fibronectin is not present, there is a

DRUG GUIDE 21.1 MEDICATIONS USED WITH PRETERM LABOR

Drug	Action/Indication	Nursing Implications
Magnesium sulfate	Relaxes uterine muscles to stop irritability and contractions, to arrest uterine contractions for preterm labor (off-label use). Has been used in seizure prophylaxis and treatment of seizures in preeclamptic and eclamptic patients for almost 100 years (Lilley, Harrington, & Snyder, 2007).	Administer IV with a loading dose of 4–6 g over 15–30 minutes initially, and then maintain infusion at 1–4 g per hour. Assess vital signs and deep tendon reflexes (DTRs) hourly; report any hypotension or depressed or absent DTRs. Monitor level of consciousness; report any headache, blurred vision, dizziness, or altered level of consciousness. Perform continuous electronic fetal monitoring; report any decreased fetal heart rate variability, hypotonia, or respiratory depression. Monitor intake and output hourly; report any decrease in output (<30 mL/hour). Assess respiratory rate; report respiratory rate <12 breaths/minute; auscultate lung sounds for evidence of pulmonary edema. Monitor for common maternal side effects, including flushing, nausea and vomiting, dry mouth, lethargy, blurred vision, and headache. Assess for nausea, vomiting, transient hypotension, lethargy. Assess for signs and symptoms of magnesium toxicity, such as decreased level of consciousness, depressed respirations and DTRs, slurred speech, weakness, and respiratory and/or cardiac arrest. Have calcium gluconate readily available at the bedside to reverse magnesium toxicity.
Terbutaline sulfate (Brethine)	Relaxes smooth muscles to calm uterus, inhibits uterine activity to arrest preterm labor	This drug is usually effective in delaying birth for up to 48 hours (Tan et al., 2006). Monitor the mother for adverse effects such as tachycardia, hypotension, palpitations, tremors, chest pain, hypokalemia, water retention, nausea, vomiting, diarrhea, hyperglycemia, decreased urinary output, and nervousness. Monitor fetal well-being, noting any adverse effects such as tachycardia or heart failure. Adverse effects are dose-related and will increase as dose is increased. Perform cardiac assessment of woman to rule out preexisting cardiac disease and diabetes. Institute continuous fetal monitoring. Assess vital signs frequently for changes. Discontinue drug for the following: maternal tachycardia >120 bpm, hypotension <90/60 mmHg, fetal heart rate >180 bpm, signs of maternal pulmonary edema. Have propranolol (Inderal) available to reverse cardiac adverse effects.
Indomethacin (Indocin)	Inhibits prostaglandins, which stimulate contractions; inhibits uterine activity to arrest preterm labor	Continuously assess vital signs, uterine activity, and fetal heart rate. Administer oral form with food to reduce GI irritation.

Drug	Action/Indication	Nursing Implications
		Do not give to women with peptic ulcer disease. Schedule ultrasound to assess amniotic fluid volume and function of ductus arteriosus before initiating therapy; monitor for signs of maternal hemorrhage. Be alert for maternal adverse effects such as nausea, vomiting, heartburn, rash, prolonged bleeding time, oligohydramnios, and hypertension. Monitor for neonatal adverse effects, including constriction of ductus arteriosus, premature ductus closure, necrotizing enterocolitis, oligohydramnios, and pulmonary hypertension.
Nifedipine (Procardia)	Blocks calcium movement into muscle cells, inhibits uterine activity to arrest preterm labor	Use caution if giving this drug with magnesium sulfate because of increased risk for hypotension. Monitor blood pressure hourly if giving with magnesium sulfate; report a pulse rate >110 bpm. Monitor for fetal effects such as decreased uteroplacental blood flow manifested by fetal bradycardia, which can lead to fetal hypoxia. Monitor for adverse effects, such as flushing of the skin, headache, transient tachycardia, palpitations, postural hypertension, peripheral edema, and transient fetal tachycardia.
Betamethasone (Celestone)	Promotes fetal lung maturity by stimulating surfactant production, prevents or reduces risk of respiratory distress syndrome and intraventricular hemorrhage in the preterm neonate less than 34 weeks' gestation	Administer two doses intramuscularly 24 hours apart. Monitor for maternal infection or pulmonary edema. Educate parents about potential benefits of drug to preterm infant. Assess maternal lung sounds and monitor for signs of infection.

98% chance that the woman will not go into preterm labor (Incerti et al., 2007).

A sterile applicator is used to collect a cervicovaginal sample during a speculum examination. The result is either positive (fetal fibronectin is present) or negative (fetal fibronectin is not present). Interpretation of fetal fibronectin results must always be viewed in conjunction with the clinical findings; it is not used as a lone indicator for predicting preterm labor.

Transvaginal Ultrasound

Transvaginal ultrasound of the cervix has been used as a tool to predict preterm labor in high-risk pregnancies and to differentiate between true and false preterm labor. Three parameters are evaluated during the transvaginal ultrasound: cervical length and width, funnel width and length, and percentage of funneling. Measurement of the closed portion of the cervix visualized during the transvaginal ultrasound is the single most reliable parameter for prediction of preterm delivery in high-risk women (Blackburn, 2007).

Cervical length varies during pregnancy and can be measured fairly reliably after 16 weeks' gestation using an ultrasound probe inserted in the vagina. A cervical length of 3 cm or more indicates that delivery within 14 days is unlikely. Women with a short cervical length of 2.5 cm during the mid-trimester have a substantially greater risk of preterm birth prior to 35 weeks' gestation. As with fetal fibronectin testing, negative results can be reassuring and prevent unnecessary interventions (Grimes-Dennis & Berghella, 2007).

Home Uterine Activity Monitoring

Home monitoring of uterine activity can identify women in preterm labor at an early stage to reduce the rate of preterm birth (Gilbert, 2007). Home uterine activity monitoring does not prevent preterm labor or birth; rather, it provides supplemental client education and

BOX 21.2 Risk Factors Associated With Preterm Labor and Birth

- African-American race (double the risk)
- Maternal age extremes less than 16 years and more than 40 years old
- Low socioeconomic status
- Alcohol or other drug use, especially cocaine
- Poor maternal nutrition
- Maternal periodontal disease
- Cigarette smoking
- Low level of education
- History of prior preterm birth (triples the risk)
- Uterine abnormalities, such as fibroids
- Low pregnancy weight for height
- Preexisting diabetes or hypertension
- Multiple gestation
- PROM
- Late or no prenatal care
- Short cervical length
- STIs: gonorrhea, *Chlamydia,* trichomoniasis
- Bacterial vaginosis (50% increased risk) (Pretorius et al., 2007)
- Chorioamnionitis
- Hydramnios
- Gestational hypertension
- Cervical insufficiency
- Short interpregnancy interval: less than 1 year between births
- Placental problems, such as placenta previa and abruption placenta
- Maternal anemia
- UTI
- Domestic violence
- Stress, acute and chronic (March of Dimes, 2007c)

clinical data for the health care provider in an effort to prolong gestation and maximize pregnancy outcomes through timely clinical interventions. It involves client education, daily client assessment, data collection, and data interpretation (Gray, 2007).

The woman is asked to wear an ambulatory tocodynamometer and transmit data to the nurse or health care provider daily via telephone lines. Uterine and fetal activity data are transmitted to perinatal nurses who are available around the clock for detection of uterine contractions, in addition to picking up the fetal heart rate. Women are also asked to record uterine activity (uterine pressure, back pain, or cramps) they experience for an hour twice a day and then speak to a perinatal nurse, who analyzes the results.

If the number of contractions exceeds a predetermined threshold, the woman drinks 8 to 12 oz of water, rests, empties her bladder, and then repeats uterine monitoring. The effectiveness of this type of screening remains controversial (Morrison & Chauhan, 2003).

Nursing Management

Nurses play a key role in reducing preterm labor and births to improve pregnancy outcomes for both mothers and their infants. Early detection of preterm labor is currently the best strategy to improve outcomes. Because of the numerous factors associated with preterm labor, it is challenging to identify and address all of them, especially when women experiencing contractions are frequently falsely reassured and not assessed thoroughly to determine the cause. This delay impedes initiation of interventions to reduce infant death and morbidity.

Preterm birth prevention programs for women at high risk have used self-monitoring of symptoms and patterns, weekly cervical examinations, telephone monitoring, home visiting, and home uterine activity monitoring, alone or in combination, with mixed results (Gray, 2006).

Nursing management of the woman with preterm labor involves administering tocolytic therapy if indicated, thoroughly educating the client, and providing psychological support during the process.

Administering Tocolytic Therapy

A firm diagnosis of preterm labor is necessary before treatment is considered. Diagnosis requires the presence of both uterine contractions and cervical change (or an initial cervical examination of more than 2 cm and/or more than 80% effacement in a nulliparous client). A cause for preterm labor should always be sought. Absolute contraindications to tocolytic agents include intrauterine infection, fetal distress, vaginal bleeding, prolonged premature rupture of the membranes, and intrauterine demise (Norwitz & Schorge, 2006). Bed rest and hydration are commonly recommended, but without proven efficacy.

Short-term pharmacologic therapy remains the cornerstone of management. However, there are no studies to suggest that any tocolytic agent can delay birth for longer than 48 hours (Stein, 2007). No single agent has a clear therapeutic advantage.

Magnesium sulfate may be ordered. This agent acts as a physiologic calcium antagonist and a general inhibitor of neurotransmission. Expect to administer it intravenously. Monitor the woman for nausea, vomiting, headache, weakness, hypotension, and cardiopulmonary arrest. Assess the fetus for decreased fetal heart rate variability, drowsiness, and hypotonia. Magnesium has a wide margin of safety and is commonly used as a first choice.

Although calcium channel blockers may be prescribed to manage preterm labor, available literature provides little evidence that they have better efficacy in treating preterm labor than magnesium sulfate (ACOG, 2003b). Administer calcium channel blockers (nifedipine) orally or sublingually every 4 to 8 hours as ordered. Monitor the woman for hypotension, reflex tachycardia, headache, nausea, and facial flushing.

If beta-adrenergic agonists (terbutaline) are ordered, expect to administer the agent intravenously during the

initial period and then switch to the oral route for maintenance therapy. Closely assess the woman for side effects, including jitteriness, anxiety, restlessness, nausea, and tachycardia. Assess the fetus for tachycardia, hypotension, and hypoglycemia.

Supportive nursing care is needed for the woman in preterm labor whether the contractions are stopped with tocolytic therapy or not. Nursing tasks include monitoring vital signs, measuring intake and output, encouraging bed rest on the woman's left side to enhance placental perfusion, monitoring the fetal heart rate via an external monitor continuously, limiting vaginal examinations to prevent an ascending infection, and monitoring the mother and fetus closely for any adverse effects from the tocolytic agents. Offering the couple ongoing explanations will help prepare them for the birth.

Educating the Client

Ensure that every pregnant woman receives basic education about preterm labor, including information about harmful lifestyles, the signs of genitourinary infections and preterm labor, and the appropriate response to these symptoms. Teach the client how to palpate for and time uterine contractions. Provide written materials to support this education at a level and in a language appropriate for the client. Also educate clients about the importance of prenatal care, risk reduction, and recognizing the signs and symptoms of preterm labor. Teaching Guidelines 21.1 highlights important instructions related to preventing preterm labor.

Explaining to the couple what is happening in terms of labor progress, the treatment regimen, and the status of the fetus is important to reduce the anxiety associated with the risk of giving birth to a preterm infant. Educate them about the importance of promotion of fetal lung maturity with corticosteroids. Include supportive family members in all education. Allow time for the woman and her family to express their concerns about the possible outcome for the infant and the possible side effects of the tocolytic therapy. Encourage them to vent any feelings, fears, and anger they may experience. Provide the woman and her family with an honest appraisal of the situation and plan of treatment throughout her care.

Providing Psychological Support

Preterm labor and birth present multifactorial challenges for everyone involved. If the woman's activities are restricted, additional stresses may be placed on the family, contributing to the crisis. Assess the stress levels of the client and family, and make appropriate referrals. Emphasize the need for more frequent supervision and office visits, and encourage clients to talk to their health care provider for reassurance.

Every case of spontaneous preterm labor is unique. Care must take into account the clinical circumstances, and the full and informed consent of the woman and her partner is needed. Half of all women who ultimately give birth prematurely have no identifiable risk factors. Nurses should be sensitive to any complaint and should provide appropriate assessment, information, and follow-up. Sensitivity to the subtle differences between normal pregnancy sensations and the prodromal symptoms of preterm labor is a key factor in ensuring timely care. Offer clarification and validation of the woman's symptoms.

TEACHING GUIDELINES 21.1

Teaching to Prevent Preterm Labor

- Avoid traveling for long distances in cars, trains, planes, or buses.
- Avoid lifting heavy objects, such as laundry, groceries, or a young child.
- Avoid performing hard, physical work, such as yard work, moving of furniture, or construction.
- Visit a dentist in early pregnancy to evaluate and treat periodontal disease.
- Enroll in a smoking cessation program if you are unable to quit on your own.
- Curtail sexual activity until after 37 weeks if experiencing preterm labor symptoms.
- Consume a well-balanced nutritional diet to gain appropriate weight.
- Avoid the use of substances such as marijuana, cocaine, and heroin.
- Identify factors and areas of stress in your life, and use stress management techniques to reduce them.
- If you are experiencing intimate partner violence, seek resources to modify the situation.

Recognize the signs and symptoms of preterm labor and notify your birth attendant if any occur:

- Uterine contractions, cramping, or low back pain
- Feeling of pelvic pressure or fullness
- Increase in vaginal discharge
- Nausea, vomiting, and diarrhea
- Leaking of fluid from vagina

If you are experiencing any of these signs or symptoms, do the following:

- Stop what you are doing and rest for 1 hour.
- Empty your bladder.
- Lie down on your side.
- Drink two to three glasses of water.
- Feel your abdomen and make note of the hardness of the contraction. Call your health care provider and describe the contraction as
  - Mild if it feels like the tip of the nose
  - Moderate if it feels like the tip of the chin
  - Strong if it feels like your forehead (Simhan & Caritis, 2007)

If tocolytic therapy isn't successful in stopping uterine contractions, support the couple through this stressful period to prepare them for the birth. Keep them informed of all progress and changes; for example, continuously monitor maternal and fetal vital signs, especially the maternal temperature to detect signs of early infection. Offer one-on-one contact and be available throughout this difficult and anxiety-producing period.

Postterm Labor

A term pregnancy usually lasts 38 to 42 weeks. A **postterm pregnancy** is one that continues past the end of the 42nd week of gestation, or 294 days from the first day of the last menstrual period. Postterm pregnancies account for about 3% to 12% of births (Butler & Wilkes, 2007). Incorrect dates account for the majority of these cases: many women have irregular menses and thus cannot identify the date of their last menstrual period accurately.

Recall Jennifer described at the beginning of the chapter, who was at 41 weeks' gestation. What information would be most important to determine on admission to the facility? What interventions might the nurse anticipate when she arrives?

The exact etiology of a postterm pregnancy is unknown because the mechanism for the initiation of labor is not completely understood. Theories suggest there may be a deficiency of estrogen and continued secretion of progesterone that prohibits the uterus from contracting, but no evidence has validated this. A woman who has one postterm pregnancy is at greater risk for another in subsequent pregnancies.

Postterm pregnancies may adversely affect both the mother and fetus or newborn. Maternal risk is related to the large size of the fetus at birth, which increases the chances that a cesarean birth will be needed. Other issues might include dystocia, birth trauma, postpartum hemorrhage, and infection. Mechanical or artificial interventions such as forceps or vacuum-assisted birth and labor induction with oxytocin may be necessary. In addition, maternal exhaustion and feelings of despair over this prolonged gestation can add to the woman's anxiety level and reduce her coping ability.

Fetal risks associated with a postterm pregnancy include macrosomia, shoulder dystocia, brachial plexus injuries, and cephalopelvic disproportion. All of these conditions predispose this fetus to birth trauma or a surgical birth. The perinatal mortality rate at more than 42 weeks of gestation is twice that at term and increases six-fold and higher at 43 weeks of gestation and beyond. Uteroplacental insufficiency, meconium aspiration, and intrauterine infection contribute to the increased rate of perinatal deaths (Heimstad et al., 2006). As the placenta ages, its perfusion decreases and it becomes less efficient at delivering oxygen and nutrients to the fetus. Amniotic fluid volume also begins to decline by 40 weeks of gestation, possibly leading to oligohydramnios, subsequently resulting in fetal hypoxia and an increased risk of cord compression because the cushioning effect offered by adequate fluid is no longer present. Hypoxia and oligohydramnios predispose the fetus to aspiration of meconium, which is released by the fetus in response to a hypoxic insult (Gümezoglu, Crowther, & Middleton, 2006). All of these issues can compromise fetal well-being and lead to fetal distress.

Nursing Assessment

Obtain a thorough history to determine the estimated date of birth. Many women are unsure of the date of their last menstrual period, so the date given may be unreliable. Despite numerous methods used to date pregnancies, many are still misdated. Accurate gestational dating via ultrasound is essential.

Antepartum assessment for a postterm pregnancy typically includes daily fetal movement counts done by the woman, nonstress tests done twice weekly, amniotic fluid assessments as part of the biophysical profile, and weekly cervical examinations to evaluate for ripening. In addition, assess the following:

- Client's understanding of the various fetal well-being tests
- Client's stress and anxiety concerning her lateness
- Client's coping ability and support network

Nursing Management

Once the dates are established and postdate status is confirmed, monitoring fetal well-being becomes critical. When determining the plan of care for a woman with a postterm pregnancy, the first decision is whether to deliver the baby or wait. If the decision is to wait, then fetal surveillance is key. If the decision is to have the woman deliver, labor induction is initiated. Both decisions remain controversial, and there is no clear answer about which option is more appropriate. Therefore, the plan must be individualized.

Think back to Jennifer, who is scheduled for labor induction. What ongoing nursing assessments would be important when providing care for her?

Providing Support

The intense surveillance is time-consuming and intrusive, adding to the anxiety and worry already being experienced by the woman about her overdue status. Be alert to the woman's anxiety and allow her to discuss her feelings. Provide reassurance about the expected time range for birth

EVIDENCE-BASED PRACTICE 21.1
Labor Induction and Outcomes for Women Beyond Term

● Study
Postterm pregnancies may adversely affect both the mother and fetus or newborn. Placental perfusion decreases as the placenta ages and becomes less efficient at delivering oxygen and nutrients to the fetus. Amniotic fluid volume also begins to decline by 40 weeks of gestation, increasing the fetus's risk for oligohydramnios, meconium aspiration, and cord compression. However, questions arise: What is the best time for inducing labor in a postterm pregnancy? Does labor induction improve maternal and fetal outcomes, or would it be better to wait for spontaneous labor to begin? A study was conducted to compare the effects of inducing labor in women at or beyond term with those of waiting for spontaneous labor to begin. A search was conducted for randomized controlled trials that compared labor induction with waiting for spontaneous labor to begin in women who were at term or postterm. Two review authors collected the data and analyzed the trials. A total of 19 trials involving almost 8,000 women were evaluated.

▲ Findings
Based on the trials analyzed, fewer perinatal deaths occurred in women who underwent labor induction at 41 completed weeks of gestation or later. Fewer newborns experienced meconium aspiration syndrome with induction at 41 weeks or more. Women at 37 to 40 weeks' gestation who received expectant management were more likely to undergo a cesarean birth compared to those in the same gestational week range who received induction. Statistical analysis, however, showed that these differences were not significant.

■ Nursing Implications
Although the study did not reveal results that were statistically significant, nurses need to be aware of the potential benefits and limitations associated with labor induction so that they can provide women and their families with the most appropriate information about options for a postterm pregnancy. Nurses can integrate information from this study in their teaching about the risks associated with postterm pregnancy. They can also use this information to help answer the couple's questions about induction and its effectiveness as well as provide anticipatory guidance about the procedure. Doing so fosters empowerment of the woman and her family, promoting optimal informed decision making.

Gülmezoglu, A. M., Crowther, C. A., & Middleton, P. (2006). Induction of labour for improving birth outcomes for women at or beyond term. *Cochrane Database of Systematic Reviews* 2006. Issue 4. Art. No.: CD004945.DOI:10.1002/14651858.CD004945.pub2.

and the well-being of the fetus based on the assessment tests. Validating the woman's stressful state due to the prolonged pregnancy provides an opportunity for her to verbalize her feelings openly.

Educating the Woman and Her Partner
Teach the woman and her partner about the testing required and the reasons for each test. Also describe the methods that may be used for cervical ripening if indicated. Explain about the possibility of induction if the woman's labor isn't spontaneous or if a dysfunctional labor pattern occurs. Also prepare the woman for the possibility of a surgical delivery if fetal distress occurs.

Providing Care During the Intrapartum Period
During the intrapartum period, continuously assess and monitor fetal heart rate (FHR) to identify potential fetal distress early (e.g., late or variable decelerations) so that interventions can be initiated. Also monitor the woman's hydration status to ensure maximal placental perfusion. When the membranes rupture, assess amniotic fluid characteristics (color, amount, and odor) to identify previous fetal hypoxia and prepare for prevention of meconium aspiration. Report meconium-stained amniotic fluid immediately when the membranes rupture. Anticipate the need for amnioinfusion to minimize the risk of meconium aspiration by diluting the meconium in the amniotic fluid expelled by the hypoxic fetus. In addition, monitor the woman's labor pattern closely because dysfunctional patterns are common (Gilbert, 2007).

Encourage the woman to verbalize her feelings and concerns, and answer all her questions. Provide support, presence, information, and encouragement throughout this time.

Women Requiring Labor Induction and Augmentation

Ideally, all pregnancies go to term, with labor beginning spontaneously. However, many women need help to initiate or sustain the labor process. **Labor induction** involves the stimulation of uterine contractions by medical or surgical means to produce delivery before the onset of spontaneous labor. The labor induction rate is at an all-time high in the United States. The widespread use of artificial induction of labor for convenience has contributed to the recent increase in the number of cesarean births.

Evidence is compelling that elective induction of labor significantly increases the risk of cesarean birth, instrumented delivery, use of epidural analgesia, and neonatal intensive care unit admission, especially for nulliparous women (Crane, 2006).

Labor induction is not an isolated event: it brings about a cascade of other interventions that may or may not produce a favorable outcome. Labor induction also involves intravenous therapy, bed rest, continuous electronic fetal monitoring, significant discomfort from stimulating uterine contractions, epidural analgesia/anesthesia, and a prolonged stay on the labor unit (Wing, 2006).

Labor augmentation enhances ineffective contractions after labor has begun. Continuous electronic FHR monitoring is necessary.

There are multiple medical and obstetric reasons for inducing labor, the most common being postterm gestation. Other indications for inductions include prolonged premature rupture of membranes, gestational hypertension, renal disease, chorioamnionitis, dystocia, intrauterine fetal demise, isoimmunization, and diabetes (Bueno et al., 2007). Contraindications to labor induction include complete placenta previa, abruptio placentae, transverse fetal lie, prolapsed umbilical cord, a prior classic uterine incision that entered the uterine cavity, pelvic structure abnormality, previous myomectomy, vaginal bleeding with unknown cause, invasive cervical cancer, active genital herpes infection, and abnormal FHR patterns (ACOG, 2004b). In general, labor induction is indicated when the benefits of birth outweigh the risks to the mother or fetus for continuing the pregnancy. However, the balance between risk and benefit remains controversial.

▶ ***Take*** NOTE!

Before labor induction is started, fetal maturity (dating, ultrasound, amniotic fluid studies) and cervical readiness (vaginal examination, Bishop scoring) must be assessed. Both need to be favorable for a successful induction.

Therapeutic Management

The decision to induce labor is based on a thorough evaluation of maternal and fetal status. Typically, this includes an ultrasound to evaluate fetal size, position, and gestational age and to locate the placenta; pelvimetry to rule out fetopelvic disproportion; a nonstress test to evaluate fetal well-being; a phosphatidylglycerol (PG) level to assess fetal lung maturity; Nitrazine paper and/or fern test to confirm ruptured membranes; complete blood count and urinalysis to rule out infection; and a vaginal examination to evaluate the cervix for inducibility (ACOG, 2004). Accurate dating of the pregnancy also is essential before cervical ripening and induction are initiated to prevent a preterm birth.

Cervical Ripening

There has been increasing awareness that if the cervix is unfavorable or unripe, a successful vaginal birth is unlikely. Cervical ripeness is an important variable when labor induction is being considered. A ripe cervix is shortened, centered (anterior), softened, and partially dilated. An unripe cervix is long, closed, posterior, and firm. Cervical ripening usually begins prior to the onset of labor contractions and is necessary for cervical dilatation and the passage of the fetus.

Various scoring systems to assess cervical ripeness have been introduced, but the Bishop score is most commonly used today. The Bishop score helps identify women who would be most likely to achieve a successful induction (Table 21.2). The duration of labor is inversely correlated with the Bishop score: a score over 8 indicates a successful vaginal birth. Bishop scores of less than 6 usually indicate that a cervical ripening method should be used prior to induction (Rai & Schreiber, 2007).

Nonpharmacologic Methods

Nonpharmacologic methods for cervical ripening are less frequently used today, but nurses need to be aware of them and question clients about their use. Methods may include herbal agents such as evening primrose oil, black haw, black and blue cohosh, and red raspberry leaves. In

TABLE 21.2 BISHOP SCORING SYSTEM

Score	Dilation (cm)	Effacement (%)	Station	Cervical Consistency	Position of Cervix
0	Closed	0–30%	–3	Firm	Posterior
1	1–2 cm	40–50%	–2	Medium	Midposition
2	3–4 cm	60–70%	–1 or 0	Soft	Anterior
3	5–6 cm	80%	+1 or +2	Very soft	Anterior

Modified from Bishop, E. H. (1964). Pelvic scoring for elective induction. *Obstetrics & Gynecology, 24*(2), 267.

addition, castor oil, hot baths, and enemas are used for cervical ripening and labor induction. The risks and benefits of these agents are unknown.

Another nonpharmacologic method suggested for labor induction is sexual intercourse along with breast stimulation. This promotes the release of oxytocin, which stimulates uterine contractions. In addition, human semen is a biological source of prostaglandins used for cervical ripening. According to a Cochrane Review, sexual intercourse with breast stimulation would appear beneficial, but safety issues have not been fully evaluated, nor can this activity be standardized (Kavanagh, Kelly, & Thomas, 2007). Therefore, its use as a method for labor induction is not validated by research.

Mechanical Methods

Mechanical methods are used to open the cervix and stimulate the progression of labor. All share a similar mechanism of action—application of local pressure stimulates the release of prostaglandins to ripen the cervix. Potential advantages of mechanical methods, compared with pharmacologic methods, may include simplicity or preservation of the cervical tissue or structure, lower cost, and fewer side effects. The risks associated with these methods include infection, bleeding, membrane rupture, and placental disruption (Boulvain et al., 2007).

For example, an indwelling (Foley) catheter (e.g., 26 French) can be inserted into the endocervical canal to ripen and dilate the cervix. The catheter is placed in the uterus, and the balloon is filled. Direct pressure is then applied to the lower segment of the uterus and the cervix. This direct pressure causes stress in the lower uterine segment and probably the local production of prostaglandins (Rai & Schreiber, 2007).

Hygroscopic dilators absorb endocervical and local tissue fluids; as they enlarge, they expand the endocervix and provide controlled mechanical pressure. The products available include natural osmotic dilators (laminaria, a type of dried seaweed) and synthetic dilators containing magnesium sulfate (Lamicel, Dilapan). Hygroscopic dilators are advantageous because they can be inserted on an outpatient basis and no fetal monitoring is needed. As many dilators are inserted in the cervix as will fit, and they expand over 12 to 24 hours as they absorb water. Absorption of water leads to expansion of the dilators and opening of the cervix. They are a reliable alternative when prostaglandins are contraindicated or unavailable (Gelber, 2006).

Surgical Methods

Surgical methods used to ripen the cervix and induce labor include stripping of the membranes and performing an amniotomy. Stripping of the membranes is accomplished by inserting a finger through the internal cervical os and moving it in a circular direction. This motion causes the membranes to detach. Manual separation of the amniotic membranes from the cervix is thought to induce cervical ripening and the onset of labor (Rai & Schreiber, 2007).

An amniotomy involves inserting a cervical hook (Amniohook) through the cervical os to deliberately rupture the membranes. This promotes pressure of the presenting part on the cervix and stimulates an increase in the activity of prostaglandins locally. Risks associated with these procedures include umbilical cord prolapse or compression, maternal or neonatal infection, FHR deceleration, bleeding, and client discomfort (Shobeiri, Tehranian, & Nazari, 2007).

When either of these techniques is used, amniotic fluid characteristics (such as whether it is clear or bloody, or meconium is present) and the FHR pattern must be monitored closely.

Pharmacologic Agents

The use of pharmacologic agents has revolutionized cervical ripening. The use of prostaglandins to attain cervical ripening has been found to be highly effective in producing cervical changes independent of uterine contractions (Sifakis et al., 2007). In some cases, women will go into labor, requiring no additional stimulants for induction. Induction of labor with prostaglandins offers the advantage of promoting both cervical ripening and uterine contractility. A drawback of prostaglandins is their ability to induce excessive uterine contractions, which can increase maternal and perinatal morbidity (Hofmeyr & Gulmezoglu, 2007). Prostaglandin analogs commonly used for cervical ripening include dinoprostone gel (Prepidil), dinoprostone inserts (Cervidil), and misoprostol (Cytotec). Misoprostol (Cytotec), a synthetic PGE1 analog, is a gastric cytoprotective agent used in the treatment and prevention of peptic ulcers. It can be administered intravaginally or orally to ripen the cervix or induce labor. It is available in 100-mcg or 200-mcg tablets, but doses of 25 to 50 mcg are typically used. However, it is not approved by the FDA for cervical ripening since several reports found higher levels of uterine rupture associated with its use (USFDA, 2007) (Drug Guide 21.2). Furthermore, it is contraindicated for women with prior uterine scars and therefore should not be used for cervical ripening in women attempting a VBAC.

Oxytocin

Oxytocin is a potent endogenous uterotonic agent used for both artificial induction and augmentation of labor. It is produced naturally by the posterior pituitary gland and stimulates contractions of the uterus. For women with low Bishop scores, cervical ripening is typically initiated before oxytocin is used. Once the cervix is ripe, oxytocin is the most popular pharmacologic agent used for inducing or augmenting labor. Frequently a woman with an unfavorable cervix is admitted the evening before induc-

DRUG GUIDE 21.2 DRUGS USED FOR CERVICAL RIPENING AND LABOR INDUCTION

Drug	Action/Indication	Nursing Implications
Dinoprostone (Cervidil insert; Prepidil gel)	Directly softens and dilates the cervix/to ripen cervix and induce labor	Provide emotional support. Administer pain medications as needed. Frequently assess degree of effacement and dilation. Monitor uterine contractions for frequency, duration, and strength. Assess maternal vital signs and FHR pattern frequently. Monitor woman for possible adverse effects such as headache, nausea and vomiting, and diarrhea.
Misoprostol (Cytotec)	Ripens cervix/to induce labor	Instruct client about purpose and possible adverse effects of medication. Ensure informed consent is signed per hospital policy. Assess vital signs and FHR patterns frequently. Monitor client's reaction to drug. Initiate oxytocin for labor induction at least 4 hours after last dose was administered. Monitor for possible adverse effects such as nausea and vomiting, diarrhea, uterine hyperstimulation, and non-reassuring FHR pattern.
Oxytocin (Pitocin)	Acts on uterine myofibrils to contract/to initiate or reinforce labor	Administer as an IV infusion via pump, increasing dose based on protocol until adequate labor progress is achieved. Assess baseline vital signs and FHR and then frequently after initiating oxytocin infusion. Determine frequency, duration, and strength of contractions frequently. Notify health care provider of any uterine hypertonicity or abnormal FHR patterns. Maintain careful I & O, being alert for water intoxication. Keep client informed of labor progress. Monitor for possible adverse effects such as hyperstimulation of the uterus, impaired uterine blood flow leading to fetal hypoxia, rapid labor leading to cervical lacerations or uterine rupture, water intoxication (if oxytocin is given in electrolyte-free solution or at a rate exceeding 20 mU/min), and hypotension.

tion to ripen her cervix with one of the prostaglandin agents. Then induction begins with oxytocin the next morning if she has not already gone into labor. Doing so markedly enhances the success of induction.

Response to oxytocin varies widely: some women are very sensitive to even small amounts. The most common adverse effect of oxytocin is uterine hyperstimulation, leading to fetal compromise and impaired oxygenation (Smith & Merrill, 2006). The response of the uterus to the drug is closely monitored throughout labor so that the oxytocin infusion can be titrated appropriately. In addition, oxytocin has an antidiuretic effect, resulting in decreased urine flow that may lead to water intoxication. Symptoms to watch for include headache and vomiting.

Oxytocin is administered via an intravenous infusion pump piggybacked into the main intravenous line at the port most proximal to the insertion site. Usually 10 units of oxytocin is added to 1 L of isotonic solution to achieve an infusion rate of 1 mU/min = 6 mL/hr. The dose is titrated according to protocol to achieve stable contractions every 2 to 3 minutes lasting 40 to 60 seconds (Briggs & Wan, 2006). The uterus should relax between contractions. If the resting uterine tone remains above 20 mmHg, uteroplacental insufficiency and fetal hypoxia can result. This underscores the importance of continuous FHR monitoring.

Oxytocin has many advantages: it is potent and easy to titrate, it has a short half-life (1 to 5 minutes), and it is generally well tolerated. Induction using oxytocin has side effects (water intoxication, hypotension, and uterine hypertonicity), but because the drug does not cross the placental barrier, no direct fetal problems have been observed (Khan, Khan, & Ashraf, 2007) (Fig. 21.4).

FIGURE 21.4 The nurse monitors an intravenous infusion of oxytocin being administered to a woman in labor.

Remember Jennifer, the young woman described at the beginning of the chapter? After her cervix is ripened, an oxytocin infusion is started and her progress is slow. What encouragement can the nurse offer? After a few hours, her contractions begin to increase in intensity and frequency. What typical pain management measures can the nurse implement, and how would the nurse evaluate the effectiveness of these measures?

Nursing Assessment

Nursing assessment of the woman who is undergoing labor induction or augmentation involves a thorough history and physical examination. Review the woman's history for relative indications for induction or augmentation, such as diabetes, hypertension, postterm status, dysfunctional labor pattern, prolonged ruptured membranes, and maternal or fetal infection, and for contraindications such as placenta previa, overdistended uterus, active genital herpes, fetopelvic disproportion, fetal malposition, or severe fetal distress.

Assist with determining the gestational age of the fetus to prevent a preterm birth. Assess fetal well-being to validate the client's and fetus's ability to withstand labor contractions. Evaluate the woman's cervical status, including cervical dilatation and effacement, and station via vaginal examination as appropriate before cervical ripening or induction is started. Determine the Bishop score to determine the probable success of induction.

▶ *Take* NOTE!

Nurses working with women in labor play an important role acting as the "eyes" and "ears" for the birth attendant because they remain at the client's bedside throughout the entire experience. Close, frequent assessment and follow-up interventions are essential to ensure the safety of the mother and her unborn child during cervical ripening and labor induction or augmentation.

Nursing Management

Explain to the woman and her partner about the induction or augmentation procedure clearly, using simple terms (Teaching Guidelines 21.2). Ensure that an informed consent has been signed after the client and her

TEACHING GUIDELINES 21.2

Teaching in Preparation for Labor Induction

- Your health care provider may recommend that you have your labor induced. This may be necessary for a variety of reasons, such as elevated blood pressure, a medical condition, prolonged pregnancy over 41 weeks, or problems with fetal heart rate patterns or fetal growth.
- Your health care provider may use one or more methods to induce labor, such as stripping the membranes, breaking the amniotic sac to release the fluid, administering medication close to or in the cervix to soften it, or administering a medication called oxytocin (Pitocin) to stimulate contractions.
- Labor induction is associated with some risks and disadvantages, such as overactivity of the uterus; nausea, vomiting, or diarrhea; and changes in fetal heart rate.
- Prior to inducing your labor, your health care provider may perform a procedure to ripen your cervix to help ensure a successful induction.
- Medication may be placed around cervix the day before you are scheduled to be induced.
- During the induction, your contractions may feel stronger than normal. However, the length of your labor may be reduced with induction.
- Medications for pain relief and comfort measures will be readily available.
- Health care staff will be present throughout labor.

partner have received complete information about the procedure, including its advantages, disadvantages, and potential risks. Ensure that the Bishop score has been determined before proceeding. Nursing Care Plan 21.1 presents an overview of the nursing care for a woman undergoing labor induction.

Administering Oxytocin

If not already done, prepare the oxytocin infusion by diluting 10 units of oxytocin in 1,000 mL of lactated Ringer's solution. Use an infusion pump on a secondary line connected to the primary infusion. Start the oxytocin infusion in mU/min or milliliters per hour as ordered. Typically, the initial dose is 0.5 to 1 mU/min; anticipate increasing the rate in increments of 1 to 2 mU/min every 30 to 60 minutes. Maintain the rate once the desired contraction frequency has been reached. To ensure adequate maternal and fetal surveillance during induction or augmentation, the nurse-to-client ratio should not exceed 1:2 (Briggs & Wan, 2006).

During induction or augmentation, monitoring of the maternal and fetal status is essential. Apply an external electronic fetal monitor or assist with placement of an internal device. Obtain the mother's vital signs and the FHR every 15 minutes during the first stage. Evaluate the contractions (frequency, duration, and intensity) and resting tone, and adjust the oxytocin infusion rate accordingly. Monitor the FHR, including baseline rate, baseline variability, and decelerations, to determine whether the oxytocin rate needs adjustment. Discontinue the oxytocin and notify the birth attendant if uterine hyperstimulation or a nonreassuring FHR pattern occurs. Perform or assist with periodic vaginal examinations to determine cervical dilation and fetal descent: cervical dilation of 1 cm/hour typically indicates satisfactory progress.

Continue to monitor the FHR continuously and document it every 15 minutes during the active phase of labor and every 5 minutes during the second stage. Assist with pushing efforts during the second stage.

Measure and record intake and output to prevent excess fluid volume. Encourage the client to empty her bladder every 2 hours to prevent soft tissue obstruction.

Providing Pain Relief and Support

Assess the woman's level of pain. Ask her frequently to rate her pain and provide pain management as needed. Offer position changes and other non-pharmacologic measures. Note her reaction to any medication given, and document its effect. Monitor her need for comfort measures as contractions increase.

Throughout induction and augmentation, frequently reassure the woman and her partner about the fetal status and labor progress. Provide them with frequent updates on the condition of the woman and the fetus. Assess the woman's ability to cope with stronger contractions (Kuczkowski, 2007). Provide support and encouragement as indicated.

After a very long day, Jennifer gives birth to a healthy baby boy with Apgar scores of 9 at 1 minute and 10 at 5 minutes. When transferring her to the postpartum unit, what information is essential to include for the accepting nurse? What specific nursing information should be given to the nursery nurse regarding the laboring experience? With such a lengthy labor, what assessments might the postpartum nurse be especially focused on for the first few hours after birth?

Intrauterine Fetal Demise

When an unborn life suddenly ends with fetal loss, the family members are profoundly affected. The sudden loss of an expected child is tragic and the family's grief can be very intense: it can last for years and can cause extreme psychological stress and emotional problems (Lindsey & Azad, 2007).

Fetal death can be due to numerous conditions, such as prolonged pregnancy, infection, hypertension, advanced maternal age, Rh disease, uterine rupture, diabetes, congenital anomalies, cord accident, abruption, premature rupture of membranes, or hemorrhage; it may go unexplained (Gilbert, 2007). Early pregnancy loss may be through a spontaneous abortion (miscarriage), an induced abortion (therapeutic abortion), or a ruptured ectopic pregnancy. A wide spectrum of feelings may be expressed, from relief to sadness and despair. A stillbirth can occur at any gestational age, and typically there is little or no warning other than reduced fetal movement.

The period following a fetal death is extremely difficult for the family. For many women, emotional healing takes much longer than physical healing. The feelings of loss can be intense. The grief response in some women may be so great that their relationships become strained, and healing can become hampered unless appropriate interventions and support are provided.

Fetal death also affects the health care staff. Despite the trauma that the loss of a fetus causes, some staff members avoid dealing with the bereaved family, never talking about or acknowledging their grief. This seems to imply that not discussing the problem will allow the grief to dissolve and vanish. As a result, the family's needs go unrecognized. Failing to keep the lines of communication open with a bereaved client and her family closes off some of the channels to recovery and healing that may be desperately needed. Subsequently, the bereaved family members may feel isolated.

Nursing Assessment

History and physical examination are of limited value in the diagnosis of fetal death, since the only history tends to be recent absence of fetal movement. An inability to obtain fetal heart sounds on examination suggests fetal demise, but an ultrasound is necessary to confirm the absence of fetal cardiac activity. Once fetal demise is confirmed, induction of labor is indicated.

Nursing Care Plan 21.1

Overview of the Woman Undergoing Labor Induction

Rose, a 29-year-old primipara, is admitted to the labor and birth suite at 40 weeks' gestation for induction of labor. Assessment reveals that her cervix is ripe and 80% effaced, and dilated to 2 cm. Rose says, "I'm a bit nervous about being induced. I've never been through labor before and I'm afraid that I'll have a lot of pain from the medicine used to start the contractions." She consents to being induced but wants reassurance that this procedure won't harm the baby. Upon examination, the fetus is engaged and in a cephalic presentation, with the vertex as the presenting part. Her partner is at her side. Induction is initiated with oxytocin. Rose reports that contractions have started and are beginning to get stronger.

NURSING DIAGNOSIS: Anxiety related to induction of labor and lack of experience with labor *as evidenced by statements about being nervous, not having gone through labor before and fear of pain*

Outcome Identification and Evaluation

Client will experience decrease in anxiety as evidenced by ability to verbalize understanding of procedures involved and use of positive coping skills to reduce anxious state.

Interventions: Minimizing Anxiety

- Provide a clear explanation of the labor induction process *to provide client and partner with a knowledge base.*
- Maintain continuous physical presence *to provide physical and emotional support and demonstrate concern for maternal and fetal well-being.*
- Explain each procedure before carrying it out and answer questions *to promote understanding of procedure and rationale for use and decrease fears of the unknown.*
- Review with client measures used in the past to deal with stressful situations *to determine effectiveness;* encourage use of past effective coping strategies *to aid in controlling anxiety.*
- Instruct client's partner in helpful measures to assist client in coping and encourage their use *to foster joint participation in the process and feelings of being in control and to provide support to the client.*
- Offer frequent reassurance of fetal status and labor progress *to help alleviate client's concerns and foster continued participation in the labor process.*

NURSING DIAGNOSIS: Risk for injury (maternal or fetal) related to induction procedure *as evidenced by client's concerns about fetal well-being and possible adverse effects of oxytocin administration*

Outcome Identification and Evaluation

Client will remain free of complications associated with induction *as evidenced by progression of labor as expected, delivery of healthy newborn, and absence of signs and symptoms of maternal and fetal adverse effects.*

Interventions: Promoting Maternal and Fetal Safety

- Follow agency's protocol for medication use and infusion rate *to ensure accurate, safe drug administration.*
- Set up oxytocin IV infusion to piggyback into the primary IV infusion line *to allow for prompt discontinuation should adverse effects occur.*
- Use an infusion pump *to deliver accurate dose as ordered.*
- Gradually increase oxytocin dose in increments of 1 to 2 mU/min every 30 to 60 minutes based on assessment findings and protocol *to promote effective uterine contractions.*
- Maintain oxytocin rate once desired frequency of contractions has been reached *to ensure continued progress in labor.*
- Accurately monitor contractions for frequency, duration, and intensity and resting tone *to prevent development of hypertonic contractions.*
- Maintain a nurse–client ratio of 1:2 *to ensure maternal and fetal safety.*
- Monitor FHR via electronic fetal monitoring during induction and continuously observe the FHR response to titrated medication rate *to ensure fetal well-being and identify adverse effects immediately.*
- Obtain maternal vital signs every 1 to 2 hours or as indicated by agency's protocol, reporting any deviations, *to promote maternal well-being and allow for prompt detection of problems.*
- Communicate with birth attendant frequently concerning progress *to ensure continuity of care.*

(continued)

Nursing Care Plan 21.1 (continued)

- Discontinue oxytocin infusion if tetanic contractions (>90 seconds), uterine hyperstimulation (<2 minutes apart), elevated uterine resting tone, or a nonreassuring FHR pattern occurs *to minimize risk of drug's adverse effects.*
- Provide client with frequent reassurance of maternal and fetal status *to minimize anxiety.*

NURSING DIAGNOSIS: Pain related to uterine contractions *as evidenced by client's statements about contractions increasing in intensity and expected effect of oxytocin administration*

Outcome Identification and Evaluation

Client will report a decrease in pain as evidenced by statements of increased comfort and pain rating of 3 or less on numeric pain rating scale.

Interventions: Promoting Comfort and Pain Relief

- Explain to the client that she will experience discomfort sooner than with naturally occurring labor *to promote client's awareness of events and prepare client for the experience.*
- Frequently assess client's pain using a pain rating scale *to quantify client's level of pain and evaluate effectiveness of pain-relief measures.*
- Provide comfort measures, such as hygiene, backrubs, music, and distraction, and encourage the use of breathing and relaxation techniques *to help promote relaxation.*
- Provide support for her partner *to aid in alleviating stress and concerns.*
- Employ nonpharmacologic methods, such as position changes, birthing ball, hydrotherapy, visual imagery, and effleurage, *to help in managing pain and foster feelings of control over situation.*
- Administer pharmacologic agents such as analgesia or anesthesia as appropriate and as ordered *to control pain.*
- Continuously reassess client's pain level *to evaluate effectiveness of pain management techniques used.*

Nursing Management

The nurse can play a major role in assisting the grieving family. With skillful intervention, the bereaved family may be better prepared to resolve their grief and move forward. To assist families in the grieving process, include the following measures:

- Provide accurate, understandable information to the family.
- Encourage discussion of the loss and venting of feelings of grief and guilt.
- Provide the family with baby mementos and pictures to validate the reality of death.
- Allow unlimited time with the stillborn infant after birth to validate the death; provide time for the family members to be together and grieve; offer the family the opportunity to see, touch, and hold the infant.
- Use appropriate touch, such as holding a hand or touching a shoulder.
- Inform the chaplain or the religious leader of the family's denomination about the death and request his or her presence.
- Assist the parents with the funeral arrangements or disposition of the body.
- Provide the parents with brochures offering advice about how to talk to other siblings about the loss.
- Refer the family to the support group SHARE Pregnancy and Infant Loss Support, Inc., which is designed for those who have lost an infant through abortion, miscarriage, fetal death, stillbirth, or other tragic circumstances.
- Make community referrals to promote a continuum of care after discharge.

Women Experiencing an Obstetric Emergency

Obstetric emergencies are challenging to all labor and birth personnel because of the increased risk of adverse outcomes for the mother and fetus. Quick clinical judgment and good critical decision making will increase the odds of a positive outcome for both mother and fetus. This chapter will discuss a few of these emergencies: umbilical cord prolapse, placental abruption, uterine rupture, and amniotic fluid embolism.

UMBILICAL CORD PROLAPSE

An **umbilical cord prolapse** is the protrusion of the umbilical cord alongside (occult) or ahead of the presenting part of the fetus (Fig. 21.5). This condition occurs in 1 out of every 300 births and requires prompt recognition and intervention for a positive outcome (March of Dimes, 2007f). Cord prolapse occurs in 3% of deliveries when the fetus is in the vertex position and in 3.7% of deliveries when the fetus is in the breech position. The risk is increased further when the presenting part does not fill the lower uterine segment, as is the case with incomplete

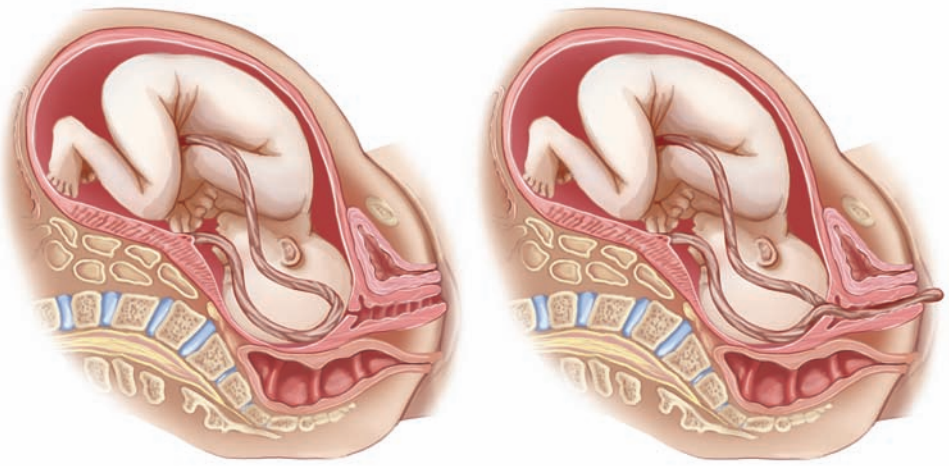

FIGURE 21.5 Prolapsed cord. (**A**) Prolapse within the uterus. (**B**) Prolapse with the cord visible at the vulva.

breech presentations (5% to 10%), premature infants, and multiparous women (Morgan & Ross, 2007). With a 50% perinatal mortality rate, it is one of the most catastrophic events in the intrapartum period (Enakpene, Omigbodun, & Arowojolu, 2006).

Pathophysiology

Prolapse usually leads to total or partial occlusion of the cord. Since this is the fetus's only lifeline, fetal perfusion deteriorates rapidly. Complete occlusion renders the fetus helpless and oxygen-deprived. The fetus will die if the cord compression is not relieved.

Nursing Assessment

Prevention is the key to managing cord prolapse by identifying clients at risk for this condition. Carefully assess each client to help predict her risk status. Be aware that cord prolapse is more common in pregnancies involving malpresentation, growth restriction, prematurity, ruptured membranes with a fetus at a high station, hydramnios, grandmultiparity, and multifetal gestation (Dilbaz et al., 2006). Continuously assess the client and fetus to detect changes and to evaluate the effectiveness of any interventions performed.

▶ ***Take*** *NOTE!*

When the presenting part does not fully occupy the pelvic inlet, prolapse is more likely to occur.

Nursing Management

Prompt recognition of a prolapsed cord is essential to reduce the risk of fetal hypoxia resulting from prolonged cord compression. When membranes are artificially ruptured, assist with verifying that the presenting part is well applied to the cervix and engaged into the pelvis. If pressure or compression of the cord occurs, assist with measures to relieve the compression. Typically, the examiner places a sterile gloved hand into the vagina and holds the presenting part off the umbilical cord until delivery. Changing the woman's position to a modified Sims, Trendelenburg, or knee–chest position also helps relieve cord pressure. Monitor fetal heart rate, maintain bedrest, and administer oxygen if ordered. Provide emotional support and explanations as to what is going on to allay the woman's fears and anxiety. If the mother's cervix is not fully dilated, prepare the woman for an emergency cesarean birth to save the fetus's life.

PLACENTAL ABRUPTION

Placental abruption refers to premature separation of a normally implanted placenta from the maternal myometrium. Abruptio placentae occurs in about 1% of all pregnancies throughout the world (March of Dimes, 2007a). Risk factors include preeclampsia, gestational hypertension, seizure activity, uterine rupture, trauma, smoking, cocaine use, coagulation defects, previous history of abruption, domestic violence, and placental pathology. These conditions may force blood into the underlayer of the placenta and cause it to detach (Deering & Satin, 2007).

Management of placental abruption depends on the gestational age, the extent of the hemorrhage, and maternal–fetal oxygenation perfusion/reserve status (see Chapter 19 for additional information on abruptio placentae). Treatment is based on the circumstances. Typically once the diagnosis is established, the focus is on maintaining the cardiovascular status of the mother and developing a plan to deliver the fetus quickly. A cesarean birth takes place if the fetus is still alive. A vaginal birth may take place if there is fetal demise.

UTERINE RUPTURE

Uterine rupture is a catastrophic tearing of the uterus at the site of a previous scar into the abdominal cavity. Its onset is often marked only by sudden fetal bradycardia, and treatment requires rapid surgery for good outcomes. From the time of diagnosis to delivery, only 10 to 30 minutes are available before clinically significant fetal morbidity occurs. Fetal morbidity occurs secondary to catastrophic hemorrhage, fetal anoxia, or both.

Nursing Assessment

Review the mother's history for risk conditions such as uterine scars, prior cesarean births, prior rupture, trauma, prior invasive molar pregnancy, history of placenta percreta or increta, malpresentation, labor induction with excessive uterine stimulation, and crack cocaine use (Nahum & Pham, 2007). Reviewing a client's history for risk factors might prove to be life-saving for both mother and fetus.

Generally, the first and most reliable symptom of uterine rupture is sudden fetal distress. Other signs may include acute and continuous abdominal pain with or without an epidural, vaginal bleeding, hematuria, irregular abdominal wall contour, loss of station in the fetal presenting part, and hypovolemic shock in the woman, fetus, or both (Nahum & Pham, 2007).

Timely management of uterine rupture depends on prompt detection. Because many women desire a trial of labor after a previous cesarean birth, the nurse must be familiar with the signs and symptoms of uterine rupture. It is difficult to prevent uterine rupture or to predict which women will experience rupture, so constant preparedness is necessary.

Screening all women with previous uterine surgical scars is important, and continuous electronic fetal monitoring should be used during labor because this may provide the only indication of an impending rupture.

Nursing Management

Because the presenting signs may be nonspecific, the initial management will be the same as that for any other cause of acute fetal distress. Urgent delivery by cesarean birth is usually indicated. Monitor maternal vital signs and observe for hypotension and tachycardia, which might indicate hypovolemic shock. Assist in preparing for an emergency cesarean birth by alerting the operating room staff, anesthesia provider, and neonatal team. Insert an indwelling urinary (Foley) catheter if one is not in place already. Inform the woman of the seriousness of this event and remind her that the health care staff will be working quickly to ensure her health and that of her fetus. Remain calm and provide reassurance that everything is being done to ensure a safe outcome for both.

The life-threatening nature of uterine rupture is underscored by the fact that the maternal circulatory system delivers approximately 500 mL of blood to the term uterus every minute (Kennare et al., 2007). Maternal death is a real possibility without rapid intervention. Newborn outcome after rupture depends largely on the speed with which surgical rescue is carried out.

Take NOTE!

When excessive bleeding occurs during the childbirth process and it persists or signs such as bruising or petechiae appear, disseminated intravascular coagulation (DIC) should be suspected.

AMNIOTIC FLUID EMBOLISM

Amniotic fluid embolism is a rare and often fatal event characterized by the sudden onset of hypotension, hypoxia, and coagulopathy. Amniotic fluid containing particles of debris (e.g., hair, skin, vernix, or meconium) enters the maternal circulation and obstructs the pulmonary vessels, causing respiratory distress and circulatory collapse (O'Shea & Eappen, 2007). The incidence is approximately 1 case per 8,000 to 80,000 pregnancies and carries a maternal mortality rate as high as 80% (Schoening, 2007).

Pathophysiology

Normally, amniotic fluid does not enter the maternal circulation because it is contained within the uterus, sealed off by the amniotic sac. An embolus occurs when the barrier between the maternal circulation and the amniotic fluid is broken and amniotic fluid enters the maternal venous system via the endocervical veins, the placental site (if the placenta is separated), or a site of uterine trauma. This condition has a high mortality rate: as many as 50% of women die within the first hour after the onset of symptoms, and about 85% of survivors have permanent hypoxia-induced neurologic damage (Moore, 2006).

Although medical science has supplied many answers to questions about this condition, health care providers remain largely unable to predict or prevent an amniotic fluid embolism or to decrease its mortality rate.

Nursing Assessment

No test can diagnose an amniotic fluid embolism. Therefore, the nurse's assessment skills are critical. Immediate recognition and diagnosis of this condition are essential to improve maternal and fetal outcomes. Until recently, the diagnosis could be made only after an autopsy of the mother revealed squamous cells, lanugo hair, or other fetal and amniotic material in the pulmonary arterial vasculature (Gilbert, 2007).

The clinical appearance is varied, but most women report difficulty breathing. Other symptoms include hypotension, cyanosis, seizures, tachycardia, coagulation failure,

disseminated intravascular coagulation, pulmonary edema, uterine atony with subsequent hemorrhage, adult respiratory distress syndrome, and cardiac arrest (Moore & Ware, 2007).

Take NOTE!

Amniotic fluid embolism should be suspected in any pregnant women with an acute onset of dyspnea, hypotension, and disseminated intravascular coagulation. By knowing how to intervene, the nurse can promote a better chance of survival for both the mother and her newborn.

Nursing Management

Upon recognizing the signs and symptoms, institute supportive measures: oxygenation (resuscitation and 100% oxygen), circulation (intravenous fluids, inotropic agents to maintain cardiac output and blood pressure), control of hemorrhage and coagulopathy (oxytocic agents to control uterine atony and bleeding), seizure precautions, and administration of steroids to control the inflammatory response (Schoening, 2007).

Care is largely supportive and aimed at maintaining oxygenation and hemodynamic function and correcting coagulopathy. There is no specific therapy that is lifesaving once this condition starts. Adequate oxygenation is necessary, with endotracheal intubation and mechanical ventilation for most women. Vasopressors are used to maintain hemodynamic stability. Management of disseminated intravascular coagulation may involve replacement with packed red blood cells or fresh-frozen plasma as necessary. Oxytocin infusions and prostaglandin analogs can be used to address uterine atony.

Explain to the client and family what is happening and what therapies are being instituted. The woman is usually transferred to a critical care unit for intensive observation and care. Assist the family to express their feelings and provide support as needed.

WOMEN REQUIRING BIRTH-RELATED PROCEDURES

Most women can give birth without the need for operative obstetric interventions. Most will expect to have a "natural" birth experience and don't anticipate the need for medical intervention. However, in some situations interventions are necessary to safeguard the health of the mother and fetus. The most common birth-related procedures are amnioinfusion, episiotomy (see Chapter 14), forceps-assisted or vacuum-assisted birth, cesarean birth, and vaginal birth following a previous cesarean birth. Nurses play a major role in helping the couple to cope with any unanticipated procedures by offering thorough explanations of the procedure, its anticipated benefits and risks, and any other options available.

AMNIOINFUSION

Amnioinfusion is a technique in which a volume of warmed, sterile, normal saline or Ringer's lactate solution is introduced into the uterus through an intrauterine pressure catheter to increase the volume of fluid when oligohydramnios is present (Boyd & Carter, 2008). It is used to change the relationship of the uterus, placenta, cord, and fetus to improve placental and fetal oxygenation. Instilling an isotonic glucose-free solution into the uterus helps to cushion the umbilical cord or dilute thick meconium (Xu et al., 2007).

This procedure is commonly indicated for severe variable decelerations due to cord compression, oligohydramnios due to placental insufficiency, postmaturity or rupture of membranes, preterm labor with premature rupture of membranes, and thick meconium fluid. However, it does not prevent meconium aspiration syndrome (ACOG, 2006). Contraindications to amnioinfusion include vaginal bleeding of unknown origin, umbilical cord prolapse, amnionitis, uterine hypertonicity, and severe fetal distress (ACOG, 2006).

There is no standard protocol for amnioinfusion. After obtaining informed consent, a vaginal examination is performed to evaluate for cord prolapse, establish dilation, and confirm presentation. Next, 250 to 500 mL of warmed normal saline or lactated Ringer's solution is administered using an infusion pump over 20 to 30 minutes. Overdistention of the uterus is a risk, so the amount of fluid infused must be monitored closely (Boyd & Carter, 2008).

When caring for the woman who is receiving an amnioinfusion, include the following:

- Explain the need for the procedure, what it involves, and how it may solve the problem.
- Inform the mother that she will need to remain on bed rest during the procedure.
- Assess the mother's vital signs and associated discomfort level.
- Maintain intake and output records.
- Assess the duration and intensity of uterine contractions frequently to identify overdistention or increased uterine tone.
- Monitor the FHR pattern to determine whether the amnioinfusion is improving the fetal status.
- Prepare the mother for a possible cesarean birth if the FHR does not improve after the amnioinfusion.

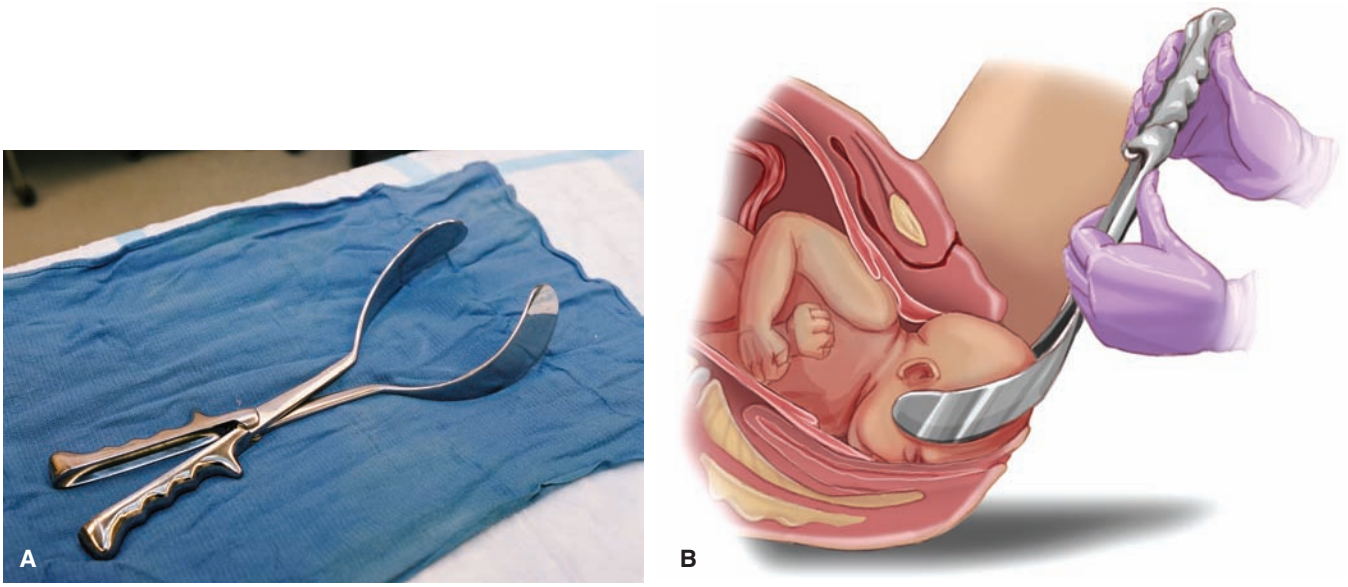

FIGURE 21.6 Forceps delivery. (**A**) Example of forceps. (**B**) Forceps being applied to the fetus.

FORCEPS- OR VACUUM-ASSISTED BIRTH

Forceps or a vacuum extractor may be used to apply traction to the fetal head or to provide a method of rotating the fetal head during birth. **Forceps** are stainless-steel instruments, similar to tongs, with rounded edges that fit around the fetus's head. Some forceps have open blades and some have solid blades. Outlet forceps are used when the fetal head is crowning and low forceps are used when the fetal head is at a +2 station or lower but not yet crowning. The forceps are applied to the sides of the fetal head. The type of forceps used is determined by the birth attendant. All forceps have a locking mechanism that prevents the blades from compressing the fetal skull (Fig. 21.6).

A **vacuum extractor** is a cup-shaped instrument attached to a suction pump used for extraction of the fetal head (Fig. 21.7). The suction cup is placed against the occiput of the fetal head. The pump is used to create negative pressure (suction) of approximately 50 to 60 mmHg. The birth attendant then applies traction until the fetal head emerges from the vagina.

The indications for the use of either method are similar and include a prolonged second stage of labor, a nonreassuring FHR pattern, failure of the presenting part to fully rotate and descend in the pelvis, limited sensation and inability to push effectively due to the effects of regional anesthesia, presumed fetal jeopardy or fetal distress, maternal heart disease, acute pulmonary edema, intrapartum infection, maternal fatigue, or infection (Pope & O'Grady, 2006).

The use of forceps or a vacuum extractor poses the risk of tissue trauma to the mother and the newborn. Maternal trauma may include lacerations of the cervix, vagina,

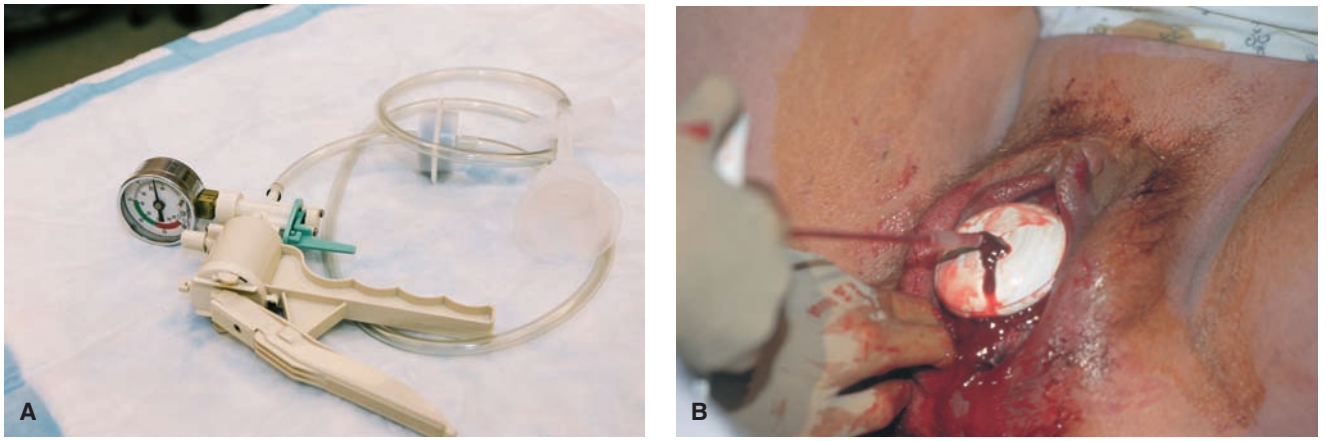

FIGURE 21.7 Vacuum extractor for delivery. (**A**) Example of a vacuum extractor. (**B**) Vacuum extractor applied to the fetal head to assist in delivery.

or perineum; hematoma; extension of the episiotomy incision into the anus; hemorrhage; and infection. Potential newborn trauma includes ecchymoses, facial and scalp lacerations, facial nerve injury, cephalhematoma, and caput succedaneum (Cunningham et al., 2005).

Prevention is key to reducing the use of these techniques. Preventive measures include frequently changing the client's position, encouraging ambulation if permitted, frequently reminding the client to empty her bladder to allow maximum space for birth, and providing adequate hydration throughout labor. Additional measures include assessing maternal vital signs, the contraction pattern, the fetal status, and the maternal response to the procedure. Provide a thorough explanation of the procedure and the rationale for its use. Reassure the mother that any marks or swelling on the newborn's head or face will disappear without treatment within 2 to 3 days. Alert the postpartum nursing staff about the use of the technique so that they can observe for any bleeding or infection related to genital lacerations.

CESAREAN BIRTH

WATCH & LEARN

A **cesarean birth** is the delivery of the fetus through an incision in the abdomen and uterus. A classic (vertical) or low transverse incision may be used; today, the low transverse incision is more common (Fig. 21.8).

High cesarean birth rates are an international concern. The number of cesarean births has steadily risen in the United States: today approximately 29% or one in three births occur this way (ACOG, 2008). Although there has been some decline in rates since the 1980s, the United States still has a way to go to reduce its surgical birth rates (USDHHS, 2000).

FIGURE 21.8 Low transverse incision for cesarean birth.

Several factors may explain this increased incidence of cesarean deliveries: the use of electronic fetal monitoring, which identifies fetal distress early; the reduced number of forceps-assisted births; older maternal age and reduced parity, with more nulliparous women having infants; convenience to the client and doctor; and a increase in malpractice suits (Katz, 2006).

Cesarean birth is a major surgical procedure with increased risks compared to a vaginal birth. The client is at risk for complications such as infection, hemorrhage, aspiration, pulmonary embolism, urinary tract trauma, thrombophlebitis, paralytic ileus, and atelectasis. Fetal injury and transient tachypnea of the newborn also may occur (Gagnon, Meir, & Waghorn, 2007).

Spinal, epidural, or general anesthesia is used for cesarean births. Epidural anesthesia is most commonly used today because it is associated with less risk and most women wish to be awake and aware of the birth experience.

Nursing Assessment

Review the woman's history for indications associated with cesarean birth and complete a physical examination. Any condition that prevents the safe passage of the fetus through the birth canal or that seriously compromises maternal or fetal well-being may be an indication for a cesarean birth. Examples include active genital herpes, fetal macrosomia, fetopelvic disproportion, prolapsed umbilical cord, placental abnormality (placenta previa or abruptio placentae), previous classic uterine incision or scar, gestational hypertension, diabetes, positive HIV status, and dystocia. Fetal indications include malpresentation (nonvertex presentation), congenital anomalies (fetal neural tube defects, hydrocephalus, abdominal wall defects), and fetal distress (Humenick, 2006).

Nursing Management

Once the decision has been made to proceed with a cesarean birth, assess the woman's knowledge of the procedure and necessary preparation. Assist with obtaining diagnostic tests as ordered. These tests are usually ordered to ensure the well-being of both parties and may include a complete blood count; urinalysis to rule out infection; blood type and cross-match so that blood is available for transfusion if needed; an ultrasound to determine fetal position and placental location; and an amniocentesis to determine fetal lung maturity if needed.

Although the nurse's role in a cesarean birth can be very technical and skill-oriented at times, the focus must remain on the woman, not the equipment surrounding the bed. Care should be centered on the family, not the surgery. Provide education and minimize separation of the mother, father, and newborn. Remember that the client is anxious and concerned about her welfare as well as that of

her child. Use touch, eye contact, therapeutic communication, and genuine caring to provide couples with a positive birth experience, regardless of the type of delivery.

Providing Preoperative Care

Client preparation varies depending on whether the cesarean birth is planned or unplanned. The major difference is the time allotted for preparation and teaching. In an unplanned cesarean birth, institute measures quickly to ensure the best outcomes for the mother and fetus. Ensure that the woman has signed an informed consent, and allow for discussion of fears and expectations. Provide essential teaching and explanations to reduce the woman's fears and anxieties.

Ascertain the client's and family's understanding of the surgical procedure. Reinforce the reasons for surgery given by the surgeon. Outline the procedure and expectations of the surgical experience. Ensure that all diagnostic tests ordered have been completed, and evaluate the results. Explain to the woman and her family about what to expect postoperatively. Reassure the woman that pain management will be provided throughout the procedure and afterward. Encourage the woman to report any pain.

Ask the woman about the time she last had anything to eat or drink. Document the time and what was consumed. Throughout the preparations, assess maternal and fetal status frequently.

Provide preoperative teaching to reduce the risk of postoperative complications. Demonstrate the use of the incentive spirometer and deep-breathing and leg exercises. Instruct the woman on how to splint her incision.

Complete the preoperative procedures, which may include:

- Preparing the surgical site as ordered
- Starting an intravenous infusion for fluid replacement therapy as ordered
- Inserting an indwelling (Foley) catheter and informing the client about how long it will remain in place (usually 24 hours)
- Administering any preoperative medications as ordered; documenting the time administered and the client's reaction

Maintain a calm, confident manner in all interactions with the client and family. Help transport the client and her partner to the operative area.

Providing Postoperative Care

Postoperative care for the mother who has had a cesarean delivery is similar to that for one who has had a vaginal birth, with a few additional measures. Assess vital signs and lochia flow every 15 minutes for the first hour, then every 30 minutes for the next hour, and then every 4 hours if stable. Assist with perineal care and instruct the client in the same. Inspect the abdominal dressing and document description, including any evidence of drainage. Assess uterine tone to determine fundal firmness. Check the patency of the intravenous line, making sure the infusion is flowing at the correct rate. Inspect the infusion site frequently for redness.

Assess the woman's level of consciousness if sedative drugs were administered. Institute safety precautions until the woman is fully alert and responsive. If a regional anesthetic was used, monitor for the return of sensation to the legs.

Assess for evidence of abdominal distention and auscultate bowel sounds. Assist with early ambulation to prevent respiratory and cardiovascular problems and to promote peristalsis. Monitor intake and output at least every 4 hours initially and then every 8 hours as indicated.

Encourage the woman to cough, perform deep-breathing exercises, and use the incentive spirometer every 2 hours. Administer analgesics as ordered and provide comfort measures, such as splinting the incision and pillows for positioning. Assist the client to move in bed and turn side to side to improve circulation. Also encourage the woman to ambulate to promote venous return from the extremities.

Encourage early touching and holding of the newborn to promote bonding. Assist with breastfeeding initiation and offer continued support. Suggest alternate positioning techniques to reduce incisional discomfort while breastfeeding.

Review with the couple their perception of the surgical birth experience. Allow them to verbalize their feelings and assist them in positive coping measures. Prior to discharge, teach the woman about the need for adequate rest, activity restrictions such as lifting, and signs and symptoms of infection.

VAGINAL BIRTH AFTER CESAREAN

Vaginal birth after cesarean (VBAC) describes a woman who gives birth vaginally after having at least one previous cesarean birth. Despite evidence that some women who have had a cesarean birth are candidates for vaginal birth, most women who have had a cesarean birth once undergo another for subsequent pregnancies (Caughey, 2006).

The choice of a vaginal or a repeat cesarean birth can be offered to women who had a lower abdominal incision. However, controversy remains. The argument against VBAC focuses on the risk of uterine rupture and hemorrhage. Although the risk of uterine rupture is relatively low, the rate of fetal mortality in the event of a uterine rupture is extremely high.

Contraindications to VBAC include a prior classic uterine incision, prior transfundal uterine surgery (myomectomy), uterine scar other than low-transverse cesarean scar, contracted pelvis, and inadequate staff or facility if an emergency cesarean birth in the event of uterine rupture is required (Caughey, 2006). Most women go through a trial of labor to see how they progress, but this must be performed in an environment capable of handling the emergency of uterine rupture. The use of cervical ripening agents increases the risk of uterine rupture and thus is contraindicated in VBAC clients. The woman considering induction of labor after a previous cesarean birth needs to be informed of the increased risk of uterine rupture with an induction than with spontaneous labor (Meddings et al., 2007).

Women are the primary decision makers about the choice of birth method, but they need education about VBAC during their prenatal course. Management is similar for any women experiencing labor, but certain areas require special focus:

- Consent: Fully informed consent is essential for the woman who wants to have a trial of labor after cesarean birth. The client must be advised about the risks as well as the benefits. She must understand the ramifications of uterine rupture, even though the risk is small.
- Documentation: Recordkeeping is an important component of safe client care. If and when an emergency occurs, it is imperative to take care of the client, but also to keep track of the plan of care, interventions and their timing, and the client's response. Events and activities can be written right on the fetal monitoring tracing to correlate with the change in fetal status.
- Surveillance: A nonreassuring fetal monitor tracing in a woman undergoing a trial of labor after a cesarean birth should alert the nurse to the possibility of uterine rupture. Terminal bradycardia must be considered an emergency situation, and the nurse should prepare the team for an emergency delivery.
- Readiness for emergency: According to ACOG criteria for a safe trial of labor for a woman who has had a previous cesarean birth, the physician, anesthesia provider, and operating room team must be immediately available. Anything less would place the women and fetus at risk (ACOG, 2004a).

Nurses must act as advocates, giving input on the appropriate selection of women who wish to undergo VBAC. Nurses also need to become experts at reading fetal monitoring tracings to identify a nonreassuring pattern and set in motion an emergency delivery. Including all these nursing strategies will make VBAC safer for all.

Key Concepts

- Risk factors for dystocia include epidural analgesia, occiput posterior position, longer first stage of labor, nulliparity, short maternal stature (<5 feet tall), high birth weight, maternal age older than 35 years, gestational age more than 41 weeks, chorioamnionitis, pelvic contractions, macrosomia, and high station at complete cervical dilation.
- Dystocia may result from problems in the powers, passenger, passageway, or psyche.
- Problems involving the powers that lead to dystocia include hypertonic uterine dysfunction, hypotonic uterine dysfunction, and precipitous labor.
- Management of hypertonic labor pattern involves therapeutic rest with the use of sedatives to promote relaxation and stop the abnormal activity of the uterus.
- Any presentation other than occiput or a slight variation of the fetal position or size increases the probability of dystocia.
- Multiple gestation may result in dysfunctional labor due to uterine overdistention, which may lead to hypotonic dystocia, and abnormal presentations of the fetuses.
- During labor, evaluation of fetal descent, cervical effacement and dilation, and characteristics of uterine contractions are paramount to determine progress or lack thereof.
- Antepartum assessment for a postterm pregnancy typically includes daily fetal movement counts done by the woman, nonstress tests done twice weekly, amniotic fluid assessments as part of the biophysical profile, and weekly cervical examinations to check for ripening for induction.
- Once the cervix is ripe, oxytocin is the most popular pharmacologic agent used for inducing or augmenting labor.
- Generally, the first and most reliable symptom of uterine rupture is fetal distress.
- Amniotic fluid embolism is a rare but often fatal event characterized by the sudden onset of hypotension, hypoxia, and coagulopathy.
- Cesarean births have steadily risen in the United States; today, approximately one in five births occurs this way. Cesarean birth is a major surgical procedure and has increased risks over vaginal birth.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. When reviewing the medical record of a client, the nurse notes that the woman has a condition in which the fetus cannot physically pass through the maternal pelvis. The nurse interprets this as:
   a. Cervical insufficiency
   b. Contracted pelvis
   c. Maternal disproportion
   d. Fetopelvic disproportion
2. The nurse would anticipate a cesarean birth for a client who has which active infection present at the onset of labor?
   a. Hepatitis
   b. Herpes simplex virus
   c. Toxoplasmosis
   d. Human papillomavirus
3. After a vaginal examination, the nurse determines that the client's fetus is in an occiput posterior position. The nurse would anticipate that the client will have:
   a. Intense back pain
   b. Frequent leg cramps
   c. Nausea and vomiting
   d. A precipitous birth
4. When assessing the following women, which would the nurse identify as being at the greatest risk for preterm labor?
   a. Woman who had twins in a previous pregnancy
   b. Client living in a large city
   c. Woman working full-time as a computer programmer
   d. Client with a history of a previous preterm birth
5. The rationale for using a prostaglandin gel for a client prior to the induction of labor is to:
   a. Stimulate uterine contractions
   b. Numb cervical pain receptors
   c. Prevent cervical lacerations
   d. Soften and efface the cervix
6. A client who was in active labor and whose cervix had dilated to 4 cm experiences a weakening in the intensity and frequency of her contractions and exhibits no further progress in labor. The nurse interprets this as a sign of:
   a. Hypertonic labor
   b. Precipitous labor
   c. Hypotonic labor
   d. Dysfunctional labor

CRITICAL THINKING EXERCISES

1. Marsha, a 26-year-old multipara, is admitted to the labor and birth suite in active labor. After a few hours, the nurse notices a change in her contraction pattern—poor contraction intensity and no progression of cervical dilatation beyond 5 cm. Marsha keeps asking about her labor progress and appears anxious about "how long this labor is taking."
   a. Based on the nurse's findings, what might you suspect is going on?
   b. How can the nurse address Marsha's anxiety?
   c. What are the appropriate interventions to change this labor pattern?
2. Marsha activates her call light and states, "I feel increased wetness down below."
   a. What might be occurring?
   b. How will the nurse confirm the suspicions?
   c. What interventions are appropriate for this finding?

STUDY ACTIVITIES

1. Visit the SHARE Pregnancy and Infant Loss Support, Inc. website (http://www.nationalshareoffice.com/) and assess its helpfulness to parents.
2. Outline the fetal and maternal risks associated with a postterm pregnancy.
3. An abnormal or difficult labor describes _____.

CHAPTER 22

Nursing Management of the Postpartum Woman at Risk

KEY TERMS

mastitis
metritis
postpartum depression
postpartum hemorrhage
subinvolution
thrombophlebitis
uterine atony
uterine inversion

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Define the major conditions that place the postpartum woman at risk.
2. Explain the risk factors, assessment, preventive measures, and nursing management of common postpartum complications.
3. Differentiate the causes of postpartum hemorrhage based on the underlying pathophysiologic mechanisms.
4. Outline the nurse's role in assessing and managing the care of a woman with a thromboembolic condition.
5. Discuss the nursing management of a woman who develops a postpartum infection.
6. Identify at least two affective disorders that can occur in women after birth, describing specific therapeutic management for each.

Joan gave birth about an hour ago to her fifth baby boy, who weighed 10 pounds, and she is resting in bed when the nurse comes in to assess her. She tells the nurse that she feels like there is "something really wet" between her legs. She also feels a bit lightheaded. What would the nurse suspect is happening? What findings would support the nurse's suspicion? What should the nurse do first?

Wow

After holding their breath during the childbirth experience, nurses shouldn't let it out fully and relax until the woman and baby are discharged.

Typically, recovery from childbirth proceeds normally both physiologically and psychologically. It is a time filled with many changes and wide-ranging emotions, and the new mother commonly experiences a great sense of accomplishment. However, the woman can experience deviations from the norm, developing a postpartum condition that places her at risk. These high-risk conditions or complications can become life-threatening. Healthy People 2010 addresses these risks in two National Health Goals.

This chapter will address the nursing management of the most common conditions that place the postpartum woman at risk: hemorrhage, infection, thromboembolic disease, and postpartum affective disorders.

Postpartum Hemorrhage

Postpartum hemorrhage is a potentially life-threatening complication that can occur after both vaginal and cesarean births. It is the leading cause of maternal mortality worldwide: it is estimated that worldwide, 150,000 women die of postpartum hemorrhage annually—one every four minutes (American College of Obstetricians & Gynecologists [ACOG], 2006). More than half of all maternal deaths occur within 24 hours of giving birth, most commonly from excessive bleeding.

Postpartum hemorrhage is defined as a blood loss greater than 500 mL after vaginal birth or more than 1,000 mL after a cesarean birth. Blood loss that occurs within 24 hours of birth is termed *early postpartum hemorrhage;* blood loss that occurs 24 hours to 6 weeks after birth is termed *late postpartum hemorrhage.* However, this definition is arbitrary, because estimates of blood loss at birth are subjective and generally inaccurate. Studies have suggested that health care providers consistently underestimate actual blood loss (Smith & Brennan, 2007). A more objective definition of postpartum hemorrhage would be any amount of bleeding that places the mother in hemodynamic jeopardy.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce maternal deaths from a baseline of 7.1 maternal deaths per 100,000 live births to 3.3 maternal deaths per 100,000 live births.	Will help foster the need for early identification of problems and prompt intervention to reduce the potential negative outcomes of pregnancy and birth
Reduce maternal illness and complications due to pregnancy	Will help to contribute to lower rates of rehospitalization, morbidity, and mortality by focusing on thorough assessments in the postpartum period
Related to postpartum complications, including postpartum depression	Will help to minimize the devastating effects of complications during the postpartum period and the woman's ability to care for her newborn

DHHS, 2000.

Pathophysiology

Excessive bleeding can occur at any time between the separation of the placenta and its expulsion or removal. The most common cause of postpartum hemorrhage is **uterine atony**, failure of the uterus to contract and retract after birth. The uterus must remain contracted after birth to control bleeding from the placental site. Any factor that causes the uterus to relax after birth will cause bleeding—even a full bladder that displaces the uterus.

Over the course of a pregnancy, maternal blood volume increases by approximately 50% (from 4 to 6 L). The plasma volume increases twice as much in comparison to the total red blood cell volume. As a result, hemoglobin and hematocrit fall. The increase in blood volume meets the perfusion demands of the low-resistance uteroplacental unit and provides a reserve for the blood loss that occurs at delivery (Cunningham et al., 2005). Given this increase, the typical signs of hemorrhage (e.g., falling blood pressure, increasing pulse rate, and decreasing urinary output) do not appear until as much as 1,800 to 2,100 mL of blood has been lost (Gilbert and Harmon, 2007). In addition, accurate determination of actual blood loss is difficult because of blood pooling inside the uterus, on peripads, mattresses, and the floor. Since no universal clinical standard exists, nurses must remain vigilant, assessing for risk factors and checking clients carefully before the birth attendant leaves the birthing area.

Other causes of postpartum hemorrhage include lacerations of the genital tract, episiotomy, retained placental fragments, uterine inversion, coagulation disorders, and hematomas of the vulva, vagina, or subperitoneal areas (ACOG, 2006). A helpful way to remember the causes of postpartum hemorrhage is by using the "4 Ts": tone, tissue, trauma, and thrombosis (Anderson & Etches, 2007).

Tone

Altered uterine muscle tone most commonly results from overdistention of the uterus. Overdistention can be caused by multifetal gestation, fetal macrosomia, polyhydramnios, fetal abnormality, or placental fragments. Other causes might include prolonged or rapid, forceful labor, especially if stimulated; bacterial toxins (e.g., chorioamnionitis, endomyometritis, septicemia); use of anesthesia, especially halothane; and magnesium sulfate used in the treatment of preeclampsia (Nash, 2007). Overdistention of the uterus is a major risk factor for uterine atony, the most common cause of early postpartum hemorrhage, which can lead to hypovolemic shock.

Tissue

Uterine contraction and retraction lead to detachment and expulsion of the placenta after birth. Classic signs of placental separation include a small gush of blood with lengthening of the umbilical cord and a slight rise of the uterus in the pelvis. Complete detachment and expulsion of the placenta permit continued contraction and optimal occlusion of blood vessels. Failure of complete placental separation and expulsion leads to retained fragments, which occupy space and prevent the uterus from contracting fully to clamp down on blood vessels; this can lead to hemorrhage. After the placenta is expelled, a thorough inspection is necessary to confirm its intactness; tears or fragments left inside may indicate an accessory lobe or placenta accreta (an uncommon condition in which the chorionic villi adhere to the myometrium, causing the placenta to adhere abnormally to the uterus and not separate and deliver spontaneously). Profuse hemorrhage results because the uterus cannot contract fully.

A prolapse of the uterine fundus to or through the cervix so that the uterus is turned inside out after birth is called **uterine inversion**. This condition is associated with grand multiparity, abnormal adherence of the placenta, excessive traction on the umbilical cord, vigorous fundal pressure, precipitous labor, or vigorous manual removal of the placenta. Acute postpartum uterine inversion is rare, with an estimated incidence of 1 in 2,000 births (Pope & O'Grady, 2006). Prompt recognition and rapid treatment to replace the inverted uterus will avoid morbidity and mortality for this serious complication (Smith & Brennan, 2006).

Subinvolution refers to incomplete involution of the uterus or failure to return to its normal size and condition after birth (Dorland, 2007). Complications of subinvolution include hemorrhage, pelvic peritonitis, salpingitis, and abscess formation (Weydert & Benda, 2006). Causes of subinvolution include retained placental fragments, distended bladder, uterine myoma, and infection. All of these conditions contribute to delayed postpartum bleeding. The clinical picture includes a postpartum fundal height that is higher than expected, with a boggy uterus; the lochia fails to change colors from red to serosa to alba within a few weeks. This condition is usually identified at the woman's postpartum examination 4 to 6 weeks after birth with a bimanual vaginal examination or ultrasound. Treatment is directed toward stimulating the uterus to expel fragments with a uterine stimulant, and antibiotics are given to prevent infection.

Trauma

Damage to the genital tract may occur spontaneously or through the manipulations used during birth. Lacerations and hematomas resulting from birth trauma can cause significant blood loss. Hematomas can present as pain or as a change in vital signs disproportionate to the amount of blood loss. Uterine inversion can occur secondary to pressure or pulling on the umbilical cord when the placenta is still firmly attached to the fundus after the infant has been born. Additionally, uterine rupture can cause damage to the genital tract and is more common in women with previous cesarean incisions or those who had undergone any procedure resulting in disruption of the uterine wall, including myomectomy, perforation of the uterus during a dilation and curettage (D&C), biopsy, or intrauterine device (IUD) insertion (Smith & Brennan, 2006).

Trauma can also occur after prolonged or vigorous labor, especially if the uterus has been stimulated with oxytocin or prostaglandins. Trauma can also occur after extrauterine or intrauterine manipulation of the fetus.

Cervical lacerations commonly occur during a forceps delivery or in mothers who have not been able to resist bearing down before the cervix is fully dilated. Vaginal sidewall lacerations are associated with operative vaginal births but may occur spontaneously, especially if the fetal hand presents with the head. Lacerations can arise during manipulations to resolve shoulder dystocia. Lacerations should always be suspected in the face of a contracted uterus with bright-red blood continuing to trickle out of the vagina.

Thrombosis

Thrombosis (blood clots) helps to prevent postpartum hemorrhage immediately after birth by providing hemostasis. Fibrin deposits and clots in supplying vessels play a significant role in the hours and days after birth. Disorders that interfere with the clot formation can lead to postpartum hemorrhage. Medication used to prevent hemorrhage by stimulating uterine contractions may delay the appearance of coagulation disorders. Coagulopathies should be suspected when postpartum bleeding persists without any identifiable cause (ACOG, 2006).

Ideally, the client's coagulation status is determined during pregnancy. However, if she received no prenatal care, coagulation studies should be ordered immediately to determine her status. Abnormal results typically include decreased platelet and fibrinogen levels, increased prothrombin time, partial thromboplastin time, and fibrin degradation products, and a prolonged bleeding time (Anderson & Etches, 2007). Conditions associated with coagulopathies in the postpartum client include idiopathic thrombocytopenic purpura, von Willebrand disease, and disseminated intravascular coagulation.

Idiopathic Thrombocytopenia Purpura

Idiopathic thrombocytopenia purpura (ITP) is a disorder of increased platelet destruction caused by the development of autoantibodies to platelet-membrane antigens. The incidence of ITP in adults is approximately 66 cases per 1 million per year (Silverman, 2007). Thrombocytopenia, capillary fragility, and increased bleeding time define the disorder, commonly manifested by easy bruising, bleeding from mucous membranes, menorrhagia, epistaxis,

bleeding gums, hematomas, and severe hemorrhage after a cesarean birth or lacerations (Sood & Abrams, 2007). Glucocorticoids and immune globulin are the mainstays of medical therapy.

von Willebrand Disease

von Willebrand disease (vWD) is a congenital bleeding disorder, inherited as an autosomal dominant trait. It is characterized by a prolonged bleeding time, a deficiency of von Willebrand factor, and impairment of platelet adhesion (Dorland, 2007). In the United States, it is estimated to affect fewer than 3% of the population (Geil, 2007). Most cases remain undiagnosed due to lack of awareness, difficulty in diagnosis, a tendency to attribute bleeding to other causes, and variable symptoms (Kadir et al., 2007). The disorder is characterized by excessive bruising, prolonged nosebleeds, and prolonged oozing from wounds after surgery and after childbirth. The goal of therapy is to correct the defect in platelet adhesiveness by raising the level of von Willebrand factor with medications (Franchini & Lippi, 2007).

Disseminated Intravascular Coagulation

Disseminated intravascular coagulation (DIC) is a life-threatening, acquired pathologic process in which the clotting system is abnormally activated, resulting in widespread clot formation in the small vessels throughout the body (Levi & Schmaier, 2007). It can cause postpartum hemorrhage by altering the blood clotting mechanism. DIC is always a secondary diagnosis that occurs as a complication of abruptio placentae, amniotic fluid embolism, intrauterine fetal death with prolonged retention of the fetus, severe preeclampsia, septicemia, and hemorrhage. Clinical features include petechiae, ecchymoses, bleeding gums, fever, hypotension, acidosis, hematomas, tachycardia, proteinuria, uncontrolled bleeding during birth, and acute renal failure (Bick, 2007). Treatment goals are to maintain tissue perfusion through aggressive administration of fluid therapy, oxygen, heparin, and blood products.

Therapeutic Management

Therapeutic management focuses on the underlying cause of the hemorrhage. For example, uterine massage is used to treat uterine atony. If retained placental fragments are the cause, the fragments are usually manually separated and removed and a uterine stimulant is given to promote the uterus to expel fragments. Antibiotics are administered to prevent infection. Lacerations are sutured or repaired. Glucocorticoids and intravenous immunoglobulin, intravenous anti-RhoD, and platelet transfusions may be given. A splenectomy may be necessary if the bleeding tissues do not respond to medical management.

In vWD, there is a decrease in von Willebrand factor, which is necessary for platelet adhesion and aggregation. It binds to and stabilizes factor VIII of the coagulation cascade (Franchini & Lippi, 2007). Desmopressin, a synthetic form of vasopressin (antidiuretic hormone), may be used to treat vWD. This drug stimulates the release of stored factor VIII and von Willebrand factor from the lining of blood vessels, which increases platelet adhesiveness and shortens bleeding time. Other treatments that may be ordered include clotting factor concentrates, replacement of von Willebrand factor and factor VIII (Alphanate, Humate-P); antifibrinolytics (Amicar); and nonsteroidal anti-inflammatory drugs (NSAIDs) that do not cause platelet dysfunction (Geil, 2007).

Nursing Assessment

Pregnancy and childbirth involve significant health risks, even for women with no preexisting health problems. There are an estimated 14 million cases of pregnancy-related hemorrhage every year, with some of these women bleeding to death. Most of these deaths occur within 4 hours of giving birth and are a result of problems during the third stage of labor (ACOG, 2006). The period after the birth and the first hours postpartum are crucial times for the prevention, assessment, and management of bleeding. Compared with other maternal risks such as infection, bleeding can rapidly become life-threatening, and nurses, along with other health care providers, need to identify this condition quickly and intervene appropriately.

Begin by reviewing the mother's history, including labor and birth history, for risk factors associated with postpartum hemorrhage (Box 22.1).

Since the most common cause of immediate severe postpartum hemorrhage is uterine atony (failure of the

BOX 22.1 Factors Placing a Woman at Risk for Postpartum Hemorrhage

- Prolonged first, second, or third stage of labor
- Previous history of postpartum hemorrhage
- Multiple gestation
- Fetal macrosomia
- Uterine infection
- Manual extraction of placenta
- Arrest of descent
- Maternal exhaustion, malnutrition, or anemia
- Mediolateral episiotomy
- Preeclampsia
- Precipitous birth
- Maternal hypotension
- Previous placenta previa
- Coagulation abnormalities
- Birth canal lacerations
- Operative birth (forceps or vacuum)
- Augmented labor with medication
- Coagulation abnormalities
- Grand multiparity
- Polyhydramnios (Anderson & Etches, 2007)

uterus to contract properly after birth), assess uterine tone after birth by palpating the fundus for firmness and location. A soft, boggy fundus indicates uterine atony.

▶ *Take* NOTE!

A soft, boggy uterus that deviates from the midline suggests that a full bladder is interfering with uterine involution. If the uterus is not in correct position (midline), it will not be able to contract to control bleeding.

Assess the amount of bleeding. If bleeding continues even though there are no lacerations, suspect retained placental fragments. The uterus remains large with painless, dark-red bleeding mixed with clots. This cause of hemorrhage can be prevented by carefully inspecting the placenta for intactness.

If trauma is suspected, attempt to identify the source and document it. Typically, the uterus will be firm with a steady stream or trickle of unclotted bright-red blood noted in the perineum. Most deaths from postpartum hemorrhage are not due to gross bleeding, but rather to inadequate management of slow, steady blood loss (Anderson & Etches, 2007).

Assess for hematoma. The uterus would be firm, with bright-red bleeding. Observe for a localized bluish bulging area just under the skin surface in the perineal area (Fig. 22.1). Often the woman will report severe perineal or pelvic pain and will have difficulty voiding. In addition, she may exhibit hypotension, tachycardia, and anemia (Gilbert & Harmon, 2007).

FIGURE 22.1 Perineal hematoma. Note the bulging swollen mass.

Inspect the skin and mucous membranes for gingival bleeding or petechiae and ecchymoses. Check venipuncture sites for oozing or prolonged bleeding. These findings might suggest a coagulopathy as a cause of postpartum hemorrhage. Also assess the amount of lochia, which would be much greater than usual. Urinary output would be diminished, with signs of acute renal failure. Vital signs would show an increased pulse rate and a decreased level of consciousness. However, signs of shock do not appear until hemorrhage is far advanced due to the increased fluid and blood volume of pregnancy.

Nursing Management

Massage the uterus if uterine atony is noted. The uterine muscles are sensitive to touch; massage stimulates the muscle fibers to contract. Massage the boggy uterus to stimulate contractions and expression of any accumulated blood clots while supporting the lower uterine segment. As blood pools in the vagina, stasis of blood causes clots to form; they need to be expelled as pressure is placed on the fundus. Overly forceful massage can tire the uterine muscles, resulting in further uterine atony and increased pain. See Nursing Procedure 22.1 for the steps in massaging the fundus.

If repeated fundal massage and expression of clots fail, medication is probably needed to cause the uterus to contract in order to control bleeding from the placental site. The injection of an uterotonic drug immediately after birth is an important intervention used to prevent postpartum hemorrhage. Oxytocin (Pitocin); methylergonovine maleate (Methergine); a synthetic analog of prostaglandin E1, misoprostol (Cytotec); and a derivative of prostaglandin (PGF2a), carboprost (Hemabate), are drugs used to manage postpartum hemorrhage (Drug Guide 22.1). However, misoprostol is not approved by the U.S. Food and Drug Association for this purpose. The choice of which uterotonic drug to use for management of bleeding depends on the judgment of the health care provider, the availability of drugs, and the risks and benefits of the drug.

Remember Joan, the woman described at the beginning of the chapter? The nurse assesses her and finds that her uterus is boggy. What would the nurse do next? What additional nursing measures might be used if Joan's fundus remains boggy? When should the health care provider be notified?

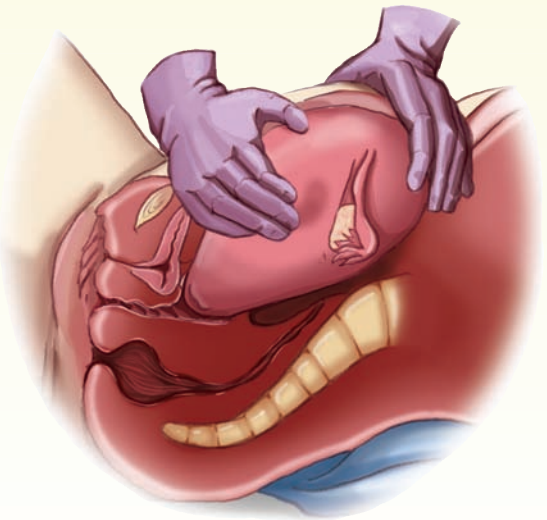
Maintain the primary IV infusion and be prepared to start a second infusion at another site if blood transfusions are necessary. Draw blood for type and cross-match and send it to the laboratory. Administer oxytocics as ordered, correlating and titrating the infusion rate to assessment findings of uterine firmness and lochia. Assess for visible vaginal bleeding, and count or weigh perineal pads.

Nursing Procedure 22.1

MASSAGING THE FUNDUS

Purpose: To Promote Uterine Contraction

1. After explaining the procedure to the woman, place one gloved hand (usually the dominant hand) on the fundus.
2. Place the other gloved hand on the area above the symphysis pubis (this helps to support the lower uterine segment).
3. With the hand on the fundus, gently massage the fundus in a circular manner. Be careful not to overmassage the fundus, which could lead to muscle fatigue and uterine relaxation.
4. Assess for uterine firmness (uterine tissue responds quickly to touch).
5. If firm, apply gentle yet firm pressure in a downward motion toward the vagina to express any clots that may have accumulated.
6. Do not attempt to express clots until the fundus is firm because the application of firm pressure on an uncontracted uterus could cause uterine inversion, leading to massive hemorrhage.
7. Assist the woman with perineal care and applying a new perineal pad.
8. Remove gloves and wash hands.



▶ *Take* NOTE!

When weighing perineal pads to determine blood loss, remember that 1 g of pad weight is equivalent to 1 mL of blood loss (Cohen, 2006).

Check vital signs every 15 to 30 minutes, depending on the acuity of the mother's health status. Monitor her complete blood count to identify any deficit or assess the adequacy of replacement. Assess the woman's level of consciousness to determine changes that may result from inadequate cerebral perfusion.

If a full bladder is present, assist the woman to empty her bladder to reduce displacement of the uterus. If the woman cannot void, anticipate the need to catheterize her to relieve bladder distention.

Prepare the woman for removal of retained placental fragments. These usually are manually separated and removed by the health care provider. Be sure that the health care provider remains long enough after birth to assess the bleeding status of the woman and determine the etiology. Assist the health care provider with suturing any lacerations immediately to control hemorrhage and repair the tissue.

Continually assess the woman for signs and symptoms of hemorrhagic shock, a condition in which inadequate perfusion of organs results in insufficient availability of oxygen to satisfy the metabolic needs of the tissues (Dorland, 2007). Subsequently a catabolic state develops, leading to inflammation, endothelial dysfunction, and disruption of normal metabolic processes in vital organs. Once these events become established, the process of shock is often irreversible, even if volume and red blood cell deficits are corrected (Cohen, 2006).

Monitor the woman's blood pressure, pulse, capillary refill, mental status, and urinary output. These assessments allow estimation of the severity of blood loss and help direct treatment. If the woman develops hemorrhagic shock, interventions focus on controlling the source of blood loss; restoring adequate oxygen-carrying capacity; and maintaining adequate tissue perfusion. Successful treatment depends on efficient collaboration among all health care team members to meet the woman's specific needs.

For the woman with ITP, expect to administer glucocorticoids, IV immunoglobulin, IV anti-RhoD, and platelet transfusions. Prepare the woman for a splenectomy if the bleeding tissues do not respond to medical management.

Be alert for women with abnormal bleeding tendencies, ensuring that they receive proper diagnosis and treatment. Teach them how to prevent severe hemorrhage by

DRUG GUIDE 22.1 DRUGS USED TO CONTROL POSTPARTUM HEMORRHAGE

Drug	Action/Indication	Nursing Implications
Oxytocin (Pitocin)	Stimulates the uterus to contract/ to contract the uterus to control bleeding from the placental site	Assess fundus for evidence of contraction and compare amount of bleeding every 15 minutes or according to orders. Monitor vital signs every 15 minutes. Monitor uterine tone to prevent hyperstimulation. Reassure client about the need for uterine contraction and administer analgesics for comfort. Offer explanation to client and family about what is happening and the purpose of the medication. Provide nonpharmacologic comfort measures to assist with pain management. Set up the IV infusion to be piggybacked into a primary IV line. This ensures that the medication can be discontinued readily if hyperstimulation or adverse effects occur while maintaining the IV site and primary infusion.
Methylergonovine maleate (Methergine)	Stimulates the uterus/to prevent and treat postpartum hemorrhage due to atony or subinvolution	Assess baseline bleeding, uterine tone, and vital signs every 15 minutes or according to protocol. Offer explanation to client and family about what is happening and the purpose of the medication. Monitor for possible adverse effects, such as hypertension, seizures, uterine cramping, nausea, vomiting, and palpitations. Report any complaints of chest pain promptly.
Prostaglandin (PGF-2α, Carboprost, Hemabate)	Stimulates uterine contractions/ to treat postpartum hemorrhage due to uterine atony when not controlled by other methods	Assess vital signs, uterine contractions, client's comfort level, and bleeding status as per protocol. Offer explanation to client and family about what is happening and the purpose of the medication. Monitor for possible adverse effects, such as fever, chills, headache, nausea, vomiting, diarrhea, flushing, and bronchospasm.

learning how to feel for and massage their fundus when boggy, assisting the nurse to keep track of the number of and amount of bleeding on perineal pads, and avoiding any medications with antiplatelet activity such as aspirin, antihistamines, or NSAIDs.

If the woman develops DIC, institute emergency measures to control bleeding and impending shock and prepare to transfer her to the intensive care unit. Identification of the underlying condition and elimination of the causative factor are essential to correct the coagulation problem. Be ready to replace fluid volume, administer blood component therapy, and optimize the mother's oxygenation and perfusion status to ensure adequate cardiac output and end-organ perfusion. Continually reassess the woman's coagulation status via laboratory studies.

Monitor vital signs closely, being alert for changes that signal an increase in bleeding or impending shock. Observe for signs of bleeding, including spontaneous bleeding from gums or nose, petechiae, excessive bleeding from the cesarean incision site, hematuria, and blood in the stool. These findings correlate with decreased blood volume, decreased organ and peripheral tissue perfusion, and clots in the microcirculation (Bick, 2007).

▶ *Take* NOTE!

Always remember the four causes of postpartum hemorrhage and the appropriate intervention for each: 1. Uterine atony—massage and oxytocics; 2. Retained placental tissue—evacuation and oxytocics; 3. Lacerations or hematoma—surgical repair; 4. Thrombosis (bleeding disorders)—blood products.

Institute measures to avoid tissue trauma or injury, such as giving injections and drawing blood. Also provide emotional support to the client and her family throughout this critical time by being readily available and providing explanations and reassurance.

An IV oxytocin infusion is started for Joan. What assessments will need to be done frequently to make sure Joan is not losing too much blood? What discharge instructions need to be reinforced with Joan?

Thromboembolic Conditions

A thrombosis (blood clot within a blood vessel) can cause an inflammation of the blood vessel lining (**thrombophlebitis**), which in turn can lead to a thromboembolism (obstruction of a blood vessel by a blood clot carried by the circulation from the site of origin). Thrombi can involve the superficial or deep veins in the legs or pelvis. Superficial venous thrombosis usually involves the saphenous venous system and is confined to the lower leg. Superficial thrombophlebitis may be caused by the use of the lithotomy position during birth. Deep venous thrombosis can involve deep veins from the foot to the calf, to the thighs, or pelvis. In both locations, thrombi can dislodge and migrate to the lungs, causing a pulmonary embolism.

The three most common thromboembolic conditions occurring during the postpartum period are superficial venous thrombosis, deep venous thrombosis, and pulmonary embolism. Although thromboembolic disorders occur in less than 1% of all postpartum women, pulmonary embolus can be fatal if a clot obstructs the lung circulation; thus, early identification and treatment are paramount.

Pathophysiology

Thrombus (blood clot) formation results typically results from venous stasis, injury to the innermost layer of the blood vessel, and hypercoagulation. Venous stasis and hypercoagulation are both common in the postpartum period.

If a clot dislodges and travels to the pulmonary circulation, pulmonary embolism can occur. Pulmonary embolism is a potentially fatal condition that occurs when the pulmonary artery is blocked by a blood clot that has traveled from another vein into the lungs, causing an obstruction and infarction. When the clot is large enough to block one or more of the pulmonary vessels that supply the lungs, it can result in sudden death. Pulmonary embolism is the leading cause of pregnancy-related death in the United States, occurring in 2 out of 100,000 live births (Shaughnessy, 2007).

Nursing Assessment

Assess the woman closely for risk factors and signs and symptoms of thrombophlebitis. Look for risk factors in the woman's history such as use of oral contraceptives before the pregnancy, smoking, employment that necessitates prolonged standing, history of thrombosis, thrombophlebitis, or endometritis, or evidence of current varicosities. Also look for other factors that can increase a woman's risk, such as prolonged bed rest, diabetes, obesity, cesarean birth, progesterone-induced distensibility of the veins of the lower legs during pregnancy, severe anemia, varicose veins, advanced maternal age (older than 35), and multiparity (Feied & Handler, 2007).

Ask the woman if she has pain or tenderness in the lower extremities. Suspect superficial venous thrombosis in a woman with varicose veins who reports tenderness and discomfort over the site of the thrombosis, most commonly in the calf area. The area appears reddened along the vein and is warm to the touch. The woman will report increased pain in the affected leg when she ambulates and bears weight.

Manifestations of deep venous thrombosis are often absent and diffuse. If they are present, they are caused by an inflammatory process and obstruction of venous return. Calf swelling, erythema, warmth, tenderness, and pedal edema may be noted. A positive Homans' sign (pain in the calf upon dorsiflexion) is not a definitive diagnostic sign and is no longer recommended as an indicator of deep vein thrombosis because calf pain can also be caused by a strained muscle or contusion (Feied & Handler, 2007).

Be alert for signs and symptoms of pulmonary embolism, including unexplained sudden onset of shortness of breath and severe chest pain. The woman may be apprehensive and diaphoretic. Additional manifestations may include tachypnea, tachycardia, hypotension, syncope, distention of the jugular vein, decreased oxygen saturation (shown by pulse oximetry), cardiac arrhythmias, hemoptysis, and a sudden change in mental status as a result of hypoxemia (Shaughnessy, 2007). Prepare the woman for a lung scan to confirm the diagnosis.

Nursing Management

Nursing management focuses on preventing thrombotic conditions, promoting adequate circulation if thrombosis occurs, and educating the client about preventive measures, anticoagulant therapy, and danger signs.

Preventing Thrombotic Conditions

Prevention of thrombotic conditions is an essential aspect of nursing management and can be achieved with the routine use of simple measures:

- Developing public awareness about risk factors, symptoms, and preventive measures
- Preventing venous stasis by encouraging activity that causes leg muscles to contract and promotes venous return (leg exercises and walking)
- Using intermittent sequential compression devices to produce passive leg muscle contractions until the woman is ambulatory
- Elevating the woman's legs above her heart level to promote venous return
- Stopping smoking to reduce or prevent vascular vasoconstriction
- Applying compression stockings and removing them daily for inspection of legs
- Performing passive range-of-motion exercises while in bed
- Using postoperative deep-breathing exercises to improve venous return by relieving the negative thoracic pressure on leg veins

- Reducing hypercoagulability with the use of warfarin, aspirin, and heparin
- Preventing venous pooling by avoiding pillows under knees, not crossing legs for long periods, and not leaving legs up in stirrups for long periods
- Padding stirrups to reduce pressure against the popliteal angle
- Avoiding sitting or standing in one position for prolonged periods
- Using a bed cradle to keep linens and blankets off extremities
- Avoiding trauma to legs to prevent injury to the vein wall
- Increasing fluid intake to prevent dehydration
- Avoiding the use of oral contraceptives

In women at risk, early ambulation is the easiest and most cost-effective method. Use of elastic compression stockings (TED hose or Jobst stockings) decrease distal calf vein thrombosis by decreasing venous stasis and augmenting venous return (Comerota & Chahwan, 2007). Women who are at a high risk for thromboembolic disease based on risk factors or a previous history of deep vein thrombosis or pulmonary embolism may be placed on prophylactic heparin therapy during pregnancy. Standard heparin or a low-molecular-weight heparin such as enoxaparin (Lovenox) can be given, since neither drug crosses the placenta. It is typically discontinued during labor and birth and then restarted during the postpartum period.

Promoting Adequate Circulation

For the woman with superficial venous thrombosis, administer NSAIDs for analgesia, provide for rest and elevation of the affected leg, apply warm compresses to the affected area to promote healing, and use antiembolism stockings to promote circulation to the extremities.

Implement bed rest and elevation of the affected extremity for the woman with deep vein thrombosis. These actions help to reduce interstitial swelling and promote venous return from that leg. Apply antiembolism stockings to both extremities as ordered. Fit the stockings correctly to avoid excess pressure and constriction and urge the woman to wear them at all times. Sequential compression devices can also be used for women with varicose veins, a history of thrombophlebitis, or a surgical birth.

Anticoagulant therapy using a continuous IV infusion of heparin usually is initiated to prolong the clotting time and prevent extension of the thrombosis. Monitor the woman's coagulation studies closely; these might include activated partial thromboplastin time (aPTT), whole blood partial thromboplastin time, and platelet levels. A therapeutic aPTT value typically ranges from 35 to 45 seconds, depending on which standard values are used (Pagana & Pagana, 2007). Also apply warm moist compresses to the affected leg and administer analgesics as ordered to decrease the discomfort.

After several days of IV heparin therapy, expect to begin oral anticoagulant therapy with warfarin (Coumadin) as ordered and monitor coagulation studies. In most cases, the woman will continue to take this medication for several months after discharge.

For the woman who develops a pulmonary embolism, institute emergency measures immediately. The objectives of treatment are to prevent growth or multiplication of thrombi in the lower extremities, prevent more thrombi from traveling to the pulmonary vascular system, and provide cardiopulmonary support if needed. Administer oxygen via mask or cannula as ordered and initiate IV heparin therapy titrated according to the results of the coagulation studies. Maintain the client on bed rest, and administer analgesics as ordered for pain relief. Be prepared to assist with administering thrombolytic agents, such as alteplase (tPA), which might be used to dissolve pulmonary emboli and the source of the thrombus in the pelvis or deep leg veins, thus reducing the potential for a recurrence.

Educating the Client

Provide teaching about the use of anticoagulant therapy and danger signs that should be reported (Teaching Guidelines 22.1). Provide anticipatory guidance, support, and education about associated signs of complications and risks. Focus teaching on the following issues:

- Elimination of modifiable risk factors for deep vein thrombosis (smoking, use of oral contraceptives, a sedentary lifestyle, and obesity)
- Importance of using compression stockings
- Avoidance of constrictive clothing and prolonged standing or sitting in a motionless, leg-dependent position
- Danger signs and symptoms (sudden onset of chest pain, dyspnea, and tachypnea) to report to the health care provider

Postpartum Infection

Infection during the postpartum period is a common cause of maternal morbidity and mortality. Overall, postpartum infection is estimated to occur in up to 8% of all births. There is a higher occurrence in cesarean births than in vaginal births (Gilbert & Harmon, 2007).

Postpartum infection is defined as a fever of 38°C or 100.4°F or higher after the first 24 hours after childbirth, occurring on at least 2 of the first 10 days after birth, exclusive of the first 24 hours (Dorland, 2007).

Infections can easily enter the female genital tract externally and ascend through the internal genital structures. In addition, the normal physiologic changes of childbirth increase the risk of infection by decreasing the vaginal acidity due to the presence of amniotic fluid, blood, and lochia, all of which are alkaline. An alkaline environment encourages the growth of bacteria.

Postpartum infections usually arise from organisms that constitute the normal vaginal flora, typically a mix of aerobic and anaerobic species. Generally, they are polymicrobial and involve the following microorganisms: *Staphylococcus aureus, Escherichia coli,* Klebsiella, *Gardnerella*

TEACHING GUIDELINES 22.1

Teaching to Prevent Bleeding Related to Anticoagulant Therapy

- Watch for possible signs of bleeding and notify your health care provider if any occur:
  - Nosebleeds
  - Bleeding from the gums or mouth
  - Black tarry stools
  - Brown "coffee ground" vomitus
  - Red to brown speckled mucus from a cough
  - Oozing at incision, episiotomy site, cut, or scrape
  - Pink, red, or brown-tinged urine
  - Bruises, "black and blue marks"
  - Increased lochia discharge (from present level)
- Practice measures to reduce your risk of bleeding:
  - Brush your teeth gently using a soft toothbrush.
  - Use an electric razor for shaving.
  - Avoid activities that could lead to injury, scrapes, bruising, or cuts.
  - Do not use any over-the-counter products containing aspirin or aspirin-like derivatives.
  - Avoid consuming alcohol.
  - Inform other health care providers about the use of anticoagulants, especially dentists.
- Be sure to comply with follow-up laboratory testing as scheduled.
- If you accidentally cut or scrape yourself, apply firm direct pressure to the site for 5 to 10 minutes. Do the same after receiving any injections or having blood specimens drawn.
- Wear an identification bracelet or band that indicates that you are taking an anticoagulant.

vaginalis, gonococci, coliform bacteria, group A or B hemolytic streptococci, *Chlamydia trachomatis,* and the anaerobes that are common to bacterial vaginosis (Kennedy, 2007). Common postpartum infections include metritis, wound infections, urinary tract infections, and mastitis.

METRITIS

Although usually referred to clinically as endometritis, postpartum uterine infections typically involve more than just the endometrial lining. **Metritis** is an infectious condition that involves the endometrium, decidua, and adjacent myometrium of the uterus. Extension of metritis can result in parametritis, which involves the broad ligament and possibly the ovaries and fallopian tubes, or septic pelvic thrombophlebitis, which results when the infection spreads along venous routes into the pelvis (Simmons & Bammel, 2007).

The uterine cavity is sterile until rupture of the amniotic sac. As a consequence of labor, birth, and associated manipulations, anaerobic and aerobic bacteria can contaminate the uterus. In most cases, the bacteria responsible for pelvic infections are those that normally reside in the bowel, vagina, perineum, and cervix, such as *E. coli, Klebsiella pneumoniae,* or *G. vaginalis.*

The risk of metritis increases dramatically after a cesarean birth; it complicates from 10% to 20% of cesarean births. This is typically an extension of chorioamnionitis that was present before birth (indeed, that may have been why the cesarean birth was performed). In addition, trauma to the tissues and a break in the skin (incision) provide entrances for bacteria to enter the body and multiply (Kennedy, 2007).

WOUND INFECTIONS

Any break in the skin or mucous membranes provides a portal for bacteria. In the postpartum woman, sites of wound infection include cesarean surgical incisions, the episiotomy site in the perineum, and genital tract lacerations (Fig. 22.2). Wound infections are usually not identified until the woman has been discharged from the hospital because symptoms may not show up until 24 to 48 hours after birth.

URINARY TRACT INFECTIONS

Urinary tract infections are most commonly caused by bacteria often found in bowel flora, including *E. coli,* Klebsiella, Proteus, and Enterobacter species. Invasive manipulation of the urethra (e.g., urinary catheterization), frequent vaginal examinations, and genital trauma increase the likelihood of a urinary tract infection.

MASTITIS

A common problem that may occur within the first 2 weeks postpartum is an inflammation of the breast, termed **mastitis**. It can result from any event that creates milk stasis: insufficient drainage of the breast, rapid weaning, oversupply of milk, pressure on the breast from a poorly fitting bra, a blocked duct, missed feedings, and breakdown of the nipple via fissures, cracks, or blisters (Betzold, 2007). The most common infecting organism is *S. aureus,* which comes from the breastfeeding infant's mouth or throat (Kennedy,

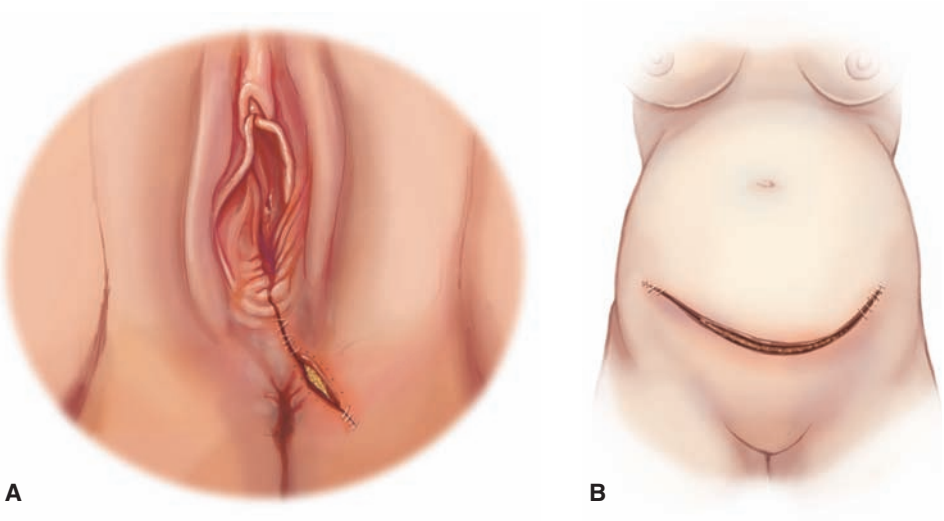


FIGURE 22.2 Postpartum wound infections. (**A**) Infected episiotomy site. (**B**) Infected cesarean birth incision.

2007). Infection can be transmitted from the lactiferous ducts to a secreting lobule, from a nipple fissure to periductal lymphatics, or by circulation (Gilbert & Harmon, 2007) (Fig. 22.3). A breast abscess may develop if mastitis is not treated adequately.

Therapeutic Management

When metritis occurs, broad-spectrum antibiotics are used to treat the infection. Management also includes measures to restore and promote fluid and electrolyte balance, provide analgesia, and provide emotional support. In most treated women, fever drops and symptoms cease within 48 to 72 hours after the start of antibiotic therapy.

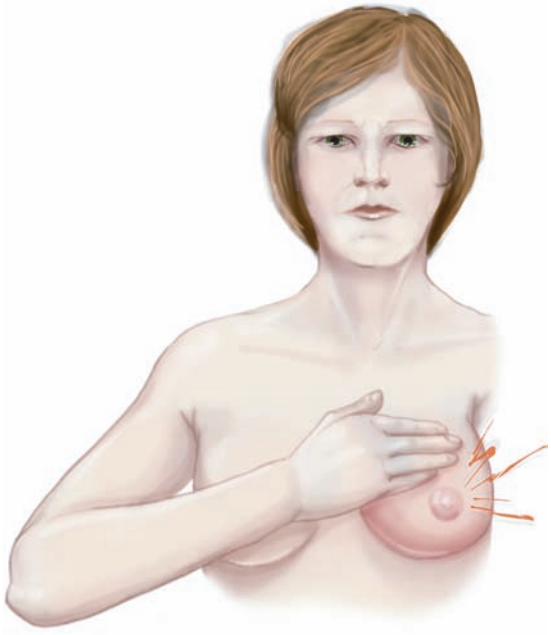

FIGURE 22.3 With mastitis, an area on one breast is tender, hot, red, and painful.

Management for wound infections involves recognition of the infection, followed by opening of the wound to allow drainage. Aseptic wound management with sterile gloves and frequent dressing changes if applicable, good handwashing, frequent perineal pad changes, hydration, and ambulation to prevent venous stasis and improve circulation are initiated to prevent development of a more serious infection or spread of the infection to adjacent structures. Parenteral antibiotics are the mainstay of treatment. Analgesics are also important, because women often experience discomfort at the wound site.

If the woman develops a urinary tract infection, fluids are used to treat dehydration. Antibiotics may be ordered if appropriate.

Treatment of mastitis focuses on two areas: emptying the breasts and controlling the infection. The breast can be emptied either by the infant sucking or by manual expression. Increasing the frequency of nursing is advised. Lactation need not be suppressed. Control of infection is achieved with antibiotics. In addition, ice or warm packs and analgesics may be needed.

▶ ***Take*** *NOTE!*

Regardless of the etiology of mastitis, the focus is on reversing milk stasis, maintaining milk supply, and continuing breastfeeding, along with providing maternal comfort and preventing recurrence.

Nursing Assessment

Perinatal nurses are the primary caregivers for postpartum women and have a unique opportunity to identify subtle changes that place women at risk for infection.

Nurses play a key role in identifying signs and symptoms that suggest a postpartum infection. Today women are commonly discharged 24 to 48 hours after giving birth. Therefore, nurses must assess new mothers for risk factors and identify early, subtle signs and symptoms of an infectious process. Factors that place a woman at risk for a postpartum infection are highlighted in Box 22.2.

Review the client's history and physical examination and labor and birth record for factors that might increase her risk for developing an infection. Then complete the assessment (using the "BUBBLE-HE" parameters discussed in Chapter 16), paying particular attention to areas such as the abdomen and fundus, breasts, urinary tract, episiotomy, lacerations, or incisions, being alert for signs and symptoms of infection (Table 22.1).

▶ *Take* NOTE!

A postpartum infection is commonly associated with an elevated temperature, as mentioned previously. Other generalized signs and symptoms may include chills, foul-smelling vaginal discharge, headache, malaise, restlessness, anxiety, and tachycardia. In addition, the woman may have specific signs and symptoms based on the type and location of the infection.

When assessing the episiotomy site, use the acronym "REEDA" (redness, ecchymosis, edema, drainage or discharge, and approximation of wound edges) to ensure complete evaluation of the site (Arenson & Drake, 2007). Monitor the woman's vital signs, especially her temperature, for changes that may signal an infection.

Nursing Management

Nursing management focuses on preventing postpartum infections. Use the following guidelines to reduce the incidence of postpartum infections:

- Maintain aseptic technique when performing invasive procedures such as urinary catheterization, when changing dressings, and during all surgical procedures.
- Use good handwashing technique before and after each client care activity.
- Reinforce measures for maintaining good perineal hygiene.
- Use adequate lighting and turn the client to side to assess the episiotomy site.
- Screen all visitors for any signs of active infections to reduce the client's risk of exposure.
- Review the client's history for preexisting infections or chronic conditions.
- Monitor vital signs and laboratory results for any abnormal values.
- Monitor the frequency of vaginal examinations and length of labor.

BOX 22.2 Factors Placing a Woman at Risk for Postpartum Infection

- Prolonged (>18 to 24 hours) premature rupture of membranes (removes the barrier of amniotic fluid so bacteria can ascend)
- Cesarean birth (allows bacterial entry due to break in protective skin barrier)
- Urinary catheterization (could allow entry of bacteria into bladder due to break in aseptic technique)
- Regional anesthesia that decreases perception to void (causes urinary stasis and increases risk of urinary tract infection)
- Staff attending to woman are ill (promotes droplet infection from personnel)
- Compromised health status, such as anemia, obesity, smoking, drug abuse (reduces the body's immune system and decreases ability to fight infection)
- Preexisting colonization of lower genital tract with bacterial vaginosis, *Chlamydia trachomatis*, group B streptococci, *Staphylococcus aureus*, and *Escherichia coli* (allows microbes to ascend)
- Retained placental fragments (provides medium for bacterial growth)
- Manual removal of a retained placenta (causes trauma to the lining of the uterus and thus opens up sites for bacterial invasion)
- Insertion of fetal scalp electrode or intrauterine pressure catheters for internal fetal monitoring during labor (provides entry into uterine cavity)
- Instrument-assisted childbirth, such as forceps or vacuum extraction (increases risk of trauma to genital tract, which provides bacteria access to grow)
- Trauma to the genital tract, such as episiotomy or lacerations (provides a portal of entry for bacteria)
- Prolonged labor with frequent vaginal examinations to check progress (allows time for bacteria to multiply and increases potential exposure to microorganisms or trauma)
- Poor nutritional status (reduces body's ability to repair tissue)
- Gestational diabetes (decreases body's healing ability and provides higher glucose levels on skin and in urine, which encourages bacterial growth)
- Break in aseptic technique during surgery or birthing process (allows entry of bacteria)

TABLE 22.1 SIGNS AND SYMPTOMS OF POSTPARTUM INFECTIONS

Postpartum Infection	Signs and Symptoms
Metritis	Lower abdominal tenderness or pain on one or both sides
	Temperature elevation (>38°C)
	Foul-smelling lochia
	Anorexia
	Nausea
	Fatigue and lethargy
	Leukocytosis and elevated sedimentation rate
Wound infection	Weeping serosanguineous or purulent drainage
	Separation of or unapproximated wound edges
	Edema
	Erythema
	Tenderness
	Discomfort at the site
	Maternal fever
	Elevated white blood cell count
Urinary tract infection	Urgency
	Frequency
	Dysuria
	Flank pain
	Low-grade fever
	Urinary retention
	Hematuria
	Urine positive for nitrates
	Cloudy urine with strong odor
Mastitis	Flulike symptoms, including malaise, fever, and chills
	Tender, hot, red, painful area on one breast
	Inflammation of breast area
	Breast tenderness
	Cracking of skin or around nipple or areola
	Breast distention with milk

- Assess frequently for early signs of infection, especially fever and the appearance of lochia.
- Inspect wounds frequently for inflammation and drainage.
- Encourage rest, adequate hydration, and healthy eating habits.
- Reinforce preventive measures during any interaction with the client.

If the woman develops an infection, review treatment measures, such as antibiotic therapy if ordered, and any special care measures, such as dressing changes, that might be needed (Nursing Care Plan 22.1).

Client teaching is a priority due to today's short lengths of stay after delivery. Some infections may not manifest until after discharge. Review the signs and symptoms of infection, emphasizing the danger signs that need to be reported to the health care provider. Most importantly, stress proper handwashing, especially after perineal care and before and after breastfeeding. Also reinforce measures to promote breastfeeding, including proper breast care (see Chapter 16). Teaching Guidelines 22.2 highlights the major teaching points for a woman with a postpartum infection.

Postpartum Affective Disorders

The postpartum period involves extraordinary physiologic, psychological, and sociocultural changes in the life

Nursing Care Plan 22.1

OVERVIEW OF THE WOMAN WITH A POSTPARTUM COMPLICATION

Jennifer, a 16-year-old G1P1, gave birth to a boy 3 days ago. It was a cesarean birth due to cephalopelvic disproportion following 25 hours of labor with ruptured membranes. Her temperature is 102.6° F (39.2° C). She is complaining of chills and malaise and says, "My incision really hurts." Jennifer rates her pain as 7 to 8 out of 10. The incision site is red, swollen, and very warm to the touch. A 5-cm area of purulent drainage is noted on the dressing; a 3-cm area of the incision is slightly opened, with the wound edges separated. Jennifer's lochia is scant and dark red, with a strong odor. She asks the nurse to take her baby back to the nursery because she doesn't feel well enough to care for him.

NURSING DIAGNOSIS: Ineffective thermoregulation related to bacterial invasion *as evidenced by fever, complaints of chills and malaise, and statement of not feeling well*

Outcome Identification and Evaluation

Jennifer will exhibit a return to normothermia *as evidenced by a body temperature being maintained below 99° F, reports of a decrease in chills and malaise, and statements of feeling better.*

Interventions: Promoting Fever Reduction

- Assess vital signs every 2 to 4 hours and record results *to monitor progress of infection.*
- Administer antipyretics as ordered *to reduce temperature and help combat infection.*
- Encourage fluid intake *to promote fluid balance.*
- Document intake and output *to assess hydration status.*
- Offer cool bed bath or shower *to reduce temperature.*
- Place cool cloth on forehead and/or back of neck *for comfort.*
- Change bed linen and gown when damp from diaphoresis *to provide comfort and hygiene.*

NURSING DIAGNOSIS: Impaired skin integrity related to wound infection as *evidenced by purulent drainage, redness, swelling, and separation of wound edges*

Outcome Identification and Evaluation

Jennifer will experience a resolution of wound infection as *evidenced by a reduction in redness, swelling, and drainage from wound, absence of purulent drainage, and beginning signs and symptoms of wound healing.*

Interventions: Promoting Wound Healing

- Administer antibiotic therapy as ordered *to treat infection.*
- Perform frequent dressing changes and wound care as ordered *to promote wound healing;* monitor dressing for drainage, including amount, color, and characteristics, *to evaluate for resolution of infection.*
- Use aseptic technique *to prevent spread of infection.*
- Encourage fluid intake *to maintain fluid balance;* encourage adequate dietary intake, including protein, *to promote healing.*

NURSING DIAGNOSIS: Acute pain related to infectious process

Outcome Identification and Evaluation

Client reports a decrease in pain *as evidenced by pain rating of 0 or 1 on pain scale; verbalization of relief with pain management, and statements of feeling better and ability to rest comfortably.*

Interventions: Relieving Pain

- Place client in semi-Fowler's position *to facilitate drainage and relieve pressure.*
- Assess pain level on pain scale of 0 to 10 *to quantify pain level;* reassess pain level after intervening *to determine effectiveness of intervention.*
- Assess fundus gently *to ensure appropriate involution.*
- Administer analgesics as needed and on time as ordered *to maintain pain relief.*
- Provide for rest periods *to allow for healing.*
- Assist with positioning in bed with pillows *to promote comfort.*
- Offer nonpharmacologic pain measures such as a backrub *to ease aches and discomfort if desired and enhance effectiveness of analgesics.*

Nursing Care Plan 22.1 (continued)

NURSING DIAGNOSIS: Risk for impaired parent–infant attachment related to effects of postpartum infection *as evidenced by mother's request to take baby back to the nursery*

Outcome Identification and Evaluation

Jennifer begins to bond with newborn appropriately with each exposure *as evidenced by desire to spend time with newborn, expression of positive feelings toward newborn when holding him, increasing participation in care of newborn as client's condition improves, and statements about help and support at home to care for self and newborn.*

Interventions: Promoting Mother–Newborn Interaction

- Promote adequate rest and sleep *to ensure adequate energy for interaction and wound healing.*
- Bring newborn to mother after she is rested and had an analgesic *to allow mother to focus her energies on the child.*
- Progressively allow the client to care for her infant or comfort him as her energy level and pain level improve *to promote self-confidence in caring for the newborn.*
- Offer praise and positive reinforcement for caretaking tasks; stress positive attributes of newborn to mother while caring for him *to facilitate bonding and attachment.*
- Contact family members to participate in care of the newborn *to allow mother to rest and recover from infection.*
- Encourage mother to care for herself first and then the newborn *to ensure adequate energy for newborn's care.*
- Arrange for assistance and support after discharge from hospital *to provide necessary backup.*
- Refer to community health nurse for follow-up care of mother and newborn at home *to foster continued development of maternal–infant relationship.*

of a woman and her family. It is an exhilarating time for most women, but for others it may not be what they had expected. Women have varied reactions to their childbearing experiences, exhibiting a wide range of emotions. Typically, the delivery of a newborn is associated with positive feelings such as happiness, joy, and gratitude for the birth of a healthy infant. However, women may also feel weepy, overwhelmed, or unsure of what is happening to them. They may experience fear about loss of control; they may feel scared, alone, or guilty, or as if they have somehow failed.

Postpartum affective disorders have been documented for years, but only recently have they received medical attention. Plummeting levels of estrogen and progesterone immediately after birth can contribute to postpartum mood disorders. It is believed that the greater the change in these hormone levels between pregnancy and postpartum, the greater the chance for developing a mood disorder (Edler, Jones, & Venis, 2007).

Many types of affective disorders occur in the postpartum period. Although their description and classification may be controversial, the disorders are commonly classified on the basis of their severity as postpartum or baby blues, postpartum depression, and postpartum psychosis.

POSTPARTUM OR BABY BLUES

Many postpartum women (approximately 50% to 90%) experience the "baby blues" (ACOG, 2007). The woman exhibits mild depressive symptoms of anxiety, irritability, mood swings, tearfulness, increased sensitivity, feelings of being overwhelmed, and fatigue (Edler, Jones, & Venis, 2007). The "blues" typically peak on postpartum days 4 and 5 and usually resolve by postpartum day 10. Although the woman's symptoms may be distressing, they do not reflect psychopathology and usually do not affect the mother's ability to function and care for her infant.

Baby blues are usually self-limiting and require no formal treatment other than reassurance and validation of the woman's experience, as well as assistance in caring for herself and the newborn. However, follow-up of women with postpartum blues is important, because up to 20% go on to develop postpartum depression (Alexander et al., 2007).

POSTPARTUM DEPRESSION

Depression is more prevalent in women than in men, which may be related to biological, hormonal, and psychosocial factors. If the symptoms of postpartum blues last beyond 6 weeks and seem to get worse, the mother may be experiencing **postpartum depression**, a major depressive episode associated with childbirth (Edler, Jones, & Venis, 2007). As many as 20% of all mothers develop postpartum depression (ACOG, 2007). It affects approximately 500,000 mothers in the United States each year, and about half of these women receive no mental health evaluation or treatment (ACOG, 2007). Unlike the postpartum blues, women with postpartum depression feel

TEACHING GUIDELINES 22.2

Teaching for the Woman With a Postpartum Infection

- Continue your antibiotic therapy as prescribed.
  - Take the medication exactly as ordered and continue with the medication until it is finished.
  - Do not stop taking the medication even when you are feeling better.
- Check your temperature every day and call your health care provider if it is above 100.4°F (38°C).
- Watch for other signs and symptoms of infection, such as chills, increased abdominal pain, change in the color or odor of your lochia, or increased redness, warmth, swelling, or drainage from a wound site such as your cesarean incision or episiotomy. Report any of these to your health care provider immediately.
- Practice good infection prevention:
  - Always wash your hands thoroughly before and after eating, using the bathroom, touching your perineal area, or providing care for your newborn.
  - Wipe from front to back after using the bathroom.
  - Remove your perineal pad using a front-to-back motion. Fold the pad in half so that the inner sides of the pad that were touching your body are against each other. Wrap in toilet tissue or place in a plastic bag and discard.
  - Wash your hands before applying a new pad.
  - Apply a new perineal pad using a front-to-back motion. Handle the pad by the edges (top and bottom or sides) and avoid touching the inner aspect of the pad that will be against your body.
  - When performing perineal care with the peribottle, angle the spray of water to that it flows from front to back.
  - Drink plenty of fluids each day and eat a variety of foods that are high in vitamins, iron, and protein.
  - Be sure to get adequate rest at night and periodically throughout the day.

▸ *Consider* THIS!

As an assertive practicing attorney in her thirties, my first pregnancy was filled with nagging feelings of doubt about this upcoming event in my life. Throughout my pregnancy I was so busy with trial work that I never had time to really evaluate my feelings. I was always reading about the bodily changes that were taking place, and on one level I was feeling excited, but on another level I was emotionally drained. Shortly after the birth of my daughter, those suppressed nagging feelings of doubt surfaced big time and practically immobilized me. I felt exhausted all the time and was only too glad to have someone else care for my daughter. I didn't breastfeed because I thought it would tie me down too much. Although at the time I thought this "low mood" was normal for all new mothers, I have since found out it was postpartum depression. How could any woman be depressed about this wondrous event?

Thoughts: Now that postpartum depression has been "taken out of the closet" and recognized as a real emotional disorder, it can be treated. This woman showed tendencies during her pregnancy but was able to suppress the feelings and go forward. Her description of her depression is very typical of many women who suffer in silence, hoping to get over these feelings in time. What can nurses do to promote awareness of this disorder? Can it be prevented?

worse over time, and changes in mood and behavior do not go away on their own.

Postpartum depression affects not only the woman but also the entire family. Identifying depression early can substantially improve the client and family outcomes. Postpartum depression usually has a more gradual onset and becomes evident within the first 6 weeks postpartum.

Postpartum depression may lend itself to prophylactic intervention because its onset is predictable, the risk period for illness is well defined, and women at high risk potentially could be identified using a screening tool. This is not the case for all women, however (see Evidence-Based Practice 22.1). Prophylaxis starts with a prenatal risk assessment and education. Based on the woman's history of prior depression, prophylactic antidepressant therapy may be needed during the third trimester or immediately after giving birth. Management mirrors that of any major depression—a combination of antidepressant medication, antianxiety medication, and psychotherapy in an outpatient or inpatient setting (Jung et al., 2007). Marital counseling may be necessary if marital problems are contributing to the woman's depressive symptoms.

POSTPARTUM PSYCHOSIS

At the severe end of the continuum of postpartum emotional disorders is postpartum psychosis, which occurs in one or two women per 1,000 births (Edler, Jones, & Venis, 2007). It generally surfaces within 3 weeks of giving birth and is manifested by sleep disturbances, fatigue, depression, and hypomania. The mother will be tearful, confused, and preoccupied with feelings of guilt and worthlessness. Early symptoms resemble those of depression, but they may escalate to delirium, hallucinations, anger toward her-

EVIDENCE-BASED PRACTICE 22.1
Preventing Postpartum Depression Using Psychosocial Interventions

● Study
Postpartum depression can be a devastating condition for women and their families. There is a lack of knowledge about its cause, and women receive limited education about the possibility of depression after birth. Research has shown the effectiveness of treatment strategies that integrate psychosocial and psychological variables. The question then arises that if management addressing these variables is effective, would psychosocial interventions provided during pregnancy and the early postpartum period be effective in preventing postpartum depression?

Two reviewers searched multiple databases and contacted experts in the field. They also scanned secondary references and contacted several trial researchers for additional information. Both reviewers were involved in evaluating the methodology of the study and in extracting data. Information was gathered from all published and unpublished randomized controlled trials that compared psychosocial or psychological interventions with typical care during the antepartal, intrapartal, and postpartal periods. The researchers used relative risk for categorical data and weighted mean difference for continuous data. The study included 15 trials involving over 7,600 women.

▲ Findings
Women who received some type of psychosocial intervention had the same risk for developing postpartum depression as the women who received routine care; thus, the psychosocial intervention was not effective in preventing postpartum depression. However, statistical analysis found that intensive psychosocial support from public health nurses or midwives in the postpartum period was beneficial. The use of psychosocial interventions primarily during the postpartum period also was more effective than when these interventions were also used in the prenatal period. Interventions focusing on women at risk appear to be more effective than those geared to the overall maternal population. Individualized interventions were found to be more effective than those designed for groups. However, the risk for developing postpartum depression for either group did not differ significantly.

■ Nursing Implications
Although the study failed to identify effective measures for preventing postpartum depression, it did provide some useful information for nurses to incorporate when providing care to pregnant women throughout the perinatal period. Nurses need to remain alert for risk factors associated with postpartum depression so they can initiate appropriate interventions for these at-risk women. Nurses can implement psychosocial interventions during the prenatal period, keeping in mind that these interventions need to be continued throughout the postpartum period. They can also advocate for their clients upon discharge to ensure appropriate follow-up and support in the community.

Dennis, C.-L., & Creedy, D. (2004). Psychosocial and psychological interventions for preventing postpartum depression. *Cochrane Database of Systematic Reviews 2004,* Issue 4. Art. No.: CD001134. DOI:10.1002/14651858.CD001134.pub2.

self and her infant, bizarre behavior, manifestations of mania, and thoughts of hurting herself and the infant. The mother frequently loses touch with reality and experiences a severe regressive breakdown, associated with a high risk of suicide or infanticide (Johnson, 2007).

Most women with postpartum psychosis are hospitalized for up to several months. Psychotropic drugs are almost always part of treatment, along with individual psychotherapy and support group therapy.

▶ *Take* NOTE!

The greatest hazard of postpartum psychosis is suicide. Infanticide and child abuse are also risks if the woman is left alone with her infant. Early recognition and prompt treatment of this disorder are imperative.

Nursing Assessment

Postpartum affective disorders are often overlooked and go unrecognized despite the large percentage of women who experience them. The postpartum period is a time of increased vulnerability, but few women receive education about the possibility of depression after birth. In addition, many women may feel ashamed of having negative emotions at a time when they "should" be happy; thus, they don't seek professional help. Nurses can play a major role in providing guidance about postpartum affective disorders, detecting manifestations, and assisting women to obtain appropriate care.

Begin the assessment by reviewing the history to identify general risk factors that could predispose a woman to depression:

- Poor coping skills
- Low self-esteem
- Numerous life stressors

- Mood swings and emotional stress
- Previous psychological problems or a family history of psychiatric disorders
- Substance abuse
- Limited or lack of social support network

Also review the history for specific pregnancy and birth factors that may increase the woman's risk for depression. These may include a history of postpartum depression, evidence of depression during the pregnancy, prenatal anxiety, a difficult or complicated pregnancy, traumatic birth experience, or birth of a high-risk or special-needs infant (Johnson, 2007).

Be alert for physical findings. Assess the woman's activity level, including her level of fatigue. Ask about her sleeping habits, noting any problems with insomnia. When interacting with the woman, observe for verbal and nonverbal indicators of anxiety as well as her ability to concentrate during the interaction. Difficulty concentrating and anxious behaviors suggest a problem. Also assess her nutritional intake: weight loss due to poor food intake may be seen. Assessment can identify women with a high-risk profile for depression, and the nurse can educate them and make referrals for individual or family counseling if needed. Some common assessment findings associated with postpartum depression are listed in Box 22.3.

Nursing Management

Nursing management focuses on assisting any postpartum woman to cope with the changes of this period. Encourage the client to verbalize what she is going through and emphasize the importance of keeping her expectations realistic. Assist the woman in structuring her day to regain a sense of control over the situation. Encourage her to seek help if necessary, using available support systems. Also reinforce the need for good nutrition and adequate exercise and sleep (Linter & Gray, 2006).

The nurse can play an important role in assisting women and their partners with postpartum adjustment. Providing facts about the enormous changes that occur during the postpartum period is critical. This information would include changes in the woman's body. Review the signs and symptoms of all three affective disorders. This information is typically included as part of prenatal visits and childbirth education classes. Know the risk factors associated with these disorders and review the history of clients and their families. Use specific, nonthreatening questions to aid in early detection, such as, "Have you felt down, depressed, or hopeless lately? Have you felt little interest or pleasure in doing things recently?"

Discuss factors that may increase a woman's vulnerability to stress during the postpartum period, such as sleep deprivation and unrealistic expectations, so couples can understand and respond to those problems if they occur. Stress that many women need help after childbirth and that help is available from many sources, including people they already know. Assisting women to learn how to ask for help is important so they can gain the support they need. Also provide educational materials about postpartum emotional disorders. Have available referral sources for psychotherapy and support groups appropriate for women experiencing postpartum adjustment difficulties.

BOX 22.3 Common Assessment Findings Associated With Postpartum Depression

- Loss of pleasure or interest in life
- Low mood, sadness, tearfulness
- Exhaustion that is not relieved by sleep
- Feelings of guilt
- Irritability
- Inability to concentrate
- Anxiety
- Despair
- Compulsive thoughts
- Loss of libido
- Loss of confidence
- Sleep difficulties (insomnia)
- Loss of appetite
- Feelings of failure as a mother (Litner & Gray, 2006)

Key Concepts

- Postpartum hemorrhage is a potentially life-threatening complication of both vaginal and cesarean births. It is the leading cause of maternal mortality in the United States.
- A good way to remember the causes of postpartum hemorrhage is the "4 Ts": tone, tissue, trauma, and thrombosis.
- Uterine atony is the most common cause of early postpartum hemorrhage, which can lead to hypovolemic shock.
- Oxytocin (Pitocin), methylergonovine maleate (Methergine), and prostaglandin PGF2a (Hemabate) are drugs used to manage postpartum hemorrhage.
- Failure of the placenta to separate completely and be expelled interferes with the ability of the uterus to contract fully, thereby leading to hemorrhage.
- Causes of subinvolution include retained placental fragments, distended bladder, uterine myoma, and infection.
- Lacerations should always be suspected when the uterus is contracted and bright-red blood continues to trickle out of the vagina.
- Conditions that cause coagulopathies may include idiopathic thrombocytopenic purpura (ITP), von Willebrand disease (vWD), and disseminated intravascular coagulation (DIC).

- Pulmonary embolism is a potentially fatal condition that occurs when the pulmonary artery is obstructed by a blood clot that has traveled from another vein into the lungs, causing obstruction and infarction.
- The major causes of a thrombus formation (blood clot) are venous stasis and hypercoagulation, both common in the postpartum period.
- Postpartum infection is defined as a fever of 38° C (100.4° F) or higher after the first 24 hours after childbirth, occurring on at least 2 of the first 10 days exclusive of the first 24 hours.
- Common postpartum infections include metritis, wound infections, urinary tract infections, and mastitis.
- Postpartum emotional disorders are commonly classified on the basis of their severity: "baby blues," postpartum depression, and postpartum psychosis.
- Management of postpartum depression mirrors the treatment of any major depression—a combination of antidepressant medication, antianxiety medication, and psychotherapy in an outpatient or inpatient setting.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. A postpartum mother appears very pale and states she is bleeding heavily. The nurse should first:
   a. Call the client's health care provider immediately.
   b. Immediately set up an intravenous infusion of magnesium sulfate.
   c. Assess the fundus and ask her about her voiding status.
   d. Reassure the mother that this is a normal finding after childbirth.
2. A postpartum woman reports hearing voices and says, "The voices are telling me to do bad things." The nurse interprets these findings as suggesting:
   a. Postpartum psychosis
   b. Postpartum anxiety disorder
   c. Postpartum depression
   d. Postpartum blues
3. When implementing the plan of care for a postpartum woman who gave birth just a few hours ago, the nurse vigilantly monitors the client for which complication?
   a. Deep vein thrombosis
   b. Postpartum psychosis
   c. Uterine infection
   d. Postpartum hemorrhage
4. Which of the following would the nurse expect to include in the plan of care for a woman with mastitis who is receiving antibiotic therapy?
   a. Stop breastfeeding and apply lanolin.
   b. Administer analgesics and bind both breasts.
   c. Apply warm or cold compresses and administer analgesics.
   d. Remove the nursing bra and expose the breast to fresh air.
5. While assessing a postpartum multiparous woman, the nurse detects a boggy uterus midline 2 cm above the umbilicus. Which intervention would be the priority?
   a. Assessing vital signs immediately
   b. Measuring her next urinary output
   c. Massaging her fundus
   d. Notifying the woman's obstetrician
6. Methergine has been ordered for a postpartum woman because of excessive bleeding. The nurse should question this order if which of the following is present?
   a. Minimal lochia flow
   b. Tender inflamed breasts
   c. Pulse rate of 68 beats per minute
   d. Blood pressure of 158/96 mm Hg

CRITICAL THINKING EXERCISES

1. Mrs. Griffin had a 22-hour labor before a cesarean birth. Her membranes ruptured 20 hours before she came to the hospital. Her fetus showed signs of fetal distress, so internal electronic fetal monitoring was used. Her most recent test results indicate she is anemic.
   a. What postpartum complication is this new mother at highest risk for? Why?
   b. What assessments need to be done to detect this complication?
   c. What nursing measures will the nurse use to prevent this complication?
2. Tammy, a 32-year-old G9P9, had a spontaneous vaginal birth 2 hours ago. Tammy has been having a baby each year for the past 9 years. Her lochia has been heavy, with some clots. She hasn't been up to void since she had epidural anesthesia and has decreased sensation to her legs.
   a. What factors place Tammy at risk for postpartum hemorrhage?
   b. What assessments are needed before planning interventions?
   c. What nursing actions are needed to prevent a postpartum hemorrhage?
3. Lucy, a 25-year-old G2P2, gave birth 2 days ago and is expected to be discharged today. She had severe postpartum depression 2 years ago with her first child. Lucy has not been out of bed for the past 24 hours, is not eating, and provides no care for herself or her newborn. Lucy states she already has a boy at home and not having a girl this time is disappointing.
   a. What factors/behaviors place Lucy at risk for an affective disorder?
   b. Which interventions might be appropriate at this time?
   c. What education does the family need prior to discharge?

Study Activities

1. Compare and contrast postpartum blues, postpartum depression, and postpartum psychosis in terms of their features and medical management.
2. Select a website from the ones listed at the end of the chapter. Critique it regarding its helpfulness to parents, the correctness of the information, and when it was last updated.
3. Interview a woman who has given birth and ask if she had any complications and what was most helpful to her during the experience.
4. The number-one cause of postpartum hemorrhage is _____.
5. When giving report to the nurse who will be caring for a woman and her newborn in the postpartum period, what information should the labor nurse convey?

This page intentionally left blank.

UNIT EIGHT

The Newborn at Risk

This page intentionally left blank.

CHAPTER 23

Nursing Care of the Newborn With Special Needs

KEY TERMS

appropriate for gestational age
asphyxia
extremely low birthweight
large for gestational age
late preterm newborn
low birthweight
postterm newborn
preterm newborn
retinopathy of prematurity
small for gestational age
term newborn
very low birthweight

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Explain factors that assist in identifying a newborn at risk due to variations in birthweight and gestational age.
2. Select contributing factors and common complications associated with dysmature infants and their management.
3. Compare and contrast a small-for-gestational-age newborn and a large-for-gestational-age newborn; a postterm and preterm newborn.
4. Discuss associated conditions that affect the newborn with variations in birthweight and gestational age, including appropriate management.
5. Outline the nurse's role in helping parents experiencing perinatal grief or loss.
6. Integrate knowledge of the risks associated with late preterm births into nursing interventions, discharge planning, and parent education.

Anna and her husband were stunned when she went into labor at 7 months' gestation. They couldn't understand what would cause her to give birth early, but it happened. When they approached the NICU, Anna took a deep breath and looked down at her tiny baby with tubes coming from everywhere. What feelings might they be experiencing at this moment? Do you think that guilt would be one of those feelings? If so, why?

Wow

Guiding a parent's hand to touch a frail or ill newborn demonstrates courage and compassion under very difficult circumstances and is a powerful tool in helping to deal with the newborn's special needs.

Most newborns are born between 38 and 40 weeks' gestation and weigh 6 to 8 lb, but variations in birthweight or gestational age can occur, and newborns with these variations have special needs. Gestational age at birth is inversely correlated with the risk that the infant will experience physical, neurologic, or developmental sequelae (March of Dimes, 2007b, 2007c). Some newborns are born very ill and need special advanced care to survive.

When a woman gives birth to a newborn with problems involving immaturity or birthweight, especially one who is considered high risk, she may go through a grieving process in which she mourns the loss of the healthy full-term newborn she had expected. Through this process she learns to come to terms with the experience she now faces.

The development of new technologies and regionalized care centers for the care of newborns with special needs has resulted in significant improvements. Nurses need to have a sound knowledge base to identify the newborn with special needs and to provide coordinated care.

The key to identifying a newborn with special needs related to birthweight or gestational age variation is an awareness of the factors that could place a newborn at risk. These factors are similar to those that would suggest a high-risk pregnancy and include:

- Maternal nutrition (malnutrition or overweight)
- Substandard living conditions
- Low socioeconomic status
- Maternal age of less than 20 or more than 35 years old
- Substance abuse
- Failure to seek prenatal care
- Smoking or exposure to passive smoke
- Periodontal disease
- Multiple gestation
- Extreme maternal stress
- Abuse and violence
- Placental complications (placenta previa or abruptio placentae)
- History of previous preterm birth
- Maternal disease (e.g., hypertension or diabetes)
- Maternal infection (e.g., urinary tract infection or chorioamnionitis)
- Exposure to occupational hazards (Gilbert, 2007)

Being able to anticipate the birth of a newborn at risk allows the birth to take place at a health care facility equipped with the resources to meet the mother's and newborn's needs. This is important in reducing mortality and morbidity.

Healthy People 2010 identifies preterm births and low birthweight as important national health goals (U.S. Department of Health and Human Services [USDHHS], 2000).

This chapter discusses the nursing management of newborns with special needs related to variations in birthweight and gestational age. It also describes selected associated conditions affecting these newborns. Due to the frailty of these newborns, the care of the family experiencing perinatal loss and the role of the nurse in helping the family cope also are addressed.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of very low birthweight (VLBW) infants born at level III hospitals or subspecialty perinatal centers	• Will help to promote the delivery of high-risk infants in settings that have the technological capacity to care for them, ultimately reducing the morbidity and mortality rates for these infants
Reduce low birthweight (LBW) from a baseline of 7.6% to a target of 5%; reduce very low birthweight (VLBW) from a baseline of 1.4% to 0.9%	• Will help to emphasize the issue of LBW as a risk factor associated with newborn death, helping to promote measures to reduce this risk factor and thus contributing to significant reductions in infant mortality
Reduce the total number of preterm births from a baseline of 11.6% to 7.6% Reduce the number of live births at 32 to 36 weeks' gestation from a baseline of 9.6% to 6.4% Reduce the number of live births at less than 32 weeks' gestation from a baseline of 2% to 1.1%	• Will help to emphasize the role of preterm birth as the leading cause of newborn deaths unrelated to birth defects • Will aid in promoting an overall reduction in infant illness, disability, and death

USDHHS, 2000.

Birthweight Variations

Fetal growth is influenced by maternal nutrition, genetics, placental function, environment, and a multitude of other factors. Assigning size to a newborn is a way to measure and monitor the growth and development of the newborn at birth. Newborns can be classified according to their weight and weeks of gestation, and knowing the group into which a newborn fits is important.

Appropriate for gestational age (AGA) characterizes approximately 80% of newborns and describes a newborn with a normal height, weight, head circumference, and body mass index (BMI; Dorland, 2007). Being in the AGA group confers the lowest risk for any problems. These infants have lower morbidity and mortality than other groups.

Small-for-gestational-age (SGA) newborns typically weigh less than 2,500 g (5 lb 8 oz) at term due to less

FIGURE 23.1 A low birthweight newborn in an isolette.

growth in utero than expected. A newborn is also classified as SGA if his or her birthweight is at or below the 10th percentile as correlated with the number of weeks of gestation on a growth chart.

Large-for-gestational-age (LGA) describes newborns whose birthweight is above the 90th percentile on a growth chart and who weigh more than 4,000 g (8 lb 13 oz) at term due to accelerated growth for length of gestation (Herranz et al., 2007).

The following terms describe other newborns with marginal weights at birth and of any gestational age:

- **Low birthweight**: less than 2,500 g (5.5 lb) (Fig. 23.1)
- **Very low birthweight**: less than 1,500 g (3 lb 5 oz)
- **Extremely low birthweight**: less than 1,000 g (2 lb 3 oz)

SMALL-FOR-GESTATIONAL-AGE NEWBORNS

Newborns are considered SGA when they weigh less than two standard deviations for gestational age or fall below the 10th percentile on a growth chart for gestational age. These infants can be preterm, term, or postterm.

In some SGA newborns, the rate of growth does not meet the expected growth pattern. Termed intrauterine growth restriction (IUGR), these newborns also are considered at risk, with the perinatal morbidity and mortality rate increased substantially compared to that of the appropriate-for-age newborn (Cunningham et al., 2005). IUGR is the pathologic counterpart of SGA. However, an important distinction to make between SGA and IUGR newborns is that not all who are SGA have IUGR. The converse also is true: not all newborns who have IUGR are SGA. Some SGA newborns are constitutionally small: they are statistically small but otherwise healthy.

Conditions altering fetal growth produce insults that affect all organ systems and are known to produce two patterns of growth that depend on the timing of the insult to the developing embryo or fetus. An early insult (typically occurring before 28 weeks) results in overall growth restriction, with all organs being small. These SGA infants never catch up in size when compared with normal children. An insult later in gestation (after 28 weeks) results in intrauterine malnutrition, but optimal postnatal nutrition generally restores normal growth potential and carries a better prognosis than earlier insults (Kenner & Lott, 2007).

Historically, IUGR has been categorized as symmetric or asymmetric. Symmetric IUGR refers to fetuses with equally poor growth rates of the head, the abdomen, and the long bones. Asymmetric IUGR refers to infants whose head and long bones are spared compared to their abdomen and internal organs. The current belief is that in most cases IUGR is a continuum from asymmetry (early stages) to symmetry (late stages) (Harper & Lam, 2007).

Fetal growth is dependent on genetic, placental, and maternal factors. Cognitive and motor development during infancy forms the basis for children's subsequent development. Newborns who experience nutritional deficiencies in utero and are born SGA are at risk for cognitive deficits that can undermine their academic performance throughout their lives (Kristensen et al., 2007).

The fetus is thought to have an inherent growth potential that, under normal circumstances, yields a healthy newborn of appropriate size. The maternal–placental–fetal units act in harmony to meet the needs of the fetus during gestation. However, growth potential in the fetus can be limited, and this is analogous to failure to thrive in the infant. The causes of both can be intrinsic or environmental. Factors that can contribute to the birth of an SGA newborn are highlighted in Box 23.1.

Nursing Assessment

Assessment of the SGA infant begins by reviewing the maternal history to identify risk factors such as smoking, drug abuse, chronic maternal illness, hypertension, multiple gestation, or genetic disorders. This information allows the nurse to anticipate a possible problem and to be prepared to intervene quickly should one occur. At birth, perform a thorough physical examination, closely observing the newborn for typical characteristics, including:

- Head disproportionately large compared to rest of body
- Wasted appearance of extremities
- Reduced subcutaneous fat stores
- Decreased amount of breast tissue
- Scaphoid abdomen (sunken appearance)
- Wide skull sutures secondary to inadequate bone growth
- Poor muscle tone over buttocks and cheeks
- Loose and dry skin that appears oversized
- Thin umbilical cord

BOX 23.1 Factors Contributing to the Birth of SGA Newborns

- Maternal causes
  - Chronic hypertension
  - Diabetes mellitus with vascular disease
  - Autoimmune diseases
  - Living at a high altitude (hypoxia)
  - Smoking
  - Substance abuse (heroin, cocaine, methamphetamines)
  - Hemoglobinopathies (sickle cell anemia)
  - Preeclampsia
  - Chronic renal disease
  - Malnutrition
  - TORCH group infections
- Placental factors
  - Abnormal cord insertion
  - Chronic abruption
  - Decreased surface area, infarction
  - Decreased placental weight
  - Placenta previa
  - Placental insufficiency
- Fetal factors
  - Trisomy 13, 18, and 21
  - Turner's syndrome
  - Chronic fetal infection (cytomegalovirus [CMV], rubella, syphilis, toxoplasmosis)
  - Congenital anomalies (heart, diaphragmatic hernia, tracheoesophageal fistula)
  - Radiation exposure
  - Multiple gestation

Sources: Harper & Lam, 2007; Kenner & Lott, 2007; and Neonatal Handbook, 2007e

Also assess the SGA newborn for any congenital malformations, neurologic insults, or indications of infection. SGA newborns commonly face problems after birth because of the decrease in placental function during gestation. Table 23.1 highlights some of the common problems associated with SGA newborns and others experiencing a variation in birthweight or gestational age. Anticipate the need for and provide resuscitation as indicated by the newborn's condition.

Nursing Management

Interventions for the SGA infant may include obtaining weight, length, and head circumference, comparing them to standards, and documenting the findings. Perform frequent serial blood glucose measurements as ordered and monitor vital signs, being particularly alert for changes in respiratory status that might indicate respiratory distress. Institute measures to maintain a neutral thermal environment to prevent cold stress and acidosis.

Initiate early and frequent oral feedings unless contraindicated. At birth the newborn's glucose level is 70% of the mother's serum glucose (Aylott, 2006a). Any newborn stressed at birth uses up available glucose stores with resulting hypoglycemia, a plasma glucose concentration at or below 40 mg/dL (Stanley, 2006). With the loss of the placenta at birth, the newborn now must assume control of glucose homeostasis through intermittent oral feedings. If oral feedings are not accepted, an intravenous infusion with 10% dextrose in water may be needed to maintain the glucose level above 40 mg/dL. Weigh the newborn daily and ensure that he or she has adequate rest periods to decrease metabolic requirements.

Observe for clinical signs of polycythemia and monitor blood results. Asymptomatic newborns with a hematocrit between 60% and 70% may simply be supported with fluids, close observation, and a repeat hematocrit level in 4 to 6 hours (Kates & Kates, 2007). If the newborn is symptomatic, partial exchange transfusion may be used, but this treatment is considered controversial.

Provide anticipatory guidance to parents about any treatments and procedures that are being done. Emphasize the need for close follow-up and careful monitoring of the infant's growth in length, weight, and head circumference and feeding patterns throughout the first year of life to confirm any "catch-up" growth taking place.

LARGE-FOR-GESTATIONAL-AGE NEWBORNS

A newborn whose weight is above the 90th percentile on growth charts or two standard deviations above the mean weight for gestational age is defined as LGA. The range of weight is 4,000 to 5,000 g, or more than 9 lb. LGA infants may be preterm, term, or postterm. Based on these definitions, up to 10% of all births involve an LGA newborn (March of Dimes, 2007a).

Because of the newborn's large size, vaginal birth may be difficult and occasionally results in birth injury. In addition, shoulder dystocia, clavicular fractures, and facial palsies are common. The incidence of cesarean births is very high with LGA newborns to avoid arrested labor and birth trauma.

Take NOTE!

Diabetes is commonly associated with LGA newborns. However, due to poor placental perfusion, the newborn may experience IUGR and be SGA.

TABLE 23.1 COMMON PROBLEMS ASSOCIATED WITH NEWBORNS EXPERIENCING A VARIATION IN BIRTHWEIGHT OR GESTATIONAL AGE

Problem	Occurrence	Etiology/Pathophysiology	Assessment Findings	Nursing Implications
Perinatal asphyxia	SGA newborns (common)	Poor tolerance to stress of labor, frequently leading to acidosis and hypoxia Living in hypoxic environment prior to birth, leaving little to no oxygen reserves available to withstand stress of labor: —Uterine contractions increase hypoxic stress —Possible depletion of glycogen stores due to chronic hypoxic state, leading to fetal distress —Impaired uteroplacental circulation due to maternal and uterine conditions predisposing to perinatal depression Compromised newborn at birth experiencing difficulty adjusting to extrauterine environment	Fetal distress (bradycardia, decelerations) during labor Low Apgar scores (Deshpande, 2007)	Anticipate possible problem; assess for maternal risk factors. Initiate resuscitation measures immediately at birth.
	Postterm newborns	Placental deprivation or oligohydramnios, leading to cord compression and subsequent reduction in perfusion to fetus		
	Preterm newborns (common)	Surfactant deficiency Unstable chest wall Immaturity of respiratory control centers in the CNS Small respiratory passages, increasing risk for obstruction Inability to clear mucus from airways		
Difficulty with thermoregulation	SGA newborns (common)	Less muscle mass, less brown fat, less heat-preserving subcutaneous fat, and limited ability to control skin capillaries (Aylott, 2006b) Associated with depleted glycogen stores, poor subcutaneous fat stores, and disturbances in CNS thermoregulation due to hypoxia (Kenner & Lott, 2007)	Temperature <36.4° C; temperature instability; skin cool to touch; cyanosis of hands and feet Bradypnea (<25 bpm) and tachypnea (>60 breaths/min)	Maintain a neutral thermal environment to promote stabilization of newborn's temperature. Assess skin temperature and respiration characteristics. Monitor arterial blood gases and blood glucose levels.

(continued)

TABLE 23.1 COMMON PROBLEMS ASSOCIATED WITH NEWBORNS EXPERIENCING A VARIATION IN BIRTHWEIGHT OR GESTATIONAL AGE (continued)

Problem	Occurrence	Etiology/Pathophysiology	Assessment Findings	Nursing Implications
		Increased risk for acidosis and hypoglycemia secondary to metabolic stress (Neonatal Handbook, 2007j)	Tremors, irritability Wheezing, crackles, retractions Restlessness, lethargy Hypotonia Weak or high-pitched cry Seizures Poor feeding Grunting (Galligan, 2006) Acidosis	Eliminate sources of heat loss: —Dry newborn thoroughly. —Wrap in warmed blanket with stockinette cap on head. —Use radiant heat source.
	Postterm newborns	Loss of subcutaneous fat second to placental insufficiency Use of stored nutrients for nutrition due to lost ability of placenta to nourish fetus Subsequent wasting of subcutaneous fat, muscle, or both (Aylott, 2006b) Loss of natural insulation (subcutaneous fat) important in temperature regulation		
	Preterm newborns (common) Late preterm infant (common)	Immaturity of CNS (temperature-regulating center) interferes with ability to regulate body temperature Inadequate amounts of subcutaneous fat Lack of muscle tone and flexion to conserve heat Inadequate brown fat to generate heat Limited muscle mass activity, reducing ability to produce own heat Inability to shiver to generate heat		
Hypoglycemia	SGA newborns (common)	Increased metabolic rate and lack of adequate glycogen stores to meet newborn's metabolic needs	Often subtle Lethargy, tachycardia Respiratory distress Jitteriness Drowsiness Poor feeding, feeble sucking Hypothermia, temperature instability Diaphoresis Weak cry Seizures Hypotonia	Monitor blood glucose levels, initially on arrival to nursery and hourly thereafter. Maintain fluid and electrolyte balance. Watch for subtle changes. Initiate early oral feedings if possible; if not, administer IV infusion with 10% dextrose in water.
	LGA newborns (common)	Commonly associated with infants of diabetic mothers Abrupt cessation of high-glucose maternal blood supply with birth and continued insulin production by the newborn Limited ability to release glucagons and catecholamines, which normally stimulate glucagon breakdown and glucose release		

Problem	Occurrence	Etiology/Pathophysiology	Assessment Findings	Nursing Implications
	Postterm newborns	Hypoxia secondary to depleted glycogen reserves Placental insufficiency secondary to placental aging contributing to chronic fetal nutritional deficiency further depleting glycogen stores	Blood glucose levels <40 mg/dL for term newborns, <20 mg/dL for preterm newborns (Kenner & Lott, 2007)	
	Preterm newborns Late preterm infants	Immature sucking and swallowing leading to insufficient intake Perinatal hypoxia Increased energy expenditure Decreased subcutaneous and brown fat with little to no glycogen stores		
Polycythemia	SGA newborns	Chronic mild hypoxia secondary to placental insufficiency Stimulation of erythropoietin release, leading to increased RBC production	Venous hematocrit >65% Plethora (ruddy appearance) Weak sucking reflex Tachypnea Jaundice Lethargy Jitteriness Hypotonia Irritability Feeding difficulties Difficulty in arousing Seizures	Ensure adequate hydration (orally or IV). Monitor hematocrit levels (goal is ~60%). Administer partial exchange transfusion, albumin or normal saline IV to reduce RBC volume and increase fluid volume (controversial).
	LGA newborns	Secondary to fetal hypoxia, trauma with bleeding, increased erythropoietin production, or delayed cord clamping (Lessaris, 2007)		
	Postterm newborns	Intrauterine hypoxia triggers increased RBC cell production to compensate for lower oxygen levels.		
Meconium aspiration	SGA newborns	Release of meconium into amniotic fluid prior to birth Inhalation of meconium-containing amniotic fluid by the newborn, leading to aspiration	Green amniotic fluid with rupture of membranes during labor Green staining of the umbilical cord or fingernails Difficulty initiating respirations	Initiate resuscitation measures as necessary. Suction airways and support ventilation (see Chapter 24 for more information).
	Postterm newborns	Commonly associated with chronic intrauterine hypoxia Struggling by fetus making respiratory efforts and bearing down with abdominal muscles, leading to expulsion of meconium into amniotic fluid Normal sucking and swallowing by fetus leads to meconium filling airways.		

(continued)

TABLE 23.1 COMMON PROBLEMS ASSOCIATED WITH NEWBORNS EXPERIENCING A VARIATION IN BIRTHWEIGHT OR GESTATIONAL AGE (continued)

Problem	Occurrence	Etiology/Pathophysiology	Assessment Findings	Nursing Implications
Hyperbilirubinemia	LGA newborns (common)	Associated with polycythemia and RBC breakdown Inability to tolerate feedings in the first few days of life, leading to increased enterohepatic circulation of bilirubin Excessive bruising secondary to birth trauma, leading to higher-than-normal bilirubin levels	Elevated serum bilirubin levels Jaundice Tea-colored urine Clay-colored stools	Ensure adequate hydration. Institute early feedings if possible. Administer phototherapy (see Chapter 24 for more information).
	Preterm newborns Late preterm infants	Increased breakdown of RBCs and immature liver function to handle excess load		
Birth trauma	LGA newborns	Large size requiring use of operative birth procedure	Obvious deformities Bruising Edema Asymmetrical movement	Perform complete physical and neurologic assessment of the newborn. Note symmetry of structure and function. Assist parents in understanding situation (see Chapter 24 for more information).

Nursing Assessment

Assessment of the LGA newborn begins with a review of the maternal history, which can provide clues as to whether the woman has an increased risk of giving birth to an LGA newborn. Maternal factors that increase the chance of bearing an LGA newborn include maternal diabetes mellitus or glucose intolerance, multiparity, prior history of a macrosomic infant, postdates gestation, maternal obesity, male fetus, and genetics (Jazayeri, 2007).

At birth, assess the newborn for common characteristics. The typical LGA newborn has a large body and appears plump and full-faced. The increase in body size is proportional. However, the head circumference and body length are in the upper limits of intrauterine growth. These newborns have poor motor skills and have difficulty in regulating behavioral states. LGA newborns are more difficult to arouse to a quiet alert state (Neonatal Handbook, 2007f).

Thoroughly assess the LGA newborn at birth to identify traumatic birth injuries such as fractured clavicles, brachial palsy, facial paralysis, phrenic nerve palsy, skull fractures, or hematomas. Perform a neurologic examination to identify any nerve palsies, looking for abnormalities such as immobility of the upper arm. Observe and document any injuries discovered to allow for early intervention and improved outcomes.

Obtain frequent blood glucose levels as ordered to evaluate for hypoglycemia. The clinical signs are often subtle and include lethargy, apathy, drowsiness, irritability, tachypnea, weak cry, temperature instability, jitteriness, seizures, apnea, bradycardia, cyanosis or pallor, feeble suck and poor feeding, hypotonia, and coma. Other disorders, including septicemia, severe respiratory distress, and congenital heart disease, may present with similar findings. In addition, be alert for other common problems, such as polycythemia and hyperbilirubinemia (see Table 23.1 earlier in this chapter).

Nursing Management

Assist in stabilizing the LGA newborn. Monitor blood glucose levels within 30 minutes of birth and repeat the screening every hour. Recheck levels before feedings and

also immediately in any infant suspected of having or showing clinical signs of hypoglycemia, regardless of age (Aylott, 2006a). To help prevent hypoglycemia, initiate feedings, which can be formula or breast milk, with intravenous glucose supplementation as needed.

If the newborn's blood glucose level is below 25 mg/dL, institute immediate treatment with intravenous glucose, regardless of clinical symptoms (Aylott, 2006a). Monitor and record intake and output and obtain daily weights to aid in evaluating nutritional intake.

Observe for signs of polycythemia and hyperbilirubinemia and report any immediately to the health care provider so that early interventions can be taken to prevent poor long-term neurologic development outcomes. Polycythemia and hyperviscosity are associated with fine and gross motor delays, speech delays, and neurologic sequelae (Neonatal Handbook, 2007g). Increasing fluid volume aids in decreasing blood viscosity. Partial exchange transfusion with plasma or normal saline may be used to lower hematocrit and decrease blood viscosity, but this treatment remains controversial. Hydration, early feedings, and phototherapy are used to treat hyperbilirubinemia (see Chapter 24 for more information about hyperbilirubinemia). Provide parental guidance about the treatments and procedures being done and about the need for follow-up care for any abnormalities identified.

Gestational Age Variations

The mean duration of pregnancy, calculated from the first day of the last normal menstrual period, is approximately 280 days, or 40 weeks. Gestational age is typically measured in weeks: a newborn born before completion of 37 weeks is classified as a **preterm newborn** and one born after completion of 42 weeks is classified as a **postterm newborn**. An infant born from the first day of 38th week through 42 weeks is classified as a **term newborn**. As of 2006, a new classification has been added, the **late preterm newborn**—one who is born between 34 weeks and 36 weeks, 6 days of gestation.

Precise knowledge of a newborn's gestational age is imperative for effective postnatal management. Determination of gestational age by the nurse assists in planning appropriate care for the newborn and provides important information regarding potential problems that need interventions. See Chapter 18 for more information on assessing gestational age.

▸ *Take* NOTE!

Although preterm and postterm newborns may appear to be at opposite ends of the gestational age spectrum and are very different in size and appearance, both are at high risk and need special care.

POSTTERM NEWBORN

A pregnancy that extends beyond 42 weeks' gestation produces a postterm newborn. Other terms used to describe these late births include postmature, prolonged pregnancy, or postdates pregnancy. Postterm newborns may be LGA, SGA, or dysmature (newborn weighs less than established normal parameters for estimated gestational age [IUGR]), depending on placental function.

The reason why some pregnancies last longer than others is not completely understood. What is known is that women who experience one postterm pregnancy are at increased risk in subsequent pregnancies. The incidence of prolonged pregnancy is approximately 10% (Gilbert, 2007).

The ability of the placenta to provide adequate oxygen and nutrients to the fetus after 42 weeks' gestation is thought to be compromised, leading to perinatal mortality and morbidity. As the placenta loses its ability to nourish the fetus, the fetus uses stored nutrients to stay alive, and wasting occurs. This wasted appearance at birth is secondary to the loss of muscle mass and subcutaneous fat.

▸ *Consider* THIS!

I had been waiting for this baby my whole married life and now I was told to wait even longer. I was into my third week past my due date and was just told that if I didn't go into labor on my own, the doctor would induce me on Monday. As I waddled out of his office into the hot summer sun, I thought about all the comments that would await me at the office: "You're not still pregnant, are you?" "Weren't you due last month?" "You look as big as a house." "Are you sure you aren't expecting triplets?" I started to get into my car when I felt warm fluid slide down my legs. Although I was embarrassed at my wetness, I was thrilled I wouldn't have to go back to the office and drove myself to the hospital. Within hours my wait was finally over with the birth of my son, a postterm infant with peeling skin and a thick head of hair. He was certainly worth the wait!

Thoughts: Although most due dates are within plus or minus 2 weeks, we can't "go to the bank with it" because so many factors influence the start of labor. This woman was anxious about her overdue status, but nature prevailed. The old adage "when the fruit is ripe, it will fall" doesn't always bring a good outcome: many women need a little push to bring a healthy newborn forth. What happens when the fetus stays inside the uterus too long? What other features are typical of postterm infants?

Nursing Assessment

A thorough assessment of the postterm newborn upon admission to the nursery provides a baseline from which to identify changes in clinical status. Review the maternal history for any risk factors associated with postterm birth. Also be aware of the common physical characteristics and be able to identify any deviation from the expected. Postterm newborns typically exhibit the following characteristics:

- Dry, cracked, wrinkled skin
- Long, thin extremities
- Creases that cover the entire soles of the feet
- Wide-eyed, alert expression
- Abundant hair on scalp
- Thin umbilical cord
- Limited vernix and lanugo
- Meconium-stained skin
- Long nails (Kenner & Lott, 2007)

Assess the newborn's gestational age and complete a physical examination to identify any abnormalities. Review the medical record to determine the color of the amniotic fluid when membranes ruptured and observe for a meconium-stained umbilical cord and fingernails to assess for possible meconium aspiration. Careful suctioning at the time of birth and afterwards, if the condition dictates it, reduces the incidence of meconium aspiration. Also be alert for other typical complications associated with a postterm newborn, such as perinatal asphyxia, hypoglycemia, hypothermia, and polycythemia, and be prepared to initiate early interventions (see Table 23.1 earlier in the chapter).

Nursing Management

The birth of a postterm newborn creates a crisis for the mother and her family. In most situations, birth of a newborn requiring special care was not anticipated. Postterm newborns are susceptible to several birth challenges secondary to placental dysfunction that place them at risk for asphyxia, hypoglycemia, and respiratory distress. The nurse must be vigilant for complications when managing these newborns.

The postterm newborn is at high risk for perinatal asphyxia, which is usually attributed to placental deprivation or oligohydramnios that leads to cord compression, thereby reducing perfusion to the fetus. Anticipating the need for newborn resuscitation is a priority. The newborn resuscitation team needs to be available in the birthing suite for immediate backup. The newborn may require transport to the neonatal intensive care unit (NICU) for continuous assessment, monitoring, and treatment, depending on his or her status after resuscitation.

Monitor and maintain the postterm newborn's blood glucose levels once stabilized. Intravenous dextrose 10% and/or early initiation of feedings will help stabilize the blood glucose levels to prevent central nervous system sequelae.

Also monitor the postterm newborn's skin temperature, respiration characteristics, results of blood studies, such as arterial blood gases (ABGs) and serum bilirubin levels, and neurologic status. Institute measures to prevent or reduce the risk of hypothermia by eliminating sources of heat loss: thoroughly dry the newborn at birth, wrap him or her in a warmed blanket, and place a stockinet cap on the newborn's head. Providing environmental warmth via a radiant heat source will help stabilize the newborn's temperature.

Closely assess all postterm newborns for polycythemia. Providing adequate hydration helps to reduce the viscosity of the newborn's blood to prevent thrombosis. Be alert to the early, often subtle signs to promote early identification and prompt treatment to prevent any neurodevelopmental delays.

PRETERM NEWBORN

A preterm newborn is one who is born before the completion of 37 weeks of gestation. Although the national birth rate has been declining since the 1990s, the preterm birth rate has been climbing rapidly. Approximately one in eight babies, or 12%, is born before the 37th week of gestation (March of Dimes, 2007c). Prematurity is now the leading cause of death within the first month of life and the second leading cause of all infant deaths.

The etiology of half of all preterm births is unknown (March of Dimes, 2007b, 2007c). Preterm births take an enormous financial toll, estimated to be in the billions of dollars. They also take an emotional toll on those involved.

Changes in perinatal care practices, including regional care, have reduced newborn mortality rates. Transporting high-risk pregnant women to a tertiary center for birth rather than transferring the neonate after birth is associated with a reduction in neonatal mortality and morbidity (Vargo & Trotter, 2007). Despite increasing survival rates, preterm infants continue to be at high risk for neurodevelopmental disorders such as cerebral palsy or mental retardation, intraventricular hemorrhage, congenital anomalies, neurosensory impairment, behavioral problems, and chronic lung disease (Kipiani, Tatishvili, & Sirbiladze, 2007). Making sure that all pregnant women receive quality prenatal care throughout pregnancy is a major method for preventing preterm births.

Effects of Prematurity on Body Systems

Since the preterm newborn did not remain in utero long enough, every body system may be immature, affecting the newborn's transition from intrauterine to extrauterine life and placing him or her at risk for complications.

Without full development, organ systems are not capable of functioning at the level needed to maintain extrauterine homeostasis (March of Dimes, 2007b, 2007c).

Recall Anna, who was described at the beginning of the chapter; she gave birth to a newborn at 7 months' gestation. What problems would you anticipate that her newborn might have?

Respiratory System

The respiratory system is one of the last body systems to mature. Therefore, the preterm newborn is at great risk for respiratory complications. A few of the problems that affect the preterm newborn's breathing ability and adjustment to extrauterine life include:

- Surfactant deficiency, leading to the development of respiratory distress syndrome
- Unstable chest wall, leading to atelectasis
- Immature respiratory control centers, leading to apnea
- Smaller respiratory passages, leading to an increased risk for obstruction
- Inability to clear fluid from passages, leading to transient tachypnea

Cardiovascular System

The preterm newborn has great difficulty in making the transition from intrauterine to extrauterine life in terms of changing from a fetal to a newborn circulation pattern. Higher oxygen levels in the circulation once air breathing begins spur this transition. If the oxygen levels remain low secondary to perinatal asphyxia, the fetal pattern of circulation may persist, causing blood flow to bypass the lungs. Another problem affecting the cardiovascular system is the increased incidence of congenital anomalies associated with continued fetal circulation—patent ductus arteriosus and an open foramen ovale. In addition, impaired regulation of blood pressure in preterm newborns may cause fluctuations throughout the circulatory system. One of special note is cerebral blood flow, which may predispose the fragile blood vessels in the brain to rupture, causing intracranial hemorrhage (Lissauer & Weindling, 2006).

Gastrointestinal System

Preterm newborns usually lack the neuromuscular coordination required to maintain the suck, swallow, and breathing regimen necessary for sufficient calorie and fluid intake to support growth. Perinatal hypoxia causes shunting of blood from the gut to more important organs such as the heart and brain. Subsequently, ischemia and damage to the intestinal wall can occur. This combination of shunting, ischemia, damage to the intestinal wall, and poor sucking ability places the preterm infant at risk for malnutrition and weight loss.

In addition, preterm newborns have a small stomach capacity, weak abdominal muscles, compromised metabolic function, limited ability to digest proteins and absorb nutrients, and weak or absent suck and gag reflexes. All of these limitations place the preterm newborn at risk for nutritional deficiency and subsequent growth and development delays (Neonatal Handbook, 2007h).

Currently, minimal enteral feeding is used to prepare the preterm newborn's gut to overcome the many feeding difficulties associated with gastrointestinal immaturity. It involves the introduction of small amounts, usually 0.5 to 1 mL/kg/h, of enteral feeding to induce surges in gut hormones that enhance maturation of the intestine. This minute amount of breast milk or formula given via gavage feeding prepares the gut to absorb future introduction of nutrients. It builds mucosal bulk, stimulates development of enzymes, enhances pancreatic function, stimulates maturation of gastrointestinal hormones, reduces gastrointestinal distention and malabsorption, and enhances transition to oral feedings (Blackburn, 2007).

Renal System

The renal system of the preterm newborn is immature, reducing the baby's ability to concentrate urine and slowing the glomerular filtration rate. As a result, the risk for fluid retention, with subsequent fluid and electrolyte disturbances, increases. In addition, preterm newborns have limited ability to clear drugs from their systems, thereby increasing the risk of drug toxicity. Close monitoring of the preterm newborn's acid–base and electrolyte balance is critical to identify metabolic inconsistencies. Prescribed medications require strict evaluation to prevent overwhelming the preterm baby's immature renal system.

Immune System

The preterm newborn's immune system is very immature, increasing his or her susceptibility to infections. A deficiency of IgG may occur because transplacental transfer does not occur until after 34 weeks' gestation. This protection is lacking if the baby was born before this time. In addition, preterm newborns have an impaired ability to manufacture antibodies to fight infection if they were exposed to pathogens during the birth process. Moreover, the preterm newborn's thin skin and fragile blood vessels provide a limited protective barrier, adding to the increased risk for infection. Thus, anticipating and preventing infections is the goal; preventing infections has a better outcome than treating them.

Central Nervous System

The preterm newborn is susceptible to injury and insult to the central nervous system (CNS), increasing the potential for long-term disability into adulthood. Like all newborns, preterm newborns have difficulty in temperature regulation and maintaining stability. However, their risk for heat loss is compounded by inadequate amounts of

insulating subcutaneous fat; lack of muscle tone and flexion to conserve heat; inadequate brown fat to generate heat; limited muscle mass activity, reducing the possibility of producing their own heat; inability to shiver to generate heat; and an immature temperature-regulating center in the brain (Blackburn, 2007). Preventing cold stress, which would increase the newborn's metabolic and oxygen needs, is crucial. The goal is to create a neutral thermal environment in which oxygen consumption is minimal but body temperature is maintained (Kenner & Lott, 2007).

In addition, the preterm newborn is especially susceptible to hypoglycemia due to immature glucose control mechanisms, decreased glucose stores, and a reduced availability of alternative fuels such as ketone bodies.

▶ ***Take*** *NOTE!*

Glucose is needed by the brain and CNS to maintain and support numerous body system functions.

Nursing Assessment

Preterm newborns are at high risk for numerous problems and require special care. When preterm labor develops and cannot be stopped by medical interventions, plans for appropriate management of the mother and the preterm newborn are necessary, such as transporting them to a regional center with facilities to care for preterm newborns or notifying the facility's NICU. Depending on the degree of prematurity, the preterm newborn may be kept in the NICU for months.

A thorough assessment of the preterm newborn upon admission to the nursery provides a baseline from which to identify changes in clinical status. Be aware of the common physical characteristics and be able to identify any deviation from the expected (Fig. 23.2). Common physical characteristics of preterm infants may include:

- Birthweight of less than 5.5 lb
- Scrawny appearance
- Head disproportionately larger than chest circumference
- Poor muscle tone
- Minimal subcutaneous fat
- Undescended testes
- Plentiful lanugo (soft, downy hair), especially over the face and back
- Poorly formed ear pinna, with soft, pliable cartilage
- Fused eyelids
- Soft and spongy skull bones, especially along suture lines
- Matted scalp hair, wooly in appearance
- Absent to a few creases in the soles and palms
- Minimal scrotal rugae in male infants; prominent labia and clitoris in female infants
- Thin, transparent skin with visible veins
- Breast and nipples not clearly delineated
- Abundant vernix caseosa (Kenner & Lott, 2007)

Be alert for evidence that might suggest that the preterm newborn is developing a complication (see Table 23.1 earlier in the chapter).

Review the maternal history to identify risk factors for preterm birth and check antepartum and intrapartum records for maternal infections to anticipate the need for treatment. Maternal risk factors associated with preterm birth include a previous preterm delivery, low socioeconomic status, preeclampsia, hypertension, poor maternal nutrition, smoking, multiple gestation, infection, advanced maternal age, and substance abuse.

Assess the newborn's gestational age and assess for IUGR if appropriate. Inspect the newborn's skin closely, especially skin color. Assess vital signs, including temperature via skin probe to identify hypothermia or fever, and heart rate for tachycardia or bradycardia. Evaluate the newborn's respiratory effort and respiratory rate. Observe for periods of apnea lasting longer than 20 seconds. Monitor oxygen saturation levels by pulse oximetry to validate perfusion status. Note and report any signs of respiratory distress. Auscultate lung and heart sounds, being especially alert for possible murmur, which would indicate the presence of patent ductus arteriosus in a preterm newborn.

Assess neurologic status by observing the newborn's behavior. Note any restlessness, hypotonia, or weak cry or sucking effort and report unusual findings.

Monitor laboratory studies such as hemoglobin and hematocrit for signs of polycythemia. Screen for hypoglycemia upon admission and then hourly, always observing for nonspecific signs of hypoglycemia such as lethargy, poor feeding, and seizures. Evaluate serum bilirubin concentrations.

Also assess the mother and family members. Identify family strengths and coping mechanisms to establish a basis for intervention.

Nursing Management

The birth of a preterm newborn creates a crisis for the mother and family. Multiple studies have found that hospitalization for preterm newborns is often followed by negative mental health/behavioral outcomes, anxiety and depressive disorders, and developmental problems (Melnyk, Feinstein, & Fairbanks, 2006). Preterm newborns present with immaturity of all organ systems, abundant physiologic challenges, and significant morbidity and mortality (Kenner & Lott, 2007). The nurse must be vigilant for complications when managing preterm newborns (Fig. 23.3 and Nursing Care Plan 23.1).

Promoting Oxygenation

Newborns normally start to breathe without assistance and often cry after birth, being stimulated by a change in pres-

FIGURE 23.2 Characteristics of a preterm newborn. (**A**) Few plantar creases. (**B**) Soft, pliable ear cartilage, matted hair, and fused eyelids. (**C**) Lax posture with poor muscle tone. (**D**) Breast and nipple area barely visible. (**E**) Male genitalia with minimal rugae on scrotum. (**F**) Female genitalia with prominent labia and clitoris.

sure gradients and environmental temperature. The work of taking that first breath is primarily due to overcoming the surface tension of the walls of the terminal lung units at the gas–tissue interface. Subsequent breaths require less inspiratory pressure since there is an increase in functional capacity and air retained. By 1 minute of age, most newborns are breathing well. A newborn who fails to establish adequate, sustained respiration after birth is said to have **asphyxia**. On a physiologic level, it is defined as an impairment in gas exchange resulting in a decrease in oxygen in the blood (hypoxemia) and an excess of carbon dioxide or hypercapnia that leads to acidosis. Asphyxia is the most

FIGURE 23.3 The physical condition of a preterm newborn demands skilled assessment and nursing care.

common clinical insult in the perinatal period that results in brain injury, which may lead to mental retardation, cerebral palsy, or seizures (Blackburn, 2007).

The preterm infant lacks surfactant. Surfactant lowers surface tension in the alveoli and stabilizes them to prevent their collapse. Even if preterm newborns can initiate respirations, they have a limited ability to retain air due to insufficient surfactant. Therefore, preterm newborns develop atelectasis quickly without alveoli stabilization. The inability to initiate and establish respirations leads to hypoxemia and ultimately hypoxia (decreased oxygen), acidosis (decreased pH), and hypercarbia (increased carbon dioxide). This change in the newborn's biochemical environment may inhibit the transition to extrauterine circulation, thus allowing fetal circulation patterns to persist.

Failure to initiate extrauterine breathing or failure to breathe well after birth leads to hypoxia (too little oxygen in the cells of the body). As a result, the heart rate falls, cyanosis develops, and the newborn becomes hypotonic and unresponsive. Although this can happen with any newborn, the risk is higher in preterm newborns.

Prevention and early identification of newborns at risk are key. Prenatal risk factors that can help identify the newborn who may need resuscitation at birth secondary to asphyxia include:

- History of substance abuse
- Gestational hypertension
- Fetal distress due to hypoxia before birth
- Chronic maternal diseases such as diabetes or a heart or renal condition
- Maternal or perinatal infection
- Placental problems (placenta previa or abruptio placentae)
- Umbilical cord problems (nuchal or prolapsed)
- Difficult or traumatic birth
- Multiple births
- Congenital heart disease
- Maternal anesthesia or recent analgesia
- Preterm or postterm birth (Neonatal Handbook, 2007i)

Note the newborn's Apgar score at 1 and 5 minutes. If the score is below 7 at either time, resuscitation efforts are needed. Several diagnostic studies may be done to identify underlying etiologies. For example, a chest x-ray helps to identify structural abnormalities that might interfere with respirations. Blood studies may be done, such as cultures to rule out an infectious process, a toxicology screen to detect any maternal drugs in the newborn, and a metabolic screen to identify any metabolic conditions (Lissauer & Weindling, 2007). Monitor vital signs continuously, check blood glucose levels for hypoglycemia secondary to stress, and maintain a neutral thermal environment to promote energy conservation and minimize oxygen consumption.

Resuscitating the Newborn

Any newborn can be born with asphyxia without warning. Approximately 10% of newborns require some assistance to begin breathing at birth. Anticipation, adequate preparation, accurate evaluation, and prompt initiation of support are critical for successful newborn resuscitation. Have all basic equipment immediately available and in working order. Ensure that the equipment is evaluated daily, and document its condition and any needed repairs. Box 23.2 lists the equipment needed for basic newborn resuscitation.

Determine the need for resuscitation by performing a rapid assessment using the following four questions:

- What is the gestational age of this newborn?
- Was the amniotic fluid clear of meconium or cloudy (infection present)?
- Is the newborn breathing or crying now?
- Does the newborn have good muscle tone?

If the answers are "yes" to all questions, then routine care is initiated: provide warmth, clear the airway, dry the newborn, and assess color. If the answer to any of these questions is "no," the newborn should receive one or more of the following actions, according to this sequence:

1. Stabilization—Dry the newborn thoroughly with a warm towel; provide warmth by placing him or her under a radiant heater to prevent rapid heat loss through evaporation; position the head in a neutral position to open the airway; clear the airway with a bulb syringe or suction catheter; stimulate breathing. At times, handling and rubbing the newborn with a dry towel may be all that is needed to stimulate respirations.

Nursing Care Plan 23.1

OVERVIEW OF THE CARE OF A PRETERM NEWBORN

Alice, an 18-year-old, felt she had done everything right during her first pregnancy and certainly didn't anticipate giving birth to a preterm newborn at 32 weeks' gestation. When Mary Kaye was born, she had respiratory distress and hypoglycemia and couldn't stabilize her temperature. Assessment revealed the following: newborn described as scrawny in appearance; skin thin and transparent with prominent veins over abdomen; hypotonia with lax, extended positioning; weak sucking reflex when nipple offered; respiratory distress with tachypnea (70 breaths/min), nasal flaring, and sternal retractions; low blood glucose level suggested by lethargy, tachycardia, jitteriness; axillary temperature of 36° C (96.8° F) despite warmed blanket; weight 2,146 g (4.73 lb); length 45 cm (17.72 inches).

NURSING DIAGNOSIS: Ineffective breathing pattern related to immature respiratory system and respiratory distress as evidenced by tachypnea, nasal flaring, and sternal retractions

Outcome Identification and Evaluation

Newborn's respiratory status returns to adequate level of functioning as evidenced by rate remaining within 30 to 60 breaths/min, maintenance of acceptable oxygen saturation levels, and minimal to absent signs of respiratory distress.

Interventions: Promoting Optimal Breathing Pattern

- Assess gestational age and risk factors for respiratory distress *to allow early detection.*
- Anticipate need for bag and mask setup and wall suction *to allow for prompt intervention should respiratory status continue to worsen.*
- Assess respiratory effort (rate, character, effort) *to identify changes.*
- Assess heart rate for tachycardia and auscultate heart sounds *to determine worsening of condition.*
- Observe for cues (grunting, shallow respirations, tachypnea, apnea, tachycardia, central cyanosis, hypotonia, increased effort) *to identify need for additional oxygen.*
- Maintain slight head elevation *to prevent upper airway obstruction.*
- Assess skin color *to evaluate tissue perfusion.*
- Monitor oxygen saturation level via pulse oximetry *to provide objective indication of perfusion status.*
- Provide supplemental oxygen as indicated and ordered *to ensure adequate tissue oxygenation.*
- Assist with any ordered diagnostic tests, such as chest x-ray and arterial blood gases, *to determine effectiveness of treatments.*
- Cluster nursing activities *to reduce oxygen consumption.*
- Maintain a neutral thermal environment *to reduce oxygen consumption.*
- Monitor hydration status *to prevent fluid volume deficit or overload.*
- Explain all events and procedures to the parents *to help alleviate anxiety and promote understanding of the newborn's condition.*

NURSING DIAGNOSIS: Ineffective thermoregulation related to lack of fat stores and hypotonia as evidenced by extended positioning, low axillary temperature despite warmed blanket, respiratory distress, and lethargy

Outcome Identification and Evaluation

Newborn will demonstrate ability to regulate temperature as evidenced by temperature remaining in normal range (36.5° to 37.5° C) and absent signs of cold stress.

Interventions: Promoting Thermoregulation

- Assess the axillary temperature every hour or use a thermistor probe *to monitor for changes.*
- Review maternal history *to identify risk factors contributing to problem.*
- Monitor vital signs, including heart rate and respiratory rate, every hour *to identify deviations.*
- Check radiant heat source or isolette *to ensure maintenance of appropriate temperature of the environment.*
- Assess environment for sources of heat loss or gain through evaporation, conduction, convection, or radiation *to minimize risk of heat loss.*
- Avoid bathing and exposing newborn *to prevent cold stress.*
- Warm all blankets and equipment that come in contact with newborn; place warmed cap on the newborn's head and keep it on *to minimize heat loss.*

(continued)

Nursing Care Plan 23.1 (continued)

- Encourage kangaroo care (mother or father holds preterm infant underneath clothing skin-to-skin and upright between breasts) *to provide warmth.*
- Educate parents on how to maintain a neutral thermal environment, including importance of keeping the newborn warm with a cap and double-wrapping with blankets and changing them frequently to keep dry *to promote newborn's adjustment.*
- Demonstrate ways to safeguard warmth and prevent heat loss.

NURSING DIAGNOSIS: Risk for imbalanced nutrition: less than body requirements related to poor sucking and lack of glycogen stores necessary to meet the newborn's increased metabolic demands as evidenced by weak sucking reflex, low birthweight, and signs and symptoms of hypoglycemia, including lethargy, tachycardia, and jitteriness

Outcome Identification and Evaluation

Newborn will demonstrate adequate nutritional intake, remaining free of signs of hypoglycemia as evidenced by blood glucose levels being maintained above 45 mg/dL, enhanced sucking ability, and appropriate weight gain.

Interventions: Promoting Optimal Nutrition

- Identify newborn at risk based on behavioral characteristics, body measurements, and gestational age *to establish a baseline and allow for early detection.*
- Assess blood glucose levels as ordered *to determine status and establish a baseline for interventions.*
- Obtain blood glucose measurements upon admission to nursery and every 1 to 2 hours as indicated *to evaluate for changes.*
- Observe behavior for signs of low blood glucose *to allow early identification.*
- Initiate early oral feedings or gavage feedings *to maintain blood glucose levels.*
- If oral or gavage feedings aren't tolerated, initiate an IV glucose infusion *to aid in stabilizing blood glucose levels.*
- Assess skin for pallor and sweating *to identify signs of hypoglycemia.*
- Assess neurologic status for tremors, seizures, jitteriness, and lethargy *to identify further drops in blood glucose levels.*
- Monitor weight daily for changes *to determine effectiveness of feedings.*
- Maintain temperature using warmed blankets, radiant warmer, or warmed isolette *to prevent heat loss and possible cold stress and reduce energy demands.*
- Monitor temperature *to prevent cold stress resulting in decreased blood glucose levels.*
- Offer opportunities for non-nutritive sucking on premature-size pacifier *to satisfy sucking needs.*
- Monitor for tolerance of oral feedings, including intake and output, *to determine effectiveness.*
- Administer IV dextrose if newborn is symptomatic *to raise blood glucose levels quickly.*
- Decrease energy requirements, including clustering care activities and providing rest periods, *to conserve glucose and glycogen stores.*
- Inform parents about procedures and treatments, including rationale for frequent blood glucose levels, *to help reduce their anxiety.*

2. Ventilation
3. Chest compressions
4. Administration of epinephrine and/or volume expansion (AHA/AAP, 2006).

The decision to progress from one set of actions to the next and the need for further resuscitative efforts is determined by the assessment of respirations, heart rate, and color (AHA/AAP, 2006).

When performing newborn resuscitation, use the mnemonic "ABCDs" (airway, breathing, circulation, and drugs) to remember the sequence of steps (Box 23.3).

Resuscitation measures are continued until the newborn has a pulse above 100 bpm, a good cry, or good breathing efforts and a pink tongue. This last sign indicates a good oxygen supply to the brain (AHA/AAP, 2006).

Throughout the resuscitation period, keep the parents informed of what is happening to their newborn and what is being done and why. Provide support through this initial crisis. Once the newborn is stabilized, encourage bonding by having them stroke, touch, and when appropriate hold the newborn.

Administering Oxygen

Oxygen administration is a common therapy in newborn nurseries. Although it has been used in newborns for over 75 years, there is no universal agreement on the most ap-

BOX 23.2 Basic Equipment for Newborn Resuscitation

- A wall vacuum suction apparatus
- A wall source or tank source of 100% oxygen with a flow meter
- A neonatal self-inflating ventilation bag with correct-sized face masks
- A selection of endotracheal tubes (2.5, 3.0, or 3.5 mm) with introducers
- A laryngoscope with a small, straight blade and spare batteries and bulbs
- Ampules of naloxone (Narcan) with syringes and needles
- A wall clock to document timing of activities and events
- A supply of disposable gloves in a variety of sizes for staff to use

BOX 23.3 ABCDs of Newborn Resuscitation

- **A**irway
  - Place infant's head in "sniffing" position.
  - Suction mouth, then nose.
  - Suction trachea if meconium-stained and newborn is NOT vigorous (strong respiratory effort, good muscle tone, and heart rate > 100 bpm).
- **B**reathing
  - Use positive-pressure ventilation (PPV) for apnea, grasping, or pulse <100 bpm.
  - Ventilate at rate of 40 to 60 breaths/minute.
  - Listen for raising heart rate, audible breath sounds.
  - Look for slight chest movement with each breath.
  - Use carbon dioxide detector after intubation.
- **C**irculation
  - Start compressions if heart rate is <60 after 30 seconds of effective PPV.
  - Give 3 compressions: 1 breath every 2 seconds.
  - Compress one third of the anterior-posterior diameter of the chest.
- **D**rugs
  - Give epinephrine if heart rate is <60 after 30 seconds of compressions and ventilation.
  - *Caution:* Epinephrine dosage is different for endotracheal and IV routes!
    - Epinephrine: 1:10,000 concentration
      - 0.1 to 0.3 mL/kg IV
      - 0.3 to 1 ml/kg via endotracheal tube (AHA/AAP, 2006)

propriate range at which oxygen levels should be maintained for newborns experiencing hypoxia, nor is there a standard time frame for oxygen to be administered (Neonatal Handbook, 2007d). While this uncertainty continues, nurses will experience a wide variation in practice in terms of modes of administration, monitoring, blood levels, and target ranges for both short- and long-term oxygen therapy.

A guiding principle, though, is that oxygen therapy should be targeted to levels appropriate to the condition, gestational age, and postnatal age of the newborn. Oxygen therapy must be used judiciously to prevent **retinopathy of prematurity (ROP)**, a major cause of blindness in preterm newborns in the past. ROP is a potentially blinding eye disorder that occurs when abnormal blood vessels grow and spread through the retina, eventually leading to retinal detachment. The incidence of ROP is inversely proportional to the preterm baby's birthweight. Approximately 400 to 600 children become blind because of ROP in the United States annually (Lyon & Warren, 2006).

Although the role of oxygen in the pathogenesis of ROP is unclear, current evidence suggests that it is linked to the duration of oxygen use rather than the concentration. Thus, the use of 100% oxygen to resuscitate a newborn should not pose a problem (National Eye Institute, 2007). However, an ophthalmology consult for follow-up after discharge is essential for preterm infants who have received extensive oxygen therapy. See Chapter 38 for a more in-depth discussion of this condition.

Respiratory distress in preterm infants is commonly caused by a deficiency of surfactant, retained fluid in the lungs (wet lung syndrome), meconium aspiration, pneumonia, hypothermia, or anemia. The principles of care are the same regardless of the cause of respiratory distress. First, keep the newborn warm, preferably in a warmed isolette or with an overhead radiant warmer, to conserve the baby's energy and prevent cold stress. Handle the newborn as little as possible, because stimulation often increases the oxygen requirement. Provide energy through calories via intravenous dextrose or gavage or continuous tube feedings to prevent hypoglycemia. Treat cyanosis with an oxygen hood or blow-by oxygen placed near the newborn's face if respiratory distress is mild and short-term therapy is needed. Record the following important observations every hour or more frequently if indicated, and document any deterioration or changes in respiratory status:

- Respiratory rate, quality of respirations, and respiratory effort
- Airway patency, including removal of secretions per facility policy
- Skin color, including any changes to duskiness, blueness, or pallor
- Lung sounds on auscultation to differentiate breath sounds in upper and lower fields
- Equipment required for oxygen delivery, such as:
  - Blow-by oxygen delivered via mask or tube for short-term therapy

FIGURE 23.4 (**A**) A preterm newborn receiving oxygen therapy via a nasal cannula. The newborn also has an enteral feeding tube inserted for nutrition. (**B**) A preterm newborn receiving mechanical ventilation.

- Oxygen hood (oxygen is delivered via a plastic hood placed over the newborn's head)
- Nasal cannula (oxygen is delivered directly through the nares) (Fig. 23.4A)
- Continuous positive airway pressure (CPAP), which prevents collapse of unstable alveoli and delivers high levels of inspired oxygen into the lungs
- Mechanical ventilation, which delivers consistent assisted ventilation and oxygen therapy, reducing the work of breathing for the fatigued infant (see Fig. 23.4B)

- Correct placement of endotracheal tube (if present)
- Heart rate, including any changes
- Oxygen saturation levels via pulse oximetry to evaluate need for therapy modifications based on hemoglobin
- Maintenance of oxygen saturation level from 87% to 95% (Aylott, 2006b)
- Nutritional intake, including calories provided, to prevent hypoglycemia and method of feeding, such as gavage, intravenous, or continuous enteral feedings
- Hydration status, including any signs and symptoms of fluid overload
- Laboratory tests, including ABGs, to determine effectiveness of oxygen therapy
- Administration of medication, such as exogenous surfactant

If the newborn shows worsening cyanosis or if oxygen saturation levels fall below 87%, prepare to give additional oxygen as ordered. Throughout care, strict asepsis, including handwashing, is vital to reduce the risk of infection.

Maintaining Thermal Regulation

Immediately after birth, dry the newborn with a warmed towel and then place him or her in a second warm, dry towel before performing the assessment. This drying prevents rapid heat loss secondary to evaporation. Newborns who are active, breathing well, and crying are stable and can be placed on their mother's chest ("kangaroo care") to promote warmth and prevent hypothermia. Preterm newborns who are not considered stable may be placed under a radiant warmer or in a warmed isolette after they are dried with a warmed towel.

Typically newborns use nonshivering thermogenesis for heat production by metabolizing their own brown adipose tissue. However, the preterm newborn has an inadequate supply of brown fat because he or she left the uterus before it was adequate. The preterm newborn also has decreased muscle tone and thus cannot assume the flexed fetal position, which reduces the amount of skin exposed to a cooler environment. In addition, preterm newborns have large body surface areas compared to weight. This allows an increased transfer of heat from their bodies to the environment.

Typically, a preterm newborn who is having problems with thermal regulation is cool to cold to the touch. The hands, feet, and tongue may appear cyanotic. Respirations are shallow or slow, or signs of respiratory distress are present. The newborn is lethargic and hypotonic, feeds poorly, and has a feeble cry. Blood glucose levels are probably low, leading to hypoglycemia, due to the energy expended to keep warm.

When promoting thermal regulation for the preterm newborn:

- Remember the four mechanisms for heat transfer and ways to prevent loss:
  - Convection: heat loss through air currents (avoid drafts near the newborn)
  - Conduction: heat loss through direct contact (warm everything the newborn comes in contact with, such as blankets, mattress, stethoscope)
  - Radiation: heat loss without direct contact (keep isolettes away from cold sources and provide insulation to prevent heat transfer)
  - Evaporation: heat loss by conversion of liquid into vapor (keep the newborn dry and delay the first bath until the baby's temperature is stable)

- Frequently assess the temperature of the isolette or radiant warmer, adjusting the temperature as necessary to prevent hypo- or hyperthermia.
- Assess the newborn's temperature every hour until stable.
- Observe for clinical signs of cold stress, such as respiratory distress, central cyanosis, hypoglycemia, lethargy, weak cry, abdominal distention, apnea, bradycardia, and acidosis.
- Remember the complications of hypothermia and frequently assess the newborn for signs:
  - Metabolic acidosis secondary to anaerobic metabolism used for heat production, which results in the production of lactic acid
  - Hypoglycemia due to depleted glycogen stores
  - Pulmonary hypertension secondary to pulmonary vasoconstriction
- Monitor the newborn for signs of hyperthermia such as tachycardia, tachypnea, apnea, warm to touch, flushed skin, lethargy, weak or absent cry, and CNS depression; adjust the environmental temperature appropriately.
- Explain to the parents the need to maintain the newborn's temperature, including the measures used; demonstrate ways to safeguard warmth and prevent heat loss.

Promoting Nutrition and Fluid Balance

Providing nutrition is challenging for preterm newborns because their needs are great but their ability to take in optimal amounts of energy/calories is reduced due to their compromised health status. Individual nutritional needs are highly variable.

Depending on their gestational age, preterm newborns receive nutrition orally, enterally, or parenterally via infusion. Several different methods can be used to provide nutrition: parenteral feedings administered through a percutaneous central venous catheter for long-term venous access with delivery of total parenteral nutrition (TPN), or enteral feedings, which can include oral feedings (formula or breast milk), continuous nasogastric tube feedings, or intermittent gavage tube feedings. Gavage feedings are commonly used for compromised newborns to allow them to rest during the feeding process. Many have a weak suck and become fatigued and thus cannot consume enough calories to meet their needs.

Most newborns born after 34 weeks' gestation without significant complications can feed orally. Those born before 34 weeks' gestation typically start with parenteral nutrition within the first 24 hours of life. Then enteral nutrition is introduced and advanced based on the degree of maturity and clinical condition. Ultimately, enteral nutrition methods replace parenteral nutrition.

To promote nutrition and fluid balance in the preterm newborn:

- Measure daily weight and plot it on a growth curve.
- Monitor intake; calculate fluid and caloric intake daily.
- Assess fluid status by monitoring weight; urinary output; urine specific gravity; laboratory test results such as serum electrolyte levels, blood urea nitrogen, creatinine, and hematocrit; skin turgor; and fontanels (Kenner & Lott, 2007). Be alert for signs of dehydration, such as a decrease in urinary output, sunken fontanels, temperature elevation, lethargy, and tachypnea.
- Continually assess for enteral feeding intolerance; measure abdominal girth, auscultate bowel sounds, and measure gastric residuals before the next tube feeding.
- Encourage and support breastfeeding by facilitating maternal breast pumping.
- Encourage nuzzling at the breast in conjunction with kangaroo care if the newborn is stable.

▶ *Take* NOTE!

When assessing the fluid status of a preterm newborn, palpate the fontanels. Sunken fontanels suggest dehydration; bulging fontanels suggest overhydration.

Preventing Infection

Prevention of infection is critical when caring for preterm newborns. Infections are the most common cause of morbidity and mortality in the NICU population (Kenner & Lott, 2007). Nursing assessment and early identification of problems are imperative to improve outcomes.

Preterm newborns are at risk for infection because their early birth deprived them of maternal antibodies needed for passive protection. Preterm newborns also are susceptible to infection because of their limited ability to produce antibodies, asphyxia at birth, and thin, friable skin that is easily traumatized, providing an entry portal for microorganisms.

Early detection is crucial. The clinical manifestations can be nonspecific and subtle: apnea, diminished activity, poor feeding, temperature instability, respiratory distress, seizures, tachycardia, hypotonia, irritability, pallor, jaundice, and hypoglycemia. Report any of these to the primary care provider immediately so that treatment can be instituted.

Include the following interventions when caring for a preterm or postterm newborn to prevent infection:

- Assess for risk factors in maternal history that place the newborn at increased risk.
- Monitor for changes in vital signs such as temperature instability, tachycardia, or tachypnea.
- Assess oxygen saturation levels and initiate oxygen therapy as ordered if oxygen saturation levels fall below acceptable parameters.
- Assess feeding tolerance, typically an early sign of infection.

- Monitor laboratory test results for changes.
- Avoid using tape on the newborn's skin to prevent tearing.
- Use equipment that can be thrown away after use.
- Adhere to standard precautions; use clean gloves to handle dirty diapers and dispose of them properly.
- Use sterile gloves when assisting with any invasive procedure; attempt to minimize the use of invasive procedures.
- Remove all jewelry on your hands prior to washing hands; wash hands upon entering the nursery and in between caring for newborns.
- Avoid coming to work when ill, and screen all visitors for contagious infections.

Preventing Complications

Preterm newborns face a myriad of possible complications as a result of their fragile health status or the procedures and treatments used. Some of the more common complications in preterm newborns include respiratory distress syndrome, periventricular-intraventricular hemorrhage, bronchopulmonary dysplasia, ROP, hyperbilirubinemia, anemia, necrotizing enterocolitis, hypoglycemia, infection or septicemia, delayed growth and development, and mental or motor delays (March of Dimes, 2007b). Several of these complications are described in Chapter 24.

Remember Anna, who was in a state of shock when she entered the NICU to see her preterm baby for the first time? How could the nurse have prepared her for this event? What information needs to be given at the isolette to reduce her anxiety and fear now?

Providing Appropriate Stimulation

Newborn stimulation involves a series of activities to encourage normal development. Research on developmental interventions shows that when preterm newborns, in particular, receive sensorimotor interventions such as rocking, skin-to-skin contact with parents, containment (swaddling and surrounded by blanket rolls), music, non-nutritive sucking, breastfeeding, massage, holding, or sleeping on waterbeds, they gain weight faster, progress in feeding abilities more quickly, and show improved interactive behavior compared to preterm newborns who were not stimulated (Field et al., 2006). Conversely, overstimulation may have negative effects by reducing oxygenation and causing stress. A newborn reacts to stress by flaying the hands or bringing an arm up to cover the face. When overstimulated, such as by noise, lights, excessive handling, alarms, and procedures, and stressed, heart and respiratory rates decrease and periods of apnea or bradycardia may follow (Blackburn, 2007).

Appropriate developmental stimulation that would not overtax the compromised newborn might include kangaroo (skin-to-skin) holding, rocking, soft singing or music, cuddling, gentle stroking of the infant's skin, colorful mobiles, gentle massage, waterbed mattresses, and non-nutritive sucking opportunities (Fig. 23.5) or providing sucrose if tolerated.

FIGURE 23.5 A preterm newborn receiving non-nutritive sucking.

The NICU environment can be altered to provide periods of calm and rest for the newborn by dimming the lights, lowering the volume and tone of conversations, closing doors gently, setting the telephone ringer to the lowest volume possible, clustering nursing activities, and covering the isolette with a blanket to act as a light shield to promote rest at night.

Encourage parents to hold and interact with their newborn. Doing so helps to acquaint the parents with their newborn, promotes self-confidence, and fosters parent–newborn attachment (Fig. 23.6).

Think back to Anna, the woman who gave birth to a preterm newborn at 7 months' gestation. Anna will be discharged but her newborn will be staying in the NICU for a while. What interventions would be appropriate to facilitate bonding despite their separation? What support can be provided specifically to her family?

Managing Pain

Pain is an unpleasant sensory and emotional experience felt by all humans. Newborns feel pain and require the same level of pain assessment and management as adults. Common indicators of pain in the newborn who is unable

FIGURE 23.6 A mother bonding with her preterm newborn.

to vocalize include facial expressions, body movements, and physiologic changes (Kenner & Lott, 2007). Untreated pain in newborns may result in increased morbidity and length of stay in the NICU, exaggerated responses to pain in later life, and altered psychosocial development (Koeppel, 2007). Parents commonly expect that health care providers will use appropriate measure to prevent pain in their newborns, but there are gaps in knowledge about the most effective way to accomplish this.

Assessment of pain in the newborn remains a contentious and vexing problem. Newborns in the NICU are subjected to repeated procedures that cause them pain. Newborns, whether preterm, full term, or postterm, do experience pain, but the pain is difficult to validate with consistent behaviors. Considering that ill newborns undergo multiple noxious stimuli from invasive procedures, such as lumbar punctures, heel sticks, venipuncture, line insertions, chest tube placement, specimen collections, endotracheal intubation and suctioning, and mechanical ventilation, common sense would suggest that newborns experience pain from these many activities and interventions. However, pain management in infants was not addressed formally until various professional and accrediting organizations issued position statements and clinical recommendations in an effort to promote effective pain management (AAP, 2006a, 2006b). An international consortium established principles of newborn pain prevention and management that all nurses must be familiar with and apply (Box 23.4).

Several psychometric tools are available to assess pain in the newborn. Examples include the Pain Assessment Tool (PAT), which evaluates respirations, heart rate, oxygen saturation, and blood pressure; the Premature Infant Pain Profile (PIPP), which assesses heart rate and oxygen saturation; the CRIES tool (cry, requires oxygen, increased vital signs, expression and sleeplessness); and the Neonatal Infant Pain Scale (NIPS), which evaluates respiratory patterns. Most are based on facial expressions, crying patterns, change in vital signs, and body movements (AAP, 2006a). See Chapter 35 for a more in-depth discussion of pain assessment and management.

Nurses play a key role in assessing a newborn's pain level. Assess the newborn frequently. Pain is considered the "fifth vital sign" and should be assessed as frequently as the other four vital signs. Differentiate pain from agitation by observing for changes in vital signs, behavior, facial expression, and body movement. Suspect pain if the newborn exhibits the following:

- Sudden high-pitched cry
- Facial grimace with furrowing of brow and quivering chin
- Increased muscle tone
- Oxygen desaturation

BOX 23.4 Newborn Pain Prevention and Management Guidelines

- Newborn pain frequently goes unrecognized and undertreated.
- Pain assessment is an essential activity prior to pain management.
- Newborns experience pain, and analgesics should be given.
- A procedure considered painful for an adult should also be considered painful for a newborn.
- Developmental maturity and health status must be considered when assessing for pain in newborns.
- Newborns may be more sensitive to pain than adults.
- Pain behavior is frequently mistaken for irritability and agitation.
- Newborns are more susceptible to the long-term effects of pain.
- Adequate pain management may reduce complications and mortality.
- Nonpharmacologic measures can prevent, reduce, or eliminate newborn pain.
- Sedation does not provide pain relief and may mask pain responses.
- A newborn's response to both pharmacologic and nonpharmacologic pain therapy should be assessed within 30 minutes of administration or intervention.
- Health care professionals are responsible for pain assessment and treatment.
- Written guidelines are needed on each newborn unit.

Source: Kenner & Lott, 2007.

- Body posturing, such as squirming, kicking, arching
- Limb withdrawal and thrashing movements
- Increase in heart rate, blood pressure, pulse, and respirations
- Fussiness and irritability (Arenson & Drake, 2007)

The goals of pain management are to minimize the amount, duration, and severity of pain and to assist the newborn in coping. Effective pain management strategies for newborns include preventing, limiting, or avoiding noxious stimuli; using nonpharmacologic techniques to reduce pain; and administering pharmacologic agents when appropriate. Box 23.5 lists some of the more commonly used nonpharmacologic pain management techniques for the preterm newborn.

The number of analgesics available for use with preterm newborns is limited. Morphine and fentanyl, usually administered intravenously, are the most commonly used opioids for moderate to severe pain. Acetaminophen is effective for mild pain. Benzodiazepines are used as sedatives during painful procedures and can be combined with opioids for more effectiveness. Local or topical anesthetics (e.g., EMLA cream) also may be used before procedures such as venipuncture, lumbar puncture, and intravenous catheter insertion (AAP, 2006b).

Be vigilant in assessing for adverse effects (respiratory depression or hypotension) when administering pharmacologic agents for pain management, especially in preterm newborns with neurologic impairment. These negative effects are usually dose- and route-related, so be knowledgeable about the pharmacokinetics and therapeutic dosing of any drug administered.

BOX 23.5 Nonpharmacologic Techniques to Reduce Pain in the Preterm Newborn

- Gentle handling, rocking, caressing, cuddling, and massaging
- Rest periods before and after painful procedures
- Kangaroo care (skin-to-skin contact) during procedure
- Breastfeeding, if able, to reduce pain from minor procedures
- Use of a facilitated tuck (holding arms and legs in a flexed position)
- Application of topical anesthetics prior to venipuncture or lumbar puncture
- Swaddling and positioning to establish physical boundaries
- Non-nutritive sucking (pacifier dipped in sucrose) prior to procedure
- Minimal use of tape, with gentle removal to avoid skin tears
- Warm blankets for wrapping to facilitate relaxation
- Reduction of environmental stimuli by removing or turning down noxious stimuli such as noise from alarms, beepers, loud conversations, and bright lights
- Distraction, such as with colored objects or mobiles (AAP, 2006a, 2006b)

Promoting Growth and Development

In the late 1970s, researchers evaluated the NICU environment in terms of light and sound levels, caregiving activities, and handling of newborns. As a result of this research, many environmental modifications were made to reduce the stress and overstimulation of the NICU, and the concept of developmentally supportive care was introduced. Developmentally supportive care is defined as care of a newborn or infant to support positive growth and development. Developmental care focuses on what newborns or infants can do at that stage of development; it uses therapeutic interventions only to the point that they are beneficial; and it provides for the development of the newborn–family unit (Neonatal Handbook, 2007b).

Developmental care is a philosophy of care that requires rethinking the relationships between newborns, families, and health care providers. It includes a variety of activities designed to manage the environment and individualize the care of the preterm or high-risk ill newborn based on behavioral observations (see Evidence-Based Practice 23.1). The goal is to promote a stable, well-organized newborn who can conserve energy for growth and development (Hendricks-Munoz & Prendergast, 2007).

Developmental care includes these strategies:

- Clustering care to promote rest and conserve the infant's energy
- Flexed positioning to simulate in utero positioning
- Environmental management to reduce noise and visual stimulation
- Kangaroo care to promote skin-to-skin sensation
- Placement of twins in the same isolette or open crib to reduce stress
- Activities to promote self-regulation and state regulation:
  - Surrounding the newborn with nesting rolls/devices
  - Swaddling with a blanket to maintain the flexed position
  - Providing sheepskin or a waterbed to simulate the uterine environment
  - Providing non-nutritive sucking (calms the infant)
  - Providing objects to grasp (comforts the newborn)
- Promotion of parent–infant bonding by making parents feel welcome in the NICU
- Open, honest communication with parents and staff
- Collaboration with the parents in planning the infant's care (Davidson et al., 2007)

Developmental care can be fostered by clustering the lights in one area so that no lights are shining directly on newborns, installing visual alarm systems and limiting overhead pages to minimize noise, and monitoring continuous and peak noise levels. Nurses can play an active role

EVIDENCE-BASED PRACTICE 23.1
Promoting Development and Preventing Morbidity in Preterm Infants

● Study
Preterm newborns are at risk due to their immature body systems. This is compounded by the newborn's increased risk for complications and illnesses and his or her exposure to numerous stimuli in the NICU environment. Together, these stressors can interfere with the newborn's growth and development. Developmental care is a philosophy that includes a wide range of activities to manage the environment and individualize care. The belief is that it can reduce the effects of these stressors. Activities typically associated with developmental care include controlling external stimuli, clustering care activities, and positioning and swaddling the preterm newborn.

A study was done to examine the effects of developmental care on preterm newborns. The study evaluated relevant outcomes such as neurodevelopment, weight gain, length of hospital stay, duration of mechanical ventilation, and physiologic stress. A computerized search of all articles, controlled trials, and conference and symposia proceedings was done. Two independent experts identified the data from all relevant randomized trials that compared the elements of developmental care to routine nursery care for newborns less than 37 weeks' gestation. The researchers identified 36 controlled trials.

▲ Findings
Assessing the benefits of developmental care was difficult because most of the studies reviewed included multiple interventions and many of the trials had small sample sizes. Therefore, the authors could not determine whether any one intervention was more effective than another. Overall, they reported that developmental care had limited benefits and no major harmful effects. It had a limited benefit on decreasing moderate to severe chronic lung disease, decreasing the incidence of necrotizing colitis, and improving family outcomes. Evidence was also limited related to the long-term positive effect on behavior and movement at 5 years corrected age. However, individualized developmental care activities showed some positive effects in improving neurodevelopmental outcomes.

■ Nursing Implications
Although the study found that developmental care for preterm newborns was of limited benefit, it emphasized that this type of care had no major harmful effects. Nurses can integrate these findings into their care for preterm newborns with the understanding that they are beneficial but that the effect may be limited. Nurses can advocate for individualizing the activities involved in developmental care based on the newborn's needs. They also can play a key role in fostering research to help determine which stressors seem to be the most troublesome and which specific activities are of the greatest benefit. In addition, nurses can assist in identifying appropriate short- and long-term outcome measures.

Symington, A., & Pinelli, J. (2006). Developmental care for promoting development and preventing morbidity in preterm infants. *Cochrane Database of Systematic Reviews* 2006. Issue 2. Art. No.: CD001814. DOI: 10.1002/14651858.CD001814.pub2.

by serving on committees that address these issues. In addition, nurses can provide direct developmentally supportive care. Doing so involves careful planning of nursing activities to provide the ideal environment for the newborn's development. For example:

- Dim the lights and cover isolettes at night to simulate nighttime.
- Support early extubation from mechanical ventilation.
- Encourage early and consistent feedings with breast milk.
- Administer prescribed antibiotics judiciously.
- Position the newborn as if he or she was still in utero (a nesting fetal position).
- Promote kangaroo care by encouraging parents to hold the newborn against the chest for extended periods each day.
- Coordinate care to respect sleep and awake states.

Throughout the newborn's stay, work with the parents, developing a collaborative partnership so they feel comfortable caring for their newborn. Be prepared to make referrals to community support groups to enhance coping (McGrath, 2006).

Promoting Parental Coping
Generally, pregnancy and the birth of a newborn are exciting times, but when the newborn has serious, perhaps life-threatening problems, the exciting experience suddenly changes to one of anxiety, fear, guilt, loss, and grief.

Parents are typically unprepared for the birth of a preterm newborn and commonly experience an array of emotions, including disappointment, fear for the survival of the newborn, and anxiety due to the separation from their newborn immediately after birth (Mok & Sui, 2006). Early interruptions in the bonding process and concern

about the newborn's survival can create extreme anxiety and interfere with attachment (Mercer & Walker, 2006).

Nursing interventions aimed at reducing parental anxiety include:

- Reviewing with them the events that have occurred since birth
- Providing simple relaxation and calming techniques (visual imagery, breathing)
- Exploring their perception of the newborn's condition and offering explanations
- Validating their anxiety and behaviors as normal reactions to stress and trauma
- Providing a physical presence and support during emotional outbursts
- Exploring the coping strategies they used successfully in the past and encouraging their use now
- Encouraging frequent visits to the NICU
- Addressing their reactions to the NICU environment and explaining all equipment used
- Identifying family and community resources available to them (Franklin, 2006)

Preparing for Discharge

Discharge planning typically begins with evidence that recovery of the newborn is certain. However, the exact date of discharge may not be predictable. The goal of the discharge plan is to make a successful transition to home care. Essential elements for discharge are a physiologically stable infant, a family who can provide the necessary care with appropriate support services in place in the community, and a primary care physician available for ongoing care.

The care of each high-risk newborn after discharge requires careful coordination to provide ongoing multidisciplinary support for the family. The discharge planning team typically includes the parents, primary care physician, neonatologists, neonatal nurses, and a social worker. Other professionals, such as surgical specialists and pediatric subspecialists, occupational, physical, speech, and respiratory therapists, nutritionists, home health care nurses, and a case manager, may be included as needed. Critical components of discharge planning are summarized in Box 23.6.

Nurses involved in the discharge process are instrumental in bridging the gap between the hospital and home. Interventions typically include:

- Assessing the physical status of the mother and the newborn
- Discussing the early signs of complications and what to do if they occur
- Reinforcing instructions for infant care and safety
- Stressing the importance of proper car seat use
- Providing instructions for medication administration
- Reinforcing instructions for equipment operation, maintenance, and troubleshooting
- Teaching infant cardiopulmonary resuscitation and emergency care

BOX 23.6 Critical Components of Discharge Planning

- Parental education—involvement and support in newborn care during NICU stay will ensure their readiness to care for the infant at home
- Evaluation of unresolved medical problems—review of the active problem list and determination of what home care and follow-up is needed
- Implementation of primary care—completion of newborn screening tests, immunizations, examinations such as funduscopic exam for ROP, and hematologic status evaluation
- Development of home care plan, including assessment of:
  - Equipment and supplies needed for care
  - In-home caregiver's preparation and ability to care for infant
  - Adequacy of the physical facilities in the home
  - An emergency care and transport plan if needed
  - Financial resources for home care costs
  - Family needs and coping skills
  - Community resources, including how they can be accessed

- Demonstrating techniques for special care procedures such as dressings, ostomy care, artificial airway maintenance, chest physiotherapy, suctioning, and infant stimulation
- Providing breastfeeding support or instruction on gavage feedings
- Assisting with defining roles in the adjustment period at home
- Assessing the parents' emotional stability and coping status
- Providing support and reassurance to the family
- Reporting abnormal findings to the health care team for intervention
- Following up with parents to assure them that they have a "lifeline"

Dealing With Perinatal Loss

Perinatal loss is a profound experience for the family. It engenders a unique kind of mourning since the infant is so much a part of the parents' identity. Instead of celebrating a new life as they expected, parents are mourning the loss of dreams and hopes and the loss of an extension of themselves. NICU nurses face a difficult situation when caring for newborns who may not survive. Newborn death is incomprehensible to most parents. This makes the grieving process more difficult because what is happening "can't be real." Deciding whether to see, touch, or hold the dying newborn is extremely difficult for many parents. Nurses play a major role in assisting parents to make their dying newborn "real" to them by providing them with as

many memories as possible and encouraging them to see, hold, touch, dress, and take care of the infant and take photographs. These actions help to validate the parents' sense of loss, relive the experience, and attach significance to the meaning of loss. A lock of hair, a name card, or an identification bracelet may serve as important mementoes that can ease the grieving process. The memories created by these interventions can be useful allies in the grieving process and in resolving grief (Callister, 2006).

Parent–newborn interaction is vital to the normal processes of attachment and bonding. The detachment process involved in a newborn's death is equally important for parents. Nurses can aid in this process by helping parents to see their newborn through the maze of equipment, explaining the various procedures and equipment, encouraging them to express their feelings about the newborn's status, and providing time for them to be with their dying newborn (Kavanaugh & Moro, 2006).

A common reaction by many people when learning that a newborn is not going to survive is one of avoidance. Nurses are no exception. It is difficult to initiate a conversation about such a sensitive issue without knowing how the parents are going to react and cope with the impending loss. One way to begin a conversation with the parents is to convey concern and acknowledge their loss. Active listening can give parents a safe place to begin the healing process. The relationship that the nurse establishes with the parents is a unique one, providing an opportunity for both the nurse and the parents to share their feelings.

Be aware of personal feelings about loss and how these feelings are part of one's own life and personal belief system. Actively listen to the parents when they are talking about their experiences. Communicate empathy (understanding and feeling what another person is feeling), respect their feelings, and respond to them in helpful and supportive ways (Kavanaugh & Moro, 2006). Table 23.2 highlights appropriate interventions for a family experiencing a perinatal loss before and after a newborn dies.

In a time of crisis or loss, individuals are often more sensitive to other people's reactions. For example, the parents may be extremely aware of the nurse's facial expressions, choice of words, and tone of voice. Talking quickly,

TABLE 23.2 ASSISTING PARENTS TO COPE WITH PERINATAL LOSS

Before the newborn's death	Respect variations in the family's spiritual needs and readiness. Assess cultural beliefs and practices that may bring comfort; respect culturally appropriate requests for truth telling and informed refusal. Initiate spiritual comfort by calling the hospital clergy if appropriate; offer to pray with the family if appropriate. Encourage the parents to take photographs, make memory boxes, and record their thoughts in a journal. Explore with family members how they dealt with previous losses. Discuss techniques to reduce stress, such as meditation and relaxation. Recommend that family members maintain a healthy diet and get adequate rest and exercise to preserve their health. Participate in early and repeated care conferencing to reduce family stress. Allow family to be present at both medical rounds and resuscitation; provide explanations of all procedures, treatments, and findings; answer questions honestly and as completely as possible. Provide opportunities for the family to hold the newborn if they choose to. Assess the family's support network. Provide suggestions as to how friends can be helpful to the family.
After the newborn's death	Help the family to accept the reality of death by using the word "died." Acknowledge their grief and the fact that their newborn has died. Help the family to work through their grief by validating and listening. Provide the family with realistic information about the causes of death. Offer condolences to the family in a sincere manner. Encourage the father to cry and grieve with his partner. Provide opportunities for the family to hold the newborn if they desire.
At the time of the release of the newborn's body	Reassure the family that their feelings and grieving responses are normal. Encourage the parents to have a funeral or memorial service to bring closure. Suggest that the parents plant a tree or flowers to remember the infant. Address attachment issues concerning subsequent pregnancies. Provide information about local support groups. Provide anticipatory guidance regarding the grieving process. Present information about any impact on future childbearing, and refer the parents to appropriate specialists or genetic resources.

in a businesslike fashion, or ignoring the loss may inhibit parents from discussing their pain or how they are coping with it. Parents may need to vent their frustrations and anger, and the nurse may become the target. Validate their feelings and attempt to reframe or refocus the anger toward the real issue of loss. An example would be to say, "I understand your frustration and anger about this situation. You have experienced a tremendous loss and it must be difficult not to have an explanation for it at this time." Doing so helps to defuse the anger while allowing them to express their feelings.

When assisting bereaved parents, start where the parents are in the grief process to avoid imposing your own agenda on them. You may feel uncomfortable at not being able to change the situation or take the pain away. The nurse's role is to provide immediate emotional support and facilitate the grieving process. Supporting and strengthening the family bond in the face of perinatal loss is essential.

LATE PRETERM NEWBORN

A late preterm newborn is an infant born between 34 weeks and 36 weeks, 6 days of gestation. In recent years, the subject of late preterm birth has received much attention, since this population of preterm newborns represents more than 70% of all preterm births in the United States and has increased by 30% in the past 20 years (National Center for Health Statistics, 2006). With the sharp rise in the number of cesarean births performed, the incidence of late preterm newborns will also rise. Perinatal nurses need to understand the risks of late preterm births and the unique needs of this population to facilitate timely assessment and intervention to improve outcomes.

Some of the challenges facing the late preterm newborn include respiratory distress (secondary to cesarean births, maternal gestational diabetes, chorioamnionitis, premature rupture of membranes, and fetal distress); thermoregulation issues related to limited ability to flex the trunk and extremities to decrease exposed surface area; hypoglycemia related to the first two challenges (respiratory distress and cold stress); jaundice and hyperbilirubinemia related to a gestational age of 36 weeks or less; and feeding challenges related to immature suck and swallowing reflexes (Askin et al., 2007). These challenges are similar to those facing the preterm newborn and require similar management. Nurses and parents must be aware of the risks associated with late preterm births to optimize care and outcomes for this group of newborns.

Key Concepts

- Variations in birthweight and gestational age can place a newborn at risk for problems that require special care.
- Variations in birthweight include the following categories: small for gestational age, appropriate for gestational age, and large for gestational age. Newborns who are small or large for gestational age have special needs.
- The small-for-gestational-age newborn faces problems related to a decrease in placental function in utero; these problems may include perinatal asphyxia, hypothermia, hypoglycemia, polycythemia, and meconium aspiration.
- Risk factors for the birth of a large-for-gestational-age infant include maternal diabetes mellitus or glucose intolerance, multiparity, prior history of a macrosomic infant, postdates gestation, maternal obesity, male fetus, and genetics. Large-for-gestational-age newborns face problems such as birth trauma due to cephalopelvic disproportion, hypoglycemia, and jaundice secondary to hyperbilirubinemia.
- Variations in gestational age include postterm and preterm newborns. Postterm newborns may be large or small for gestational age or dysmature, depending on placental function.
- The postterm newborn may develop several complications after birth, including fetal hypoxia, hypoglycemia, hypothermia, polycythemia, and meconium aspiration.
- Preterm birth is the leading cause of death within the first month of life and the second leading cause of all infant deaths.
- The preterm newborn is at risk for complications because his or her organ systems are immature, thereby impeding the transition from intrauterine life to extrauterine life.
- Newborns can experience pain, but their pain is difficult to validate with consistent behaviors.
- Newborns with gestational age variations, primarily preterm newborns, benefit from developmental care, which includes a variety of activities designed to manage the environment and individualize the care based on behavioral observations.
- Nurses play a key role in assisting the parents and family of a newborn with special needs to cope with this crisis situation, including dealing with the possibility that the newborn may not survive. Nurses working with parents experiencing a perinatal loss can help by actively listening, understanding the parents' experiences, and communicating empathy.
- The goal of discharge planning is to make a successful transition to home care.

Chapter Worksheet

Multiple Choice Questions

1. The nurse documents that a newborn is postterm based on the understanding that he was born after:
   a. 38 weeks' gestation
   b. 40 weeks' gestation
   c. 42 weeks' gestation
   d. 44 weeks' gestation
2. SGA and LGA newborns have an excessive number of red blood cells because of:
   a. Hypoxia
   b. Hypoglycemia
   c. Hypocalcemia
   d. Hypothermia
3. Because subcutaneous and brown fat stores were used for survival in utero, the nurse would assess an SGA newborn for which of the following?
   a. Hyperbilirubinemia
   b. Hypothermia
   c. Polycythemia
   d. Hypoglycemia
4. In assessing a preterm newborn, which of the following findings would be of greatest concern?
   a. Milia over the bridge of the nose
   b. Thin transparent skin
   c. Poor muscle tone
   d. Heart murmur
5. In dealing with parents experiencing a perinatal loss, which of the following nursing interventions would be most appropriate?
   a. Sheltering the parents from the bad news
   b. Making all the decisions regarding care
   c. Encouraging them to participate in the newborn's care
   d. Leaving them by themselves to allow time to grieve
6. The nurse is providing care to several newborns with variations in gestational age and birthweight. When developing the plan of care for these newborns, the nurse focuses on energy conservation to promote growth and development. Which measures would the nurse include in the nursing plans of care? Select all that apply.
   a. Keeping the handling of the newborn to a minimum
   b. Maintaining a neutral thermal environment
   c. Decreasing environmental stimuli
   d. Initiating early oral feedings
   e. Using thermal warmers in all cribs
7. Which of the following concepts would the nurse incorporate into the plan of care when assessing pain in a newborn with special needs?
   a. Newborns experience pain primarily with surgical procedures.
   b. Preterm newborns in the NICU are at least risk for pain.
   c. Pain assessment needs to be comprehensive and frequent.
   d. A newborn's facial expression is the primary indicator of pain.

Critical Thinking Exercises

1. After fetal distress was noted on the monitor, a postterm newborn was delivered via a difficult vacuum extraction. The newborn had low Apgar scores and had to be resuscitated before being transferred to the nursery. Once admitted, the nurse observed the following behaviors: jitteriness, tremors, hypotonia, lethargy, and rapid respirations.
   a. What might these behaviors indicate?
   b. For what other conditions might this newborn be at high risk?
   c. What intervention is needed to address this newborn's condition?
2. A preterm newborn was born at 35 weeks following an abruptio placentae due to a car accident. He was transported to the NICU at a nearby regional medical center. After being stabilized, he was placed in an isolette close to the door and placed on a cardiac monitor. A short time later, the nurse notices that he is cool to the touch and lethargic, has a weak cry, and has an axillary temperature of 36°C.
   a. What might have contributed to this newborn's hypothermic condition?

b. What transfer mechanism may have been a factor?

c. What intervention would be appropriate for the nurse to initiate?

3. A term SGA newborn weighing 4 lb was brought to the nursery for admission a short time after birth. The labor and birth nurse reports the mother was a heavy smoker and a cocaine addict and experienced physical abuse throughout her pregnancy. After stabilizing the newborn and correcting the hypoglycemia with oral feedings, the nurse observes the following: acrocyanosis, ruddy color, poor circulation to the extremities, tachypnea, and irritability.

   a. What complication might this SGA newborn be manifesting?

   b. What factors may have contributed to this complication?

   c. What would be an appropriate intervention to manage this condition?

Study Activities

1. At a community health department maternity clinic, secure permission to interview the parents of a special needs child. Ask about their feelings throughout the experience. How are they managing and coping now?

2. Visit the March of Dimes website and review this group's national campaign to reduce the incidence of prematurity. Are their strategies workable or not? Explain your reasoning.

3. A common metabolic disorder present in both SGA and LGA newborns after birth is _____.

4. A 10-lb LGA newborn is brought to the nursery after a difficult vaginal birth. The nursery nurse should focus on detecting birth injuries such as _____.

CHAPTER 24

Nursing Management of the Newborn at Risk: Acquired and Congenital Newborn Conditions

KEY TERMS

alcohol-related birth defects
asphyxia
caput succedaneum
cephalhematoma
fetal alcohol spectrum disorder
fetal alcohol syndrome
gastrochisis
hyperbilirubinemia
infant of a diabetic mother
kernicterus
meconium aspiration syndrome
neonatal abstinence syndrome
neonatal sepsis
omphalocele
respiratory distress syndrome

LEARNING OBJECTIVES

After completion of the chapter, the learner will be able to:

1. Identify the most common acquired conditions affecting the newborn.
2. Describe the nursing management of a newborn experiencing respiratory distress syndrome.
3. Outline the birthing room preparation and procedures necessary to prevent meconium aspiration syndrome in the newborn at birth.
4. Differentiate risk factors for the development of necrotizing enterocolitis.
5. Explain the impact of maternal diabetes on the newborn and the care needed.
6. Describe the assessment and intervention for a newborn experiencing substance withdrawal after birth.
7. Identify assessment and nursing management for newborns sustaining trauma and birth injuries.
8. Outline the assessment, interventions, prevention, and management of hyperbilirubinemia in newborns.
9. Summarize the interventions appropriate for a newborn with neonatal sepsis.
10. Describe four gastrointestinal system congenital anomalies that can occur in a newborn.

Kelly, a 27-year-old G2P1, comes to the labor and birth area in active labor. She tells you she is overdue and relieved to finally be giving birth. Her membranes rupture on admission, revealing meconium-stained fluid. What additional nursing assessments need to be carried out now? What risk factors need to be considered in when developing Kelly's plan of care?

Wow

Courage and faith in oneself project onto others, giving them the strength to persevere.

LEARNING OBJECTIVES (continued)

11. Formulate a plan of care for a newborn with an acquired or congenital condition.
12. Discuss the importance of parental participation in care of the newborn with a congenital or acquired condition, including the nurse's role in facilitating parental involvement.

Advances in prenatal and neonatal medical and nursing care throughout the industrialized world have led to a marked increase in the number of newborns who have survived a high-risk pregnancy but experience acquired or congenital conditions. These newborns are considered at risk: that is, they are susceptible to morbidity and mortality because of the acquired or congenital disorder. Several National Health Goals address the issues of acquired and congenital conditions in newborns (Healthy People 2010 24.1).

Technological and pharmacologic advances, in conjunction with standardized policies and procedures, over the past several decades have significantly improved survival rates for at-risk newborns. However, morbidity remains an important sequela. For example, some of these newborns are at risk for continuing health problems that require long-term technological support. Other newborns remain at risk for physical and developmental problems into the school years and beyond. Providing the complex care needed to maintain the child's health and well-being will have a tremendous emotional and economic impact on the family. Nurses are challenged to provide support to mothers and their families when neonatal well-being is threatened.

Acquired disorders typically occur at or soon after birth. They may result from problems or conditions experienced by the woman during her pregnancy or at birth, such as diabetes, maternal infection, or substance abuse, or conditions associated with labor and birth, such as prolonged rupture of membranes or fetal distress. However, there may be no identifiable cause for the disorder.

Congenital disorders are disorders present at birth, usually due to some type of malformation that occurred during the antepartal period. Congenital disorders, which typically involve a problem with inheritance, include structural anomalies (commonly referred to as birth defects), chromosomal disorders, and inborn errors of metabolism. Most congenital disorders have a complex etiology, involving many interacting genes, gene products, and social and environmental factors during organogenesis. Some alterations can be prevented or compensated for with pharmacologic, nutritional, or other types of interventions, while others cannot be changed. Only through a better understanding of the complex interplay of genetic, environmental, social, and cultural factors can these devastating and life-changing outcomes be prevented (Arenson & Drake, 2007).

This chapter addresses selected acquired and congenital newborn conditions. In addition, it describes the nurse's role in assessment and management, emphasiz-

HEALTHY PEOPLE 2010

Objective	Significance
1. Reduce fetal and infant deaths Decrease the number of all infant deaths (within 1 year) from a baseline of 7.2/ 1,000 live births to 4.5/ 1,000 live births. Decrease the number of neonatal deaths (within the first 28 days of life) from a baseline of 4.8 to 2.9 deaths/ 1,000 live births. Decrease the number of post-neonatal deaths from a baseline of 2.4 to 1.2 deaths/ 1,000 live births. Reduce the number of deaths related to all birth defects from a baseline of 1.6 to 1.1 deaths/1,000 live births.	Will foster early and consistent prenatal care, including education to place infants on their backs for naps and sleeping to prevent SIDS and avoidance of exposing the newborn to cigarette smoke
2. Reduce the occurrence of developmental disabilities Reduce the number of children with mental retardation from a baseline of 131 to 124 children/10,000. Reduce the number of children with cerebral palsy from a baseline of 32.2 to 31.5 children/ 10,000. Reduce the number of children with autism spectrum disorder.	Will promote measures for close antepartal and intrapartal monitoring of women at risk, subsequently reducing the incidence of disabilities, leading to a reduction in long-term effects and costs of care
3. Reduce the occurrence of fetal alcohol syndrome	Will foster programs for at-risk groups, including adolescents, about the effects of substance abuse, especially alcohol, during pregnancy

DHHS, 2000; available online at www.healthypeople.gov

ing parental education and support. Nurses play a key role in helping the parents cope with the stress of having an ill newborn.

Acquired Disorders

NEONATAL ASPHYXIA

As the newborn makes the transition to life outside the fluid-filled intrauterine environment, dramatic changes must occur to facilitate newborn respirations. Newborns normally start to breathe with routine warming, drying, airway suctioning, and mild stimulation. Most newborns make this transition such that by 1 minute of age, they are breathing well on their own. A newborn who fails to establish adequate, sustained respiration after birth is said to have **asphyxia**. Physiologically, asphyxia can be defined as impairment in gas exchange resulting in a decrease in blood oxygen levels (hypoxemia) and an excess of carbon dioxide or hypercapnia that leads to acidosis.

Asphyxia is the most common clinical insult in the perinatal period. As many as 10% of newborns require some degree of active resuscitation to stimulate breathing (Cunningham et al., 2005). According to the World Health Organization, 4 to 9 million cases of neonatal asphyxia occur annually worldwide, accounting for approximately 20% of all newborn deaths. More than a million newborns who survive asphyxia at birth develop long-term problems such as cerebral palsy, mental retardation, and speaking, hearing, visual, and learning disabilities (Maternal and Neonatal Health [MNH], 2007).

Pathophysiology

Asphyxia occurs when oxygen delivery is insufficient to meet metabolic demands, resulting in hypoxia, hypercarbia, and metabolic acidosis. Any condition that reduces oxygen delivery to the fetus can result in asphyxia. These conditions may include maternal hypoxia, such as from cardiac or respiratory disease, anemia, or postural hypotension; maternal vascular disease that leads to placental insufficiency, such as diabetes or hypertension; cord problems such as compression or prolapse; and postterm pregnancies, which may trigger meconium release into the amniotic fluid.

Initially, the newborn uses compensatory mechanisms including tachycardia and vasoconstriction to help bring oxygen to the vital organs for a time. However, without intervention, these mechanisms fail, leading to hypotension, bradycardia, and eventually cardiopulmonary arrest.

With failure to breathe well after birth, the newborn will develop hypoxia (too little oxygen in the cells of the body). As a result, the heart rate falls, cyanosis develops, and the newborn becomes hypotonic and unresponsive.

Think back to Kelly, described at the beginning of the chapter. She gives birth to a son weighing approximately 2,500 g; he appears postterm and small for gestational age. His skin is stained yellow-green and he is limp, cyanotic, and apneic at birth. The initial assessment once the newborn is under the radiant warmer indicates that resuscitation and tracheal suctioning are needed. What is the nurse's role during resuscitation? What assessments will be needed during this procedure?

Nursing Assessment

The key to successful treatment of newborn asphyxia is early identification and recognition of newborns who may be at risk. Review the perinatal history for risk factors, including:

- Trauma: injury to the central or peripheral nervous system secondary to a long or difficult labor, a precipitous birth, multiple gestation, abnormal presentation, cephalopelvic disproportion, shoulder dystocia, or extraction by forceps or vacuum
- Intrauterine asphyxia: for example, fetal hypoxia secondary to maternal hypoxia, diabetes, hypertension, anemia, cord compression, or meconium aspiration
- Sepsis: acquired bacterial or viral organisms from infected amniotic fluid, maternal infection, or direct contact while passing through the birth canal
- Malformation: congenital anomalies including facial or upper airway deformities, renal anomalies, pulmonary hypoplasia, neuromuscular disorders, esophageal atresia, or neural tube defects
- Hypovolemic shock: secondary to abruptio placentae, placenta previa, or cord rupture resulting in blood loss to the fetus
- Medication: drugs given to mother during labor that can affect the fetus by causing placental hypoperfusion and hypotension; use of hypnotics, analgesics, anesthetics, narcotics, oxytocin, and street drugs during pregnancy

At birth, assess the newborn immediately. Observe the infant's color, noting any pallor or cyanosis. Assess the work of breathing. Be alert for apnea, tachypnea, gasping respirations, grunting, nasal flaring, or retractions. Evaluate heart rate and note bradycardia. Assess the newborn's temperature, noting hypothermia. Determine the Apgar score at 1 and 5 minutes; an Apgar score below 7 at either time indicates that resuscitation is needed.

Anticipate diagnostic testing to identify etiologies for the newborn's asphyxia. For example, a chest x-ray may identify structural abnormalities that might interfere with respiration. A blood culture may identify an infectious process. A blood toxicology screen may detect any maternal drugs in the newborn (Kenner & Lott, 2007).

Nursing Management

Management of the newborn experiencing asphyxia includes immediate resuscitation. Ensure that the equipment needed for resuscitation is readily available and in working order. Essential equipment includes a wall suction apparatus, an oxygen source, a newborn ventilation bag, endotracheal tubes (2 to 3 mm), a laryngoscope, and ampules of naloxone (Narcan) with syringes and needles for administration (see Chapter 23 for a more detailed discussion of resuscitation).

Dry the newborn quickly with a warm towel and then place him or her under a radiant heater to prevent rapid heat loss through evaporation. Handling and rubbing the newborn with a dry towel may be all that is needed to stimulate the onset of breathing. If the newborn fails to respond to stimulation, then active resuscitation is needed.

The procedure for newborn resuscitation is easily remembered by the "ABCDs"—airway, breathing, circulation, and drugs (see Chapter 23, Box 23.3). Continue resuscitation until the newborn has a pulse above 100 bpm, a good cry, or good breathing efforts and a pink tongue. This last sign indicates a good oxygen supply to the brain (Brodsky & Ouellette, 2007).

▶ *Take* NOTE!

According to the American Heart Association and American Academy of Pediatrics Emergency Care Guidelines for Neonatal Resuscitation, resuscitation efforts may be stopped if the newborn exhibits no heart beat and no respiratory effort after 10 minutes of continuous and adequate resuscitation (AHA/AAP, 2005; Zaichkin, 2006).

Provide continued observation and assessment of the newborn who has been successfully resuscitated. Monitor the newborn's vital signs and oxygen saturation levels closely for changes. Maintain a neutral thermal environment to prevent hypothermia, which would increase the newborn's metabolic and oxygen demands. Check the blood glucose level and observe for signs of hypoglycemia; if this develops, it can further stress the newborn.

The need for resuscitative measures can be extremely upsetting for the parents. Explain to them the initial resuscitation activities being performed and offer ongoing explanations about any procedures being done, equipment being used, or medications given. Provide physical and emotional support to the parents through the initial crisis and throughout the newborn's stay. When the newborn is stable, allow parents to spend time with their newborn to promote bonding (Fig. 24.1). Point out the newborn's positive attributes and give frequent updates on his or her status. Role-model techniques for holding, interacting with, and caring for the newborn to decrease the parents' anxiety.

FIGURE 24.1 A father interacting with his newborn once the newborn's condition has stabilized.

Remember Kelly, the young woman described at the beginning of the chapter? Her son is intubated and tracheal suctioning is performed. Positive-pressure ventilation is also started with a self-inflating bag and 50% oxygen. Ventilation is continued for 1 minute and then gradually discontinued. The heart rate is now 120 bpm, and spontaneous respirations are noted. When free-flow oxygen is administered, the newborn begins to cry and turn pink. What continued care is needed in the special care nursery? What explanation should be offered to Kelly regarding her son?

TRANSIENT TACHYPNEA OF THE NEWBORN

Transient tachypnea of the newborn (TTN) is a condition involving a mild degree of respiratory distress. It is described as the retention of lung fluid or transient pulmonary edema (McLenan, 2007). It usually occurs within a few hours of birth and resolves by 72 hours of age. TTN occurs in approximately 11 per 1,000 live births (Asenjo, 2007).

Pathophysiology

Most newborns make the transition from fetal to newborn life without incident. During fetal life, the lungs are filled with a serous fluid because the placenta, not the lungs, is used for nutrient and gas exchange. During and after birth, this fluid must be removed and replaced with air. Passage through the birth canal during a vaginal birth

compresses the thorax, which helps remove the majority of this fluid. Pulmonary circulation and the lymphatic drainage remove the remaining fluid shortly after birth. TTN occurs when the liquid in the lung is removed slowly or incompletely.

Nursing Assessment

Astutely observe the newborn with respiratory distress because TTN is a diagnosis of exclusion. Initially it might be difficult to distinguish this condition from respiratory distress syndrome or group B streptococcal pneumonia, since the clinical picture is similar. However, the symptoms of transient tachypnea rarely last more than 72 hours (McLenan, 2007).

History and Physical Examination

Review the perinatal history for contributing factors. TTN is commonly seen in newborns who are sedated or have been born via cesarean birth. Also check the history for evidence of a prolonged labor, fetal macrosomia, and maternal asthma and smoking. These factors are associated with a higher incidence of TTN (Rodriguez, 2006).

Closely assess the newborn for signs of TTN. Within the first few hours of birth, observe for tachypnea, expiratory grunting, retractions, labored breathing, nasal flaring, and mild cyanosis (Asenjo, 2007). Mild to moderate respiratory distress is present by 6 hours of age, with respiratory rates as high as 100 to 140 breaths per minute (Kenner & Lott, 2007). Also inspect the newborn's chest for hyperextension or a barrel shape. Auscultate breath sounds, which may be slightly diminished secondary to reduced air entry.

Laboratory and Diagnostic Testing

To aid in the diagnosis, a chest x-ray may be done. It usually reveals mild symmetric lung overaeration and prominent perihilar interstitial markings and streaking. These findings correlate with lymphatic engorgement of retained fetal fluid (Asenjo, 2007).

Nursing Management

Nursing management focuses on providing adequate oxygenation and determining whether the newborn's respiratory manifestations appear to be resolving or persisting. Provide supportive care while the retained lung fluid is reabsorbed. Administer intravenous (IV) fluids and/or gavage feedings until the respiratory rate decreases enough to allow safe oral feeding. Provide supplemental oxygen via a nasal cannula or oxygen hood to maintain adequate oxygen saturation. Maintain a neutral thermal environment with minimal stimulation to minimize oxygen demand.

Provide ongoing assessment of the newborn's respiratory status. As TTN resolves, the newborn's respiratory rate declines to 60 breaths per minute or less, the oxygen requirement decreases, and the chest x-ray shows resolution of the perihilar streaking. Provide reassurance and progress reports to the parents to help them cope with this crisis.

RESPIRATORY DISTRESS SYNDROME

Despite improved survival rates and advances in perinatal care, many high-risk newborns are at risk for respiratory problems, particularly **respiratory distress syndrome** (RDS), a breathing disorder resulting from lung immaturity and lack of alveolar surfactant. Since the link between RDS and surfactant deficiency was discovered more than 30 years ago, tremendous strides have been made in understanding the pathophysiology and treatment of this disorder. The introduction of prenatal steroids to accelerate lung maturity and the development of synthetic surfactant can be credited with the dramatic improvements in the outcome of newborns with RDS (Rodriguez, 2006).

RDS affects an estimated 25,000 infants born alive in the United States annually. The incidence declines with degree of maturity at birth. It occurs in 60% of preterm newborns of less than 28 weeks' gestation, 30% of those born at 28 to 34 weeks, and less than 5% of those born after 34 weeks (American Lung Association [ALA], 2007). Intensive respiratory care, usually with mechanical ventilation, is necessary.

Pathophysiology

Lung immaturity and surfactant deficiency contribute to the development of RDS. Surfactant is a complex mixture of phospholipids and proteins that adheres to the alveolar surface of the lungs. Surfactant forms a coating over the inner surface of the alveoli, reducing the surface tension and preventing alveolar collapse at the end of expiration. In the affected newborn, surfactant is deficient or lacking, and this deficit results in stiff lungs and alveoli that tend to collapse, leading to diffuse atelectasis. The work of breathing is increased because increased pressure similar to that required to initiate the first breath is needed to inflate the lungs with each successive breath. Hypoxemia and acidemia result, leading to vasoconstriction of the pulmonary vasculature. Right-to-left shunting occurs and alveolar capillary circulation is limited, further inhibiting surfactant production. As the disease progresses, fluid and fibrin leak from the pulmonary capillaries, causing hyaline membranes to form in the bronchioles, alveolar ducts, and alveoli. These membranes further decrease gas exchange. A vicious cycle is created, compounding the problem (Blackburn, 2007).

Nursing Assessment

Nursing assessment focuses on keen observation to identify the signs and symptoms of respiratory distress. In addition, assessment aids in differentiating RDS from other

respiratory conditions, such as TTN or group B streptococcal pneumonia.

History and Physical Examination

Review the history for risk factors associated with RDS; these include perinatal asphyxia regardless of gestational age, cesarean birth in the absence of preceding labor (related to the lack of thoracic squeezing), male gender, and maternal diabetes. It is believed that each of these conditions has an impact on surfactant production, thus resulting in RDS in the term infant (Stoll & Kliegman, 2004).

▶ *Take* NOTE!

Prolonged rupture of membranes, intrauterine growth restriction (IUGR), gestational hypertension, maternal heroin addiction, and use of prenatal corticosteroids reduce the newborn's risk for RDS because of the physiologic stress imposed on the fetus. Chronic stress experienced by the fetus in utero accelerates the production of surfactant before the 35th week of gestation and thus reduces the incidence of RDS at birth.

The newborn with RDS usually demonstrates signs at birth or within a few hours of birth. Observe the infant for expiratory grunting, nasal flaring, chest wall retractions, see-saw respirations, and generalized cyanosis. Auscultate the heart and lungs, noting tachycardia (rates above 150 to 180), fine inspiratory crackles, and tachypnea (rates above 60 breaths per minute). Use the Silverman-Anderson index assessment tool to determine the degree of respiratory distress. The index involves observation of five features, each of which is scored as 0, 1, or 2 (Fig. 24.2). The higher the score, the greater the respiratory distress. A score over 7 suggests severe respiratory distress.

Laboratory and Diagnostic Testing

The diagnosis of RDS is based on the clinical picture and x-ray findings. A chest x-ray reveals hypoaeration, underexpansion, and a "ground glass" pattern (Brodsky & Ouellette, 2007; Mattson & Smith, 2004).

Nursing Management

If untreated, RDS will worsen. However, it appears to be a self-limiting disease, with respiratory symptoms declining after 72 hours. This decline parallels the production of surfactant in the alveoli (McLenan, 2007). The newborn needs supportive care until surfactant is produced. Effective therapies for established RDS include conventional mechanical ventilation, continuous positive airway pressure (CPAP), or positive end-expiratory pressure (PEEP) to prevent volume loss during expiration, and surfactant therapy. The use of exogenous surfactant replacement therapy to stabilize the newborn's lungs until postnatal surfactant synthesis matures has become a life-saver.

Care of the newborn with RDS is primarily supportive and requires a multidisciplinary approach to obtain the best outcomes. Therapy focuses on improving oxygenation and maintaining optimal lung volumes. Expect to transfer the newborn to the neonatal intensive care unit (NICU) soon after birth. Apply the basic principles of newborn care, such as thermoregulation, cardiovascular and nutritional support, normal glucose level maintenance, and infection prevention, to achieve the therapeutic goals of reducing mortality and minimizing lung trauma.

Anticipate the administration of surfactant replacement therapy, prophylactically or as a rescue approach. With prophylactic administration, surfactant is given within minutes after birth, thus providing replacement surfactant before severe RDS develops. Rescue treatment is indicated for newborns with established RDS who require mechanical ventilation and supplemental oxygen. The earlier the surfactant is administered, the better the effect on gas exchange (Kenner & Lott, 2007).

Administer the prescribed oxygen concentration via nasal cannula. Anticipate the need for ventilator therapy, which has greatly improved in the past several years, with significant advances in conventional and high-frequency ventilation therapies (Fig. 24.3). Recent studies show no difference in outcomes for newborns who received early treatment with high-frequency oscillatory ventilation compared with those receiving conventional mechanical ventilation (Blackburn, 2007). Although mechanical ventilation has increased survival rates, it is also a contributing factor to bronchopulmonary dysplasia, pulmonary hypertension, and retinopathy of prematurity (Cunningham et al., 2005).

In addition, support the newborn with RDS using the following interventions:

- Continuously monitor the infant's cardiopulmonary status via invasive or noninvasive means (e.g., arterial lines or auscultation, respectively).
- Monitor oxygen saturation levels continuously; assess pulse oximeter values to determine oxygen saturation levels.
- Closely monitor vital signs, acid–base status, and arterial blood gases.
- Administer broad-spectrum antibiotics if blood cultures are positive.
- Administer sodium bicarbonate or acetate as ordered to correct metabolic acidosis.
- Provide fluids and vasopressor agents as needed to prevent or treat hypotension.
- Test blood glucose levels and administer dextrose as ordered for prevention or treatment of hypoglycemia.
- Cluster caretaking activities to avoid overtaxing and compromising the newborn.
- Place the newborn in the prone position to optimize respiratory status and reduce stress.

Feature observed	Score 0	1	2
Chest movement	Synchronized respirations	Lag on respirations	Seesaw respirations
Intercostal retraction	None	Just visible	Marked
Xiphoid retraction	None	Just visible	Marked
Nares dilation	None	Minimal	Marked
Expiratory grunt	None	Audible by stethoscope	Audible by unaided ear

FIGURE 24.2 Assessing the degree of respiratory distress. (Used with permission from Silverman, W. A., & Anderson, D. H. [1956]. A controlled clinical trial of effects of water mist on obstructive respiratory signs, death rate, and necroscopy findings among premature infants. *Pediatrics, 17*[4], 1–9.)

FIGURE 24.3 A newborn with RDS receiving mechanical ventilation.

- Perform gentle suctioning to remove secretions and maintain a patent airway.
- Assess level of consciousness to identify intraventricular hemorrhage.
- Provide sufficient calories via gavage and IV feedings.
- Maintain adequate hydration and assess for signs of fluid overload.
- Provide information to the parents about treatment modalities; give thorough but simple explanations about the rationales for interventions.
- Encourage the parents to participate in care (Blackburn, 2007).

Provide ongoing assessment and be alert for complications. These may include air leak syndrome, bronchopulmonary dysplasia (chronic lung disease), patent ductus

arteriosus, congestive heart failure, intraventricular hemorrhage, retinopathy of prematurity, necrotizing enterocolitis, complications resulting from intravenous catheter use (infection, thrombus formation), and developmental delay or disability (Stoll & Kliegman, 2004).

MECONIUM ASPIRATION SYNDROME

Meconium is a viscous green substance composed primarily of water and other gastrointestinal secretions that can be noted in the fetal gastrointestinal tract as early as 10 to 16 weeks' gestation (Clark & Clark, 2007). It is expelled as the newborn's first stool after birth. **Meconium aspiration syndrome** occurs when the newborn inhales particulate meconium mixed with amniotic fluid into the lungs while still in utero or on taking the first breath after birth. It is a common cause of newborn respiratory distress and can lead to severe illness. Meconium staining of the amniotic fluid, with the possibility of aspiration, occurs in approximately 20% of pregnancies at term (Cunningham et al., 2005). Aspiration induces airway obstruction, surfactant dysfunction, hypoxia, and chemical pneumonitis with inflammation of pulmonary tissues. In severe cases, it progresses to persistent pulmonary hypertension and death (Cunningham et al., 2005). About 3% to 5% of infants with meconium aspiration syndrome die (Wiswell, Tin, & Ohler, 2007).

Pathophysiology

Meconium may be passed in utero secondary to hypoxic stress. Hypoxia induces the fetus to gasp or attempt to breathe. The fetus may bear down and pass meconium into the amniotic fluid or he or she may experience a vagal reflex that causes relaxation of the anal sphincter, allowing meconium to be passed into the amniotic fluid. The fetus then sucks or swallows this amniotic fluid in utero, or the infant may aspirate meconium with the first breath after birth as air rushes into the lungs.

Although the etiology is not well understood, the effects of meconium can be harmful to the fetus. Meconium alters the amniotic fluid by reducing antibacterial activity and subsequently increasing the risk of perinatal bacterial infection. Additionally, meconium is very irritating because it contains enzymes from the fetal pancreas.

When aspirated into the lungs, meconium blocks the bronchioles, causing an inflammatory reaction as well as a decrease in surfactant production. Gas exchange is impaired and atelectasis occurs. A ball–valve effect occurs when air is inspired into the alveoli but cannot be fully expired secondary to reduced airway diameter. Significant respiratory distress is followed by persistent pulmonary hypertension, right-to-left shunting of blood, and patent ductus arteriosus. Conventional mechanical ventilation, extracorporeal membrane oxygenation (ECMO), nitric oxide, high-frequency ventilation, or liquid ventilation may be necessary.

Nursing Assessment

Review prenatal and birth records to identify newborns who may be at high risk for meconium aspiration. Predisposing factors for meconium aspiration syndrome include postterm pregnancy; breech, forceps, or vacuum extraction births; prolonged or difficult labor associated with fetal distress in a term or postterm newborn; maternal hypertension or diabetes; oligohydramnios; IUGR; prolapsed cord; or acute or chronic placental insufficiency (Kenner & Lott, 2007).

Assess the amniotic fluid for meconium staining when the maternal membranes rupture. Green-stained amniotic fluid suggests the presence of meconium in the amniotic fluid and should be reported immediately. After birth, note any yellowish-green staining of the umbilical cord and nails and skin. This staining indicates that meconium has been present for some time.

Consider Kelly, the 27-year-old woman who gave birth to a son who required resuscitation. What findings would lead the nurse to suspect that her son aspirated meconium? What risk factors in Kelly's history would support the diagnosis of meconium aspiration syndrome?

Take NOTE!

Recent evidence suggests that newborns with meconium staining do not routinely require intrapartum suctioning (before the birth of the shoulders). Tracheal suctioning is warranted if the newborn does not exhibit a strong respiratory effort, good muscle tone, and a heart rate greater than 100 beats per minute (AHA/AAP, 2005).

Observe the newborn for a barrel-shaped chest with an increased anterior-posterior (AP) chest diameter (similar to that found in a patient with chronic obstructive pulmonary disease), prolonged tachypnea, progression from mild to severe respiratory distress, intercostal retractions, end-expiratory grunting, and cyanosis (Clark & Clark, 2007). Auscultate the lungs, noting coarse crackles and rhonchi.

Chest x-rays show patchy, fluffy infiltrates unevenly distributed throughout the lungs and marked hyperaeration mixed with areas of atelectasis. Arterial blood gas analysis will indicate metabolic acidosis with a low blood pH, decreased PaO_2, and increased $PaCO_2$ (Wiswell,

Tin, & Ohler, 2007). Direct visualization of the vocal cords for meconium staining using a laryngoscope can confirm the presence of meconium below the larynx.

Nursing Management

Nursing management focuses on ensuring adequate tissue perfusion and minimizing oxygen demand and energy expenditure. Caring for the newborn with meconium aspiration begins in the birthing unit when the birth attendant identifies meconium-stained amniotic fluid with membrane rupture during labor. Upon delivery of the newborn's head, before the newborn takes the first breath, the nasal cavity and then the posterior pharynx are gently suctioned to decrease the potential for aspiration. If the newborn is significantly depressed at birth, secondary clearing of the lower airways by direct tracheal suctioning may be necessary. Repeated suctioning and stimulation are limited to prevent overstimulation and further depression (Clark & Clark, 2007). Usually the newborn is transferred to the NICU for close monitoring.

Maintain a neutral thermal environment, including placing the newborn under a radiant warmer or in a warmed isolette, to prevent hypothermia. In addition, minimize handling to reduce energy expenditure and oxygen consumption that could lead to further hypoxemia and acidosis.

Administer oxygen therapy as ordered via nasal cannula or with positive-pressure ventilation. Monitor oxygen saturation levels via pulse oximetry to evaluate the newborn's response to treatment and to detect changes. Increased pulmonary pressures associated with meconium aspiration may cause blood to be shunted away from the lungs. The newborn may exhibit uneven pulmonary ventilation, with hyperinflation in some areas and atelectasis in others. This leads to poor perfusion and subsequent hypoxemia, which in turn may increase pulmonary vasoconstriction, resulting in a worsening of hypoxemia and acidosis.

Expect to administer hyperoxygenation to dilate the pulmonary vasculature and close the ductus arteriosus or nitric oxide inhalation to decrease pulmonary vascular resistance, or to use high-frequency oscillatory ventilation to increase the chance of air trapping (Clark & Clark, 2007). In addition, administer vasopressors and pulmonary vasodilators as prescribed and administer surfactant as ordered to counteract inactivation by meconium. Monitor arterial blood gas results for changes and assist with measures to correct acid–base imbalances to facilitate perfusion of tissues and prevent pulmonary hypertension (Cunningham et al., 2005). If these measures are ineffective, be prepared to assist with the use of ECMO, a modified type of heart–lung machine.

In addition, perform the following interventions:

- Cluster newborn care to minimize oxygen demand.
- Administer broad-spectrum antibiotics to treat bacterial pneumonia.
- Administer sedation to reduce oxygen consumption and energy expenditure.
- Continuously monitor the newborn's condition.
- Reassure and support the parents throughout the experience (McLenan, 2007).

PERSISTENT PULMONARY HYPERTENSION OF THE NEWBORN

Persistent pulmonary hypertension of the newborn, previously referred to as persistent fetal circulation, is a cardiopulmonary disorder characterized by marked pulmonary hypertension that causes right-to-left extrapulmonary shunting of blood and hypoxemia. Persistent pulmonary hypertension can occur idiopathically or as a complication of perinatal asphyxia, meconium aspiration syndrome, pneumonia, congenital heart defects, metabolic disorders such as hypoglycemia, hypothermia, hypovolemia, hyperviscosity, acute hypoxia with delayed resuscitation, sepsis, and RDS. It occurs in 2 to 6 newborns per 1,000 live births of term, near-term, or postterm infants (Steinhorn, 2007).

Pathophysiology

Normally, pulmonary artery pressure decreases when the newborn takes the first breath. However, interference with this ability to breathe allows pulmonary pressures to remain increased. Hypoxemia and acidosis also occur, leading to vasoconstriction of the pulmonary artery. These events cause an elevation in pulmonary vascular resistance. Normally, the decrease in pulmonary artery pressure and pulmonary vascular resistance with breathing leads to the closure of the ductus arteriosus and foramen ovale. However, with persistent pulmonary hypertension, pulmonary vascular resistance is elevated to the point that venous blood is diverted to some degree through fetal structures, such as the ductus arteriosus or foramen ovale, causing them to remain open, leading to a right-to-left shunting of blood into the systemic circulation. This diversion of blood bypasses the lungs, resulting in systemic arterial hypoxemia.

Nursing Assessment

Assess the newborn's status closely. A newborn with persistent pulmonary hypertension demonstrates tachypnea within 12 hours after birth. Observe for marked cyanosis, grunting, and retractions. Auscultate the heart, noting a systolic ejection murmur, and measure blood pressure for hypotension resulting from both heart failure and persistent hypoxemia (Kenner & Lott, 2007). Measure oxygen saturation via pulse oximetry and report low values. Prepare the newborn for an echocardiogram, which will reveal right-to-left shunting of blood that confirms the diagnosis.

Nursing Management

When caring for the newborn with persistent pulmonary hypertension, pay meticulous attention to detail, with continuous monitoring of the newborn's oxygenation and perfusion status and blood pressure. The goals of therapy include improving alveolar oxygenation, inducing metabolic alkalosis by administering sodium bicarbonate, correcting hypovolemia and hypotension with the administration of volume replacement and vasopressors, and anticipating use of ECMO when support has failed to maintain acceptable oxygenation (Steinhorn, 2007).

Provide immediate resuscitation after birth and administer oxygen therapy as ordered. Early and effective resuscitation and correction of acidosis and hypoxia are helpful in preventing persistent pulmonary hypertension. Monitor arterial blood gases frequently to evaluate the effectiveness of oxygen therapy. Provide respiratory support, which frequently necessitates the use of mechanical ventilation. Administer prescribed medications, monitor cardiopulmonary status, cluster care to reduce stimulation, and provide support and education to the parents.

▶ *Take* NOTE!

Almost any procedure, such as suctioning, weighing, changing diapers, or positioning, can precipitate severe hypoxemia due to the instability of the pulmonary vasculature. Therefore, minimize the newborn's exposure to stimulation as much as possible.

PERIVENTRICULAR–INTRAVENTRICULAR HEMORRHAGE

Periventricular–intraventricular hemorrhage is defined as bleeding that usually originates in the subependymal germinal matrix region of the brain, with extension into the ventricular system (Brodsky & Ouellette, 2007). It is a common problem in preterm infants, especially in those born before 32 weeks. A significant number of these newborns will incur brain injury, leading to complications that may include hydrocephalus, seizure disorders, periventricular leukomalacia (an ischemic injury resulting from inadequate perfusion of the white matter adjacent to the ventricles), cerebral palsy, learning disabilities, vision or hearing deficits, and mental retardation. Identifying preventive strategies to reduce the incidence of these brain insults is a national public health priority (McLenan, 2007).

The incidence of ventricular hemorrhage depends on the gestational age at birth. Up to 50% of newborns weighing 1,500 g or less or born at 30 weeks' gestation or less will have evidence of hemorrhage. Only about 4% of term newborns show evidence of ventricular hemorrhage. Very-low-birthweight infants have the earliest onset of hemorrhage and the highest mortality rate (Brodsky & Ouellette, 2007).

Pathophysiology

The preterm newborn is at greatest risk for periventricular–intraventricular hemorrhage because cerebral vascular development is immature, making it more vulnerable to injury. The earlier the newborn is, the greater the likelihood for brain damage. While all areas of the brain can be injured, the periventricular area is the most vulnerable.

Each ventricular area contains a rich network of capillaries that are very thin and fragile and can rupture easily. The causes of rupture vary and include fluctuations in systemic and cerebral blood flow, increases in cerebral blood flow from hypertension, IV infusions, seizure activity, increases in cerebral venous pressure due to vaginal delivery, hypoxia, and respiratory distress. With a preterm birth, the fetus is suddenly transported from a well-controlled uterine environment into a highly stimulating one. This tremendous physiologic stress and shock may contribute to the rupture of periventricular capillaries and subsequent hemorrhage. Most hemorrhages occur in the first 72 hours after birth (Cunningham et al., 2005).

Periventricular–intraventricular hemorrhage is classified according to a grading system of I to V (least severe to most severe) (Blackburn, 2007). The prognosis is guarded, depending on the grade and severity of the hemorrhage. Generally, newborns with mild hemorrhage (grades I and II) have a much better developmental outcome than those with severe hemorrhage (grades III and IV).

Nursing Assessment

The signs of periventricular–intraventricular hemorrhage vary significantly; no clinical signs may be evident. Closely monitor newborns who are at an increased risk, such as those who are preterm or of low birthweight. Also assess for risk factors such as acidosis, asphyxia, unstable blood pressure, meningitis, seizures, acute blood loss, hypovolemia, respiratory distress with mechanical ventilation, intubation, apnea, hypoxia, suctioning, use of hyperosmolar solutions, rapid volume expansion, and activities that involve handling.

Evaluate the newborn for an unexplained drop in hematocrit, pallor, and poor perfusion as evidenced by respiratory distress and oxygen desaturation. Note seizures, lethargy or other changes in level of consciousness, weak suck, high-pitched cry, or hypotonia. Palpate the anterior fontanel for tenseness. Assess vital signs, noting bradycardia and hypotension. Evaluate laboratory data for changes indicating metabolic acidosis or glucose instability (Annibale & Hill, 2007). Frequently a bleed can progress rapidly

and result in shock and death. Prepare the newborn for cranial ultrasonography, the diagnostic tool of choice to detect hemorrhage.

Nursing Management

Prevention of preterm birth is essential in preventing periventricular–intraventricular hemorrhage. Promote community awareness of factors that may contribute to periventricular–intraventricular hemorrhage, such as a lack of prenatal care, maternal infection, alcohol consumption, and smoking (Kenner & Lott, 2007). Identify risk factors that can lead to hemorrhage, and focus care on interventions to decrease the risk of hemorrhage. For example, institute measures to prevent perinatal asphyxia and birth trauma and provide developmental care in the NICU. If a preterm birth is expected, having the mother deliver at a tertiary care facility with a NICU would be most appropriate.

Care of the newborn with periventricular-intraventricular hemorrhage is primarily supportive. Correct anemia, acidosis, and hypotension with fluids and medications. Administer fluids slowly to prevent fluctuations in blood pressure. Avoid rapid volume expansion to minimize changes in cerebral blood flow. Keep the newborn in a flexed, contained position with the head elevated to prevent or minimize fluctuations in intracranial pressure. Continuously monitor the newborn for signs of hemorrhage, such as changes in the level of consciousness, bulging fontanel, seizures, apnea, and reduced activity level. Also, measure head circumference daily.

Minimize handling of the newborn by clustering nursing care, and limit stimulation in the newborn's environment to reduce stress. Also reduce the newborn's exposure to noxious stimuli to avoid a fluctuation in blood pressure and energy expenditure. Provide adequate oxygenation to promote tissue perfusion but controlled ventilation to decrease the risk of pneumothorax.

Support for the parents to cope with the diagnosis and potential long-term sequelae is essential. The long-term neurodevelopmental outcome is determined by the severity of the bleed. Provide education and emotional support for the parents throughout the newborn's stay. Discuss expectations for short-term and long-term care needs with the parents and assist them in obtaining the necessary support from appropriate community resources.

NECROTIZING ENTEROCOLITIS

Necrotizing enterocolitis (NEC) is a serious gastrointestinal disease occurring in newborns. It is the most common and most serious acquired gastrointestinal disorder among hospitalized preterm neonates and is associated with significant acute and chronic morbidity and mortality (Stoll & Kliegman, 2007). NEC occurs in 1 to 3 cases per 1,000 live births, affecting 1% to 5% of all newborns in intensive care units (Stoll & Kliegman, 2007). Attempts to improve gastrointestinal function and reduce the risk of NEC include enteral antibiotics, judicious administration of parenteral fluids, human milk feedings, antenatal corticosteroids, enteral probiotics (*Lactobacillus acidophilus*), and slow continuous drip feedings (Neu, 2007).

Pathophysiology

The pathophysiology of NEC is not clearly understood and is thought to be multifactorial in nature. Current research points to three major pathologic mechanisms that lead to NEC: bowel ischemia, bacterial flora, and the effect of feeding (Neu, 2007).

During perinatal or postnatal stress, oxygen is shunted away from the gut to more important organs such as the heart and brain. Ischemia and intestinal wall damage occur, allowing bacteria to invade. High-solute feedings allow bacteria to flourish. Mucosal or transmucosal necrosis of part of the intestine occurs (Wood, 2007). Although any region of the bowel can be affected, the distal ileum and proximal colon are the regions most commonly involved. NEC usually occurs between 3 and 12 days of life, but it can occur weeks later in some newborns.

Nursing Assessment

NEC can be devastating, and astute assessment is crucial. Assessing the newborn for the development of NEC includes the health history and physical examination as well as laboratory and diagnostic testing.

Health History and Physical Examination

Assess the newborn's history for risk factors associated with NEC. In addition to preterm birth, prenatal and postnatal predisposing risk factors are highlighted in Box 24.1.

Also observe the newborn for common signs and symptoms, which may include:

- Abdominal distention and tenderness
- Bloody stools
- Feeding intolerance, characterized by bilious vomiting
- Signs of sepsis
- Lethargy
- Apnea
- Shock

Always keep the possibility of NEC in mind when dealing with preterm newborns, especially when enteral feedings are being administered. Note respiratory distress, cyanosis, lethargy, decreased activity level, temperature instability, feeding intolerance, diarrhea, bile-stained emesis, or grossly bloody stools. Assess blood pressure, noting hypotension. Evaluate the neonate's abdomen for distention, tenderness, and visible loops of bowel (Verklan & Walden, 2004). Measure the abdominal circumference,

BOX 24.1 Predisposing Factors for the Development of Necrotizing Enterocolitis

Prenatal Factors
- Preterm labor
- Prolonged rupture of membranes
- Preeclampsia
- Maternal sepsis
- Amnionitis
- Uterine hypoxia

Postnatal Factors
- Respiratory distress syndrome
- Patent ductus arteriosus
- Congenital heart disease
- Exchange transfusion
- Low birthweight
- Low Apgar scores
- Umbilical catheterization
- Hypothermia
- Gastrointestinal infection
- Hypoglycemia
- Asphyxia

noting an increase. Determine residual gastric volume prior to feeding; when it is elevated, be suspicious for NEC.

Laboratory and Diagnostic Testing

Common laboratory and diagnostic tests ordered for assessment of NEC include:

- Kidney, ureter, and bladder (KUB) of the abdomen x-ray: confirms the presence of pneumatosis intestinalis (air in the bowel wall) and persistently dilated loops of bowel (Verklan & Walden, 2004; Wood, 2007)
- Blood values: may demonstrate metabolic acidosis, increased white blood cells, thrombocytopenia, neutropenia, electrolyte imbalance or disseminated intravascular coagulation (DIC)

Nursing Management

Nursing management of the newborn with NEC focuses on maintaining fluid and nutritional status, providing supportive care, and teaching the family about the condition and prognosis. Therapeutic management initially consists of bowel rest and antibiotic therapy. Serial KUB x-rays are used to assess the resolution or progression of NEC. If medical treatment fails to stabilize the newborn or if free air is present on a left lateral decubitus film, surgical intervention will be necessary to resect the portion of necrotic bowel. Surgery for NEC usually requires the placement of a proximal enterostomy until the anastomosis site is ready for reconnection.

Maintaining Fluid and Nutritional Status

If NEC is suspected, immediately stop enteral feedings until a diagnosis is made. Administer IV fluids initially to restore proper fluid balance. If ordered, administer total parenteral nutrition (TPN) to keep the newborn supported nutritionally. Give prescribed IV antibiotics to prevent sepsis from the necrotic bowel (if surgery is required, antibiotics may be needed for an extended period of time). Institute gastric decompression as ordered with an orogastric tube attached to low intermittent suction. Carefully monitor intake and output. Restart enteral feedings once the disease has resolved (normal abdominal examination and KUB negative for pneumatosis) or as determined postoperatively by the surgeon.

Providing Supportive Care

Manage pain by administering analgesics as ordered. Infection control is important, with an emphasis on careful handwashing. In addition, implement these interventions in an ongoing manner:

- Check stools for evidence of blood and report any positive findings.
- Measure the abdominal girth.
- Palpate the abdomen for tenderness and rigidity.
- Auscultate for normal bowel sounds.
- Observe the abdomen for redness or shininess, which indicates peritonitis.

Teaching the Family

The diagnosis of NEC may cause significant family anxiety. Listen to the family's worries and fears. Answer their questions honestly. Inform the family that medically treated NEC is usually limited to a short period and resolves within 48 hours of stopping oral feedings. Explain that surgically treated NEC, however, can be a much lengthier process. The amount of bowel that has necrosed, as determined during the bowel resection, significantly increases the likelihood of long-term medical problems. Short bowel syndrome may result from a large resection (short bowel syndrome is discussed in Chapter 41). Reassure the family that although some infants have more involved cases of NEC, the improved parenteral nutrition formulations have improved the outcomes for these infants. Provide education about ostomy care if surgery is required (refer to page 1335 for a discussion of ostomy care). Promote interaction with their newborn.

INFANTS OF DIABETIC MOTHERS

An **infant of a diabetic mother** is one born to a woman with pregestational or gestational diabetes (see Chapter 20 for additional information). The newborn of a diabetic

woman is at high risk for numerous health-related complications, especially hypoglycemia. In light of the increasing incidence of type 2 diabetes among women of childbearing age due to obesity, it is important to educate women about the potential impact of poor glycemic control on their offspring.

Impact of Diabetes on the Newborn

For more than a century, it has been known that diabetes during pregnancy can have severe adverse effects on fetal and newborn outcomes. Infants of diabetic mothers have increased morbidity and mortality in the perinatal period. The incidence of major congenital anomalies is much greater for these newborns than for other newborns. Poor glycemic control in the first trimester, during organogenesis, is thought to be a major reason for congenital malformations. The most common types of malformations in infants of diabetic mothers involve the cardiovascular, skeletal, central nervous, gastrointestinal, and genitourinary systems. Cardiac anomalies are the most common (Kwik et al., 2007).

Infants of diabetic mothers are longer and weigh more than newborns of similar gestational age. They also have increased organ weights (organomegaly) and excessive fat deposits on the shoulders and trunk, contributing to the increased overall body weight and predisposing them to shoulder dystocia. These newborns are macrosomic (an infant whose birthweight exceeds 4,500 g). These oversized newborns frequently require cesarean births for cephalopelvic disproportion and are often hypoglycemic in the first few hours after birth.

Despite their increased size and weight, they may be remarkably frail, showing behaviors similar to those of a preterm newborn. Thus, birthweight may not be a reliable criterion of maturity. Newborns of women with diabetes but without vascular complications often tend to be large for gestational age (LGA), whereas those of women with diabetes and vascular disease are usually small for gestational age (SGA).

Pathophysiology

The large size of the infant born to a diabetic mother occurs secondary to exposure to high levels of maternal glucose crossing the placenta into the fetal circulation. Maternal hyperglycemia acts as a fuel to stimulate increased production of fetal insulin, which in turn promotes somatic growth within the fetus. The fetus responds to these high levels by producing more insulin, which acts as a growth factor in the fetus (Blackburn, 2007). How the fetus will be affected and the problems that the newborn experiences depend on the severity, duration, and control of the diabetes in the mother. Table 24.1 summarizes the common problems that may occur in infants of diabetic mothers.

Nursing Assessment

Assessment begins in the prenatal period by identifying women with diabetes and taking measures to control maternal glucose levels (see Chapter 20 for information on management of the pregnant woman with diabetes).

Physical Examination

At birth, inspect the newborn for these characteristic features:

- Full rosy cheeks with a ruddy skin color
- Short neck (some describe "no-neck" appearance)
- Buffalo hump over the nape of the neck
- Massive shoulders with a full intrascapular area
- Distended upper abdomen due to organ overgrowth
- Excessive subcutaneous fat tissue, producing fat extremities (Fig. 24.4)

Be alert for hypoglycemia, which may occur immediately after birth or within an hour. Assess blood glucose levels, which should remain above 40 mg/dL. Closely assess the newborn for signs of hypoglycemia, including listlessness, hypotonia, apathy, poor feeding, apneic episodes with a drop in oxygen saturation, cyanosis, temperature instability, pallor and sweating, tremors, irritability, and seizures.

Assess the newborn for signs of birth trauma involving the head (tense, bulging fontanels, cephalhematoma, skull fractures, and facial nerve paralysis), shoulders and extremities (posturing, paralysis), and skin (bruising). Inspect the newborn for compromised oxygenation by examining the skin for cyanosis, pallor, mottling, and sluggish capillary refill. Take the newborn's temperature frequently and provide a neutral thermal environment to prevent cold stress, which would increase the glucose utilization and contribute to the hypoglycemic state.

Laboratory and Diagnostic Testing

Determine baseline serum calcium, magnesium, and bilirubin levels and monitor them frequently for changes (Table 24.2). Hypocalcemia is typically manifested in the first 2 to 3 days of life as a result of birth injury or a prolonged delay in parathyroid hormone production. Hypomagnesemia parallels calcium levels and is suspected only when hypocalcemia does not respond to calcium replacement therapy. Red blood cell breakdown leads to increased hematocrit and polycythemia. In addition, hyperbilirubinemia may be caused by slightly decreased extracellular fluid volume, hepatic immaturity, and birth trauma forming enclosed hemorrhages. It can appear within the first 24 hours of life (pathologic) or after 24 hours of life (physiologic).

Nursing Management

The focus of care for these infants is early detection and initiation of therapy to address potential problems (Nursing

TABLE 24.1 COMMON PROBLEMS OF INFANTS OF DIABETIC MOTHERS

Condition	Description	Effects
Macrosomia	Newborn with an excessive birthweight; arbitrarily defined as a birthweight >4,000 g (8 lb 13 oz) to 4,500 g (9 lb 15 oz) or >90% for gestational age Complication in 10% of all pregnancies in the United States	Increased risk for shoulder dystocia, traumatic birth injury, birth asphyxia Risks for newborn hypoglycemia and hypomagnesemia, polycythemia, and electrolyte disturbances Increased maternal risk for surgical birth, postpartum hemorrhage and infection, and birth canal lacerations Increased risk of developing type 2 diabetes later in life for both Higher weight and accumulation of fat in childhood and a higher rate of obesity in adults
Respiratory distress syndrome (RDS)	Cortisol-induced stimulation of lecithin/sphingomyelin (phospholipids) necessary for lung maturation is antagonized due to the high insulin environment within the fetus due to mother's hyperglycemia. Less mature lung development than expected for gestational age Decrease in the phospholipid phosphatidylglycerol (PG), which stabilizes surfactant, compounding risk	Most commonly, breathing normally at birth but developing labored, grunting respiration with cough and a hoarse complaining cry within a few hours with chest retractions and varying degrees of cyanosis IDMs with vascular disease seldom develop RDS because the chronic stress of poor |intrauterine perfusion leads to increased production of steroids, which accelerates lung maturation.
Hypoglycemia	Glucose is the major source of energy for organ function. Typical characteristics: – Poor feedings – Jitteriness – Lethargy – High-pitched or weak cry – Apnea – Cyanosis and seizures Some newborns asymptomatic.	Low blood glucose levels are problematic during early post-birth period due to abrupt cessation of high-glucose maternal blood supply and the continuation of insulin production by the newborn. Limited ability to release glucagon and catecholamines, which normally stimulate glucagon breakdown and glucose release Prolonged and untreated hypoglycemia leads to serious, long-term adverse neurologic sequelae such as learning disabilities and mental retardation.
Hypocalcemia and hypomagnesemia	Hypocalcemia (drop in calcium levels) manifested by tremors, hypotonia, apnea, high-pitched cry, and seizures due to abrupt cessation of maternal transfer of calcium to fetus primarily in third trimester and experiencing birth asphyxia Associated hypomagnesemia directly related to the maternal level before birth About half of IDMs affected	Newborn is at risk for a prolonged delay in parathyroid hormone production and cardiac dysrhythmias.
Polycythemia	Venous hematocrit of >65% in the newborn Increased oxygen consumption by IDM secondary to fetal hyperglycemia and hyperinsulinemia Increased fetal erythropoiesis secondary to intrauterine hypoxia due to placental insufficiency from maternal diabetes Hypoxic stimulation of increased red blood cell (RBC) production as compensatory mechanism	Increased viscosity, resulting in poor blood flow predisposing newborn to decreased tissue oxygenation and development of microthrombi

(continued)

TABLE 24.1 Common Problems of Infants of Diabetic Mothers (continued)

Condition	Description	Effects
Hyperbilirubinemia	Usually seen within the first few days after birth, manifested by a yellow appearance of the sclera and skin Excessive red cell hemolysis necessary to break down increased RBCs in circulation due to polycythemia Resultant elevated bilirubin levels Excessive bruising secondary to birth trauma of macrosomic infants, further adding to high bilirubin levels	If untreated, high levels of unconjugated bilirubin may lead to kernicterus (neurologic syndrome that results in irreversible damage) with long-term sequelae that include cerebral palsy, sensorineural hearing loss, and mental retardation.
Congenital anomalies	Occur in up to 10% of IDMs, accounting for 30% to 50% of perinatal deaths Incidence is greatest among SGA newborns. Overall, approximately three times the usual incidence of congenital anomalies compared to newborns from the non-diabetic general population.	Most common anomalies: – Coarctation of the aorta – Atrial and ventricular septal defects – Transposition of the great vessels – Sacral agenesis – Hip and joint malformations – Anencephaly – Spina bifida – Caudal dysplasia – Hydrocephalus

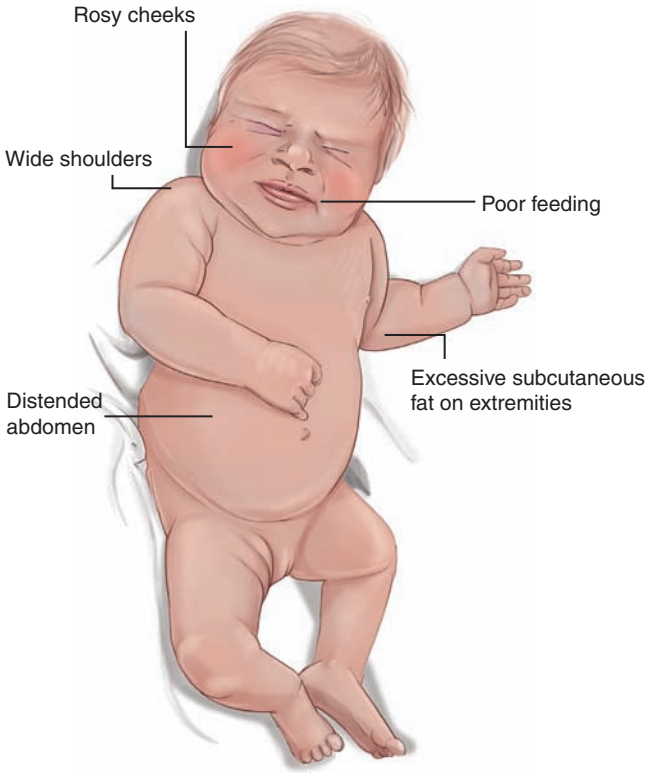

FIGURE 24.4 Characteristics of an infant of a diabetic mother.

Care Plan 24.1). Perform a head-to-toe physical assessment to identify congenital anomalies. Institute measures to correct hypoglycemia, hypocalcemia, hypomagnesemia, dehydration, and jaundice. Provide oxygenation and ventilatory support as necessary.

Preventing Hypoglycemia

Prevent hypoglycemia by providing early oral feedings with formula or breast milk at frequent intervals (every 2 to 3 hours). Feedings help to control glucose levels, reduce hematocrit, and promote bilirubin excretion. Maintain a neutral thermal environment to avoid cold stress, which may stimulate the metabolic rate, thereby increasing the demand for glucose. Provide rest periods to decrease energy demand and expenditure.

Monitor blood glucose levels via heel stick every hour for the first 4 hours of life and then every 3 to 4 hours

TABLE 24.2 Critical Laboratory Values for Infants of Diabetic Mothers

Hypoglycemia	<40 mg/dL
Hypocalcemia	<7 mg/dL
Hypomagnesemia	<1.5 mg/dL
Hyperbilirubinemia	>12 mg/dL (term infant)
Polycythemia	>65% (venous hematocrit)

Nursing Care Plan 24.1

Overview of an Infant of a Diabetic Mother

Jamie, a 38-year-old Hispanic woman, gave birth to a term large-for-gestational-age newborn weighing 10 lb. She had a history of gestational diabetes but had not received any prenatal care. She arrived at the hospital in active labor. Despite macrosomia, the newborn's Apgar scores were 8 and 9 at 1 and 5 minutes respectively. No resuscitative measures were needed.

One hour after birth, assessment revealed a pale, irritable newborn with sweating and several episodes of apnea. A glucose level obtained at this time via a heel stick was 35 mg/dL. Two hours later, the newborn begins exhibiting signs of respiratory distress—grunting, nasal flaring, retractions, tachypnea (respiratory rate 72 breaths/minute), and tachycardia (heart rate 176 bpm).

NURSING DIAGNOSIS: Risk for unstable glucose level related to hypoglycemia secondary to intrauterine hyperinsulin state resulting from maternal gestational diabetes as evidenced by low blood glucose level, irritability, pallor, sweating, and apnea

Outcome Identification and Evaluation

The newborn will exhibit adequate glucose control *as evidenced by maintaining blood glucose levels above 40 mg/dL and an absence of clinical signs of hypoglycemia.*

Interventions: Promoting Glucose Control

- Monitor blood glucose levels hourly for the first 4 hours and then every 3 to 4 hours or as necessary *to detect hypoglycemia, which would be <40 mg/dL.*
- Continue to observe for manifestations of hypoglycemia, such as pallor, tremors, jitteriness, lethargy, and poor feeding, *to allow for early detection and prompt intervention, thereby minimizing the risk of complications associated with hypoglycemia.*
- Monitor temperature frequently and institute measures to maintain a neutral thermal environment *to prevent cold stress, which would increase metabolic demands and further deplete glycogen stores.*
- Initiate early feedings every 2 to 3 hours or as appropriate or administer glucose supplements as ordered *to prevent hypoglycemia caused by the newborn's hyperinsulin state.* Administer IV glucose infusions as ordered *to correct hypoglycemia if glucose levels do not stabilize with feeding.*
- Cluster infant care activities and provide for rest periods *to conserve the newborn's energy and reduce use of glucose and glycogen stores.*
- Reduce environmental stimuli by dimming lights and speaking softly *to reduce energy demands and further utilization of glucose.*
- Explain all events and procedures to the mother *to help alleviate anxiety and promote understanding of the newborn's condition.*

NURSING DIAGNOSIS: Impaired gas exchange related to respiratory distress secondary to delayed lung maturity resulting from inhibition of pulmonary surfactant production due to fetal hyperinsulinemia as evidenced by grunting, nasal flaring, retractions, tachypnea, and tachycardia

Outcome Identification and Evaluation

Newborn will demonstrate signs of adequate oxygenation without respiratory distress *as evidenced by respiratory rate and vital signs within acceptable parameters, absence of nasal flaring, retractions, and grunting, and oxygen saturation and arterial blood gas levels within acceptable parameters.*

Interventions: Promoting Oxygenation

- Monitor newborn's vital signs *to establish a baseline and evaluate for changes.*
- Assess airway patency and perform gentle suctioning as ordered *to ensure patency and allow for adequate oxygen intake.*
- Position the newborn prone *to optimize respiratory status and reduce stress.*
- Assess lung sounds for changes *to allow early detection of change in status.*
- Continuously monitor oxygen saturation levels via pulse oximetry *to determine adequacy of tissue perfusion.*
- Assess arterial blood gas results *to detect changes indicating acidosis, hypoxemia, or hypercarbia, which would suggest hypoxia.* Administer medications as ordered *to correct acidosis.*
- Administer oxygen as ordered *to promote adequate tissue perfusion.*
- Assess newborn's skin to identify cyanosis, pallor, and mottling *to detect changes indicating compromised oxygenation.*
- Administer surfactant replacement therapy as ordered *to aid in stabilizing the newborn's lungs until postnatal surfactant synthesis improves.*
- Institute measures to maintain normal blood glucose levels and a neutral thermal environment, cluster care activities, and reduce excessive stimuli *to reduce oxygen demand and consumption.*

until stable. Document the results. Report unstable glucose values if oral feedings do not maintain and stabilize the newborn's blood glucose levels. If glucose levels are not stabilized, initiate IV glucose infusions as ordered and monitor that the infusions are flowing at the prescribed rate.

Maintaining Fluid and Electrolyte Balance

Monitor serum calcium levels for changes indicating the need for supplementation, such as with oral or IV calcium gluconate. Assess the newborn for signs of hypocalcemia, such as tremors, jitteriness, twitching, seizures, and high-pitched cry.

Also administer fluid therapy as ordered to maintain adequate hydration. Monitor serum bilirubin levels and institute phototherapy if the newborn is over 24 hours old.

Providing Parental Support

Assist the parents and family in understanding the newborn's condition and need for frequent monitoring. Offer support and information to the parents and family. They may erroneously interpret the newborn's large size as an indication that the newborn is free of problems. Encourage open communication and listen with empathy to the family's fears and concerns. Provide frequent opportunities for the parents to interact with their newborn. Make appropriate referrals to social services and community resources as necessary to help the family cope.

BIRTH TRAUMA

Injuries to the newborn from the forces of labor and birth are categorized as birth trauma. In the past, numerous injuries were associated with difficult births requiring external or internal version or mid- or high forceps deliveries. Today, however, cesarean births have contributed to the decline in birth trauma.

Significant birth trauma accounts for fewer than 2% of neonatal deaths and stillbirths in the United States (Kenner & Lott, 2007). Improved prenatal diagnosis and monitoring during labor have helped to reduce the incidence of birth injuries today.

Pathophysiology

The process of birth is a blend of compression, contractions, torques, and traction. Birth traumas are injuries sustained by the newborn during the birthing process. When fetal size, presentation, or neurologic immunity complicates this process, the forces of labor and birth may lead to tissue damage, edema, hemorrhage, or fracture in the newborn. For example, birth trauma may result from the pressure of birth, especially in a prolonged or abrupt labor, abnormal or difficult presentation, cephalopelvic disproportion, or mechanical forces, such as forceps or vacuum used during delivery. Table 24.3 summarizes the most common types of birth trauma.

Nursing Assessment

Recognition of trauma and birth injuries is imperative so that early treatment can be initiated. Review the labor and birth history for risk factors, such as a prolonged or abrupt labor, abnormal or difficult presentation, cephalopelvic disproportion, or mechanical forces, such as forceps or vacuum used during delivery. Also review the history for multiple fetus deliveries, large-for-date infants, extreme prematurity, large fetal head, or newborns with congenital anomalies.

Complete a careful physical and neurologic assessment of every newborn admitted to the nursery to establish whether injuries exist. Inspect the head for lumps, bumps, or bruises. Note if swelling or bruising crosses the suture line. Assess the eyes and face for facial paralysis, observing for asymmetry of the face with crying or appearance of the mouth being drawn to the unaffected side. Ensure that the newborn spontaneously moves all extremities. Note any absence of or decrease in deep tendon reflexes or abnormal positioning of extremities.

Assess and document symmetry of structure and function. Be prepared to assist with scheduling diagnostic studies to confirm trauma or injuries, which will be important in determining treatment modalities.

Nursing Management

Nursing management is primarily supportive and focuses on assessing for resolution of the trauma or any associated complications along with providing support and education to the parents. Provide the parents with explanations and reassurance that these injuries usually resolve with minimal or no treatment. Parents are alarmed when their newborn is unable to move an extremity or demonstrates asymmetric facial movements. Provide parents with a realistic picture of the situation to gain their understanding and trust. Be readily available to answer questions and teach them how to care for the newborn, including any modifications that might be necessary. Allow parents adequate time to understand the implications of the birth trauma or injury and what treatment modalities are needed, if any. Provide them with information about the length of time until the injury will resolve and when and if they need to seek further medical attention for the condition. Spending time with the parents and providing them with support, information, and teaching are important to allow them to make decisions and care for their newborn. Anticipate the need for community referral for ongoing follow-up and care, if necessary.

TABLE 24.3 COMMON TYPES OF BIRTH TRAUMA

Type	Description	Findings	Treatment
Fractures	Most often occur during breech births or shoulder dystocia in newborns with macrosomia Mid-clavicular fractures are the most common type of fracture, secondary to shoulder dystocia. Long bone fractures of humerus or femur, usually mid-shaft, also can occur.	Mid-clavicular fractures: The newborn presents with irritability and does not move the arm on the affected side either spontaneously or when the Moro reflex is elicited. Femoral or humeral long bone fractures: The newborn shows loss of spontaneous leg or arm motion respectively; usually swelling and pain accompany the limited movement. X-rays confirm the fracture.	Mid-clavicular fractures typically heal rapidly and uneventfully; arm motion may be limited by pinning the newborn's sleeve to the shirt. Femoral and humeral shaft fractures are treated with splinting. Healing and complete recovery are expected within 2 to 4 weeks without incident (Laroia, 2007). Explanation to the parents and reassurance are needed.
Brachial plexus injury	Primarily in large babies, babies with shoulder dystocia, or breech delivery Results from stretching, hemorrhage within a nerve, or tearing of the nerve or the roots associated with cervical cord injury Associated traumatic injuries include fracture of the clavicle or humerus or subluxations of the shoulder or cervical spine. Erb's palsy is an upper brachial plexus injury. Klumpke's palsy is an injury to the lower brachial plexus (lower brachial injuries are less common).	In Erb's palsy, the involved extremity usually presents adducted, prone, and internally rotated; shoulder movement is absent; Moro, bicep, and radial reflexes are absent, but the grasp reflex is usually present. Klumpke's palsy is manifested by weakness in the hand and wrist; grasp reflex is absent.	Erb's palsy usually involves immobilization of the upper arm across the upper abdomen/chest to protect the shoulder from excessive motion for the first week; then gentle passive range-of-motion exercises are performed daily to prevent contractures. There is usually no associated sensory loss, and this condition usually improves rapidly. Treatment for Klumpke's palsy involves placing the hand in a neutral position and using passive range-of-motion exercises. In some cases deficits may persist, requiring continuing observation.
Cranial nerve trauma	Most common is facial nerve palsy. Frequently attributed to pressure resulting from forceps May also result from pressure on the nerve in utero, related to fetal positioning such as the head lying against the shoulder	Physical findings include asymmetry of the face when crying; mouth may be drawn towards the unaffected side; wrinkles are deeper on the unaffected side. The paralyzed side may be smooth, with a swollen appearance. Eye is persistently open on the affected side.	Most infants begin to recover in the first week, but full resolution may take up to several months; parents need reassurance about this. In most cases, treatment is not necessary, only observation. If the eye is affected and unable to close, protection with patches and synthetic tears may be necessary. Parents need instruction about how to feed the newborn, since he or she cannot close the lips around the nipple without having milk seep out.

(continued)

TABLE 24.3 COMMON TYPES OF BIRTH TRAUMA (continued)

Type	Description	Findings	Treatment
Head trauma	Mild trauma can cause soft tissue injuries such as cephalhematoma and caput succedaneum; greater trauma can cause depressed skull fractures. **Cephalhematoma** (subperiosteal collection of blood secondary to the rupture of blood vessels between the skull and periosteum) occurs in 2.5% of all births and typically appears within hours after birth (Cunningham et al., 2005). **Caput succedaneum** (soft tissue swelling) is caused by edema of the head against the dilating cervix during the birth process. Subarachnoid hemorrhage (one of the most common types of intracranial trauma) may be due to hypoxia/ischemia, variations in blood pressure, and the pressure exerted on the head during labor. Bleeding is of venous origin, and underlying contusions also may occur (Laroia, 2007). Subdural hemorrhage (hematomas) occurs less often today because of improved obstetric techniques. Typically, tears of the major veins or venous sinuses overlying the cerebral hemispheres or cerebellum (most common in newborns of primaparas and large newborns, or after an instrumented birth) are the cause. Increased pressure on the blood vessels inside the skull leads to tears. Depressed skull fractures (rare) may result from the pressure of a forceps delivery; can also occur during spontaneous or cesarean births and may be associated with other head trauma causing subdural bleeding, subarachnoid hemorrhage, or brain trauma (Laroia, 2007).	In cephalhematoma, suture lines delineate its extent; usually located on one side, over the parietal bone. In caput succedaneum, swelling is not limited by suture lines: it extends across the midline and is associated with head molding. It does not usually cause complications other than a misshapen head. Swelling is maximal at birth and then rapidly decreases in size. In subarachnoid hemorrhage, some RBCs may appear in the CSF of full-term newborns. Newborns may present with apnea, seizures, lethargy, or abnormal findings on a neurologic examination (Rodriguez, 2007). Subdural hemorrhage can be asymptomatic, or the neonate can exhibit seizures, enlarging head size, decreased level of consciousness, or abnormal findings on a neurologic examination, with hypotonia, a poor Moro reflex, or extensive retinal hemorrhages. Depressed skull fractures can be observed and palpated as depressions. Confirmation by x-ray is necessary.	Cephalhematoma resolves gradually over 2 to 3 weeks without treatment (see Chapter 18). Caput succedaneum usually resolves over the first few days without treatment (see Chapter 18). Subarachnoid hemorrhage requires minimal handling to reduce stress. Subdural hematoma requires aspiration; can be life-threatening if it is in an inaccessible location and cannot be aspirated (Laroia, 2007). Depressed skull fractures typically require a neurosurgical consultation.

NEWBORNS OF SUBSTANCE-ABUSING MOTHERS

It is generally assumed that all pregnant women want to provide a healthy environment for their unborn child and know how to avoid harm. However, for women who use substances such as drugs or alcohol, this may not be the case. Substance use during pregnancy exposes the fetus to the possibility of IUGR, prematurity, neurobehavioral and neurophysiologic dysfunction, birth defects, infections, and long-term developmental sequelae (Kenner & Lott, 2007).

It is difficult to establish the true prevalence of substance use in pregnant women; many women deny taking any nonprescribed substance because of the associated social stigma and legal implications. The National Institute on Drug Abuse (NIDA) suggests that approximately 1 in 10 newborns are exposed to one or more mood-altering drugs in utero (NIDA, 2007f). Drug exposure may go unrecognized in these newborns, and they may be discharged from the newborn nursery at risk for medical and social problems, including abuse and neglect.

Tobacco, alcohol, and marijuana are the substances most commonly abused during pregnancy. Other drugs may include opioids such as morphine, codeine, methadone, meperidine, and heroin; CNS stimulants such as amphetamines and cocaine; CNS depressants such as barbiturates, diazepam (Valium), and sedative–hypnotics; and hallucinogens, such as LSD, inhalants, glue, paint thinner, nail polish remover, and nitrous oxide (NIDA, 2007f). Table 24.4 highlights commonly used substances and their effects on the fetus and newborn.

▶ *Consider* THIS!

I admit, I had led a reckless life since I was a teen. I rebelled against my mother's authority and started smoking and doing drugs just to "check out" of my painful world. It was one big blast after another with a high and then a low. I never considered the consequences of my behavior then and never thought it would hurt anyone until I learned I was about 4 months pregnant. I convinced myself that if I cut back, everything would be fine.

Now, as I stand here in the NICU watching my tiny son struggle for air and tremble all over, I am not so convinced that I didn't hurt anyone except myself. As I witness my son fight against MY nicotine and drug addiction, my heart is heavy with guilt. I wonder how I could have thought that my troubles wouldn't become another's plight sooner or later. What must I have been thinking to isolate my addiction and not

(continued)

▶ *Consider* THIS! *(continued)*

consider the impact that it would have on my mother and my son?

Thoughts: This woman honestly regrets what her addiction has done to her son as she stands watching him go through withdrawal. Her lifestyle choices do affect others, despite her previous denial. One problem with addiction is the difficulty in getting help after deciding to finally quit. There aren't enough rehab centers to deal with the large numbers needing their services and it can be difficult to get into one. What can be offered to pregnant women who abuse substances? How can nurses increase community awareness about the impact of this problem, especially during pregnancy?

Substance abuse during pregnancy is the subject of much controversy. The timing of drug ingestion usually determines the type and severity of damage to the fetus. Frequently, the woman uses more than one substance, which compounds the problem. Nurses must be knowledgeable about the issues of substance abuse and must be alert for opportunities to identify, prevent, manage, and educate women and families about this key public health issue.

Fetal Alcohol Syndrome

The adverse effects of alcohol consumption have been recognized for centuries, but the associated pattern of fetal anomalies was not labeled until the early 1970s. The distinctive pattern identified three specific findings: growth restriction (prenatal and postnatal), craniofacial structural anomalies, and CNS dysfunction. These distinctive findings were called **fetal alcohol syndrome**, characterized by physical and mental disorders that appear at birth and remain problematic throughout the child's life. However, there are also circumstances in which the effects of prenatal alcohol exposure are apparent, but the newborn does not meet all of the criteria. In an attempt to include those who do not meet the strict criteria, the terms "fetal alcohol effects," "alcohol-related birth defects," and "alcohol-related neurologic defects" are used to describe children with a variety of problems thought to be related to alcohol consumption during pregnancy. The Institutes of Medicine coined the term **fetal alcohol spectrum disorder** as a way of describing the broader effects of prenatal alcohol exposure. Children with fetal alcohol syndrome are at the severe end of the spectrum (Manning & Hoyne, 2007). Newborns with some but not all of the symptoms of fetal alcohol syndrome are described as having **alcohol-related birth defects**. Fetal alcohol effects may include

(text continues on page 747)

TABLE 24.4 Substances and Their Effects on the Fetus and Newborn

Substance	Description	Effects on Fetus and Newborn	Nursing Implications
Alcohol	Consumption is pervasive and widely accepted, with use, abuse, and addiction affecting all levels of society. It is a common misconception that a substance sold to the public without restriction is safe.	Fetal alcohol syndrome (one of the most common known causes of mental retardation) Fetal alcohol spectrum disorders Alcohol-related birth defects	Provide education that decreasing or eliminating alcohol consumption during pregnancy is the only way to prevent fetal alcohol syndrome and fetal alcohol effects. Assist pregnant woman in finding a treatment program if possible. Inform all women who are pregnant or planning to become pregnant about the detrimental effects of alcohol during pregnancy. Educate women using a nonjudgmental, culturally connected approach. Warn women that there is no safe time to drink or amount of alcohol they can consume.
Tobacco/nicotine	Nicotine is an addictive substance. It causes epinephrine release from adrenal cortex, leading to initial stimulation followed by depression and fatigue, causing the user to seek more nicotine. Increased numbers of women are smoking (at least 11% smoke during pregnancy; March of Dimes, 2007c). Over 2,500 chemicals are found in cigarette smoke, including nicotine, tar, carbon monoxide, and cyanide. It is unknown which are harmful, but nicotine and carbon monoxide are believed to play a role in causing adverse pregnancy outcomes.	Impaired oxygenation of mother and fetus due to nicotine crossing placenta and carbon monoxide combining with hemoglobin Increased risk for low birthweight (risk almost doubled), small for gestational age, and preterm birth Increased risk for sudden infant death syndrome (SIDS) and chronic respiratory illness (MNH, 2007)	Provide teaching to women about healthy behaviors. Provide support for smoking cessation. Individualize counseling based on factors associated with the woman's smoking and challenges faced (why woman smokes, stressors in life, and social support network). Suggest options such as group smoking cessation programs, relaxation techniques, individual counseling, hypnosis, and partner-support counseling.
Marijuana	Most widely used illicit psychoactive substance in Western world and most commonly used illicit drug in the United States (NIDA, 2007d) Derived from *Cannabis sativa* plant	Not shown to have teratogenic effects on fetus; no consistent types of malformations identified Intrauterine growth restriction (IUGR) is common due to delivery of carbon monoxide to fetus (NIDA, 2007d). Increased risk for small for gestational age	Provide teaching to women about healthy behaviors. Provide support for cessation of marijuana use.

Substance	Description	Effects on Fetus and Newborn	Nursing Implications
		Altered responses to visual stimuli, sleep-pattern abnormalities, photophobia, lack of motor control, hyperirritability, increased tremulousness, and high-pitched cry noted in infants of mothers who smoked marijuana Research related to long-term effects is continuing (NIDA, 2007d).	
Methamphetamines	Addictive stimulant; use releases high levels of dopamine, which stimulates brain cells, enhancing mood and body movement High potential for abuse and addiction; can be inhaled, injected, smoked, or taken orally Many street names, such as speed, meth, ice, and chalk Primary effects include accelerated heart and respiratory rate, elevated blood pressure, papillary dilation; secondary effects include loss of appetite. Used medically as treatment for obesity and narcolepsy in adults and hyperactivity in children	Little research on use during pregnancy because its use is less common than cocaine or narcotics Fetal effects similar to cocaine (suggesting vasoconstriction as possible underlying mechanism) Possible maternal malnutrition, leading to problems with fetal growth and development Increased risk for preterm birth and low-birthweight newborns Infants may have withdrawal symptoms, including dysphoria, agitation, jitteriness, poor weight gain, abnormal sleep patterns, poor feeding, frantic fist sucking, high-pitched cry, respiratory distress soon after birth, frequent infections, and significant lassitude (Arenson & Drake, 2007). Long-term effects are not known.	Provide teaching to women about healthy behaviors. Provide support for cessation of methamphetamine use. Monitor the woman for weight changes; emphasize the need for adequate nutritional intake to support fetal growth and development.
Cocaine	Strong CNS stimulant that interferes with reabsorption of dopamine Physical effects: vasoconstriction; pupillary dilation; increased temperature, heart rate, and blood pressure Taken orally, sublingually, intranasally, intravenously, and via inhalation Estimated that 30% to 40% of cocaine addicts are female Maternal cocaine use during pregnancy is a significant health problem (March of Dimes, 2007b). Increased potential for use of multiple drugs if mother using cocaine	Preterm birth and lower birthweight Unclear impact on later development Speculation that cocaine interferes with infant's cognitive development, leading to learning and memory difficulties later in life (Kenner & Lott, 2007) Associated congenital anomalies: GU, cardiac, and CNS defects, and prune belly syndrome Other typical newborn characteristics: smaller head circumference, piercing cry, limb defects, ambiguous genitalia, poor feeding, poor visual and auditory responses, poor sleep patterns, decreased impulse control, stiff, hyperextended positioning, irritability and hypersensitivity, inability to respond to caretaker (Blackburn, 2007)	Educate the woman about the effects of cocaine use on the fetus and newborn. Assess for use of other substances. Provide teaching to women about healthy behaviors. Provide support and guidance for cessation of cocaine and other substance use.

(continued)

TABLE 24.4 SUBSTANCES AND THEIR EFFECTS ON THE FETUS AND NEWBORN (continued)

Substance	Description	Effects on Fetus and Newborn	Nursing Implications
Heroin	Illegal, highly addictive opiate derived from morphine that can be sniffed, smoked, or injected Possible consequences include HIV infection, tuberculosis, crime, violence, and family disruption. Severe physical addiction; CNS depressant producing mental dullness and drowsiness	Newborns of heroin-addicted mothers are born dependent on heroin. Increased risk for transmission of hepatitis B and C and HIV to newborns when mothers share needles Significantly increased rates of stillbirth, IUGR, preterm birth, and newborn mortality (3 to 7 times greater; NIDA, 2007b, 2007c) Small-for-gestational age newborns, meconium aspiration, high incidence of SIDS, and delayed effects from subacute withdrawal (restlessness, continual crying, agitation, sneezing, vomiting, fever, diarrhea, seizures, irritability, and poor socialization [possibly persisting for 4 to 6 months]; March of Dimes, 2007b) Intrauterine death or preterm birth is possible with abrupt cessation of heroin use.	Educate the woman about the effects of heroin use on the fetus and newborn. Assess for use of other substances. Provide teaching to women about healthy behaviors. Warn the woman not to abruptly stop heroin use. Encourage her to enroll in a methadone maintenance program.
Methadone	Synthetic opiate narcotic used primarily as maintenance therapy for heroin addiction	Improvement in many of the detrimental fetal effects associated with heroin use Withdrawal symptoms are common in newborns. Possible low birthweight due to symmetric fetal growth restriction Increased severity and longer period of withdrawal (due to methadone's longer half-life) Seizures (commonly severe) do not usually occur until 2 to 3 weeks of age, when the newborn is at home. Increased rate of SIDS (3 to 4 times higher; Goff & O'Connor, 2007)	Methadone maintenance programs are the standard of care for women with narcotic addiction. Inform the woman about the benefits and risks of methadone use vs. heroin use. Advantages include improved fetal and newborn growth, reduced risk of fetal death, and reduced risk of HIV infections. Advise the woman that she will need to return consistently to receive the prescribed methadone dose. Reinforce the need for continued prenatal care. Inform the woman that she can breastfeed her newborn while receiving methadone. Teach mother and caregivers about signs and symptoms of methadone withdrawal.

such problems as low birthweight, developmental delays, and hyperactivity. Box 24.2 summarizes the manifestations of fetal alcohol syndrome.

Worldwide, the incidence of fetal alcohol syndrome is 1 to 3 cases per 1,000 live births, and that of fetal alcohol effects is 3 to 5 per 1,000 live births (March of Dimes, 2007a). Current estimates indicate that approximately 13% of women of childbearing age are either problem drinkers or alcoholics; therefore, the number of fetuses exposed to alcohol during utero increases dramatically (March of Dimes, 2007a).

Fetal alcohol syndrome is one of the most common known causes of mental retardation, and it is the only cause that is entirely preventable. The effects last a lifetime. Children with this syndrome have varying degrees of psychological and behavioral problems and often find it difficult to hold a job and live independently (CDC, 2007b).

Decreasing or eliminating alcohol consumption during pregnancy is the only way to prevent fetal alcohol syndrome and fetal alcohol effects. Unfortunately, few treatment programs address the needs of pregnant women, so many newborns are exposed to alcohol in utero.

BOX 24.2 Clinical Picture of Fetal Alcohol Syndrome

- Microcephaly (head circumference <10th percentile)*
- Small palpebral (eyelid) fissures*
- Abnormally small eyes
- Intrauterine growth restriction
- Maxillary hypoplasia (flattened or absent)
- Epicanthal folds (folds of skin of the upper eyelid over the eye)
- Thin upper lip*
- Missing vertical groove in median portion of upper lip*
- Short upturned nose
- Short birth length and low birthweight
- Joint and limb defects
- Altered palmar crease pattern
- Prenatal or postnatal growth ≤10th percentile*
- Congenital cardiac defects (septal defects)
- Delayed fine and gross motor development
- Poor eye–hand coordination
- Clinically significant brain abnormalities*
- Mental retardation
- Narrow forehead
- Performance substantially below expected level in cognitive or developmental functioning, executive or motor functioning, and attention or hyperactivity; social or language skills*
- Inadequate sucking reflex and poor appetite

*Diagnosis of fetal alcohol syndrome requires the presence of three findings:

1. Documentation of all three facial abnormalities
2. Documentation of growth deficits (height, weight or both below 10th percentile)
3. Documentation of CNS abnormalities (structural, neurologic, or functional)

Neonatal Abstinence Syndrome

Newborns of women who abuse tobacco, illicit substances, caffeine, and alcohol can exhibit withdrawal behavior. Withdrawal symptoms occur in 60% of all newborns exposed to drugs (Arenson & Drake, 2007). Drug dependency acquired in utero is manifested by a constellation of neurologic and physical behaviors and is known as **neonatal abstinence syndrome**. Although often treated as a single entity, neonatal abstinence syndrome is not a single pathologic condition. The manifestations of withdrawal are a function of the drug's half-life, the specific drug or combination of drugs used, dosage, route of administration, timing of drug exposure, and length of drug exposure (Kuschel, 2007). Typical newborn behaviors include CNS hypersensitivity, autonomic dysfunction, and gastrointestinal disturbances (Marcellus, 2007). Neonatal abstinence syndrome has both medical and developmental consequences for the newborn.

Nursing Assessment

Several assessment tools can be used to assess a drug-exposed newborn. Figure 24.5 shows an example. Regardless of the tool used for assessment, address these key areas:

- Maternal history to identify risk behaviors for substance abuse:
  - Previous unexplained fetal demise
  - Lack of prenatal care
  - History of missed prenatal appointments
  - Severe mood swings
  - Precipitous labor
  - Poor nutritional status
  - Abruptio placentae
  - Hypertensive episodes
  - History of drug abuse
- Laboratory test results (toxicology) to identify substances in mother and newborn
- Signs of neonatal abstinence syndrome (use the "WITHDRAWAL" acronym; see description below)
- Evidence of seizure activity and need for protective environment

The newborn's behavior often prompts the health care provider or nurse to suspect intrauterine drug exposure (Box 24.3). The newborn physical examination may also reveal low birthweight for gestational age or drug- or alcohol-related birth defects and dysfunction.

CENTRAL NERVOUS SYSTEM DISTURBANCES													
SIGNS AND SYMPTOMS	SCORE	AM							PM				
Excessive high-pitched cry	2												
Continuous high-pitched cry	3												
Sleeps <1 hour after feeding	3												
Sleeps <2 hours after feeding	2												
Sleeps <3 hours after feeding	1												
Hyperactive Moro reflex	2												
Markedly hyperactive Moro refex	3												
Mild tremors disturbed	1												
Moderate–severe tremors disturbed	2												
Mild tremors undisturbed	1												
Moderate–severe tremors undisturbed	4												
Increased muscle tone	2												
Excoloration (specify area)	1												
Myoclonic jerks	3												
Generalized convulsions	5												
METABOLIC / VASOMOTOR/RESPIRATORY DISTURBANCES													
Sweating													
Fever <101 (99–100.8°F/37.2–38.2°C)	1												
Fever >101 (38.2°C and higher)	2												
Frequent yawning (>3– 4 times/interval)	1												
Mottling	1												
Nasal stuffiness	1												
Sneezing (>3–4 times/interval)	1												
Nasal flaring	2												
Respiratory rate >60 / min	1												
Respiratory rate >60 / min, with retractions	2												
GASTROINTESTINAL DISTURBANCES													
Excessive sucking	1												
Poor feeding	2												
Regurgitation	2												
Projectile vomiting	3												
Loose stools	2												
Watery stools	3												
TOTAL SCORE													

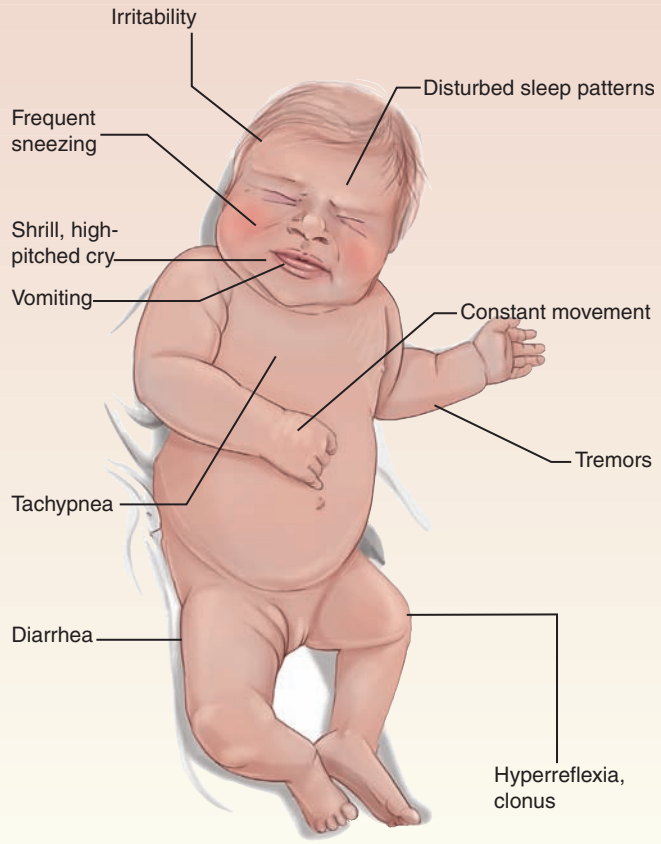
FIGURE 24.5 Neonatal abstinence scoring system (From Cloherty, J. P., & Stark, A. P. [1998]. *Manual of neonatal care* [4th ed., pp. 26–27]. Boston: Little, Brown.)

BOX 24.3 Manifestations of Neonatal Abstinence Syndrome

CNS Dysfunction
- Tremors
- Generalized seizures
- Hyperactive reflexes
- Restlessness
- Hypertonic muscle tone, constant movement
- Shrill, high-pitched cry
- Disturbed sleep patterns

Metabolic, Vasomotor, and Respiratory Disturbances
- Fever
- Frequent yawning
- Mottling of the skin
- Sweating
- Frequent sneezing
- Nasal flaring
- Tachypnea >60 bpm
- Apnea

Gastrointestinal Dysfunction
- Poor feeding
- Frantic sucking or rooting
- Loose or watery stools
- Regurgitation or projectile vomiting (Belik & Hawes, 2007; Kuschel, 2007; Marcellus, 2007)



▶ *Take* NOTE!

Cocaine-exposed newborns are typically fussy, irritable, and inconsolable at times. Cocaine-exposed infants demonstrate poor coordination of sucking and swallowing, making feeding time frustrating for the newborn and caregiver alike.

Assess the newborn for signs of neonatal abstinence syndrome. Use the acronym WITHDRAWAL to focus the assessment:

W = Wakefulness: sleep duration less than 1 to 3 hours after feeding
I = Irritability
T = Temperature variation, tachycardia, tremors
H = Hyperactivity, high-pitched persistent cry, hyperreflexia, hypertonus
D = Diarrhea, diaphoresis, disorganized suck
R = Respiratory distress, rub marks, rhinorrhea
A = Apneic attacks, autonomic dysfunction
W = Weight loss or failure to gain weight
A = Alkalosis (respiratory)
L = Lacrimation (Belik & Hawes, 2007)

Assist with obtaining diagnostic studies to identify the severity of withdrawal. Toxicology screening of the newborn's blood, urine, and meconium identifies the substances to which the newborn has been exposed.

In general, a urine screen signifies only recent newborn exposure to maternal use of drugs. It can detect marijuana use up to a month earlier, cocaine use up to 96 hours earlier, heroin use 24 to 48 hours earlier, and methadone use up to 10 days earlier (Belik & Hawes, 2007).

Nursing Management

The needs of the substance-exposed newborn are multiple, complex, and costly, both to the health care system and to society. Substance abuse takes place among people of all colors, sizes, shapes, incomes, types, and conditions. Most pregnant women are unaware of the adverse impact their substance abuse can have on the newborn.

Nurses are in a unique position to help because they interact with high-risk mothers and newborns in many settings, including the community, health care facilities, and family agencies. It is the responsibility of all nurses to identify, educate, counsel, and refer pregnant women with substance-abusing problems. For example, nurses can be instrumental in increasing the number of pregnant women who make a serious attempt to quit smoking by using the "5 A's" approach:

- Ask: Ask all women if they smoke and would like to quit.
- Advise: Encourage the use of clinically proven treatment plans.
- Assess: Provide motivation by discussing the "5 R's":
  - Relevance of quitting to the woman
  - Risk of continued smoking to the fetus
  - Rewards of quitting for both
  - Roadblocks to quitting
  - Repeat at every visit
- Assist: Help the woman to protect her fetus and newborn from the negative effects of smoking.
- Arrange: Schedule follow-up visits to reinforce the woman's commitment to quit.

Although this approach is geared to smoking cessation, nurses can adapt it to focus on cessation for any substance use. Early, supportive, ongoing nursing care is critical to the well-being of the mother and her newborn.

Caring for a substance-exposed newborn remains a major challenge to health care professionals. The major goals include providing comfort to the newborn by relieving symptoms, improving feeding and weight gain, preventing seizures, promoting mother–newborn interactions, and reducing the incidence of newborn mortality and abnormal development (Belik & Hawes, 2007).

Promoting Comfort

Keep environmental stimuli to a minimum. For example, decrease stimuli by dimming the lights in the nursery, and swaddle the newborn tightly to decrease irritability behaviors. Other techniques such as gentle rocking, using a flexed position, and offering a pacifier can help manage CNS irritability. A pacifier also helps satisfy the newborn's need for nonnutritive sucking. Use a calm, gentle approach when handling the newborn and plan activities to avoid overstimulating the newborn, allowing time for rest periods.

Meeting Nutritional Needs

When feeding the newborn, use small amounts and position the newborn upright to prevent aspiration and to facilitate rhythmic sucking and swallowing. Breastfeeding is encouraged unless the mother is still using drugs. Monitor the newborn's weight daily to evaluate the success of food intake. Assess hydration; check skin turgor and fontanels. Assess the frequency and characteristics of bowel movements and monitor the newborn's fluid and electrolyte and acid–base status.

Preventing Complications

Pharmacologic treatment is warranted if conservative measures, such as swaddling and decreased environmental stimulation, are not adequate. The AAP recommends that for newborns with confirmed drug exposure, drug therapy is indicated if the newborn has seizures, diarrhea and vomiting resulting in excessive weight loss and dehydration, poor feeding, inability to sleep, and fever unrelated to infection (AAP Committee on Substance Abuse, 2005). Common medications used in the management of newborn withdrawal include morphine, paregoric, phenobarbital, tincture of opium, methadone, clonidine, chlorpromazine, and diazepam (Marcellus, 2007). Administer the prescribed medications and document the newborn's behavioral responses.

The newborn is at risk for skin breakdown. Weight loss, diarrhea, dehydration, and irritability can contribute to this risk. Provide meticulous skin care and protect the newborn's elbows and knees against friction and abrasions.

Promoting Parent–Newborn Interaction

For a mother who abuses substances, the birth of a drug-exposed newborn is both a crisis and an opportunity. The mother may feel guilty about the newborn's condition. Many of these newborns are unresponsive and have disorganized sleeping and feeding patterns. When awake, they can be easily overstimulated and irritated. Such characteristics make parent–newborn interactions difficult and frustrating, leading to possible detachment and avoidance (Burd, 2007). In addition, the mother may be single and a victim of physical and sexual abuse and may have a limited support system. Many of these mothers may have had poor parenting themselves, lack information about characteristic infant behaviors, and have unrealistic expectations about the newborn's abilities (Goff & O'Connor, 2007). Instruct the mother or caretaker how to care for the newborn, including what to do after the newborn goes home (Teaching Guidelines 24.1).

On the other hand, the newborn may be a powerful motivator for the mother to undergo treatment and seek recovery. Refer the mother to community agencies to address addiction and the infant's developmental needs (Gilbert, 2006). The nurse can play a pivotal role in assisting her to abstain from drug use and to promote effective parenting skills.

HYPERBILIRUBINEMIA

Hyperbilirubinemia is a total serum bilirubin level above 5 mg/dL resulting from unconjugated bilirubin being deposited in the skin and mucous membranes (Blackburn, 2007). Hyperbilirubinemia is exhibited as jaundice (yellowing of the body tissues and fluids). Newborn jaundice is one of the most common reasons for hospital readmission. It occurs in 60% to 80% of term

TEACHING GUIDELINES 24.1

Caring for Your Newborn at Home

- Position your newborn with the head elevated to prevent choking.
- To aid your newborn's sucking and swallowing during feeding, position the chin downward and support it with your hand.
- Place your newborn on his or her back to sleep or nap, never on the stomach.
- Keep a bulb syringe close by to suction your newborn's mouth in case of choking.
- Cluster newborn care (bathing, feeding, dressing) to prevent overstimulation.
- If your newborn is fussy or crying, try these measures to help calm him or her:
  - Wrap your newborn snugly in a blanket and gently rock in rocking chair.
  - Take the baby for a ride in the car (using a newborn car seat).
  - Play soothing music and "dance" with the newborn.
  - Use a wind-up swing with music.
- To help your newborn get to sleep, try these measures:
  - Schedule a bath with a gentle massage prior to bedtime.
  - Change diaper and clothes to make the baby comfortable.
  - Feed the baby just prior to bedtime.
  - If the newborn cries when put in crib and all needs are met, allow him or her to cry.
  - Use a rocking chair to feed and sing a soft lullaby.
- Call your primary care provider if you observe withdrawal behaviors such as:
  - Slight tremors (shaking) of hands and legs
  - Stiff posture when held in your arms
  - Irritability and frequent fussiness
  - High-pitched cry, excessive sucking motions
  - Erratic sleep pattern
  - Frequent yawning, nasal stuffiness, sweating
  - Prolonged time needed to feed
  - Frequent vomiting after feeding

newborns in the first week of life and in virtually all preterm newborns (Rodriguez et al., 2008).

Pathophysiology

Newborn jaundice results from an imbalance in the rate of bilirubin production and bilirubin elimination. This imbalance determines the pattern and degree of newborn hyperbilirubinemia (Blackburn, 2007).

During the newborn period, a rapid transition from the intrauterine to the extrauterine pattern of bilirubin physiology occurs. Fetal unconjugated bilirubin is normally cleared by the placenta and the mother's liver in utero, so total bilirubin at birth is low. After the umbilical cord is cut, the newborn must conjugate bilirubin (convert a lipid-soluble pigment into a water-soluble pigment) in the liver on his or her own. The rate and amount of bilirubin conjugation depend on the rate of red blood cell breakdown, the bilirubin load, the maturity of the liver, and the number of albumin-binding sites (Kenner & Lott, 2007). Bilirubin production increases after birth mainly because of a shortened red blood cell lifespan (70 days in the newborn vs. 90 days in the adult) combined with an increased red blood cell mass. Therefore, the amount of bilirubin the newborn must deal with is large compared to that of an adult.

Bilirubin has two forms—unconjugated or indirect, which is fat-soluble and toxic to body tissues, and conjugated or direct, which is water-soluble and nontoxic. Elevated serum bilirubin levels are manifested as jaundice in the newborn. Typically the total serum bilirubin level rises over the first 3 to 5 days and then declines.

Physiologic Jaundice

Physiologic jaundice is the manifestation of the normal hyperbilirubinemia seen in newborns, appearing during the third to fourth days of life, due to the limitations and abnormalities of bilirubin metabolism. It occurs in 60% of term infants and up to 80% of preterm infants (Blackburn, 2007). Serum bilirubin levels reach up to 10 mg/dL and then decline rapidly over the first week after birth (Cunningham et al., 2005). Most newborns have been discharged by the time this jaundice peaks (at about 72 hours).

Physiologic jaundice may result from an increased bilirubin load because of relative polycythemia, a shortened red blood cell lifespan, immature hepatic uptake and conjugation process, and increased enterohepatic circulation (McLenan, 2007). Newborns with delayed passage of meconium are more likely to develop physiologic jaundice (Blackburn, 2007).

Physiologic jaundice differs between breastfed and bottle-fed newborns in relation to the onset of symptoms. Breastfed newborns typically have peak bilirubin levels on the fourth day of life; levels for bottle-fed newborns usually peak on the third day of life. The rate of bilirubin decline is less rapid in breastfed newborns compared to bottle-fed newborns because bottle-fed newborns tend to have more frequent bowel movements. Jaundice associated with breastfeeding presents in two distinct patterns: early-onset breastfeeding jaundice and late-onset breast milk jaundice.

Early-Onset Breastfeeding Jaundice

Early-onset breastfeeding jaundice is probably associated with ineffective breastfeeding practices because of relative

caloric deprivation in the first few days of life. Decreased volume and frequency of feedings may result in mild dehydration and the delayed passage of meconium. This delayed defecation allows enterohepatic circulation reuptake of bilirubin and an increase in the serum level of unconjugated bilirubin. To prevent this, strategies to promote early effective breastfeeding are important. The AAP guidelines recommend early and frequent breastfeeding without supplemental water or dextrose-water unless medically indicated (AAP, 2005). Early frequent feedings can provide the newborn with adequate calories and fluid volume (via colostrum) to stimulate peristalsis and passage of meconium to eliminate bilirubin.

Late-Onset Breastfeeding Jaundice

Late-onset breastfeeding jaundice occurs later in the newborn period, with the bilirubin level usually peaking in the 6th to 14th day of life. Total serum bilirubin levels may be 12 to 20 mg/dL, but the levels are not considered pathologic (Simpson, 2007). The specific cause of late-onset breast milk jaundice is not entirely understood, but it may be related to a change in the milk composition resulting in enhanced enterohepatic circulation. Additional research is needed to determine the cause. Interrupting breastfeeding is not recommended unless bilirubin levels reach dangerous levels; if this occurs, breastfeeding is stopped for only 1 or 2 days. Substituting formula during this short break usually results in a prompt decline of bilirubin levels.

Pathologic Jaundice

Pathologic jaundice is manifested within the first 24 hours of life when total bilirubin levels increase by more than 5 mg/dL/day and the total serum bilirubin level is higher than 17 mg/dL in a full-term infant (Ozen & Mukherjee, 2007). Conditions that alter the production, transport, uptake, metabolism, excretion, or reabsorption of bilirubin can cause pathologic jaundice in the newborn. A few conditions that contribute to red blood cell breakdown and thus higher bilirubin levels include polycythemia, blood incompatibilities, and systemic acidosis. These altered conditions can lead to high levels of unconjugated bilirubin, possibly reaching toxic levels and resulting in a severe condition called kernicterus.

Kernicterus (yellow nucleus) or bilirubin encephalopathy is a preventable neurologic disorder characterized by encephalopathy, motor abnormalities, hearing and vision loss, and death (Maisels & Newman, 2007). Neurotoxicity develops because unconjugated bilirubin has a high affinity for brain tissue, and bilirubin not bound to albumin is free to cross the blood–brain barrier and damage cells of the CNS.

In the acute stage, the newborn becomes lethargic, irritable, and hypotonic and sucks poorly. If the hyperbilirubinemia is not treated, the newborn becomes hypertonic, with arching and seizures. A high-pitched cry may be noted. These changes can occur rapidly, so all newborns must be assessed for jaundice and tested if indicated so that treatment can be initiated.

The most common condition associated with pathologic jaundice is hemolytic disease of the newborn secondary to incompatibility of blood groups of the mother and the newborn. The most frequent conditions are Rh factor and ABO incompatibilities.

▶ *Take* NOTE!

Significant jaundice in the newborn less than 24 hours of age should be immediately reported to the physician, as it may indicate a pathologic process.

Rh Isoimmunization

Rh incompatibility or isoimmunization develops when an Rh-negative woman who has experienced Rh isoimmunization subsequently becomes pregnant with an Rh-positive fetus. The maternal antibodies cross the placenta into the fetal circulation and begin to break down the red blood cells (Fig. 24.6). Destruction of the fetal red blood cells leads to fetal anemia and hemolytic disease of the newborn. The severity of the fetal hemolytic process depends on the level and effectiveness of anti-D antibodies and the capacity of the fetal system to remove antibody-coated cells.

Intrauterine transfusions with Rh-negative, type O blood may be life-saving if done in time. The widespread administration of Rh immune globulin (RhoGAM), combined with aggressive fetal surveillance and transfusion, has reduced the incidence of hemolytic disease of the newborn.

Immune hydrops, also called hydrops fetalis, is a severe form of hemolytic disease of the newborn that occurs when pathologic changes develop in the organs of the fetus secondary to severe anemia. Hydrops fetalis results from fetal hypoxia, anemia, congestive heart failure, and hypoproteinemia secondary to hepatic dysfunction. ABO and Rh incompatibilities can both cause hydrops fetalis, but Rh disease is the more common cause. Typically, hydrops is not observed until the hemoglobin drops below approximately 4 g/dL (hematocrit <15%) (Huang et al., 2007). Fetuses with hydrops may die in utero from profound anemia and circulatory failure. The placenta is very enlarged and edematous. One sign of severe anemia and impending death is the sinusoidal fetal heart rate pattern (Cunningham et al., 2005).

ABO Incompatibility

ABO incompatibility is an immune reaction that occurs when the mother has type O blood and the fetus has type A, B, or AB blood. Although it occurs more frequently

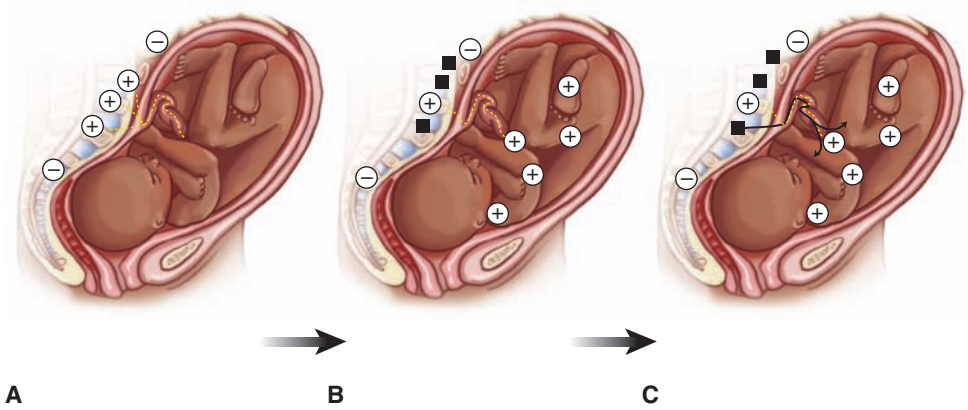


FIGURE 24.6 Rh isoimmunization. (**A**) The Rh-negative mother is exposed to Rh-positive antigens. (**B**) Maternal antibodies form. (**C**) Rh antibodies are transferred to the fetus.

than Rh incompatibilities, it causes less severe problems and rarely results in hemolytic disease severe enough to be clinically diagnosed and treated. Enlargement of the spleen and liver may be found in newborns with ABO incompatibility, but hydrops fetalis is rare (Kenner & Lott, 2007). Because the antibodies resulting in ABO incompatibility occur naturally, it is impossible to eliminate this type of incompatibility.

Women with type O blood develop anti-A or anti-B antibodies throughout their life through foods they eat and exposure to infections. Most species of anti-A and anti-B antibodies are immunoglobin M (IgM), which cannot cross the placenta and thus cannot gain access to the fetal red blood cells. Some anti-A and anti-B antibodies from the mother may cross the placenta to the fetus during the first pregnancy and can cause hemolysis of fetal blood cells.

Nursing Assessment

Nurses play an important role in early detection and identification of jaundice in the newborn. Keen observation skills are essential.

Health History and Physical Examination

Review the medical record for factors that might predispose the newborn to hyperbilirubinemia, such as:

- Polycythemia
- Significant bruising or cephalhematoma, which increases bilirubin production
- Infections such as TORCH (toxoplasmosis, hepatitis B, rubella, cytomegalovirus, herpes simplex virus)
- Use of drugs during labor and birth such as diazepam (Valium) or oxytocin (Pitocin)
- Prematurity
- Gestational age of 34 to 36 weeks
- Hemolysis due to ABO incompatibility or Rh isoimmunization
- Macrosomic infant of a diabetic mother
- Delayed cord clamping, which increases the erythrocyte volume
- Decreased albumin binding sites to transport unconjugated bilirubin to the liver because of acidosis
- Delayed meconium passage, which increases the amount of bilirubin that returns to the unconjugated state and can be absorbed by the intestinal mucosa
- Siblings who had significant jaundice
- Inadequate breastfeeding leading to dehydration, decreased caloric intake, weight loss, and delayed passage of meconium
- Ethnicity, such as Asian-American, Mediterranean, or Native American
- Male gender (Kenner & Lott, 2007)

Perform a complete physical examination. Assess the skin, mucous membranes, sclerae, and bodily fluids (tears, urine) for a yellow color. Detect jaundice by observing the infant in a well-lit room and blanching the skin with digital pressure over a bony prominence. Typically, jaundice begins on the head and gradually progresses to the abdomen and extremities. Also inspect for pallor (anemia), excessive bruising (bleeding), and dehydration (sluggish circulation), which may contribute to the development of jaundice and the risk for kernicterus.

Assess the newborn for Rh incompatibility. Be alert for clinical manifestations such as ascites, congestive heart failure, edema, pallor, jaundice, hepatosplenomegaly, hydramnios, thick placenta, and dilation of the umbilical vein (Blackburn, 2007).

The hydropic newborn appears pale, edematous, and limp at birth and typically requires resuscitation. The newborn with immune hydrops exhibits severe generalized edema, organ hypertrophy and enlargement, and effusion of fluid into body cavities.

Laboratory and Diagnostic Testing

Determine maternal and fetal blood types, checking for incompatibilities (Comparison Chart 24.1). Assess lab-

COMPARISON CHART 24.1 **Rh vs. ABO Incompatibility**

Clinical Picture	Rh Incompatibility	ABO Incompatibility
First-born	Rare	Common
Later pregnancies	More severe	No increase in severity
Jaundice	Moderate to severe	Mild
Hydrops fetalis	Frequent	Rare
Anemia	Frequently severe	Rare
Ascites	Frequent	Rare
Hepatosplenomegaly	Frequent	Common

oratory values for bilirubin (both unconjugated and conjugated). Bilirubin levels establish the diagnosis of hyperbilirubinemia. The newborn with Rh incompatibility demonstrates a rapidly rising unconjugated bilirubin level at birth or in the first 24 hours. Also expect to obtain alkaline phosphatase, liver enzymes, and prothrombin time and partial thromboplastin time, as well as:

- Direct Coombs test—to identify hemolytic disease of the newborn; positive results indicate that the newborn's red blood cells have been coated with antibodies and thus are sensitized
- Hemoglobin concentration—for evidence of anemia
- Blood type—to determine Rh status and any incompatibility of the newborn
- Total serum protein—to detect reduced binding capacity of albumin
- Reticulocyte count—to identify an elevated level indicating increased hemolysis

Assist with obtaining blood specimens. Use cord blood for hemoglobin concentration measurements; use a heel stick for direct Coombs testing and bilirubin levels. Prepare the parents and newborn for radiologic evaluation if necessary to determine abnormalities that may be causing the jaundice.

Nursing Management

Nursing management of a newborn with hyperbilirubinemia requires a comprehensive approach. As members of the health care team, nurses share in the responsibility for early detection and identification, family education, management, and follow-up of the mother and newborn. Documentation of the timing of onset of jaundice is essential to differentiate between physiologic (>24 hours) and pathologic jaundice (<24 hours). Nurses can improve care by offering their presence and support.

Reducing Bilirubin Levels

Encourage early initiation of feedings to prevent hypoglycemia and provide protein to maintain the albumin levels to transport bilirubin to the liver. Ensure newborn feedings (breast milk or formula) every 2 to 3 hours to promote prompt emptying of bilirubin from the bowel. Encourage the mother to breastfeed (8 to 12 feedings per day) to prevent inadequate intake and thus dehydration. Supplement breast milk with formula to supply protein if bilirubin levels continue to increase with breastfeeding only. Monitor serum bilirubin levels frequently to reduce the risk of severe hyperbilirubinemia.

Phototherapy

For the newborn with jaundice, regardless of its etiology, phototherapy is used to convert unconjugated bilirubin to the less toxic water-soluble form that can be excreted. Phototherapy, via special lights placed above the newborn or a fiber-optic blanket placed under the newborn and wrapped around him or her, involves blue wavelengths of light to alter unconjugated bilirubin in the skin. For the newborn receiving phototherapy, place the newborn under the lights or on the fiberoptic blanket, exposing as much skin as possible. Cover the newborn's genitals and shield the eyes to protect these areas from becoming irritated or burned when using direct lights. Assess the intensity of the light source to prevent burns and excoriation (Fig. 24.7).

FIGURE 24.7 A newborn receiving phototherapy. Here the nurse is checking the intensity of the lights with a meter.

Turn the newborn every 2 hours to maximize the area of exposure, removing the newborn from the lights only for feedings. Maintain a neutral thermal environment to decrease energy expenditure, and assess the newborn's neurologic status frequently.

Assess the newborn's temperature every 3 to 4 hours as indicated. Monitor fluid intake and output closely and assess daily weights for gains or losses. Check skin turgor for dehydration.

With feedings, remove the newborn from the lights and remove the eye shields to allow interaction with the newborn. Encourage breast or bottle feedings every 2 to 3 hours. Follow agency policy about removing the eye shields periodically to assess the eyes for discharge or corneal irritation secondary to eye shield pressure. Typically, the eyes are assessed and eye shields removed once a shift.

Monitor stool for consistency and frequency. Unconjugated bilirubin excreted in the feces will produce a greenish appearance, and typically stools are loose. Lack of frequent green stools is a cause for concern.

Provide meticulous skin care. Assess skin surfaces frequently for dryness and irritation secondary to the dehydrating effects of phototherapy and irritation from highly acidic stool to prevent excoriation and skin breakdown (Simpson, 2007). Monitor the newborn's skin turgor.

Exchange Transfusion

If the total serum bilirubin level remains elevated after intensive phototherapy, an exchange transfusion, the quickest method for lowering serum bilirubin levels, may be necessary (Springer & Annibale, 2007). In the presence of hemolytic disease, severe anemia, or a rapid rise in the total serum bilirubin level, an exchange transfusion is recommended. An exchange transfusion removes the newborn's blood and replaces it with nonhemolyzed red blood cells from a donor. During the transfusion, monitor the newborn's cardiovascular status continuously because serious complications can arise, such as acid–base imbalances, infection, hypovolemia, and fluid and electrolyte imbalances. Exchange transfusion is used only as a second-line therapy after phototherapy has failed to yield results. Intensive nursing care is needed.

Assist the physician with an exchange transfusion if necessary. Monitor the newborn's status closely for changes, especially in vital signs and heart rate and rhythm, before, during, and after the procedure.

Providing Parent Teaching and Support

Nurses can help the parents to understand the diagnostic tests and treatment modalities by offering individualized teaching. Explore with the family their understanding of jaundice and treatment modalities to reduce anxiety and gain their cooperation in monitoring the infant. Teach the parents about jaundice and its potential risk using written and verbal material. Also show the parents how to identify newborn behaviors that might indicate rising bilirubin levels. Emphasize the need to seek treatment from their pediatrician should any of the following occur:

- Lethargy, sleepiness, poor muscle tone, floppiness
- Poor sucking, lack of interest in feeding
- High-pitched cry

Teach the parents how to assess their newborn for signs of jaundice because physiologic jaundice may not occur until after the newborn is discharged. Reinforce the need for appropriate follow-up with the primary care provider within 48 to 72 hours after discharge to assess jaundice status (Keren & Bhutani, 2007).

The need for phototherapy can be anxiety-producing for the parents. Explain the rationale for the procedure and demonstrate techniques that the parents can use to interact with their newborn. Additional education about phototherapy may be necessary when home phototherapy is used (Teaching Guidelines 24.2).

NEWBORN INFECTIONS

Newborns are susceptible to infections because their immune system is immature and slow to react. The antibodies that newborns received from their mother during pregnancy and from breast milk help protect them from invading organisms. However, these need time to reach optimal levels.

Bacterial infections of the newborn affect approximately 4 out of every 1,000 live births (McLenan, 2007). Making the diagnosis of sepsis in newborns is difficult due to its nonspecific symptoms. The mortality rate from newborn sepsis may be as high as 50% if untreated. Infection is a major cause of death during the first month of life, contributing to 13% to 15% of all neonatal deaths (Anderson-Berry & Bellig, 2007).

Pathophysiology

When a pathologic organism overcomes the newborn's defenses, infection and sepsis results. **Neonatal sepsis** is the presence of bacterial, fungal, or viral microorganisms or their toxins in blood or other tissues. Infections that have an onset within the first month of life are termed newborn infections. Exposure to a pathogenic organism, whether a virus, fungus, or bacteria, occurs, and it enters the newborn's body and begins to multiply.

Newborn infections are usually grouped into three classes according to their time of onset: congenital infection, acquired in utero (intrauterine infections) by vertical transmission with onset before birth; early-onset infections, acquired by vertical transmission in the perinatal period, either shortly before or during birth; and late-onset infections, acquired by horizontal transmission in the nursery. As many as 80% to 90% of neonatal infections have

TEACHING GUIDELINES 24.2

Caring for Your Newborn Receiving Home Phototherapy

- Inspect your newborn's skin, eyes, and mucous membranes for a yellow color.
- Remember that a home health nurse will come to visit and help you set up the light system.
- Keep the lights about 12 to 30 inches above your newborn.
- Cover your newborn's eyes with patches or cotton balls and gauze to protect them.
- Keep the newborn undressed except for the diaper area; fold the diaper down below the newborn's navel in the front and as far as possible in the back to expose as much skin area as possible.
- Turn your newborn every 2 hours so that all areas of the body are exposed.
- Remove the newborn from the lights only for feeding.
- Remove the eye patches during feedings so that you can interact with your newborn.
- Record your newborn's temperature, weight, and fluid intake daily.
- Document the frequency, color, and consistency of all stools; the stools should be loose and green as the bilirubin is broken down.
- Keep the skin clean and dry to prevent irritation.
- Feed your newborn frequently, including supplemental glucose water if allowed to provide added fluid, protein, and calories.
- Rock, cuddle, or hold the newborn to promote bonding when out of the lights.
- Contact your pediatrician or home health care agency with any questions or changes, including refusing feedings, fewer than five wet diapers in one day, vomiting of complete amounts of feeding, or elevated temperature.
- Keep appointments for follow-up laboratory testing to monitor bilirubin levels.

their onset in the first 2 days of life (CDC, 2007). Comparison Chart 24.2 compares the three classes of newborn infections.

Nursing Assessment

Nursing assessment focuses on early identification of a newborn at risk for infection to allow for prompt treatment, thus reducing mortality and morbidity. Be aware of the myriad risk factors associated with newborn sepsis. Among the factors that contribute to the newborn's overall vulnerability to infection are poor skin integrity, invasive procedures, exposure to numerous caregivers, and an environment conducive to bacterial colonization (Kenner & Lott, 2007).

Few newborn infections are easy to recognize because manifestations usually are nonspecific. Early symptoms can be vague because of the newborn's inability to mount an inflammatory response. Often, the observation is that the newborn does not "look right." Assess the newborn for common nonspecific signs of infection, including:

- Hypothermia
- Pallor or duskiness
- Hypotonia
- Cyanosis
- Poor weight gain
- Irritability
- Seizures
- Jaundice
- Grunting
- Nasal flaring
- Apnea and bradycardia
- Lethargy
- Hypoglycemia
- Poor feeding (lack of interest in feeding)
- Abdominal distention (Anderson-Berry & Bellig, 2007)

Since infection can be confused with other newborn conditions, laboratory and radiographic tests are needed to confirm the presence of infection. Be prepared to coordinate the timing of the various tests and assist as necessary.

Evaluate the complete blood count with a differential to identify anemia, leukocytosis, or leukopenia. Elevated C-reactive protein levels may indicate inflammation. As ordered, obtain x-rays of the chest and abdomen, which may reveal infectious processes located there. Blood, cerebrospinal fluid, and urine cultures are indicated to identify the location and type of infection present. Positive cultures confirm that the newborn has an infection.

Nursing Management

To enhance the newborn's chance of survival, early recognition and diagnosis are key. Often the diagnosis of sepsis is based on a suspicious clinical picture. Antibiotic therapy is usually started before the laboratory results identify the infecting pathogen (see Evidence-Based Practice). Along with antibiotic therapy, circulatory, respiratory, nutritional, and developmental support is important. Antibiotic therapy is continued for 7 to 21 days if cultures are positive, or it is discontinued within 72 hours if cultures are negative. With the use of antibiotics along with early recognition and supportive care, mortality and morbidity rates have been reduced greatly.

Nurses possess the education and assessment tools to decrease the incidence of and reduce the impact of infections on women (see Chapter 20 for additional information) and their newborns. Implement measures for prevention and early recognition, including:

COMPARISON CHART 24.2 INTRAUTERINE VS. EARLY-ONSET VS. LATE-ONSET NEWBORN INFECTIONS

	Intrauterine (Congenital)	Early-Onset Infections	Late-Onset Infections
Risk factors	-Immature immune system IgM, IgA, and T lymphocytes -Decreased gastric acid, which is needed to reduce organisms	-Prolonged rupture of membranes -Urinary tract infections -Preterm labor -Prolonged or difficult labor -Maternal fever -Colonization with group B streptococci -Maternal infections	-Low birthweight -Prematurity -Meconium staining -Need for resuscitation -Birth asphyxia -Improper handwashing
Common causative organisms	-Cytomegalovirus -Rubella -Toxoplasmosis -Syphilis	-*Escherichia coli* -Group B streptococci -*Klebsiella pneumoniae* -*Listeria monocytogenes* -Other enteric gram-negative bacilli	-*Candida albicans* -Coagulase-negative staphylococci -*Staphylococcus aureus* -*E. coli* -Enterobacter -Klebsiella -Serratia -Pseudomonas -Group B streptococci
Mechanism of infection	-Organism crossing placenta into fetal circulatory system; organism residing in amniotic fluid -Ascent of organism via the vagina, ultimately infecting membranes and causing rupture and leading to respiratory and gastrointestinal tract infections	Most occur during birthing process when newborn comes into contact with infected birth canal (newborn cannot defend against host organisms). -Newborn susceptibility to infection by exogenous organisms possibly due to inadequacy of physical barriers (thin, friable skin with little subcutaneous tissue) -Lack of gastric acidity, possibly resulting in easy colonization by environmental organisms -Aspiration of microorganisms during birth with development of pneumonia	More common in newborns undergoing invasive procedures such as endotracheal intubation or catheter insertion; break in skin or mucosal protection barrier.

Sources: Blackburn (2007); Brousseau & Sharieff (2007), Kenner & Lott (2007).

- Formulating a sepsis prevention plan that includes education of all members of the health care team on identification and treatment of sepsis
- Screening all newborns daily for signs of sepsis
- Monitoring sepsis cases and outcomes to reinforce continued quality-improvement measures or to modify current practices
- Outlining and carrying out measures to prevent nosocomial infections, such as:
  - Thorough handwashing hygiene for all staff
  - Frequent oral care and inspections of mucous membranes
  - Proper positioning and turning to prevent skin breakdown
  - Use of strict aseptic technique for all wound care
  - Frequent monitoring of invasive catheter sites for signs of infection
- Identifying newborns at risk for sepsis by reviewing risk factors
- Monitoring vital sign changes and observing for subtle signs of infection
- Monitoring for signs of organ system dysfunction:
  - Cardiovascular compromise—tachycardia and hypotension

EVIDENCE-BASED PRACTICE 24.1
Treating Neonatal Sepsis With Gentamicin Given as a Once-Daily Dose or as Multiple Doses per Day

● Study
Sepsis in a newborn can be fatal, and the signs and symptoms can be vague. Antibiotic therapy is usually initiated before the infection is confirmed by cultures. Gentamicin is a common antibiotic used to treat neonatal sepsis because of its effectiveness against gram-negative pathogens. However, gentamicin, like other aminoglycosides, can have adverse effects on hearing and kidney function, leading to questions about the most effective dosing regimen. Studies have shown that once-a-day dosing is most effective in older children and adults, but these studies do not address the neonatal population.

A study involving neonates with confirmed or suspected sepsis was completed to evaluate the effectiveness and safety of two types of dosing regimens: once-a-day dosing and multiple-doses-per-day dosing. All randomized or quasi-randomized controlled trials involving a comparison of one daily dose with multiple doses per day of gentamicin to newborns less than 28 days of age were selected. Information about clinical effectiveness, pharmacokinetic effectiveness, ototoxicity, and nephrotoxicity was collected. Of the 24 studies initially selected, 11 were evaluated. Most of the studies used intravenous infusion of gentamicin as the method of administration. One study used a bolus dose of gentamicin administered over 1 minute; two other studies used intramuscular administration.

▲ Findings
Regardless of the dosing regimen, gentamicin was shown to be effective in treating the sepsis. The once-daily dosing regimen appeared to be more effective: appropriate peak and trough levels of the drug were obtained more frequently when compared to the multiple dosing regimen. The studies found no evidence of ototoxicity or nephrotoxicity with either regimen.

■ Nursing Implications
The study confirmed the effectiveness of gentamicin in the treatment of neonatal sepsis, but it did not determine whether a once-daily dose was more effective than multiple doses per day in treating sepsis. Nurses can integrate the findings of this study into their practice when caring for newborns who are at risk for or have developed sepsis. Regardless of the regimen ordered, nurses can be diligent in ensuring that peak and trough drug levels are monitored. Although the study showed no evidence of hearing and kidney adverse effects, nurses still need to monitor the newborns for this possibility.

Rao, S. C., Ahmed, M., & Hagan, R. (2006). One dose per day compared to multiple doses per day of gentamicin for treatment of suspected or proven sepsis in neonates. *Cochrane Database of Systematic Reviews* 2006. Issue 1. Art. No.: CD005091.

- Respiratory compromise—respiratory distress and tachypnea
- Renal compromise—oliguria or anuria
- Systemic compromise—abnormal blood values

- Providing comprehensive sepsis treatment:
  - Circulatory support with fluids and vasopressors
  - Supplemental oxygen and mechanical ventilation
  - Obtaining culture samples as requested
  - Antibiotic administration as ordered, observing for side effects
  - Promoting newborn comfort
  - Assessing the family's educational needs and providing instructions as necessary

Perinatal infections continue to be a public health problem, with severe consequences for those affected. By promoting a better understanding of newborn infections and appropriate use of therapies, nurses can lower the mortality rates associated with severe sepsis, especially with appropriate timing of interventions. The potential for nursing interventions to identify, prevent, and minimize the risk for sepsis is significant. Primary disease prevention must be a major focus for nurses. Family education plays a key role in the prevention of perinatal infections, in addition to following accepted practices in immunization.

Congenital Conditions

Congenital conditions can arise from many etiologies, including single-gene disorders, chromosome aberrations, exposure to teratogens, and many sporadic conditions of unknown cause. Congenital conditions may be inherited or sporadic, isolated or multiple, apparent or hidden, gross or microscopic. They cause nearly half of all deaths in term newborns and cause long-term sequelae for many. The incidence varies according to the type of defect. When a serious anomaly is identified prenatally, the parents can decide whether or not to continue the pregnancy. When an anomaly is identified at or after birth, parents need to be informed promptly and given a realistic appraisal of the severity of the condition, the prognosis, and treatment options so that they can participate in all decisions pertaining to their child.

Congenital conditions can affect virtually any body system. This chapter describes those congenital conditions

that require immediate treatment or affect the newborn in the period immediately after birth. Other congenital conditions, such as congenital heart disease or CNS defects, are discussed in later chapters due to their long-term nature and ongoing effects.

ESOPHAGEAL ATRESIA AND TRACHEOESOPHAGEAL FISTULA

Esophageal atresia and tracheoesophageal fistula are gastrointestinal anomalies in which the esophagus and trachea do not separate normally during embryonic development. Esophageal atresia refers to a congenitally interrupted esophagus where the proximal and distal ends do not communicate; the upper esophageal segment ends in a blind pouch and the lower segment ends a variable distance above the diaphragm (Fig. 24.8).

Tracheoesophageal fistula is an abnormal communication between the trachea and esophagus. When associated with esophageal atresia, the fistula most commonly occurs between the distal esophageal segment and the trachea. The incidence of esophageal atresia is 1 per 3,000 to 4,000 live births (Blackburn, 2007).

Pathophysiology

Several types of esophageal atresia exist, but the most common anomaly is a fistula between the distal esopha-

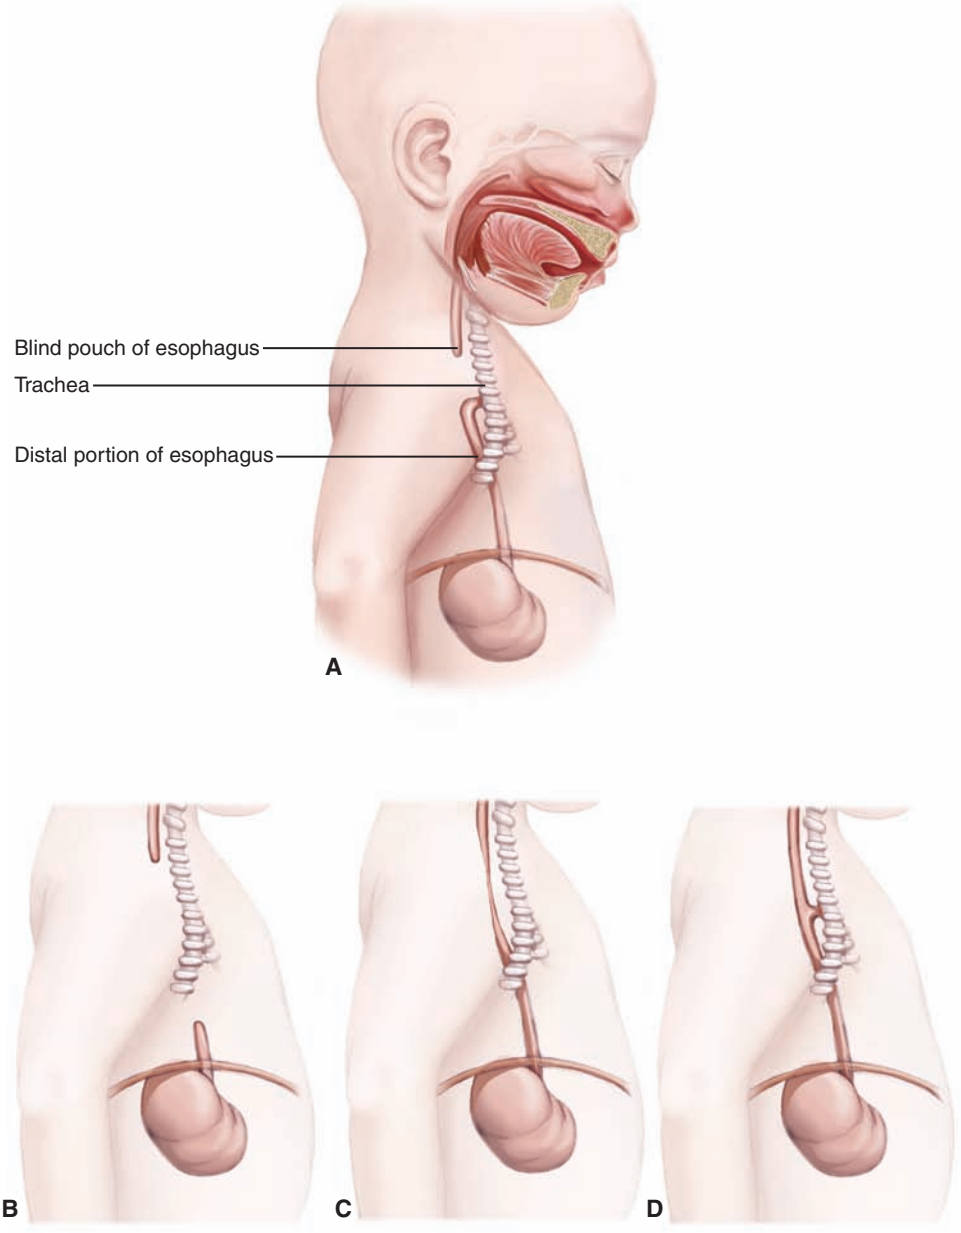

FIGURE 24.8 Esophageal atresia and tracheoesophageal fistula. (**A**) The most common type of esophageal atresia, in which the esophagus ends in a blind pouch and a fistula connects the trachea with the distal portion of the esophagus. (**B**) The upper and distal portions of the esophagus end in a blind pouch. (**C**) The esophagus is one segment, but a portion of it is narrowed. (**D**) The upper portion of the esophagus connects to the trachea via a fistula.

gus and the trachea, which occurs in 86% of newborns with an esophageal defect. Esophageal atresia and tracheoesophageal fistula are thought to be the result of incomplete separation of the lung bed from the foregut during early fetal development. A large percentage of these newborns have other congenital anomalies involving the vertebra, kidneys, heart, and musculoskeletal and gastrointestinal systems (Rodriguez, 2006); most have several anomalies.

Nursing Assessment

Review the maternal history for polyhydramnios. Often this is the first sign of esophageal atresia because the fetus cannot swallow and absorb amniotic fluid in utero, leading to accumulation. Soon after birth, the newborn may exhibit copious, frothy bubbles of mucus in the mouth and nose, accompanied by drooling. Abdominal distention develops as air builds up in the stomach. In esophageal atresia, a gastric tube cannot be inserted beyond a certain point because the esophagus ends in a blind pouch. The newborn may have rattling respirations, excessive salivation and drooling, and "the three C's" (coughing, choking, and cyanosis) if feeding is attempted. The presence of a fistula increases the risk of respiratory complications such as pneumonitis and atelectasis due to aspiration of food and secretions (Kenner & Lott, 2007).

▶ *Take* NOTE!

The "three C's" of choking, coughing, and cyanosis in conjunction with feeding are considered the classic signs of tracheoesophageal fistula and atresia.

Prepare the newborn and parents for radiographic evaluation. Diagnosis is made by x-ray: a gastric tube appears coiled in the upper esophageal pouch, and air in the gastrointestinal tract indicates the presence of a fistula (Kenner & Lott, 2007). Once a diagnosis of esophageal atresia is established, begin preparations for surgery if the newborn is stable.

Nursing Management

Nursing management focuses on preparing the newborn and parents for surgery and providing meticulous postoperative care.

Providing Preoperative Care

Preoperative nursing interventions include the following measures:

- Initiate nothing by mouth (NPO) status.
- Elevate the head of the bed 30 to 45 degrees to prevent reflux and aspiration.
- Monitor hydration status and fluid and electrolyte balance; administer and monitor parenteral IV fluid infusions.
- Assess and maintain the patency of the orogastric tube; monitor the functioning of the tube, which is attached to low continuous suction; and avoid irrigation of the tube to prevent aspiration.
- Have oxygen and suctioning equipment readily available should the newborn experience respiratory distress.
- Assist with diagnostic studies to rule out other anomalies.
- Use comfort measures to minimize crying and prevent respiratory distress; provide nonnutritive sucking.
- Inform the parents about the rationales for the aspiration prevention measures.
- Document frequent observations of the newborn's condition (Kenner & Lott, 2007).

Providing Postoperative Care

Surgery consists of closing the fistula and joining the two esophageal segments. Postoperative care involves closely observing all of the newborn's body systems to identify any complications. Expect to administer TPN and antibiotics until the esophageal anastomosis is proven intact and patent. Then begin oral feedings, usually within a week after surgery (Blackburn, 2007). Keep the parents informed of their newborn's condition and progress. Closely assess the newborn during feeding and report any difficulty with swallowing. Provide parent teaching. Demonstrate and reinforce all teaching prior to discharge.

OMPHALOCELE AND GASTROSCHISIS

Omphalocele and gastroschisis are congenital anomalies of the anterior abdominal wall. An **omphalocele** is a defect of the umbilical ring that allows evisceration of the abdominal contents into an external peritoneal sac. Defects vary in size; they may be limited to bowel loops or may include the entire gastrointestinal tract and liver (Fig. 24.9). Bowel malrotation is common, but the displaced organs are usually normal. Omphaloceles are associated with other anomalies in more than 70% of the cases. This anomaly is usually detected during routine prenatal ultrasound of the fetus or during investigation of an increased alpha-fetoprotein level (Glasser, 2006).

Gastroschisis is a herniation of the abdominal contents through an abdominal wall defect, usually to the left or right of the umbilicus (McLenan, 2007). Gastroschisis differs from omphalocele in that there is no peritoneal sac protecting the herniated organs, and thus exposure to amniotic fluid makes them thickened, edematous, and inflamed (Rodriguez, 2006). Gastroschisis is associated

FIGURE 24.9 Omphalocele in a newborn. Note the large, protruding sac.

with significant newborn mortality and morbidity rates. Despite surgical correction, feeding intolerance, failure to thrive, and prolonged hospital stays occur in nearly all newborns with this anomaly (Glasser, 2006).

Each of these diagnoses requires that a pediatric surgeon be available at delivery to determine the extent of the defect and complications.

Nursing Assessment

Review the maternal history for factors associated with high-risk pregnancies, such as maternal illness and infection, drug use, smoking, and genetic abnormalities. These factors are also associated with omphalocele and gastroschisis. They contribute to placental insufficiency and the birth of a small-for-gestational-age or preterm newborn, the populations in which both of these abdominal defects most commonly occur. The combined incidence of both congenital abdominal wall anomalies is 1 in 2,000 births (Glasser, 2006).

Omphalocele and gastroschisis are readily observed. Note the appearance of the protrusion on the abdomen and evidence of a sac. Inspect the sac closely for the presence of organs, most commonly the intestines but sometimes the liver. Also inspect the contents for any twisting of the intestines. Note the color of the organs within the sac and measure the size of the omphalocele.

Also perform a complete physical examination of the newborn. Typically these congenital conditions are associated with other congenital anomalies, such as those involving the cardiovascular, genitourinary, and central nervous systems.

Nursing Management

Nursing management of newborns with omphalocele or gastroschisis focuses on preventing hypothermia, maintaining perfusion to the eviscerated abdominal contents by minimizing fluid loss, and protecting the exposed abdominal contents from trauma and infection. These objectives can be accomplished by placing the infant in a sterile drawstring bowel bag that maintains a sterile environment for the exposed contents, allows visualization, reduces heat and moisture loss, and allows heat from radiant warmers to reach the newborn. The newborn is placed feet-first into the bag and the drawstring is secured around the torso (McLenan, 2007). Strict sterile technique is necessary to prevent contamination of the exposed abdominal contents.

An orogastric tube attached to low suction is used to prevent intestinal distention. IV therapy is administered to maintain fluid and electrolyte balance and provide a route for antibiotic therapy. Monitor the newborn's fluid status frequently. Closely observe the exposed bowel for vascular compromise, such as changes in color or a decrease in temperature, and report these immediately.

Providing Postoperative Care

Surgical repair of both defects occurs after initial stabilization and comprehensive evaluation for any other anomalies. It may have to occur in stages, depending on the defect (Box 24.4).

Postoperative care involves providing pain management, monitoring respiratory and cardiac status, monitoring intake and output, assessing for vascular compromise, maintaining the orogastric tube to suction, documenting the amount and color of drainage, and administering ordered medications and treatments (Lund, Bauer, & Berrios, 2007). Also be alert for complications, such as short bowel syndrome (see Chapter 41 for additional information).

BOX 24.4 Surgery to Repair Omphalocele and Gastroschisis

Surgical repair of gastroschisis is an emergency due to the high risk of intestinal atresia, resulting in obstruction. Primary repair of gastroschisis is usually performed without incident, unless the contents are unable to fit into the abdominal cavity. This occurs more often with a large omphalocele, requiring the surgeon to do a staged closure. This involves covering the defect with a synthetic material that is sequentially squeezed like toothpaste to reduce the defect into the abdominal cavity. After enough of the defect is in the abdominal cavity, a surgical repair is then performed (Islam, 2008). If damage to the exposed organs occurs, such as necrosis, then the necrotic sections are removed during the repair. If a significant amount of small intestine is lost, then the complication of short bowel syndrome may occur.

Promoting Parent–Newborn Interaction

The parents need continued support and progress reports on their newborn. They may be distraught at the sight of the anomaly, and they may be frightened to touch their newborn. Encourage the parents to touch the newborn and participate in care as much as possible. Because of the nature of this defect, bonding opportunities will be limited initially. However, strongly encourage frequent visiting. In addition, provide information to the parents about the defect, treatment modalities, and prognosis. After surgery, instruct the parents in care measures and provide them with home care instructions. Anticipate the need for a referral to a home health care agency and community resources for support.

IMPERFORATE ANUS

An imperforate anus is a gastrointestinal system malformation of the anorectal area that may occur in several forms. The rectum may end in a blind pouch that does not connect to the colon, or it may have fistulas (openings) between the rectum and the perineum, the vagina in girls or the urethra in boys (Fig. 24.10). The malformations occur during early fetal development and are associated with anomalies in other body systems.

Imperforate anus occurs in about 1 of every 5,000 live births (March of Dimes, 2006). The defect can be further classified as a high or low type, depending on its level. The level significantly influences the outcome in terms of fecal continence as well as management (Blackburn, 2007).

Surgical intervention is needed for both high and low types of imperforate anus. Surgery for a high type of defect involves a colostomy in the newborn period, with corrective surgery performed in stages to allow for growth. Surgery for the low type of anomaly, which frequently includes a fistula, involves closure of the fistula, creation of an anal opening, and repositioning of the rectal pouch into the anal opening. A major challenge for either type of surgical repair is finding, using, or creating adequate nerve and muscle structures around the rectum to provide for normal evacuation.

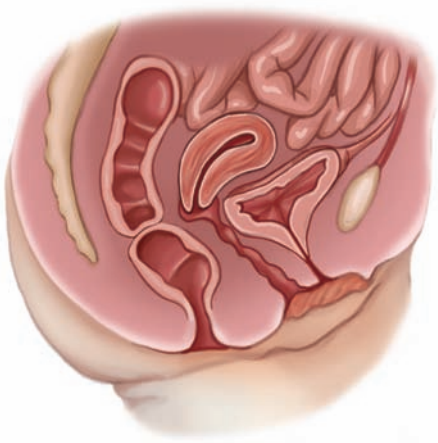

FIGURE 24.10 Imperforate anus, in which the rectum ends in a blind pouch.

Nursing Assessment

In the newborn, observe for an appropriate anal opening. If the anal opening exists, observe for passage of meconium stool within the first 24 hours of life. Assess urine output to identify genitourinary problems. For the newborn with an imperforate anus, inspection of the perineal area would reveal absence of the usual opening. In addition, meconium generally is not passed or present within 24 hours of birth.

In the infant with suspected imperforate anus, assess for common signs of intestinal obstruction, which may occur as a result of the malformation. These include abdominal distention and bilious vomiting.

Prepare the newborn and family for radiographic studies that may be ordered to assess for complications associated with imperforate anus.

Nursing Management

Nursing management focuses on preparing the newborn and parent for surgery and providing postoperative care. Preoperatively, maintain the newborn's NPO status and provide gastric decompression. Administer IV therapy and antibiotic therapy as ordered and monitor the newborn's hydration status. Provide a full explanation of the defect, surgical options, potential complications, typical postoperative course, and long-term care needed to the parents. Make sure they are aware of the available treatment modalities. Prepare them for the possibility that the newborn may require an ostomy. Provide support to the parents and family.

Postoperative care includes ensuring adequate pain relief, maintaining NPO status and gastric decompression until normal bowel function is restored, and providing colostomy care if applicable.

BLADDER EXSTROPHY

In bladder exstrophy, the bladder protrudes onto the abdominal wall because the abdominal wall failed to close during embryonic development. Wide separation of the rectus muscles and the symphysis pubis accompanies this defect. Virtually all affected male infants have associated epispadias. The upper urinary tract is usually normal. The incidence is approximately 1 in 24,000 to 40,000 live births (Kenner & Lott, 2007). Initial bladder closure is completed within 48 hours after birth. Further surgical re-

construction is performed in several stages at about 2 to 3 years of age. (See Chapter 42 for more information.)

Key Concepts

- Asphyxia, the most common clinical insult in the perinatal period, results in brain injury and may lead to mental retardation, cerebral palsy, or seizures.
- Transient tachypnea of the newborn occurs when the liquid in the lung is removed slowly or incompletely.
- Common risk factors for respiratory distress syndrome (RDS) include young gestational age, perinatal asphyxia regardless of gestational age, cesarean birth in the absence of labor (related to the lack of thoracic squeeze), male gender, and maternal diabetes.
- Meconium aspiration has three major pulmonary effects: airway obstruction, surfactant dysfunction, and chemical pneumonitis.
- The management of persistent pulmonary hypertension of the newborn requires meticulous attention to detail, with continuous monitoring of oxygenation, blood pressure, and perfusion.
- Periventricular/intraventricular hemorrhage is bleeding that usually originates in the subependymal germinal matrix region of the brain with extension into the ventricular system.
- Necrotizing enterocolitis (NEC) is a serious gastrointestinal disease of unknown etiology in newborns that can result in necrosis of a segment of the bowel.
- Infants of diabetic mothers are at risk for malformations most frequently involving the cardiovascular, skeletal, central nervous, gastrointestinal, and genitourinary systems; cardiac anomalies are the most common.
- Factors that place the newborn at risk for birth trauma include cephalopelvic disproportion, maternal pelvic anomalies, oligohydramnios, prolonged or rapid labor, abnormal presentation, fetal prematurity, fetal macrosomia, and fetal abnormalities.
- Women who use drugs during their pregnancy expose their unborn child to the possibility of intrauterine growth restriction, prematurity, neurobehavioral and neurophysiologic dysfunction, birth defects, infections, and long-term developmental sequelae.
- Newborns of women who abuse tobacco, illicit substances, caffeine, and alcohol can exhibit withdrawal behavior.
- Physiologic jaundice is a common, normal newborn phenomenon that appears during the second or third day of life and then declines over the first week after birth. Pathologic jaundice is manifested within the first 24 hours of life when total bilirubin levels increase by more than 5 mg/dL/day and the total serum bilirubin level is higher than 17 mg/dL in a full-term infant.
- Newborn infections are usually classified according to the time of onset and grouped into three categories: congenital infection, acquired in utero by vertical transmission with onset before birth; early-onset neonatal infections, acquired by vertical transmission in the perinatal period, either shortly before or during birth; and late-onset neonatal infections, acquired by horizontal transmission in the nursery.
- Congenital conditions can arise from many etiologies including single-gene disorders, chromosome aberrations, exposure to teratogens, and many sporadic conditions of unknown cause. Congenital structural anomalies may be inherited or sporadic, isolated or multiple, apparent or hidden, and gross or microscopic.
- Esophageal atresia refers to a congenitally interrupted esophagus where the proximal and distal ends do not communicate; the upper esophageal segment ends in a blind pouch and the lower segment ends a variable distance above the diaphragm. Tracheoesophageal fistula is an abnormal communication between the trachea and esophagus.
- Omphalocele and gastroschisis are congenital anomalies of the anterior abdominal wall. An omphalocele is a defect of the umbilical ring that allows evisceration of abdominal contents into an external peritoneal sac. Gastroschisis is a herniation of abdominal contents through an abdominal wall defect, usually to the left or right of the umbilicus.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. Which finding would lead the nurse to suspect that a newborn is experiencing respiratory distress syndrome?
   a. Abdominal distention
   b. Acrocyanosis
   c. Depressed fontanels
   d. Nasal flaring
2. When assessing the substance-exposed newborn, which finding would the nurse expect?
   a. Calm facial appearance
   b. Daily weight gain
   c. Increasing irritability
   d. Feeding and sleeping well
3. A newborn with tracheoesophageal fistula is likely to present with which assessment finding?
   a. Subnormal temperature
   b. Absent Moro reflex
   c. Inability to swallow
   d. Drooling from mouth
4. The nurse would be most alert for the development of transient tachypnea in a newborn who:
   a. Was born by cesarean birth
   b. Received no sedation
   c. Has a mother with heart disease
   d. Is small for gestational age

CRITICAL THINKING EXERCISES

1. As the nursery nurse, you receive a newborn from the labor and birth suite and place him under the radiant warmer. The nurse who gives you the report states that the mother couldn't remember when her membranes broke before labor and that she ran a fever during labor for the past few hours. The Apgar scores were good, but the newborn seemed lethargic. As you begin your assessment, you note that he is pale and floppy and has a subnormal temperature; heart rate is 180 bpm and respiratory rate is 70 breaths per minute.
   a. What in the mother's history should raise a red flag to the nurse?
   b. What condition is this newborn at high risk for?
   c. What interventions are appropriate for this condition?
2. Terry, a day-old baby girl, is very fretful, and calming measures don't seem to work. As the nursery nurse you notice that she is losing weight and her formula intake is poor, even though she is manifesting hungry behavior. The mother received no prenatal care and denied drug use, but her drug screen was positive for heroin.
   a. What additional information do you need to obtain from the mother?
   b. What additional laboratory work might be needed for Terry?
   c. What specific measures need to be made for her ongoing care?
3. Baby boy Sims, a term newborn, was brought to the nursery. His mother received no prenatal care, but the newborn's Apgar scores were fine. As the nurse carried out her newborn assessment, she noted an imperforate anus and palpated no testicles in the scrotal sac.
   a. What additional assessments should the nurse complete?
   b. Are anorectal agenesis and genitourinary tract anomalies common?
   c. What diagnostic tests might be ordered? What might be included in the treatment plan for this newborn?

STUDY ACTIVITIES

1. Arrange for a tour of a regional NICU to see the nurse's role in caring for sick neonates. Ask the nurse to give a quick history of each newborn's condition. Was the nurse's role like you imagined? What was your impression of the NICU, and how would you describe it to expectant parents?
2. Select a website from the list at the end of the chapter. What kind of information is given? How helpful would it be for parents with an infant diagnosed with a specific condition?
3. A herniation of a newborn's abdominal contents present at birth describes _____.

CHAPTER 25

Growth and Development of the Newborn and Infant

KEY TERMS

anticipatory guidance
binocularity
cephalocaudal
colic
development
discipline
growth
maturation
object permanence
proximodistal
solitary play
stranger anxiety
temperament

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify normal developmental changes occurring in the newborn and infant.
2. Identify the gross and fine motor milestones of the newborn and infant.
3. Express an understanding of language development in the first year of life.
4. Describe nutritional requirements of the newborn and infant.
5. Develop a nutritional plan for the first year of life.
6. Identify common issues related to growth and development in infancy.
7. Demonstrate knowledge of appropriate anticipatory guidance for common developmental issues.

Allison Johnson is a 6-month-old girl brought to the clinic by her mother and father for her 6-month check-up. As new parents, they have a list of questions and concerns. On assessment you find that Allison's weight is 16 pounds, length 25¾ inches, and head circumference 17 inches. As the nurse caring for her, assess Allison's growth and development, and then teach the parents what changes to expect in Allison over the next few months.

Wow

Of all the joys that lighten our hearts, what joy is welcomed like a newborn child?

The newborn or neonatal period of infancy is defined as the period from birth until 28 days of age. Infancy is defined as the period from birth to 12 months of age. Growth and development are interrelated, ongoing processes in infancy and childhood. **Growth** refers to an increase in physical size. **Development** is the sequential process by which infants and children gain various skills and functions. Heredity influences growth and development by determining the child's potential, while environment contributes to the degree of achievement. **Maturation** refers to an increase in functionality of various body systems or developmental skills.

Growth and Development Overview

Growth and developmental changes in the first year of life are numerous and dramatic. Physical growth, maturation of body systems, and gross and fine motor skills progress in an orderly and sequential fashion. Though timing may vary from infant to infant, the order in which developmental skills are acquired is consistent. Infants also exhibit vast amounts of learning in the psychosocial and cognitive, language and communication, and social/emotional domains. Adequate growth and development are indicative of health in the infant or young child. Nurses must be familiar with normal developmental milestones so that they can accurately assess the infant's development as well as provide age-appropriate anticipatory guidance to the parents.

Achievement of developmental milestones may be assessed in a variety of ways. While obtaining the health history, the nurse may ask the parent or caregiver if the skill is present and when it was attained. The infant may also demonstrate the skill during the interview or examination, or the nurse may elicit the skill from the infant. A number of screening tools are also used to assess development, such as the Denver II Developmental Screening Test (see Appendix B), Prescreening Developmental Questionnaire (PDQ II), Ages and Stages Questionnaire (ASQ), Infant Toddler Checklist for Language and Communication, and Infant Development Inventory.

Ill or premature infants may exhibit delayed acquisition of physical growth and developmental skills. When assessing the growth and development of a premature infant, use the infant's adjusted age to determine expected outcomes. To determine adjusted age, subtract the number of weeks that the infant was premature from the infant's chronological age. Plot growth parameters and assess developmental milestones based on adjusted age. For example, a 6-month-old boy who was born at 28 weeks' gestation was born 12 weeks early (3 months), so subtract 3 months from his chronological age of 6 months to obtain an adjusted age of 3 months. This infant would demonstrate healthy growth if he were the size of a 3-month-old, and he should be expected to achieve the developmental milestones of a 3-month-old rather than a 6-month-old.

PHYSICAL GROWTH

Ongoing assessments of growth are important so that too-rapid or inadequate growth can be identified early. With early identification, the cause can be diagnosed and the potential for further appropriate growth maximized. Infants grow very rapidly over the first 12 months of life. Weight, length, and head and chest circumference are all indicators of physical growth in the newborn and infant (Table 25.1).

Weight

The average newborn weighs 7 lb 8 oz (3,400 g) at birth. Newborns lose up to 10% of their body weight over the first 5 days of life. The average newborn then gains about 20 to 30 g per day and regains his or her birthweight by 10 to 14 days of age. Most infants double their birthweight by 4 to 6 months of age and triple their birthweight by the time they are 1 year old.

Height

The average newborn is 19 to 21 inches (48 to 53 cm) long at birth. During the first 6 months, length increases by 1 inch (2.5 cm) per month, then by about a half-inch per month in the second 6 months.

Head and Chest Circumference

Average head circumference of the full-term newborn is 13 to 14 inches (33 to 35 cm). The head circumference

TABLE 25.1 AVERAGE MEASUREMENTS OF INFANTS AT BIRTH AND 6 AND 12 MONTHS

Age	Weight	Length	Head Circumference
Birth	7.5 lb (3,400 g)	19–21 in (48–53 cm)	13–14 in (33–35 cm)
6 months	15 lb (6.8 kg)	25–27 in (63.5–68.5 cm)	16.5–17.5 in (42–44.5 cm)
12 months	23 lb (10.5 kg)	28–30 in (71–76 cm)	17.7–18.7 in (45–47.5 cm)

is about 1 inch (2 to 3 cm) greater than the chest circumference, which averages 12 to 13 inches (30.5 to 33 cm). The head circumference increases rapidly during the first 6 months: the average increase is about 0.6 inch (1.5 cm) per month. From 6 to 12 months of age, the head circumference increases an average of 0.2 inch (0.5 cm) monthly. The chest circumference is not routinely measured after the newborn period but does increase in size as the child grows.

ORGAN SYSTEM MATURATION

The newborn and infant's organ systems undergo significant changes as the infant grows. Systems that undergo significant change include the neurologic system, the cardiovascular system, the respiratory system, the gastrointestinal (digestive) system, the renal system, the hematopoietic system, the immunologic system, and the integumentary system.

Neurologic System

The infant experiences tremendous changes in the neurologic system over the first year of life. Critical brain growth and continued myelinization of the spinal cord are occurring. Involuntary movement progresses to voluntary control, and immature vocalizations and crying progress to the ability to speak as a result of maturational changes of the neurologic system.

States of Consciousness

The normal term newborn's ability to move sequentially through states of consciousness reassures parents and health care providers that the neurologic system, though immature, is intact. A normal newborn will ordinarily move through six states of consciousness:

1. Deep sleep: The infant lies quietly without movement.
2. Light sleep: The infant may move a little while sleeping and may startle to noises.
3. Drowsiness: Eyes may close; the infant may be dozing.
4. Quiet alert state: The infant's eyes are open wide and the body is calm.
5. Active alert state: The infant's face and body move actively.
6. Crying: The infant cries or screams and the body moves in a disorganized fashion.

Newborns usually progress through these states slowly, rather than going from deep sleep immediately into outright crying.

Brain Growth

The nervous system continues to mature throughout infancy, and the increase in head circumference is indicative of brain growth. The brain undergoes tremendous growth during the first 2 years of life. By 6 months of age the infant's brain weighs half that of the adult brain. At age 12 months, the brain has grown considerably, weighing 2½ times what it did at birth. Usually, the anterior fontanel remains open until 12 to 18 months of age to accommodate this rapid brain growth. However, the fontanel may close as early as 9 months of age, and this is not of concern in the infant with age-appropriate growth and development.

In general, the neurologic system matures a significant amount over the first year of life. Myelination of the spinal cord and nerves continues over the first 2 years. Maturation of the nervous system and continued myelination are necessary for the tremendous developmental skills that are achieved in the first 12 months. During the first few months of life, reflexive behavior is replaced with purposeful action.

Reflexes

Primitive reflexes are subcortical and involve a whole-body response. Selected primitive reflexes present at birth include Moro, root, suck, asymmetric tonic neck, plantar and palmar grasp, step, and Babinski. Except for the Babinski, which disappears around 1 year of age, these primitive reflexes diminish over the first few months of life, giving way to protective reflexes. Protective reflexes (also termed postural responses or reflexes) are motor responses related to maintenance of equilibrium. These responses are prerequisites for appropriate motor development and remain throughout life once they are established. The protective reflexes include the righting and parachute reactions. Appropriate presence and disappearance of primitive reflexes, as well as development of protective reflexes, are indicative of a healthy neurologic system. Persistence of primitive reflexes beyond the usual age of disappearance may indicate an abnormality of the neurologic system and should be investigated.

Table 25.2 gives descriptions and illustrations of several primitive and protective reflexes, as well as the timing of appearance and disappearance of these reflexes.

Respiratory System

The respiratory system continues to mature over the first year of life. The respiratory rate slows from an average of 30 to 60 breaths in the newborn to about 20 to 30 in the 12-month-old. The newborn breathes irregularly, with periodic pauses. As the infant matures, the respiratory pattern becomes more regular and rhythmic.

In comparison with the adult, in the infant:

- The nasal passages are narrower.
- The trachea and chest wall are more compliant.
- The bronchi and bronchioles are shorter and narrower.
- The larynx is more funnel-shaped.
- The tongue is larger.
- There are significantly fewer alveoli.

(text continues on page 775)

TABLE 25.2 SELECTED PRIMITIVE AND PROTECTIVE REFLEXES IN INFANCY

	Description	Age Reflex Appears	Age Reflex Disappears
Primitive Reflexes			
Root	When infant's cheek is stroked, the infant turns to that side, searching with mouth.	Birth	3 months
Suck	Reflexive sucking when nipple or finger is placed in infant's mouth	Birth	2–5 months
Moro	With sudden extension of the head, the arms abduct and move upward and the hands form a "C."	Birth	4 months

	Description	Age Reflex Appears	Age Reflex Disappears
Asymmetric tonic neck	While lying supine, extremities are extended on the side of the body to which the head is turned and opposite extremities are flexed (also called the "fencing" position). 	Birth	4 months
Palmar grasp	Infant reflexively grasps when palm is touched. 	Birth	4–6 months
Plantar grasp	Infant reflexively grasps with bottom of foot when pressure is applied to plantar surface. 	Birth	9 months

(continued)

TABLE 25.2 SELECTED PRIMITIVE AND PROTECTIVE REFLEXES IN INFANCY (continued)

	Description	Age Reflex Appears	Age Reflex Disappears
Babinski	Stroking along the lateral aspect of the sole and across the plantar surface results in fanning and hyperextension of the toes.	Birth	12 months
Step	With one foot on a flat surface, the infant puts the other foot down as if to "step."	Birth	4–8 weeks
Protective Reflexes			
Neck righting	Neck keeps head in upright position when body is tilted.	4–6 months	Persists
Parachute (sideways)	Protective extension with the arms when tilted to the side in a supported sitting position	6 months	Persists
Parachute (forward)	Protective extension with the arms when held up in the air and moved forward. The infant reflexively reaches forward to catch himself.	6–7 months	Persists
Parachute (backward)	Protective extension with the arms when tilted backward	9–10 months	Persists

These anatomic differences place the infant at higher risk for respiratory compromise. The respiratory system does not reach adult levels of maturity until about 7 years of age. The lack of IgA in the mucosal lining of the upper respiratory tract also contributes to the frequent infections that occur in infancy.

Cardiovascular System

The heart doubles in size over the first year of life. As the cardiovascular system matures, the average pulse rate decreases from 120 to 140 in the newborn to about 100 in the 1-year-old. Blood pressure steadily increases over the first 12 months of life, from an average of 60/40 in the newborn to 100/50 in the 12-month-old. The peripheral capillaries are closer to the surface of the skin, thus making the newborn and young infant more susceptible to heat loss. Over the first year of life, thermoregulation (the body's ability to stabilize body temperature) becomes more effective: the peripheral capillaries constrict in response to a cold environment and dilate in response to heat.

Gastrointestinal System

Teeth

Occasionally, an infant is born with one or more teeth (termed natal teeth) or develops teeth in the first 28 days of life (termed neonatal teeth). The presence of natal or neonatal teeth may be associated with other birth anomalies. The vast majority of newborns do not have teeth at birth, nor do they develop them in the first month of life. On average, the first primary teeth begin to erupt between the ages of 6 and 8 months. The primary teeth (also termed deciduous teeth) are lost later in childhood and will be replaced by the permanent teeth. The gums around the emerging tooth often swell. The lower central incisors are usually the first to appear, followed by the upper central incisors (Fig. 25.1). The average 12-month-old has four to eight teeth.

Digestion

The newborn's digestive system is not developed fully. Small amounts of saliva are present for the first 3 months of life and ptyalin is present only in small amounts in the saliva. Gastric digestion occurs as a result of the presence of hydrochloric acid and rennin. The small intestine is about 250 cm long and grows to the adult length over the first few years of life. The stomach capacity is relatively small at birth, holding about one-half to 1 ounce. However, by 1 year of age the stomach can accommodate three full meals and several snacks per day. In the duodenum, three enzymes in particular are important for digestion. Trypsin is available in sufficient quantities for protein digestion after birth. Amylase (needed for complex carbohydrate digestion) and lipase (essential for appropriate fat digestion) are both deficient in the infant and do not reach adult levels until about 5 months of age.

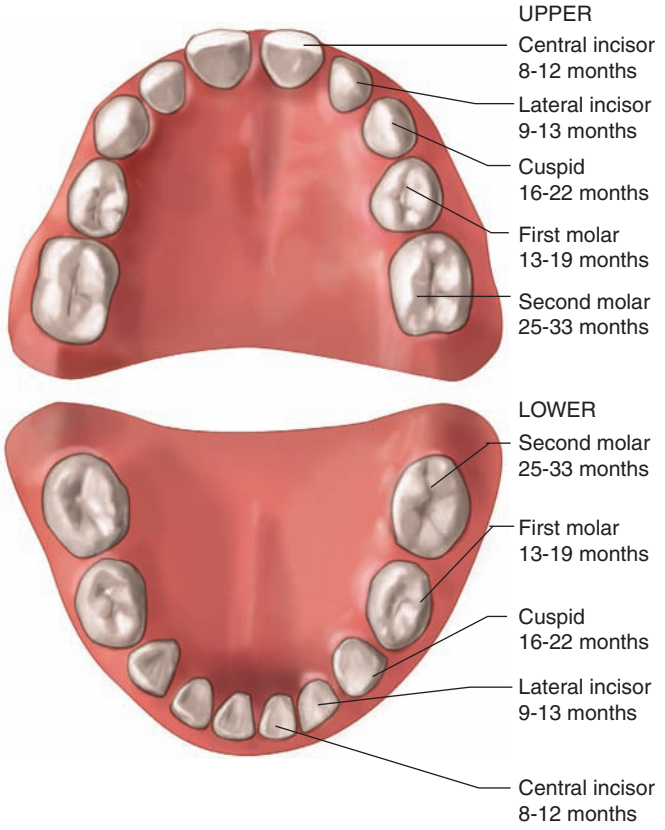

FIGURE 25.1 Sequence and average age of tooth eruption.

The liver is also immature at birth. The ability to conjugate bilirubin and secrete bile is present after about 2 weeks of age. Conjugation of medications may remain immature over the first year of life. Other functions of the liver, including gluconeogenesis, vitamin storage, and protein metabolism, remain immature during the first year of life.

Stools

The consistency and frequency of stools change over the first year of life. The newborn's first stools (meconium) are the result of digestion of amniotic fluid swallowed *in utero*. They are dark green to black and sticky (Fig. 25.2). In the first few days of life the stools become yellowish or tan. Generally the formula-fed infant has stools the consistency of peanut butter. Breastfed infants' stools are usually looser in texture and appear seedy. Newborns may have as many as eight to ten stools per day or as few as one stool every day or two. After the newborn period, the number of stools may decrease, and some infants do not have a bowel movement for several days. Infrequent stooling is considered normal if the bowel movement remains soft. Due to the immaturity of the gastrointestinal system, newborns and young infants often grunt, strain, or cry while attempting to have a bowel movement. This is not of concern unless the stool is hard and dry. Stool color and texture may change depending on the foods

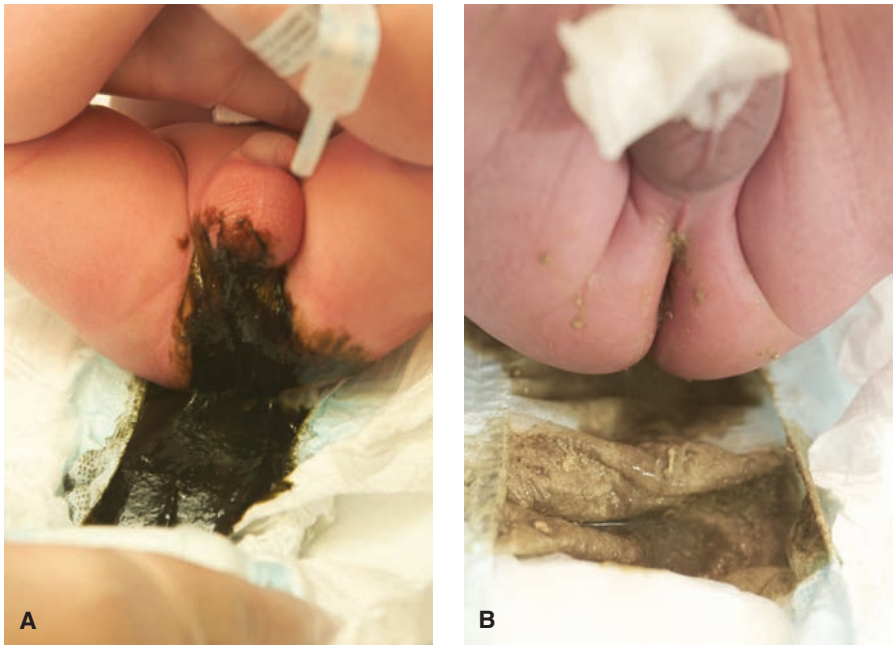

FIGURE 25.2 (**A**) Meconium stool. (**B**) Typical stool after the first few days. Note the yellowish, seedy stool of a breastfed infant.

that the infant is ingesting. Iron supplements may cause the stool to appear black or very dark green.

▶ ***Take*** *NOTE!*

Parents should call the primary care provider if the infant's stools are red, white, or black; mucus-like; frequent and watery; frothy or foul-smelling; hard, dry, formed, or pellet-like; or if the baby is vomiting.

Genitourinary System

In the infant, extracellular fluid (lymph, interstitial fluid, and blood plasma) accounts for about 35% of body weight and intracellular fluid accounts for 40%, compared with the adult quantities of 20% and 40% respectively. Thus, the infant is more susceptible to dehydration. Infants urinate frequently and the urine has a relatively low specific gravity. The renal structures are immature and the glomerular filtration rate, tubular secretion, and reabsorption as well as renal perfusion are all reduced compared with the adult. The glomeruli reach full maturity by 2 years of age.

Integumentary System

In utero the infant is covered with vernix caseosa, which protects the developing infant's skin. At birth, the infant may be covered with vernix (earlier gestational age) or vernix may be found in the folds of the skin, axilla, and groin areas (later gestational age). Production of vernix ceases at birth. Fine downy hair (lanugo) covers the body of many newborns. Often this hair is lost over time and is not replaced. Darker-skinned races tend to have more lanugo present at birth than those with light skin.

Acrocyanosis (blueness of the hands and feet) is normal in the newborn; it decreases over the first few days of life (Fig. 25.3). Newborns often experience mottling of the skin (a pink-and-white marbled appearance) because of their immature circulatory system. Mottling decreases over the first few months of life.

The newborn and young infant's skin is relatively thinner than that of the adult, with the peripheral capillaries being closer to the surface. This may cause increased absorption of topical medications.

Hematopoietic System

Significant changes in the hematopoietic system occur over the first year of life. At birth, fetal hemoglobin (HgbF) is present in large amounts. After birth the production of fetal hemoglobin nearly ceases, and adult hemoglobin (HgbA) is produced in steadily increasing amounts throughout the first 6 months. Since HgbF has a shorter lifespan than HgbA, infants may experience physiologic anemia at age 2 to 3 months. During the last 3 months of gestation, maternal iron stores are transferred to the fetus. The newborn typically has 0.3 to 0.5 g of iron stores available. As the high hemoglobin concentration of the newborn decreases over the first 2 to 3 months, iron is reclaimed and stored. These stores may be sufficient for the first 6 to 9 months of life but will become depleted if iron supplementation does not occur. Ongoing iron intake is required throughout the first 15 years of life in order to reach the adult level of 5 g.

FIGURE 25.3 (**A**) Acrocyanosis. Note blueness of the hands. (**B**) Mottling of the skin in a young infant.

Take NOTE!

Maternal iron stores are transferred to the fetus throughout the last trimester of pregnancy. Infants born prematurely miss all or at least a portion of this iron store transfer, placing them at increased risk for iron deficiency anemia compared with term infants.

Immunologic System

Newborns receive large amounts of immunoglobulin G (IgG) through the placenta from their mothers. This confers immunity during the first 3 to 6 months of life for antigens to which the mother was previously exposed. Infants then synthesize their own IgG, reaching approximately 40% of adult levels at age 12 months. Immunoglobulin M (IgM) is produced in significant amounts after birth, reaching adult levels by 9 months of age. Immunoglobulin A (IgA), immunoglobulin D (IgD), and immunoglobulin E (IgE) production increases very gradually, maturing in early childhood.

PSYCHOSOCIAL DEVELOPMENT

Erik Erikson (1963) identifies the psychosocial crisis of infancy as Trust versus Mistrust. Development of a sense of trust is crucial in the first year, as it serves as the foundation for later psychosocial tasks. The parent or primary caregiver can have a significant impact on the infant's development of a sense of trust. When the infant's needs are consistently met, the infant develops this sense of trust. But if the parent or caregiver is inconsistent in meeting the infant's needs in a timely manner, then the infant develops a sense of mistrust. Table 25.3 lists activities that promote a sense of trust in infancy.

COGNITIVE DEVELOPMENT

The first stage of Jean Piaget's theory of cognitive development is referred to as the sensorimotor stage (birth to 2 years) (Piaget, 1969). Infants learn about themselves and the world through their developing sensory and motor capacities. Infants' development from birth to 1 year of age can be divided into four substages within the sensorimotor stage: reflexes, primary circular reaction, secondary circular reaction, and coordination of secondary schemes. Cause and effect guides most of the cognitive development seen in infancy (see Table 25.3).

The concept of **object permanence** begins to develop between 4 and 7 months of age and is solidified by about 8 months of age. If an object is hidden from the infant's sight, he or she will search for it in the last place it was seen, knowing it still exists. This development of object permanence is essential for the development of self-image. By age 12 months the infant knows he or she is separate from the parent or caregiver. Self-image is also promoted through the use of mirrors. By 12 months of age, infants can see themselves in the mirror. The 12-month-old will explore objects in different ways, such as throwing, banging, dropping, and shaking. He or she may imitate gestures and knows how to use certain objects correctly (e.g., puts phone to ear, turns up cup to drink, attempts to comb hair).

MOTOR SKILL DEVELOPMENT

Infants exhibit phenomenal increases in their gross and fine motor skills over the first 12 months of life.

Gross Motor Skills

The term "gross motor skills" refers to those that use the large muscles (e.g., head control, rolling, sitting, and walking). Gross motor skills develop in a **cephalocaudal**

TABLE 25.3 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
Erikson	Trust vs. Mistrust (birth to 1 year)	Caregivers respond to the infant's basic needs by feeding, changing diapers, and cleaning, touching, holding, and talking to the infant. This creates a sense of trust in the infant. As the nervous system matures, infants realize they are separate beings from their caregivers. Over time the infant learns to tolerate small amounts of frustration and trusts that although gratification may be delayed, it will eventually be provided.
Piaget	Sensorimotor (birth to 2 years)	Infant uses senses and motor skills to learn about the world.
	Substage 1: use of reflexes (birth to 1 month)	Reflexive sucking brings the pleasure of ingesting nutrition. Infant begins to gain control over reflexes; recognizes familiar objects, odors, and sounds.
	Substage 2: primary circular reactions (1 to 4 months)	Thumb-sucking may occur by chance; then the infant repeats it on purpose to bring pleasure. Imitation begins. Object permanence begins. Infant shows affect.
	Substage 3: secondary circular reactions (4 to 8 months)	Infant repeats actions to achieve wanted results (e.g., shakes rattle to hear the noise it makes). The infant's actions are purposeful but the infant does not always have an end goal in mind.
	Substage 4: coordination of secondary schemes (8 to 12 months)	Infants coordinate previously learned schemes with previously learned behaviors. They may grasp and shake a rattle intentionally or crawl across the room to reach a desired toy. Infant can anticipate events. Object permanence is present at about 8 months of age. The infant begins to associate symbols with events (e.g., waving goodbye means someone is leaving)
Freud	Oral stage (birth to 1 year)	Pleasure is focused on oral activities: feeding and sucking.

fashion (from the head to the tail) (Fig. 25.4). In other words, the baby learns to lift the head before learning to roll over and sit. At birth, babies have poor head control and need to have their necks supported when being held. They can lift their heads only slightly while in a prone position. Over the next several months the infant's motor skills progress at a dramatic rate. First the infant achieves head control, then the ability to roll over, sit, crawl, pull to stand, and, usually around a year of age, to walk independently. Table 25.4 gives details on when the infant develops each specific gross motor skill. Progression of gross motor skills is illustrated in Figures 25.5 through 25.7.

▶ ***Take*** *NOTE!*

Warning signs that may indicate problems with motor development include the following: arms and legs are stiff or floppy; child cannot support head at 3 to 4 months of age; child reaches with one hand only; child cannot sit with assistance at 6 months of age; child does not crawl by 12 months of age; child cannot stand supported by 12 months of age.

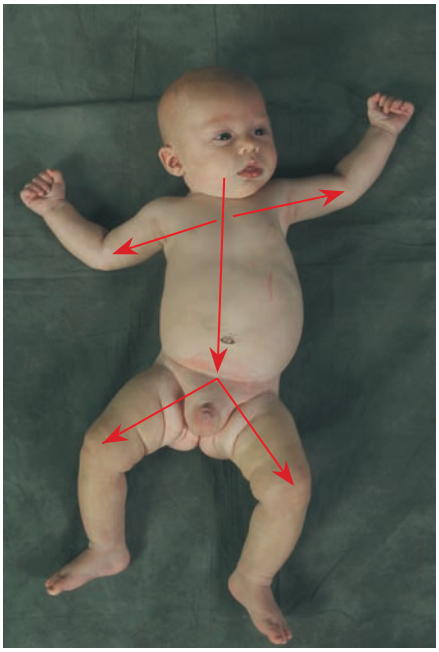

FIGURE 25.4 Gross motor skills develop in a cephalocaudal direction, fine motor skills in a proximodistal fashion.

TABLE 25.4 DEVELOPMENT OF GROSS MOTOR SKILLS IN INFANCY

Age	Gross Motor Skills
1 month	Lifts and turns head to side in prone position Head lag when pulled to sit Rounded back in sitting
2 months	Raises head and chest, holds position Improving head control
3 months	Raises head to 45 degrees in prone Slight head lag in pull to sit
4 months	Lifts head and looks around Rolls from prone to supine Head leads body when pulled to sit
5 months	Rolls from supine to prone and back again Sits with back upright when supported
6 months	Tripod sits
7 months	Sits alone with some use of hands for support
8 months	Sits unsupported
9 months	Crawls, abdomen off floor
10 months	Pulls to stand Cruises
12 months	Sits from standing position Walks independently

Fine Motor Skills

Fine motor development includes the maturation of hand and finger use. Fine motor skills develop in a **proximodistal** fashion (from the center to the periphery) (see Fig. 25.4). In other words, the infant first bats with the whole hand, eventually progressing to gross grasping, before being capable of fine fingertip grasping (Fig. 25.8). The newborn's hand movements are involuntary in nature, whereas the 12-month-old is capable of feeding himself or herself with a cup and spoon. By 12 months of age the infant should be able to eat with his or her fingers and assist with dressing (e.g., pushing an arm through the sleeve). Table 25.5 gives details on when the infant develops each specific fine motor skill.

SENSORY DEVELOPMENT

Though hearing should be fully developed at birth, the other senses continue to develop as the infant matures. Though they mature at different rates, sight, smell, taste, and touch all continue to develop after birth.

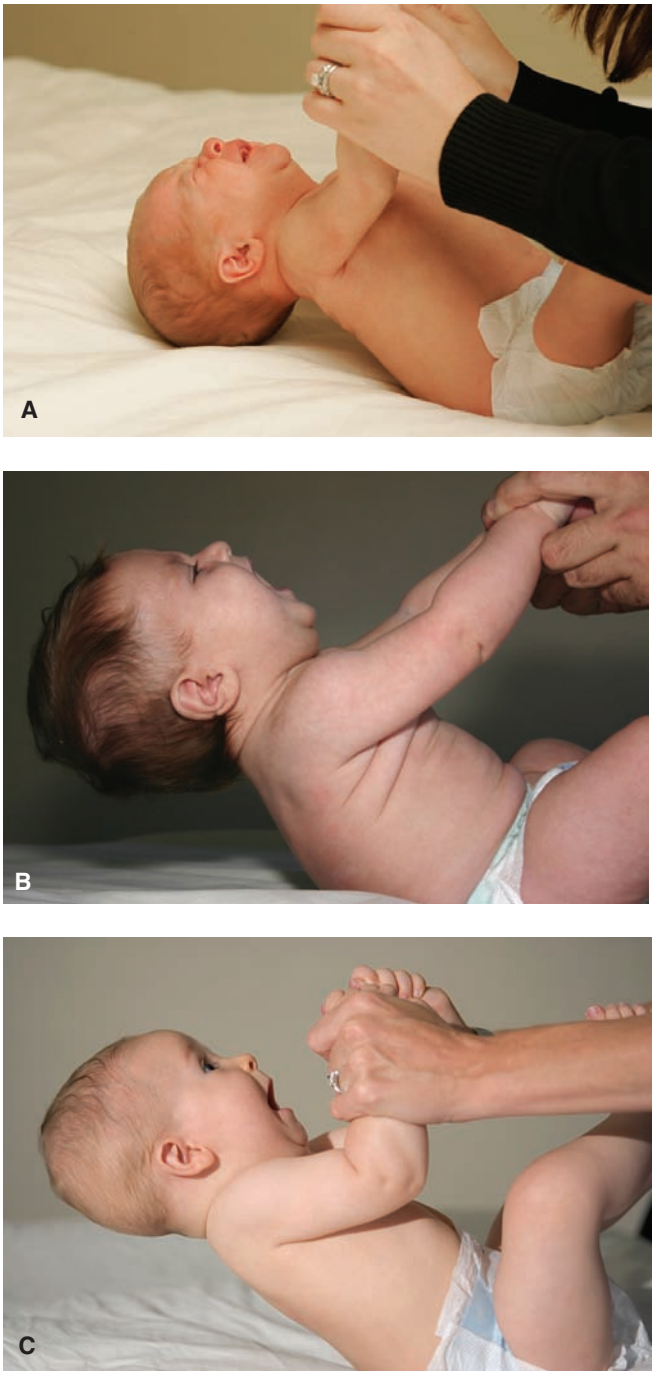

FIGURE 25.5 When pulled to sit, an infant shows (**A**) significant head lag (newborn; 2 or 3 weeks old), (**B**) improving head control (2 months old), and (**C**) no head lag (4 months old).

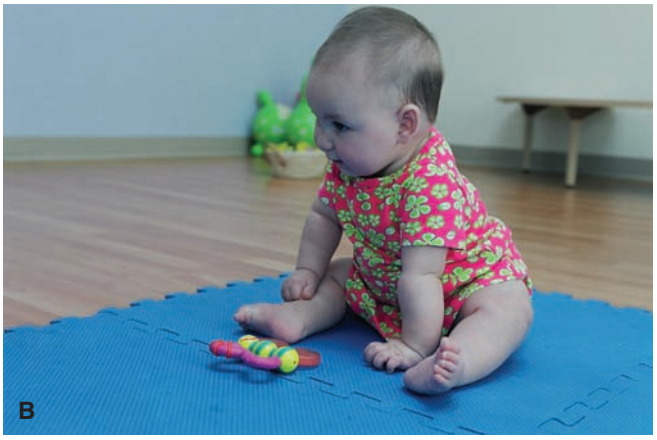
Sight

The newborn is nearsighted, preferring to view objects at a distance of 8 to 15 inches. Newborns prefer the human face to other objects and may even imitate the facial expressions made by those caring for them. In addition to human faces, newborns show a preference for certain objects, particularly those with contrasts such as black-and-white stripes. The



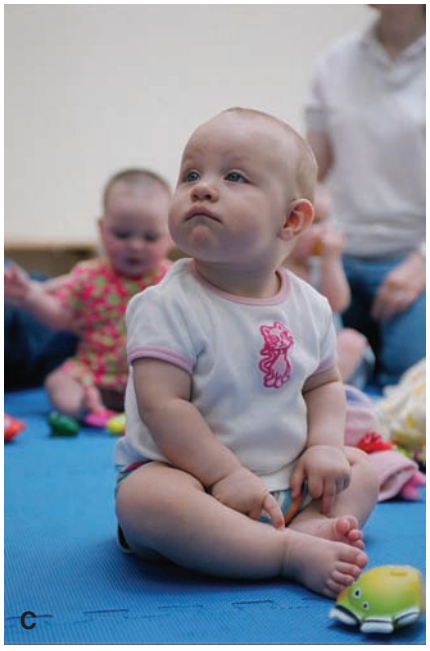


FIGURE 25.6 Development of sitting. (**A**) At 4 months, the infant requires significant support. (**B**) The 6-month-old infant sits in tripod fashion. (**C**) The 8-month-old sits alone.

newborn's eyes wander and occasionally cross. At 1 month of age the infant can recognize by sight the people he or she knows best. The infant will study objects within his or her visual range closely. The ability to fuse two ocular images into one cerebral picture (**binocularity**) begins to develop at 6 weeks of age and is well established by 4 months of age. Full color vision develops by 7 months of age, as do distance vision and the ability to track objects.

Hearing

The newborn's hearing is intact at birth and as acute as that of an adult. Newborns prefer the sound of human voices to nonhuman sounds. By 1 month of age the infant can recognize the sounds of those he or she knows best.

Smell and Taste

The sense of smell develops rapidly: the 7-day-old infant can differentiate the smell of his or her mother's breast milk from that of another woman and will preferentially turn toward the mother's smell. Newborns prefer sweet tastes to all others. This persists for several months, and eventually the infant will accept non-sweet flavors.

Touch

The sense of touch is perhaps the most important of all the senses for newborn communication. Even the most immature infant responds to soothing stroking. The infant prefers soft sensations to coarse sensations. The infant dislikes rough handling and may cry. Holding, stroking, rocking, and cuddling calms infants when they are upset and makes them more alert when they are drowsy. Infants learn to understand their caregiver's moods by the way they touch them.

▶ *Take* NOTE!

Warning signs that may indicate problems with sensory development include the following: young infant does not respond to loud noises; child does not focus on a near object; infant does not start to make sounds or babble by 4 months of age; infant does not turn to locate sound at age 4 months; infant crosses eyes most of the time at age 6 months.

COMMUNICATION AND LANGUAGE DEVELOPMENT

For several months, crying is the only means of communication for the newborn and infant. The basic reason for crying is unmet needs. The 1- to-3-month-old baby coos, makes other vocalizations, and demonstrates differentiated crying. At 4 to 5 months of age, the infant makes simple vowel sounds, laughs aloud, performs "raspberries," and vocalizes in response to voices. The infant also responds

FIGURE 25.7 Development of locomotion. (**A**) At 4 months the infant pushes up from a prone position. (**B**) At 8 months, the infant crawls with the abdomen off the floor. (**C**) The infant pulls to stand by 10 months of age. (**D**) The infant cruises along furniture or (**E**) takes steps with assistance at 10 to 11 months of age. (**F**) The infant independently stands from a crouched position and walks around 12 months of age (plus or minus 3 months).

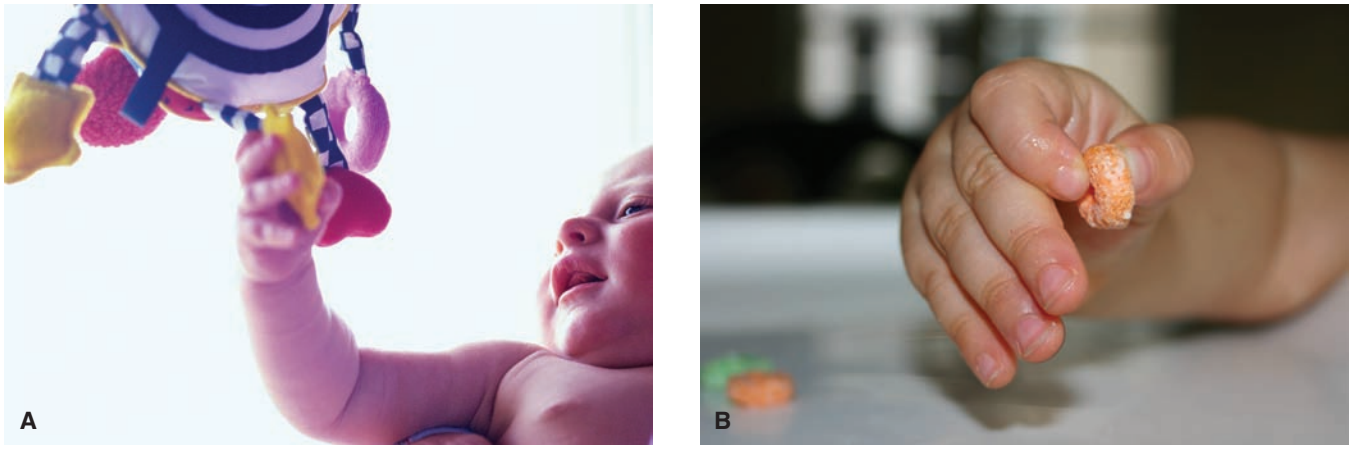

FIGURE 25.8 Development of the pincer grasp. Note the gross (whole-hand) approach to grasping a small object (**A**), compared with the fine (thumb-to-finger) ability (**B**).

to his or her own name and begins to respond to "no." Between 4 and 7 months the infant begins to distinguish emotions based on tone of voice. Squealing and yelling begin around 6 months of age; these may be used to express joy or displeasure. At age 7 to 10 months, babbling begins and progresses to strings (e.g., mamama, dadada) without meaning. The infant at this age is also able to respond to simple commands. At 9 to 12 months of age the infant begins to attach meaning to "mama" and "dada" and starts to imitate other speech sounds. The average 12-month-old uses two or three recognizable words with meaning, recognizes objects by name, and starts to imitate animal sounds. At this age, the infant pays increasing attention to speech and tries to imitate words; he or she may also say, "uh-oh." The 12-month-old also babbles with inflection (this babbling has the rhythm and timing of spoken language, but few of the "words" make sense).

It is very important for the parent or caregiver to talk to the infant in order for the infant to learn communication skills. Sometimes regression in language development occurs briefly when the child is focusing energy on other skills, such as crawling or walking. As long as the infant's hearing is normal, language acquisition should continue to progress. Infants in bilingual families may "language mix" (uses some words from each language). This is considered to be a normal progression in language development for these children, but it makes it more difficult for the health care provider to determine delays in communication skills (Goldstein, 2006).

TABLE 25.5 DEVELOPMENT OF FINE MOTOR SKILLS IN INFANCY

Age	Fine Motor Skills
1 month	Fists mostly clenched Involuntary hand movements
3 months	Holds hand in front of face, hands open
4 months	Bats at objects
5 months	Grasps rattle
6 months	Releases object in hand to take another
7 months	Transfers object from one hand to the other
8 months	Gross pincer grasp (rakes)
9 months	Bangs objects together
10 months	Fine pincer grasp Puts objects into container and takes them out
11 months	Offers objects to others and releases them
12 months	Feeds self with cup and spoon Makes simple mark on paper Pokes with index finger

▶ ***Take*** *NOTE!*

Warning signs that may indicate problems in language development are as follows: infant does not make sounds at 4 months of age; infant does not laugh or squeal by 6 months of age; infant does not babble by 8 months of age; infant does not use single words with meaning at 12 months of age (mama, dada).

SOCIAL AND EMOTIONAL DEVELOPMENT

The newborn spends much of the time sleeping, but by 2 months of age the infant is ready to start socializing. The infant exhibits a first real smile at age 2 months. He or she spends a great deal of time while awake watching and observing what is going on around him or her. By about 3 months of age the infant will start an interaction with a caregiver by smiling widely and possibly gurgling.

This prompts the caregiver to smile back and talk to the infant. The infant responds with more smiling, cooing, and gurgles as well as moving the arms and legs. The 3- to 4-month-old will also mimic the parent's facial movements, such as widening the eyes and sticking out the tongue. The baby may hesitate at first, but once the other person responds pleasantly to the infant, the infant engages and gets into the interaction. The infant may cry when the pleasant interaction stops. At 6 to 8 months of age the infant may enjoy socially interactive games such as patty-cake and peek-a-boo.

Stranger Anxiety

Around the age of 8 months the infant may develop **stranger anxiety**. The previously happy and very friendly infant may become clingy and whiny when approached by strangers or people not well known. Stranger anxiety is an indicator that the infant is recognizing himself or herself as separate from others. As the infant becomes more aware of new people and new places, he or she may view an interaction with a stranger as threatening and may start crying, even if the parent is right there. Family members whom the child sees infrequently, as well as others the child does not spend a lot of time with, should approach the infant calmly and slowly, with the parent in sight. Sometimes this will prevent a sudden crying spell.

Separation Anxiety

Separation anxiety may also start in the last few months of infancy. The infant becomes quite distressed when the parent leaves. The infant will eventually calm down and become engaged with the current caregiver. It is not until the infant is older that cognition and memory are sufficient for him or her to understand that the parent will come back.

▶ *Take* NOTE!

Warning signs of possible problems with social/emotional development include the following: child does not smile at people at 3 months of age; child refuses to cuddle; child does not seem to enjoy people; child shows no interest in peek-a-boo at 8 months of age.

Temperament

Temperament is an individual's nature; it is referred to as the "how" of behavior (Zolten & Long, 2006). Temperament ranges from low or moderately active, regular, and predictable to highly active, more intense, and less adaptable. These are all considered normal along a continuum. An infant's innate temperament affects the way he or she responds to the environment. As parents take note of their infant's usual activity level, how intensely he or she reacts with others and the environment, and how stimulated the baby becomes with interactions, they start to learn about their infant's temperament. The parent should note how adaptable and flexible the infant is as well as how predictable and persistent the baby is.

When parents are familiar with how the baby approaches life on a routine basis, they will be better able to recognize when the baby is not acting like himself or herself. Nurses can help parents interpret observations about their infant's temperament and recommend ways to support the infant's individual behavior. Some infants are slower to warm up than others; those infants should be approached slowly and calmly. Some infants exhibit increased levels of activity compared to quieter, more passive babies; those infants generally require more direct play with the parent or caregiver and will be the type of older infant who is in constant motion. Some infants are loud and some are not. The quiet infant may become overwhelmed with excessive stimulation, whereas the very active baby may need additional stimulation to be satisfied. Becoming familiar with the infant's temperament also helps the parents describe the best approach to the infant by others (e.g., child care workers or health care professionals).

CULTURAL INFLUENCES ON GROWTH AND DEVELOPMENT

Many cultural differences have an impact on growth and development. For instance, certain ethnic groups tend to be shorter than others because of their genetic makeup. These children will not grow to be as tall as those of another ethnic background. Cultural feeding practices in some cultures may lead to overweight in some children. Some cultures and certain religions advocate vegetarianism; those children need nutritional assessment to ensure they are getting enough protein intake for adequate growth.

Parenting styles and health promotion behaviors can also be significantly influenced by culture. Parents and extended family are the most significant influences in an infant's life in most cultures. Certain cultures place a high value upon independence and may encourage their infants to develop quickly, while other cultures "baby" their infants for longer periods. In most cultures the mother takes primary responsibility for caring for the child, but in some cultures, major health-related decisions may be deferred to the father or grandparents.

Health beliefs are often strongly influenced by an individual's religious or spiritual background. Sometimes this creates conflict in the health care setting when the health providers have a different value system than that of the infant's family.

In some cultures infants and children share a bed with their parents. When an infant or child is hospitalized and is accustomed to sleeping with the parents, it may be difficult and distressing for him or her to try to sleep alone.

The nurse should explore the family's cultural practices related to growth and development. Usually these practices are not harmful and can be supported by the health care team, but safety must always be considered.

The nurse should not make assumptions about a family's cultural practices based on their skin color, accent, or name; rather, the nurse should perform an adequate assessment.

▶ *Take* NOTE!

Many communities now include people from a variety of cultures, so it is important for nurses to practice transcultural nursing (nursing care that is directed by cultural aspects and that respects the individual's differences). Many nurse researchers are exploring the cultural aspects of health care and the impact that cultural diversity has upon health.

Refer back to Allison Johnson, who was introduced at the beginning of the chapter. What developmental milestones would you expect Allison to have reached by this age? How would this be different if Allison had been born 6 weeks premature?

The Nurse's Role in Newborn and Infant Growth and Development

WATCH & LEARN

Growth and development affect every aspect of the infant's life. As infants progress through various stages of development, they do so in a predictable fashion. Growth and development are sequential and orderly, though some children develop at faster rates than others. It is important for the nurse to understand growth and development. Health care visits through infancy often focus primarily on **anticipatory guidance** (educating parents and caregivers about what to expect in the next phase of development). The purpose of anticipatory guidance is to give parents the tools they need to support their infant's development in a safe fashion.

Hospital nurses also need to use their knowledge of growth and development when caring for ill infants. Hospitalization often requires the infant to be confined to the crib or the hospital room. Nurses must support growth and development within the constraints imposed by the child's illness.

NURSING PROCESS OVERVIEW

After the infant's current growth and development status has been assessed, problems related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Ineffective breastfeeding
- Risk for disproportionate growth
- Imbalanced nutrition, less than body requirements
- Risk for impaired parent/infant attachment
- Delayed growth and development
- Risk for caregiver role strain

Nursing care planning for the infant with growth and development issues should be individualized based on the infant's and family's needs. The Nursing Care Plan Overview can be used as a guide in planning nursing care for the infant with a growth and development problem. The nurse may choose the appropriate nursing diagnoses from the plan and individualize them as needed. The nursing care plan is intended to serve as a guide, not as an all-inclusive growth and development care plan.

PROMOTING HEALTHY GROWTH AND DEVELOPMENT

Adding a new person to the family produces both excitement and anxiety. Newborns are completely reliant upon their parents or caregivers to fill every need. It is quite a burden and precious responsibility that new parents are taking on. Many parents read the latest books about caring for newborns, while others rely on information received from family and friends. Newborns and their mothers spend only a short time in the hospital after delivery, so it is very important that parents can care for their newborn and know when to call the primary care provider with concerns.

Periodic screening for adequate growth and development is recommended by the American Academy of Pediatrics (AAP) for all infants and children. The prevention of devastating disease is another priority for infants and children. The AAP and the Advisory Committee on Immunization Practices (ACIP) have made recommendations for immunization schedules. Immunizations are a very important part of the newborn and infant's health visits. Nurses caring for newborns and infants should be familiar with the recommended infant/child periodic screenings (check-ups) as well as the current immunization schedule (see Chapter 30, for further information on immunizations).

Promoting Growth and Development Through Play

Experts in child development and behavior have said repeatedly that play is the work of children. Infants practice their gross and fine motor skills and language through play. Play is a natural way for infants and children to learn. Play is critical to infant development, as it gives infants the opportunity to explore their environment, practice new skills, and solve problems. The newborn prefers

(text continues on page 787)

Nursing Care Plan 25.1

GROWTH AND DEVELOPMENT ISSUES IN THE NEWBORN AND INFANT

NURSING DIAGNOSIS: Breastfeeding, ineffective, related to lack of exposure, misconceptions, or knowledge deficit as evidenced by first baby, mother's verbalization, or nursing observations

Outcome Identification and Evaluation

Mother/infant dyad will experience successful breastfeeding: *infant will latch on, suck and swallow at the breast; mother will not experience sore nipples.*

Interventions: Promoting Effective Breastfeeding

- Educate mother on recognition of and response to infant hunger cues *to promote on-cue breastfeeding, which will establish milk supply.*
- Educate mother on appropriate diet and fluid intake *to ensure ability to manufacture adequate supply of breast milk.*
- Demonstrate breastfeeding positions with infant at the breast *(appropriate positioning increases probability of successful latch).*
- Assess infant's latch technique, sucking motion, and audible swallowing *(an appropriately latched infant will take most of the areola in the mouth, suck in spurts, and demonstrate audible swallowing).*
- Assess infant voiding/stool patterns: *at least six voids per day and passage of stool ranging from one or more per day to one every several days is a normal pattern for breastfed infants.*
- Assess infant weight gain: *gain of 15 to 30 g per day after the second week of life indicates infant is receiving appropriate nutrition.*
- Assess mother's nipples for redness or soreness; *if infant appropriately latches on, nipples will not become sore.*

NURSING DIAGNOSIS: Risk for altered growth pattern (risk factors: caregiver knowledge deficit, first infant, premature infant, or maladaptive feeding behaviors)

Outcome Identification and Evaluation

Infant will demonstrate adequate growth and appropriate feeding behaviors: *steady increases in weight, length, and head circumference; infant feeds appropriately for age.*

Interventions: Promoting Adequate Growth

- Observe mother/infant dyad breastfeeding or bottle-feeding *to determine need for further education or identify infant difficulties with feeding.*
- Educate mother about appropriate breastfeeding or bottle-feeding *so that mother is aware of what to expect in normal feeding pattern.*
- When infant is old enough, provide education about addition of solid foods, spoon and cup feeding: *after 6 months of age breast milk or formula needs to be supplemented with a variety of foods.*
- Determine need for additional caloric intake if necessary *(premature infants and infants with chronic illnesses or metabolic disorders often need adjustments in caloric intake to demonstrate adequate or catch-up growth).*
- Obtain daily weights (if hospitalized, weekly if outpatient) and weekly length and head circumference *to determine whether feeding pattern is sufficient to promote adequate growth.*

(continued)

Nursing Care Plan 25.1 (continued)

NURSING DIAGNOSIS: Nutrition, altered, less than body requirements, related to possible ineffective feeding pattern or inadequate caloric intake as evidenced by failure to gain weight or by inadequate increases in weight, length, and head circumference over time

Outcome Identification and Evaluation

Infant will take in adequate nutrients using effective feeding pattern: *infant will demonstrate adequate weight gain (15 to 30 g per day) and steady increases in length and head circumference.*

Interventions: Promoting Adequate Nutritional Intake

- Assess current feeding pattern and daily intake *to determine areas of concern.*
- Increase frequency of breastfeeding or volume of bottle feeding *if needed to meet caloric needs.*
- Introduce solid foods on age-appropriate schedule: *introducing solids at the right time improves the chances that the child will learn to take solid foods.*
- Limit juice intake or discontinue altogether *(juice has little nutritive value and displaces nutrients from breast milk or formula).*
- Use human milk fortifier (if ordered) *to increase caloric density of breast milk.*
- Increase caloric density of formula (if ordered) by mixing to a more concentrated level or with additives (fats or carbohydrates) *to provide increased calories needed to support adequate growth.*
- If infant is taking solids already, choose higher-calorie foods *to maximize nutrient intake.*

NURSING DIAGNOSIS: Parent/infant attachment, altered, risk for (risk factors: premature infant, parental knowledge deficit about normal newborn activity and care, infant with difficult temperament or medical problems)

Outcome Identification and Evaluation

Parent and infant will demonstrate appropriate attachment via *eye contact, parental response to infant cues, parental verbalization of caring for infant, infant response to parent's caretaking behaviors.*

Interventions: Encouraging Appropriate Parent–Infant Attachment

- Assess parent's response to infant cues *to determine degree of attachment and level of parent's knowledge about infant care.*
- Assess infant's response to parent's caretaking behaviors *to determine degree of attachment.*
- Determine infant's temperament *to counsel parent effectively about responses appropriate for that type of temperament.*
- Encourage *en face* positioning for holding or feeding the young infant *to encourage give-and-take response between infant and parent.*
- Encourage parent to meet infant's needs promptly and with affection *to promote sense of trust in the infant.*
- Reinforce parent's attempts at improving attachment with infant *(positive reinforcement naturally encourages appropriate behaviors).*

NURSING DIAGNOSIS: Growth and development, altered, related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be maximized: *infant will make continued progress toward attainment of developmental milestones.*

Interventions: Maximizing Development

- Perform developmental evaluation of the infant *to determine infant's current level of functioning.*
- Offer age-appropriate play, activities, and toys *to encourage further development.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist *(repeated exposure to the activities or exercises is needed to make developmental progress).*
- Provide support to parents of infants with developmental concerns, *as developmental progress can be slow and it is difficult for families to stay motivated and maintain hope.*

Nursing Care Plan 25.1 (continued)

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: first baby, knowledge deficit about infant care, lack of prior exposure, fatigue if premature, ill, or developmentally delayed infant)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in new role.*

Interventions: Preventing Caregiver Role Strain

- Assess parent's knowledge of newborn/infant care and the issues that arise as a part of normal development *to determine parent's needs.*
- Provide education on normal newborn/infant care *so that parents have the knowledge they need to appropriately care for their new baby.*
- Provide anticipatory guidance related to normal infant development *to prepare parents for what to expect next and how to intervene.*
- Encourage respite for parents *(even a few hours away from the demands of an infant's care can rejuvenate the parents).*

NURSING DIAGNOSIS: Injury, risk for (risk factors: developmental age, infant curiosity, rapidly progressing motor abilities)

Outcome Identification and Evaluation

Infant safety will be maintained: *infant will remain free from injury.*

Interventions: Preventing Injury

- Encourage car seat safety *to decrease risk of injury related to motor vehicles.*
- Childproof home: *as infant becomes more mobile, he or she will want to explore everything, increasing risk of injury.*
- Parents should have the Poison Control Center phone number available: *should an accidental ingestion occur, Poison Control can give parents the best advice for appropriate intervention.*
- Never leave an infant unattended in the sink, bathtub, or swimming pool *to prevent drowning.*
- Teach parents first aid measures and infant CPR *to minimize consequences of injury should it occur.*
- Parents should watch the infant at all times *(no amount of childproofing can replace the watchful eye of a caring parent).*

interacting with the parent to toys. Parents can talk to and sing to their newborns while participating in the daily activities that infants need, such as feeding, bathing, and changing diapers. Newborns and young infants love to watch people's faces and often appear to mimic the expressions they see.

As infants become older, toys may be geared toward the motor skills or language skills that the child is developing. Parents can promote fine motor development in infants by providing age-appropriate toys. For example, a rattle that a young infant can hold promotes reaching and attaining. The older infant builds fine motor skills by stacking cups or placing smaller toys inside of larger ones. Gross motor skills are reinforced and practiced over and over again when the infant wants to reach something he or she is interested in.

When playing with toys, the infant usually engages in **solitary play**; he or she does not share with other infants or directly play with other infants. A wide variety of toys are available for infants, but infants often enjoy the most basic ones, such as plastic containers of various shapes and sizes, soft balls, and wooden or plastic spoons.

Books are also very important toys for infants. Reading to all ages of infants is appropriate, and the older infant develops fine motor skills by learning to turn book pages.

Table 25.6 lists age-appropriate toys.

Promoting Early Learning

Research has shown that reading aloud and sharing books during early infancy are critical to the development of neural networks that are important in the later tasks of reading and word recognition. Reading books increases listening comprehension. Infants demonstrate their excitement about picture books by kicking and waving their arms and babbling when looking at them. At 6 to 12 months, the infant reaches for books and brings them to the mouth. Over time, reading leads to acquisition of language skills. Reading picture books and simple stories to infants starts a good habit that should be continued throughout childhood.

Promoting Safety

The most common cause of death in infants between the ages of 6 and 12 months is injury. As infants become more mobile, they risk injury from falls down stairs and off chairs, tables, and other structures. Curiosity leads the

TABLE 25.6 APPROPRIATE TOYS FOR NEWBORNS AND INFANTS

Age	Appropriate Toys
Newborn to 1 month	• Mobile with contrasting colors or patterns • Unbreakable mirror • Soft music via tape or music box • Soft, brightly colored toys
1 to 4 months	• Bright mobile • Unbreakable mirror • Rattles • Singing by parent or caregiver, varied music • High-contrast patterns in books or images
4 to 7 months	• Fabric or board books • Different types of music • Easy-to-hold toys that do things or make noise (fancy rattles) • Floating, squirting bath toys • Soft dolls or animals
8 to 12 months	• Plastic cups, bowls, buckets • Unbreakable mirror • Large building blocks • Stacking toys • Busy boxes (with buttons or knobs that make things happen) • Balls • Dolls • Board books with large pictures • Toy telephone • Push–pull toys (older infants)

infant to explore potentially dangerous items, such as electrical outlets, hot stove or furnace vents, mop buckets, and toilets. Since infants explore so much with their mouths, small objects or hard foods pose a choking hazard. The infant will invariably pick up any accessible object and bring it to the mouth. With increasing dexterity, poisoning from medications, household cleaning products, or other substances also becomes a problem.

Safety in the Car

Motor vehicle accidents are one source of injury, particularly if the infant is improperly restrained. Infants should never be transported in a motor vehicle without proper restraint. Infant car seats should face the rear of the car until the infant is 12 months of age and weighs 20 pounds. The car seat should be secured tightly in the center of the back seat. The infant should never be placed in a front seat that is equipped with an airbag.

Infants should never be left unattended in a motor vehicle. The temperature rises very quickly inside a closed vehicle, and an infant can suffocate from heat in a closed vehicle in the summer. Even during cooler weather, the heat generated within a closed vehicle can reach three to five times the exterior temperature. Kidnapping is also a concern if the baby is left unattended in a vehicle.

Additional information on car safety can be found on www.childsafety.org, www.safekids.org, and www.carseat.org and through the National Highway Traffic Safety Administration at www.nhtsadot.gov.

Safety in the Home

The baby's crib should have a firm mattress that fits snugly in the crib on a secure support. The distance between crib slats should be 2⅜ inches or less to prevent injury. All crib edges should be smooth. Only well-fitting crib sheets should be used, not sheets intended for large beds. Crib side rails should always be raised when the parent is not right next to the crib. Additional information about crib and playpen safety can be found at www.safekids.org.

Even before the infant can roll over, he or she wiggles and pushes with the feet. The infant can easily fall from a changing table, sofa, or crib with the side rails down, so the infant should never be left unattended on any surface. If infant seats, bouncy seats, or swings are used, the infant should always be restrained in the seat with the appropriate straps.

The AAP does not recommend the use of infant walkers, because the walker may tip over and the baby fall out of it or the infant may fall down the stairs in it. Walkers allow infants access to things they may not otherwise be capable of reaching until they are able to walk alone, such as hot stoves and items on the edge of the countertop.

As the infant becomes more mobile, learning to crawl and walk, new safety issues arise. Safety gates should be used at the tops and bottoms of stairways. Gates may also be used to block curious infants from rooms that may pose physical danger to them because of sharp-edged furniture or decorative objects. Electrical outlets should be covered with approved safety covers. Cabinets and drawers should be secured with child safety latches. Medications, household cleaning supplies, and other potentially hazardous substances should be stored completely out of reach of infants.

Choking is a risk because infants immediately bring small items to the mouth for exploration. To avoid choking, recommend the following to parents:

- Use only toys recommended for children 0 to 12 months of age.
- Avoid stuffed animals with eyes or buttons that can be dislodged by the persistent infant.
- Keep the floor free of small items (accidentally dropped coins, paper clips, straight pins).
- Avoid feeding popcorn, nuts, carrot slices, grapes, and hot dog pieces to infants.

Suffocation is also a risk for infants. Cribs should not have pillows, comforters, stuffed animals, or other soft items in them. Keep plastic bags of any size away

from infants. Avoid the risk of strangulation by keeping window blind and drapery cords out of the infant's reach.

Though no safety measure is as effective as close supervision by a watchful parent or caregiver, the above safety measures can be critical to the infant's well-being.

Safety in the Water

Infants can drown in a very small amount of water. Never leave an infant unattended in the sink, a baby bathtub or standard bathtub, a swimming or wading pool, or any other body of water, even if it is quite shallow. The bathroom door should be kept closed and the toilet lid down. Water should be emptied from tubs, pails, or buckets immediately after use. If the family has a swimming pool, a locked fence or locked screen enclosure should surround it. Exterior doors should be kept locked to prevent the older infant from wandering out to the pool. The AAP recommends that parents use caution when enrolling their infant in an aquatic or swim program. The program should be geared toward water survival skills rather than swimming skills, as the infant is not developmentally ready for formal swimming lessons. Completing an aquatic program does not decrease the risk of drowning; vigilant supervision is still always required.

Remember Allison Johnson, the infant described in the beginning of the chapter? What anticipatory guidance related to safety would you provide to Allison's parents?

Promoting Nutrition

Adequate nutrition is essential for growth and development. Breastfeeding and bottle-feeding of infant formula are both acceptable means of nutrition in the newborn and infant. Breast milk or formula supplies all of the infant's daily nutritional requirements until 4 to 6 months of age, at which time solid foods may be introduced.

Cultural Factors

Many dietary practices are affected by culture, both in the types of food eaten and in the approach to progression of infant feeding. Some ethnic groups tend to be lactose-intolerant (particularly blacks, Native Americans, and Asians); therefore, alternative sources of calcium must be offered. Explore the cultural practices of the family related to infant feeding so that you can support the family's cultural values.

Nutritional Needs

Newborns and infants are experiencing tremendous growth and need diets that support these rapid changes. Table 25.7 compares fluid and caloric needs in the newborn and infant.

Breastfeeding

The National Association of Pediatric Nurse Practitioners (NAPNAP), the AAP, the American College of Obstetrics and Gynecology, the American Dietetic Association, and the U.S. Breastfeeding Committee of the Department of Health and Human Services all recommend breastfeeding as the natural and preferred method of newborn and infant feeding. In their position statement on breastfeeding (2001), NAPNAP identifies "human milk as superior to all substitute feeding methods." Breast milk provides complete infant nutrition.

Breastfeeding or feeding of expressed human milk is recommended for all infants, including sick or premature newborns (with rare exceptions). The exceptions include infants with galactosemia, maternal use of illicit drugs and a few prescription medications, maternal untreated active tuberculosis, and maternal human immunodeficiency virus (HIV) infection in developed countries.

Data from *Healthy People 2010* (2000) indicate that in 1998 64% of U.S. women breastfed in the early postpartum period, 29% of infants were breastfeeding at 6 months of age, and only 16% were still breastfeeding at 1 year of age. Even partial breastfeeding is helpful and offers some of the health benefits of breastfeeding. Pediatric nurses in the community and the hospital are in an excellent position to promote and support breastfeeding, thereby contributing to the *Healthy People 2010* goal of increasing the proportion of mothers who breastfeed their babies.

Breastfeeding Technique

Breastfeeding mothers may not have established adequate breastfeeding prior to leaving the hospital after birth of the newborn. The pediatric nurse may encounter an infant-mother dyad experiencing difficulty with breastfeeding for

TABLE 25.7 NUTRITIONAL REQUIREMENTS

Nutritional Requirements	Newborn	Infant
Fluid	140–160 mL/kg/day	100 mL/kg/day for first 10 kg, 50 mL/kg/day for next 10 kg
Calories	105–108 kcal/kg/day	1 to 6 months: 108 kcal/kg 6 to 12 months: 98 kcal/kg

HEALTHY PEOPLE 2010

Objective		Significance
Increase the proportion of mothers who breastfeed their babies.		• Encourage breastfeeding in all mothers beginning with the prenatal visit if applicable.
2010 target:		• Provide accurate education related to breastfeeding.
Early postpartum period	75%	• Be available for questions or problems related to initiation and continuation of breastfeeding. Consult lactation consultant as needed or available.
At 6 months	50%	• Encourage pumping of breast milk when mother returns to work in order to continue breastfeeding.
At 1 year	25%	• Refer to local breastfeeding support groups such as La Leche League.

a variety of reasons. Thus the pediatric nurse must be competent in counseling the breastfeeding mother. Refer to Chapter 18 for complete information related to breastfeeding positions and technique.

The breastfeeding infant does not need supplementation with water or formula even in the first few days of life as long as the newborn continues to wet 6 to 8 diapers per day. After several days of age, the mother's milk supply should be well established. Adequate urine output and bowel movements, as well as continued weight gain in the infant, indicate the adequacy of breastfeeding. Working mothers in particular may need additional support from the nurse in order to continue breastfeeding if they desire to do so. Common problems occurring with breastfeeding are addressed in Teaching Guidelines 25.1. Additional reliable resources for mothers who desire to breastfeed may be found on the following websites: www.aap.org/healthtopics/breastfeeding.cfm, www.breastfeeding.com, www.lalecheleague.org, www.medela.com, and www.promom.org.

Bottle Feeding

For the mother who does not desire to, or cannot, breastfeed, commercially prepared formulas are available for bottle-feeding. These formulas are designed to imitate human milk. Standard infant formulas based on cow's milk provide 20 kcal/ounce and use lactose as a source for carbohydrates. Vegetable oil is used as the source of fat; whey or casein provides protein. Newer cow's milk–based formulas contain long-chain polyunsaturated fatty acids that are thought to improve brain development. Ordinary cow's milk is not recommended for the first year of life.

▶ *Take* NOTE!

Cow's milk does not provide an adequate balance of nutrients for the growing infant, especially iron. It may also overload the infant's renal system with inappropriate amounts of protein, sodium, and minerals.

TEACHING GUIDELINES 25.1

Promoting Breastfeeding

Problem	Solutions
Sore nipples	Prevention: encourage appropriate latch on from the beginning. Expose nipples to air between feedings. Allow breast milk to dry on nipples. Aloe vera or vitamin E may help to heal sore nipples. Medical-grade lanolin or preservative-free lanolin (Lansinoh) may be helpful.
Engorgement	Apply warm compresses or encourage the mother to take a warm shower prior to having the baby latch on. Warmth encourages some of the milk to be released, allowing the breast to soften and making it easier for the infant to latch on.
Poor sucking	Feed on cue, not on a schedule. Encourage the sleepy infant by stroking the feet, undressing, and rubbing the head.
Inadequate milk supply	Decrease maternal stress. Encourage adequate maternal diet and fluid intake. Mothers who return to work must pump in order to keep up milk supply when away from infant.
Father feels left out	Encourage father to participate in other aspects of care.
Mother worries about adequacy of breast milk	If infant is voiding six times per day and gaining weight, then he or she is receiving enough milk and appropriate nutrition.

Only formulas that are fortified with iron should be used. Iron stores that the infant received prenatally are depleted by 4 to 6 months of age. To prevent iron-deficiency anemia, poor growth patterns, and impaired development, iron-fortified formulas must be used. The AAP recommends that commercial formulas provide 10 to 12 mg of iron per liter (AAP, Committee on Nutrition, 1999). Commercial formulas also provide an adequate blend of essential vitamins and minerals.

Feeding Patterns

Infant feeding is an opportune time to establish good eating behaviors. The infant should always be held while being bottle-fed. Cradling in a semi-upright position allows for additional bonding time, as the infant can see the caregiver's face while feeding (Fig. 25.9). Talking or singing during feeding time also increases bonding. As with breastfed infants, the bottle-fed infant should be fed on cue. Overfeeding with the bottle increases the incidence of gastroesophageal reflux, so families need to learn their baby's cues to hunger and satiety.

It is important to feed the baby when he or she displays signs of hunger. Crying is a late sign of hunger; earlier signs include making sucking motions, sucking on hands, or putting the fist to the chin. The infant should be burped two or three times per feeding, when he or she slows feeding or stops sucking. Newborns may only take a half-ounce to 1 ounce per feeding initially, working up to 2 to 3 ounces in the first few days. They need to feed about six to ten times per day. The infant will gradually be able to ingest more formula per feeding. By 3 to 4 months of age, babies feed four or five times per day and take 6 to 7 ounces per feeding. Most infants will not require specific amounts per feeding; the infant should be fed until full. To prevent overfeeding, healthy bottle-fed infants should be allowed to self-regulate the amount of formula ingested per feeding. When the baby is satiated, he or she might fall asleep, spit out the nipple or formula, play with the nipple, or lie quietly, only sucking once in a while.

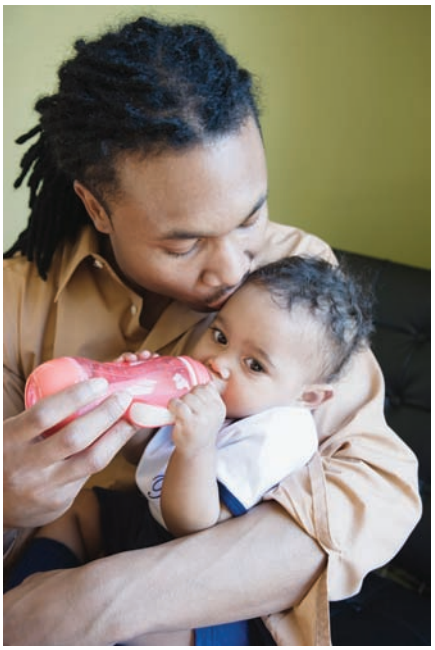

FIGURE 25.9 Technique for bottle-feeding the infant.

Types of Formulas and Bottles

Parents may choose to use commercial formulas that are ready-to-feed or available as a concentrate or as a powder. Parents should follow the instructions for mixing the concentrate or powder to avoid dehydration or fluid and electrolyte imbalances. Ready-to-feed formula should be used as is and never diluted.

A wide variety of baby bottle and nipple types are available for formula feeding, and the choice is purely individual. Few infants require special nipples or bottles. Box 25.1 gives guidelines on preparation and storage of formula and care of bottles.

Special Formulas

Special formulas may be needed for the infant who is allergic to a particular component of standard formula or has a renal, hepatic, metabolic, or intestinal disorder. For example, lactose-free cow's milk formulas are available for the lactose-intolerant child. Formulas using soy as the base ingredient instead of whey or casein are also available. Soy formulas are necessary for infants with a milk allergy, and they may be appealing to the vegetarian family.

These special formulas are designed to meet the nutritional needs of infants, depending on the disorder. Infants who fail to gain weight may be placed on standard infant formula prepared to deliver a higher caloric density per

BOX 25.1 Preparation and Storage of Bottles and Formula

- Wash nipples and bottles in hot soapy water and rinse well OR
- Run nipples and bottles through the dishwasher.
- Store tightly covered ready-to-feed formula can after opening in refrigerator for up to 48 hours.
- After mixing concentrate or powdered formula, store tightly covered in refrigerator for up to 48 hours.
- Do not reheat and reuse partially used bottles. Throw away the unused portion after each feeding.
- Do not add cereal to the formula in the bottle.
- Do not sweeten formula with honey.
- Warm formula by placing bottle in a container of hot water.
- Do not microwave formula.

ounce. Preterm infants (those born at less than 36 weeks' gestation) need adequate nutrition to exhibit catch-up growth. Good catch-up growth (quadrupling or even quintupling the birth weight) in the first year or so of life is critical for adequate head growth and avoidance of neurodevelopmental consequences. Premature infant follow-up formulas are designed to provide additional calories, protein, and a particular calcium-to-phosphorus ratio as well as the vitamins and minerals needed for adequate catch-up growth.

Progressing to Solid Foods

After 6 months of age, infants usually require the nutrients available in solid foods in addition to their breast milk or formula. Progressing to feeding solid foods can be exciting and trying. Before solid foods are attempted, the infant should be assessed for readiness to progress. Parents need instruction in choosing appropriate solid foods and support in the progression process.

Assessing Infant Readiness

Several factors contribute to the appropriate timing of solid food introduction. The tongue extrusion reflex is necessary for sucking to be an automatic reaction—that is, when a nipple or other item is placed in the mouth, the tongue extrudes and sucking begins. This reflex disappears at about 4 to 6 months of age. Introducing solid food with a spoon prior to 4 to 6 months of age will result in extrusion of the tongue. The parent may think that the infant does not want the food and is spitting it out intentionally, but this is not the case; the infant simply must be mature enough to eat with a spoon (absence of extrusion reflex).

The ability to swallow solid food does not become completely functional until 4 to 6 months of age. Enzymes to appropriately digest food other than breast milk and formula are also not present in sufficient quantities until the age of 4 to 6 months.

Before the introduction of solid foods and the cup, the infant should be able to sit supported in a high chair. Solids should be fed with a spoon, with the infant in an upright position.

Choosing Appropriate Solid Foods

Iron-fortified rice cereal mixed with a small amount of breast milk or formula is a good choice for the first solid food. The cereal is easily digested and its taste is generally well accepted. The cereal should be quite thin at first; it can be mixed to a thicker consistency as the infant gets older. Once the feeding of cereal with a spoon is successful, other single foods may be introduced. The foods should be puréed to a smooth consistency, whether prepackaged "baby food" or puréed at home.

The introduction of one new food every 4 to 7 days is recommended. This allows for identification of food allergies (Box 25.2). No salt, sugar, or other seasoning should be added to these first foods.

BOX 25.2 Foods to Avoid in Infancy

- Honey
- Egg yolks and meats (until 10 months of age)
- Excessive amounts of fruit juice
- Foods likely to cause choking
  - Peanuts
  - Popcorn
  - Other small hard foods (e.g., raw carrot chunks)
  - Grapes and hot dog slices (must be cut in smaller pieces)
- Foods likely to result in allergic reaction
  - Citrus
  - Strawberries
  - Wheat
  - Cow's milk
  - Egg whites
  - Peanut butter

Generally, by 8 months of age the infant is ready for more texture in his or her foods. Soft, smashed table food without large chunks is appropriate. Finger foods such as Cheerios, soft green bean pieces, or soft peas may also be offered. Avoid hard foods that the infant may choke on. Strained, puréed, or mashed meats may be introduced at 10 to 12 months of age.

The cup should be introduced at 6 to 8 months of age. One ounce of breast milk or formula should be placed in the cup while the infant is learning. This will decrease the amount of mess should the cup be spilled. Old-fashioned sippy cups are generally acceptable for use, though older infants quickly learn to drink from an ordinary cup with assistance when they are thirsty. Newer "no-spill" sippy cups are not recommended for general home use. They require sucking much like a bottle and do not really encourage the child to learn cup drinking. They should be reserved for use on long trips in the car or other instances in which spills should be avoided (Bailey, 2007).

Fruit juice is unnecessary and should not be introduced until 6 months of age. If juice is given, it should be limited to 2 to 4 ounces per day. Fruit itself is much more nutritious than fruit juice. If infants are allowed to consume larger quantities of juice, it can displace important nutrients from breast milk or formula.

Promoting Healthy Eating Habits

Infants and children learn about food within a social context, so the family plays an important role in creating healthy eating habits. Families "model" eating behaviors; infants and children learn about eating through watching others. Lifelong eating patterns are often established in childhood, so it is important to emphasize healthy eating

practices beginning in infancy (Savage et al., 2007). Parents should not let infants eat whatever they want (permissive feeding style); this will lead to fights over eating in the future. Infants may require as many as 20 exposures to a new food before it is accepted. On the other hand, infants should not be coerced into eating all that is provided (authoritarian feeding style). Forcing an infant to eat when he or she is full sets the child up for overeating in the future and may lead to more power struggles. Parents need to find a balance between the permissive and authoritarian feeding styles to establish lifelong healthy eating patterns in their children. By providing education about appropriate diet and feeding behaviors, the nurse can help the family to accomplish this goal.

Think back to Allison Johnson. What questions should you ask Allison's parents related to her nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

Newborns sleep about 20 hours a day, waking frequently to feed and quickly returning to sleep. By 3 months of age, most infants sleep 7 to 8 hours per night without waking. They will continue to take about three naps a day. By 4 months of age the infant is more active and alert and may have more trouble going to sleep in the evening. Night waking may occur, but the infant should be capable of sleeping through the night and does not require a night feeding. By 12 months of age infants sleep 8 to 12 hours per night and take two naps per day.

Discuss safe sleeping practices with parents of newborns and infants; the baby should sleep on a firm mattress without pillows or comforters. The baby's bed should be placed away from air conditioner vents, open windows, and open heaters. Sudden infant death syndrome (SIDS) has been associated with prone positioning of newborns and infants, so the infant should be placed to sleep on the back. See Healthy People 2010.

▶ **Take** NOTE!

The AAP has determined that side sleeping is not as safe as supine sleeping.

In the newborn period, the primary caregiver should try to sleep when the baby is sleeping. Since newborns need to be fed every 1½ to 3 hours around the clock, parents may become exhausted quickly and are often eager for the infant to sleep through the night. Adding rice cereal to the evening bottle has not been proven to discourage night waking and is not recommended. Provide support to parents of newborns and educate them on infant sleeping patterns.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the percentage of healthy full-term infants who are put down to sleep on their backs.	• Begin teaching about "back to sleep" at prenatal or newborn visit. • Use each encounter with the young infant as an opportunity to reinforce the supine position for sleep.

It is important to establish a bedtime routine around 4 months of age due to the infant's increased alertness and activity level. The baby who is 4 months or older needs a time of calming and relaxation before going to sleep. A consistent bedtime routine should be established, perhaps a bath followed by rocking, singing, or reading. The infant should fall asleep in his or her own crib rather than being rocked to sleep or held until sleeping and then put in the crib. After 4 months of age, infants must learn to soothe themselves back to sleep following night waking. Older infants may exhibit head banging as a form of self-soothing and use it to fall asleep at night. Night feedings are unnecessary at this age and will create a routine of further night waking that will be difficult to break. Parents should minimize attention and stimulation provided during a night waking. Briefly checking on the infant to ascertain his or her safety, followed by placing the infant back in a lying position and telling him or her good night, is all that is needed. This may have to be repeated several times before the infant falls back to sleep. It is important to keep interactions brief during the night waking so that the infant learns to fall back to sleep on his or her own. Continued issues with night waking should be discussed with the infant's primary care provider.

What anticipatory guidance should you provide to Allison's parents in relation to sleep?

Promoting Healthy Teeth and Gums

Healthy teeth and gums require proper oral hygiene and appropriate fluoride supplementation. Children over 6 months of age whose drinking water source contains less than 0.3 parts per million may require fluoride supplementation. Excess fluoride ingestion can result in discoloration of the teeth (fluorosis). Early childhood dental caries can result from pooling of milk or juice around teeth and gums.

Before tooth eruption, parents should clean the child's gums after feeding with a damp washcloth. After teeth have erupted, parents can continue to use a soft cloth for tooth cleaning and then eventually use a small soft-bristled toothbrush. Toothpaste is unnecessary in infancy. Infants should not be allowed to take milk or juice bottles to bed, as the high sugar content of the fluid in contact with the teeth all night leads to dental caries (see section on baby bottle mouth below). Weaning from the bottle at age 12 to 15 months may help prevent dental caries. No-spill sippy cups have also been implicated in the development of dental caries and should be avoided. The American Academy of Pediatric Dentistry recommends that infants receive their first dental visit by the age of 1 year.

Promoting Appropriate Discipline

Parenting requires ever-changing adaptations to the developing infant's needs. Unconditional love, patience, and compassion must be balanced with the parents' needs. **Discipline** helps build self-esteem in children as well as sets standards for social interactions. The primary goal of discipline is to teach an infant limits. Discipline should be used to help the infant solve problems. The infant's activities are based on the basic needs of food, security, warmth, love, and comfort. Misbehavior is the result of an unmet need, and the parents should respond accordingly.

As the infant is undergoing rapid changes in motor skills, safety needs increase. Nurses should encourage the parents to "childproof" their home so that the infant can develop physical skills without being at risk. In a childproof home, fewer restrictions need to be placed on the infant's behavior, and he or she can explore.

Physical punishment or spanking should never be used in infancy. Infants are at increased risk for physical injury from spanking and cannot make the connection between the spanking and the undesirable behavior (Brazelton & Sparrow, 2006). Providing a safe environment, redirection away from undesirable behaviors, and saying "no" in appropriate instances are far more effective. For example, when the infant is in potential danger (e.g., inserting a key into an electrical outlet, attempting to ingest a poisonous substance, or reaching into the toilet), the parent must use a firm but calm and brisk approach. If the infant knows the parent is serious, he or she will usually comply more quickly.

Remaining calm, firm, and consistent is necessary. Immediacy is also an important component of appropriate discipline. The infant cannot make the connection between a subsequent punishment or discussion of behavior with the earlier event itself. Positive reinforcement should be used to support good behavior.

Addressing Child Care Needs

Many mothers work outside the home, there are many single-parent families, and many families live a distance away from relatives. In all of these circumstances, infants may need to be cared for outside the home, often in child care settings or home day care centers.

Parents contemplating child care must consider a number of factors. Do they want a sitter to come to their home? Will they use a traditional day care center or a home care situation with fewer children? How much can they afford? If families choose to use a freestanding day care center or a home-based day care center, they should make sure that the provider is appropriately licensed. Parents should feel comfortable with the caregiver-to-child ratio. Are the caregivers trained in infant CPR and first aid? Families may need to visit or interview several facilities before finding one that meets their requirements.

When an older infant is attending a child care situation for the first time, it may be helpful to visit the center once or twice beforehand so that the infant can get used to the caregivers from the comfort and security of the parent's lap. Warn parents that separation anxiety in late infancy can cause a disturbing crying episode when the parent leaves. Reassure parents that the infant will not suffer harm due to the separation.

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

Parents commonly have multiple concerns during normal infant growth and development. Although most of these issues are not actual disease states or behavior problems, nurses must be aware of these issues to recognize them and to intervene appropriately.

Colic

Healthy 6-week-old infants cry for a total of about 3 hours every day. Crying and fussing are more prevalent in the evenings. By age 12 weeks, the total amount of crying is about 1 hour per day, and infants are better able to soothe themselves by this age. **Colic** is defined as inconsolable crying that lasts 3 hours or longer per day and for which there is no physical cause. It typically resolves by 3 months of age, coinciding with the age at which infants are better able to soothe themselves (e.g., by finger sucking). The cause of colic is thought to be problems in the gastrointestinal or neurologic system (probably system immaturity), temperament, or parenting style of the mother or father (Lobo et al., 2004). Some parents are overly anxious or overly attentive or, at the other extreme, may not give the infant the attention he or she needs. Any of these may contribute to a baby's fussing and crying.

Prolonged crying leads to increased stress among caregivers. Failure to stop the crying leads to frustration, and crying that prevents the parents from sleeping contributes to the exhaustion they are already experiencing.

Educate parents that normal crying increases by the time the infant is 6 weeks old and diminishes by about 12 weeks. When faced with a colicky baby, parents should develop a stepwise approach to checking that all of the infant's basic needs are met. When these needs are met, attempts at soothing the infant may be used. Reducing stimulation may decrease the length of crying. Carrying the infant more may also be helpful. Some infants respond to the motion of an infant swing or a car ride. Vibration, white noise, or swaddling may also help to decrease fussing in some infants. Pacifiers can be soothing to babies who need additional non-nutritive sucking. Parents should try one intervention at a time, taking care not to stimulate the infant excessively in the process of searching for solutions. Nurses should provide ongoing support to the parents of a colicky infant and reassure them that this is a temporary condition that will resolve in time.

Spitting Up

Spitting up (regurgitating small amounts of stomach contents) occurs in all infants, and a significant number of normal infants spit up excessively (Barr, 2003). Although spitting up after feeding is normal, it can be a cause of great concern to parents. Overfed babies who feed based on a parent-designed schedule and those who burp poorly are more likely to spit up. For some infants, the amount and frequency of spitting up are significant, and it may indicate gastroesophageal reflux.

Teach parents that feeding smaller amounts on a more frequent basis may help to decrease spitting-up episodes. Always burp the baby at least two or three times per feeding. Keep the baby upright for 30 minutes after feeding and do not lay the infant prone after feeding. Avoid bouncing or excess activity immediately after feeding. Positioning in an infant seat compresses the stomach and is not recommended. When placing the baby in bed, position him or her on the side with the head of the bed slightly elevated.

Reassure parents that if the infant is wetting at least six diapers per 24 hours and gaining weight, the spitting up is normal. If the infant vomits one third or more of most feedings, chokes when vomiting, or experiences forceful emesis, the primary care provider should be notified.

Thumb Sucking, Pacifiers, and Security Items

Infants demonstrate a clear need for non-nutritive sucking: even fetuses can be observed sucking their thumbs or fingers *in utero.* Thumb sucking is a healthy self-comforting activity. Infants who suck their thumbs or pacifiers often are better able to soothe themselves than those who do not. Studies have not shown that sucking either thumbs or pacifiers leads to the need for orthodontic braces unless the sucking continues well beyond the early school-age period. However, pacifier use has been associated with the increased incidence of otitis media (Comina et al., 2006), and hygiene is always a concern as pacifiers often fall on the floor.

Infants may also become attached to a doll, stuffed animal, or blanket. Just like thumb sucking, the attachment item gives the infant the security to self-soothe when he or she is uncomfortable.

Families need to explore their feelings and cultural preferences about sucking habits and security items. Parents should not try to break the habit during a stressful time for the infant. When the infant is intensely trying to master a new skill such as sitting or walking, he or she may need the sucking or security item to self-soothe. Pacifiers and security items can be physically taken away at some point, but the thumb is attached. The infant who has become attached to thumb sucking should not have additional attention drawn to the issue, as that may prolong thumb sucking.

Families of infants who use pacifiers may want to wean the infant from the pacifier when the child is 6 to 9 months of age. This is the time when the need for additional sucking naturally decreases. Attempts to wean the child from a security blanket or toy should probably be reserved for after infancy (see Evidence-Based Practice).

Teething

Discomfort is common as the tooth breaks through the periodontal membrane. Infants may drool, bite on hard objects, or increase finger sucking. Some infants may become very irritable, refuse to eat, and not sleep well. Fever, vomiting, and diarrhea are generally not considered a sign of teething but rather of illness.

Teething pain results from inflammation. Teach parents that application of cold may be soothing to the gums. The infant may chew on a frozen teething ring, or parents can rub an ice cube wrapped in a washcloth on the gums. Over-the-counter topical anesthetics such as baby Orajel may also be helpful. Parents should apply the ointment correctly to the gums, avoiding the lips, as these ointments cause numbing. Occasionally, oral acetaminophen or ibuprofen may be given to relieve pain.

Refer back to 6-month-old Allison Johnson. List some common developmental concerns of 6-month-old infants. What anticipatory guidance related to these concerns would you provide to her parents?

Key Concepts

- Infancy encompasses the period from birth to age 12 months.
- The infant exhibits tremendous growth, doubling the birthweight by 6 months of age and tripling it by 12 months of age.
- Most organ systems are immature at birth and develop and mature over the first year of life.

EVIDENCE-BASED PRACTICE 25.1
Benefits and Risks of Pacifier Use

● Study
The authors review the history of pacifier use and several recent research studies that attempted to determine the risks and benefits of pacifier use. The majority of the studies were performed within the early part of the 21st century.

▲ Findings
Upon analysis of the various research studies, the authors reached several conclusions. Pacifier use has been shown to lower the risk of Sudden Infant Death Syndrome (SIDS) when used at the time of sleep. Additional benefits include assistance in development of neurologic maturity in preterm infants and not shortening breastfeeding duration in preterm or term infants older than 1 month of age. Potential risks include shortening of breastfeeding duration if a pacifier is used before 1 month of age, increased incidence of otitis media when used after 1 year of age, and development of dental misalignment.

■ Nursing Implications
In light of the potential risks and benefits of pacifier use, nurses must be prepared to provide parents with accurate information related to the use of pacifiers. Educate parents to avoid introduction of the pacifier until breastfeeding is well established (4 weeks of age), to use pacifiers only during periods of sleep, and to never force a pacifier on an infant or replace a pacifier in a sleeping infant's mouth. Additionally, parents should begin to wean the infant from the pacifier in late infancy so that it is not used past 1 year of age.

- Child development is orderly, sequential, and predictable, progressing in a cephalocaudal and proximodistal fashion.
- The infant is mastering the psychosocial task of Trust versus Mistrust.
- Cognitive development in infancy is sensorimotor; infants use their senses and progressing motor skills to master their environment.
- The 12-month-old babbles expressively and uses two or three words with meaning.
- Promotion of safety is of key importance throughout infancy.
- Breastfeeding is the natural and preferred method for infant feeding.
- Breastfed and bottle-fed infants should both be fed on cue rather than on a parent-designed schedule.
- Solid foods should be introduced at age 4 to 6 months. A spoon should be used to feed the infant, and rice cereal should be the first food. New foods should be introduced no more frequently than every 4 to 7 days.
- The cup may be introduced at 6 months of age. No-spill sippy cups are generally not recommended.
- Spitting up and colic are parts of normal development in the otherwise thriving infant and do not require medical intervention.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The mother of a 3-month-old boy asks the nurse about starting solid foods. What is the most appropriate response by the nurse?
   a. "It's okay to start puréed solids at this age if fed via the bottle."
   b. "Infants don't require solid food until 12 months of age."
   c. "Solid foods should be delayed until age 6 months, when the infant can handle a spoon on his own."
   d. "The tongue extrusion reflex disappears at age 4 to 6 months, making it a good time to start solid foods."
2. The father of a 2-month-old girl is expressing concern that his infant may be getting spoiled. The nurse's best response is:
   a. "She just needs love and attention. Don't worry; she's too young to spoil."
   b. "Consistently meeting the infant's needs helps promote a sense of trust."
   c. "Infants need to be fed and cleaned; if you're sure those needs are met, just let her cry."
   d. "Consistency in meeting needs is important, but you're right, holding her too much will spoil her."
3. Parents of an 8-month-old girl express concern that she cries when left with the babysitter. How does the nurse best explain this behavior?
   a. Crying when left with the sitter may indicate difficulty with building trust.
   b. Stranger anxiety should not occur until toddlerhood; this concern should be investigated.
   c. Separation anxiety is normal at this age; the infant recognizes parents as separate beings.
   d. Perhaps the sitter doesn't meet the infant's needs; choose a different sitter.
4. The nurse is providing anticipatory guidance to the mother of a 6-month-old-infant. What is the best instruction by the nurse in relation to the infant's oral health?
   a. "Start brushing her teeth after all the baby teeth come in."
   b. "Use a washcloth with toothpaste to clean her mouth."
   c. "Clean your baby's gums, then new teeth, with a washcloth."
   d. "Rinse your baby's mouth with water after every feeding."
5. A 9-month-old infant's mother is questioning why cow's milk is not recommended in the first year of life as it is much cheaper than formula. What rationale does the nurse include in her response?
   a. It is permissible to substitute cow's milk for formula at this age as he is so close to 1 year old.
   b. Cow's milk is iron poor and does not provide the proper balance of nutrients for the infant.
   c. As long as the mother provides whole milk, rather than skim, she can start cow's milk in infancy.
   d. If the mother cannot afford the infant formula, she should dilute it to make it last longer.

CRITICAL THINKING EXERCISES

1. The mother of an 11-month-old boy who was born at 24 weeks' gestation is concerned about his size and motor skills. What information should the nurse provide?
2. An infant's mother thinks there may be something wrong with him because "he spits up so much." What further information should the nurse obtain?
3. If you determine that the infant in the question above is experiencing normal spitting up associated with his developmental age, develop a brief teaching plan to review with the mother.

STUDY ACTIVITIES

1. A mother brings her 9-month-old boy to the clinic for a well-child check-up. She has questions about feeding, speech, and walking. Develop a teaching plan of anticipatory guidance for the 9-month-old infant.
2. Develop a safety plan for the 12-month-old infant.
3. In the clinical setting, observe two infants of the same age, one who is developing appropriately for his or her age and one who is delayed. Note the similarities and differences between the two infants.

CHAPTER 26

Growth and Development of the Toddler

KEY TERMS

animism
echolalia
egocentrism
expressive language
food jag
individuation
parallel play
physiologic anorexia
receptive language
regression
ritualism
separation
separation anxiety
sibling rivalry
telegraphic speech

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Explain normal physiologic, psychosocial, and cognitive changes occurring in the toddler.
2. Identify the gross and fine motor milestones of the toddler.
3. Demonstrate an understanding of language development in the toddler years.
4. Discuss sensory development of the toddler.
5. Demonstrate an understanding of emotional/social development and moral/spiritual development during toddlerhood.
6. Implement a nursing care plan to address common issues related to growth and development in toddlerhood.
7. Encourage growth and learning through play.
8. Develop a teaching plan for safety promotion in the toddler period.
9. Demonstrate an understanding of toddler needs related to sleep and rest, as well as dental health.
10. Develop a nutritional plan for the toddler based on average nutritional requirements.
11. Provide appropriate anticipatory guidance for common developmental issues that arise in the toddler period.
12. Demonstrate an understanding of appropriate methods of discipline for use during the toddler years.
13. Identify the role of the parent in the toddler's life and determine ways to support, encourage, and educate the parents about toddler growth, development, and concerns during this period.

Jose Gonzales is a 2-year-old boy brought to the clinic by his mother and father for his 2-year-old check-up. During your assessment, you find that his weight is 30 pounds, height 33 inches, and head circumference 19.5 inches. As the nurse caring for him, assess Jose's growth and development, and then provide appropriate anticipatory guidance to the parents.

Wow

Toddlers will take risks and make many mistakes, but remember that both are an essential part of their growth.

The toddler period encompasses the second 2 years of life, from age 1 year to age 3 years. This period is a time of significant advancement in growth and development for the child. It can also be quite a challenging time for parents. The theme during the toddler years is one of holding on and letting go. Having learned that parents are predictable and reliable, the toddler is now learning that his or her behavior has a predictable, reliable effect on others. The challenge is to encourage independence and autonomy while keeping the curious toddler safe.

▶ *Take* NOTE!

As more grandparents are assuming the primary caregiver role for their grandchildren, nurses should be alert to the possibility of increased stress that is placed upon the older caregiver, particularly during the active and sometimes trying years of toddlerhood.

FIGURE 26.1 The typical toddler appearance is that of a rounded abdomen, a slight swayback, and a wide-based stance.

Growth and Development Overview

Infancy is a time of intense growth and development. Both physical growth and acquisition of new motor skills slow somewhat during the toddler years. Refinement of motor skills, continued cognitive growth, and acquisition of appropriate language skills are of prime importance during toddlerhood. The nurse uses the knowledge of normal toddler development as a roadmap for behavioral assessment of the 1- to 3-year-old child.

PHYSICAL GROWTH

The toddler's height and weight continue to increase steadily, though the increase occurs at a slower velocity compared to infancy. Toddler gains in height and weight tend to occur in spurts, rather than in a linear fashion (Fig. 26.1). The average toddler weight gain is 3 to 5 pounds per year. Length/height increases by an average of 3 inches per year. Toddlers generally reach about half of their adult height by 2 years of age. Head circumference increases about 1 inch from when the child is between 1 and 2 years of age, then increases an average of a half-inch per year until age 5. The anterior fontanel should be closed by the time the child is 18 months old. Head size becomes more proportional to the rest of the body near the age of 3 years.

ORGAN SYSTEM MATURATION

Though not as pronounced as the changes occurring during infancy, the toddler's organ systems continue to grow and mature in their functioning. Significant functional changes occur within the neurologic, gastrointestinal, and genitourinary systems. The respiratory and cardiovascular systems undergo changes as well.

Neurologic System

Brain growth continues through toddlerhood, and the brain reaches about 90% of its adult size by 2 years of age. Myelinization of the brain and spinal cord continues to progress and is complete around 24 months of age. Myelinization results in improved coordination and equilibrium as well as the ability to exercise sphincter control, which is important for bowel and bladder mastery. Integration of the primitive reflexes occurs in infancy, allowing for the emergence of the protective reflexes near the end of infancy or early in toddlerhood. The forward or downward parachute reflex is particularly helpful when the child starts to toddle. Rapid increase in language skills is evidence of continued progression of cognitive development.

Respiratory System

The respiratory structures continue to grow and mature throughout toddlerhood. The alveoli continue to increase

in number, not reaching the adult number until about 7 years of age. The trachea and lower airways continue to grow but remain small compared with the adult. The tongue is relatively large in comparison to the size of the mouth. Tonsils and adenoids are large and the Eustachian tubes are relatively short and straight.

Cardiovascular System

The heart rate decreases and blood pressure increases in toddlerhood. Blood vessels are close to the skin surface and so are compressed easily when palpated.

Gastrointestinal System

The stomach continues to increase in size, allowing the toddler to consume three regular meals per day. Pepsin production matures by 2 years of age. The small intestine continues to grow in length, though it does not reach the maximum length of 2 to 3 meters until adulthood. Stool passage decreases in frequency to one or two per day, with as many as 25% of toddlers having a bowel movement every other day. The color of the stool may change (yellow, orange, brown, or green) depending upon the toddler's diet. Since the toddler's intestines remain somewhat immature, the toddler often passes whole pieces of difficult-to-digest food such as corn kernels. Bowel control is generally achieved by the end of the toddler period.

Genitourinary System

Bladder and kidney function reach adult levels by 16 to 24 months of age. The bladder capacity increases, allowing the toddler to retain urine for increased periods of times. Urine output should be about 1 mL/kg/hour. The urethra remains short in both the male and female toddler, making them more susceptible to urinary tract infections compared to adults.

Musculoskeletal System

During toddlerhood, the bones increase in length and the muscles mature and become stronger. The abdominal musculature is weak in early toddlerhood, resulting in a pot-bellied appearance. The toddler appears to have a swayback along with the potbelly. Around 3 years of age, the musculature strengthens and the abdomen is flatter in appearance.

PSYCHOSOCIAL DEVELOPMENT

Erikson defines the toddler period as a time of autonomy versus shame and doubt. It is a time of exerting independence. Since the toddler developed a sense of trust in infancy, he or she is ready to give up dependence and to assert his or her sense of control and autonomy (Erikson, 1963). The toddler is struggling for self-mastery, to learn to do for himself or herself what others have been doing for him or her. Toddlers often experience ambivalence about the move from dependence to autonomy, and this results in emotional lability. The toddler may quickly change from happy and pleasant to crying and screaming. Exertion of independence also results in the toddler's favorite response, "no." The toddler will often answer "no" even when he or she really means "yes."

This negativism—always saying "no"—is a normal part of healthy development and is occurring as a result of the toddler's attempt to assert his or her independence. Table 26.1 gives further information related to developing a sense of autonomy.

Cognitive Development

According to Jean Piaget (1969), toddlers move through the last two substages of the first stage of cognitive development, the sensorimotor stage, between 12 and 24 months of age. Young toddlers engage in tertiary circular reactions and progress to mental combinations. Rather than just repeating a behavior, the toddler is able to experiment with a behavior to see what happens. By 2 years of age, toddlers are capable of using symbols to allow for imitation. With increasing cognitive abilities, toddlers may now engage in delayed imitation. For example, they may imitate a household task that they observed a parent doing several days ago.

Piaget identified the second stage of cognitive development as the preoperational stage. It occurs in children between ages 2 and 7 years. During this stage toddlers begin to become more sophisticated with symbolic thought. The thinking of the older toddler is far more advanced than that of the infant or young toddler, who views the world as a series of objects. During the preoperational stage, objects begin to have characteristics that make them unique from one another. Objects are considered large or small, a particular color or shape, or a unique texture. This moves beyond the connection of sensory information and physical action. Words and images allow the toddler to begin this process of developing symbolic thought by providing a label for the objects' characteristics.

Toddlers also use symbols in dramatic play. First they imitate life with appropriate toy objects, and then they are able to substitute objects in their play. A bowl may be used to pretend to eat from, but then later it can be used upside down on the head as a hat (Fig. 26.2). Human feelings and characteristics may also be attributed to objects (**animism**). See Table 26.1 for further explanation of cognitive development in toddlerhood.

TABLE 26.1 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
Erikson	Autonomy vs. Shame & Doubt Age 1–3 years	Achieves autonomy and self-control Separates from parent/caregiver Withstands delayed gratification Negativism abounds Imitates adults and playmates Spontaneously shows affection Increasingly enthusiastic about playmates Cannot take turns in games until age 3 years
Piaget	Sensorimotor Substage 5: Tertiary Circular Reactions Age: 12–18 months	Differentiating self from objects Increased object permanence (knows that objects that are out of sight still exist [e.g., cookies in the cabinet]) Uses ALL senses to explore environment Places items in and out of containers
	Substage 6: Mental Combinations Age: 18–24 months	Imitates domestic chores (domestic mimicry) Imitation is more symbolic Starting to think before acting Understands requests and is capable of following simple directions Has a sense of ownership (my, mine)
	Preoperational Age: 2–7 years	Time, space, and causality understanding is increasing Uses mental trial and error rather than physical Makes mechanical toys work Plays make-believe with dolls, animals, and people Increased use of language for mental representation Understands concept of "two" Starting to make connections between an experience in the past and a new one that is currently occurring Sorts objects by shape and color Completes puzzles with four pieces Play becomes more complex
Freud	Anal Stage Age: 1–3 years	Focus is on achieving anal sphincter control. Satisfaction and/or frustration may occur as the toddler learns to withhold and expel stool.

FIGURE 26.2 The toddler will (**A**) pretend with items in the way they are intended to be used as well as (**B**) find other creative uses for them.

▶ *Take* NOTE!

Mothers who are depressed may not be as sensitive to their children as other mothers. For this reason, maternal depression is a risk factor for poor cognitive development. Be alert to the mental status of a toddler's mother so that appropriate referrals can be made if needed.

MOTOR SKILL DEVELOPMENT

Toddlers continue to gain new motor skills as well as refine others. Walking progresses to running, climbing, and jumping. Pushing or pulling a toy, throwing a ball, and pedaling a tricycle are accomplished in toddlerhood. Fine motor skills progress from holding and pinching to the ability to manage utensils, hold a crayon, string a bead, and use a computer. Development of eye–hand coordination is necessary for the refinement of fine motor skills. These increased abilities of mobility and manipulation help the curious toddler explore and learn more about his or her environment (Fig. 26.3). As the toddler masters a new task, he or she has confidence to conquer the next challenge. Thus, mastery in motor skill development contributes to the toddler's growing sense of self-esteem. The toddler who is eager to face challenges will likely develop more quickly than one who is reluctant. The senses of sight, hearing, and touch are useful in helping to coordinate gross and fine motor movement.

Gross Motor Skills

As gross motor skills are mastered and then used repeatedly, the large muscle groups in the toddler are strengthened. The "toddler gait" is characteristic of new walkers. The toddler does not walk smoothly and maturely. Instead, the legs are planted widely apart, toes are pointed forward, and the toddler seems to sway from side to side while moving forward (Fig. 26.4). Often the toddler seems to speed along, pitching forward, appearing ready to topple over at any moment. The toddler may fall often, but will use outstretched arms to catch himself or herself (parachute reflex). After about 6 months of practice walking, the toddler's gait is smoother and the feet are closer together. By 3 years of age, the toddler walks in a heel-to-toe fashion similar to that of adults. Toddlers often use physical actions such as running, jumping, and hitting to express their emotions because they are only just learning to express their thoughts and feelings verbally. Table 26.2 lists motor skill expectations in relation to age.

Fine Motor Skills

Fine motor skills in the toddler period are improved and perfected. Holding utensils requires some control and agility, but even more is needed for buttoning and zipping. Adequate vision is necessary for the refinement of fine motor skills because eye–hand coordination is crucial for directing the fingers, hand, and wrist to accomplish small muscle tasks such as fitting a puzzle piece or stringing a bead. See Table 26.2 for age expectations for various motor skills.

FIGURE 26.3 The toddler's curiosity about the world increases, as does her ability to explore it.

FIGURE 26.4 The young toddler (early walker) walks with a wide-based stance, feet pointing forward and arms akimbo.

TABLE 26.2 MOTOR SKILL DEVELOPMENT

Age	Expected Gross Motor Skill	Expected Fine Motor Skills
12–15 months	Walks independently	Feeds self finger foods Uses index finger to point
18 months	Climbs stairs with assistance Pulls toys while walking	Masters reaching, grasping, and releasing: stacks blocks, puts things in slots Turns book pages (singly with board book, multiple if paper) Removes shoes and socks Stacks four cubes
24 months	Runs Kicks ball Can stand on tiptoe Carries several toys, or a large toy while walking Climbs onto and down from furniture without assistance	Builds tower of six or seven cubes Right- or left-handed Imitates circular and vertical strokes Scribbles and paints Starting to turn knobs Puts round pegs into holes
36 months	Climbs well Pedals tricycle Runs easily Walks up and down stairs with alternate feet Bends over easily without falling	Undresses self Copies circle Builds tower of nine or ten cubes Holds a pencil in writing position Screws/unscrews lids, nuts, bolts Turns book pages one at a time

SENSORY DEVELOPMENT

Toddlers use all of their senses to explore the world around them. Toddlers examine new items by feeling them, looking at them, shaking them to hear what sound they make, smelling them, and placing them in their mouths. Toddler vision continues to progress and should be 20/50 to 20/40 in both eyes. Depth perception also continues to mature. Hearing should be at the adult level, as infants are ordinarily born with hearing intact. The sense of smell continues to mature, and toddlers may comment if they do not care for the scent of something. Though taste discrimination is not completely developed, toddlers may exhibit preferences for certain flavors of foods. The toddler is more likely to try a new food if its appearance or smell is familiar. Lack of complete taste discrimination places the toddler at risk of accidental ingestion.

COMMUNICATION AND LANGUAGE DEVELOPMENT

Language development occurs rapidly during the toddler years. The acquisition of language is a dynamic and complex process. The child's age and social interactions and the types of language to which he has been exposed influence language development. **Receptive language** development (the ability to understand what is being said or asked) is typically far more advanced than **expressive language** development (the ability to communicate one's desires and feelings). In other words, the toddler understands language and is able to follow commands far sooner than he or she can actually use the words themselves. Language is a very important part of the toddler's ability to organize his or her world and actually make sense of it. Thoughtfully planned use of language can provide behavior guidance and contribute to the avoidance of power struggles. In regard to expressive language development, the young toddler begins to use short sentences and will progress to a vocabulary of 50 words by 2 years of age. **Echolalia** (repetition of words and phrases without understanding) normally occurs in toddlers less than 30 months of age. "Why" and "what" questions dominate the older toddler's language. Telegraphic speech is common in the 3-year-old. **Telegraphic speech** refers to speech that contains only the essential words to get the point across, much like a telegram. Rather than "I want a cookie and milk," the toddler might say, "Want cookie milk." In telegraphic speech the nouns and verbs are present and are verbalized in the appropriate order. Table 26.3 gives an overview of receptive and expressive language development in the toddler.

Take NOTE!

Stuttering usually has its onset at between 2 and 4 years of age. It occurs more often in boys than in girls. About 75% of all cases of stuttering resolve within 1 to 2 years after they start.

TABLE 26.3 LANGUAGE DEVELOPMENT IN TODDLERS

Age	Receptive Language	Expressive Language
12 months	Understands common words independent of context Follows a one-step command accompanied by gesture	Uses a finger to point to things Imitates or uses gestures such as waving goodbye Communicates desires with word and gesture combinations Vocal imitation First word
15 months	Looks at adult when communicating Follows a one-step command without gesture Understands 100–150 words	Repeats words that he or she hears Babbles in what sound like sentences
18 months	Understands the word "no" Comprehends 200 words Sometimes answers the question, "What's this?"	Uses at least 5–20 words Uses names of familiar object
24 months	Points to named body parts Points to pictures in books Enjoys listening to simple stories Names a variety of objects in the environment Beginning to use "my" or "mine"	Vocabulary of 40–50 words Sentences of two or three words (me up, want cookie) Asks questions (what that?) Uses simple phrases Uses descriptive words (hungry, hot) Two thirds of what child says should be understandable Repeats overheard words
30 months	Follows a series of two independent commands	Vocabulary of 150–300 words
36 months	Understands most sentences Understands physical relationships (on, in, under) Participates in short conversations May follow a three-part command	Speech usually understood by those who know the child, about half understood by those outside family Asks "why?" Three- to four-word sentences Talks about something that happened in the past Vocabulary of 1,000 words Can say name, age, and gender Uses pronouns and plurals

Early identification and referral of children with potential speech delays is critical. If a delay is identified, early intervention may increase the child's potential to acquire age-appropriate receptive and expressive language skills.

▶ ***Take*** NOTE!

Children with preexisting conditions such as genetic syndromes that are known to have an effect on language development should be referred to a speech–language pathologist as soon as the condition is recognized rather than waiting until the child exhibits a delay.

Of special concern in the toddler years is the development of speech and language in potentially bilingual children. At the age of 1 to 2 years, the potentially bilingual child may blend two languages—that is, parts of the word in both languages are blended into one word. At age 2 to 3 years, the potentially bilingual toddler may mix languages within a sentence. Thus, the assessment of adequate language development is more complicated in bilingual children. Parents of potentially bilingual children may find support and resources at the website www.nethelp.no/cindy/biling-fam.html.

▶ ***Take*** NOTE!

Bilingual children often mix languages, and thus speech delay may be more difficult to assess in this population. The bilingual child should have command of 20 words (between both languages) by 20 months of age and should be making word combinations. If this is not the case, further investigation may be warranted.

EMOTIONAL AND SOCIAL DEVELOPMENT

Emotional development in the toddler years is focused on **separation** and **individuation**. Seeing oneself as separate

from the parent or primary caregiver is accompanied by forming a sense of self and learning to exert control over one's environment. As this need to feel in control of his or her world emerges, the toddler displays **egocentrism** (focus on self). This need for control results in emotional lability: very happy and pleasant one moment, then overreacting to limit setting with a temper tantrum in the next moment. As toddlers identify the boundaries between themselves and the parent or primary caregiver, they learn to negotiate a balance between attachment and independence. Toddlers initially rely on the parents' communication and signals in order to initiate appropriate behavior or inhibit undesirable behavior. They have a difficult time choosing between sets of behaviors as they occur in different situations. Power struggles often occur in this age group, and it is important for parents and caregivers to thoughtfully and intentionally develop the rituals and routines that will provide stability and security for the toddler. Many toddlers rely upon a security item (blanket, doll, or bear) to comfort themselves in stressful situations (Fig. 26.5). This ability to self-soothe is a function of autonomy and is viewed as a sign of a nurturing environment, rather than, as one might suspect, one of neglect.

Children also begin to learn about gender differences in the toddler years. They observe the differences between male and female body parts if they are exposed to them. Toddlers may question parents about these differences and may begin to explore their own genitals. Toddlers also begin to understand and mimic social gender differences. They make observations about gender-specific behavior dependent upon what they are exposed to.

FIGURE 26.5 The toddler may be able to self-soothe and produce a sense of comfort during this stage of establishing autonomy by relying upon a security item such as a doll, bear, or blanket.

Aggressive behaviors are typically displayed during the toddler years. Toddlers may hit, bite, or push other children and grab toys. Adults can assist the toddler in building empathy by pointing out when someone is hurt and explaining what happened. Toddlers should not be blamed for their impulsive behavior; rather, they should be guided toward socially acceptable actions in order to foster development of appropriate social judgment. It is particularly important for the parent or caregiver to serve as a role model for appropriate behavior, rather than losing his or her own temper, in order for the toddler to be able to learn how to acceptably handle frustrations. Offering limited choices is one way of allowing toddlers some control over their environment and helping them to establish a sense of mastery. Since toddlers naturally have a short attention span, they tend to dawdle. As the toddlers become more self-aware, they start to develop emotions of self-consciousness such as embarrassment and shame.

Though toddlers are becoming more self-aware, they still do not have clear body boundaries. They do not clearly understand the body's functions, though they are beginning to make appropriate connections. Feces may be viewed as a part of the child, and the toddler may become upset at seeing it disappear in the toilet. The toddler will protect his or her body by resisting intrusive procedures such as temperature or blood pressure measurement.

Separation Anxiety

As toddlers become increasingly skilled at mobility, they realize that if they have the capability of leaving, then so does the parent. As self-awareness develops and conflicts over closeness versus exploration occur, **separation anxiety** may reemerge in the 18- to 24-month period. Power struggles may escalate and distress at separating from the parent may increase. Again, a predictable routine with appropriate limit setting may help toddlers to feel safer and more secure during this period. From the age of 24 to 36 months, separation anxiety again eases. The older toddler begins to have a concept of object constancy: he or she has an internal representation of the parent or caregiver and is better able to tolerate separation, knowing that a reunion will occur.

Temperament

Temperament is the biological basis for personality. It is our emotional and motivational core, around which the personality develops over time. Temperament affects how the toddler interacts with the environment. The easygoing toddler may adapt more easily and not mind changes in routine as much as other toddlers. The easygoing toddler usually sleeps and eats well and has more predictable and regular behaviors. However, the toddler may still express

frustration by having a temper tantrum. The "difficult" toddler is more likely to have intense reactions, negative or positive, with temper tantrums being more likely, more frequent, and more intense than in other toddlers. The structure and routine that toddlers need to feel secure are essential for the difficult toddler; otherwise, the child feels insecure and as a result is more likely to behave inappropriately. The difficult toddler is also the most active of the three temperament types. The slow-to-warm-up toddler is more of a loner and may be very shy. He or she may experience more difficulty with separation anxiety. The behavior of the slow-to-warm-up toddler is more passive; the toddler may be very watchful and withdrawn and may take longer to mature. Changes in routine usually do not result in as much upset, since the toddler's natural reaction is one of passivity.

Based on the toddler's temperament, make suggestions to the parents for interacting with the toddler in various situations. For example, to avoid temper tantrums in the difficult toddler, suggest that the parent should be especially diligent about maintaining structure and routine as well as avoiding tantrum triggers such as fatigue and hunger. Explain to parents that they may need to exercise additional patience with new activities to which the slow-to-warm-up toddler may need extra time becoming accustomed.

Fears

Common fears of toddlers include loss of parents (which contributes to separation anxiety) and fear of strangers. Some toddlers may be very slow to warm up to people they do not know. The nurse caring for a toddler in the outpatient or hospital setting should take the time to establish a relationship with the toddler in order to allay the toddler's fears. Toddlers may be afraid of loud noises and large or unfamiliar animals. Going to sleep may be a scary time for toddlers as they may be afraid of the dark. A nightlight in the toddler's room may be very helpful.

MORAL AND SPIRITUAL DEVELOPMENT

During the toddler years, children may feel comfort from the routine of praying, but they do not understand religious beliefs because of their limited cognitive abilities. Reading simple Bible stories can lay a foundation for later religious teachings. Kohlberg's (1984) description of moral development places the older toddler in the preconventional level. The toddler is only just beginning to learn right from wrong and does not understand the larger concept of morality. The toddler will base his or her actions on the avoidance of punishment and the attainment of pleasure. Older toddlers begin to feel empathy for others.

CULTURAL INFLUENCES ON GROWTH AND DEVELOPMENT

Homelessness or poverty may directly influence the toddler's ability to grow adequately, as resources for the purchase and preparation of appropriate food may be lacking. Appropriate toys (safe ones) may also not be available in those situations. Food customs continue to have an impact on the child's diet and ability to ingest appropriate nutrients. Individual families' value systems have an impact on the toddler's development as well. Some parents desire to keep their child a "baby" for a longer period, thus delaying weaning or continuing to feed the child baby food or puréed food for a longer period. Other families may highly value independence and encourage the toddler to walk everywhere on his or her own rather than carrying the child.

Culture may also affect emotional development. Some families start at a very young age to discourage crying in boys, encouraging them to "act like a big boy" or "be a man." Ridicule for crying at this age may hurt the toddler's self-concept. Educating families about normal growth and development while continuing to value and support cultural practices is important.

Remember Jose Gonzales, whom you met at the beginning of the chapter? What developmental milestones would you expect him to have reached at his age?

The Nurse's Role in Toddler Growth and Development

WATCH & LEARN

The toddler's growth and development affects his or her everyday life as well as the family's. Though some toddlers may grow more quickly or reach developmental milestones sooner than others, growth and development remains orderly and sequential. Health care visits throughout toddlerhood continue to focus on growth and development. The nurse must have a good understanding of the changes that occur during the toddler years in order to provide appropriate anticipatory guidance and support to the family.

When the toddler is hospitalized, growth and development may be altered. The toddler's primary task is establishing autonomy, and the toddler's focus is mobility and language development. Hospitalization removes most opportunities for the toddler to learn through exploration of the environment. Isolation for contagious illness further constrains the toddler's ability to find some control over the environment. The nurse caring for the hospitalized toddler must use knowledge of normal growth and development to be successful in interactions with the toddler,

promote continued development, and recognize delays (see Chapter 32) (Fig. 26.6).

NURSING PROCESS OVERVIEW

Upon completion of assessment of the toddler's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Nursing care planning for the toddler with growth and development issues should be individualized based on the toddler's and family's needs. The nursing care plan may be used as a guide in planning nursing care for the toddler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the following plan and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be an inclusive growth and development plan.

FIGURE 26.6 The hospitalized toddler continues to enjoy developmental tasks appropriate for his or her age, such as coloring.

PROMOTING HEALTHY GROWTH AND DEVELOPMENT

Parents who give their toddler love and respect regardless of the child's gender, behavior, or capabilities are helping to lay the foundation for self-esteem. Self-esteem is also built through familiarity with the daily routine. Routine and ritual help toddlers develop a conscience. Making expectations known through everyday routines helps to avoid confrontations. If the toddler knows the routine, he or she knows what to expect and how he or she is expected to act. When routine and limits are absent, the toddler develops feelings of uncertainty and anxiety. Limit setting (and remaining consistent with those limits) helps toddlers master their behavior, develop self-esteem, and become successful participants in the family. Children then are able to learn about cooperation throughout the predictable flow of daily life. Nurses need to be aware of normal developmental expectations in order to determine whether the toddler is progressing appropriately. Table 26.4 lists potential signs of developmental delay. Any toddler with one or more of these concerns should be referred for further developmental evaluation.

Promoting Growth and Development Through Play

Play is the major socializing medium for toddlers. Parents should limit television viewing and encourage creative and physical play instead. Toddlers typically play alongside another child (**parallel play**) rather than cooperatively (Fig. 26.7). The short attention span of the toddler will make him or her often change toys and types of play. It is important to provide a variety of safe toys to allow the toddler many different opportunities for exploring the environment. Toddlers do not need expensive toys; in fact, regular household items sometimes make the most enjoyable toys. Toddlers are egocentric, a normal part of their development. This makes it difficult for them to share. As they are developing a sense of self (who they are as a person), they may see their toys as an extension of themselves. Learning to share occurs in later toddlerhood. Toddlers also like dramatic play and play that recreates familiar activities in the home. Toddlers like to listen to music of all kinds and will often dance to whatever they hear on the radio. Toddlers enjoy drums, xylophones, cymbals, and toy pianos. Musical instruments made at home are also enjoyed. A few pebbles or coins inside an empty water bottle with the top tightly secured is a great music maker; an empty butter tub with a lid and a pair of wooden spoons makes a nice drum.

Adequate physical activity is necessary for the development and refinement of movement skills. Toddlers need

(text continues on page 811)

Nursing Care Plan 26.1

GROWTH AND DEVELOPMENT ISSUES IN THE TODDLER

NURSING DIAGNOSIS: Risk for injury related to curiosity, increased mobility, and developmental immaturity

Outcome Identification and Evaluation

Toddler safety will be maintained: *Toddler will remain free from injury.*

Interventions: Preventing Injury

- Teach and encourage appropriate use of forward facing car seat *to decrease risk of toddler injury related to motor vehicles.*
- Teach toddlers to stay away from the street and provide constant supervision *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Childproof the home *to provide a developmentally safe environment for the curious and increasingly mobile toddler.*
- Post poison control center phone number *in case of accidental ingestion.*
- Never leave a toddler unattended in a tub or pool or near any body of water *to prevent drowning.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on crib/bed in hospital *because toddlers are at particularly high risk for falling or becoming entangled in tubing as they attempt mobility.*

NURSING DIAGNOSIS: Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

Outcome Identification and Evaluation

Toddler will consume adequate nutrients while using an appropriate feeding pattern: *Toddler will demonstrate weight gain and increases in height.*

Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine toddler's ability to drink from cup, finger feed, swallow, and consume textures *to determine if additional exposure is needed or if further interventions such as speech or occupational therapy are required.*
- Weigh toddler daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Wean from bottle by 15 months of age *to discourage excess milk or juice intake in toddler who can carry bottle around.*
- Limit juice to 4 to 6 ounces per day and milk to 16 to 24 ounces per day *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed toddler on a similar schedule daily, without distractions and with the family: *toddlers respond well to routine and structure and may eat better in the social context of meals, and they become distracted easily (TV should be off).*

NURSING DIAGNOSIS: Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be enhanced: *Toddler will make continued progress toward realization of expected developmental milestones.*

Interventions: Enhancing Growth and Development

- Screen for developmental capabilities *to determine toddler's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of toddlers with developmental delay *(progress in achieving developmental milestones can be slow and ongoing motivation is needed).*
- Reinforce positive attributes in the toddler *to maintain motivation.*
- Model age-appropriate communication skills *to illustrate suitable means for parenting the toddler.*

(continued)

Nursing Care Plan 26.1 (continued)

NURSING DIAGNOSIS: Risk for disproportionate growth related to excess milk or juice intake, late bottle weaning, and consumption of inappropriate foods or in excess amounts

Outcome Identification and Evaluation

Toddler will grow appropriately and not become overweight or obese: *Toddler will achieve weight and height within the 5th to 85th percentiles on standardized growth charts.*

Interventions: Promoting Proportionate Growth

- Wean from bottle and discourage use of no-spill sippy cups by 15 months of age *(will keep mobile toddler from carrying around and continually drinking from cup or bottle).*
- Provide juice (4–6 ounces per day) and milk (16–24 ounces per day) from a cup at meal and snack time *to encourage appropriate cup drinking and limit intake of nutrient-poor, high-calorie fluids.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the toddler won't eat, it is inappropriate to provide high-calorie junk food just so the toddler eats something.*
- Ensure adequate physical activity *to stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming life-long habit of appropriate physical activity.*

NURSING DIAGNOSIS: Interrupted family processes related to issues with toddler development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the toddler

Outcome Identification and Evaluation

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

Interventions: Enhancing Family Functioning

- Assess the family's level of stress and ability to cope *to determine family's ability to cope with multiple stressors.*
- Engage in family-centered care *to provide a holistic approach to care of the toddler and family.*
- Encourage the family to verbalize feelings *(verbalization is one method of decreasing anxiety levels),* and acknowledge feelings and emotions.
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the toddler *(contributes to family's sense of control of situation).*
- Involve family members in toddler's care, *giving them a feeling of control and connectedness.*

NURSING DIAGNOSIS: Readiness for enhanced parenting related to parental desire for increased skills and success with toddler as evidenced by current healthy relationships and verbalization of desire for improved skills

Outcome Identification and Evaluation

Parent will provide safe and nurturing environment for the toddler.

Interventions: Increasing Parenting Skill Set

- Use family-centered care *to provide holistic approach.*
- Educate parent about normal toddler development *to provide basis for understanding the parenting skills needed in this time period.*
- Acknowledge and encourage parent's verbalization of feelings related to chronic illness of child or difficulty with normal toddler behavior *to validate the normalcy of the parent's feelings.*
- Encourage positive parenting with respect to toddlers and their normal development *(helps parents develop approaches to toddlers that can be used in place of anger and frustration).*
- Acknowledge and admire positive parenting skills already present *to contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the toddler *(role modeling actually shows rather than just telling the parent what to do).*

TABLE 26.4 SIGNS OF DEVELOPMENTAL DELAY

Age or Time Frame	Concern
After independent walking for several months	• Persistent tiptoe walking • Failure to develop a mature walking pattern
By 18 months	• Not walking • Not speaking 15 words • Does not understand function of common household items
By 2 years	• Does not use two-word sentences • Does not imitate actions • Does not follow basic instructions • Cannot push a toy with wheels
By 3 years	• Difficulty with stairs • Frequent falling • Cannot build tower of more than four blocks • Difficulty manipulating small objects • Extreme difficulty in separation from parent or caregiver • Cannot copy a circle • Does not engage in make-believe play • Cannot communicate in short phrases • Does not understand simple instructions • Little interest in other children • Unclear speech, persistent drooling

at least 30 minutes of structured physical activity and anywhere from 1 to several hours of unstructured physical activity per day. Indoor and outdoor play areas should encourage play activities that use the large muscle groups. The activity must occur within a safe environment. Outdoor play structures should be positioned over surfaces that are soft enough to absorb a fall, such as sand, wood chips, or sawdust (Fig. 26.8). Box 26.1 lists recommended age-appropriate toys.

FIGURE 26.7 Parallel play. The toddler usually plays alongside another child rather than cooperatively.

Promoting Early Learning

The parent–child relationship and the interactions between parent and child form the context for the toddler's early learning.

Promoting Language Development

Talking and singing to the toddler during routine activities such as feeding and dressing provides an environment

FIGURE 26.8 Toddlers love outdoor physical play, such as climbing on playground equipment. An adult should always supervise toddlers when they are playing outdoors.

BOX 26.1 Appropriate Toys for Toddlers

- Familiar household items such as plastic bowls and cups of various sizes, large plastic serving utensils, pots and pans, wooden spoons, cardboard boxes and tubes (from paper towel rolls), old magazines, baskets, purses, hats
- Child-size household item toys (kitchen, broom, vacuum cleaner, lawnmower, telephone, and so on)
- Blocks, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), simple dolls, stuffed animals, balls, doll beds and carriages
- Manipulative toys with knobs, wind-ups and buttons that make things happen; putting large pegs or shapes into matching holes, stringing large beads on shoelaces, blocks and containers that stack, jigsaw puzzles with large pieces, toys that can be taken apart and put back together again
- Gross motor toys: play gym, push and pull toys, wagons, tricycle or other ride-on toys, tunnels
- Tape or CD players for music, various musical instruments
- Chalk, large crayons, finger paint, Play-Doh, washable markers
- Bucket, plastic shovel and other containers for sand and water play
- Squeaking, floating, squirting toys for the bath

that encourages conversation. Frequent, repetitive naming helps the toddler learn appropriate words for objects. The parent or caregiver should be attentive to what the toddler is saying as well as to his or her moods. Using clarification validates the toddler's emotions and ideas. Parents should listen to and answer the toddler's questions. They should sit down quietly with the toddler and gently repeat what the toddler is saying. Encouragement and elaboration convey confidence and interest to the toddler. The toddler needs time to complete his or her thoughts without being interrupted or rushed because he or she is just starting to be able to make the connections necessary to transfer thoughts and feelings into language.

Parents should not overreact to the child's use of the word "no." They can give the toddler opportunities to use the word "no" appropriately by asking silly questions such as, "Can a cat drive a car?" or "Is a banana purple?" When promoting language development, the parent or primary caregiver should teach the toddler appropriate words for body parts and objects and should help the toddler choose appropriate words to label feelings and emotions. Toddlers' receptive language and interpretation of body language and subtle signs far surpass their expressive language, especially at a younger age.

Parents should avoid discussing scary or serious topics in the presence of the toddler, since the toddler is very adept at reading emotions.

If the parents speak a foreign language in addition to English, both languages should be used in the home.

Encouraging Reading

Reading to the toddler every day is one of the best ways to promote language and cognitive development (Fig. 26.9). Toddlers particularly enjoy homemade or purchased books about feelings, family, friends, everyday life, animals and nature, and fun and fantasy. Board books have thick pages that are easier for young toddlers to turn; older toddlers can turn paper pages one at a time. The toddler may also enjoy "reading" the story to the parent. Reach Out and Read, a program designed to promote early literacy, offers tips for reading with young children (see Teaching Guidelines 26.1).

Choosing a Preschool

The older toddler may benefit from the structure and socialization provided by attending preschool. Attending preschool will help the toddler become more mature and independent and give the toddler a different source for a sense of accomplishment. At this age, toddlers need supervised play with some direction that fosters their cognitive development. A strict curriculum is not necessary in this age group. When choosing a preschool, the parent or caregiver should look for an environment that has the following qualities:

- Goals and an overall philosophy with which the parents agree (promotion of independence and self-confidence through structured and free play)
- Teachers and assistants trained in early childhood development as well as child cardiopulmonary resuscitation (CPR)
- Small class sizes and an adult-to-child ratio with which the parent feels comfortable
- Disciplinary procedures consistent with the parents' values
- Parents can visit at any time

FIGURE 26.9 Reading to a toddler daily is one of the best ways to promote language development and school readiness.

TEACHING GUIDELINES 26.1

Tips for Reading with Young Children

- Make reading part of every day: Read at bedtime or on the bus.
- Have fun: Children who love books learn to read. Books can be part of special time with your child.
- A few minutes is OK: Young children can sit for only a few minutes for a story, but as they grow they will sit longer.
- Talk about the pictures: You do not have to read the book to tell a story.
- Let your child turn the pages: Babies need board books and help to turn pages, but your 3-year-old can do it alone.
- Show your child the cover page: Explain what the story is about.
- Show your child the words: Run your finger along the words as you read them.
- Make the story come alive: Create voices for the story characters and use your body to tell the story.
- Ask questions about the story: What do you think will happen next? What is this?
- Let your child ask questions about the story: Use the story as an opportunity to engage in conversation and to talk about familiar activities and objects.
- Let your child tell the story: Children as young as 3 years old can memorize a story, and many children love an opportunity to express their creativity. (Reach Out and Read, 2006)

- School is childproofed inside and out
- Appropriate hygiene procedures, including prohibiting sick children from attending

Teach the parents how to ease the toddler's transition to attending preschool. Encourage parents to talk about going to preschool and visit the school a couple of times. On the first day, parents should calmly and in a matter-of-fact tone tell the toddler that they will return to pick him or her up. If the toddler expresses separation anxiety, the parent should remain calm and follow through with the plan for school attendance. After a few days of attendance, the toddler will be accustomed to the new routine and crying when parting from the parent should be minimal.

Promoting Safety

Safety is of prime concern throughout the toddler period. Curiosity, mobility, and lack of impulse control all contribute to the incidence of unintentional injury in toddlerhood. Even the most watchful and caring parents have toddlers who run into the street, otherwise disappear from parents, and fall down the stairs. Toddlers require direct observation and cannot be trusted to be left alone. A childproof environment provides a safe place for the toddler to explore and learn. Motor vehicle accidents, drowning, choking, burns, falls, and poisoning are the most common injuries suffered by toddlers. Safety and injury prevention focuses on these categories.

Safety in the Car

The safest place for the toddler to ride is in the back seat of the car. Parents should use the appropriate size and style of car seat for the child's weight and age as required by the state. At a minimum, all children over 20 pounds and up to 40 pounds should be in a forward-facing car seat with harness straps and a clip. A toddler riding in a pickup truck should never ride in the cargo area or truck bed. A full rear seat in the truck is the preferred placement for the toddler car seat. If an appropriate rear seat is unavailable, the air bag should be disarmed and the forward-facing car seat should be secured appropriately in the truck seat. The top tether is additionally required for all forward-facing car seats (Fig. 26.10). Drivers should avoid using the cell phone or attempting to intervene with the children while they are driving. Excellent resources about car seat safety appropriate for both parents and professionals can be found at www.bucklebear.com, www.nhtsa.dot.gov, www.usa.safekids.org, and www.seatcheck.org.

Safety in the Home

Key areas of concern for keeping toddlers safe in the home include avoiding exposure to tobacco smoke, preventing injury, and preventing poisoning.

Avoiding Exposure to Tobacco Smoke

Environmental exposure to tobacco smoke has been associated with increased risk of respiratory disease and infection, decreased lung function, and increased incidence of middle ear effusion and recurrent otitis media. It may also hinder neurodevelopment and may be associated with behavior problems (World Health Organization, 2007). Parents should avoid cigarette smoking entirely to best protect their children. Even smoking outside of the home is suboptimal because smoke lingers on parents' clothing and children who are often carried (such as younger toddlers) face more exposure. Counsel parents to stop smoking (optimal), but if they continue smoking never to smoke inside the home or car with children present.

Preventing Injury

The toddler is able to open drawers and doors, unlock deadbolts, and climb anywhere he or she wants to go. Toddlers have a limited concept of body boundaries and essentially no fear of danger. Toddlers may fall from any height to which they can climb (e.g., play structures, tables, counters). They may also fall from wheeled toys such as tricycles. As toddlers gain additional height and hand dexterity they are able to reach potentially dangerous items

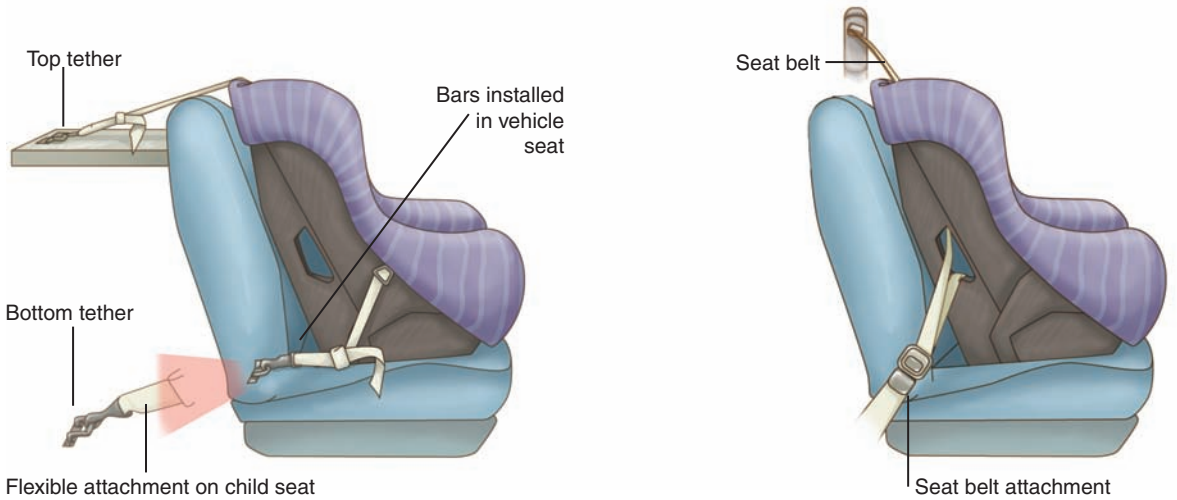

FIGURE 26.10 The top tether further secures the forward-facing car seat. This tether has been a requirement on all forward-facing car seats manufactured since 1999, and most vehicles manufactured after 1999 have a specific attachment for the top tether. (U.S. Department of Transportation, National Highway Traffic Safety Administration.)

on the counter or stove, leading to an accidental ingestion, burn, or cut.

To prevent injury in the home, stress the following to parents:

- Never leave a toddler unsupervised out of doors.
- Lock doors to dangerous rooms.
- Install safety gates at the top and bottom of staircases.
- Ensure that window locks are operable; if windows are left opened, then secure all window screens.
- Keep pot handles on the stove turned inward, out of an inquisitive toddler's reach.
- Teach the toddler to avoid the oven, stove, and iron.
- Keep electrical equipment, cords, and matches out of reach.
- Remove firearms from the home, or keep them in a locked cabinet out of the toddler's reach.
- Always require the child to wear a helmet approved by the Consumer Products Safety Commission (CSPC) when riding a wheeled toy. This starts the habit of helmet wearing early, so it can be more easily carried over to the bicycle-riding years of the future.
- Begin teaching the toddler about watching for cars when crossing the street, but always carry or hold the hand of the toddler when crossing the street.
- Teach the toddler to avoid unknown animals.

▶ ***Take*** NOTE!

"Bernie Burn," by Sarah Cruz, RN, is a book designed to educate parents and their toddlers about burn prevention while entertaining them. It is endorsed by the American Journal of Nursing and is available from www.littleboots publishing.com.

Preventing Poisoning

As toddlers become more mobile, they are increasingly able to explore their environment and more easily and efficiently gain access to materials that may be unsafe for them to handle. Their natural curiosity leads them into situations that may place them in danger. Poor taste discrimination in this age group allows for ingestion of chemicals or other materials that older children would find too unpleasant to swallow. Box 26.2 lists most potentially dangerous ingested poisons. Discuss poison prevention in the home at each well-child visit (see Healthy People 2010). The American Academy of Pediatrics recommends that potentially poisonous substances (e.g., medications, cleaners, hair care products, car care products) be stored out of the toddler's teach, out of the toddler's sight, and in a childproof, locked cabinet.

Encourage all families to:

- Store all substances in original containers only.
- Never store any liquid other than soda in a soda pop bottle.
- Do not allow toddlers access to baby powder, lotion, cream, or other toddler hygiene products.

BOX 26.2 Most Dangerous Potential Poisons

- Medicines (especially iron)
- Cleaning products
- Antifreeze, windshield washer solution
- Alcohol
- Pesticides
- Gasoline, kerosene, lamp oil, furniture polish
- Wild mushrooms

American Association of Poison Control Centers, 2004

HEALTHY PEOPLE 2010

Objective	Significance
Reduce nonfatal poisonings	• Use every encounter with the toddler's family as an opportunity to educate about preventing poisonings.

- Ensure all medications have child-safety caps.
- Do not leave within the toddler's reach medications such as lozenges or samples that are not packaged in safety bottles.
- Be very careful with medications that are provided in transdermal patch form.
- Do not refer to medicines as candy, as the toddler may mistake pills for candy and ingest them.
- Do not expose toddlers to hazardous vapors such as paints, cleaners, tobacco smoke, and especially street drugs such as crack and marijuana.
- Keep "button" batteries secured and away from a toddler's reach.
- Keep house plants off the floor, remove them from the home, or hang them or place them on a high shelf.

▶ **Take** NOTE!

The American Academy of Pediatrics (AAP, 2007b) recommends that all families post the Poison Control Center number in a readily accessible place in the home: (800) 222-1222. The AAP discourages the use of syrup of ipecac in the home to induce vomiting after an accidental ingestion.

Safety in the Water

Drowning is the leading cause of unintentional injury and death in U.S. children, with the highest rate of drowning occurring in 1- to 2-year-olds (AAP, 2003, 2004b). Drowning may occur in very small volumes of water such as a toilet, bucket, or bathtub, as well as the obvious sites such as swimming pools and other bodies of water. Toddlers' large heads in relation to their body size place them at risk for toppling over into a body of water that they are inquisitive about. Toddlers should be supervised at all times when in or around the water. In general, most children do not have the physical and cognitive capabilities necessary to truly learn how to swim until 4 years of age. Parents who want to enroll a toddler in a swimming class should be aware that a water safety skills class would be most appropriate. However, even toddlers who have completed a swimming program still need *constant* supervision in the water. Box 26.3 gives recommendations for the prevention of drowning.

BOX 26.3 Preventing Drowning

- Pools should be fenced with locked gates or screened with locked doors.
- Interior doors should be kept locked.
- Young children should never be left unattended in or near water.
- Water wings or "floaties" are not a substitute for adult supervision or for personal flotation devices.
- U.S. Coast Guard-approved life preservers or personal flotation devices should be available when a young child is in or near a body of water.
- Parents and caregivers should be trained in child cardiopulmonary resuscitation (CPR).

Remember Jose Gonzales, the 2-year-old introduced at the beginning of the chapter? What anticipatory guidance related to safety should you provide to his parents?

Promoting Nutrition

The toddler's ability to chew and swallow is improving, and he or she learns to use utensils effectively to feed himself or herself. The early years lay a foundation for the future, and a great deal of parental and societal interest is focused upon nutrition and eating. Forming healthy eating habits has its foundation early in life, and diet has significant influence upon the child's future health status. By establishing healthier food choice patterns early in life, the child is better able to continue these healthy choices later in life. The child less than 2 years of age should not have his or her fat intake restricted, but this does not mean that unhealthy foods such as sweets should be eaten liberally. A diet high in nutrient-rich foods and low in nutrient-poor high-calorie foods such as sweets is appropriate for children of all ages. See Healthy People 2010.

Weaning

The timing of weaning from breastfeeding is influenced by a number of factors such as cultural beliefs, local and regional ethnic beliefs, the mother's work schedule, desired child spacing, or societal feelings about the nature

HEALTHY PEOPLE 2010

Objective	Significance
Reduce growth retardation among low-income children under age 5 years.	• Counsel families about the appropriate toddler diet. • Refer eligible families to WIC for grocery supplementation and nutritional counseling.

of the mother–infant relationship. The extent and duration of breastfeeding are inversely related to the development of obesity later in life: children who breastfeed longer are less likely to become obese than those who breastfeed for shorter periods of time. Thus, extending breastfeeding into toddlerhood is believed to be beneficial to the child. Extended breastfeeding provides nutritional, immunologic, and emotional benefits to the child. Contrary to popular belief, it is biologically possible to become pregnant while breastfeeding. Breastfeeding a newborn appropriately can occur while continuing to nurse its older sibling.

Weaning from breastfeeding tends to occur earlier in the United States than in countries around the world, despite recommendations on length of breastfeeding by a number of organizations. Most professional organizations recommend breastfeeding for at least 1 year.

Weaning is a highly individualized decision. Educate the mother about the benefits of extended breastfeeding and support her in her decision to wean at a given time.

Weaning from the bottle should occur by 12 to 15 months of age. Prolonged bottle-feeding is associated with the development of dental caries. No-spill "sippy cups" contain a valve that requires sucking by the toddler in order to obtain fluid, thus functioning similar to a baby bottle. Hence, no-spill sippy cups can also be associated with dental caries and are not recommended. Cups with spouts that do not contain valves are acceptable. The 12- to 15-month-old is developmentally capable of consuming adequate fluid amounts using a cup.

Teaching About Nutritional Needs

Adequate calcium intake and appropriate exercise lay the foundation for proper bone mineralization. The toddler requires an average intake of 500 mg calcium per day. Dairy products are considered the primary sources of dietary calcium. One cup of low-fat or whole milk, 8 ounces of low-fat yogurt, and 1½ ounces of cheddar cheese each provide 300 mg of calcium. Broccoli, oranges, sweet potatoes, tofu, and dried beans or legumes are also good sources of calcium (35 to 120 mg calcium per serving).

▶ *Take* NOTE!

Though a half-cup of cooked spinach contains 120 mg of calcium, it is essentially non-bioavailable, making spinach a poor source of calcium.

Iron-deficiency anemia in the first 2 years of life may be associated with developmental and psychomotor delays. Although it is important for toddlers to consume adequate amounts of iron, they tend to have the lowest daily iron intake of any age group. When breastfeeding or formula feeding ends (most often at 1 year of age), it is often replaced with iron-poor cow's milk. Limiting milk intake to 16 ounces per day, as well as limiting juice intake, can be helpful. Encourage the parents to provide iron-fortified cereals and other foods rich in iron and vitamin C.

▶ *Take* NOTE!

Toddlers who consume a strictly vegan diet (no food from animal sources) are at risk for deficiencies in vitamin D, vitamin B12, and iron. Supplementation with these nutrients should occur to promote adequate nutrition and growth.

Fat or cholesterol intake should not be restricted in children under age 2 years. The first 2 years of life require high energy intake because they are a time of very rapid growth and development. To promote healthy cholesterol levels, children over age 2 years should consume a diet with a total fat content between 20% and 30% of total calories. Saturated fats should account for less than 10% of total calories. Due to daily variations and the pickiness of the toddler, fat intake should be evaluated over a period of several days. The daily recommended intake of fiber for a 1- to 3-year-old is 19 grams. Figure 26.11 gives guidance on serving sizes and daily nutritional needs. Box 26.4 lists common sources of several nutrients.

Parents should encourage toddlers to drink water. Juice intake should be limited to 4 to 6 ounces per day. Milk intake should be limited to 16 to 24 ounces per day. Juice and milk should be served along with meals or snacks. Water should be offered for between-meal drinking. Toddlers should drink from a cup.

Advancing Solid Foods

Parents should offer three full meals and two snacks daily. Portion sizes for toddlers are about one-quarter the size of adult portions. Large portions of a new or different food on the toddler's plate may intimidate the toddler. Normal toddler behaviors of mouthing, handling, tasting, extruding the food from the mouth, and then resampling the food often occur. These behaviors are distasteful to some parents but are a normal part of toddler development. Parents need to understand and tolerate these behaviors rather than scolding the toddler for them. Toddlers are often afraid to try new things anyway, so the parent or caregiver should be flexible with the toddler's acceptance or rejection of new foods. If the toddler refuses healthy food choices at meal or snack time, parents should not substitute high-fat, high-sugar, processed food "just to make sure he's eating something." This sets the stage for future power struggles. The parent decides which foods will be served or

Food Guide Pyramid For Your Young Child

FOOD IS FUN and learning about food is fun, too. Eating foods from the Food Guide Pyramid and being physically active will help you grow healthy and strong.

What Counts As One Serving?

Grain Group
1 slice of bread
1/2 cup of cooked rice or pasta
1/2 cup of cooked cereal
1 ounce of ready-to-eat cereal

Vegetable Group
1/2 cup of chopped raw or cooked vegetables
1 cup of raw leafy vegetables

Fruit Group
1 piece of fruit or melon wedge
3/4 cup of juice
1/2 cup of canned fruit
1/4 cup of dried fruit

Milk Group
1 cup of milk or yogurt
2 ounces of cheese

Meat Group
2 to 3 ounces of cooked lean meat, poultry, or fish

1/2 cup of cooked dry beans, or 1 egg counts as 1 ounce of lean meat.
2 tablespoons of peanut butter count as 1 ounce of meat

Fats and Sweets
Limit calories from these.

Four- to 6-year-olds can eat these serving sizes. Offer 2- to 3-year-olds less, except for milk. Two- to 6-year-old children need a total of 2 servings from the milk group each day.

Provided by

NIBBLES FOR HEALTH 2 Nutrition Newsletters for Parents of Young Children, USDA, Food and Nutrition Service

FIGURE 26.11 The U.S. Department of Agriculture's Young Child Food Pyramid provides a guide for parents and caregivers for determining adequate nutritional intake. (USDA, http://www.fns.usda.gov/tn/Resources/Nibbles/fgp_nibbles.pdf.)

BOX 26.4 Key Nutrients Provided by Fruits and Vegetables

Dietary fiber: applesauce, carrots, corn, green beans, mangos, pears
Folate: avocados, broccoli, green peas, oranges, spinach and dark greens, strawberries
Vitamin A: apricots, cantaloupe, carrots, mangos, spinach and dark greens, sweet potatoes
Vitamin C: broccoli, cantaloupe, green peas, oranges, potatoes, strawberries, tomatoes

offered. The toddler decides how much will be eaten. The toddler self-regulates the amount of food needed to sustain and allow further growth and development. The toddler may not eat well every day but generally, over the course of several days, will consume the foods he or she needs.

Foods should be served near room temperature. Some of the food on the plate should be soft and moist. Food should always be cut into bite-size pieces. Teaching Guidelines 26.2 gives recommendations on ways to prevent choking.

Promoting Self-Feeding

Toddlers most often eat with their fingers, but they do need to learn to use utensils properly. The following are suggestions for parents:

- Use a child-sized spoon and fork with dull tines.
- Seat the toddler in a high chair or at a comfortable height in a secure chair. The toddler should have his or her feet supported rather than dangling (Fig. 26.12).

FIGURE 26.12 The toddler should be appropriately and safely seated in the high chair. The safety strap is secure, the toddler's feet are supported, and the tray table is locked in place.

TEACHING GUIDELINES 26.2

Avoiding Choking

- Slowly add foods that are more difficult to chew as the toddler becomes more adept at chewing.
- Cut all foods into bite-sized pieces.
- Avoid foods that are hard to chew and may become lodged in the airway, such as:
  - Nuts
  - Gumdrops or other chewy candies
  - Raw carrots
  - Peanut butter (by itself)
  - Popcorn
- Cut hotdogs and grapes into quarters. Cook carrots until soft; if serving raw, then grate them.
- Always supervise the toddler while he or she is eating.
- Never leave the toddler unattended while eating.
- Minimize distractions during mealtime. Turn off the television and serve food to the toddler along with the other members of the family.

Promoting Healthy Eating Habits

Since the toddler's rate of growth has slowed somewhat compared to that in infancy, the toddler requires less caloric intake for his or her size compared to the infant. This results in **physiologic anorexia**: toddlers simply do not require as much food intake for their size as they did in infancy. The toddler will also exhibit **food jags**. During a food jag, the toddler may prefer only one particular food for several days, then not want it for weeks. Again, it is important for the parent to continue to offer healthy food choices during a food jag and not give in by allowing the toddler to eat junk food.

The normal developmental issue of testing limits will also occur for the toddler at mealtime. Since toddlers still have limited ability to express their emotions with words, they use nonverbal behaviors to do so. While eating, the toddler may dislike the taste of a particular food or experience a feeling of fullness but will communicate that feeling by screaming or throwing food. When the child exhibits these behaviors, the parent must remain calm and remove the toddler from the situation. Meals should be eaten in a calm and pleasant environment. Parents should serve as role models for appropriate eating habits, but toddlers may also be willing to try more foods if they are

exposed to other children who eat those foods. Praise the child for trying a new food, and never punish the toddler for refusing to try something new. A new food may need to be offered many times in a row before the toddler chooses to try it. Parents should be sure to include foods the child is familiar with and likes to eat at the same meal that the new food is being introduced. Teaching Guidelines 26.3 lists alternative foods that meet nutritional needs and a list of books for parents of the picky eater.

Preventing Overweight and Obesity

In the child younger than 3 years of age, the greatest risk factor for the development of overweight or obesity is having an obese parent. The nurse can screen for overweight in the child over 2 years of age by calculating the body mass index (BMI) and plotting the BMI on the standardized age- and gender-appropriate growth charts (see Appendix A for growth charts, and refer to Chapter 31 for BMI calculation instructions). Trends over time may be predictive of the development of overweight or obesity.

TEACHING GUIDELINES 26.3

Meeting Nutritional Needs of the Picky Eater

Alternative Food Choices for the Picky Eater

- Won't drink milk? Obtain calcium through yogurt (frozen or regular), cheese, pudding, and hot cocoa.
- Poor meat intake? Obtain iron through unsweetened iron-fortified cereals or breakfast bars, raisins; cook with an iron skillet.
- Loves processed white bread? Encourage fiber intake with fresh fruits and vegetables, bran muffins, beans or peas (can be in soup).
- Refuses vegetables? Encourage vitamin A intake with apricots, sweet potatoes, and vegetable juices.

Books for Parents of the Picky Eater

- *Coping with a Picky Eater: A Guide for the Perplexed Parent* by W. Wilkoff. New York: Simon & Schuster, 1998.
- *First Foods* by M. Stoddard. New York: Dorling-Kindersley Publishing, Inc., 1998.
- *How to Get Your Kid to Eat . . . but not too much* by E. Satter. Boulder, CO: Bull Publishing Co., 1987.
- *The "Everything" Baby's First Food Book* by J. Tarlou. Holbrook, MA: Adams Media Corp., 2001.
- *The Family Nutrition Book* by W. Sears & M. Sears. Boston: Little Brown & Co., 1999.
- *The Healthy Baby Meal Planner* by A. Karmel. New York: Simon & Schuster, 2001.

Another factor in development of obesity in young children is juice intake. Since most young children like the sweet taste of juice, they may drink excessive amounts of it. Toddlers who drink excess fruit juice and eat well may develop overweight or obesity because of the high sugar content in the juice. On the other end of the spectrum, some children may actually feel full from juice consumption and decrease their intake of solid foods. These children are at risk for malnutrition. Fruit juice intake should be limited to 4 to 6 ounces per day.

▶ ***Take*** NOTE!

Young children should consume only pasteurized juice, as unpasteurized juice consumption places the toddler at increased risk of Escherichia coli, Salmonella, *and* Cryptosporidium *infection.*

Refer back to Jose Gonzales. What questions should you ask his parents related to his nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The 18-month-old requires 13.5 hours of sleep per day, the 24-month-old 13 hours, and the 3-year-old 12 hours. A typical toddler should sleep through the night and take one daytime nap. Most children discontinue daytime napping at around 3 years of age. The toddler who slept in a crib as an infant will need to move to a youth or toddler bed or even a full-size bed usually sometime in the toddler period. When the crib becomes unsafe (that is, when the toddler becomes physically capable of climbing over the rails), then he or she must make the transition to a bed.

Consistent bedtime rituals help the toddler prepare for sleep. Choose a bedtime and stick to it as much as possible. The nightly routine might include a bath followed by reading a story. The routine should be a calm period with minimal outside distractions. Toddlers often require a security item to help them get to sleep. Older toddlers may be afraid of the dark, so a nightlight is often helpful.

Night waking is a problem for some toddlers. This may occur as a result of change in routine or as a desire for nighttime attention. Attention during night waking should be minimized so that the toddler receives no reward for being awake at night. The book, "Solve Your Child's Sleep Problems," by Dr. Richard Ferber (2006, New York: Fireside Publishing), is an excellent resource for the family

with a toddler who resists bedtime or is a persistent night waker. For some toddlers, night waking is caused by nightmares. As the imagination and capacity for make-believe grow, the toddler may not be able to distinguish between reality and pretend. The parent should hold and comfort the toddler after a nightmare. Limiting television viewing (especially shortly before bedtime) may be helpful in limiting nightmares.

Some families practice "co-sleeping" (when children sleep in the parents' bed). Although some professionals believe that co-sleeping may interfere with the toddler's struggle for independence, this theory has not been proven. The nurse should support the family's choice for sleep arrangements unless the co-sleeping is unsafe either physically or psychologically. Refer to safebedsharing.org for bedsharing safety guidelines.

Provide anticipatory guidance to Jose Gonzales' parents in relation to his sleep.

Promoting Healthy Teeth and Gums

By 30 months of age, the toddler should have a full set of primary ("baby") teeth. Parents may not be aware of the importance of preventing cavities in primary teeth since they will eventually be replaced by the permanent teeth. Poor oral hygiene, prolonged use of a bottle or no-spill sippy cup, lack of fluoride intake, and delayed or absent professional dental care may all contribute to the development of dental caries. Cleaning of the toddler's teeth should progress from brushing with simply water to using a very small amount (pea-sized) of fluoridated toothpaste with brushing beginning at 2 years of age (Fig. 26.13). Weaning from the bottle no later than 15 months of age and severely restricting use of a no-spill sippy cup (the kind that requires sucking for fluid delivery) is recommended.

At age 1 year, the toddler should have his or her first dentist visit to establish current health of the teeth and gums. Eating should be limited to meal and snack times, as "grazing" throughout the day exposes the teeth to food throughout the day. Carbohydrate-containing foods combined with oral bacteria create a decreased oral pH level that is optimal for the development of dental caries (cavities). See Healthy People 2010.

Public water fluoridation is a public health initiative that ensures that most children receive adequate fluoride intake to prevent dental caries. Table 26.5 gives recommendations regarding fluoride supplementation. If the water supply contains adequate fluoride, no other supplementation is necessary other than brushing with a small amount of fluoride-containing toothpaste after age 2 years. Excess fluoride ingestion should be avoided, as it contributes to the development of fluorosis (mottling of the enamel). Fluorosis occurs most often in the toddler years. Risk factors for fluorosis development include:

FIGURE 26.13 The parent should brush the toddler's teeth to ensure proper cleaning of the teeth, gums, and tongue. Use only water for brushing before 2 years of age and a pea-sized amount of fluoride-containing toothpaste after age 2 years.

- High fluoride levels in the local water supply
- Use of fluoride-containing toothpaste prior to age 2 years
- Excessive ingestion of fluoride either in toothpaste or foods
  - Fluoride-containing foods: tea, ready-to-eat infant foods containing chicken, white or purple grape juice, and beverages, processed foods and cereals that were manufactured with fluoride-containing water

Promoting Appropriate Discipline

Discipline is a common concern during toddlerhood. The toddler's intense personality and extreme emotional re-

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children with untreated dental decay.	• Encourage weaning from bottle by 15 months of age. • Discourage use of no-spill sippy cups. • Refer any toddler with potential or existing caries to pediatric dentist.

TABLE 26.5 RECOMMENDATIONS FOR FLUORIDE SUPPLEMENTATION

	Fluoride Ion Level in Drinking Water (ppm)		
Age	<0.3 ppm	0.3–0.6 ppm	>0.6 ppm
Birth to 6 months	None	None	None
6 months to 3 years	0.25 mg/day	None	None
3–6 years	0.50 mg/day	0.25 mg/day	None
6–16 years	1.0 mg/day	0.50 mg/day	None

ppm: parts per million is equivalent to 1 mg/liter

These recommendations are public domain at www.ada.org and were approved by the American Dental Association, the American Academy of Pediatrics, and the American Academy of Pediatric Dentistry.

actions can be difficult for parents to understand and cope with. The toddler needs firm, gentle guidance to learn what the expectations are and how to meet them. The parent's love and respect for the toddler teach the toddler to care about himself or herself and for others. Affection is as important as the guidance aspect of discipline. Having realistic expectations of what the toddler is capable of learning and understanding can help the parent in the disciplinary process. The toddler's intense push for autonomy can often test a parent's limits. The easygoing infant usually becomes more challenging in toddlerhood. The toddler's continual quest for new experiences often places the toddler at risk, and his or her negativism very often taxes the parent's patience.

In an effort to prevent the toddler from experiencing harm and in response to his or her continual testing of limits, parents often resort to spanking. Though commonly accepted, the American Academy of Pediatrics and the National Association of Pediatric Nurse Practitioners recommend against corporal or physical punishment (AAP 2004a; NAPNAP, 2006b). Recent research points out the dangers inherent in the use of corporal punishment as well as the possibilities for negative effects on the child's future behavior (Box 26.5). Spanking or other forms of corporal punishment lead to a pro-violence attitude, create resentment and anger in some children, and contribute to the cycle of violence (NAPNAP, 2006). See Evidence-Based Practice 26.1.

▶ ***Take*** *NOTE!*

Toddlers less than 18 months of age should NEVER be spanked, as there is an increased possibility of physical injury in this age group. Also, the infant/young toddler is not capable of linking the spanking with the undesired behavior.

Normal toddler development includes natural curiosity, and this curiosity often results in dangerous or problematic activities for the toddler. Toddlers have a difficult time learning the rules and in general do not behave badly intentionally. Providing a childproof environment will allow the toddler to participate in safe exploration, which will meet his or her developmental needs and decrease the frequency of intervention needed on the part of the parents.

BOX 26.5 **Negative Impact of Physical Punishment**

- Spanking is less effective than time-out or other discipline measures to reduce undesired behavior in children.
- The toddler less than 18 months of age:
  - Is not capable of making the appropriate connections between spanking and the undesired behavior
  - Is at increased risk for physical injury from spanking than older children
- Physical punishment:
  - May lead to a pro-violence attitude
  - May create resentment in the toddler
  - Is a poor model for learning effective problem solving
  - May be correlated with antisocial and criminal behavior later in life
  - Leads to increased aggression in preschoolers, school-aged children, and adults
  - When used frequently, may weaken the parent–child relationship
- Childhood corporal punishment increases the probability of depression and substance abuse in adulthood.
- Spanking may lead to more severe forms of punishment and to actual child abuse and maltreatment.
- The more frequently children are hit or spanked, the more likely they are to hit their own children and to be involved in spouse abuse as adults.

AAP, 2004a; NAPNAP, 2006b

EVIDENCE-BASED PRACTICE 26.1
Corporal Punishment and Behavior Problems in Early Childhood

● Study
A large volume of research indicates that there are few, if any, positive developmental outcomes associated with the use of corporal punishment (spanking). In order to determine if negative consequences resulted, the authors used data from a large longitudinal ongoing multicenter study, the National Institute of Child Health and Human Development Study of Early Child Care and Youth Development. They reviewed the data from over 100 children, performing analyses that specifically controlled for contextual and parenting variables as well as for partial child effects. The Home Observation for the Measurement of the Environment (HOME) was administered when the children were 15, 36, and 54 months of age. The HOME measurement determined the use of corporal punishment. To determine the presence of behavior problems, the Child Behavior Checklist was administered at 36 months of age and again when the child was in the first grade.

▲ Findings
Multiple regression analysis was performed on the data sets, controlling for variables such as the child's gender, ethnicity, and temperament as well as maternal sensitivity and depression. The results established a causal link between the use of corporal punishment and child adjustment, particularly an increase in behavior problems during toddlerhood.

■ Nursing Implications
Targeted interventions may have a positive impact on decreasing the use of corporal punishment in young children. Advise parents about the risks associated with corporal punishment. Provide them with education about appropriate alternative methods of discipline, including limit-setting with consistent follow-through, extinction, and time-out. Support parents' efforts to use alternative methods of discipline.

Mulvaney, M. K., & Mebert, C. J. (2007). Parental corporal punishment predicts behavior problems in early childhood. *Journal of Family Psychology, 21*(3), 389–397.

Discipline should focus on limit setting, negotiation, and techniques to assist the toddler to learn problem solving. Parents should provide consistency and commit to the limits that are set.

Offering realistic choices helps give the toddler a sense of mastery. Rules should be simple and limited in number. Maintaining the toddler's schedule of meals and rest/sleep will help to prevent conflicts that occur as a result of hunger or fatigue. Toddlers should not be made to share, as this is a concept they do not understand. Parents should encourage simple activities enjoyed by the children involved and avoid confrontation over toys. Parents should offer toddlers appropriate choices to help them develop autonomy, but should not offer a choice when none exists.

Positive reinforcement should be used as much as possible. "Catching" a child being good helps to reinforce appropriate or desirable behaviors. When the toddler is displaying appropriate behavior, the parent should reward the child consistently with praise and physical affection.

"Time out" can be used effectively at around 2.5 to 3 years of age (refer to Chapter 6 for details). "Extinction" is a particularly useful technique with 2- and 3-year-olds. Extinction involves systematic ignoring of the undesired behavior. Parents sometimes unknowingly contribute to the occurrence of an unwanted behavior simply by the attention they give the toddler (even if is negative in nature, it is still attention). Parents who want to extinguish an annoying (non-dangerous) behavior should resolve to ignore it every time it occurs. When the child withholds the behavior or performs the opposite (appropriate) behavior, they should use compliments and praise. It may be difficult to ignore a difficult behavior, but the results are well worth the effort. Teaching Guidelines 26.4 provides tips on avoiding power struggles and offering appropriate guidance to toddlers.

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

Common developmental concerns of the toddler period are toilet teaching, temper tantrums, thumb sucking or pacifier use, sibling rivalry, and regression. An understanding of the normalcy of negativism, temper tantrums, and sibling rivalry will help the family cope with these issues. Prepare parents for these developmental events by giving appropriate anticipatory guidance.

Toilet Teaching

When myelinization of the spinal cord is achieved around age 2 years, the toddler is capable of exercising voluntary control over the sphincters. Girls may be ready for toilet teaching earlier than boys. Toddlers are ready for toilet teaching when:

• Bowel movements occur on a fairly regular schedule.

TEACHING GUIDELINES 26.4

Providing Toddlers with Guidance

- When giving the toddler instructions, tell the child what to do, NOT what not to do. This allows for a positive focus. If you must say "no," "don't," or "stop," then follow with a direction of what to do instead.
- Offer limited choices, when a choice is truly available. Say, "Do you want to wear your blue hat or your red hat?" NOT "Do you want to put on your hat?" This gives the toddler some, but not all, control.
- Role model appropriate communication, but don't feel like you have to speak nicely all the time. If the situation warrants, use a firm and even tone to get the point across. Avoid yelling.
- Pay attention to the inflection in your voice. A statement or direction should not end in a questioning tone or with "Okay?" Be clear. Statements should sound like statements, and only questions should end in a questioning tone.
- When a toddler behaves aggressively, label the child's feelings calmly, but be firm and consistent with the expectation. For example, "I know you're mad at your friend, but it is not okay to hit."

FIGURE 26.14 The toddler will feel most comfortable with a potty chair that sits on the floor.

- The toddler expresses knowledge of the need to defecate or urinate. This may be through verbalization, change in activity, or gestures such as:
  - Looks into or grabs diaper
  - Squats
  - Crosses legs
  - Grimaces and/or grunts
  - Hides behind a door or the couch when defecating
- The diaper is not always wet (this indicates the ability to hold the urine for a period of time).
- The toddler is willing to follow instructions.
- The toddler walks well alone and is able to pull down his or her pants.
- The toddler follows caregivers to the bathroom.
- The toddler climbs onto the potty chair or toilet.

Parents should approach toilet teaching with a calm, positive, and nonthreatening manner. Initially it may be helpful to allow the toddler to observe a same-sex family member using the toilet. Start with the toddler fully clothed on the potty chair or toilet while the parent or caregiver talks about what the toilet is used for and when. The toddler will feel most comfortable with a toddler potty chair that sits on the floor (Fig. 26.14). If a potty chair is unavailable, facing toward the toilet tank may make the toddler feel more secure, as the buttocks remain on the front of the seat rather than sinking through the toilet seat opening. After a week or longer, remove a dirty diaper and place the contents in the toilet. Next try having the toddler sit on the potty chair or toilet without pants or diaper on. The toddler may benefit from watching a caregiver or friend use the toilet. It may also be beneficial to demonstrate using the potty chair with a baby doll that wets.

Parents should always use gentle praise and no reproaches. Usually the best time to achieve success with defecation on the toilet is following a meal. When the toddler has achieved success with bowel control, bladder control will come next. It may be many months before nighttime bladder control is achieved, and the toddler may still require a diaper at night. Parents should use appropriate words for body parts, urination, and defecation, then use those words consistently so the toddler understands what to say and do.

After a couple of weeks of successful toileting, the toddler may start wearing training pants. When toddlers have an accident and don't make it to the toilet, gently remind them about toileting and let them help clean up. Toddlers should never be punished for bowel or bladder "accidents."

With so much attention focused on the genitalia during toilet teaching and the frequency of being without a diaper, it is natural for toddlers to become more focused on their own genitalia. Boys and girls both will explore their genitalia and discover the resulting pleasurable sensation. Masturbation in the toddler often causes a great deal of discomfort in the parent. The parent should not draw attention to the activity, as that may increase its frequency. The parent should calmly explain to the toddler that this is an activity that may only be done in private. If the toddler is masturbating excessively or refuses to stop

when in public, then there may be additional stressors in the toddler's life that should be explored.

Negativism

Negativism is common in the toddler period. As the toddler separates from the parent, recognizes his or her own individuality, and exerts autonomy, negativism abounds. Parents should understand that this negativism is a normal developmental occurrence and not necessarily deliberate defiance (though that also occurs). Avoid asking yes-or-no questions, as the toddler's usual response will be "no," whether he or she means it or not. Offering the child simple choices will give the toddler a sense of control. The parent should not ask the toddler if he or she "wants" to do something, if there is actually no choice. "Do you want to use the red cup or the blue cup?" is more appropriate than "Do you want your milk now?" When it is time to go outside, don't ask, "Do you want to put your shoes on?" Instead, state in a matter-of-fact tone that shoes must be worn outside, and give the toddler a choice of type of shoe or color of socks. If the child continues with negative answers, then the parent should remain calm and make the decision for the child.

Temper Tantrums

Even children who displayed an easygoing personality as infants may lose their temper frequently during the toddler years (Fig. 26.15). A toddler who was more intense as an infant may have more temper tantrums. Temper tantrums are a natural result of the frustration that toddlers experience. Toddlers are eager to explore new things, but their efforts are often thwarted (usually for safety reasons). Toddlers do not behave badly on purpose. They need time and maturity to learn the rules and regulations. Some of their frustration may come from lack of language skills to express themselves. Toddlers are just starting to learn how to verbalize feelings and to use alternative actions rather than just "pitching a fit." The temper tantrum may be manifested as a screaming and crying fit or a full-blown episode in which the toddler throws himself or herself on the floor kicking, screaming, and pounding, perhaps even holding the breath. Fatigue or hunger may limit the toddler's coping abilities and promote negative behavior and temper tantrums.

FIGURE 26.15 Tantrums are a normal component of toddler development.

Although tantrums are annoying to parents and caregivers, they are a normal part of the toddler's quest for independence. As toddlers mature, they become better able to express themselves and to understand their environment.

Parents need to learn their toddler's behavioral cues in order to limit activity that is frustrating. When the parent notes the beginnings of frustration, a friendly warning might be given. Intervening early with an activity change might prevent a tantrum. Use distraction, refocusing, or removal from the situation.

When a temper tantrum does occur, the best course of action is to ignore the behavior and ensure that the child is safe during the tantrum. Physical punishment will probably just prolong the tantrum and in fact produce more intense negative behavior. If the tantrum occurs in public, it may be necessary for the parent to immobilize the child with a big bear hug and use a calm voice to soothe the toddler. It is very important for parents to model self-control. Since toddlers' tantrums most often result from frustration, the role-modeled behavior of self-control helps to teach toddlers to control their temper when they can't get what they want.

Thumb Sucking and Pacifiers

Infants bring their hands to their mouths and begin thumb sucking as a form of self-soothing. This habit may continue into the toddler years and beyond. The pacifier is used for the same reason. Toddlers may calm themselves in a stressful situation by thumb sucking or sucking on a pacifier. Opinions about thumb and finger sucking and pacifier use are significantly affected by family history and culture. For most children there is no need to worry about a sucking habit until it is time for the permanent teeth to erupt. Prolonged and frequent sucking in the withdrawn child is more likely to yield changes to the tooth and jaw structure than sucking that is primarily used for self-soothing. Parents must sort through their own feelings about thumb sucking and pacifier use and then decide how they want to handle the habit.

To ensure safety with pacifier use:

- Use only one-piece pacifiers.
- Replace worn pacifiers with new ones.
- Never tie a pacifier around a toddler's neck.

Parents may want to limit thumb sucking and pacifier use to bedtime, in the car, and in stressful situations. The parent should calmly discuss these limits with the toddler and then remain consistent about enforcing them.

Sibling Rivalry

Many families have subsequent children when their first child is a toddler. The toddler has been accustomed to being the baby and receiving a great deal of attention, both at home and with the extended family. Since toddlers are normally egocentric, bringing a new baby into the home may be quite disruptive. To minimize issues with **sibling rivalry**, parents should attempt to keep the toddler's routine as close to normal as possible. Spend individual time with the toddler on a daily basis. Involve the toddler in the care of the baby. The toddler is capable of fetching a diaper or T-shirt, entertaining the baby with a toy, or helping sing a song to calm the baby. "Helping" the parent care for the baby gives the toddler a sense of importance (Fig. 26.16). The toddler will need significant support while holding the baby.

Regression

Some toddlers experience **regression** during a stressful event (e.g., the birth of a sibling, hospitalization). Stress in a toddler's life affects his or her ability to master new developmental tasks. During regression, the toddler may want to go back to an earlier stage. He or she may desire a bottle or pacifier long ago forgotten. The toddler may stop displaying previously achieved language or motor skills. A significant stress in the toddler's life may also disrupt the toilet teaching process (toilet teaching may not be achieved near the time a sibling is born). When regression occurs, parents should ignore the regressive behavior and offer praise for age-appropriate behavior or attainment of skills.

FIGURE 26.16 The toddler may be more likely to accept the new baby in a positive manner if she feels that this is "our baby," not just "mommy's baby." This toddler is meeting her new brother for the first time.

Refer to Jose Gonzales, the 2-year-old in the case study. List common developmental concerns of the toddler. What anticipatory guidance related to these concerns would the nurse provide to Jose's parents?

Key Concepts

- The toddler's organ systems are continuing to mature, and growth slows during this period as compared with infancy.
- The psychosocial task of the toddler years is to attain a sense of autonomy and to experience separation and individuation.
- Cognitive development in toddlerhood progresses from sensorimotor in nature to preoperational.
- The toddler refines gross motor skills after learning to walk and builds fine motor skills through the use of utensils and various manipulative toys.
- The toddler progresses from limited expressive language capabilities to a vocabulary of 900 by age 3 years.
- Toddlers use all of their senses to explore and learn about their environment.
- Visual acuity progresses to at least 20/50 in the toddler period.
- Negativism abounds in toddlers as they attempt to exert their independence.
- Very ritualistic, toddlers feel safer and more secure when clear limits are enforced and a structured routine is followed.
- The toddler is starting to learn right from wrong and bases actions on punishment avoidance.
- Toddler development may be promoted through active gross motor play, books, music, and block building.
- Safety is a primary concern in the toddler years as the child is more mobile, very curious, and experimenting with autonomy.
- Poisoning in the toddler period may be prevented through proper storage of medications and other potentially poisonous substances and appropriate supervision.
- Consistent bedtime rituals help ease the toddler's transition to sleep.
- All primary teeth are erupted by 30 months of age and may be kept healthy with appropriate tooth brushing and fluoride supplementation.
- The toddler may experience a decrease in appetite as growth slows, yet he or she still needs appropriate nutritional intake for continued development.

- Toilet teaching can be achieved after myelinization of the spinal cord is complete, usually around 2 years of age.
- Thumb sucking, pacifier use, security items, and temper tantrums are expected issues in the toddler years.
- Toddler discipline should focus on clear limits and consistency. It should not involve spanking. It should be balanced with a caring and nurturing environment along with frequent praise for appropriate behavior.
- Parental role modeling of appropriate behavior, especially related to dealing with frustration, is beneficial to toddlers.
- Parents play an important role in toddler development, not only by providing a loving environment but also by role modeling appropriate behavior in most areas of daily life.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a hospitalized 30-month-old who is resistant to care, angry, and yells "no" all the time. The nurse identifies this toddler's behavior as
   a. Problematic, as it interferes with needed nursing care
   b. Normal for this stage of growth and development
   c. Normal because the child is hospitalized and out of his routine
2. The mother of a 15-month-old is concerned about a speech delay. She describes her toddler as being able to understand what she says, sometimes following commands, but using only one or two words with any consistency. What is the nurse's best response to this information?
   a. The toddler should have a developmental evaluation as soon as possible.
   b. If the mother would read to the child, then speech would develop faster.
   c. Receptive language normally develops earlier than expressive language.
   d. The mother should ask her pediatrician for a speech therapy evaluation.
3. A 2-year-old is having a temper tantrum. What advice should the nurse give the mother?
   a. For safety reasons, the toddler should be restrained during the tantrum.
   b. Punishment should be initiated, as tantrums should be controlled.
   c. The mother should promise the toddler a reward if the tantrum stops.
   d. The tantrum should be ignored as long as the toddler is safe.
4. What is the best advice about nutrition for the toddler?
   a. Encourage cup drinking and give water between meals and snacks.
   b. Encourage unlimited milk intake, because toddlers need the protein for growth.
   c. Avoid sugar-sweetened fruit drinks and allow as much natural fruit juice as desired.
   d. Allow the toddler unlimited access to the sippy cup to ensure adequate hydration.
5. To gain cooperation from a toddler, what is the best approach by the nurse?
   a. Immediately pick the toddler up from the mother's lap.
   b. Kneel in front of the toddler while he or she is on the mother's lap.
   c. Do the nursing tasks quickly so the toddler can play.
   d. Ask the toddler if it is okay if you begin the needed task.

CRITICAL THINKING EXERCISES

1. Develop a teaching plan about safety to present to a toddler-age preschool class.
2. Construct a 3-day menu for a 2-year-old, one that is realistic and will provide the nutrients needed.
3. Develop a plan for educating the parent of a 34-month-old who has been resistant to toilet teaching. Include assessments the nurse will make as well as the plan for teaching.

STUDY ACTIVITIES

1. Visit a preschool that provides care for special-needs toddlers as well as typical toddlers. Perform a developmental assessment on a typical toddler and one with special needs (both the same age). Compare and contrast your findings.
2. Care for two average 2-year-olds in the clinical setting. Describe each toddler's behavior, response to the parent, and response to the nurse and list strategies used to gain compliance and minimize stress to the toddler.
3. Observe in the toddler classroom of a typical preschool. Choose two toddlers the same age with different temperaments. Record the toddlers' differences and similarities in response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

CHAPTER 27

Growth and Development of the Preschooler

KEY TERMS

animism
empathy
imaginary friend
magical thinking
preoperational thought
school readiness
telegraphic speech
transduction

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify normal physiologic, cognitive, and psychosocial changes occurring in the preschool-aged child.
2. Express an understanding of language development in the preschool years.
3. Implement a nursing care plan that addresses common concerns or delays in the preschooler's development.
4. Integrate knowledge of preschool growth and development with nursing care and health promotion of the preschool-aged child.
5. Develop a nutrition plan for the preschool-aged child.
6. Identify common issues related to growth and development during the preschool years.
7. Demonstrate knowledge of appropriate anticipatory guidance for common developmental issues that arise in the preschool period.

Nila Patel is a 4-year-old girl brought to the clinic by her mother and father for her school check-up. During your assessment you measure her weight to be 44 pounds and her height 40 inches. As the nurse caring for her, assess Nila's growth and development, and then provide appropriate anticipatory guidance to her parents.

Wow

Quality parenting is achieved only by example.

The preschool period is the period between 3 and 6 years of age. This is a time of continued growth and development. Physical growth continues much more slowly compared to earlier years. Gains in cognitive, language, and psychosocial development are substantial throughout the preschool period. Many tasks that began during the toddler years are mastered and perfected during the preschool years. The child has learned to tolerate separation from parents, has a longer attention span, and continues to learn skills that will lead to later success in the school-age period. Preparation for success in school occurs during the preschool period because most children enter elementary school by the end of the preschool period.

Growth and Development Overview

The healthy preschooler is slender and agile, with an upright posture. The formerly clumsy toddler becomes more graceful, demonstrating the ability to run more smoothly. Athletic abilities may begin to develop. Major development occurs in the area of fine motor coordination. Psychosocial development is focused on the accomplishment of initiative. Preconceptual thought and intuitiveness dominate cognitive development. The preschooler is an inquisitive learner and absorbs new concepts like a sponge absorbs water.

PHYSICAL GROWTH

The average preschool age child will grow 2.5 to 3 inches (6.5–7.8 cm) per year. The average 3-year-old is 37 inches tall (96.2 cm), the average 4-year-old is 40.5 inches tall (103.7 cm), and the average 5-year-old is 43 inches tall (118.5 cm). Average weight gain during this time period is about 5 pounds (2.3 kg) per year. The average weight of a 3-year-old is 32 pounds (14.5 kg), increasing to an average weight of 41 pounds (18.6 kg) by age 5. The loss of baby fat and the growth of muscle during the preschool years give the child a stronger and more mature appearance (Fig. 27.1). The length of the skull also increases slightly, with the lower jaw becoming more pronounced. The upper jaw widens through the preschool years in preparation for the emergence of permanent teeth, usually starting around age 6.

FIGURE 27.1 The preschool child has a more slender appearance and erect posture than the toddler.

ORGAN SYSTEM MATURATION

Most of the body systems have matured by the preschool years. Myelination of the spinal cord allows for bowel and bladder control to be complete in most children by age 3 years. The respiratory structures are continuing to grow in size, and the number of alveoli continues to increase, reaching the adult number at about 7 years of age. The eustachian tubes remain relatively short and straight. Heart rate decreases and blood pressure increases slightly during the preschool years. An innocent heart murmur may be heard upon auscultation, and splitting of the second heart sound may become evident. The preschooler should have 20 deciduous teeth present.

The small intestine is continuing to grow in length. Stool passage usually occurs once or twice per day in the average preschooler. The 4-year-old generally has adequate bowel control. The urethra remains short in both boys and girls, making them more susceptible to urinary tract infections than adults. Bladder control is usually present in the 4- and 5-year-old child, but an occasional accident may occur, particularly in stressful situations or when the child is absorbed in an interesting activity.

The bones continue to increase in length and the muscles continue to strengthen and mature. However, the musculoskeletal system is still not fully mature, making the preschooler susceptible to injury, particularly with overexertion or excess activity.

PSYCHOSOCIAL DEVELOPMENT

According to Erik Erikson, the psychosocial task of the preschool years is establishing a sense of initiative versus guilt (Erikson, 1963). The preschooler is an inquisitive

FIGURE 27.2 Allowing the preschooler to assist with simple household tasks such as preparing a sandwich encourages the development of initiative.

learner, very enthusiastic about learning new things. Preschoolers feel a sense of accomplishment when succeeding in activities (Fig. 27.2), and feeling pride in one's accomplishment helps the child to use initiative. However, when the child extends himself or herself further than current capabilities allow, he or she may feel a sense of guilt. The superego or conscience development is completed during the preschool period, and this is the basis for moral development (understanding right and wrong). Table 27.1 gives examples illustrating the stage of initiative versus guilt.

COGNITIVE DEVELOPMENT

According to Jean Piaget's theory, the preschool-age child continues in the preoperational stage. Preoperational thought dominates during this stage and is based on a self-centered understanding of the world. In the preconceptual phase of preoperational thought, the child remains egocentric and is able to approach a problem from a single point of view only. The young preschooler may understand the concept of counting and begins to engage in fantasy play.

Magical thinking is a normal part of preschool development. The preschooler believes that his or her thoughts are all-powerful. The fantasy experienced through magical thinking allows the preschooler to make room in his or her world for the actual or the real. Through make-believe and magical thinking, preschool children satisfy their curiosity about differences in the world around them.

The preschooler often has an **imaginary friend** as well. This friend serves as a creative way for the preschooler to sample different activities and behaviors and practice conversational skills. Despite this imagination, the preschooler is able to switch easily between fantasy and reality throughout the day.

The child in the intuitive phase can count 10 or more objects, correctly name at least four colors, and better understand the concept of time, and he or she knows about things that are used in everyday life, such as appliances, money, and food. The preschooler uses **transduction** when reasoning: he or she extrapolates from a particular situation to another, even though the events may be unrelated. The preschooler also attributes lifelike qualities to inanimate objects (**animism**). Table 27.1 gives further examples illustrating this developmental stage.

The acquisition of language skills in the toddler period is enhanced in the preschool period. The expansion of vocabulary enables the preschooler to progress further with symbolic thought. At this age, children do not completely understand the concept of death or its permanence: they may ask when their grandparent or pet who died is returning.

MORAL AND SPIRITUAL DEVELOPMENT

The preschool child can understand the concepts of right and wrong and is developing a conscience. That inner voice that warns or threatens is developing in the preschool years. Kohlberg identified this stage (between 4 and 10 years) as the preconventional stage, which is characterized by a punishment-and-obedience orientation. Preschool children see morality as external to themselves; they defer to power (that of the adult). The child's moral standards are those of their parents or other adults who influence them, not necessarily their own. Preschoolers adhere to those standards to gain rewards or avoid punishment. Since the preschool child is facing the psychosocial task of initiative versus guilt, it is natural for the child to experience guilt when something goes wrong. The child may have a strong belief that if someone is ill or dying, then he or she may be at fault and the illness or death is punishment.

As the child's moral development progresses, he or she learns how to deal with angry feelings. Sometimes the way the child chooses to deal with those feelings may be inappropriate, such as fighting and biting. Preschoolers are so involved in imagination and fantasy that lying begins to occur at this age. Preschoolers also use their limited life experiences to make sense of and help them cope with crisis. They need to learn the socially acceptable limits of behavior and are also learning the rewards of manners. The preschool child begins to help out in the family and begins to understand the concept of give-and-take in relationships.

During the preoperational phase of cognitive development, the preschooler's concept of faith is intuitive and projective in nature (Fosarelli, 2003). The preschool child's imagination allows for anything to be possible, so he or she does not have a logical view of the world (as adults

TABLE 27.1 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
Erikson	Initiative vs. Guilt Age 3–6 years	Likes to please parents Begins to plan activities, make up games Initiates activities with others Acts out the roles of other people (real and imaginary) Develops sexual identity Develops conscience May take frustrations out on siblings Likes exploring new things Enjoys sports, shopping, cooking, working Feels remorse when makes wrong choice or behaves badly Cooperates with other children Negotiates solutions to conflicts
Piaget	Preoperational substage: Preconceptual phase Age: 2–4 years	Exhibits egocentric thinking, which lessens as the child approaches age 4 Short attention span Learns through observing and imitating Displays animism Forms concepts that are not as complete or as logical as the adult's Able to make simple classifications By age 4 understands the concept of opposites (hot/cold, soft/hard) Reasoning is that of specific to specific Has an active imagination
	Preoperational substage: Intuitive phase Age 4–7 years	Able to classify and relate objects Has intuitive thought processes; knows if something is right or wrong, though cannot state why Tolerates others' differences but doesn't understand them Very curious about facts Knows acceptable cultural rules Uses words appropriately but often without true understanding of their meaning Has a more realistic sense of causality May begin to question parents' values
Kohlberg	Punishment–obedience orientation Age 2–4 years (preconventional morality)	Determines good vs. bad dependent upon associated punishment Children may learn inappropriate behavior at this stage if parental intervention does not occur (if the child hits, bites, or is verbally disrespectful but is not punished for these activities, the child will view those behaviors as good and continue to participate in them)
Freud	Phallic stage Age 3–7 years	Child's pleasure centers on genitalia and masturbation. Superego is developing and conscience is emerging. Oedipal stage occurs: jealousy and rivalry toward same-sex parent, with love of the opposite-sex parent. This usually resolves by the end of the preschool years, when the child develops a strong identification with the same-sex parent.

do). Preschool children have limited life experiences, so they may project a feeling onto a new person or situation. They may use this projection to help them understand what is going on around them. Preschoolers may project their parents' or caregiver's feelings or characteristics onto "God": if mommy gets angry, then God is probably also angry.

The family's religious beliefs may affect the child's diet, the mode of discipline that parents use, and even how the parents view their children. Knowing about a family's practices of prayer or meditation is helpful to the pediatric nurse, who can help continue the ritual when the child is ill or hospitalized (Fig. 27.3).

MOTOR SKILL DEVELOPMENT

As the preschooler's musculoskeletal system continues to mature, existing motor skills become refined and new ones develop. The preschooler has more voluntary control over his or her movements and is less clumsy than the toddler.

FIGURE 27.3 The preschool child may participate in religious rituals without having full understanding of their meaning.

FIGURE 27.4 The older toddler runs well, can hold a ball, and can balance on one foot.

Significant refinement in fine motor skills occurs during the preschool period (Table 27.2).

Gross Motor Skills

The preschooler is agile while standing, walking, running, and jumping (Fig. 27.4). He or she can go up and down stairs and walk forward and backward easily. Standing on tiptoes or on one foot still requires extra concentration. The preschooler seems to be in constant motion. He or she also uses the body to understand new concepts (such as using the arms in a "chug-chug" motion when describing how the train wheels work).

Fine Motor Skills

The 3-year-old can move each finger independently and is capable of grasping utensils and crayons in adult fashion,

TABLE 27.2 MOTOR SKILL DEVELOPMENT

Age	Expected Gross Motor Skills	Expected Fine Motor Skills
4 years	• Throws ball overhand • Kicks ball forward • Catches bounced ball • Hops on one foot • Stands on one foot up to 5 seconds • Alternates feet going up and down steps • Moves backward and forward with agility	• Uses scissors successfully • Copies capital letters • Draws circles and squares • Traces a cross or diamond • Draws a person with two to four body parts • Laces shoes
5 years	• Stands on one foot 10 seconds or longer • Swings and climbs well • May skip • Somersaults • May learn to skate and swim	• Prints some letters • Draws person with body and at least six parts • Dresses/undresses without assistance • Can learn to tie laces • Uses fork, spoon, and knife (supervised) well • Copies triangle and other geometric patterns • Mostly cares for own toileting needs

FIGURE 27.5 The 5-year-old has the fine motor dexterity to cut well with scissors.

with the thumb on one side and the fingers on the other. He or she can also scribble freely, copy a circle, trace a square, and feed himself or herself without spilling much. These skills become refined over the next 2 years, and by 5 years of age the child can write letters, cut with scissors more accurately, and tie shoelaces (Fig. 27.5).

SENSORY DEVELOPMENT

Hearing is intact at birth and should remain so throughout the preschool years. The senses of smell and touch continue to develop throughout the preschool years. The young preschooler may have a less discriminating sense of taste than the older child, putting him or her at increased risk for accidental ingestion. Visual acuity continues to progress and should be equal bilaterally. The typical 5-year-old has visual acuity of 20/40 or 20/30. Color vision is intact at this age.

COMMUNICATION AND LANGUAGE DEVELOPMENT

The acquisition of language allows the preschool child to express thoughts and creativity. The preschool years are a time of refinement of language skills. The 3-year-old exhibits **telegraphic speech**, using short sentences that contain only the essential information. Vocabulary at 3 years comprises about 900 words. The preschool child may acquire as many as 10 to 20 new words per day and at age 5 usually has a vocabulary of 2,100 words. By the end of the preschool period, the child is using sentences that are adult-like in structure (Table 27.3).

The 3- to 6-year-old is starting to develop fluency (the ability to smoothly link sounds, syllables, and words when speaking). Initially, the child may exhibit dysfluency or stuttering. Speech may sound choppy, or the child may say repeated consonants or "um." Stuttering usually has its onset between 2 and 4 years of age, and about 75% of children will recover from it without therapy. Parents should slow down their speech and should give the child time to speak without rushing or interrupting. Some sounds remain difficult for the preschooler to enunciate properly: "f," "v," "s," and "z" sounds are usually mastered by age 5 years, but some children do not master the sounds of "sh," "l," "th," and "r" until age 6 or later.

Communication in preschool children is concrete in nature, as they are not yet capable of abstract thought. Despite its concrete nature, the preschooler's communication can be quite elaborate and involved; he or she may talk about dreams and fantasies. In addition to acquiring vocabulary and learning the correct use of grammar, the preschool child's receptive language skills are also becoming refined.

The preschooler is very much in tune with the parent's moods and easily picks up on negative emotions in conversations. If the preschooler hears parents discussing things that are frightening to the child, the preschooler's imagination may fuel the development of fears and lead to misinterpretation of what the child has heard.

In the potentially bilingual child, by 4 years of age the child will cease the language mixing exhibited during the toddler years and should be able to use each language as a separate system.

EMOTIONAL AND SOCIAL DEVELOPMENT

By the time a child enters kindergarten, he or she should have developed a useful set of social skills that will help him or her have successful experiences in the school setting as well as in life in general. These skills include cooperation, sharing (of things and feelings), kindness, generosity, affection display, conversation, expression of feelings, helping others, and making friends.

Preschoolers tend to have strong emotions. They can be very excited, happy, and giddy in one moment, then extremely disappointed in the next. The preschool child has a vivid imagination, and fears are very real to preschoolers. Most children this age have learned to control their behaviors. They should be able to name the feelings they are having rather than acting on them. Strong feelings may be expressed through outlets such as clay or Play-Doh, water play, drawing or painting, or through dramatic play such as with puppets.

Preschoolers are developing a sense of identity. They recognize that they are boys or girls. They know that they belong to a particular family, community, or culture.

TABLE 27.3 COMMUNICATION SKILLS IN THE PRESCHOOL CHILD

Age	Communication Abilities
4 years	• Speaks in complete sentences using adult-like grammar • Tells a story that is easy to follow • 75% of speech understood by others outside of family • Asks questions with "who," "how," "how many" • Stays on topic in a conversation • Understands the concepts of "same" and "different" • Asks many questions • Knows names of familiar animals • Names common objects in books and magazines • Knows at least one color • Uses language to engage in make-believe • Follows a three-part command • Can count a few numbers • Vocabulary of 1,500 words
5 years	• Persons outside of the family can understand most of the child's speech • Explains how an item is used • Participates in long, detailed conversations • Talks about past, future, and imaginary events • Answers questions that use "why" and "when" • Can count to 10 • Recalls part of a story • Speech should be completely intelligible, even if the child has articulation difficulties • Speech is generally grammatically correct • Vocabulary of 2,100 words • Says name and address

They take pride in using self-control rather than giving in to their impulses. The preschool child is capable of helping others and being involved in routines and transitions.

Parents can encourage and assist preschool children with developing the social and emotional skills that will be needed when the child enters school. Preschool children thrive on one-to-one communication with a parent. During interactive communication, children learn to express their feelings and ideas. Interactive communication fosters not only emotional and moral development but also self-esteem and cognitive development. Asking the preschool child questions requires the child to think out his or her own intention or motivation and encourages vocabulary development. Parents may use individual communication as a time to explore right and wrong, thus further contributing to moral development. Being listened to while answering parents' questions gives preschoolers a sense that they are valued, that what they think and have to say matters.

Establishing a few simple rules and enforcing them consistently gives preschoolers the structure and security they need while promoting moral development. Parents or caregivers can help the child give a name to the emotion that is being experienced. Fears are very real to preschoolers because of their active imaginations and may result in a variety of emotions. Parents should validate the feeling or emotion, then discuss with the child alternatives for dealing with the emotion.

Preschoolers are developing their sense of identity, and parents should encourage preschoolers to do simple things for themselves, like dressing and washing their hands and face (Fig. 27.6). Parents should give the child the time he or she needs to complete the task. This helps to establish a sense of accomplishment.

At this age, the child may begin to show an interest in basic sexuality. The preschooler may want to know why boys' and girls' bodies are different, how the reproductive organs function, and where babies come from. The parent should answer the child honestly and directly, using the correct anatomic terms. Long explanations are not necessary, just simple answers. This curiosity is a normal function of the preschool years, and the curiosity may also involve playing with the genitals (see the section on masturbation later in this chapter).

Friendships

Preschoolers need interactions with friends as well. Learning how to make and keep a friend is an important part of social development. Friends may be other children in the neighborhood or those at preschool or day care. A special

FIGURE 27.6 Encouraging the preschooler to complete simple tasks by himself or herself helps to build self-esteem.

friend is someone the preschooler can care about, talk to, and play with (Fig. 27.7). The preschooler is more likely to agree to rules and wants to please friends and be like them. The preschooler loves to sing, dance, and act and will enjoy these activities with friends. Disagreements may occur, but the parent can encourage the children to express their views, discuss and resolve conflicts, and continue being friends.

FIGURE 27.7 The preschool child begins to develop friendships.

Temperament

By the time children are 3 years old, they recognize that what they do actually matters. It is helpful for the parent to view the child as an active participant in the parent–child relationship. The child's temperament has become a reliable indicator of how a parent might expect the child to react in a certain situation. When the parent is in tune with the preschooler's temperament, it is easier to find ways to ease transitions and changes for that child. In the area of task orientation, temperament may range from the highly attentive and persistent to the more distractible and active.

A child's social flexibility is also evident by this age. A child who is quite adaptable will handle stimuli from the outside world in an approaching rather than a withdrawing manner. Temperament also determines the extent of reactivity (the child's sensory threshold of responsiveness, high versus low). This determines the quality of the child's mood and the intensity of reactions to stimuli, change, or situations. When the parents are familiar with the child's task orientation, social flexibility, and reactivity, they can better structure activities and situations for the child.

The 4-year-old is better at learning self-control and can use setbacks in appropriate behavior as opportunities for growth. Temper tantrums should ease off by this age as the child's language skills are more capable of keeping up with complex ideas. The 4-year-old is able to see the rewards of growing up. This awareness of self-power may, however, lead to additional fears. The 5-year-old who has a more vulnerable type of temperament, as opposed to a confident temperament, may be more apt to experience fears.

Fears

With their vivid imaginations, preschoolers experience a variety of fears. Preschoolers may be scared of loud noises such as fire engine sirens or barking dogs. Imaginary monsters may scare the child. Preschoolers are often afraid of people they do not know as well as strange people (Santa Claus or people who look or dress very differently from what they are accustomed to). Many preschoolers are afraid of the dark. Preschoolers may also fear insects as well as animals they are not familiar with. The preschooler's memory is long enough that he or she may fear returning to the doctor's office when a painful procedure occurred during the prior visit.

Parents should acknowledge fears rather than minimizing them. They can then collaborate with the child on strategies for dealing with the fear.

CULTURAL INFLUENCES ON GROWTH AND DEVELOPMENT

Children may learn prejudice or bias at home before entering school or day care. The ways that families view other

races or cultures may be subtly or overtly demonstrated in routine daily activities. The preschool child is developing a conscience, so attitudes of tolerance or bias may influence the child's values. As in the toddler period, the value that the family places on independence will affect the child's development of a healthy self-concept.

Some cultures value reading and education more than others. If reading is not valued in the home, the preschool child's first experience with books may not occur until he or she is in school.

Food served in the home is often very specific to the family's ethnic background. As the preschool child is exposed to persons of other cultures in school, he may or may not like the food that is served. Exploring customs or cultural practices that the family participates in is important so that these practices may be safely incorporated into the child's plan of care.

Refer back to Nila, who was introduced in the beginning of the chapter. What developmental milestones would you expect Nila to have reached at this age? Nila's mother expresses concerns about her child's imaginary friend, Sasha. How would you respond?

The Nurse's Role in Preschool Growth and Development

WATCH & LEARN

Growth and development in the preschool child remains orderly and sequential. Some preschoolers grow faster than others or reach various developmental milestones sooner than others. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess preschool children appropriately and provide guidance to their families. The changes that the preschool child is experiencing affect not only the child but also the family. Health care visits throughout the preschool period continue to focus on expected growth and development and anticipatory guidance. An additional concern is the preparation for school entry (school readiness).

If the preschooler is hospitalized, growth and development may be altered. Hospitalization hinders the preschool child's ability to explore the environment and engage in make-believe play and thus presents a challenge for the curious and inquisitive child. If the child must be isolated for a contagious illness, the opportunities for exploration and experimentation are further restricted. In addition, a sick preschooler may feel a sense of guilt, worrying that maybe he or she caused the illness by negative thoughts or behaviors.

When caring for the hospitalized preschooler, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the preschooler.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the preschool child's growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Planning nursing care for the preschool child with growth and development issues should take into account the preschooler's and family's individual needs. The nursing care plan may be used as a guide in planning nursing care for the preschooler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the following plan and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be an inclusive growth and development plan.

PROMOTING HEALTHY GROWTH AND DEVELOPMENT

The building of self-esteem continues throughout the preschool period. It is of particular importance during these years, as the preschooler's developmental task is focused on the development of initiative rather than guilt. A sense of guilt will contribute to low self-esteem, whereas a child who is rewarded for his or her initiative will have increased self-confidence. The parent who provides a loving and nurturing environment for the preschooler builds upon the earlier foundation.

Routine and ritual continue to be important throughout the preschool years, as they help the child to develop a sense of time as well as provide the structure for the child to feel safe and secure. Daily routine continues to assist with the development of conscience in the preschooler. As in toddlerhood, making expectations known through everyday routines helps to avoid confrontations. The preschooler is developing the maturity to know how to behave in various situations and is capable of learning manners.

(text continues on page 840)

Nursing Care Plan 27.1

GROWTH AND DEVELOPMENT ISSUES IN THE PRESCHOOL CHILD

NURSING DIAGNOSIS: Risk for injury related to developmental age, environment, and motor vehicle travel

Outcome Identification and Evaluation

Child's safety will be maintained: *Child will remain free from injury.*

Interventions: Preventing Injury

- Teach and encourage appropriate use of forward-facing car seat or booster seat if greater than 40 pounds *to decrease risk of injury related to motor vehicles.*
- Teach preschoolers to stay away from street and to cross the street only when holding the hand of an adult *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Teach the preschooler appropriate safety rules in the home (avoiding electric outlets, etc.): *the preschooler is able to follow simple directions and carry out directives. Limits help him or her to organize the environment.*
- Post poison control center phone number *(in case of accidental ingestion; the preschool child is very curious).*
- Never leave a preschool child unattended in a tub or pool or near any body of water *to prevent drowning.*
- Provide swimming lessons for children age 4 or 5 *to encourage water safety, but not as a replacement for adult supervision.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on bed in hospital *because the preschool child continues to be at risk for falling or injuring self on equipment or tubing (because of curiosity).*

NURSING DIAGNOSIS: Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

Outcome Identification and Evaluation

Child will consume adequate nutrients: *Child will demonstrate weight gain and increases in height.*

Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine if the preschooler is unable to drink from a cup or does not finger feed or use utensils properly, or if the child has difficulty swallowing or tolerating certain textures of foods *to determine if further interventions such as speech or occupational therapy are required.*
- Weigh child daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Limit juice to 4 to 6 ounces per day, milk to 16 to 24 ounces per day, *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for appropriate solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed child on a similar schedule daily, without distractions and with the family: *preschool children continue to respond well to routine and structure. They are more interested in the social context of meals and are still apt to become distracted easily, so the TV should be off at mealtimes.*

Nursing Care Plan 27.1 (continued)

NURSING DIAGNOSIS: Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be enhanced: *Child will make continued progress toward realization of expected developmental milestones.*

Interventions: Enhancing Growth and Development

- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of preschoolers with developmental delay *(progress in achieving developmental milestones can be slow and ongoing motivation is needed).*
- Reinforce positive attributes in the child *to maintain motivation.*
- Model age-appropriate communication skills *to illustrate suitable means for parenting the preschooler.*

NURSING DIAGNOSIS: Risk for disproportionate growth related to excess milk or juice intake, consumption of inappropriate foods or in excess amounts

Outcome Identification and Evaluation

Child will grow appropriately and not become overweight or obese: *Child will achieve weight and height within the 5th to 85th percentiles on standardized growth charts.*

Interventions:

- Discourage use of no-spill sippy cups *(they contribute to dental caries and allow unlimited access to fluids, possibly decreasing appetite for appropriate solid foods).*
- Provide juice (4–6 ounces per day) and milk (16–24 ounces per day) from a cup at meal and snack time and water in between *to avoid having the child drink excessive juice or milk.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the preschooler is a picky eater, it is inappropriate to provide high-calorie junk food just so the child eats something.*
- Teach parents to role model appropriate eating (nutrient-rich, varied diet) *to encourage child to try/accept new foods, as well as become familiar with a variety of food.*
- Severely limit the intake of fast foods and foods with high sugar and fat content *to decrease intake of nutrient-poor, high-calorie foods.*
- Ensure adequate physical activity *to stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming lifelong habit of appropriate physical activity.*
- Teach parents to limit television viewing to 1 to 2 hours per day *to encourage participation in physical activities.*

NURSING DIAGNOSIS: Interrupted family processes related to issues with preschool child's development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the preschool child

Outcome Identification and Evaluation

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

Interventions: Enhancing Family Functioning

- Assess the family's level of stress and ability to cope *to determine family's ability to cope with multiple stressors.*
- Engage in family-centered care *to provide a holistic approach to care of the preschooler and family.*
- Encourage the family to verbalize feelings *(verbalization is one method of decreasing anxiety levels)* and acknowledge feelings and emotions.
- Use puppets or dramatic play with the child *to elicit the preschooler's feelings about the current situation.*
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the preschooler; *this contributes to family's sense of control in situation.*
- Involve family members in preschooler's care, *giving them a feeling of control and connectedness.*

(continued)

Nursing Care Plan 27.1 (continued)

NURSING DIAGNOSIS: Readiness for enhanced parenting related to parental desire for increased skill level and success with preschool child as evidenced by current healthy relationships and verbalization of desire for improved skills

Outcome Identification and Evaluation

Parent will provide safe and nurturing environment for the preschool child: *Parents will verbalize new skills they will employ in the family.*

Interventions: Increasing Parenting Skill Set

- Use family-centered care *to provide holistic approach.*
- Educate parent about normal preschool development *to provide basis of understanding for parenting skills needed in this time period.*
- Acknowledge and encourage parents' verbalization of feelings related to chronic illness of child or difficulty with normal preschool behavior; *this validates the normalcy of parents' feelings.*
- Encourage positive parenting and respect for preschooler and his/her normal development *(helps parents develop approaches to preschoolers that can be used in place of anger and frustration).*
- Acknowledge and admire positive parenting skills already present *to contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the child *(role modeling actually demonstrates rather than just verbalizes what the parent should strive for).*

Setting limits (and remaining consistent with those limits) continues to be important in the preschool period. Consistent limits provide the preschooler with expectation and guidance. As the preschooler increasingly participates in fantasy and imagination, the limits of routine and structure help guide his or her behavior and ability to distinguish reality.

Nurses caring for preschoolers should have knowledge of normal developmental expectations so they can determine whether the preschool child is progressing appropriately. Table 27.4 lists potential signs of developmental delay. A preschool child with one or more of these concerns should be referred for further developmental evaluation.

Promoting Growth and Development Through Play

Providing sincere encouragement for the preschool child's efforts and accomplishments helps him or her develop a sense of initiative. Giving children opportunities to decide how and with whom they want to play also helps them develop initiative. Preschool children like to write, color, draw, paint with a brush or their fingers, and trace or copy patterns (Fig. 27.8). They may start small collections that may be sorted. They like using toys for their intended purpose as well as for whatever invented purpose they can imagine.

Preschoolers begin to play cooperatively with one another. Play may be focused around a distinct theme. They define roles, make up rules, and assign jobs. They are able to work together toward a common goal such as building a house or fort with discarded boxes. Cooperative play encourages the preschool child to learn to share, take turns and compromise, listen to others' opinions, consider the feelings of others, and use self-control and overcome fears.

Preschoolers have incredible imaginations and love to play "make-believe" (Fig. 27.9). Encouraging pretend play and providing props for dress-up stimulates curiosity and creativity. Fantasy play is usually cooperative in nature. It encourages the preschooler to develop social skills such as taking turns, communication, paying attention, and responding to one another's words and actions. Fantasy play also allows preschoolers to explore complex social ideas such as power, compassion, and cruelty. Through role playing, children begin to develop their sexual identity as well.

Since preschool children have vivid imaginations, it is important to be careful about what television they watch. The preschooler should be limited to 1 to 2 hours per day of quality television. The violence in some television programs may scare the preschool child or inspire him or her to act out violent behavior.

Most preschoolers also engage in dramatic play, fueled by their innate curiosity and vivid imaginations. Three-year-olds may not realize that they are pretending. They run from scary creatures, make plans, and pack their backpacks (never intending to actually leave). Four-year-olds are more sophisticated with dramatic or pretend play: they know they are pretending, and they use dress-up clothes and props to act out more complex roles and scenarios (Fig. 27.10). Five-year-olds are capable of quite complex scenarios. They pretend they are real or fantasy characters.

TABLE 27.4 SIGNS OF DEVELOPMENTAL DELAY

Age	Concern
4 years	• Cannot jump in place or ride a tricycle • Cannot stack four blocks • Cannot throw ball overhand • Does not grasp crayon with thumb and fingers • Difficulty with scribbling • Cannot copy a circle • Does not use sentences with three or more words • Cannot use the words "me" and "you" appropriately • Ignores other children or does not show interest in interactive games • Will not respond to people outside the family; still clings or cries if parents leave • Resists using toilet, dressing, sleeping • Does not engage in fantasy play
By 5 years	• Unhappy or sad often • Little interest in playing with other children • Unable to separate from parent without major protest • Is extremely aggressive • Is extremely fearful or timid, or unusually passive • Cannot build tower of six to eight blocks • Easily distracted; cannot concentrate on single activity for 5 minutes • Rarely engages in fantasy play • Trouble with eating, sleeping, or using the toilet • Cannot use plurals or past tense • Cannot brush teeth, wash and dry hands, or undress efficiently

They often use dramatic play to express anxiety, try out negative feelings, or conquer their fears. For example, a child who is afraid of getting a shot at the doctor's office may work through that feeling with pretend play.

Parents should encourage physical activity in the preschool child. Regular physical activity improves gross motor skills, may enhance the child's self-confidence, and allows the child to expend excess energy. Establishing the habit of daily physical activity in the early years is important in the long-term goal of avoiding obesity. The main goal of organized sports at this age should be fun and enjoyment, although of course safety must remain a priority.

Beware of sophisticated toys that claim to teach the young child. These toys are often very expensive and are not necessary. Box 27.1 lists appropriate playthings for the preschool child.

FIGURE 27.8 The preschool child loves to create things, so coloring and molding clay are ideal activities for children this age.

FIGURE 27.9 Preschool children enjoy imitative play.

Promoting Early Learning

The family is the foundation for the child's early growth and development. Parents serve as role models for behavior related to education and learning, as well as instilling values in their children. School readiness is a topic that has received a significant amount of national attention in recent years. To succeed in school, children need a safe, responsive home environment that allows them to learn and explore, as well as structure and limits that allow them to learn the socially acceptable behaviors that they will need in school. Language development is critical to the ability to succeed in school and can be encouraged through books and reading. Each of these components is important in readying the child for education in a more formal setting. Promoting language development, choosing a preschool, and making the transition to kindergarten are discussed in more detail below.

FIGURE 27.10 Preschool children love to dress up and pretend.

BOX 27.1 Appropriate Toys for Preschoolers

- Blocks, simple jigsaw puzzles (four to six large pieces), pegboards, wooden bead with string
- Supplies for creativity: chalk, large crayons, finger paint, Play-Doh or clay, washable markers, paper, paint and paintbrush, scissors, paste, or glue
- Puppets, dress-up clothes and props for dramatic play
- Bucket, plastic shovel and other containers for sand and water play
- Play kitchen with accessories and pretend food (empty food boxes can be recycled for kitchen play)
- Squeaking, floating, squirting toys for the bath
- Sandbox with shovel and various toys for building
- Dolls that can be dressed and undressed (large buttons, zippers, and snaps), doll care accessories (diapers, bottles, carriage, crib)
- Gross motor toys: tricycle or big wheel (with helmet), jungle gym or swing set (with supervision), hula hoop, tunnel, wagon
- Blocks, Legos, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), stuffed animals, balls, sewing cards
- Tape or CD players for music, various musical instruments
- Simple card and board games (older preschooler)
- Dollhouse with furniture and accessories, people and animals

Promoting Language Development

The parent serves as the child's first teacher. The interactions between parent and child in relation to books and other play activities model the types of interactions that the child will later have in school. Asking open-ended questions stimulates the development of thinking as well as language in the preschool child. The preschooler is a great imitator, so the parent should serve as a role model for appropriate language. Parents should avoid swearing, as the child is sure to repeat "bad words" even if he or she does not understand what they mean. Allowing children to pursue interests at their own pace will help them to develop the literacy and numeric skills that will enable them to later focus on academic skills.

Preschoolers enjoy books with pictures that tell stories (Fig. 27.11). Stories with repeated phrases help to keep the child's attention. Children like stories that describe experiences similar to their own. The preschool child demonstrates early literacy skills by reciting stories or portions of books. He or she also may retell the story from the book, pretend to read books, and ask questions about the story. The preschool child has enough focus and expanded atten-

FIGURE 27.11 Preschool children enjoy being read to and looking at the pictures that go along with the story.

tion to notice when a page is skipped during reading and will call it to the parent's attention.

▶ ***Take NOTE!***

Risk factors for lack of social and emotional readiness for school include insecure attachment in the early years, maternal depression, parental substance abuse, and low socioeconomic status. Nurses should screen for these factors and make referrals if appropriate.

Choosing a Preschool/Starting Kindergarten

Many parents choose to enroll their child in preschool. Preschool should be used primarily as an opportunity to foster the child's social skills and accustom him or her to the group environment. When selecting a preschool the parent may want to consider the accreditation of the school, the teachers' qualifications, and recommendations of other parents. The focus of the school environment is also important: What is the daily schedule of activities? Is the school very structured, or does it have a looser environment? The parents must decide how focused on curriculum they want the school to be. The parent should observe the classroom, evaluating the environment, noise level, and sanitary practices as well as how the children interact with each other and how the teachers interact with the children.

The type of discipline used in the school is also an important factor. Parents should not choose a preschool that uses corporal punishment. The American Academy of Pediatrics discourages the use of corporal punishment in the school setting. Corporal punishment may hurt a child's self-esteem as well as his or her ability to achieve in school. It may also lead to disruptive and violent behavior in the classroom. As preschool is the foundation for later education, the child should have the opportunity to build self-esteem and the skills needed for the more formal setting of elementary school.

Whether or not the child attended preschool, kindergarten will be the next big step. Kindergarten hours may be longer than preschool hours, and kindergarten is usually held 5 days per week. This may be a significant change for some children. For most children, the setting and personnel in kindergarten will be new to the child. Rules and expectations are often very different as well. When discussing starting kindergarten with the preschool child, parents should do so in an enthusiastic fashion, keeping the conversation light and positive. Parents should meet with the child's teacher prior to the start of school, if possible, to discuss particular needs or concerns. Parents may want to schedule a tour of the school for the preschooler or attend the school's open house with the child to ease the transition. Practicing the new daily routine prior to the start of school will also be helpful.

Most states require up-to-date immunizations and a health screening of the child before he or she enters kindergarten, so advise parents to plan ahead and schedule these in a timely fashion so that school entrance is not delayed.

Promoting Safety

In the United States, accidental injury remains the leading cause of death for children between the ages of 1 and 14 years. Preschoolers are at an ideal age to be taught about safety and safe behaviors. They are cognitively able to absorb concrete information and they desire to master the situations they are in, but they continue to display poor judgment related to safety issues. Their engagement in fantasy is so strong that it makes it difficult for them to master complicated cause-and-effect relationships. The preschool child is capable of learning safe behaviors but may not always be able to transfer those behaviors to a different situation. Parents must continue to closely supervise preschool children to avoid accidental injury during this period.

Safety in the Car

The young preschooler who weighs less than 40 pounds should use a forward-facing car seat with harness and top tether. The preschooler who weighs between 40 and 80 pounds should ride in a booster seat that uses both the lap and shoulder belts (Fig. 27.12). When the child is large enough to sit up straight with the knees bent at the front edge of the seat, he or she may sit directly on the seat of the car with the lap/shoulder belt securely and appropriately

FIGURE 27.12 The preschool child who weighs more than 40 pounds should be appropriately secured in an approved booster seat.

attached. The lap belt should sit low over the hips and upper thighs and the shoulder belt should stay on the shoulder and close to the chest. The back seat of the car is always the safest place for a child to ride. If a child under 12 years of age must sit in the front seat because there are not enough rear seats available, then the front passenger seat air bag should be deactivated. Children should never ride in the cargo area of a pickup truck. See Healthy People 2010 (see Evidence-Based Practice 27.1).

▶ *Take* NOTE!

Although motor vehicle accidents remain a major cause of injury and death in the preschool age group, many families do not use appropriate car seat/seat belt safety with their children. Child passenger safety technicians are available to provide proper installation of car seats. To find one in your area, visit www.nhtsa.dot.gov/people/injury/childps/contacts or www.seatcheck.org. The NHTSA Auto Safety Hot Line may be reached at (888) 327-4236.

Safety in the Home

Handguns, matches, bodies of water, bicycle riding, and poisons continue to be sources of potential injury during the preschool years. The majority of injuries in the preschool years result from motor vehicle accidents, with a significant number of injuries also occurring in or around the home. Bike riders struck by motor vehicles and burns account for a significant percentage of deaths in the preschool age group (Dowd et al., 2002).

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase use of child restraints.	• Encourage car seat and booster seat use until the child is of the appropriate size and age to progress to seat belts.

Preventing Exposure to Tobacco Smoke

Parents should protect their preschoolers from secondhand tobacco smoke. Exposure to tobacco smoke is associated with an increased incidence of otitis media and respiratory infections, as well as increased symptoms and medication use in children with asthma. Other effects include decreased lung function and behavioral difficulties. The preschool child should never be in an enclosed space (such as a car) where tobacco smoke is present.

Preventing Injury

The preschool child who runs out into the street is at risk for being struck by a car. Teach preschoolers to stop at the curb and never go into the street without a grown-up. The preschooler may learn to ride a bicycle (with or without training wheels). The child must wear an approved bicycle helmet any time he or she rides the bicycle, even if it is just in the driveway. Requiring helmet use in the early years will lead to the habit of helmet use as the child gets older. Allowing the preschooler to choose his or her own helmet may encourage the child to use the helmet.

Bicycles should be safe for this age group. The size must be correct; the balls of the feet should reach both pedals while the child is sitting on the seat and has both hands on the handlebars. Children under 5 years of age have difficulty learning to use hand-operated brakes, so traditional pedal-back brakes are recommended in this age group. Preschoolers are not mature enough to ride a bicycle in the street even if they are riding with adults, so they should always ride on the sidewalk.

It is important to make the inside of the home safe for the preschool child. Parents should install and maintain smoke alarms in the home. Increased physical dexterity and refinement of motor skills enable the preschooler to strike matches or use a lighter and start a fire. The preschool child is capable of washing his or her hands independently, so the water heater should be set at 120°F or below to prevent scalding.

The preschooler's active imagination and desire to play make-believe may result in a firearm injury. The average preschooler is physically capable of handling and firing a gun, particularly a handgun, which is smaller and lighter. If present in the home, firearms should be kept in a locked cabinet with the ammunition stored elsewhere.

Preventing Poisoning

Though it is continuing to develop, preschoolers still have unrefined taste discrimination, placing them at risk for accidental ingestion. Parents should never try to coax a child to take a vitamin supplement, tablet, or pill by calling

EVIDENCE-BASED PRACTICE 27.1
Interventions Directed Toward Acquiring and Using Booster Seats for Children 4 to 8 Years Old

● Study
Children outgrow toddler car seats around the age of 4 years or when they weigh 40 pounds. Regular seat belts do not fit children properly. The purpose of booster seats for the 4- to 8-year-old child is to raise him or her higher on the seat of the car, in order for the adult seat belt to secure the child properly. Booster seats provide increased comfort and safety for this age group. Booster seat use in this age group has been shown to decrease injury and death via motor vehicle accident by nearly 60%. The authors reviewed five studies involving 3,070 subjects and performed a meta-analysis of the study results. Each of the randomized controlled trials reviewed assessed the efficacy of interventions directed toward increasing booster seat use.

▲ Findings
The authors' meta-analysis of the studies revealed that interventions directed toward improving booster seat use can make a difference. Enforcement of booster seat law was the weakest intervention. More successful interventions all included education of parents about the importance and appropriate use of booster seats. Providing a free booster seat upon completion of the training or an incentive coupon to receive a discount upon purchase were the most helpful interventions.

■ Nursing Implications
Parents want to protect their children from injury when riding in motor vehicles, but many may lack the knowledge or financial resources to do so. Nurses are in a unique position to provide ongoing, repeated education about the importance of booster seat use for the preschooler to families wherever they encounter them. Nurses can also seek out resources in their individual communities to provide financial incentives to assist families with obtaining a booster seat. Nurses should always praise preschoolers for complying with booster seat use while riding in vehicles.

Ehiri, J. E., Ejere, H. O. D., Magnussen, L., Emusu, D., King, W., & Osberg, J. S. (2007). Interventions for promoting booster seat use in four to eight year olds traveling in motor vehicles. *The Cochrane Library 2007, 4.*

it "candy." Dangerous fluids should be stored in their original containers and should be kept out of reach of preschoolers; they should not be poured into containers that look like ordinary drinking glasses or cups. Potentially dangerous cleaning or personal health and beauty products, gardening and pool chemicals, as well as automotive materials should be kept out of reach of preschoolers and in a locked cabinet if possible. Medications should have childproof caps and should be kept in a locked cabinet. The poison control telephone number should be posted on or near the home phone (1-800-222-1222).

Safety in the Water
Five years of age is an appropriate time for a child to learn to swim. Children at this age are physically capable of this activity and have the cognitive maturity to accomplish the task of swimming and basic water safety. Swimming programs should focus on appropriate swim techniques as well as safety measures. Parents and caregivers should be trained in infant/child CPR. Homes with swimming pools should have lifesaving devices readily accessible. Preschoolers should be taught never to dive into water until an adult has verified its depth. Preschoolers are still too young to be left unattended around any body of water, even if they know how to swim. Preschoolers should never be allowed to swim in a canal or any fast-moving water. Preschoolers who are riding in boats or fishing off riverbanks should wear a personal flotation device. Parents should also be cautioned about close supervision of young children walking, skating, or riding near thin or weak ice. See Healthy People 2010.

▶ *Take* NOTE!

The American Academy of Pediatrics recommends that all swimming pools be secured by a fence that is at least 5 feet high and has a self-latching gate to protect young children from entering a pool area unattended (AAP, 2003).

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce drownings.	• Never leave a young child unattended in or near the water. • Educate families about water safety. • Remind families that the preschooler's ability to swim does not replace the need for constant supervision while in the pool or other body of water.

Recall Nila Patel, the 4-year-old presented at the beginning of the chapter. What anticipatory guidance related to safety should you provide to her parents?

Promoting Nutrition

The preschool child has a full set of primary teeth, is able to chew and swallow competently, and has learned to use utensils fairly effectively to feed himself or herself (Fig. 27.13). As in the toddler years, it is important for the preschool child to continue to learn and build upon healthy eating habits. These habits will last throughout the child's life. A diet high in nutrient-rich foods such as whole grains, vegetables, fruits, appropriate dairy foods, and lean meats is appropriate for the preschooler. Nutrient-poor, high-calorie foods such as sweets and typical fast foods should be offered only in limited amounts.

Nutritional Needs

The 3- to 5-year-old requires 500 to 800 mg calcium and 10 mg iron daily. The 3-year-old should consume 19 mg dietary fiber daily, while the 4- to 8-year-old requires 25 mg dietary fiber per day. Box 27.2 lists good calcium and iron sources. The typical preschooler requires about 85 kcal/kg of body weight. Saturated fats should account for less than 10% of total calories. Preschool children's diets should include a daily total fat intake of no less than 20% and not more than 30% of total calories to promote and maintain healthy cholesterol levels.

▶ *Take* NOTE!

Drinking excess amounts of milk may lead to iron deficiency, as the calcium in milk blocks iron absorption.

FIGURE 27.13 The preschool child has the manual dexterity to handle utensils appropriately and feed himself or herself independently.

BOX 27.2 Daily Calcium and Iron Recommendations for Preschool Children

Calcium: 500 mg (3-year-old), 800 mg (4- to 8-year-old)	Iron: 10 mg
Calcium in foods:	**Iron in foods:**
• 8 oz low-fat or whole milk: 300 mg	• ¾ cup 100% fortified prepared cereal: 18 mg
• 8 oz low-fat yogurt: 300 mg	• ¾ cup 50% fortified prepared cereal: 9 mg
• 1½ oz cheddar cheese: 300 mg	• 3 oz beef: 3 mg
• 1 oz dried white beans (cooked): 160 mg	• 3 oz chicken leg: 3 mg
• ¼ cup tofu: 125 mg	• ½ cup cooked lentils: 3 mg
• 1 medium orange: 50 mg	• 3 oz chicken breast: 2 mg
• ½ cup mashed sweet potatoes: 44 mg	• ¼ cup fresh cooked spinach: 1.6 mg
• ½ cup cooked or 1½ cup raw broccoli: 35 mg	• ¼ cup tofu: 0.9 mg
	• 1 slice enriched bread: 0.8 to 0.9 mg
	• ¼ cup frozen spinach, cooked: 0.7 mg

Promoting Healthy Eating Habits

Preschool children may be picky eaters. They may eat only a limited variety of foods or foods prepared in certain ways and may not be very willing to try new things. The 3- or 4-year-old may exhibit "food fads," eating only certain foods over a several-day period. As the child gets older, pickiness lessens. By 5 years of age the child is more focused on the social context of eating: table conversation and manners. The 5-year-old is generally more willing to at least try new foods and may like to help with meal preparation and clean-up as appropriate.

If the preschooler is growing well, then the pickiness is not a cause for concern. A larger concern may be the negative relationship that can develop between the parent and child relating to mealtime. The more the parent coaxes, cajoles, bribes, and threatens, the less likely the child is to try new foods or even eat the ones he or she likes that are served. The parent must maintain a positive and patient demeanor at mealtime. The child should be offered a healthy diet, with foods from all groups over the course of the day as recommended by the USDA. The "Food Guide Pyramid for Your Young Child" (from the United States Department of Agriculture) may be used to plan the preschool child's daily diet. See Figure 26.9 in Chapter 26, and note the explanation of serving sizes at the bottom of the chart.

The parent should maintain a matter-of-fact approach, offer the meal or snack, and then allow the child to decide

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the proportion of persons aged 2 years and older who meet dietary recommendations for calcium.	• Screen preschoolers for appropriate dietary intake of calcium. • Educate families about calcium content in foods. • Assist families with choosing a diet that meets calcium needs and is appealing to the young child.

how much of the food, if any, he or she is going to eat. High-fat, nutrient-poor snacks should not be substituted for healthy foods just to coax the child to "eat something." See Healthy People 2010.

Preventing the Development of Overweight and Obesity

Worldwide, over 22 million children under 5 years old are obese. In the past 30 years, the number of U.S. children and adolescents who are overweight has doubled. According to the National Health and Nutrition Examination Survey, 21% of all 2- to 5-year-olds are either overweight or at risk of overweight (NAPNAP, 2006a). Overweight and obese children are at risk for hypertension, hyperlipidemia, and the development of insulin resistance. Children whose weight is at or above the 95th percentile when 3 to 6 years old have a 50% chance of being obese as adults (Krebs et al., 2004). The risk is increased if one or both parents are overweight.

Parents are in an opportune position to exert a positive influence on their preschooler's nutritional intake and activity level. The habits learned in early childhood will likely carry over into the school-age, adolescent, and adult years. Children whose parents take an authoritarian approach to mealtime may learn to overeat, as they are encouraged to finish the entire meal ("Clean your plate!"). If they are offered appropriate, healthy food choices and access to high-calorie, nutrient-poor food is limited, preschoolers will learn to self-regulate (eat only until full). Food should not be used as either reward or punishment.

Parents should remain positive and patient at mealtime. Mealtimes should continue to be structured. Unstructured meals lead to an increase in fat and calorie consumption. Increased amount of calories as fat has been linked to a higher body mass index (BMI) in preschool children. To limit the chance that overeating will occur, preschoolers should be offered a variety of healthy foods at each meal. This may include one each of a protein source, grain, vegetable, and fruit. The preschool child's serving size is usually one third to one half of the recommended size of an adult serving. The preschool child may imitate the other eaters at the table. Parents have a prime chance to be good role models, setting an example of eating vegetables and fruits.

As with toddlers, fruit juice should be limited to 4 to 6 ounces per day, as excess consumption can lead to excess weight gain. Preschoolers should be encouraged to drink water.

Limiting television viewing and encouraging physical activity are also important strategies for the prevention of overweight and obesity.

Refer back to Nila Patel, the 4-year-old introduced at the beginning of the chapter. What questions should you ask Nila's parents related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate? Nila's mother expresses concerns regarding obesity. How would you address these?

Promoting Healthy Sleep and Rest

The preschool child needs about 12 hours of sleep each day. Some preschool children continue to take a nap during the day. Unless very tired, many preschool children will resist going to bed from time to time. Bedtime rituals continue to be reassuring to children, and it is important to continue them in the preschool years. Having a time of relaxation with a decrease in stimulation will allow the child to fall asleep more easily. Some children continue to need a security item at bedtime or naptime. A nightlight in the bedroom may be necessary, as many children this age are afraid of the dark. Teaching Guidelines 27.1

TEACHING GUIDELINES 27.1

Bedtime Routines

- Establish a bedtime as well as morning wake-up time, and enforce them consistently.
- Avoid sugar or caffeine consumption in the evening.
- Avoid stimulating activities such as roughhousing before bedtime.
- Do not allow television watching in bed.
- Make the child's bedroom an inviting and comfortable area of the home.
- Provide a nightlight in the child's bedroom if he or she is afraid of the dark.
- Conform to a nightly routine:
  - Television off at a certain time
  - Bath
  - Quiet game or story reading/telling
  - Bedtime prayer or song
- Maintain quiet in the bedroom and nearby to increase the child's ability to fall asleep.

gives information about assisting parents to establish a bedtime routine.

Nightmares often occur in preschool children as a result of the child's struggle to distinguish what is real from what is not. When a child awakens from a nightmare, he or she is often crying and may be able to recount what the dream was about. Parents should validate the child's fear rather than discounting it. Saying, "Yes, I agree, monsters are scary; it's a good thing they aren't real" is more appropriate than, "Don't be silly: monsters aren't real." Sometimes children benefit from reading stories about dreams. Recommended books include:

- *Bedtime for Frances* by Russell Hoban
- *Ben's Dream* by Chris van Allsberg
- *In the Night Kitchen* by Maurice Sendak
- *There's a Nightmare in My Closet* by Mercer Mayer

Nightmares should not be confused with night terrors. After a nightmare, the child is aroused and interactive, but night terrors are different: a short time after falling asleep, the child seems to awaken and is screaming. The child usually does not respond much to the parent's soothing, but he or she eventually stops screaming and goes back to sleep. Night terrors are often frightening for parents because the child does not seem to be responding to them. One technique that may help to decrease the incidence of night terrors is to wake the child about 30 to 45 minutes into the sleep cycle. If continued nightly for about a week, the cycle of night terrors may be broken. See Comparison Chart 27.1.

Think back to Nila Patel. What anticipatory guidance would you provide to her parents in relation to sleep during the preschool years?

Promoting Healthy Teeth and Gums

Dental caries prevention continues to be important and can be achieved through daily brushing and flossing. Parents should use only a pea-sized amount of toothpaste to prevent excess fluoride consumption, which can contribute to fluorosis. The preschooler may brush his or her own teeth, but the parent must continue to supervise to ensure adequate brushing. Parents must perform flossing because the preschool child cannot perform this task adequately.

Cariogenic foods should be avoided. If sugary foods are consumed, the mouth should be rinsed with water if it is not possible to brush the teeth immediately. The preschool child should visit the dentist every 6 months.

▶ *Take* NOTE!

Dental caries prevention is important in the primary teeth, because loss of these teeth to caries may affect the proper formation of permanent teeth as well as the width of the dental arch.

Promoting Appropriate Discipline

Successful discipline results from a loving and nurturing environment in which the preschooler's self-esteem is fostered and where limits are well chosen and enforced consistently. Spanking (striking with the open hand) is the least effective discipline practice and is discouraged by the American Academy of Pediatrics and the National Association of Pediatric Nurse Practitioners. Belts, switches, paddles, or other items should never be used to strike a

COMPARISON CHART 27.1 NIGHTMARES VERSUS NIGHT TERRORS

	Nightmare	Night Terror
Definition	Scary or bad dream followed by awakening	Partial arousal from deep sleep
When parents become aware	Child awakens parent after episode is over	Screaming and thrashing during the episode awakens the parent
Timing	Usually in the second half of the night	Usually about an hour after falling asleep
Behavior	Crying, may be scared after awakening	Sits up, thrashes, cries, screams, talks, looks wild-eyed. Sweats, may have racing heartbeat.
Responsiveness	Responsive to parent's soothing and reassurances	Child unaware of parent's presence, may scream and thrash more if restrained
Return to sleep	Difficulty going back to sleep if afraid	Rapidly returns to sleep without full awakening
Memory of occurrence	May remember the dream and talk about it later	No memory of event

Information from Ferber, R. (2006). *Solve your child's sleep problems*. New York: Fireside.

child. The use of physical punishment has been associated with a number of additional problems in adulthood, such as antisocial and criminal behaviors (see Chapter 26).

If parents are consistent with discipline while encouraging the preschooler's normal growth and development of imagination and make-believe, the child will learn to accept that certain things are not allowed. The sense of initiative can be preserved and guilt avoided if the rules are clear and enforced consistently.

▶ *Take* NOTE!

The more frequently children are hit in the preschool years, the more anger they report as adults (AAP, 2004a).

Minimize the occurrence of misbehavior by anticipating conditions likely to lead to the undesired or risky action. When the situation becomes difficult, parents should use distraction to changes the preschooler's focus. When discussing the misbehavior, be certain to label the behavior and not the child. This helps to preserve the preschooler's self-esteem. When teaching preschoolers about undesired behavior, be sure they also understand the reason why it is wrong or unacceptable to do it. This helps to encourage the child to use internal controls over behavior. Parents should serve as role models for self-control, including choice of words, the tone they are delivered in, and the actions that accompany them.

Children work harder to obtain praise than to receive punishment, so always reward positive behaviors. Preschool children are becoming capable of understanding the concept of right and wrong. They start to understand each other's feelings (**empathy**) and are cognitively capable of remembering basic rules.

Time-out or time away from the situation can be very effective in this age group. The punishment should be used only for intentional misbehavior (knowing something is forbidden but doing it anyway). It is particularly helpful with dangerous or destructive behavior. The preschooler is given a warning that time-out will occur if the behavior does not stop. The preschooler is removed from the situation and must stay in time-out for a specified period of time. A particular time-out area is helpful; a boring corner of the room without distractions available is a good location. The generally recommended period of time is to require 1 minute of time-out per year of age; thus, a 4-year-old would be in time-out for 4 minutes. Set the timer so the child will know when the time-out is over. If the child gets up before the prescribed time, replace the child in time-out and restart the timer. Time-out works best if used each and every time the undesirable behavior occurs. Also, praise the child when he or she follows the rules and behaves appropriately.

A simple and clear explanation of the misbehavior should be given to the child; parents should also talk about acceptable alternative strategies that the child can use in the future instead of the undesired behavior. Removal of a privilege such as playing with a favorite toy can be as effective as time-out.

Books and other media that are available to help educate parents about appropriate discipline and to help the child learn self-control are listed in Box 27.3.

BOX 27.3 Selected Resources for Parent and Preschoolers

Books for Parents (about discipline)

- *How to Talk so Kids will Listen and Listen so Kids will Talk* by A. Faber & E. Mazlish (Harper Resource)
- *Kids are Worth It: Giving Your Children the Gift of Inner Discipline* by B. Colorosos (Harper Collins Publishers)
- *Positive Discipline A to Z: 1001 Solutions to Everyday Parenting Problems* by J. Nelson, L. Lott, & S. G. Glenn (Three Rivers Press)
- *Setting Limits with Your Strong-willed Child: Eliminating Conflict by Establishing Clear, Firm and Respectful Boundaries* by R. MacKenzie (Three Rivers Press)
- *The Case Against Spanking: How to Discipline Children without Hitting* by I. A. Hyman (Jossey-Bass)
- *The Nurturing Parent: How to Raise Creative, Loving, Responsible Children* by J. S. Dacey & A. J. Packer (Fireside)
- *Without Spanking or Spoiling: a Practical Approach to Toddler and Preschool Guidance* by E. Crary (Parenting Press)

Books for Preschoolers (about dealing with feelings and learning how to behave):

- *Hands are Not for Hitting* by M. Agassi (Free Spirit Publishing)
- *I Can't Wait* by E. Crary (Parenting Press)
- *I Want It* by E. Crary (Parenting Press)
- *I Want to Play* by E. Crary (Parenting Press)
- *I Was so Mad* by M. Mayer (Golden Books)
- *I Was so Mad* by N. Simon & D. Leder (Albert Whitman & Company)
- *I'm Excited* by E. Crary (Parenting Press)
- *I'm Frustrated* by E. Crary (Parenting Press)
- *I'm Mad* by E. Crary (Parenting Press)
- *I'm Scared* by E. Crary (Parenting Press)
- *Feet are not for Kicking* by E. Verdick (Free Spirit Publishing)
- *Teeth are not for Biting* by E. Verdick (Free Spirit Publishing)
- *When Sophie gets Angry . . . Really, Really Angry* by M. Bang (Blue Sky Press)
- *Words are not for Hurting* by E. Verdick (Free Spirit Publishing)

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

Common developmental concerns of the preschool period include lying, sex education, and masturbation. Parents often express difficulty in dealing with these issues with their preschool children. Offering appropriate anticipatory guidance may give the parents the support and confidence they need to deal with these issues.

Lying

Lying is common in preschool children. It may occur because the child fears punishment, has gotten carried away with imagination, or is imitating what he or she sees the parent do. The parent should ascertain the reason for the lie before punishing the child. If the child has broken a rule and fears punishment, then the parent must determine the truth. The child needs to learn that lying is usually far worse than the misbehavior itself. The punishment for the misbehavior should be lessened if the child admits the truth. The parent should remain calm and serve as a role model of an even temper. The next time the misbehavior occurs, the child will be more apt to simply tell the truth.

If the child's lying is really just his or her imagination getting carried away, then the parent should guide the child in distinguishing between myth and reality. The preschooler's imagination is very vivid, and the child needs direction in the use of that faculty. Parents should serve as role models of appropriate behavior for their children to learn it. Children who lie because they hear their parents do it simply must not see or hear their parents do it.

Sex Education

Preschoolers are keen observers but are still not able to interpret all that they see correctly. The child may recognize, but not understand, sexual activity. Preschoolers are very inquisitive and want to learn about everything around them; therefore, they are very likely to ask questions about sex and where babies come from. Before attempting to answer questions, parents should try to find out first what the child is really asking and what the child already thinks about that subject. Then they should provide a simple, direct, and honest answer. The child needs only the information that he or she is requesting. Additional questions will occur in the future and should be addressed as they arise.

Masturbation

The normal curiosity of the preschool years often leads children to explore their own genitals. This behavior may be upsetting to some parents, but masturbation is a healthy and natural part of normal preschool development if it occurs in moderation. If the parent overreacts to this behavior, then it may occur more frequently. Masturbation should be treated in a matter-of-fact way by the parent. The child needs to learn certain rules about this activity: nudity and masturbation are not acceptable in public. The child should also be taught safety: no other person can touch the private parts unless it is the parent, doctor, or nurse checking to see when something is wrong.

Think back to Nila Patel. What are some developmental concerns that are common during the preschool years? What anticipatory guidance related to these concerns would you provide to Nila's parents?

Key Concepts

- The preschool child grows at a slower rate and takes on a more slender and upright appearance than the toddler.
- The primary psychosocial task of the preschool period is developing a sense of initiative.
- Cognitive development moves from an egocentric approach to the world toward a more empathetic understanding of what happens outside of the self.
- The preschooler gains additional motor skills and displays significant refinement of fine motor abilities.
- Cognitive and language skills that develop in the preschool years help prepare the child for success in school.
- Dysfluency or hesitancy in speech is a normal finding in the preschool period and occurs as a result of the fast pace with which the preschooler is gaining language skills and vocabulary.
- The vocabulary of a preschooler increases to about 2,100 words, and the child speaks in full sentences with appropriate use of tense and prepositions.
- Appropriate growth and development should be maintained in the ill or hospitalized child.
- Recognizing concerns or delays in growth and development is essential so that the appropriate referrals may be made and intervention can begin.
- The preschool child requires a well-balanced diet with fat content between 20 and 30 percent of calories consumed.
- Adequate physical activity and provision of a nutrient-dense diet (rather than foods high in fat and sugar) are the foundation for obesity prevention in the preschool child.
- Adequate dental care is important for the health of the primary teeth.
- Preschoolers need about 12 hours of sleep per day and benefit from a structured bedtime routine.
- Due to the active imagination of the preschooler, nightmares and night terrors may begin during this period.
- Safety and injury prevention remain a focus in the preschool years.
- Structure, appropriate limit setting, and consistency are the keys for effective discipline in the preschool period.

- Time-out is an effective disciplinary measure for preschoolers.
- Masturbation may occur as the preschooler discovers his or her body. If not excessive, it is considered a normal part of growth and development.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a hospitalized 4-year-old who insists on having the nurse perform every assessment and intervention on her imaginary friend first. She then agrees to have the assessment or intervention done to herself. The nurse identifies this preschooler's behavior as:
   a. Problematic; the child is old enough to begin to have a basis in reality.
   b. Normal, because the child is hospitalized and out of her routine.
   c. Normal for this stage of growth and development.
   d. Problematic, as it interferes with needed nursing care.
2. The mother of a 3-year-old is concerned about her child's speech. She describes her preschooler as hesitating at the beginning of sentences and repeating consonant sounds. What is the nurse's best response?
   a. Hesitancy and dysfluency are normal during this period of development.
   b. Reading to the child will help model appropriate speech.
   c. Expressive language concerns warrant a developmental evaluation.
   d. The mother should ask her pediatrician for a speech therapy evaluation.
3. The mother of a 4-year-old asks for advice on using time-out for discipline with her child. What advice should the nurse give the mother?
   a. If spanking is not working, then time-out is not likely to be helpful either.
   b. Place the child in time-out for 4 minutes.
   c. Use time-out only if removing privileges is unsuccessful.
   d. The child should stay in time-out until crying ceases.
4. A 5-year-old child is not gaining weight appropriately. Organic problems have been ruled out. What is the priority action by the nurse?
   a. Allow the child unlimited access to the sippy cup to ensure adequate hydration.
   b. Encourage sweets for the extra caloric content.
   c. Teach the mother about nutritional needs of the preschooler.
   d. Assess the child's usual intake pattern at home.

CRITICAL THINKING EXERCISES

1. Teach a preschool class about bicycle and street safety. Be certain to design the content at an appropriate developmental level.
2. Construct a 3-day menu for a picky 4-year-old. Include three daily meals and two snacks. Follow the nutritional guidelines recommended by the USDA.
3. Color or draw with a preschool child. Analyze the drawings and interactions or discussions you have with the child, relating them to psychosocial and cognitive development expected at this age.

STUDY ACTIVITIES

1. Care for two average 3-, 4-, or 5-year-old children in the clinical setting (make sure both are the same age). Describe each child's development level, response to hospitalization, and family dynamics.
2. Visit a preschool that provides care for special needs children as well as typically developing children. Perform a development assessment on a typical child and one with special needs (both the same age). Compare and contrast your findings.
3. Observe in a 3-, 4- or 5-year-old classroom of a typical preschool. Choose two children who are the same age with different temperaments. Record the differences and similarities in their response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

CHAPTER 28

Growth and Development of the School-Age Child

KEY TERMS

bruxism
caries
industry
inferiority
malocclusion
prepubescence
principle of conservation
school-age child
school refusal
secondary sexual characteristics
self-esteem

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify normal physiologic, cognitive, and moral changes occurring in the school-age child.
2. Describe the role of peers and schools in the development and socialization of the school-age child.
3. Identify the developmental milestones of the school-age child.
4. Identify the role of the nurse in promoting safety for the school-age child.
5. Demonstrate knowledge of the nutritional requirements of the school-age child.
6. Identify common developmental concerns in the school-age child.
7. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

Lawrence Jones is a 10-year-old boy brought to the clinic by his mother for his annual school check-up. During your assessment you measure his weight at 62 pounds and his height at 54 inches. As the nurse caring for him, assess Lawrence's growth and development, and then provide appropriate anticipatory guidance to his mother.

Wow

Always give a hundred percent, and you will never doubt your ability to succeed.

School-age children, between the ages of 6 and 12 years, are experiencing a time of slow progressive physical growth, while their social and developmental growth accelerates and increases in complexity. The focus of their world expands from family to teachers, peers, and other outside influences (e.g., coaches, media). The child at this stage becomes increasingly more independent while participating in activities outside the home.

Growth and Development Overview

The school-age years are a time of continued maturation of the child's physical, social, and psychological characteristics. It is during this time that children move toward abstract thinking and seek approval of peers, teachers, and parents. Their eye–hand–muscle coordination allows them to participate in organized sports in school or the community. The **school-age child** values school attendance and school activities. The nurse uses knowledge of normal growth and development of the school-age child to assist the child with coping with disruptions and changes during this time period.

PHYSICAL GROWTH

From 6 to 12 years of age, children grow an average of 2 inches (5 centimeters) per year, increasing their height by at least 1 foot. An increase of 4 to 6 pounds (2 to 3 kilograms) per year in weight is expected. In the early school-age years, girls and boys are similar in height and weight and appear thinner and more graceful than in previous years. In later school-age years, most girls begin to surpass boys in both height and weight. (See Appendix A for growth charts.)

Preadolescent boys and girls do not want to be different from peers of the same sex or the opposite sex, although there are differences in physical and physiologic growth during the school-age years. These differences, especially **secondary sexual characteristics**, are concerning and often a source of embarrassment for both sexes.

The differences between girls and boys are more apparent at the end of the middle-school years and may become extreme and a source of emotional problems. These differences in height and weight relationships, and changes in growth patterns, should be explained to parents and children (Fig. 28.1). Physical maturity is not necessarily associated with emotional and social maturity. An 8-year-old who is the size of an 11-year-old will think and act like an 8-year-old. Many times, the expectations placed on these children are unrealistic and can impact the self-esteem and competence of the child. This can work in reverse, to similar effect, for an 11-year-old who is the size of an 8-year-old and is therefore treated as such.

ORGAN SYSTEMS MATURATION

Maturation of organs may differ with age or gender. Maturation of organs remains fairly consistent until late school age. In the late school-age years (10- to 12-year-olds), boys experience a slowed growth in height and increased weight gain, which may lead to obesity. During this time,

FIGURE 28.1 The different growth rates of school-age children are depicted by these same-age school-age children.

girls may begin to have changes in the body that soften body lines. Preadolescence is a period of rapid growth, especially for girls.

Neurologic System

The brain and skull grow very slowly during the school-age years. Brain growth is complete by the time the child is 10 years of age. The shape of the head is longer and the growth of the facial bones changes facial proportions.

Respiratory System

The respiratory system continues to mature with the development of the lungs and alveoli, resulting in fewer respiratory infections. Respiratory rates decrease, abdominal breathing disappears, and respirations become diaphragmatic in nature. The frontal sinuses are developed by 7 years of age. Tonsils decrease in size from the preschool years, but they remain larger than adolescents'. The adenoids and tonsils may appear large normally, even in the absence of infection.

Cardiovascular System

The school-age child's blood pressure increases and the pulse rate decreases. The heart grows more slowly during the middle years and is smaller in size in relation to the rest of the body than at any other development stage.

Gastrointestinal System

During the school-age years, all 20 primary deciduous teeth are lost, replaced by 28 of 32 permanent teeth, with the exception of the third molars. The school-age child experiences fewer gastrointestinal upsets compared with earlier years. Stomach capacity increases, which permits retention of food for longer periods of time. In addition, the caloric needs of the school-age child are lower than in the earlier years.

Genitourinary System

Bladder capacity increases, but varies among individual children. Girls generally have a greater bladder capacity than boys. Urination patterns vary with the amount of fluids ingested, the time they were ingested, and the stress level of the child. The formula for bladder capacity is age in years plus 2 ounces. Therefore, the bladder capacity of the 7-year-old would be 9 ounces. The larger capacity of the bladder allows for the child to experience longer periods between voiding.

Prepubescence

The late school-age years are also referred to as *preadolescence* (the time between middle childhood and the 13th birthday). During preadolescence, **prepubescence** occurs. Prepubescence typically occurs in the 2 years before the beginning of puberty and is characterized by the development of secondary sexual characteristics, a period of rapid growth for girls, and a period of continued growth for boys. There is approximately 2 years' difference in the onset of prepubescence between boys and girls. Sexual development in both boys and girls can lead to a negative perception of physical appearance and lowered self-esteem. Early development in girls can lead to embarrassment, concern over physical appearance, and low self-esteem. Delayed development in boys can lead to a negative self-concept, resulting in substance abuse or reckless use of non-automobile vehicles. Early development may lead to risk-taking behaviors in both boys and girls. It is important for the nurse and parents to educate the late school-age child about body changes to decrease anxiety and promote comfort with these body changes.

Musculoskeletal System

Musculoskeletal growth leads to greater coordination and strength, yet the muscles are still immature and can be injured easily. Bones continue to ossify throughout childhood, but mineralization is not complete until maturity.

Immune System

Lymphatic tissues continue to grow until the child is 9 years old; immunoglobulins A and G (IgA and IgG) reach adult levels at around 10 years of age. Due to the lymphatic system becoming more competent in localizing infections and producing antibody–antigen responses, school-age children may have fewer infections. They may experience more infections during the first 1 to 2 years of school due to exposure to other children who may have infections.

PSYCHOSOCIAL DEVELOPMENT

Erikson (1963) describes the task of the school-age years to be a sense of **industry** vs. **inferiority**. During this time, the child is developing his sense of self-worth by becoming involved in multiple activities at home, school, and in the community, which develops his cognitive and social skills. He is very interested in learning how things are made and work. The school-age child's satisfaction from achieving success in developing new skills leads him to an increased sense of self-worth and level of competence. It is the role of the parents, teachers, coaches, and nurses of the school-age child to identify areas of competency and to build on the child's successful experiences to promote mastery, success, and self-esteem. If the expectations of adults are set too high, the child will develop a sense of inferiority and incompetence that can affect all aspects of his life. See Table 28.1 for a further explanation of psychosocial development in school-age children.

TABLE 28.1 DEVELOPMENTAL THEORIES

Theorist	Stage	Activities
Erikson	Industry vs. inferiority	Interested in how things are made and run Success in personal and social tasks Increased activities outside home—clubs, sports Increased interactions with peers Increased interest in knowledge Needs support and encouragement from important people in child's life Needs support when child is not successful Inferiority occurs with repeated failures with little support or trust from those who are important to the child
Piaget	Concrete operational	Learns by manipulating concrete objects Lacks ability to think abstractly Learns that certain characteristics of objects remain constant Understands concepts of time Engages in serial ordering, addition, subtraction Classifies or groups objects by their common elements Understands relationships among objects Starts collections of items Can reverse thought process
Kohlberg	Conventional Stage 3: interpersonal conforming,"good child, bad child" Age 7–10 years Stage 4: "law and order" Age 10–12 years	An act is wrong because it brings punishment Behavior is completely wrong or right Does not understand the reason behind rules If child and adult differ in opinions, the adult is right Can put self in another person's position Begins to exercise the "golden rule" Acts are judged in terms of intention, not just punishment
Freud	Latency	A time of tranquility between the Oedipal phase of early childhood and adolescence—focuses on activities that develop social and cognitive skills Develops social skills in relating to same-sex friends through joining clubs like Brownies, Girl Scouts, Boy Scouts

COGNITIVE DEVELOPMENT

Piaget's stage of cognitive development for the 7- to 11-year-old is the period of concrete operational thoughts. In developing concrete operations, the child is able to assimilate and coordinate information about her world from different dimensions. She is able to see things from another person's point of view and think through an action, anticipating its consequences and the possibility of having to rethink the action. She is able to use stored memories of past experiences to evaluate and interpret present situations. The school-age child also develops the ability to classify or divide things into different sets and to identify their relationships to each other. The school-age child is able to classify members of four generations on a family tree vertically and horizontally, and at the same time see that one person can be a father, son, uncle, and grandson. It is at this time that the school-age child develops an interest in collecting objects. She starts out collecting multiple objects and becomes more selective as she gets older. Also, during concrete operational thinking, the school-age child develops an understanding of the **principle of conservation**—that matter does not change when its form changes. For example, if the child pours a half-cup of water into a short, wide glass and into a tall, thin glass, she still only has a half-cup of water despite the fact that it looks like the tall, thin glass has more (Fig. 28.2). She learns about conserving matter in a sequence ranging from the simplest to the more complex. See Table 28.1 for further information about cognitive development of school-age children.

MORAL AND SPIRITUAL DEVELOPMENT

During the school-age years, the child's sense of morality is constantly being developed. According to Kohlberg, the school-age child is at the conventional stage of moral development. The 7- to 10-year-old usually follows rules out of a sense of being a "good" person. He wants to be a good person to his parents, friends, and teachers and to

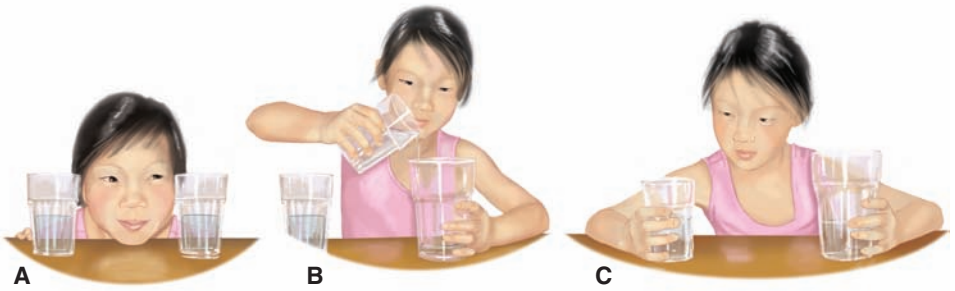

FIGURE 28.2 School-age children understand the theory of conservation (**A**). If you pour an equal amount of liquid into two glasses of unequal shape (**B**), the amount of water you have remains the same despite the unequal appearance in the two glasses (**C**).

himself. The adult is viewed as being right. This is stage 3: interpersonal conformity (good child, bad child), according to Kohlberg. Ten- to 12-year-olds progress to stage 4: the "law and order" stage. At this stage, the child can determine if an action is good or bad based upon the reason for the action, not just on the possible consequences of the action. The older school-age child's behavior is guided by the child's desire to cooperate and by his respect for others. This leads to the school-age child's ability to understand and incorporate into his behavior the concept of the "golden rule." See Table 28.1 for additional information about the moral development of school-age children.

It is during school age that children develop an interest in religion. They are still concrete thinkers and are guided by their family's religious and cultural beliefs. They are comforted by the rituals of their religion, but are just beginning to understand the differences between natural and supernatural. Incorporating religious practices in their lives can assist school-age children in coping with different stressors.

MOTOR SKILL DEVELOPMENT

Gross and fine motor skills continue to mature throughout the school-age years. Refinement of motor skills occurs, and speed and accuracy increase. To assess the motor skills of school-age children, ask questions about participation in sports and after-school activities, band membership, constructing models, and writing skills.

Gross Motor Skills

During the school-age years, coordination, balance, and rhythm improve, facilitating the opportunity to ride a two-wheel bike, jump rope, dance, and participate in a variety of other sports (Fig. 28.3). Older school-age children may become awkward due to their bodies growing faster than their ability to compensate.

School-age children between the ages of 6 and 8 enjoy gross motor activities such as bicycling, skating, and swimming. They are enthralled with the world and are in constant motion. Sometimes fear is limited due to the strong impulses of exploration. Children between 8 and 10 years of age are less restless, but their energy level continues to be high with activities more subdued and directed. These children exhibit greater rhythm and gracefulness of muscular movements, allowing them to participate in physical activities that require longer and more concentrated attention and effort, such as baseball or soccer.

Between the ages of 10 and 12 years of age (the pubescent years for girls), energy levels remain high but are more controlled and focused. Physical skills in this age group are similar to adults', with strength and endurance increasing during adolescence.

All school-age children should be encouraged to engage in physical activities and learn physical skills that contribute to their health for the rest of their lives. Cardiovascular fitness, weight control, emotional tension release, and development of leadership and following skills are enhanced through physical activity and team sports.

FIGURE 28.3 Jumping rope is an example of the increased development of gross motor skills of the school-age child.

Fine Motor Skills

Myelinization of the central nervous system is reflected by refinement of fine motor skills. Eye–hand coordination and balance improve with maturity and practice. Hand usage improves, becoming steadier and independent and granting an ease and precision that allows these children to write, print words, sew, or build models or other crafts. The child between 10 and 12 years of age begins to exhibit manipulative skills comparable to adults. School-age children take pride in activities that require dexterity and fine motor skills such as playing musical instruments (Fig. 28.4). Talent and practice become the keys to proficiency.

SENSORY DEVELOPMENT

All senses are mature early in the school-age years. The typical school-age child has 20/20 visual acuity. In addition, ocular muscular control, peripheral vision, and color discrimination are fully developed by the time the child is 7 years of age. Good vision is essential to the physical development and educational progression of school-age children. Vision screening programs conducted by school nurses identify problems with vision and result in appropriate referrals when warranted. Some problems frequently identified include amblyopia, uncorrected refractive errors or other eye defects, and malalignment of the eyes (called *strabismus*). If untreated by age 9 years of age, amblyopia can cause irreversible visual loss. This condition is correctable prior to this time with glasses or patching. Proper screening and referral, as well as notification to parents of the existing condition, are essential to the education and socialization of the school-age child (www.aao.org).

Hearing deficits that are severe are usually diagnosed in infancy, but the less severe may not be diagnosed until the child enters school and has difficulty learning or with speech. It is important to screen children for hearing deficits to ensure proper educational and social progression. With loud music heard over long periods of time each day, there are concerns about these environmental noises affecting hearing in the school-age and adolescent populations.

The sense of smell is mature and can be tested in the school-age child by using scents that children are familiar with, such as chocolate or other familiar odors. In addition, the school-age child may be tested for the sense of touch with objects to discriminate cold from hot, soft from hard, and blunt from sharp.

FIGURE 28.4 School-age children improve their fine motor skills so they can play musical instruments well.

COMMUNICATION AND LANGUAGE DEVELOPMENT

Language skills continue to accelerate during the school-age years. Vocabulary expands to 8,000 to 14,000 words. Culturally specific words are used, with bilingual children speaking English in school and a second language at home. The school-age child learns to read and reading efficiency improves language skills. Reading skills are improved with increased reading exposure. School-age children begin to use more complex grammatical forms such as plurals and pronouns. Also, they develop metalinguistic awareness—an ability to think about language and comment on its properties. This enables them to enjoy jokes and riddles due to their understanding of double meanings, and play on words and sounds. They are also beginning to understand metaphors such as "a stitch in time saves nine." School-age children may experiment with profanity and dirty jokes if exposed. This age group tends to imitate parents, family members, or others. Therefore, role modeling is very important.

EMOTIONAL AND SOCIAL DEVELOPMENT

Patterns of temperamental traits identified in infancy may continue to influence behavior in the school-age child. Analyzing past situations may provide clues to the way a child may react to new or different situations. Children may react differently over time due to their experiences and abilities. Self-esteem is the child's view of their individual worth. This view is impacted by feedback from family, teachers, and other authority figures.

Temperament

Temperament has been described as the way individuals behave. Some descriptions of temperament are that the

child is *easy, slow to warm,* or *difficult.* These behaviors vary from the child who is easy (even-tempered and predictable) to the child labeled as difficult (due to high activity levels, irritability, and moodiness). The child who is easy may adapt to school entry and other experiences smoothly and with little or no stress. The slow-to-warm child may be slow to adapt to changes. The slow-to-warm school-age child may exhibit discomfort when placed in different or new situations such as school. This child may need time to adjust to the new place or situation, and may demonstrate frustration with tears or somatic complaints. The slow-to-warm child should be allowed time to adjust to new situations and people (such as teachers) within his or her own time frame. All of these factors may impact the younger school-age child upon entering the school environment, with changes in authority and the introduction of many peers. The difficult or easily distracted child may benefit from an introduction to the new experience and people by role-playing, by visiting the site and being introduced to the teachers, and by hearing stories or participating in conversations about the upcoming school experience. These children require patience, firmness, and understanding to make the transition into a new situation or experience such as school. The Behavioral Style Questionnaire (BSQ) (McDevitt & Carey, 1978) is a temperament questionnaire for children 3 to 7 years old; the Middle Childhood Temperament Questionnaire is another tool for children 8 to 12 years of age (Hegvik, McDevitt, & Carey, 1982). These tools may be useful for determining type of temperament and guiding interventions.

Self-Esteem Development

Self-esteem mirrors the child's individual self-worth and consists of both positive and negative qualities. Children strive to achieve internalized goals of attainment, although they continually receive feedback from individuals they perceive as authorities (parent or teacher). By the school-age years, children have received feedback related to their performance or tasks. The direction of this feedback influences the child's opinion of self-worth, which influences self-esteem and self-evaluation.

Children face the process of self-evaluation from a framework of either self-confidence or self-doubt. Children who have mastered the earlier developmental task of autonomy and initiative face the world with feelings of pride rather than shame.

If school-age children regard themselves as worthwhile, they have a positive self-concept and high self-esteem. Significant adults in school-age children's lives can manipulate the environment to facilitate success. This success impacts the self-esteem of the child.

Body Image

Body image is how the school-ager perceives his or her body. School-age children are knowledgeable about the human body but may have different perceptions about body parts. School-age children are very interested in peers' views and acceptances of their body, body changes, and clothing. This age group may model themselves after parents, peers, and persons in movies or on television. It is important for late school-agers to feel accepted by peers. If they feel different and are teased, there may be lifelong effects.

School-Age Fears

School-age children are less fearful of harm to their body than in their preschool years, but fear being kidnapped or undergoing surgery. They continue to fear the dark and worry about their past behaviors. They fear death and are fascinated by death and dying. They are less fearful of dogs and noises. The school-age child needs reassurance that his or her fears are normal for this developmental age. Parents, teachers, and other caretakers should discuss the fears and answer questions posed by the child (Child Development Institute, 2007).

Peer Relationships

The child's concept of self is shaped by relationships with others. Peer relationships influence children's independence from parents. Peers play an important role in the approval and critiquing of skills of school-age children. Previously, only adults such as parents and teachers have been authorities; now, peers influence school-age children's perceptions of themselves. Peer relationships help to support the school-age child by providing enough security to risk the parental conflict brought about when establishing independence. School-age children associate with peers of the same sex most of the time. Although games and other activities are shared by both boys and girls, the child's concept of the appropriate sex role is influenced by his or her relationship with peers.

Continuous peer relationships provide the most important social interaction for school-age children. Valuable lessons are learned from interactions with children their own age. Children learn to respect differing points of view that are represented in their groups (Fig. 28.5). Peer groups establish norms and standards that signify acceptance or rejection. Children may modify behavior to gain acceptance. A characteristic of school-age children is their formation of groups with rules and values. Peer and peer-group identification are essential to the socialization of the school-age child.

Teacher and School Influences

School serves as a means to transmit values of society and to establish peer relationships. Secondary only to the family, school exerts a profound influence on the social development of the child. Often school requires changes for the child and parent. The child enters an environment that requires conforming to group activities that are structured

FIGURE 28.5 School-age children like to join clubs. These children, in the acting club at school, are rehearsing for a play.

and directed by an adult other than the parent. The parent's attitude and support influences the child's transition into the school setting. Parents that are positive and supportive promote a smooth entry into school. Parents that encourage clinging behaviors may delay a successful transition into school.

To facilitate the transition from home to school, the teacher must have the personality and knowledge of development that will allow him or her to meet the needs of young children. Even though the teacher's responsibilities are primarily to stimulate and guide intellectual development, they must share in shaping the child's attitudes and values. The system of awards and punishment administered by teachers affects the self-concept of children and influences their response to school. Teachers and school are important in shaping the socialization, self-concept, and intellectual development of children.

Family Influences

The school-age years are a time for peer relationships, questioning of parents, and the potential for parental conflict but continued respect for family values. School-age years are the beginning of the time of peer-group influence, with testing of parental and family values. Although the peer group is influential, the family's values usually predominate when parental and peer-group values come into conflict. Even though the school-age child may question the parents' values, the child will usually incorporate the values from parents into his or her values.

Many times in the late school-age and preadolescent period, the child may prefer to be in the company of peers and show a decreased interest in family functions. This may require an adjustment for parents. Parents' awareness of this developmental trend and their continuing support for the child is important while they continue to enforce restrictions and control of behaviors. The school-ager is beginning to strive for independence, but parental authority and controls continue to impact choices and values. School-age children continue to need parenting. They do not need parents as pals.

CULTURAL INFLUENCES ON GROWTH AND DEVELOPMENT

Culture influences habits, beliefs, language, and values. School-age children thrive on learning the music, language, traditions, holidays, games, values, gender roles, and other aspects of culture. Nurses must be aware of the effects on children of various groups' family structures and traditional values. The school-age child's cultural and ethnic backgrounds must be considered when assessing growth and development, including differences in growth in children of different racial and cultural backgrounds. Cultural implications must be considered for all children and families in order to provide appropriate care.

Refer back to Lawrence Jones, who was introduced at the beginning of this chapter. What developmental milestones would you expect him to have reached by this age?

The Nurse's Role in School-Age Growth and Development

WATCH & LEARN

The nurse's role in school-age growth and development includes assessing growth and development, promoting healthy growth and development, and addressing common developmental concerns. The nursing process overview would include an assessment of the individual child and identification of nursing diagnoses needing intervention or referral. The nurse promotes healthy growth and development through anticipatory guidance and goal attainment.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the school-age child's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development

- Risk for caregiver role strain
- Risk for injury

Nursing care planning for the school-age child with growth and development issues should be individualized based on the school-age child's and family's needs. The nursing care plan can be used as a guide in planning nursing care for the school-age child with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from Nursing Care Plan 28.1 and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

PROMOTING HEALTHY GROWTH AND DEVELOPMENT

The family plays a critical role in promoting healthy growth and development of the school-age child. Respectful interchange of communication between the parent and child will foster self-esteem and self-confidence. This respect will give the child confidence in achieving personal, educational, and social goals appropriate for his or her age. The nurse should study interactions between parents and school-age children to observe for this respect or lack of respect ("putting the child down"). The nurse can model appropriate behaviors by listening to the child and making appropriate responses. The nurse can be a resource for parents and an advocate for the child in promoting healthy growth and development.

Promoting Growth and Development Through Play

Cooperative play is exhibited by the school-age child. Play for the school-age child includes both organized cooperative activities (such as team sports) and solitary activities. School-age children have the coordination and intellect to participate with other children their age in sports such as soccer, baseball, football, and tennis. The school-age child comprehends that his or her cooperation with others will lead to a unified whole for the team. Additionally, the child learns rules and the value of playing by the rules.

School-age children also enjoy solitary activities including board, card, video, and computer games, and dollhouse and other small-figure play (Fig. 28.6). Many schoolagers start collections of stamps, cars, or other valuable or not-so-valuable items. During the school-age years, children may also begin a scrapbook or keep a diary. They may participate in activities such as dance or karate. Girls and boys may join clubs, gangs, or special interest groups.

Active play has decreased in recent years as television viewing and computer games have increased. This trend has resulted in health risks such as obesity, type 2 diabetes, and cardiovascular problems.

Promoting Learning

School attendance and learning are very important to the school-age child. Parent–child, child–teacher, and child–peer relationships and activities influence the school-age child's learning.

Formal Education

Most children are excited about starting school and making new friends. They like the notion of getting books, having book bags, and having homework assignments. The reality of the work involved with school and homework may decrease the enthusiasm about school.

Peers are very important within this age group. Both peers and teachers influence children. Attending school may be their first experience interacting with a large number of children their own age. Through this interaction, children learn cooperation, competition, and the importance of following the rules. Peer approval and influences grow as the child matures. Teachers have significant influences on children. They help to guide the child's intellectual development by rewarding successes and helping the child deal with failures. The student–teacher relationship is a key to success. Teachers play a role in fostering feelings of industry and preventing feelings of inferiority (Fig. 28.7). School-age children also learn skills, rules, values, and other ways to work with peers and other authority figures.

Parental support is important for school adjustment and achievement. Parents must collaborate with teachers and school personnel to ensure that the child is fulfilling the expectations and requirements for this age group in school. Parents must monitor the child's homework assignments and friends, and observe for any changes in behavior that would indicate school or behavioral problems.

Reading

Encouraging reading is an excellent way to promote learning in the school-age child. Trips to the library and purchasing books help to promote a love of reading. School-age children enjoy being read to as well as reading on their own. Younger school-age children (6 to 8 years) enjoy books that are simple to read with few words on a page, such as the Dr. Seuss books. They enjoy books about animals and trains and simple mysteries. Children 8 to 10 years of age have more advanced reading skills and enjoy those books from early childhood, plus more classic novels and adventures such as the Harry Potter series. Older children enjoy horror stories, mysteries, romances, and adventure stories as well as classic novels. School-age children of all ages benefit from books on topics related to things they may be experiencing, such as a visit to the hospital for a surgical procedure. See Box 28.1 for ideas for parents to promote reading in the school-age child.

Nursing Care Plan 28.1

GROWTH AND DEVELOPMENT ISSUES OF THE SCHOOL-AGE CHILD

NURSING DIAGNOSIS: Risk for disproportionate growth (risk factors: caregiver knowledge deficit, frequent illnesses)

Outcome Identification and Evaluation

School-age child will demonstrate adequate growth: *appropriate weight gain for age and gender*

Interventions: Promoting Proportionate Growth

- Assess parent's knowledge of nutritional needs of school-age children *to determine need for further education.*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Educate mother about appropriate serving sizes and foods *so that mother is aware of what to expect for school-age children.*

NURSING DIAGNOSIS: Imbalanced nutrition, more than body requirements, related to lack of exercise, increased caloric intake, poor food choices

Outcome Identification and Evaluation

School-age child will lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and gender*

Interventions: Promoting Nutrition

- Assess knowledge of parents and child about nutritional needs of school-age children *to determine deficits in knowledge.*
- Have child keep food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview parents in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Analyze preceding data, and base recommendations for changes on these data.
- Discuss ways to decrease temptation to overeat and to make good meal choices (see Teaching Guideline 28.2).
- Have child assist in meal planning and grocery shopping *to allow him some sense of control in process.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement *to increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight-loss program for school-age children *to increase self-esteem and to increase awareness that other children have the same problem.*

NURSING DIAGNOSIS: Growth and development, delayed related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

Outcome Identification and Evaluation

Development will be maximized: School-age child will make continued progress toward attainment of expected school performances.

Interventions: Promoting Growth and Development

- Perform scheduled evaluation of the school-age child by school and health care provider *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings to be able *to adapt interventions as soon as possible.*

Nursing Care Plan 28.1 (continued)

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: new sibling in household, knowledge deficit about school-age issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for a school-age child*

Interventions: Preventing Caregiver Role Strain

- Assess parent's knowledge of school-age children and the issues that arise as a part of normal development *to determine parent's needs.*
- Provide education on normal issues of school-age children so that parents are armed with the knowledge they need *to appropriately care for their school-age child.*
- Provide anticipatory guidance related to upcoming expected issues related to school-age development *to prepare parents for what to expect next and how to intervene.*

NURSING DIAGNOSIS: Injury, risk for (risk factors: curiosity, increasing cognitive skills and motor abilities)

Outcome Identification and Evaluation

School-age child's safety will be maintained: *will remain free from injury*

Interventions: Preventing Injury

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, water, and playground *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending upon age, sex, and maturity of child *to prevent possible injury and to promote child's self-esteem.*
- Parents should have the poison control center phone number available *(in the event of accidental ingestion, poison control can give parents the best advice for appropriate intervention).*
- Teach parents and child first-aid measures and child cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers on actions of school-age children *to prevent possible injury due to mimicking behavior.*

FIGURE 28.6 This school-age girl enjoys solitary play with her dollhouse and dolls.

FIGURE 28.7 School is important to the school-age child.

BOX 28.1 Promotion of Reading in School-Age Children

- Parents, read to and with your children.
- Ask teachers and librarians for advice on books appropriate for your child.
- Choose stories that the child can relate to if the child has difficulty reading.
- Choose books with movement if the child has a short attention span.
- Take advantage of all reading opportunities (cereal boxes, road signs).
- Provide choices for the child to select a book of interest.
- Talk about the text and ask questions to improve understanding.
- Keep a record of what the child is reading.
- Visit a library, get a library card, and check out books.
- Parents, demonstrate role modeling through reading books.

Promoting Safety

School-age children become more independent with age. This independence leads to an increased self-confidence and decreased fears, which may contribute to accidents and injuries. School age is a time that the child may walk to school with peers who may influence his or her behavior. Increased independence may also increase exposure to dangerous situations such as the approach of strangers or unsafe streets. Promotion of safe habits during the school-age years is important for parents and nurses. See Teaching Guidelines 28.1 for additional information on safety education for nurses and parents.

Unintentional injuries are the leading cause of death in children between 1 and 21 years of age (CDC, 2007a). Each year, 20 million children sustain an injury sufficiently severe to seek medical attention (CDC, 2007b). School-age children are very active at home, in the community, and at school. This increased mobility, activity, and time away from parents increases the risk for unintentional injuries. School-age children continue to need supervision and guidance. They need information and rules about car safety, pedestrian safety, bicycle and other sport safety, fire safety, and water safety.

Car Safety

Motor vehicle accidents are a common cause of injury in the school-age child. While traveling in the car, school-age children should always sit in the rear seat. The front seat is dangerous because of passenger-side airbags in most new-model cars. The school-age child should use a three-point restraint system in the rear seat of the car with the shoulder strap and lap belt fitted snugly. In addition, a school-age child over 40 pounds (generally 4 to 8 years of age) should use a belt-positioning, forward-facing booster seat using both lap and shoulder belts. School-age children who outgrow the convertible restraint can sit in a booster seat until their head is higher than the vehicle seat back (usually 4′9″ and taller). Children under 12 years of age should not ride in the front seat of a vehicle with an airbag.

Pedestrian Safety

Children between the ages of 5 and 9 have the highest incidence of pedestrian-related injuries. Young school-age children between 6 and 8 years of age should walk to school or the bus with an older friend, sibling, or parent. Darting out into the street without looking both ways or from between cars is a common occurrence in the school-age years. Teach children safe street and pedestrian practices.

Bicycle and Sport Safety

Bicycling, riding scooters, skateboarding, and inline skating or rollerskating are common activities of school-age children. Laws in most states require helmets for riding bicycles and scooters. In addition, when skating or skateboarding, school-age children should wear a helmet, kneepads, and elbow pads.

Research has shown that head injuries due to bicycle accidents have been reduced by 85% by wearing a well-fitting helmet. National estimates of bicycle helmet ownership in school-age children are 50%, and only approximately 50% of those wear helmets each time they ride their bicycles (see Healthy People 2010). It is important for children to wear helmets that fit and that do not obstruct their vision or hearing. Because school-age children have completed most of their skull growth, a helmet can be worn into adolescence. It is important for the child to have a bicycle that is appropriate for his or her size and age. The child should be able to plant both feet on the ground when sitting on the seat of the bike (Fig. 28.8). It is important to stress to parents the importance of appropriate size and not to get a bike for the child to "grow into." If older school-agers are using the bike for transportation on busy streets, they should be taught to use bike lanes and to give appropriate hand signals for turning. Non-motorized and motorized scooters also place children at risk for injury, so counsel families about the use of protective gear.

Fire Safety

School-age children are eager to help parents with cooking and ironing. They are curious about fire and are drawn to play with fire, matches, and fireworks. Serious burns can occur from any exposure to fire. Educate children about the hazards of fire. In addition, teach children proper behavior around fires at home and outdoors. Always supervise children in the use of matches. In the home setting, parents should develop a fire safety plan with their children, teach children what to do if their clothes catch on fire, and practice evacuating the house in the event of a fire.

TEACHING GUIDELINES 28.1

Safety Issues and Interventions of the School-Age Child

Safety Issue	Interventions
Car safety	• Should wear seat belt or be in age- and weight-appropriate booster seat at all times. • Fasten seat belt before car is started. • Children under 12 years must sit in back seat. • Utilize childproof locks in back seat. • Establish rules of conduct in car.
Pedestrian safety	• Child should look right, left, then right again before crossing the street. • Cross only at safe crossings. • Older children and adults should provide supervision of younger children. • Should only walk on sidewalks. • Should not dart out between parked cars. • In parking lots, should watch for cars backing up. • If children are playing outside, drivers should be aware of their presence before backing up.
Bike safety: general	• Have a well-maintained and appropriate-size bike for child. • Parents should orient the child to the bike. • Child should demonstrate his or her ability to ride bike safely before being allowed to ride on street. • Safe areas for bike riding should be established as well as routes to and from area of activities. • Should not ride bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike. • Should wear sturdy, well-fitting shoes. • Should wear ANSI-approved helmets. • Bike should be inspected often to ensure it is in proper working order. • A basket should be used to carry heavy objects.
Bike safety in traffic	• All traffic signs and signals must be observed. • If riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes. • Should ride on the side of the road traveling with traffic. • Should keep close to the side of the road and in single file. • Should watch and listen for cars. • Should not wear headphones while riding a bike. • Never hitch a ride on any vehicles.
Sports safety	• Match sport to child's ability and desire. • Sports program should have warm-up procedure. • Coaches should be trained in cardiopulmonary resuscitation (CPR) and first aid. • Child should wear appropriate protection devices for individual sport.
Skateboarding and inline skating safety	• Should wear helmet, and protective padding on knees, elbows, and wrists • Should not skate in traffic or on streets or highways. • Skating on homemade ramps could be dangerous—should assess ramps for any hazards before skating.
All-terrain vehicle safety	• Should not be operated by children less than 16 years of age. • Should wear helmet and protective coverings. • No nighttime riding. • Should not be used on public roads. • Should not stand up in the vehicle or ride in a person's lap.

(continued)

TEACHING GUIDELINES 28.1 (continued)

Safety Issues and Interventions of the School-Age Child

Safety Issue	Interventions
Fire safety	• All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year. • Should have fire-escape plan. • Should practice fire-escape plan routinely. • Nobody should smoke in bed. • Should teach what to do in case of a fire: use fire extinguisher, call 911, and how to put out clothing fire. • Should wear flame-retardant clothing in bed. • Should use stove and other cooking facilities under adult supervision. • All flammable materials and liquids should be stored safely. • Fireplaces should have protective gratings. • Teach children to avoid touching wires they might encounter while playing.
Water safety	• Teach children how to swim. • If swimming skill is limited, must wear life preserver at all times. • Never swim alone—should if at all possible, swim only where there is a life guard. • Should be taught basic CPR. • Should not run or fool around at edge of pool. • Drains in pool should be covered with appropriate cover. • Should wear life jacket when on boat. • Make sure water is deep enough to support diving.
Firearm safety	• Should teach never to touch gun—tell adult. • If have guns in household, need to secure them in safe place, use gun safety locks, store bullets in separate place. • Never point a gun at a person.
Toxin safety	• Teach child the hazards of accepting illegal drugs, alcohol, or dangerous drugs. • Store potential dangerous material in safe place.

In the school setting, children should be aware of the appropriate response to fire drills and fire drills should be conducted on a regular basis.

Water Safety

Teach school-age children swim and water safety. An adult should always supervise children when they are swimming to prevent water-related accidents.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase use of helmets by bicyclists.	• Provide education to children and their parents about avoiding head injury through helmet use. • Encourage child to choose a helmet that appeals to him or her (one that looks "cool").

Abuse in Children

Child abuse, including physical abuse and sexual abuse, are common crimes of violence against children. Three million reports of child abuse are made annually, but the true incidence may be triple that figure (ChildHelp, 2006). In 2002, more than 88,000 children were victims of sexual abuse (Kellogg & Committee on Child Abuse and Neglect, 2005). The abusers of children are family, friends, and strangers. It is important for parents to teach children the concept of "good touch" vs. "bad touch" prior to school-age years. Whenever the school-age child's behavior yields suspicion of physical or sexual abuse, the nurse should report to the appropriate authorities in his or her state. These topics will be discussed in more depth in Chapter 51.

Remember Lawrence Jones, the 10-year-old presented in the case study? What anticipatory guidance related to safety should you provide to his mother?

FIGURE 28.8 Wearing the appropriate safety equipment and having an appropriately sized bicycle are important to prevent injuries in school-age children.

Promoting Nutrition

Growth, body composition, and body shape remain constant during late school-age years. Needed calories decrease while the appetite increases. In preparation for adolescence, the body fat composition of school-age children increases. This tendency toward increased body fat occurs earlier in girls than in boys, with the amount of increase greater in girls. Boys have more lean body mass per inch of height than girls.

Diet preferences established in the preschool years continue during the school-age period. As the child grows older, influences of family, media, and peers can impact the eating habits of this age group. Some of these influences are parents' work schedule, outside activities, and exercise level of the child. Decreased exercise levels and poor nutritional choices lead to the mounting problem of obesity seen in this age group. See Box 28.2 for appropriate questions to ask the child and parent regarding nutritional status. Healthy People 2010 provides objectives and actions to improve the nutritional health of children.

Nutritional Needs

School-age children with an average body weight of 20 to 35 kilograms need approximately 70 calories per kilogram daily (1,400 to 2,100 calories per day). The average water requirement per 24 hours ranges from 1,800 to 2,200 milliliters per day. The child needs 28 grams of protein and 800 milligrams of calcium for maintenance of growth and good nutrition. Calcium is needed for the development of strong bones and teeth. Milk, yogurt, and cheese provide protein, vitamins, and minerals and are an excellent source of calcium. Meats, poultry, fish, and eggs provide protein, vitamins, and minerals.

BOX 28.2 Dietary Questions

Questions for the Child

- How often do you eat together as a family?
- What are the usual mealtimes?
- How often does the family eat out?
- Do you eat breakfast regularly?
- Where do you eat lunch?
- What do you drink/how much?
- What foods do you eat most often?
- What is your favorite food?
- How often do you eat fast foods?
- What type of exercise do you do?

Questions for the Parents

- How would you describe your child's usual appetite?
- Do you have any special cultural/religious practices regarding food?
- Has your child gained or lost weight recently?
- Do you have any concerns about his or her eating behaviors?
- How does your child exercise? Your family?
- Is there a family history of cancer, hypertension, diabetes, obesity, or heart disease?

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the proportion of persons age 2 years and older who consume at least two daily servings of fruit; three daily servings of vegetables, with at least one-third being dark-green or deep-yellow vegetables; and six daily servings of grain products, with at least three being whole grain. Increase the proportion of persons age 2 years and older who consume less than 10% of calories from saturated fat, and who consume no more than 30% of calories from fat.	• Educate families about the importance of whole grains, fruits, and vegetables in the diet. • Encourage the child to choose fruits and vegetables that appeal to him or her. • Provide creative suggestions for vegetable preparation to make them more appealing to children. • Educate families about saturated fat–containing foods. • Offer suggestions for alternate sources of protein and fats (chicken or fish, olive oil).

Nutritional Guidelines

School-age children should choose culturally appropriate foods and snacks from the Food Guide Pyramid. School-age children need to limit intake of fat and processed sugars. A prudent diet limits the use of fatty meats, high-fat dairy products, eggs, and hydrogenated shortenings and promotes the consumption of fish and the substitution of polyunsaturated vegetable oils and margarines. The American Heart Association has endorsed a diet for school-age children that includes the recommendations listed in Box 28.3.

Regarding Lawrence Jones, what questions should you ask Lawrence's mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The number of hours of sleep required for growth and development decreases with age. Children between the ages of 6 and 8 years require about 12 hours of sleep per night. Children between 8 and 10 years of age require 10 to 12 hours of sleep per night, and children between 10 and 12 years of age need 9 to 10 hours of sleep per night. Young school-age children may need an occasional brief nap for an energy boost after being in school for most of the day. Bedtime rituals and consistent schedules continue to be important throughout the school-age years. Parents must facilitate the bedtime schedule and quiet time before bed. Bedtime is a special time for parents and children to read together, listen to stories or soothing music, share events of the day, and exchange expressions of affection. Children should have bedtime expectations as well as wake-up times and methods for waking up (alarm, calling by parent, and so forth).

BOX 28.3 American Heart Association's DietRecommendations for School-Age Children

- A high-quality protein with every meal
- Milk with added vitamin D and other low-fat dairy products
- Vegetables high in vitamin A
- Fruits high in vitamin C
- Whole-grain or enriched breads or cereals
- Vegetable oils high in polyunsaturated fats
- Meats (4 servings per week of 4 ounces each)
- Fish (1–2 times per week)
- Poultry (1–2 times per week)
- Dark green, leafy, or deep yellow vegetables (at least 4 times per week)
- Eggs (4 times per week)

Night terrors or sleepwalking may occur in 6- to 8-year-olds but should be resolved between the ages of 8 and 10 years. In the older school-age child (11 to 12 years), encourage parents to allow a variation in the sleep schedule on the weekends and a regular schedule on weekdays.

Provide anticipatory guidance to Lawrence Jones's mother in relation to proper sleep for her 10-year-old son.

Promoting Healthy Teeth and Gums

Dental **caries** remains the leading disease in the United States, even though the incidence has been reduced since the introduction of fluoride (www.dentalcare.com). Dental care with emphasis on prevention of caries is important in this age group. Sometimes dental care is not considered to be important by parents of young children because the primary teeth will be replaced by permanent teeth. This perception leads to complications of permanent teeth such as **malocclusion** (see Healthy People 2010).

Proper alignment of teeth is important to tooth formation, speech development, and physical appearance. Many school-age children need braces or other orthodontic devices to correct malocclusion, a condition in which the teeth are crowded, crooked, or misaligned. **Bruxism** or teeth grinding while asleep may continue in the school-age years. Bruxism may result in grinding away of tooth enamel. Teeth grinding may be due to malalignment. A dental evaluation should be scheduled if consistent teeth grinding occurs.

School-age children need to brush their teeth two to three times per day for 3 minutes each time (Fig. 28.9). Parents should replace the toothbrush (soft) every 3 to 4 months. Flossing the teeth at least once daily is recommended by the American Dental Association. Parents must monitor teeth brushing, observe for abnormal alignment of their child's teeth, and schedule regular dental examinations every 6 months to ensure good dental health and prevent dental problems. Children may need help with brushing teeth until they are between 7 and 10 years of age. Dental sealants are recommended for all school-age children. The sealant is a plastic coating applied to biting surfaces to seal out tooth decay on permanent back teeth.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth. Increase the proportion of children who have received dental sealants to their molar teeth.	• Encourage appropriate tooth-brushing and flossing. • Educate child and family about fluoride use. • Refer school-age children to dentist for molar sealants. • Assist families lacking dental insurance to find resources for the provision of dental care.

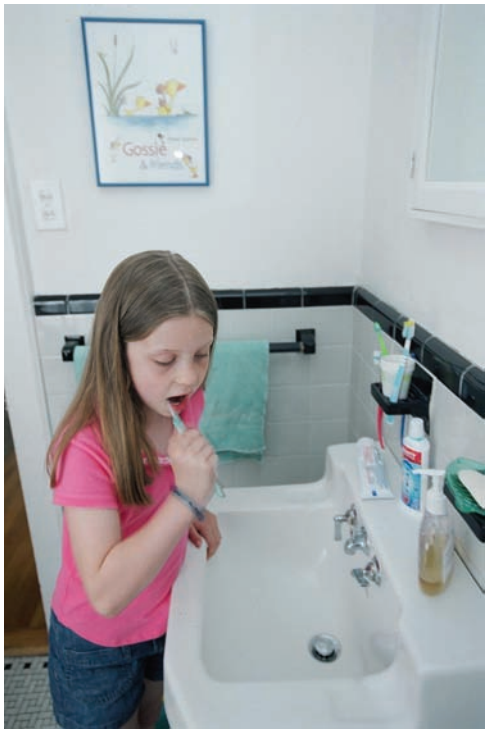

FIGURE 28.9 Using correct technique to brush the teeth is important in the prevention of cavities.

In addition, parents should give a fluoride supplement (as directed by the dentist) to their children if fluoride is not in the town's water supply.

Children wearing braces are more prone to cavities; encourage them to brush their teeth after meals and snacks. School nurses can assist these children with brushing after lunch. In addition, the school nurse should promote dental health through education on dental care and gum problems that result from lack of proper dental care. Diet can play a part in dental health. Limiting sticky, high-sugar, and high-carbohydrate foods will decrease the possibility of cavities.

Promoting Appropriate Discipline

Because of the increasing ability of the school-age child to view situations from different angles, the school-age child should be able to see how his actions affect others. Children between 6 and 8 years old are beginning to see the effects of behaviors on others. They are also beginning to realize that their behaviors can have consequences. Children between 8 and 12 years of age are fully aware of the cause and effect of their behaviors. They should be able to express emotions without using violence. Discipline techniques with consequences have both *natural* and *logical* consequences. Natural consequences allow the child to learn the results of their actions. For example, if the child throws a toy out of the window, then he cannot play with the toy anymore. In logical consequences, if the child does not put away her bike, she does not get to ride the bike for the rest of the day.

In disciplining children, parents should teach children the rules established by the family, values, and social rules of conduct. Rules should provide the school-age child with guidelines about behavior that is acceptable and unacceptable. School-age children look to their parents for guidance and as role models. Parents should role model appropriate expressions of feelings and emotions and allow the child to express emotions and feelings. Discuss the effects of the child's temperament on his or her behavior, as well as what constitutes age-appropriate behavior. Include how the parents' temperament can influence the child's temperament.

Effective guidance and discipline focus on the development of the child. They can preserve the child's self-esteem and dignity. Discuss with parents guidelines regarding discipline. Explain to parents that they should never belittle the child. Children may view parents and caretakers negatively if they are consistently belittled or insulted. These negative actions can inhibit learning and teach the child to react unkindly to others. Instead, parents should discipline with praise. Positive acknowledgements of progress are likely to encourage healthy development and appropriate behavior (AAP, 2004). Discuss with parents how to be realistic when planning activities so as to not overwhelm the child, resulting in misbehavior. Encourage parents to say "no" only when they mean it, to avoid a negative atmosphere in the home, and to avoid inconsistency.

When misbehaviors occur, the type and amount of discipline is based upon different factors:

- Developmental level of both the child and the parents
- Severity of the misbehavior
- Established rules of the family
- Temperament of the child
- Response of the child to rewards

Keep in mind that school-age children should participate in developing a plan of action for their misbehavior. Whatever methods of discipline are chosen, it is important that parents are consistent in providing discipline in a nurturing environment.

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

The developmental task (according to Erikson) of the school-age child is industry. The school-age child is busy learning, achieving, and exploring. As the school-age child becomes more independent, forces other than the family such as television, video games, and peers influence them. Some of these influences are positive and others are negative. Some of the common developmental concerns for the school-age child are discussed in the following sections. Guidelines to assist the parents and nurses when encountering these concerns are included in Teaching Guidelines 28.2.

TEACHING GUIDELINES 28.2

Addressing Common Developmental Concerns

Television and Video Games

- Limit television watching and video-game playing to 2 hours per day.
- Monitor television programs.
- Prohibit television or video games with violence.
- Do not put television or video games in children's bedrooms.
- Provide a schedule of accepted television programs for viewing each week.
- Co-view television and video games with the child.
- Encourage sports, interactive play, and reading.

Obesity

- Provide healthy meals and snacks.
- Schedule and encourage daily exercise.
- Encourage involvement in sports.
- Restrict TV and computer-game use.
- Limit the amount of fast-food intake.
- Provide education about healthy nutrition.
- Never use food as a reward.
- Be a good role model.

School Phobia

- Return child to school.
- Investigate cause of the fear.
- Support child.
- Collaborate with teachers.
- Praise success in school attendance.

Latchkey Kids

- Provide rules to follow and expectations, such as
  - Not answering the door or phone
  - No friends in the house when parents are not home
  - No playing with fire
- Teach child to call a trusted neighbor when help is needed and 911 in the event of emergency.
- Post all resource numbers, including after-school help lines if available, in a clearly viewable spot.
- Purchase caller ID for the phone system.
- Enroll the child in an after-school program if available.
- Discuss limitations of outside play.
- Discuss limitations of television viewing and video-game use.
- Make sure the child knows how to contact the parent.
- Set clear homework expectations.
- DO NOT keep guns in the home.

Stealing

- Educate parents about possibility of stealing.
- Discuss ways to teach concept of ownership and property rights.
- Handle situation openly.
- Assist child in developing and enacting a plan to return what was stolen.
- Make sure the punishment is appropriate for the action.

Lying

- Help parents in understanding why the child is lying.
- When the child lies, calmly confront the child and explain why the behavior is not acceptable.
- Educate parents that their behavior should reflect what they teach and expect from their child.
- Educate parents that too-rigid or severe punishments can decrease the child's sense of worth.
- Seek professional help if lying persists in the older school-age child, to rule out underlying problems.

Cheating

- Educate parents that the child must be mature enough to understand the concept of rules.
- Handle cheating situations openly.
- Help parents to understand why their child is cheating and to modify the trigger.
- Develop appropriate punishment; inappropriate punishment could undermine the child.
- Educate parents that their behavior should reflect what they expect from their child.
- Seek professional help if cheating persists in the older school-age child, to rule out underlying problems.

Bullying

The Bullied Child

- Educate parents whose children are at risk for being bullied
  - Children who appear different from the majority
  - Children who act different from the majority
  - Children who have low self-esteem
  - Children with a mental or psychological problem
- Teach parents to role play different scenarios the child may face at school; show the child different ways to react to being bullied.

TEACHING GUIDELINES 28.2 (continued)

Addressing Common Developmental Concerns

- Impress upon the child that he or she did not cause the bullying.
- Develop ways to increase the child's self-esteem at home.
- Discuss the situation with the teacher and develop a plan of care.

The Bullying Child

- Educate parents on reasons why it is important to correct the behavior.
- Discuss ways the child can appropriately show his or her anger and feelings.
- Have parents help the child to see how it feels to be bullied.
- Do not allow fighting at home.
- Reward settling of conflicts without violence.

Tobacco and Alcohol Education

- Inquire about tobacco and alcohol use.
- Discuss the physical and social dangers of tobacco and alcohol use.
- Urge parents to be good role models.
- Limit reading and media materials about alcohol and tobacco use.
- Discuss the influences of tobacco and alcohol use by peers.
- Educate the child on spit tobacco. Let them know it is just as dangerous as smoking tobacco.
- Advocate for a smoke-free environment in the home and other places frequented.
- Avoid having tobacco and alcohol products readily available in the home.

Television and Video Games

The influence of television and video games upon the school-age child is a growing concern for parents and child specialists. Children in the United States spend about 4 hours a day either watching TV or playing video games. During that time, a child will see 8,000 murders by the end of grade school and 40,000 commercials a year. Although a school-age child can determine what is real from what is fantasy, research has shown that this amount of time in front of the TV—watching it or playing video games—can lead to aggressive behavior, less physical activity, and altered body image (see Healthy People 2010).

Although some television shows and video games can have positive influences on children, teach parents guidelines on the use of TV and video games. Parents should set limits on how much TV watching the child can have. The American Academy of Pediatrics recommends 2 hours or less of television viewing per day. The parent should establish guidelines on when the child can watch TV, for example, after homework or when chores are completed. Television watching should not be used as a reward. The parents should be aware of what the child is watching. Watch the programs together and use that opportunity to discuss the subject matter with the child. There should be no TV during dinner and no TV in the child's room. The parents need to set an example for the child. Read instead of watching TV or do a physical activity together as a family. If the TV causes fights or arguments, it should be turned off for a period of time.

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Increase the proportion of children and adolescents who view television 2 or fewer hours per day.	• Assist families to identify activities other than television for the child to participate in. • Praise craft, music, and sports participation.

Obesity

The National Health and Nutrition Examination Survey (NHANES) found that more and more children are overweight. Over the past three decades the number of overweight children and adolescents more than tripled. Thirty percent of 6- to 11-year-olds are overweight or at risk for overweight (NAPNAP, 2006). Overweight is classified as a body mass index (BMI) greater than 85% and obese is classified as a BMI greater than 95% (see Healthy People 2010).

Obesity occurs when the intake of calories and food exceeds the expenditures. Some factors linked to causing

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce the proportion of children and adolescents who are overweight or obese.	• Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age. • Provide accurate diet counseling. • Encourage daily physical activity. • Counsel parents to limit television/computer time daily.

obesity include family role modeling, lack of exercise, and unstructured meals as well as cultural, genetic, environmental, and socioeconomic factors. Some factors that influence lack of exercise include the decreased number of days that school systems offer physical education programs and recess. Also, some children live in unsafe neighborhoods and have no safe place to play outside; therefore they spend time in sedentary activities such as watching TV. Children with low metabolic rates and increased numbers of fat cells tend to gain more weight. Obese children are at risk for cardiovascular diseases, type 2 (non–insulin dependent) diabetes, and orthopedic problems. Also, psychosocial problems and eating disorders are prevalent. When parents do not have knowledge of nutrition, do not monitor snacks or meals, and have unstructured meals, habits are established that lead to obesity. A lack of exercise also contributes to obesity.

Preventing obesity in childhood is important because the fat cells of childhood are carried into adulthood obesity and contribute to disease. Due to the risk of obesity, encourage parents to never use food as a reward. To prevent obesity, establish regular mealtimes and offer healthy foods and snacks. Encourage parents to praise their child's good food choices and to role model appropriate eating and exercise.

School Phobia

School refusal (also called *school phobia* or *school avoidance*) has been defined as frequent absences, dropping out of school, or academic disengagement or disruption (Kearney, 2006). School phobia needs to be defined both symptomatically and operationally as the cause for the anxiety. School avoidance occurs in approximately 5% of school-age children. These children may refuse to attend school or create reasons why they cannot go to school.

Some of the fears expressed by school-refusing children include tests, bullying, teacher reprimands, anxieties over toileting in a public bathroom, physical harm, or undressing in the locker room. Due to the emotional distress caused in these children when attending school, they are frequently classified as having school phobia. Young children may complain of stomachache or headache and older children may complain of palpitations or feeling faint.

It is important to investigate specific causes of school refusal/school phobia and take appropriate actions. The physician or nurse practitioner should conduct a physical examination of the child to rule out any physical illness. After these measures are taken, the parent, teacher, school counselor, and school administrator may devise a plan to assist the student to overcome a specific fear. In uncomplicated cases, parents must return the child to school as soon as possible. There may be altered schedules (partial days or decreased hours) to help promote a successful transition back to school. Another idea to help desensitize the child may be to have him or her spend part of the day in the counselor's or school nurse's office.

Latchkey Children

With both parents in the workforce, many children return home alone without adult supervision for a number of hours. These "latchkey kids" are more prone to misbehave and to take risks. The American Academy of Pediatrics recommends that a child come home to a parent, another adult, or a responsible adolescent (www.aap.org).

Most young children are not capable of handling stress or making decisions on their own before 11 or 12 years of age. However, some school-age children are more mature and can be left alone by 8 to 10 years of age; maturity is the key, not the age. Despite the level of maturity, children who are unsupervised are more likely to use alcohol and illegal drugs. In addition, latchkey children may feel isolated from friends because friends may be prohibited from entering the home when parents are not present (American Academy of Child and Adolescent Psychiatry, 2004).

If children come home to no supervision, they should know the names, addresses, and phone numbers of parents and a neighbor, as well as emergency numbers. They should be given rules about answering the door and the phone. They should tell anyone who comes to the door or who calls that mom is home but busy at this time. Directions as to the handling of the house key and fire safety should be taught and demonstrated (see Teaching Guidelines 28.2).

Stealing, Lying, and Cheating

It is during the school-age years that antisocial behaviors can emerge. Children who were previously well behaved may now exhibit behaviors of stealing, lying, and cheating. Parents are usually disturbed by this change in behavior. In turn, they have difficulty in addressing these issues and need help in providing appropriate interventions.

Children between 6 and 8 years old do not fully understand the concept of ownership and property rights. These children may steal things because they like the look of the item. Stealing in the 8- to 10-year-old may occur because the child desires the item or to impress the child's peers. The 10- to 12-year-old child may steal for the same reasons as children between 8 and 10 years of age. In addition, these older children may steal to supplement their perceived inadequate income.

Lying is more common in children between 6 and 8 years old. It is acceptable for these children to tell tall tales, but they should know what truth is and what make-believe is. These younger children typically lie to avoid punishment. However, they do not like others to lie and will tell on them if they lie. Children between 8 and 12 years old typically lie because they are unable to meet expectations of family and peers. They also lie to impress others. If lying persists in older school-age children, parents should discuss the matter with a health care provider because the lying may be evidence of underlying problems.

The concept of cheating is not well understood until the child is 7 years old. Before this age, the desire to "win"

EVIDENCE-BASED PRACTICE 28.1
Benefits of Bully-Prevention Education

● Study
Child conduct problems continue to pose a problem in elementary schools. In addition to the behavioral disruption that occurs as a result of bullying and victimization, prior research has demonstrated that child bullies and victims are at increased risk for mental health problems and antisocial behavior. This study was performed over a 2-year period utilizing fourth-grade classrooms at 28 public elementary schools. The group-randomized trial assigned classrooms to receive a program aimed at bullying and aggression prevention or to receive no treatment at all. Self-reported bullying and victimization were then analyzed after the 2-year trial.

▲ Findings
Upon analysis of the findings, the researchers reported a mild decrease in bullying and a greater decrease in bullying victimization. It appears that bullying-prevention programs in elementary schools may be effective in decreasing aggression and violence in the school-age group.

■ Nursing Implications
Nurses should continue to educate parents and teachers about bullying. Encourage children to be involved in peer groups. Become actively involved in the local elementary school bullying-prevention program. When bullies are identified, refer them for education in alternative means of emotional expression such as social skills training.

Jensen, J. M., & Dieterich, W. A. (2007). Effects of a skills-based prevention program on bullying and bully victimization among elementary school children. *Prevention Science, 8,* 285–296.

is most important and rigid rules are hard to understand. In children between 8 and 12 years old, the concept of cheating is fully understood. It is usually done because of peer pressure, strong pressure placed on the child to succeed by parents, and a sense of low self-esteem. If cheating persists in older school-age children, parents should discuss the matter with a health care provider because the behavior may indicate underlying problems.

In dealing with children who exhibit stealing, lying, or cheating behaviors, parents must first realize the importance of their own behaviors in those areas. Parents are role models to the school-age child. Therefore, when the child sees or hears that parents lie, steal, or cheat (e.g., parents bragging about cheating on their taxes), they think it is all right to mimic those behaviors. Secondly, parents must directly confront any stealing, lying, or cheating behaviors and discuss (and follow through consistently with) the consequences of such behaviors (see Teaching Guideline 28.2).

Bullying

Bullying, defined as inflicting verbal, emotional, or physical abuse upon others, is on the increase during the school-age years. Bullied children are those who report themselves as being lonely and having difficulty in forming friendships. The children who perform the bullying are those children who are reported to have low self-esteem, poor grades, and poor interpersonal skills.

In general, about 10% of all children attending school are frightened and afraid most of the day. Most of the bullying occurs at school. Both boys and girls are bullied; boys usually bully boys and use force more often. Girls can be bullied by both sexes using mainly social alienation and intimidation. Both girls and boys can bully. Girls are usually the bullies in grades 1 through 3, and boys are typically the bullies in grades 4 and above.

Being bullied can have negative results on children throughout life. These children often have increased episodes of common childhood illnesses of headaches, stomachaches, and sleep problems. After the problem of either being bullied or being the bully has been identified, parents must work with the child, the school, and the health care provider to solve the problem (see Teaching Guidelines 28.2 and Evidence-Based Practice).

Tobacco and Alcohol Education

School-age children are eager to grow up and be independent. Peers and acceptance are very important at this time. School-age children may be exposed to messages that are in conflict with their parents' values regarding smoking and alcohol. Peers often exert pressure for children to experiment with tobacco and alcohol (see Healthy People 2010).

School-age children are ready to absorb information that deals with drugs and alcohol. Information from parents or other adults who are major influences in the child's life is essential at this time to set clear rules and model

HEALTHY PEOPLE 2010

Objective	Nursing Significance
Reduce initiation of tobacco use among children and adolescents.	• Educate children and families about the dangers of tobacco use.

behaviors for children to embrace. Discussions with children need to be based on facts and focused on the present. Some topics for discussion include:

- What alcohol and drugs are like and how they harm you
- Differences in medical use vs. illegal use of drugs
- How to think critically to interpret messages seen in advertising, media, sports, and entertainment personalities

See Teaching Guidelines 28.2.

Recall Lawrence Jones, the 10-year-old presented at the beginning of the chapter. List potential developmental problems he may experience. What anticipatory guidance related to these concerns should you provide to his mother?

Key Concepts

- Physical growth is slow and steady, with social and cognitive development progressing rapidly, during the school-age years of 6 to 12. Height increases approximately 2 inches per year and weight gain is 1½ to 3 kilograms (3 to 6 pounds) per year. Boys are taller and heavier than girls during this time period.
- With the entrance into the school system, school-age children have the influences of peers and teachers.
- With the development of gross motor skills and involvement in sports at school and in the community, safety education and practices are required. Also, with the participation in cooperative sports, injuries occur.
- Visual acuity is reaching maturation and 20/20 vision is expected by 7 years of age.
- Increased independence leads to increased exposure to safety hazards.
- The school-age child develops the cognitive ability to classify objects and to identify relationships among objects.
- Dental care is very important to prevent dental caries, malocclusion, and other problems. In early school age, the first primary teeth will be lost.
- The onset of puberty may occur by the later school-age years.
- Erikson's developmental task for the age group is the development of a sense of industry.
- Peers are very important, especially peers of the same sex. School-age children usually have a best friend and belong to clubs. They have collections of nonvaluable items such as rocks, clips, and so forth.
- School-age children are capable of concrete operations, solving problems, and making decisions. They continue to need guidance, rules, and directions from parents.
- The school-age child develops a conscience and knows cultural and social values. He can understand and obey rules.
- The school-age child incorporates religious practices into her life, which may be a source of comfort during stressful times.
- The nurse's role includes educating parents and school-age children in promoting health and safety.
- Nurses should inform the school-age child about expected developmental changes in the body to promote self-esteem and self-confidence.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The successful resolution of developmental tasks for the school-age child, according to Erikson, would be identified by:
   a. Learning from repeating tasks.
   b. Developing a sense of worth and competence.
   c. Using fantasy and magical thinking to cope with problems.
   d. Developing a sense of trust.
2. Which of the following are reasons that stealing occurs in school-age children? (Choose all that apply)
   a. To escape punishment
   b. High self-esteem
   c. Low expectations of family/peers
   d. Lack of sense of propriety
   e. Strong desire to own something
3. Which activities will promote weight loss in an obese school-age child? (Choose all that apply)
   a. Unlimited computer and TV time
   b. Role modeling by family
   c. Becoming active in sports
   d. Eating unstructured meals
   e. Involving child in meal planning and grocery shopping
   f. Drinking three glasses of water per day
4. As the school nurse conducting screening for vision in a 6-year-old child, you would refer the child to a specialist if the visual acuity in both eyes is:
   a. 20/20
   b. 20/25
   c. 20/30
   d. 20/50
5. The mother of two sons, ages 6 and 9, states they want to play on the same baseball team. As the school nurse, what advice would you give their mother?
   a. Having the boys on the same team will make it more convenient for the mother.
   b. Levels of coordination and concentration differ, so the boys need to be on different teams.
   c. Put the boys on the same team because they are both school-age children.
   d. It is best to avoid putting the boys on the same team to prevent sibling rivalry.

CRITICAL THINKING EXERCISES

1. Ms. Sams brings her 8-year-old son (Frank) to the pediatrician's office for his annual exam. She states that she is concerned about his recent behavior. He went to the grocery store with his friend and his friend's mother and he came home with a Matchbox car. The friend's mother stated she had not purchased the car.
   a. What would be your response to Ms. Sams?
   b. Ms. Sams said she still has the car. What would you advise Ms. Sams to do to make Frank aware of consequences of his actions?
2. Sally's mother is asking the nurse advice about purchasing a 2-wheeled bike for her 7-year-old. What guidance should the nurse offer this parent?
3. Ms. Shaw brings in her 11-year-old daughter for a well-child check. The schoolager says to the nurse, "I look different from my friends. I do not wear bras and my friends are already wearing bras." What would be an appropriate response to this schoolager?
4. Johnny is a 9-year-old whose mother and father both work during the day. He returns home after school. How should the parents prepare Johnny for this experience? What safety rules would be included in the education for Johnny?

STUDY ACTIVITIES

1. Attend a sporting event (such as soccer or baseball) with school-age teams. Describe the coordination and gross motor functioning of this group.
2. Attend a first-grade class. Observe the behaviors exhibited by the school-age children in this class. How do these behaviors compare with normal values for this age group?

CHAPTER 29

GROWTH AND DEVELOPMENT OF THE ADOLESCENT

KEY TERMS

adolescence
adolescent egocentrism
invincibility
menarche
peer groups
puberty
risk-taking behaviors
sexuality

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify normal physiologic changes, including puberty, occurring in the adolescent.
2. Discuss psychosocial, cognitive, and moral changes occurring in the adolescent.
3. Identify changes in relationships with peers, family, teachers, and community during adolescence.
4. Describe interventions to promote safety during adolescence.
5. Demonstrate knowledge of the nutritional requirements of the adolescent.
6. Demonstrate knowledge of the development of sexuality and its influence on dating during adolescence.
7. Identify common developmental concerns of the adolescent.
8. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

Cho Chung is a 15-year-old girl brought to the clinic by her mother for her annual school check-up. During your assessment you measure Cho's weight at 110 pounds and her height at 60 inches. As the nurse caring for her, assess Cho's growth and development, and then provide appropriate anticipatory guidance to her and her mother.

Wow

The only way to grow is to let go . . .

Adolescence spans the years of transition from childhood to adulthood, which is usually between the ages of 11 and 20 years. There is some overlap between late school age and adolescence. The adolescent experiences drastic changes in the physical, cognitive, psychosocial, and psychosexual areas. With this rapid growth during adolescence, the development of secondary sexual characteristics, and interest in the opposite sex, the adolescent needs the support and guidance of parents and nurses to facilitate healthy lifestyles and to reduce **risk-taking behaviors**.

Growth and Development Overview

Adolescence is a time of rapid growth with dramatic changes in body size and proportions. The magnitude of these changes is second only to the growth in infancy. During this time sexual characteristics develop and reproductive maturity is achieved. The age of onset and the duration of the physiologic changes vary from individual to individual. Generally girls enter **puberty** earlier (at 9 to 10 years of age) than boys (at 10 to 11 years). Adolescents will represent varying levels of identity formation and will offer unique challenges to the nurse (Table 29.1).

PHYSIOLOGIC CHANGES ASSOCIATED WITH PUBERTY

The secretion of estrogen in girls and testosterone in boys stimulates the development of breast tissue in girls, pubic hair in both sexes, and changes in male genitalia. These biological changes that occur during adolescence are known as *puberty*. Puberty is the result of triggers among the environment, the central nervous system, the hypothalamus, the pituitary gland, the gonads, and the adrenal glands. Gonadotropin-releasing hormone (GnRH), produced by the hypothalamus, travels to the anterior pituitary gland to stimulate the production and secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH). The increased levels of FSH and LH stimulate the gonadal response. LH stimulates ovulation in girls and acts on testicular Leydig cells in boys, prompting maturation of the testicles and testosterone production. FSH with LH stimulates sperm production. Estrogen, progesterone, and testosterone and other androgens are released from the gonads and affect biological changes and changes in various organs, including alterations in muscles, bones, skin, and hair follicles.

Adolescents experience physical development, hormonal changes, and sexual maturation during puberty

TABLE 29.1 PHYSIOLOGIC CHANGES OF ADOLESCENCE

Stage of Adolescence	Changes in Females	Changes in Males
Early adolescence (11–14 years)	Pubic hair begins to curl and spread over mons pubis; genitalia pigmentation increases. Breast bud and areola continue to enlarge; no separation of breast First menstrual period (average 12.8 years)	Pubic hair spreads laterally, begins to curl; pigmentation increases. Growth and enlargement of testes in scrotum (scrotum reddish in color) and continued lengthening of penis Leggy look due to extremities growing faster than the trunk
Middle adolescence (14–16 years)	Pubic hair becomes coarse in texture and continues to curl; amount of hair increases. Areola and papilla separate from the contour of the breast to form a secondary mound.	Pubic hair becomes coarser in texture and takes on adult distribution. Testes and scrotum continue to grow; scrotal skin darkens; penis grows in width, and glans penis develops. May experience breast enlargement Voice changes; more masculine due to rapid enlargement of the larynx and pharynx as well as lung changes
Late adolescence (17–20 years)	Mature pubic hair distribution and coarseness	Mature pubic hair distribution and coarseness Breast enlargement disappears. Adult size and shape of testes, scrotum, and penis; scrotal skin darkening

that correlate to Freud's genital stage of psychosexual development. The genital stage begins with the production of sex hormones and maturation of the reproductive system.

Girls reach physical maturity before boys and menstruation usually begins between the ages of 9 and 15 years (average 12.8 years). Breast budding (thelarche) occurs at approximately age 9 to 11 years and is followed by the growth of pubic hair. African-American girls reach **menarche** slightly earlier than Caucasian girls (Burns et al., 2004).

The first sign of pubertal changes in boys is testicular enlargement in response to testosterone secretion, usually occurring in Tanner stage 2. As testosterone levels increase, the penis and scrotum enlarge, hair distribution increases, and scrotal skin texture changes. During late puberty, boys will typically experience their first ejaculation, which may occur while they are sleeping (nocturnal emissions). Nurses should provide anticipatory guidance to adolescent males regarding involuntary nocturnal emissions (wet dreams) to assure them that this is a normal occurrence.

Tanner stages 3 to 5 usually occur during adolescence. Refer to Figures 31.28, 31.34, and 31.36 for an illustration of the increase in breast tissue and pubic hair distribution in girls, and scrotal and penile changes as well as hair distribution changes in boys. The nurse should provide guidance to adolescents about the normalcy of the sexual feelings and evolving body changes that occur during puberty.

PHYSICAL GROWTH

Diet, exercise, and hereditary factors influence the height, weight, and body build of the adolescent. Over the past three decades, adolescents have become taller and heavier than their ancestors and the beginning of puberty is earlier. During the early adolescent period, there is an increase in the percentage of body fat and the head, neck, and hands reach adult proportions.

The rapid growth during adolescence is secondary only to that of the infant years and is a direct result of the hormonal changes of puberty. Both girls and boys experience changes in appearance and size. Height in girls increases rapidly after menarche and usually ceases 2 to 2½ years after menarche. Boys' growth spurt occurs later than girls' and usually begins between the ages of 10½ and 16 years and ends sometime between the ages of 13½ and 17½ years. Peak height velocity (PHV) occurs at approximately 12 years of age in girls or at about 6 to 12 months after menarche. Boys reach PHV at about 14 years of age. Peak weight velocity (PWV) occurs about 6 months after menarche in girls and at about 14 years of age in boys. Muscle mass increases in boys and fat deposits increase in girls (Fig. 29.1).

During early adolescence growth is rapid, but it decreases in middle and late adolescence. Height for adolescent boys who are between the 50th and 95th percentile ranges from 52½ inches (132 centimeters) to 69½ inches (176.8 centimeters). Weight of boys in these percentiles ranges from 77¼ pounds (35.3 kilograms) to 211 pounds

FIGURE 29.1 These adolescents reflect the differences in sizes and shapes seen in adolescents of the same age.

(95.76 kilograms). On average, boys will gain 10 to 30 centimeters (4 to 12 inches) in height and 7 to 30 kilograms (15 to 65 pounds) in weight.

Height for girls who are between the 50th and 95th percentile ranges from 57 inches (144.8 centimeters) to 68½ inches (173.6 centimeters), with weight ranging from 60 pounds (27.24 kilograms) to 181 pounds (82.47 kilograms). On average, girls will gain 5 to 20 centimeters (2 to 8 inches) in height and 7 to 25 kg (15 to 55 pounds) in weight during adolescence. See Appendix A for growth charts for this age group. Refer to Chapter 31 for instructions for calculating body mass index (BMI).

ORGAN SYSTEM MATURATION

Adolescence is a time of metabolic slowing and of increasing size of some organs. The basal metabolic rate (BMR) reaches the adult level during late adolescence.

Neurologic System

During adolescence there is continued brain growth although the size of the brain does not increase significantly. Neurons do not increase in number, but growth of the myelin sheath enables faster neural processing.

Respiratory System

The adolescent years see an increase in diameter and length of the lungs. Respiratory rate decreases and reaches the adult rate of 15 to 20 breaths per minute. Respiratory volume and vital capacity increase. Volume and capacity are greater in boys than girls, which may be associated with increased chest and shoulder size in boys. The growth of the laryngeal cartilage, larynx, and vocal cords produces the voice changes experienced in adolescence. Deepening of both male and female voices occurs but is more pronounced in boys (Edelman & Mandle, 2006).

Cardiovascular System

There is an increase in size and strength of the heart. Systolic blood pressure increases and heart rate decreases. Blood volume reaches higher levels in boys than girls, which may be due to boys' greater muscle mass.

Gastrointestinal System

The adolescent has a full set of permanent teeth with the exception of the last four molars (permanent teeth) which may erupt at age 17 to 20 years. The liver, spleen, kidneys, and digestive tract enlarge during the growth spurt in early adolescence, but do not change in function. These systems are mature in early school age.

Musculoskeletal System

The ossification of the skeletal system is incomplete until late adolescence in boys. Ossification is more advanced in girls and occurs at an earlier age. During the growth spurt, muscle mass and strength increase. At similar stages of development, muscle development is generally greater in boys. Estrogen, progesterone, and testosterone (sex steroids) and other androgens are released from the gonads and affect changes in the muscles and bones. Low estrogen levels tend to stimulate skeletal growth, while higher levels inhibit growth. During middle adolescence, shoulder, chest, and hip breadth increase.

Integumentary System

During adolescence the skin becomes thick and tough. Under the influence of androgens, the sebaceous glands become more active, particularly on the face, back, and genitals. Due to the increased levels of testosterone during Tanner stages 4 and 5 in both boys and girls, both sexes may have increased sebum production, which may lead to the development of acne and oily hair.

The exocrine and apocrine sweat glands function at adult levels during adolescence. The exocrine glands are all over the body and they produce sweat that helps to eliminate body heat through evaporation. The apocrine glands are found in the axillae, genital, and anal areas, and around the breasts. The apocrine sweat glands produce sweat in response to hair follicles. This sweat is produced continuously and is stored and released in response to emotional stimuli.

PSYCHOSOCIAL DEVELOPMENT

According to Erikson, it is during adolescence that teenagers achieve a sense of identity. As the adolescent is trying out many different roles in regard to his relationships with peers, family, community, and society, he is developing his own individual sense of self. If he is not successful in forming his own sense of self, he develops a sense of role confusion or diffusion. The adolescent culture becomes very important to the teenager. It is through his involvement with teenage groups that the adolescent finds support and help with developing his own identity.

Erikson believed that during the task of developing his own sense of identity, the adolescent revisits each of the previous stages of development. The sense of trust is encountered as the adolescent strives to find out whom and what ideals he can have faith in. In revisiting the stage of autonomy, the adolescent is seeking out ways to express his individuality in an effective manner. He would avoid behaviors that would "shame" or ridicule him in front of

his peers. The sense of initiative is revisited as the adolescent develops his vision for what he might become. And the sense of industry is again encountered as the adolescent makes his choice to participate in different activities at school, in the community, at church, and in the work force.

The ability of the adolescent to successfully form a sense of self is dependent upon how well the adolescent successfully completed the former stages of development. Erikson believed that if the adolescent has been successful, he could develop resources during adolescence to overcome any gaps in previous developmental stages. If the adolescent believes that he cannot express himself in any manner due to societal restrictions, he will develop role confusion. See Table 29.2 for additional information.

TABLE 29.2 DEVELOPMENTAL THEORIES

Theories	Stages	Activities
Erikson (psychosocial)	Identity vs. role confusion or diffusion Early (11–14 years)	Focuses on bodily changes Experiences frequent mood changes Importance placed upon conformity to peer norms and peer acceptance Strives to master skills within peer groups Defining boundaries with parents and authority figures Early stage of emancipation—struggles to separate from parents while still desiring dependence upon them Identifies with same-sex peers Takes more responsibility for own behaviors
	Middle (14–16 years)	Continues to adjust to changed body image Tries out different roles within peer groups Need for acceptance by peer group at the highest level Interested in attracting opposite gender Time of greatest conflict with parents/authority figures Able to understand implications of behavior and decisions
	Late (17–20 years)	Roles within peer groups established Feels secure with body image Has matured sexual identity Has idealistic career goals Importance of individual friendships emerges Process of emancipation from family almost complete
Piaget (cognitive)	Formal Operations Early (11–14 years)	Limited abstract thought process Egocentrically thinking Eager to apply limited abstract process to different situations and to peer groups
	Middle (14–17 years)	Increased ability to think abstractly or in more idealistic terms Able to solve verbal and mental problems using scientific methods Thinks he or she is invincible—risky behaviors increase Likes making independent decisions Becomes involved/concerned with society, politics
	Late (17–20 years)	Abstract thinking is established Develops critical thinking skills—tests different solutions to problems Less risky behaviors Develops realistic goals and career plans
Kohlberg	Postconventional Level III Early (11–14 years)	Morals based upon peer, family, church, and societal morals Asks broad, usually unanswerable questions about life
	Middle (14–17 years)	Developing own set of morals—evaluates individual morals in relation to peer, family, and societal morals
	Late (17–20 years)	Internalizes own morals and values Continues to compare own morals and values to those of society Evaluates morals of others

COGNITIVE DEVELOPMENT

According to Piaget, the adolescent progresses from a concrete framework of thinking to an abstract one. It is the formal operational period. During this period, the adolescent develops the ability to think outside of the present; that is, he or she can incorporate into thinking concepts that do exist as well as concepts that might exist. Her thinking becomes logical, organized, and consistent. She is able to think about a problem from all points of view, ranking the possible solutions while solving the problem. Not all adolescents achieve formal operational reasoning at the same time.

In the early stages of formal operational reasoning, the adolescent's thinking is egocentric. She is very idealistic, constantly challenging the way things are and wondering why things cannot change. These activities lead to the adolescent's feeling of being omnipotent. The adolescent must undergo this way of thinking, even though it can frustrate adults, in her quest to reach formal operational reasoning. As the teenager progresses towards middle adolescence, her thinking becomes very introspective. She assumes others are just as interested in what interests her, which leads her to feel unique, special, and exceptional. That feeling of "being exceptional" leads to the risk-taking behaviors of which teenagers are well known. Also, the teenager feels very committed to her viewpoints. She tries very hard to convince others of her viewpoints and embraces strongly those causes that support her opinions. This idealism can cause the adolescent to reject her family, her culture, her church, and her community beliefs, which can cause conflict with her family, culture, church, and community. See Table 29.2 for additional information.

MORAL AND SPIRITUAL DEVELOPMENT

It is during the adolescent years that teenagers develop their own set of values and morals. According to Kohlberg, adolescents are experiencing the postconventional stage of moral development. It is only because adolescents are developing their formal operational way of thinking that they can experience the postconventional stage of moral development. At the beginning of this stage, teenagers begin to question the status quo. The majority of their choices are based upon emotions while they are questioning societal standards. As they progress to developing their own set of morals, adolescents realize that moral decisions are based upon rights, values, and principles that are agreeable to a given society. They also realize that those rights, values, and principles can be in conflict with the laws of the given society, but they are able to reconcile the differences. Because adolescents undergo the process of developing their own set of morals at different rates, they might find that their friends view a situation differently. This difference can lead to conflicts and the forming of different friendships. See Table 29.2 for additional information.

Adolescents also begin to question their formal religious practices. As they progress through adolescence, teenagers become more interested in the spiritualism of their religion than in the actual practices of their religion. As teenagers become older, organized religion becomes less important in their lives; rather, their religious beliefs become more personalized.

Referring back to Cho Chung, identify the stage of psychosocial development that she should be in according to Erikson. What approaches for assessment and teaching would be most effective based on the stage you identified?

MOTOR SKILL DEVELOPMENT

During adolescence, the teenager refines and continues to develop his or her gross and fine motor skills. Because of this period of rapid growth spurts, teenagers may experience times of decreased coordination and have a diminished ability to perform previously learned skills, which can be worrisome for the teenager.

Gross Motor Skills

It is usually during early adolescence that teenagers begin to develop endurance. Their concentration has increased so they can follow complicated instructions. Coordination can be a problem because of the uneven growth spurts. During middle adolescence, speed and accuracy increase while coordination also improves. Teenagers become more competitive with each other (Fig. 29.2). During late adolescence, the teenager usually

FIGURE 29.2 Adolescents become involved in competitive sports, which draw upon their gross motor skills.

FIGURE 29.3 Using computers has increased the fine motor skills of adolescents.

narrows his or her areas of interest and concentrates on the needed relevant skills.

Fine Motor Skills

The use of computers has greatly increased the fine motor skills of teenagers (Fig. 29.3). In the early adolescent years, the teenager increases his ability to manipulate objects. His handwriting is neat and he increases his finger dexterity. The middle adolescent years see the teenager refining his dexterity skills. By late adolescence, the teenager has developed precise eye–hand coordination and finger dexterity.

COMMUNICATION AND LANGUAGE DEVELOPMENT

Language skills continue to develop and be refined during adolescence. During early adolescence, verbal vocabulary is close to 8,000 words and reading vocabulary is over 50,000 words. Adolescents have improved communication skills, using correct grammar and parts of speech. Vocabulary and communication skills continue to develop during middle adolescence. However, the usage of colloquial speech (slang) increases, causing communication with people other then peers to be difficult at times. By late adolescence, language skills are comparable to those of adults.

EMOTIONAL AND SOCIAL DEVELOPMENT

Adolescents undergo a great deal of change in the areas of emotional and social development as they grow and mature into adults. Areas that are affected include the adolescent's relationship with parents; self-concept and body image; importance of peers; and **sexuality** and dating.

Relationship With Parents

Families and parents of adolescents experience changes and conflict that require adjustments and the understanding of adolescent development. The adolescent is striving for self-identity and increased independence. He or she spends more time with peers and less time with family and attending family functions. Parents sense that they have less influence on the adolescent as the teen questions family values and becomes more mobile. This may lead to a family crisis, and the parents may respond by setting stricter limits or asking questions about the teen's activities and friends. Other parents may drop all rules and assume that the adolescent can manage herself. Both of these responses increase tension in the family.

With the adolescent attempting to establish some level of independence—and the family learning to let go while focusing on aging parents, their marriage, and other children—a state of disequilibrium occurs. The family may experience more stress than at any other time.

Some families have better outcomes with their adolescents than others. Families who listen to and continue to demonstrate affection for and acceptance of their adolescent have a more positive outcome. This does not mean that the family accepts all of the teen's ideas or actions, but they are willing to listen and attempt to negotiate some limits. For tips to improve communication with teenagers, see Box 29.1.

Siblings experience changes in the relationship with the adolescent brother or sister; the older sibling may attempt to parent and the younger sibling may regress in an attempt to avoid the family conflict. Understanding the

BOX 29.1 Ways to Improve Communication with Teens

- Set aside appropriate amount of time to discuss subject matter without interruptions.
- Talk face to face. Be aware of body language.
- Ask questions to see why he feels that way.
- Ask her to be patient as you tell your thoughts.
- Choose words carefully so he understands you.
- Tell her exactly what you mean.
- Give praise and approval to your teenager often.
- Speak to him as an equal—don't talk down to him.
- Be aware of your tone of voice and body language.
- Don't pretend you know all the answers.
- Admit that you do make mistakes.
- Rules and limits should be set fairly.

status of the adolescent–family relationship is essential for the nurse.

Self-Concept and Body Image

Self-concept and self-esteem are tied to body image many times. Adolescents who perceive their body as being different than peers or as less than ideal may view themselves negatively. Adolescent girls often are influenced by peers and the media and want to weigh less and have smaller hips, waist, or thighs. Boys tend to view themselves as being too thin or not muscular enough.

Sexual characteristics are important to the adolescent's self-concept and body image. Boys are concerned about the size of their penis and facial hair while girls are concerned about breast size and the onset of menstruation. Larger breasts are considered more feminine and menstruation is considered the right of passage into adulthood. All of these body changes are important to the adolescent's self-concept.

Importance of Peers

Peer groups play an essential role in the identity of the adolescent. Adolescent peer relationships are very important in providing opportunities to learn about negotiating differences; for recreation, companionship, and someone to share problems with; for learning peer loyalty; and for creating stability during transitions or times of stress. Learning to work out differences with peers is a skill that is important throughout life. Peers serve as someone safe to discuss family issues with, as the teen emotionally moves away from the family while trying to find his or her identity. Due to changes that have taken place within family systems in society, peer groups play a significant role in the socialization of adolescents (Fig. 29.4).

Peers serve as credible sources of information, role model social behaviors, and act as sources of social reinforcement. Friends provide an opportunity for fun and excitement. Peers impact teens' appearance, dress, social behavior, and language. Peers also can have positive influences on each other, such as promoting college attendance, or negative influences such as involvement with alcohol, drugs, or gangs. Early and middle adolescence are periods when teens are prone to join gangs. Peer role modeling and peer acceptance may lead to the formation of a gang that provides a collective identity and gives a sense of belonging. Peer pressure, companionship, and protection are the most frequent reasons given for joining gangs, particularly those associated with criminal activity.

Parents must know their teen's friends and continue to be aware of potential problems while allowing the teen the independence to become his or her own person. Nurses must remind parents of the importance of peers and the impact they have on the teen's decisions and life choices. The transition to greater peer involvement requires guidance and support. Adolescents who do not have parental or adult supervision and opportunities for conversation with adults may be more susceptible to peer influences and at higher risk for poor peer selections.

Sexuality and Dating

Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors related to the adolescent's sexual identity. Adolescents usually begin experimentation with heterosexual and homosexual behaviors, although these behaviors may occur earlier in some cultures.

An interest in the opposite sex occurs during adolescence (Fig. 29.5). Some of the reasons cited for this devel-

FIGURE 29.4 Peers play an important role in shaping the adolescent's identity.

FIGURE 29.5 Dating becomes an important aspect of the teenager's life.

oping interest are physical development and body changes, peer-group pressure, and curiosity. During the past several decades, the age of beginning to date in the United States has dropped. Girls are between 14 and 15 years old, and boys are 15 to 16 years old. Teen dating can range from group dating to single dating to serious relationships. Most early adolescents spend more time in activities with mixed-sex groups, such as dances and parties, than they do dating as a couple. Popular dating activities today include going out to dinner or the movies, "hanging out" at the mall, or visiting each other's home. During early adolescence, teens tend to date for fun and recreation. Also, they may see dating as a way to upgrade social standing by being seen with a popular boy or an attractive girl.

Middle and late adolescents have group and single dates. Most teens have been involved in at least one romantic relationship by middle adolescence (O'Sulliven et al., 2007). Dating or spending time with a potential romantic partner is viewed as a major developmental marker for teens and is one of the most challenging adjustments. Teens who date frequently report more depression and lower levels of autonomy, and experience a higher level of parental conflict even though they have been found to have higher levels of self-esteem and are classified as more popular.

Trends in dating are changing, but dating remains a developmental milestone for the adolescent.

Adolescents may experiment with homosexual behavior, though homosexual behavior as a teen does not necessarily indicate that the adolescent will maintain a homosexual orientation. Gay and lesbian adolescents face many challenges due to society's nonacceptance and peer insensitivity. Teens who self-declare as homosexual during high school are at increased risk for such problems as suicide, victimization, risky sexual behaviors, and substance abuse.

Of greatest concern to parents during the adolescent period of developing sexuality and dating are unwanted pregnancy, sexually transmitted infections (STIs), and teen feelings of despair over failed relationships. Many times adolescents are not worried about negative consequences of sexual activity and believe "it will not happen to me."

Cho Chung's mother states that she is concerned about the changes that have occurred in her and Cho's relationship over the past year. Cho seems much more self-centered, always wants to be with her friends, is very critical of her mother and father and seems to be constantly in conflict with them. Based on what you know about this stage of development, what guidance, including approaches and techniques, can you discuss with Mrs. Chung to address her concerns?

CULTURAL INFLUENCES ON GROWTH AND DEVELOPMENT

Although the adolescent's culture continues to influence the teenager, the desire to be in harmony with peers becomes paramount. That desire can cause conflict with his family and culture. Today's adolescents live in a rapidly changing, increasingly culturally diverse world. They are exposed to many different cultures and ethnic groups. In 2006, over 40% of children and adolescents in the United States will be minorities (Federal Interagency Forum on Child and Family Statistics, 2007).

Attitudes regarding adolescence vary among different cultures. Certain cultures may have more permissive attitudes toward issues facing adolescents, while others are more conservative, for example towards sexuality. Experiencing a rite of passage ceremony to signal the adolescent's movement to adult status varies among cultures. The American culture does not universally have a rite of passage for teenagers. Some religious and social groups do have ceremonies that signal a movement toward the maturity of adulthood, for example, the Jewish bar or bat mitzvah, the Catholic confirmation, and social debuts. In many parts of the world, separate "youth cultures" have developed in an attempt to blend traditional and modern worlds for the adolescent.

It is important for the nurse to recognize the ethnic background of each client. Research has shown that certain ethnic groups are at higher risk for certain diseases. For example, adolescent African-Americans are at higher risk for developing hypertension. But the major barrier to the adolescent's health and successful achievement of the tasks of adolescence is socioeconomic status. Adolescents at a lower socioeconomic level are at higher risk for developing health care problems and risk-taking behaviors; this may be due to their inability to access health care and to obtain needed services. In caring for adolescents, recognize the influence of their culture, ethnicity, and socioeconomic level upon them.

The Nurse's Role in Adolescent Growth and Development

During adolescence, the teenager faces many challenges. His or her fluctuating relationships with parents and other adult figures may limit the teen from seeking assistance in dealing with the common issues of adolescence. In dealing with adolescents, be aware that they behave unpredictably, are inconsistent with their need for independence, have sensitive feelings, may interpret situations differently from what they are, think friends are extremely important, and have a strong desire to belong. The following Nursing Process Overview will address promoting healthy growth and development and dealing with common developmental concerns.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the adolescent's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development
- Risk for caregiver role strain
- Risk for injury
- Ineffective coping

Nursing care planning for the adolescent with growth and development issues should be individualized based on the adolescent's and family's needs. Nursing Care Plan 29.1 can be used as a guide in planning nursing care for the adolescent with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from this plan and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

PROMOTING HEALTHY GROWTH AND DEVELOPMENT

WATCH & LEARN

It takes multiple groups who address multiple issues to promote healthy growth and development in the adolescent. Some of these groups include sports teams in the school or the community, peers, teachers, band and choir members, and so forth. Also, the family's support and love will influence growth and development.

Promoting Growth and Development Through Sports and Physical Fitness

Many adolescents are involved in team sports that provide avenues for exercise. High levels of physical activity may reduce cardiovascular disease risk factors during adolescence. Adolescents probably spend more time and energy participating in sports than any other age group. Participation in sports contributes to the adolescent's development, educational process, and better health. Sports and games provide an opportunity to interact with peers while enjoying socially accepted stimulation and conflict. Competition in sports activities helps the teenager in processing self-appraisal and in developing self-respect and concern for others.

Every sport has some potential for injury. Rapidly growing bones, muscles, joints, and tendons are more vulnerable to unusual strains and fractures (see Evidence-Based Practice 29.1). The American Academy of Pediatrics (2006) encourages sports participation by young persons and encourages parents and coaches to be aware of early warning signs of fatigue, dehydration, and injury. See Chapter 44 for a discussion of sports injuries.

In relation to youth sports, the role of the nurse is to educate to prevent injuries (Fig. 29.6). This education should include discouraging participation when the teen is tired or has an existing injury.

Additionally, adolescence is a good time to develop an exercise program, with aerobic exercise at least 30 minutes per day, four times per week. Nurses should encourage all adolescents to be physically active daily or at least four times per week.

Promoting Learning

School, teachers, family, and peers influence education and learning for the adolescent. Also, activities such as athletics and club membership enhance learning through interactions with peers, coaches, club leaders, and others.

School

School plays an essential part in preparing adolescents for the future. Completing school prepares the adolescent for college or employment to make an adequate income. Schools in the United States may not meet the developmental needs of all adolescents. Minority students may not be at the appropriate grade level and the dropout rate may be higher than in nonminority students. Dropout rates are highest among Hispanic and American Indian students. Another influencing factor is a lack of parental involvement. Due to single parent families and both parents being in the work force, parents have less time to devote to involvement in their child's school activities.

There is evidence that the transition from elementary school to middle school at age 12 or 13, and then the transition to high school, both occur at the time of physical changes, which may have a negative effect on teens. It is important to observe for transition problems into middle or high school, which may be exhibited by failing grades or behavior problems. Also, students who experience difficulties in school, resulting in negative evaluations and failing grades, may feel alienated from school. Students with failing grades and those repeating grades exhibit more emotional behavior and are more likely to engage in risky behaviors such as tobacco and alcohol use. In 2003, 9% of adolescent boys and 3% of adolescent girls reported carrying a weapon to school (CDC, 2004b). Schools that support peer-group relationships, promote health and fitness, encourage parental involvement, and strengthen community relationships have better student outcomes. Parents, teachers, and health care providers should provide guidance and support.

Nursing Care Plan 29.1

GROWTH AND DEVELOPMENT OF THE ADOLESCENT

NURSING DIAGNOSIS: Risk for disproportionate growth (risk factors: caregiver and adolescent knowledge deficit, low self-esteem, frequent illnesses)

Outcome Identification and Evaluation

Adolescent will demonstrate adequate growth: *appropriate weight gain for age and sex*

Intervention: Promoting Appropriate Physical Growth

- Assess parents' and adolescent's knowledge of nutritional needs of adolescents *to determine need for further education.*
- Educate parents and adolescent about appropriate serving sizes and foods *so that they are aware of what to expect for adolescents.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Assess for risk factors for developing eating disorder *to refer to if needed and plan interventions.*

NURSING DIAGNOSIS: Nutrition, more than body requirements, imbalanced, related to lack of exercise, increased caloric intake, poor food choices, and stresses of adolescence

Outcome Identification and Evaluation

Adolescent will lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and sex*

Intervention: Promoting Appropriate Nutrition

- Assess knowledge of parents and adolescent about nutritional needs of teenagers *to determine deficits in knowledge.*
- Have adolescent keep a detailed food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview family in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Discuss changes in a positive manner—talk about developing healthy eating habits instead of dieting *to promote compliance.*
- Analyze preceding data, and base recommendations for changes on these data *to promote compliance and to prioritize recommendations.*
- Discuss ways to decrease temptation to overeat, for example, eat slowly, put down the fork between bites, serve food on smaller plates, and count mouthfuls *to allow time to realize that you are full.*
- Have adolescent create meal plans and grocery shop *to allow him or her some sense of control and decision-making.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement to *increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Encourage peer exercise activities *to increase peer interactions and to help teen to realize that others are like him or her.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight loss program for adolescents *to increase self-esteem and encourage weight loss.*

NURSING DIAGNOSIS: Growth and development, delayed, related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

Outcome Identification and Evaluation

Development will be maximized: Adolescent will make continued progress toward attainment of expected school performance.

Interventions: Promoting Growth and Development

- Perform scheduled evaluation of the adolescent by school and health care provider *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings *to be able to adapt interventions as soon as possible.*

(continued)

Nursing Care Plan 29.1 (continued)

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: knowledge deficit about adolescent issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for an adolescent*

Interventions: Preventing Caregiver Role Strain

- Assess parent's knowledge of adolescents and the issues that arise as a part of normal development *to determine parent's needs.*
- Provide education on normal issues of adolescence *so that parents are armed with the knowledge they need to appropriately care for their adolescents.*
- Provide anticipatory guidance related to upcoming expected issues related to adolescent development *to prepare parents for what to expect next and how to intervene in an appropriate manner.*

NURSING DIAGNOSIS: Injury, risk for (risk factors: increased motor and cognitive skills and feeling of invincibility)

Outcome Identification and Evaluation

Adolescent's safety will be maintained: *will remain free from injury*

Interventions: Preventing Injury

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, and water *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending upon age, sex, and maturity of adolescent *to prevent possible injury.*
- Teach parents and adolescent first-aid measures and cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers upon actions of adolescents *to prevent possible injury due to mimicking behavior.*

NURSING DIAGNOSIS: Coping, ineffective, risk for (risk factors: low self-esteem, poor relationship with parents and peers, participating in risk-taking behaviors)

Outcome Identification and Evaluation

Adolescent will demonstrate adequate coping abilities *as evidenced by management of stress of adolescence and no evidence of participating in risk-taking behaviors.*

Interventions: Promoting Effective Coping

- Assess adolescent's knowledge of normal stress facing teenagers *to determine current knowledge.*
- Assess adolescent's present coping skills *to determine areas for improvement/support.*
- Encourage parents to accept teenager as a unique individual.
- Discuss with parents and adolescent normal developmental issues facing teens *to give them knowledge needed to cope.*
- Provide different situations the teen might be faced with and encourage teen to develop different solutions.
- Allow for increasing independence and opportunities to solve own problems *to improve coping skills.*
- Encourage parents to provide unconditional l*ove to improve self-esteem.*
- Assess for any evidence of any risk-taking behaviors (drugs, smoking, suicide) *to identify need for early interventions.*

Other Activities

Adolescents are involved in many other activities that influence learning. Some of these activities include: (1) school activities such as band, choir, or clubs requiring high achievement; (2) athletic activities in the school and community and sometimes in the state or region; (3) art, sewing, and building classes; and (4) work activities when the late adolescent may have a part-time job.

Promoting Safety

Unintentional and intentional injuries are the leading causes of death in persons in the United States under 35 years of age (Minoño, Heron, & Smith, 2006). "At least one adolescent (10 to 19 years of age) dies of an injury every hour of every day," resulting in about 15,000 such deaths each year. Injuries kill more adolescents than

FIGURE 29.6 Stretching before exercise is an important part of exercise.

all diseases combined. Unintentional injury accounts for about 60% of adolescent injury deaths, while violence (homicide and suicide) accounts for the remaining 40%. Males are more likely than females to die of any type of injury (CDC, 2004b).

Influencing factors related to the prevalence of adolescent injuries include increased physical growth; insufficient psychomotor coordination for the task; abundance of energy; impulsivity; peer pressure; and inexperience. Impulsivity, inexperience, and peer pressure may place the teen in a vulnerable situation between knowing what is right and wanting to impress peers. On the other hand, teens have a feeling of invulnerability, which may contribute to negative outcomes. Alcohol and other drugs are contributing factors in automobile and firearm accidents among adolescents. Most of the serious or fatal injuries in adolescents are preventable (Fig. 29.7). Nurses must educate parents and adolescents on car, gun, and water safety to prevent unintentional injuries. See Teaching Guideline 29.1 for information on promoting safety.

HEALTHY PEOPLE 2010

Objective	Significance
Increase high-school completion.	• Encourage school attendance and completion when encountering teens for well-child or sick visits. • Refer children who have difficulty concentrating or learning for further evaluation. • Praise school accomplishments.

Motor Vehicle Safety

The largest numbers of adolescent injuries are due to motor vehicle crashes. When the adolescent passes his or her driving test, he or she is able to drive legally. However, driving is complex and requires judgments that the teen is often incapable of exhibiting. Also, the typical adolescent

EVIDENCE-BASED PRACTICE 29.1
Interventions Directed Toward Prevention of Ankle Ligament Injury or Sprain

● Study

Adolescents are increasingly involved in organized sports that put them at risk for injury. Soccer and basketball, in particular, result in a very high incidence of ankle injuries, and ankle sprains are very commonly treated in acute care. Inversion of the plantar-flexed foot is the most common mechanism of ankle injury resulting in damage to the lateral ligament complex. The authors analyzed 14 randomized or quasi-randomized trials that included data for a total of 8,279 participants. The intervention evaluated included use of modified footwear (high-top athletic shoes), external ankle supports, coordination training, and health education. The study evaluated the occurrence as well as the recurrence of ankle sprains.

▲ Findings

Ankle coordination and strength training may be beneficial in the prevention of ankle sprains, but the results from the included studies were not powerful. However, the review provided sufficient evidence that the use of semi-rigid orthoses reduces the risk of ankle sprain in the young athlete and adult. Use of these devices was shown to be particularly helpful in preventing reinjury of the ankle.

■ Nursing Implications

Nurses should recommend the use of semi-rigid ankle orthoses to adolescent athletes participating in sports such as soccer and basketball. Although physical conditioning of the ankle was not decisively proved to decrease the risk of ankle injury, it was not proved to be harmful so it should still be encouraged in student athletes. Exercises designed to improve coordination and proprioception should be included. At a minimum, adolescent athletes participating in high-risk sports should wear high-top athletic shoes in order to provide some protection against the occurrence of ankle injury.

Handoll, H. H. G., Rowe, B. H., Quinn, K. M., & de Bie, R. (2007). Interventions for preventing ankle ligament injuries. *The Cochrane Library 2007, 4.*

FIGURE 29.7 Wearing appropriate safety equipment can prevent injuries.

is opposed to authority and is interested in showing peers and others his or her independence. The Youth Risk Behavior Surveillance Survey of high school students found that 16.4% had rarely worn seat belts, and over 33% had ridden with a driver who was drinking alcohol. Adolescents who drive after drinking are more likely than adults to have a crash. Adolescents are also vulnerable to crashes at night. Adolescents do most of their driving at night and have over 50% of their accidents then. Adolescents also cause a disproportionate number of deaths among other passengers and pedestrians (National Highway Traffic Safety Association, n.d.).

It is essential to promote driver education, to teach about the importance of wearing seat belts, and to explain laws about teen driving and curfews (Fig. 29.8). See Teaching Guidelines 29.1 for additional information.

Firearm Safety

The risk of dying from a firearm injury among 15- to 19-year-olds has increased by 77% since 1985. In this age group, a firearm causes one in four deaths. Provide education about gun safety. Guns in the home must be kept and locked in a safe location, with ammunition kept separately. Parents must teach adolescents about the dangers

TEACHING GUIDELINES 29.1

Promoting Safety

Safety Issue	Activity
Motor vehicle	• Wear seat belt at all times. • Do not drive with someone who is impaired. • Take driver-education course. • Establish driving rules between parent and adolescent prior to getting license. • Have all passengers wear seat belts. • Do not use cell phone while driving, drink and drive, or drive when tired. • Maintain car in good condition. • Drive with adult supervision for period of time after receiving license.
Bike: General	• Have a well-maintained and appropriate-size bike for adolescent. • Adolescent should demonstrate his or her ability to ride bike safely before being allowed to ride on street. • Safe areas for bike riding should be established as well as routes to and from area of activities. • Should not ride bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike. • Should wear sturdy, well-fitting shoes and ANSI-approved helmets. • Bike should be inspected often to ensure it is in proper working order. • A basket should be used to carry heavy objects.
Bike: in traffic	• All traffic signs and signals must be observed. • If riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes. • Should ride on the side of the road traveling with traffic and keep close to the side of the road in single file. • Should watch and listen for cars and never hitch a ride on any vehicle. • Should not wear headphones while riding a bike.

TEACHING GUIDELINES 29.1 (continued)

Promoting Safety

Safety Issue	Activity
All-terrain vehicles	• Should not be operated by adolescent less than 16 years of age. • Helmet and protective coverings required. • No nighttime riding. • Not for use on public roads or if teen has been drinking or using drugs. • Do not stand up in the vehicle or ride in a person's lap.
Skateboards/Skates	• Wear helmet, and protective padding on knees, elbows, and wrists. • Do not skate in traffic or on streets or highways. • Skating on homemade ramps could be dangerous—assess ramps for any hazards before skating.
Water safety	• Learn how to swim; if swimming skill is limited, must wear life preserver at all times. • Never swim alone—should, if at all possible, swim only where there is a life guard. • Learn basic cardiopulmonary resuscitation (CPR). • Do not run or fool around at edge of pool. • Drains in pool should be covered with appropriate cover. • Wear life jacket when on boat. • Make sure there is enough water to support diving. • Do not swim if drinking alcohol or using drugs.
Firearms	• If guns are in household, should take firearm safety class, secure guns in safe place, use gun safety locks, store bullets in separate place. • Never point a gun at a person.
Fire safety	• All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year. • Have fire-escape plan and practice the plan routinely. • No smoking in bed. • Teach what to do in case of a fire: use fire extinguisher, call 911, and how to put out clothing fire. • All flammable materials and liquids should be stored safely. • Fireplaces should have protective gratings. • Avoid touching any downed power lines.
Machinery	• Use safety devices. • Receive training on how to use equipment. • Do not use when alone.
Sports	• Match sport to adolescent's ability and desire. • Sports program should have warm-up procedure and hydration policy. • Undergo sports physical before start of activity. • Coaches should be trained in CPR and first aid. • Wear appropriate protection devices for individual sport.
Sun	• Use sunscreen with both ultraviolet A (UVA) and ultraviolet B (UVB) protection. • Apply sunscreen prior to going out and reapply sunscreen often. • Limit sun exposure, especially between 10 a.m. and 2 p.m. • Wear hat and sunglasses while outside.
Personal safety	• Never go with a stranger. • Do not enter a car when the driver has been drinking. • Notify adult where you are when out after dark. • Keep cell phone fully charged. • Never give out personal information over the Internet. • Say "no" to drugs, alcohol, smoking, or to being touched when you do not want to be touched.
Toxins	• Teach the hazards of accepting illegal drugs, alcohol, dangerous drugs. • Store potential dangerous material in safe place.

FIGURE 29.8 The use of seat belts has led to fewer fatal injuries in car accidents.

of playing with firearms. See Teaching Guidelines 29.1 for additional information on gun safety.

Water Safety

Drowning is a needless cause of death in adolescents. Many drownings are a result of risk-taking behaviors. With the independence of the adolescent, many times adult supervision is not prevalent and the teen takes a dare that results in drowning. Provide water safety education and proper supervision to decrease the incidence of risk taking. Teach about swimming lessons for nonswimmers. See Teaching Guidelines 29.1 for additional information.

Remember Cho Chung, the 15-year-old presented at the beginning of the chapter? What anticipatory guidance related to safety should you provide to Cho and her mother?

Promoting Nutrition

Nutritional needs are increased during adolescence due to accelerated growth and sexual maturation. Adolescents may appear to be hungry constantly and need regular meals and snacks with adequate nutrients to meet the body's anaerobic requirements. Multiple factors influence the adolescent's diet and eating habits (Box 29.2). According to Centers for Disease Control and Prevention (CDC) data, 67% of children between 6 and 19 years of age exceed the dietary guidelines recommended for fat intake; 72% exceed recommendations for saturated fat; and only 21% of high school students eat the five recommended daily servings of fruits and vegetables. Due to this, over 9 million children and adolescents are overweight. In 6- to 11-year-olds, the number of children who are overweight has doubled in the past 20 years. In 12- to 19-year-olds, the obesity rate has tripled over the same period of time.

BOX 29.2 Factors Influencing the Adolescent's Diet

- Peer pressure
- Busy schedules
- Concern about weight control
- Convenience of fast food

Nutritional Needs

Teenagers have a need for increased calories, zinc, calcium, and iron for growth. However, the number of calories needed for adolescence depends on the teen's age and activity level as well as growth patterns. Teenage girls who are active require about 2,200 calories per day. Teenage boys who are active require between 2,500 and 3,000 calories per day. Adolescents require about 1,200 to 1,500 milligrams of calcium each day. Adolescents should be made aware of foods high in calcium, including milk, white beans, broccoli, cheese, and yogurt. Adolescent males require 12 milligrams of iron each day and females require 15 milligrams each day. Advise adolescents about foods high in iron (see Box 29.3 and Healthy People 2010). Protein requirements for adolescent girls are 46 grams per day, and 45 to 59 grams for boys. Some foods high in protein are meats, fish, poultry, beans, and dairy products.

BOX 29.3 Foods High in Iron

- Beef, chicken, fish
- Liver
- Peanut butter
- Nuts and seeds
- Green peas, lima beans
- Spinach
- Strawberries
- Tomato juice
- Whole-grain bread
- Raisins
- Watermelon

HEALTHY PEOPLE 2010

Objective	Significance
Reduce iron deficiency among young children and females of childbearing age.	• Educate parents and teens about iron-containing foods. • Encourage adolescent females to consume a diet high in iron-rich foods.

Nutritional Assessment

The nurse must understand normal growth and development of the adolescent in order to provide guidance that fits the quest for independence and the need for teens to make their own choices. Assess the eating habits and diet preferences of the adolescent. The assessment should include an evaluation of foods from the different food groups that the adolescent eats each day. Also, assess the number of times that fast foods, snacks, and other junk food are eaten per week. This assessment will help the nurse to guide the adolescent in making better food choices at home and in fast-food establishments. Many fast-food restaurants offer baked chicken sandwiches and salads with fewer calories and less fat. Adolescents may be guided in alternating hamburger and fries with more nutritious choices. Remember that planning should always include the adolescent.

Nutritional Guidelines

The official U.S. dietary guidelines are based on the Food Guide Pyramid (see Appendix H). This pyramid, designed by the U.S. Department of Agriculture, illustrates a healthy, balanced diet with recommendations for eating foods from the main food groups each day with the exception of fats, oils, and sweets. Table 29.3 outlines daily serving recommendations based on caloric requirements (lower, moderate, or higher). Nurses may use the information in Table 29.3 to help teens plan a healthy diet for themselves. Active teenage girls should eat the number of servings recommended in the "Moderate" column of Table 29.3. Active teenage boys should eat the number of servings recommended in the "Higher" column. Adolescents who are overweight and dieting should base their daily intake on the serving recommendations in the "Lower" column.

What questions should you ask Cho Chung and her mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The average number of hours of sleep that teens require per night is 8. On the weekends, they may sleep 10 to 12 hours per night. In this independence-seeking phase of adolescence, the teen may stay up later to do homework or to complete projects and may have difficulty awakening in the morning. Rapid growth and increased activities may produce fatigue and the need for more rest. Parents may relate that the teen sleeps all the time and never has the time or energy to help with household chores. Explain to parents the need to discourage late hours on school nights because they may affect school performance. Provide advice to teens and parents about having realistic expectations; encourage them to agree on a level of normalcy and adequate rest for the teen so that he or she can still fulfill responsibilities in the home.

Provide anticipatory guidance to Cho Chung and her mother in relation to sleep during the adolescent years.

Promoting Healthy Teeth and Gums

Most permanent teeth have erupted with the possible exception of the third molars (wisdom teeth). These molars may become impacted and require surgical removal. The rate of cavities decreases but the need for routine dental visits every 6 months and brushing two to three times per day is very important. Some of the conditions that occur during adolescence include malocclusion, gingivitis, and tooth avulsion. Malocclusion occurs in approximately 50% of adolescents, resulting from facial and mandibular bone growth. The treatment includes braces and other

TABLE 29.3 SAMPLE DIET FOR THREE CALORIC LEVELS

Calories for Three Caloric Levels	Lower (About 1,600 Calories)	Moderate (About 2,200 Calories)	Higher (About 2,800 Calories)
Grain group servings	6	9	11
Vegetable group servings	3	4	5
Fruit group servings	2	3	4
Milk group servings	2–3	2–3	2–3
Meat group (ounces)	5	6	7

dental devices. Teach the adolescent to brush the teeth more frequently if he or she has braces or other dental devices. Gingivitis is inflammation of the gums and breakdown of gingival epithelium due to diet and hormonal changes. The use of dental devices/braces makes cleaning more difficult and contributes to gingivitis. Tooth avulsion (knocked-out teeth) may occur during sports and other activities such as falls. The avulsed tooth should be reimplanted as soon as possible. The nurse may see the teen first so it is important that nurses know the proper procedure, which is to reinsert the tooth into its socket if possible or to store it in cool milk or normal saline for transport to the dentist.

Promoting Personal Care

Promotion of personal care during adolescence is an important topic to cover with the adolescent and his or her parents. Topics to discuss include general hygiene tips, caring for body piercings and tattoos, preventing suntanning, and promoting a healthy sexual identity.

General Hygiene Tips

Adolescents find that frequent baths and deodorant use are important due to apocrine sweat gland secretory activity. Also, to decrease oily skin due to sexual steroids and hormones, teach the adolescent to wash his or her face two to three times per day with plain unscented soap. Vigorous scrubbing should be discouraged because it could irritate the skin and lead to follicular rupture. The hair should be shampooed daily to remove excess oil from the hair and scalp. Many over-the-counter medications are available for beginning acne or acne with a few lesions. These preparations may cause drying or redness. Discourage adolescents from squeezing acne lesions to prevent further irritation and permanent scarring. If the adolescent has severe acne, encourage him or her to ask a parent to make an appointment with a dermatologist.

Caring for Body Piercings and Tattoos

Today, body piercing on the tongue, lip, eyebrow, navel, and nipple is common (Fig. 29.9). Other sites such as the genitals, chin cleft, knuckles, and even the uvula have been used. Generally, body piercing is harmless, but nurses should caution teens about performing these procedures under nonsterile conditions and should educate them about complications. Qualified personnel using sterile needles should perform the procedure. Teach the adolescent to cleanse the pierced area twice a day and more often at some sites.

The complications of body piercing vary by site. Infections from body piercing usually result from unclean tools of the trade. Some of the infections that may occur as a result of unclean tools include hepatitis, tetanus, tuberculosis, and human immunodeficiency virus (HIV). Also, keloid formation and allergies to metal may occur. The navel is an area prone to infection because it is a moist area that endures friction from clothing. After a navel infection occurs, it may take up to a year to heal. Pierced ear cartilage also heals slowly and is prone to infection. Tongue piercings heal very quickly, usually within 4 weeks, probably due to the antiseptic effects of saliva. Other concerns with tongue piercing include tooth damage from biting on the jewelry or partial paralysis if the jewelry pierces a nerve.

FIGURE 29.9 Having multiple piercings and tattoos can lead to certain health risks.

Tattoos are becoming more popular among adolescents and are not necessarily a mark of gang membership. Tattoos serve to define one's identity (see Fig. 29.9). Because of the invasiveness of the tattooing procedure, it should be considered a health-risk situation. Like piercings, tattoos are open wounds predisposing to infection.

Little regulation exists in the tattoo business, and nurses should educate adolescents about the risk of bloodborne infections, skin infections, and allergic reactions to dyes used in the tattoo process. Teach teens to cleanse tattoos with an antibacterial soap and water several times a day and to keep the area moist with an ointment to prevent scab formation. Refer to Box 29.4 for additional information about tattoos.

BOX 29.4 What Adolescents Need to Know About Tattooing

- Infections occur as a result of nonsterile equipment used in the procedure.
- Tattoos are open wounds predisposing to infection; sites require proper care with antibacterial soap and water several times per day and application of ointment.
- For most people a tattoo is permanent; new procedures for removal are painful and expensive.

Preventing Suntanning

Suntanning is popular among adolescents and is influenced by the media, which promotes a link between tan skin and beauty. There is no such thing as a good tan. Most exposure to ultraviolet rays occurs during childhood and adolescence, thereby putting people at risk for the development of skin cancer. However, it is difficult to convince adolescents that tanning is harmful to their skin and puts them at risk for skin cancer later in life (see Healthy People 2010).

Educate teens about the benefits and effects of different sun protection products. Explain to them that sun damage and skin cancers can be prevented if sunscreens are used as directed on a regular basis. Encourage sunscreen or sunblock use for water sports, beach activities, and participation in outdoor sports. Also, make adolescents aware of allergies to some sunscreen products. See Teaching Guideline 29.1 for additional information.

Promoting a Healthy Sexual Identity

Encourage parents and teens to have sexuality discussions. In addition, nurses should ensure that adolescents have the knowledge, skills, and opportunities that enable them to make responsible decisions regarding sexual behaviors and sexual orientation. Education for the adolescent should include a discussion about media influences and the use of sexuality to promote products. This discussion should make the adolescent aware of the motives of the media and the need to be an individual and not be influenced by television, magazines, and other forms of advertisement. Encourage parents to be aware of who their adolescents are dating and where they go on their dates. Refer to Teaching Guidelines 29.2 for information on counseling related to adolescent sexuality.

Promoting Appropriate Discipline

Adolescents naturally misbehave or do not follow the rules of the house, and parents must determine how to respond.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of persons who use at least one of the following protective measures that may reduce the risk of skin cancer: avoid the sun between 10 a.m. and 4 p.m., wear sun-protective clothing when exposed to sunlight, use sunscreen with a sun protection factor (SPF) of 15 or higher, and avoid artificial sources of ultraviolet light.	• Encourage female teens to use sunscreen-containing makeup. • Discourage teen use of tanning beds. • Remind students to use sunscreen during outdoor organized-sports practice. • Educate teens and families about the risks associated with sun exposure.

TEACHING GUIDELINES 29.2

Adolescent Sexuality

- It should be your choice to engage in sexual relations. Do not be influenced by peers. When you say "no," be firm and clear about your position.
- Pregnancy, sexually transmitted infections, and human immunodeficiency virus (HIV) infection can occur with any sexual encounter without the use of barrier methods of contraception. Use appropriate contraception if sexually active. Discuss abstinence as a contraceptive method.
- Sexual activity in a mature relationships should be pleasurable to both parties. If your sexual partner is not interested in your pleasure, you need to reconsider the relationship.

Adolescents need to know the rules and expectations. After rules are established, parents must explain to the adolescent the consequences of breaking the rules.

Offer guidance to parents related to disciplining teens. The parent and the teen should collaborate on what the consequences will be if the rules are broken. Parents must acknowledge and offer reinforcement and support when the teen follows the rules. Consistency and predictability are the cornerstones of discipline, and praise is the most powerful reinforcer of learning.

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

Adolescence is a time of rapid growth and development with maturation of sexuality. The adolescent period begins with a child and ends with the expectation of adulthood. There are many developmental concerns that present during this period, including obesity, violence, suicide, and homicide. The following is an overview of some of these concerns.

Obesity

Over 9 million children and adolescents in the United States are overweight. Over a 20-year time period, from 1980 to 2000, the number of overweight adolescents tripled from 5% to 15%. Although obesity has increased in all segments of the U.S. population, there are differences specific to race, ethnicity, and socioeconomic status. The prevalence of obesity is highest in Hispanic and African-American teens between the ages of 12 and 19 years. Obesity rates are higher in females and in adolescents of lower socioeconomic status.

This increase in obesity in adolescents has led to increases in hypertension, heart disease, and type 2 diabetes. Influential factors causing obesity include food choices, eating practices, and lack of exercise. One study indicated that only 75% to 78% of adolescents ages 11 to 19 eat breakfast. Also, less than 40% of adolescents ages 12 to 19 meet the daily dietary requirement of vegetables and fruits while exceeding the recommendation for saturated fats. Adolescents are busy and eat on the run with many meals from fast-food facilities. In addition, many schools have decreased or discontinued physical education, which has resulted in a more sedentary lifestyle leading to weight gain. Interest in computer games and television watching at home has decreased physical activity and exercise and further contributed to weight gain and obesity (see Healthy People 2010).

Nurses must make parents and adolescents aware of factors leading to obesity. Nurses should recommend:

- Proper nutrition and healthy food choices
- Good eating habits
- Decreased fast-food intake
- Exercising for 30 minutes at least four times per week
- Parents/adolescents exercising more at home
- Decreased computer use and television watching

Violence

The CDC's Injury Center defines violence as threatened or actual physical force or power initiated by an individual that results in physical or psychological injury or death. More than 877,700 adolescents and young adults between 10 and 24 years of age were injured as a result of violence in 2002. Approximately 1 in 13 of these injuries resulted in hospitalization (CDC, 2007f). The issue of youth violence is a growing concern in America's communities. The health and well-being of adolescents and society are threatened by this violence. See Box 29.5 for factors contributing to adolescent violence.

BOX 29.5 Factors Contributing to Adolescent Violence

- Crowded conditions/housing
- Low socioeconomic status
- Limited parental supervision
- Single parent families/both parents in workforce
- Access to guns or cars
- Drug or alcohol use
- Low self-esteem
- Racism
- Peer or gang pressure
- Aggression

Homicide

Homicide is the fourth leading cause of death in children between 10 and 14 years old, and the second leading cause of death in 15- to 19-year-olds. Most young homicide victims are killed with guns. In 2003, 82% of homicide victims age 10 to 24 years were killed with firearms (CDC, 2006b). Refer to Box 29.5 for factors that contribute to violence among adolescents. In a nationwide survey conducted in 2004, 17% of students reported carrying a weapon on one or more days within the past 30 days (CDC, 2006b) (see Healthy People 2010).

Suicide

Suicide is the third leading cause of death in adolescents 15 to 19 years of age. In a CDC study in 2001, 19.3% of adolescents surveyed related that they had seriously considered suicide within the past 12 months. The rate of suicide among teens between 15 and 19 years old increased by 11% from 1980 to 1997, and by 10% in 10- to 14-year-olds in the same time period. In 1999, more teenagers and young adults died from suicide than from cancer, heart disease, acquired immunodeficiency syndrome (AIDS),

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of adolescents who engage in moderate physical activity for at least 30 minutes on 5 or more of the previous 7 days, and vigorous physical activity that promotes cardiorespiratory fitness 3 or more days per week for 20 or more minutes per occasion.	• For the nonexercising teen, advise to start slowly by walking. • Work with the teen to identify physical activities that interest the teen. • Praise efforts to participate in a routine exercise plan. • Identify an athletic individual that the teen identifies with and encourage similar activities in the teen.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce homicides, physical fighting among adolescents, weapon carrying by adolescents on school property, rate of suicide attempts by adolescents.	• Screen teens at all encounters for indications of violent behaviors. • Provide education related to decreasing school violence at middle and high schools. • Encourage alternate, appropriate methods for dispelling anger. • Screen teens at all encounters for indications of depression.

birth defects, stroke, and chronic lung disease combined (CDC, 2007c). Among adolescents ages 15 to 19, firearm-related suicides accounted for more than 60% of the increase in the overall suicide rate from 1980 to 1997 (see Healthy People 2010).

Dating Violence

Violent behavior that takes place in a context of dating or courtship is not a rare event. Thirty percent of teens state that either they or someone they know has experienced dating violence. Females are victims of dating violence more often than males and suffer more injuries than males. Dating violence in the teen years is a risk factor for continued violence exposure in adulthood. Risk factors for dating violence include living in a broken home or rural area, inadequate parental supervision, condoning violence, substance use, prior victimization, dropping out of high school, and risky sexual practices (Mars & Valdez, 2007).

Gangs

Much of youth violence is a result of the behavior of adolescent gangs. Nationwide there are an estimated 23,388 gangs with 664,906 members; approximately 3% are female. In one study, the risk factors for gang involvement were family, friends, neighborhood, and interpersonal issues. Peers are ranked as being most influential in female gang involvement, followed by neighborhood, family, and self. Gang membership may aid in the formation of identity by providing status and a sense of belonging. Gang membership occurs in cities and in suburban areas, but may differ in composition. The gangs in rural or suburban areas are more diverse racially and include both males and females. All socioeconomic groups are represented in gang membership. Gangs threaten and intimidate with violent behaviors and guns (Archer & Grascia, 2005).

Nursing Interventions to Decrease Youth Violence

Nurses working with adolescents should include violence prevention in anticipatory guidance. Violence is a learned behavior. It is often reinforced by the media, television, music, and personal example. Explain to parents, teachers, and peers the importance of being good role models because violence is a learned behavior. Parents should monitor video games, music, television, and other media to decrease exposure to violence. Parents need to know who their adolescent's friends are and monitor for negative behaviors and actions.

The identification of adolescents at risk for suicide is a very important task for the nurse, parents, peers, and counselors. See Box 29.6 for signs of risk factors. The National Center for Injury Prevention and Control (NCIPC) is working to create awareness of suicide as a serious public health problem and is developing strategies to reduce injuries and deaths due to suicide.

BOX 29.6 Risk Factors for Suicide in Adolescents

- Depression
- Mental health changes
- Poor school performance
- Family disorganization
- Substance abuse
- Homosexuality
- Giving away valued possessions
- Being a loner/having no close friends
- Changes in behavior

Substance Use

Agents commonly abused by children and adolescents include alcohol, hallucinogens, sedatives, analgesics, anxiolytics, steroids, inhalants, and stimulants. The substance abused is related to its availability and cost. Two common substances that are more accessible and have the highest incidence of use are tobacco and alcohol. Each day, approximately 4,000 young people under the age of 18 try their first cigarette; 80% of adult smokers started smoking before age 18. It is estimated that 90% of adolescents have tried alcohol by the time they reach adulthood. Research consistently supports the hypothesis that drug use progresses from beer or wine to cigarettes or hard liquor and then to marijuana, followed by illicit drugs.

Some of the long-term effects and consequences of drug and alcohol use include: possibility of overdose and death; unintentional injuries; irrational behaviors; inability to think clearly; unsafe driving and legal consequences; problems with relationships with family and friends; sexual activity and STIs; and health problems such as liver problems (hepatitis) and cardiac problems (sudden death with cocaine). Refer to Table 29.4 for commonly abused drugs and behaviors exhibited (see Healthy People 2010).

Tobacco

Tobacco use remains the leading preventable cause of death in the United States, causing more than 440,000 deaths each year. Long-term consequences of youth smoking are reinforced by the fact that most young people who smoke regularly continue to smoke throughout adulthood. Each day in the United States, about 4,000 12- to 17-year-olds take their first cigarette. More than 6.4 million people will die prematurely because of smoking as adolescents. Although the overall rate of smoking has declined since 1999, rates still remain high: 22% of high-school students report current cigarette use. Seven percent of high-school students use smokeless tobacco (CDC, 2004a). Teens who smoke are three times more

TABLE 29.4 DRUGS COMMONLY ABUSED

Drug	Manifestations	Considerations
Marijuana	Red eyes, dry mouth, euphoria, relaxation, decreased motivation, loss of inhibition	Considered a gateway drug
Cocaine	Weight loss, euphoria, elation, agitation, pressured speech, tachycardia, hypertension, anorexia, insomnia	Psychotic behavior with large doses; if combined with other drugs can be fatal
Opiates	Elation, euphoria, detachment, drowsiness, constricted pupils, slurred speech, impaired judgment	Self-neglect with malnutrition and dehydration; criminal behaviors to get drugs; infections at injection sites
Amphetamines	Euphoria, agitation, weight loss, insomnia, tachycardia, hypertension	Possible paradoxical effect of depression in children
Hallucinogens	Hallucinations, illusions, depersonalization, heightened awareness, dilated pupils, hypertension, increased salivation, distorted perceptions	Panic flashbacks long after use of drugs; psychotic behaviors
Phencyclidine hydrochloride (PCP)	Euphoria, distorted perceptions, agitation, violence, antisocial behaviors, hypertension, increased salivation, increased pain response	Irrational behaviors, panic, psychosis
Barbiturates	Euphoria followed by depression or hostility; impaired judgment; decreased inhibitions; slurred speech; incoordination	Often used with stimulants; may have a paradoxical effect of hyperactivity in children

likely than nonsmokers to use alcohol, eight times more likely to use marijuana, and 22 times more likely to use cocaine. Smoking is associated with a host of other risky behaviors, including fighting and engaging in unprotected sex (Focus Adolescent Services, 2007). The short-term health effects of smoking include damage to the respiratory system, addiction to nicotine, and the associated risk of other drug use. Smoking negatively impacts physical fitness and lung growth and increases the potential for addiction in adolescents. Smokeless tobacco may also cause many problems. It can lead to bleeding gums and sores in the mouth that never heal. Smokeless tobacco use leads to discoloration of the teeth and eventually may lead to cancer.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol. Reduce steroid use among adolescents. Increase the proportion of adolescents who disapprove of substance abuse and smoking.	• Provide education in the office, hospital, or school related to adverse effects of tobacco, alcohol, and illicit substance use. • Educate families, teens, and coaches about the negative effects of anabolic steroids. • Praise teens for abstaining from the above substances and rising above peer pressure.

Alcohol

The Youth Risk Behavior Survey found that about 75% of adolescents under the age of 18 have consumed alcohol, although the legal drinking age is 21. Forty-three percent of teens reported current alcohol use, and 25% admitted to episodic binge drinking (CDC, 2006b). The findings revealed that there were no substantial differences among various sociodemographic subgroups with respect to drinking rates, although alcohol use is lowest in African-Americans and highest in whites. The incidence of alcohol use increases throughout adolescence. Almost two thirds of 12th graders who report consuming alcohol also reported at least one alcohol-related problem. Alcohol use as an adolescent can lead to prevailing alcohol use as an adult and contribute to physical health problems. It may also precede other drug abuse.

Illicit Drugs

Adolescents may also experiment with or abuse illicit drugs. Substance abuse remains a widespread problem among American adolescents. Although experimentation with marijuana has decreased between 1991 and 2003 among the adolescent population, it still remains the most widely used illicit drug (Eaton et al., 2006). The Youth Risk Behavior Survey revealed that almost 8% of teens

had used cocaine, 12.5% had tried inhalants, and 4% had used illegal steroids (CDC, 2006b).

Data reveal that illicit drug usage for individual drugs reflects rapidly changing determinants specific to that drug. Influencing factors include the psychoactive potential and benefits reported, how risky the drug is to use, how acceptable is it to peer groups, and the accessibility of the drug (Johnston et al., 2006).

Nursing Interventions to Decrease Substance Use Among Teens

Educate the adolescent on the problems related to alcohol use and abuse. Topics that should be discussed include:

- Short- and long-term effects of alcohol, tobacco, and drugs on health
- Risk factors and implications for unintentional injuries and sexual activity
- Short- and long-term effects of alcohol, tobacco, and drugs on relationships and school performance and progression
- The how and why of chemical dependency
- Impact of substance abuse on society
- Importance of maintaining a healthy lifestyle
- Importance of resisting peer pressure to use drugs and alcohol
- Importance of having confidence in his or her own judgement
- Providing the teen with accurate and up-to-date information (Children of Alcoholics Foundation, n.d.)

Think back to Cho, who was introduced at the beginning of the chapter. List common developmental concerns of the adolescent. What anticipatory guidance related to these concerns would you provide?

Key Concepts

- Adolescence is a period of rapid and variable growth in the areas of physical, psychosocial, cognitive, and moral development.
- The adolescent is developing his own identity, becoming an abstract thinker, and developing his own set of morals and values. Inability to successfully develop an individual identity leads to poor preparation for the challenges of adulthood.
- Relationships with parents fluctuate widely during adolescence. The teenager eventually becomes emancipated from her parents.
- Peers become most important—guiding mainly the early and middle adolescent in his decisions, while the late adolescent can usually formulate his own decisions.
- Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors surrounding the adolescent's sexual identity.
- The egocentric and invincible thought processes of the adolescent can lead to injuries. Health care providers must emphasis safety regarding cars, bikes, water, firearms, and fire.
- Motor vehicle accidents are the number one cause of death in adolescents.
- Nutritional habits of the adolescent lead to deficiency in vitamins and minerals needed for the rapid growth during this period.
- Obesity in adolescents is a growing health concern. Health care providers are facing increased numbers of adolescents with hypertension, type 2 diabetes, and hyperlipidemia.
- Substance abuse and experimentation is common during adolescence; it is associated with other risk-taking behaviors such as injuries and sexual activity.
- Health care providers must work collaboratively with the adolescent in the development of interventions to promote health.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. When giving parents guidance for the adolescent years, the nurse would advise the parents to: (Choose all that apply)
   a. Accept the adolescent as a unique individual.
   b. Provide strict, inflexible rules.
   c. Listen and try to be open to the adolescent's views.
   d. Screen all of his or her friends.
   e. Respect the adolescent's privacy.
   f. Provide unconditional love.
2. In developing a weight-loss plan for an adolescent, which would the nurse include? (Choose all that apply)
   a. Have parents make all of the meal plans.
   b. Eat slowly and place the fork down between each bite.
   c. Have the family exercise together.
   d. Refer to an adolescent weight-loss program.
   e. Keep a food and exercise diary.
3. Which is associated with early adolescence? (Choose all that apply)
   a. Uses scientific reasoning to solve problems
   b. Still at times wants to be dependent upon parents
   c. Incorporates own set of morals and values
   d. Is influenced by peers and values memberships in cliques
4. What has the most influence in deterring an adolescent from beginning to drink alcohol?
   a. Drinking habits of parents
   b. Drinking habits of peers
   c. Drinking philosophy of adolescent's culture
   d. Drinking philosophy of adolescent's religion

CRITICAL THINKING EXERCISES

1. During a sports physical examination, Susan, a 16-year-old, tells her health care provider that she is overweight. What additional information would the health care provider obtain?
2. The parents of Joe, a 14-year-old, talk to the school nurse about Joe's behavior at home. He is moody, fights with his younger siblings, only wants to be on his computer, and does not want to go on the family vacation. What advice would the nurse give the parents?
3. Jane tells the school nurse that she might be homosexual. What additional information would the nurse obtain?
4. Alicia's parents are worried because all of Alicia's friends wear heavy makeup and have multiple piercings and hair colors. What advice would the nurse give Alicia's parents?

STUDY ACTIVITIES

1. Talk to an early, middle, and late adolescent. Compare and contrast their interactions with you. Identify what psychosocial, cognitive, and moral stage they are in, using examples from their conversations with you.
2. Have an adolescent keep a food and exercise diary for one week. Analyze the information. Develop with the adolescent any interventions needed to promote healthy eating and exercise habits.
3. Plan a class on the dangers of smoking for 15-year-olds.
4. Plan a class for parents on how to keep the lines of communication open for adolescents.

CHAPTER 30

HEALTH SUPERVISION

KEY TERMS

active immunity
developmental screenings
developmental surveillance
immunity
medical home
passive immunity
risk assessment
screening tests
selective screening
universal screening

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Describe the principles of health supervision.
2. List the three components of a health supervision visit.
3. Use instruments appropriately for developmental and functional testing of children.
4. Demonstrate knowledge of the principles of immunization.
5. Identify barriers to immunization.
6. Identify challenges to health supervision for children with chronic illnesses.

Three-year-old Maya Randall and 9-month-old Evan Randall are brought to the clinic by their father. Maya was last seen in the clinic when she was 1 year old, and Evan has never been seen. The father says that they have both been healthy so they did not need to come to the clinic before this. Maya is complaining of a sore throat, which is what prompted today's visit.

Wow

It is never too late to start prevention. It begins with a genuine desire for health improvement.

Principles of Health Supervision

Health supervision involves providing services proactively, with the goal of optimizing the child's level of functioning. This chapter is organized around the three components of health supervision: developmental surveillance and screening; injury and disease prevention; and health promotion. Health supervision begins at birth and continues through adolescence. Health supervision is vital to every child and is most effective when the child has a centralized source of health care. Any place publicly accessible by children and families can be an appropriate setting for health supervision services—private physicians' offices, community health departments, sliding-scale clinics, homeless shelters, daycare centers, and schools. The framework for the health supervision visit is developed from national guidelines available through the U.S. Department of Health and Human Services (DHHS), the American Medical Association (AMA), and the American Academy of Pediatrics (AAP). These organizations also provide guidelines for children with chronic health problems and services and information regarding unique situations such as the internationally adopted child.

Wellness

The focus of pediatric health supervision is wellness. The health supervision visit provides an opportunity to maximize health promotion for the child, family, and community. Nurses have the ability to promote optimal health during these encounters. Health supervision visits must be viewed as part of a continuum of care, not as the accomplishment of isolated tasks.

Medical Home

A **medical home** is the primary health care provider who has a long-term and comprehensive relationship with the family. This continuing relationship promotes trust between the provider and the family and leads to comprehensive, coordinated, and cost-effective care. The medical home is the setting that allows the highest level of health supervision. To be effective, the medical home must be accessible, family-centered, and community-based. It must be integrated into the child's world, not adjacent to it. Characteristics of a medical home are displayed in Box 30.1.

Partnerships

The child is the focus of the health supervision visit. However, the child's health is linked to the needs and resources of his or her family and community. For instance, if the family is in turmoil because of divorce, drug abuse, or parental health problems, the child is less likely to receive the attention and energy that he or she needs to thrive. Likewise, a community with high levels of poverty, poor infrastructure, and lack of resources will not be able to provide the support services needed to allow children to reach their full potential. To be effective, the nurse must offer commitment and develop an ongoing partnership with the child, family, and community. These partnerships allow for mutual goal setting, marshalling of resources, and development of optimal health practices.

The partnership between the child and the health supervision team develops over time. In infancy the family is the surrogate for the child in the partnership. The child's participation in the partnership increases at a rate that is developmentally appropriate. The child's increasing influence in the partnership allows the nurse to tailor health supervision to the child's needs. The partnership allows the child to take increasing responsibility for his or her personal health and optimizes health promotion.

Nurses must validate and enhance the role of family members as they influence and inform the child's concept of wellness. The health care community must involve the family to have a significant impact on a child's health. The family wants the best possible outcome for their child, and health care decisions are based on the knowledge they possess. The nurse can greatly facilitate trust by acknowledging that the family has unique insights to offer on their child's health. Nurses can also strengthen the partnership between the family and the health care community by recognizing the family's healthy practices, addressing their health issues, and strengthening their skills. By contributing to the partnership, both the nurse and the family enhance the chance of success for health care plans, but families are the ones who must implement any health care strategy and know what expected outcomes are reasonable. Their feedback is invaluable to formulating an effective long-term health supervision plan that optimizes their child's wellness.

BOX 30.1 Characteristics of a Medical Home

- Preventive care activities
- Ambulatory and inpatient care available 24 hours a day
- Continuity of care from infancy through adolescence
- Availability of subspecialty consultation and referrals
- Interactive relationships with school and community agencies
- A centralized database containing all pertinent information

Green, M., & Palfrey, J. (Eds.) (2002). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (2nd ed.). Arlington, VA: National Center for Education in Maternal and Child Health.

▶ *Take* NOTE!

Observe the parent–child interaction during the health supervision visit. The nurse can learn much about the family dynamic by observing the family for behavioral clues:

- *Does the parent make eye contact with the infant?*
- *Does the parent anticipate and respond to the infant's needs?*
- *Are parents effective when dealing with a toddler's temper tantrum?*
- *Do the parents' comments increase the school-age child's sense of self-worth?*

Behavioral observations are crucial to the proper assessment of the family's needs and issues.

Partnerships between the community and the health promotion team benefit the community as well as individual clients. When nurses develop partnerships with community agencies such as schools, churches, and ancillary health facilities, barriers to care can be overcome. The nurse becomes aware of available resources in the community that can benefit an individual family. With input from community partners, the nurse can perform an assessment of the community's needs. The assessment then provides the foundation for the development of community-based health promotion programs. These programs expand the resources of the community, which in turn enhances the health of its members.

Special Issues in Health Supervision

Special issues in health supervision include cultural influences, community influences, health supervision and the chronically ill child, and health supervision and the internationally adopted child.

Cultural Influences on Health Supervision

A person's definition of health is influenced by his or her culture. Successful interactions result when the nurse is aware of the beliefs and interactive styles that are often present in members of a specific culture. If the goals of the health care plan are not consistent with the health belief system of the family, the plan has little chance for success. Optimal wellness for the child requires the nurse and the family to negotiate a mutually acceptable plan of care. A plan must balance the cultural beliefs and practices of the family with those of the health care establishment. The nurse must possess cultural competence and sensitivity for the partnership to be successful.

Most health promotion and disease prevention strategies in the United States have a future-based orientation and view the client as an active and controlling agent in his or her own health. This reflects the dominant culture; however, the challenge to the nurse is to develop strategies that are meaningful to clients from other cultures. Significant numbers of clients belong to cultures with a present-based orientation. For these clients, health promotion activities need shorter-term goals and outcomes to be useful. Clients with a fatalistic worldview will see any actions on their part as ineffective. They may feel that a god figure or supernatural forces control their fate and that health is a gift to be appreciated, not a goal to be pursued. Certain cultures believe health is the result of being in harmony within oneself and the larger universe. From this viewpoint, taking a medication or receiving a treatment is not an effective way to restore health because it does not address the problem of being "out of harmony."

However, just because an individual belongs to a certain culture does not guarantee that he or she subscribes to all of its values. The nurse should explore each client's specific beliefs during the health interview.

Community Influences on Health Supervision

The child is a member of a community as well as a family and a culture. Each community has unique strengths, weaknesses, and values. A community can be a contributor to a child's health or be the cause of his or her illnesses. The child's health cannot be totally separated from the health of the surrounding community.

Ideally the child's medical home is within the family's community. If home and access to medical care are close, barriers such as lack of transportation, expense of travel, and time away from the parents' workplace are reduced. Having the medical home within the community facilitates bonds between the health team and schools, churches, and support services and agencies. Community support and resources are necessary for children with significant problems. A close working relationship between the child's health care provider and community agencies is an enormous benefit to the child (see the earlier section on partnerships).

The community assessment may reveal problems that are causing or contributing to the child's health problems. A deteriorating infrastructure can contribute to decreased access to care and increased risk of injury or illness. Poverty has been linked to low birthweight and premature birth, among other health problems. Substandard housing can be directly related to lead poisoning and asthma. Children from communities suffering the large-scale breakdown of family relationships and loss of support systems will be at increased risk for depression, violence and abuse,

substance abuse, and human immunodeficiency virus (HIV) infection. A thorough knowledge of the family's community is needed before a health surveillance program can be effective.

Health Supervision and the Child With Chronic Illness

Effective health supervision must be responsive to the individual child's situation. The child with a chronic illness needs to be assessed repeatedly to determine his or her health maintenance needs. These assessments determine the frequency of visits and types of interventions needed. The impact of the illness on the child's functional health patterns determines whether standard health supervision visits need to be augmented.

An effective partnership among the child's medical home, family, and community is vital for a child with a chronic illness. Coordination of specialty care, community agencies, and family support networks enhances the quality of life and health of these children. Access to care and services minimizes the risk of injury from the illness. Support groups and community-based resources optimize the family's adaptation to the stressors of chronic illness.

Comprehensive health supervision includes frequent psychosocial assessments. Issues to be covered include:

- Health insurance coverage
- Transportation to health care facilities
- Financial stressors
- Family coping
- School's response to the chronic illness

These are often stressful and emotionally charged issues. The nurse with a trusting and ongoing relationship with the child and family is in the best position to help with these issues. The nurse can assist the family to find financial and medical assistance programs, take advantage of community resources, and participate in support groups. The nurse can also educate school personnel about the child's illness and assist them in maximizing the child's potential for academic success.

Health Supervision and the Child Adopted Internationally

Health supervision of the internationally adopted child must include comprehensive screening for infectious disease. In 2000, nearly 20,000 children were adopted from countries outside the United States, many from areas with a high prevalence of infectious diseases. China and Russia typically supply 50% of all international adoptees. Korea, Guatemala, Romania, Vietnam, and the Ukraine account for 32% of internationally adopted children. Proper screening is important not only to the child's health but also to the adopting family and the larger community. Screening is recommended within the first few weeks of the child's arrival into the United States.

Intestinal parasites are a common problem: approximately 25% of international adoptees have one or more pathogens. *Giardia lamblia,* the most common pathogen, is found in 19% of these children. Infected children are frequently symptom-free, so universal screening is recommended.

Latent tuberculosis is also common, affecting up to 19% of this population. Though active tuberculosis infection has been rarely reported, an extensive outbreak of tuberculosis occurred in a North Dakota community in 1998. The index case was an internationally adopted child from the Marshall Islands. Universal screening is recommended for this high-risk population.

Universal screening for hepatitis B, HIV, and syphilis infections is recommended. Due to lack of resources in the home country, screening and treatment for these diseases are sporadic and ineffective. If testing is documented, it is likely to be unreliable. Testing supplies may have been outdated or improperly stored. Also, the test may have been performed before the child's seroconversion occurred.

Components of Health Supervision

Developmental surveillance and screening, injury and disease prevention, and health promotion are the critical components of health supervision for children. Disease prevention and health promotion are concepts well established in adult health supervision. Injury prevention and developmental surveillance/screening are additional components of pediatric health supervision visits that help every child achieve his or her optimal state of wellness.

Developmental Surveillance and Screening

Developmental surveillance is an ongoing collection of skilled observations made over time during health care visits. Components include:

- Noting and addressing parental concerns
- Obtaining a developmental history
- Making accurate observations
- Consulting with relevant professionals

Developmental screenings are brief assessment procedures that identify children who warrant more intensive assessment and testing. Developmental screening assessments may be observational or by caregiver report (Fig. 30.1).

Development, or the emergence of the child's abilities, is a longitudinal process. Within the trust and security of the medical home, family and health care providers

FIGURE 30.1 Developmental screening provides the opportunity for the nurse to identify problems in the child's development.

can share observations and concerns. In collaboration, the family and the health care provider observe the child's accomplishments or milestones over time. Data collection for developmental surveillance of infants and young children is performed through developmental questionnaires, health care provider observations, and a thorough physical examination. School records and test results can provide academic performance data for the older child. Input from teachers, coaches, and other adults involved with the child can give insight into the child's emotional and social development.

When developmental delay is suspected, frequent developmental surveillance is warranted. Reemphasizing parental roles and responsibilities fosters cooperation and compliance. It is therefore crucial that parents understand the need for frequent assessments. A pattern of developmental delays warrants a formal evaluation.

The pediatric nurse must understand normal growth and development and become proficient at screening for problems related to development. The historical information obtained from the parent or primary caregiver about developmental milestones may indicate warning signs or identify risks for developmental delay (Table 30.1). Factors placing the infant or toddler at risk for developmental problems include:

- Birthweight less than 1,500 g
- Gestational age less than 33 weeks
- Central nervous system abnormality
- Hypoxic ischemic encephalopathy
- Maternal prenatal alcohol or drug abuse
- Hypertonia
- Hypotonia
- Hyperbilirubinemia requiring exchange transfusion
- Kernicterus
- Congenital malformations
- Symmetric intrauterine growth deficiency

TABLE 30.1 INFANT/TODDLER DEVELOPMENTAL WARNING SIGNS

Age	Warning Sign	Possible Developmental Concern
Any age	No response to environmental stimulus	Sensory deficit
Any age	Persistently up on toes (longer than 30 seconds) in supported standing position	Cerebral palsy
Before 3 months	Rolls over	Hypertonia
After 2–3 months	Persistent fisting	Neurologic dysfunction
After 4 months	Persistent head lag	Hypotonia
5 months	Not reaching for toys	Motor, visual, or cognitive deficit
6 months	Lack of tripod sitting	Hypotonia
6 months	Not smiling	Visual deficit, attachment issue
6 months	Primitive reflex persistence	Neurologic dysfunction
6 months	Not babbling	Hearing deficit
9 months	No reciprocal vocalizations or facial expressions	Autism spectrum disorders
12 months	No spoon or crayon use	Fine motor delay
15–18 months	Not walking	Gross motor delay
18 months	No imitative play	Autism spectrum disorders
Prior to 18 months	Hand dominance present	Hemiplegia in opposite upper extremity
18 months	No first word	Hearing deficit, expressive language deficit
24 months	Echolalia (repetitive speech) or inability to follow simple commands	Social delay or autism spectrum disorders

- Perinatal or congenital infection
- Suspected sensory impairment
- Chronic (more than 3 months) otitis media with effusion
- Inborn error of metabolism
- HIV infection
- Lead level above 19 mg/dL
- Parental concern about developmental issues
- Parent with less than high school education
- Single parent
- Sibling with developmental problems
- Parent with developmental disability or mental illness

Infants or children with any of these risk factors should be carefully screened for developmental delays. This screening should occur in a prospective manner, with screenings occurring at frequent intervals to identify concerns early.

▶ *Take* NOTE!

Any child who "loses" a developmental milestone—for example, the child able to sit without support who now cannot—needs an immediate full evaluation, since this indicates a significant neurologic problem.

A number of developmental screening tools are available to guide the nurse in assessing development (Table 30.2). The Denver II is a frequently used tool (see Appendix G). The Denver II should be used for diagnostic purposes only when administered by specifically trained personnel. Nurses not trained in the use of the Denver II should use screening tools based on the Denver II. Many screening methods assist the nurse in identifying infants and children who may have developmental delays, thus allowing for prompt identification and referral for evaluation. Additional data can be used to determine a school-age child's developmental level, include handwriting samples, ability to draw, school performance, and social skills.

Injury and Disease Prevention

Disease prevention is defined as interventions performed to protect clients from a disease or to identify it at an early stage and lessen its consequences. These interventions are determined by the results of the nurse's assessment, nationally accepted practice guidelines, and the family's goals. Components of disease prevention include screening tests and immunizations.

Injury prevention is primarily accomplished through education, anticipatory guidance, and physical changes in the environment. Injuries can be unintentional (poisoning, falls, or drowning) or intentional (child abuse, homicide, or suicide). The types of injuries a child is most likely to encounter vary greatly among age groups. Although aggressive public health initiatives have decreased mortality rates of childhood injuries significantly in the past 50 years, continued vigilance and innovation are needed. The nurse, in partnership with the family and the community, can have an enormous impact on child safety. Specific interventions are discussed in Chapters 4 through 8.

Screening Tests

Screening tests are procedures or laboratory analyses used to identify clients with a certain condition. These tests are done to ensure that no person with the disorder is missed. They have a high sensitivity (a high false-positive rate) and a low specificity (a low false-negative rate). If a screening test is positive, follow-up tests with higher specificity are performed. A **risk assessment** is performed by the health care professional in conjunction with the client and includes objective as well as subjective data to determine the likelihood that the client will develop a condition.

In **universal screening**, an entire population is screened regardless of the client's individual risk. This type of screening is performed when a reliable risk assessment procedure is not available. In contrast, **selective screening** is done when a risk assessment indicates the client has one or more risk factors for the disorder.

▶ *Take* NOTE!

To increase cooperation from young children during screenings, set up a reward system. Easy-to-do rewards include:

- *Stamping the back of the child's hand with a "smiley face"*
- *Making an eye cover by placing two stickers back to back over a tongue blade and letting the child keep the cover after the screening*
- *Copying a design onto a sheet of paper and letting the child take it home to color*
- *Letting the child play with a simple device such as a penlight or stethoscope*

Metabolic Screening

State law determines which metabolic screening tests are mandatory in that state. In some states, mandatory screening is limited to as few as four diseases. In addition to screening for hearing loss, the March of Dimes currently recommends universal newborn metabolic screening tests for 28 disorders for which effective treatment is available:

- Amino acid metabolism disorders: phenylketonuria, maple syrup urine disease, homocystinuria, citrullinemia, argininosuccinic acidemia, tyrosinemia type I

TABLE 30.2 DEVELOPMENTAL SCREENING TOOLS

Age	Screening Tool	Definition	Nursing Implications
Birth–6 years	Denver II	Assesses personal–social, fine motor–adaptive, language, and gross motor skills	Administered by nurse. Requires props (e.g., ball, crayon, doll), available in the Denver II kit. Simple to learn to administer.
Birth–6 years	Denver PRQ	Assesses personal–social, fine motor–adaptive, language, and gross motor skills	Parental report of all items on the Denver II
Birth–6 years	Child Development Inventory (CDI)	Simple questions about infant, toddler, or preschooler behaviors. Measures social, self-help, gross motor, fine motor, expressive language, language comprehension, letters, numbers, and general development as appropriate.	A parental-report screening tool
Birth–6 years	Ages and Stages Questionnaire (ASQ)	Assesses communication, gross motor, fine motor, personal–social, and problem-solving skills	A parental-report screening tool, scored by the nurse after completion to determine child's progress in each of the developmental areas
Birth–8 years	Parents' Evaluation of Developmental Status (PEDS)	Screens for a wide range of developmental, behavioral, and family issues	A parental-report screening tool that can also be used in nurse interview format. Also available in Spanish.
12–96 months	Batelle Developmental Inventory Screening Test	Assesses fine and gross motor, adaptive, personal–social, receptive and expressive language, and cognitive skills	Direct elicitation, parental description, and examiner observation. Requires special training.
1–42 months	Bayley Scales of Infant Development II	Provides a mental and motor scale for assessment of cognitive, language, personal–social, and fine and gross motor development. A behavior rating scale is obtained during the testing.	Direct elicitation. Thorough. Requires special training.
Birth–3 years	Early Language Milestone Scale	Screens for auditory expressive and receptive, visual components of speech	Requires standardized kit
2½–7 years	Denver Articulation Screening	Screens for articulation disorders	5 minutes to administer. Does not evaluate language ability.
5–17 years	Goodenough-Harris Drawing Test	A nonverbal screen for mental ability (intelligence)	Child draws a person, which is analyzed for body parts, clothing, proportion, and perspective.

- Organic acid metabolism disorders: isovaleric acidemia, glutaric acidemia type I, hydroxymethylglutaric aciduria, multiple carboxylase deficiency, methylmalonic acidemia due to mutase deficiency, methylmalonic acidemia cblA and cblB forms, 3-methylcrotonyl-CoA carboxylase deficiency, propionic acidemia, beta-ketothiolase deficiency
- Fatty acid oxidation disorders: medium-chain acyl-CoA dehydrogenase deficiency, very-long-chain acyl-CoA dehydrogenase deficiency, long-chain 3-OH acyl-CoA dehydrogenase deficiency, trifunctional protein deficiency, carnitine uptake defect
- Hemoglobinopathies: sickle cell anemia, HbS/beta-thalassemia, HbS/C disease

- Others: congenital hypothyroidism, biotinidase deficiency, congenital adrenal hyperplasia, classical galactosemia, cystic fibrosis

During the initial health supervision visit, the nurse should confirm that newborn metabolic screening was performed prior to discharge from the birthing unit. If the test was not performed or was performed at less than 48 hours of age, the screening should be performed at that visit. The metabolic screening results need to be noted in the child's permanent record at the medical home.

Hearing Screening

The AAP recommends hearing screening of all infants. Hearing loss is a common condition in newborns, and even mild hearing loss can cause serious delays in social and emotional development, language acquisition, and cognitive function. Identification of hearing loss by 3 months of age is crucial to reduce the impact on the child's development. Targeted screening based on risk factors will identify only 50% of infants with hearing loss. Screening should be done before discharge from the birthing unit; if not, the newborn needs to be screened before 1 month of age. Behavioral observations of the infant's response to sounds, such as a ringing bell, are not sensitive enough to preclude mild to moderate hearing loss. Accepted methodologies for screening newborn hearing are displayed in Table 30.3.

Screening for hearing loss in older children begins with a history from the primary caregivers. If any problems are noted, audiometry should be performed. When the child is capable of following simple commands reliably, the nurse can perform some basic procedures to screen for hearing loss. The whisper test is easy to perform but to be valid requires a quiet room that is away from distractions. The Weber and Rinne tests can be used to screen for sensorineural or conductive hearing loss (Fig. 30.2).

Universal hearing screening with objective testing is recommended at ages 4, 5, 6, 8, 10, 12, 15, and 18 years. More frequent screening is recommended if there is any behavior that indicates the child's hearing may be impaired. Repeated hearing screenings are recommended if a child has risk factors for acquired hearing loss such as those listed in Box 30.2.

Vision Screening

Newborns with ocular structural abnormalities are at high risk for vision impairment. Vision screening is performed at every scheduled health supervision visit. The screening procedures for children younger than 3 years of age or for nonverbal children involve evaluating the child's ability to fixate on and follow objects. The neonate should be able to fixate on an object 10 to 12 inches from the face. After fixation, the infant should be able to follow the object to the midline. By 2 months of age, the infant should be able to follow the object 180 degrees. The technique of photoscreening can help identify problems such as ocular malalignment, refractive error, and lens and retinal problems.

▶ *Take* NOTE!

Use objects with black and white patterns when performing vision screening on an infant less than 6 months of age. The infant's vision at this age is more attuned to high-contrast patterns than to colors. Try checkerboard patterns or concentric circles. Animal figures like pandas and dalmatians also work well.

After the age of 3 years, a variety of standardized age-appropriate vision screening charts are available. These charts include the "tumbling E" and Allen figures (Fig. 30.3A, B). These charts allow for a more precise vision assessment and aid the nurse in identifying preschool children with visual acuity problems. By age 5 or 6, most children know the alphabet well enough to use the traditional Snellen chart for vision screening (see Fig. 30.3C). Table 30.4 gives further information about vision screening tools.

Screenings should be performed when children are alert, as fatigue and lack of interest can mimic poor vision. When using any vision screening chart, several simple steps need to be followed:

- Place the chart at the child's eye level.
- Place a mark on the floor 20 feet from the chart.
- Align the child's heels on the mark.
- Have the child read each line with one eye covered and then with the other eye covered (Fig. 30.4).
- Have the child read each line with both eyes.

In addition to visual acuity screening, children should also be screened for color discrimination.

Any child with eye abnormalities or who has failed visual screening needs to be evaluated by a specialist appropriately trained to treat children.

Iron Deficiency Anemia Screening

Iron deficiency is the leading nutritional deficiency in the United States. The increased incidence of iron deficiency anemia is directly associated with periods of diminished iron stores, rapid growth, and high metabolic demands. At 6 months of age, the in utero iron stores of a full-term infant are almost depleted. The adolescent growth spurt warrants constant iron replacement. Pregnant adolescents are at even higher risk for iron deficiency due to the demands of the mother's growth spurt and the needs of the developing fetus.

TABLE 30.3 HEARING SCREENING METHODS

Test Name	Age Group	Characteristics	Nursing Implications
Auditory brain stem response (ABR)	Newborn–6 months	Measures electroencephalographic waves Test results may be affected by ear debris	Infant must be quiet (sedation may be needed).
Evoked otoacoustic emissions (EOAE)	Newborn–6 months or developmentally delayed children at the infant's level of functioning	The machine produces clicks that stimulate cilia in the cochlea and measures the response.	Infant must be quiet. Test results may be inaccurate in first 24 hours of life.
Visual reinforcement audiometry (VRA)	6 months–2 years	Visual reward is linked to a tone signal. Child looks to the visual reward in response to the tone. Reward is activated, reinforcing the response.	Child must be alert and happy for best results. Schedule for after sleep/rest period. Allow child to sit in parent's lap.
Tympanometry	Over 7 months	Measures tympanic membrane mobility and determines middle ear pressure	The probe must form a seal with the canal. The child must remain still to obtain a valid result.
Conditioned play audiometry (CPA)	2–4 years	Similar to VRA except uses "listening games" Child does listening game at the tone and receives social reward. May be used when developmental age is 2 years	See Nursing Implications for VRA.
Pure-tone (conventional) audiometry	4 years and older	Measures hearing acuity through a range of frequencies and intensities Child must wear earphones. Performed in a soundproof room if possible	Teach the child the desired motor response before screening. Administer conditioning trials. Offer two presentations of stimulus to ensure reliability. At a minimum, screen 1,000-, 2,000-, and 4,000-hertz levels at 20 decibels.
Whisper test	4 years and older	One ear is occluded. Examiner stands behind the child and whispers a word. The child must accurately repeat the whispered word.	The child must be in a quiet room and away from distractions. The child should be alert and well rested for accurate results. Consider a reward system to increase compliance.
Weber test	6 years and older	Place a vibrating tuning fork in the middle of the top of the head. Ask if the sound is in one ear or both ears. The sound should be heard in both ears.	The child must understand the instructions and be able to cooperate.
Rinne test	6 years and older	Place a vibrating tuning fork on the mastoid process to assess bone conduction. The child signals when the sound is gone. Next place a vibrating tuning fork outside the ear to test air conduction. The child signals when the sound is gone. For a passing test, air conduction time should be twice as long as bone conduction time.	The child must understand the instructions and be able to cooperate.

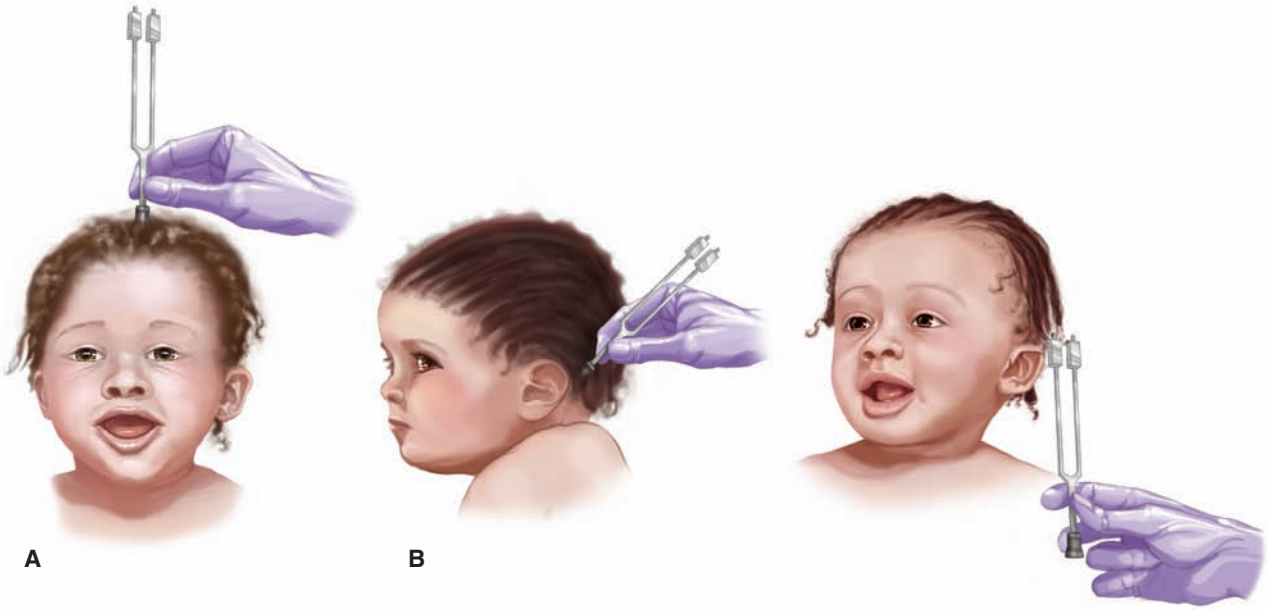

FIGURE 30.2 (**A**) The Weber test screens for hearing by assessing sound conducted via bone. (**B**) The Rinne test screens for hearing by comparing sound conduction via bone to sound conduction via air.

Guidelines for universal iron deficiency anemia screening vary. The Centers for Disease Control and Prevention (CDC) recommend universal screening of high-risk children at various age intervals. The AAP recommends universal screening of all infants at 9 to 12 months, boys at 12 to 18 years, and adolescent girls during all routine physical examinations. Both the CDC and the AAP have similar recommendations for selective screening (Boxes 30.3 and 30.4).

Lead Screening

Elevated blood lead levels (10 mcg/dL or higher) remain a preventable environmental health threat. Although the prevalence of elevated lead levels has declined over the past two decades, certain communities still possess a high level of lead exposure. In 1997 the CDC released guidelines to aid state and local health authorities in determining which children are at risk for elevated blood lead levels. These children are likely to benefit from lead screening. Federal Medicaid policy requires that all participating children be screened for blood lead levels.

The CDC recommends universal screening for children living in areas where more than 27% of the houses were constructed before 1950. It also recommends universal screening of children if more than 12% of the 1- and 2-year-olds in a specific population have elevated blood lead levels. Targeted screening based on risk assessment is

BOX 30.2 Risk Factors for Hearing Impairment

- Family history of hearing loss
- Prenatal infection
- Anomalies of the head, face, or ears
- Low birthweight (<1,500 g)
- Hyperbilirubinemia requiring exchange transfusion
- Ototoxic medications
- Low Apgar scores: 4 or less at 1 minute, or 6 or less at 5 minutes
- Mechanical ventilation lasting 5 days
- Syndrome associated with hearing loss
- Bacterial meningitis
- Neurodegenerative disorders
- Persistent pulmonary hypertension
- Otitis media with effusion for 3 months

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of newborns who are screened for hearing loss by age 1 month, have audiologic evaluation by age 3 months, and are enrolled in appropriate intervention services by age 6 months. Increase the proportion of persons who have had a hearing examination on schedule.	• Determine results of newborn hearing screening at first newborn checkup. • Refer any infant with possible hearing deficit for further evaluation. • Ensure infants with hearing impairment receive appropriate augmentation (hearing aids). • Ensure all children and adolescents receive hearing screenings with well-child checkups as appropriate.

Source: USDHHS, 2007.

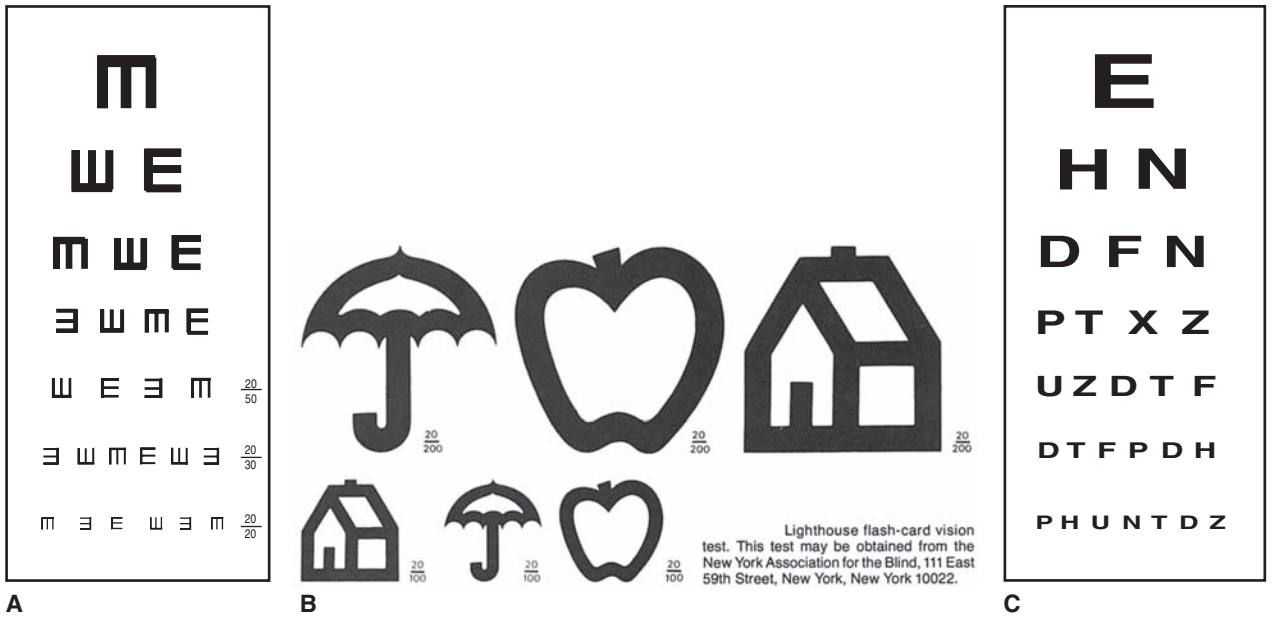

FIGURE 30.3 (**A**) The "tumbling E" chart is appropriate for children who do not yet know the alphabet but who can follow instructions to indicate the direction that the arms of the "E" are pointing. (**B**) A picture chart similar to the Allen object recognition chart is appropriate for vision screening in the preschool-age child. (**C**) The Snellen eye chart may be used for children age 6 or older who know the alphabet.

recommended for other children. In addition to assessing risk by location and population, an individual assessment needs to be performed. A community-specific questionnaire or the three-question personal risk questionnaire from the AAP (Box 30.5) should be used.

Hypertension Screening

Systemic hypertension occurs in 1% to 3% of children. Universal hypertension screening for children beginning at 3 years of age is recommended. If the child has risk factors for systemic hypertension, such as preterm birth or congenital heart disease, then screening begins when the risk factor becomes apparent.

The guidelines for determining hypertension in children and adolescents mirror the adult guidelines (Box 30.6). Preadolescents whose blood pressure is in the 90th to 95th percentile are considered to have prehypertension. Adolescents whose blood pressure is 120/80 mmHg are considered prehypertensive, even if their ranking is below the 90th percentile. Anticipatory guidance on diet and lifestyle changes is appropriate for any child with prehypertension. Refer to Chapter 40 for additional information on hypertension.

Hyperlipidemia Screening

Atherosclerosis has been documented in children, and a link exists between high lipid levels and the development of these lesions. Selectively screening children at high risk for hyperlipidemia can reduce their lifelong risk of coronary artery disease.

TABLE 30.4 VISION SCREENING TOOLS

Screening Tool	Age	Nursing Implications
Snellen letters or numbers	School-age	The child must know his or her letters or numbers for the test to be valid.
"Tumbling E"	Preschool	The child points in the direction that the "E" is facing.
LEA symbols or Allen figures	Preschool	The child should first identify the pictures with both eyes at a comfortable distance prior to monocular testing to ensure validity of the test.
Ishihara	School-age	Screens for color discrimination (numbers composed of dots, hidden within other dots)
Color Vision Testing Made Easy (CVTME)	Preschool	Uses dot pictures like the Ishihara, but instead of numbers has easily identified shapes imbedded in the dots

FIGURE 30.4 One eye must be covered while the other is tested in order to detect discrepancies in visual acuity between the two eyes and identify amblyopia early.

The risk assessment focuses on the child's family history. Children whose parents or grandparents had premature cardiovascular disease (before 55 years of age) or who have a parent with hypercholesterolemia are screened. If the child's family history is not available, screening is done at the discretion of the health care provider. The nurse also assesses for factors that may contribute to hyperlipidemia, such as sedentary lifestyle, cigarette smoking, obesity, and high-fat dietary intake. Children with diseases such as diabetes and hypertension are also candidates for hyperlipidemia screening. Box 30.7 gives details.

Remember Maya and Evan, the children introduced at the beginning of the chapter? How would you assess their growth and development? Which screening tests are warranted for them, and why? What further information would you need to determine which tests should be performed?

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of preschool children age 5 years and under who receive vision screening.	• Use preschool-appropriate vision screening tool to assess vision. • Ensure screening begins at age 3.

Source: USDHHS, 2007.

BOX 30.3 Comparing Iron Deficiency Anemia Screening Guidelines

CDC Recommendations

Universal Screening
- High-risk children only:
  - Ages 9–12 months
  - Repeat 6 months later
  - Ages 2–5 years annually
- Girls ages 12–18 years: once every 5–10 years

Selective Screening
Assess infants and children for risk factors at:
- 9–12 months
- 15–18 months
- 2–18 years annually

Screen clients with risk factors.

AAP Recommendations

Universal Screening
- Screen all infants at 9–12 months.
- Screen boys ages 12–18 years at routine physical examinations during their peak growth period.
- Screen adolescent girls during all routine physical examinations.

Selective Screening
Assess infants and children for risk factors at:
- 9–12 months
- 15–18 months
- 2–18 years annually

Screen clients with risk factors.

Immunizations

Immunization is the key disease prevention activity during childhood health supervision visits. The development of effective vaccines, beginning in the 1940s, revolutionized children's health care. Immunization allowed the focus to shift from disease treatment to disease prevention. The nurse needs to understand the principles of immunizations, the proper use of vaccines, and barriers to immunization. Armed with this knowledge, the nurse can partner with families to provide the highest level of disease protection to children (Fig. 30.5).

Principles of Immunization

The immune system has the ability to recognize materials present in the body as "self" or "non-self." Foreign materials (non-self) are called antigens. When an antigen is recognized by the immune system, the immune system responds by producing antibodies (immunoglobulins) or directing special cells to destroy and remove the antigen.

Immunity is the ability to destroy and remove a specific antigen from the body. The acquisition of immunity

BOX 30.4 Risk Factors for Iron Deficiency Anemia

- Periods of rapid growth
- Low-birthweight or preterm infants
- Low dietary intake of meat, fish, poultry, and ascorbic acid
- Macrobiotic diets
- Inappropriate consumption of cow's milk
- Use of infant formula not fortified with iron
- Exclusive breastfeeding after age 6 months without iron-fortified supplemental foods
- Meal skipping, frequent dieting
- Pregnancy or recent pregnancy
- Intensive physical training
- Recent blood loss, heavy/lengthy menstrual periods
- Chronic use of aspirin or nonsteroidal anti-inflammatory drugs
- Parasitic infections

Children at High Risk for Iron Deficiency Anemia

- Low-income families
- Those eligible for the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC)
- Migrants or recently arrived refugees

BOX 30.5 A Basic Personal-Risk Questionnaire for Lead Exposure in Children

1. Does your child live in or regularly visit a house or childcare facility that was built before 1950?
2. Does your child live in or regularly visit a house or childcare facility built before 1978 that is being or has recently been renovated or remodeled (within the past 6 months)?
3. Does your child have a sibling or playmate who has or did have lead poisoning?

Reproduced with permission from *Pediatrics, 101,* 1072–1078. Copyright ©1998 American Academy of Pediatrics.

HEALTHY PEOPLE 2010

Objective	Significance
Eliminate elevated blood lead levels in children.	• Screen for lead exposure. • Ensure that high-risk children have blood lead levels measured.

Source: USDHHS, 2007.

BOX 30.6 Preadolescent Childhood Hypertension Guidelines

Optimal	<90th percentile
Prehypertension	90th to 95th percentile
Stage I	>95th percentile up to 5 mmHg above 99th percentile
Stage II	5 mmHg above 99th percentile, or higher

can be active or passive. **Passive immunity** is produced when the immunoglobulins of one person are transferred to another. This immunity lasts only weeks or months. Passive immunity can be obtained by injection of exogenous immunoglobulins. It can also be transferred from mothers to infants via colostrum or the placenta. **Active immunity** is acquired when a person's own immune system generates the immune response. Active immunity lasts for many years or for a lifetime. This long-term protection is the result of immunologic memory. After the initial immune response, specialized cells for that antigen continue to exist. When an antigen returns, these memory cells very rapidly produce a fresh supply of antibodies to reestablish protection. This immunity can occur after exposure to natural pathogens or after exposure to vaccines. Vaccines mimic the characteristics of the natural antigen. The immune system mounts a response and establishes an immunologic memory as it would for an infection.

BOX 30.7 Hyperlipidemia Screening

Screen if parents or grandparents, at <55 years of age, have/had documented:
- Coronary atherosclerosis
- Myocardial infarction
- Angina pectoris
- Peripheral vascular disease
- Cerebrovascular disease
- Sudden cardiac death

Screen if a parent's blood cholesterol level is 240 mg/dL or higher. Screen at health care provider's discretion:
- Parental history is unobtainable.
- Child has diabetes or hypertension.
- Child has lifestyle risk factors:
  - Cigarette smoking
  - Obesity
  - Sedentary lifestyle
  - High-fat dietary intake

FIGURE 30.5 Nurse restraining infant for intramuscular injection into the vastus lateralis.

The classification of vaccines is based on the characteristics of the antigen present. The antigen may be viral or bacterial. It may be live attenuated (weakened) or killed. It may be the whole antigen or a portion of it (fractional).

- Live attenuated vaccines are modified living organisms that are weakened. The organism can produce an immune response but does not produce the complications of the illness.
- Killed vaccines contain whole dead organisms; they are incapable of reproducing but are capable of producing an immune response.
- Toxoid vaccines contain protein products produced by bacteria called toxins. The toxin is heat-treated to weaken its effect, but it retains its ability to produce an immune response.
- Conjugate vaccines are the result of chemically linking the bacterial cell wall polysaccharide (sugar-based) portions with proteins. This dramatically increases the immune response compared to presenting the polysaccharide portion alone.
- Recombinant vaccines use genetically engineered organisms. For example, the hepatitis B vaccine is produced by splicing a gene portion of the virus into a gene of a yeast cell. The yeast cell is then able to produce hepatitis B surface antigen to use for vaccine production.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of young children who receive all vaccines that have been recommended for universal administration for at least 5 years.	• Immunize at every opportunity. If a child is due or past due for vaccinations, provide them at a sick visit if not contraindicated. • Educate families about the benefits and risks of immunization.

Source: USDHHS, 2007.

The safety and efficacy of existing vaccines are constantly being reviewed, and research to improve vaccines is ongoing. The goal is to refine vaccines so that a maximum immune response is produced with the least amount of risk for the client.

Immunization Management

The Advisory Committee on Immunization Practices (ACIP), a branch of the CDC, reviews the recommended immunization schedules at least yearly and updates the schedule to ensure that it reflects current best practices (Tables 30.5 and 30.6). In addition to the recommended schedule, the ACIP publishes a "catch-up" schedule for children who have not been adequately immunized (Table 30.7). The child's immunization record must be compared with the latest edition of these schedules when assessing the need for immunization.

▶ *Take* NOTE!

When obtaining an immunization history from the parent, ask, "When and where did your child receive his (or her) last immunization?" The answer will provide more information than simply asking, "Are your child's immunizations up to date?" The nurse can compare this information with that on the immunization record; discover in what settings the child is getting health care; and use the information as a starting point in a discussion of any reactions to previous immunizations.

Vaccine storage and administration affect the efficacy of a vaccine. Improperly stored or reconstituted vaccines can be ineffective. The vaccine must be given by the correct route; not all vaccines are given intramuscularly (Box 30.8; Table 30.8). The manufacturer's package insert is the best reference source for any vaccine.

▶ *Take* NOTE!

Proper vaccine storage is critical to vaccine efficacy. If you suspect that a vaccine was not maintained at the proper storage temperature, do not use it! An ineffective vaccine is of no use in preventing disease.

The Public Health Service Act outlines standards of practice for immunization programs. The act requires that Vaccine Information Statements (VIS; Fig. 30.6) be provided to parents before an immunization is given. In accordance with the concept of partnership with the

Range of recommended ages

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2007, for children aged 0 through 6 years. Additional information is available at **www.cdc.gov/vaccines/recs/schedules**. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including for **high-risk conditions: http://www.cdc.gov/vaccines/pubs/ACIP-list.htm**. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at **www.vaers.hhs.gov** or by telephone, **800-822-7967**.

1. Hepatitis B vaccine (HepB). *(Minimum age: birth)*

At birth:

- Administer monovalent HepB to all newborns prior to hospital discharge.
- If mother is hepatitis B surface antigen (HBsAg) positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine the HBsAg status as soon as possible and if HBsAg positive, administer HBIG (no later than age 1 week).
- If mother is HBsAg negative, the birth dose can be delayed, in rare cases, with a provider's order and a copy of the mother's negative HBsAg laboratory report in the infant's medical record.

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1–2 months. The final dose should be administered no earlier than age 24 weeks. Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of at least 3 doses of a licensed HepB series, at age 9–18 months (generally at the next well-child visit).

4-month dose:

- It is permissible to administer 4 doses of HepB when combination vaccines are administered after the birth dose. If monovalent HepB is used for doses after the birth dose, a dose at age 4 months is not needed.

2. Rotavirus vaccine (Rota). *(Minimum age: 6 weeks)*

- Administer the first dose at age 6–12 weeks.
- Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks. Do not administer any dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP). *(Minimum age: 6 weeks)*

- The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4–6 years.

4. *Haemophilus influenzae* type b conjugate vaccine (Hib). *(Minimum age: 6 weeks)*

- If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required.
- TriHIBit® (DTaP/Hib) combination products should not be used for primary immunization but can be used as boosters following any Hib vaccine in children age 12 months or older.

5. Pneumococcal vaccine. *(Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPV])*

- Administer one dose of PCV to all healthy children aged 24–59 months having any incomplete schedule.
- Administer PPV to children aged 2 years and older with underlying medical conditions.

6. Influenza vaccine. *(Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])*

- Administer annually to children aged 6–59 months and to all eligible close contacts of children aged 0–59 months.
- Administer annually to children 5 years of age and older with certain risk factors, to other persons (including household members) in close contact with persons in groups at higher risk, and to any child whose parents request vaccination.
- For healthy persons (those who do not have underlying medical conditions that predispose them to influenza complications) ages 2–49 years, either LAIV or TIV may be used.
- Children receiving TIV should receive 0.25 mL if age 6–35 months or 0.5 mL if age 3 years or older.
- Administer 2 doses (separated by 4 weeks or longer) to children younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time last season but only received one dose.

7. Measles, mumps, and rubella vaccine (MMR). *(Minimum age: 12 months)*

- Administer the second dose of MMR at age 4–6 years. MMR may be administered before age 4–6 years, provided 4 weeks or more have elapsed since the first dose.

8. Varicella vaccine. *(Minimum age: 12 months)*

- Administer second dose at age 4–6 years; may be administered 3 months or more after first dose.
- Do not repeat second dose if administered 28 days or more after first dose.

9. Hepatitis A vaccine (HepA). *(Minimum age: 12 months)*

- Administer to all children aged 1 year (i.e., aged 12–23 months). Administer the 2 doses in the series at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children.

10. Meningococcal vaccine. *(Minimum age: 2 years for meningococcal conjugate vaccine (MCV4) and for meningococcal polysaccharide vaccine (MPSV4))*

- Administer MCV4 to children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. MPSV4 is also acceptable.
- Administer MCV4 to persons who received MPSV4 3 or more years previously and remain at increased risk for meningococcal disease.

TABLE 30.6 CDC RECOMMENDED IMMUNIZATION SCHEDULE FOR PERSONS AGED 7–18 YEARS—UNITED STATES, 2008

For those who fall behind or start late, see the green bars and the catch-up schedule

Vaccine ▼ Age ▶	7–10 years	11–12 years	13–18 years
Diphtheria, Tetanus, Pertussis[1]	*see footnote 1*	Tdap	Tdap

Measles, Mumps, Rubella[9]	MMR Series		
Varicella[10]	Varicella Series		

Range of recommended ages

Catch-up immunization

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2007, for children aged 7–18 years. Additional information is available at **www.cdc.gov/vaccines/recs/schedules**. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including for **high risk conditions: http://www.cdc.gov/vaccines/pubs/ACIP-list.htm**. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at **www.vaers.hhs.gov** or by telephone, **800-822-7967**.

1. Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap). *(Minimum age: 10 years for BOOSTRIX® and 11 years for ADACEL™)*
- Administer at age 11–12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a tetanus and diphtheria toxoids (Td) booster dose.
- 13–18-year-olds who missed the 11–12 year Tdap or received Td only are encouraged to receive one dose of Tdap 5 years after the last Td/DTaP dose.

2. Human papillomavirus vaccine (HPV). *(Minimum age: 9 years)*
- Administer the first dose of the HPV vaccine series to females at age 11–12 years.
- Administer the second dose 2 months after the first dose and the third dose 6 months after the first dose.
- Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.

3. Meningococcal vaccine.
- Administer MCV4 at age 11–12 years and at age 13–18 years if not previously vaccinated. MPSV4 is an acceptable alternative.
- Administer MCV4 to previously unvaccinated college freshmen living in dormitories.
- MCV4 is recommended for children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups.
- Persons who received MPSV4 3 or more years previously and remain at increased risk for meningococcal disease should be vaccinated with MCV4.

4. Pneumococcal polysaccharide vaccine (PPV).
- Administer PPV to certain high-risk groups.

5. Influenza vaccine.
- Administer annually to all close contacts of children aged 0–59 months.
- Administer annually to persons with certain risk factors, health-care workers, and other persons (including household members) in close contact with persons in groups at higher risk.
- Administer 2 doses (separated by 4 weeks or longer) to children younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time last season but only received one dose.
- For healthy nonpregnant persons (those who do not have underlying medical conditions that predispose them to influenza complications) ages 2–49 years, either LAIV or TIV may be used.

6. Hepatitis A vaccine (HepA).
- Administer the 2 doses in the series at least 6 months apart.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children.

7. Hepatitis B vaccine (HepB).
- Administer the 3-dose series to those who were not previously vaccinated.
- A 2-dose series of Recombivax HB® is licensed for children aged 11–15 years.

8. Inactivated poliovirus vaccine (IPV).
- For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if the third dose was administered at age 4 years or older.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.

9. Measles, mumps, and rubella vaccine (MMR).
- If not previously vaccinated, administer 2 doses of MMR during any visit, with 4 or more weeks between the doses.

10. Varicella vaccine.
- Administer 2 doses of varicella vaccine to persons younger than 13 years of age at least 3 months apart. Do not repeat the second dose if administered 28 or more days following the first dose.
- Administer 2 doses of varicella vaccine to persons aged 13 years or older at least 4 weeks apart.

TABLE 30.7 CATCH-UP IMMUNIZATION SCHEDULE FOR PERSONS AGED 4 MONTHS–18 YEARS WHO START LATE OR WHO ARE ≥1 MONTH BEHIND—UNITED STATES, 2008

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
CATCH-UP SCHEDULE FOR PERSONS AGED 4 MONTHS–6 YEARS					
Hepatitis B[1]	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Rotavirus[2]	6 wks	4 weeks	4 weeks		
Diphtheria, Tetanus, Pertussis[3]	6 wks	4 weeks	4 weeks	6 months	6 months[3]
Haemophilus influenzae type b[4]	6 wks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose) if first dose administered at age 12-14 months No further doses needed if first dose administered at 15 months of age or older	4 weeks[4] if current age is younger than 12 months 8 weeks (as final dose)[4] if current age is 12 months or older and second dose administered at younger than 15 months of age No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Pneumococcal[5]	6 wks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose) if first dose administered at age 12 months or older or current age 24–59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Inactivated Poliovirus[6]	6 wks	4 weeks	4 weeks	4 weeks[6]	
Measles, Mumps, Rubella[7]	12 mos	4 weeks			
Varicella[8]	12 mos	3 months			
Hepatitis A[9]	12 mos	6 months			
CATCH-UP SCHEDULE FOR PERSONS AGED 7–18 YEARS					
Tetanus, Diphtheria/ Tetanus, Diphtheria, Pertussis[10]	7 yrs[10]	4 weeks	4 weeks if first dose administered at younger than 12 months of age 6 months if first dose administered at age 12 months or older	6 months if first dose administered at younger than 12 months of age	
Human Papillomavirus[11]	9 yrs	4 weeks	12 weeks (and 24 weeks after the first dose)		
Hepatitis A[9]	12 mos	6 months			
Hepatitis B[1]	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Inactivated Poliovirus[6]	6 wks	4 weeks	4 weeks	4 weeks[6]	
Measles, Mumps, Rubella[7]	12 mos	4 weeks			
Varicella[8]	12 mos	4 weeks if first dose administered at age 13 years or older 3 months if first dose administered at younger than 13 years of age			

1. Hepatitis B vaccine (HepB).
- Administer the 3-dose series to those who were not previously vaccinated.
- A 2-dose series of Recombivax HB® is licensed for children aged 11–15 years.

2. Rotavirus vaccine (Rota).
- Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks.
- Do not administer a dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).
- The fifth dose is not necessary if the fourth dose was administered at age 4 years or older.
- DTaP is not indicated for persons aged 7 years or older.

4. *Haemophilus influenzae* type b conjugate vaccine (Hib).
- Vaccine is not generally recommended for children aged 5 years or older.
- If current age is younger than 12 months and the first 2 doses were PRP-OMP (PedvaxHIB® or ComVax® [Merck]), the third (and final) dose should be administered at age 12–15 months and at least 8 weeks after the second dose.
- If first dose was administered at age 7–11 months, administer 2 doses separated by 4 weeks plus a booster at age 12–15 months.

5. Pneumococcal conjugate vaccine (PCV).
- Administer one dose of PCV to all healthy children aged 24–59 months having any incomplete schedule.
- For children with underlying medical conditions, administer 2 doses of PCV at least 8 weeks apart if previously received less than 3 doses, or 1 dose of PCV if previously received 3 doses.

6. Inactivated poliovirus vaccine (IPV).
- For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if third dose was administered at age 4 years or older.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
- IPV is not routinely recommended for persons aged 18 years and older.

7. Measles, mumps, and rubella vaccine (MMR).
- The second dose of MMR is recommended routinely at age 4–6 years but may be administered earlier if desired.
- If not previously vaccinated, administer 2 doses of MMR during any visit with 4 or more weeks between the doses.

8. Varicella vaccine.
- The second dose of varicella vaccine is recommended routinely at age 4–6 years but may be administered earlier if desired.
- Do not repeat the second dose in persons younger than 13 years of age if administered 28 or more days after the first dose.

9. Hepatitis A vaccine (HepA).
- HepA is recommended for certain groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006;55(No. RR-7):1–23.

10. Tetanus and diphtheria toxoids vaccine (Td) and tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).
- Tdap should be substituted for a single dose of Td in the primary catch-up series or as a booster if age appropriate; use Td for other doses.
- A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose. A booster (fourth) dose is needed if any of the previous doses were administered at younger than 12 months of age. Refer to ACIP recommendations for further information. See *MMWR* 2006;55(No. RR-3).

11. Human papillomavirus vaccine (HPV).
- Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.

BOX 30.8 Vaccine Administration Routes

Intramuscular	Subcutaneous
DTaP, DT, Tdap	IPV
Hepatitis A, hepatitis B	MMR
Hib	Varicella
Influenza (trivalent)	MPSV4
Pneumococcal	
HPV	
MCV4	

Modified from Immunization Action Coalition (2007). *Administering vaccines: dose, route, site, and needle size.* Available at http://www.immunize.org/catg.d/p3085.pdf.

parents, allow ample time for them to read the VIS and to discuss their concerns. If the parents do not understand the information presented, they should feel comfortable asking questions. If the parents are illiterate, present the information orally and verify that the parents understand it. If the information in the VIS is not in the parent's native language, have a translator present the information.

At this time, ask the parents about the child's reactions to previous immunizations, and screen for precautions and contraindications for each vaccine to be administered. Before the vaccine is given, the parents must sign consent forms.

Any clinically significant adverse event that occurs after an immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). For assistance in obtaining and completing a VAERS form, call 800-822-7967 or visit www.vaers.hhs.gov.

Documentation in the child's permanent record includes the following:

- Date the vaccine was administered
- Name of vaccine (commonly used abbreviation is acceptable)
- Lot number and expiration date of vaccine
- Manufacturer's name
- Site and route by which vaccine was administered (e.g., left deltoid, IM)
- Edition date of VIS given to the parents
- Name and address of the facility administering the vaccine (where the permanent record will be kept)
- Name of the person administering the immunization

Families should be provided with a copy of the child's immunizations. This reinforces the importance of the procedure and reminds the parents to keep the child's immunizations up to date.

Figure 30.7 shows a typical vaccine administration record.

Vaccine Descriptions

This section reviews the most commonly used vaccines. These immunizations are recommended by the ACIP and the AAP. Each state has laws that determine which immunizations are required for school admittance. These requirements can be waived if a contraindication or precaution to the vaccine exists. *Contraindications* are conditions that justify withholding an immunization either permanently or temporarily. There are only two permanent contraindications: (1) an anaphylactic or systemic allergic reaction to a vaccine component or (2) with pertussis immunization, encephalopathy without an identified cause within 7 days of the immunization. Temporarily postponing vaccinations is recommended if the child has a severe illness with a high fever or immunosuppression or has recently received blood products. Vaccination should not be postponed because of a minor respiratory illness or a low-grade fever. *Precautions* are conditions

TABLE 30.8 VACCINE ADMINISTRATION: NEEDLE AND SITE SELECTION

Client	Needle Size	Needle Length (Inches)	Site
Intramuscular			
Birth–28 days	25 gauge	5/8	Anterolateral thigh
1–12 months	23–25 gauge	1	Anterolateral thigh
1–2 years	23–25 gauge	1 to 1.25 5/8 to 1	Anterolateral thigh Deltoid
3–18 years	22–25 gauge	1 to 1.25 5/8 to 1	Anterolateral thigh Deltoid
Subcutaneous			
1–12 months	23–25 gauge	5/8	Fat of anterolateral thigh
>12 months	23–25 gauge	5/8	Fatty tissue over triceps

DIPHTHERIA TETANUS & PERTUSSIS VACCINES

WHAT YOU NEED TO KNOW

1 Why get vaccinated?

Diphtheria, tetanus, and pertussis are serious diseases caused by bacteria. Diphtheria and pertussis are spread from person to person. Tetanus enters the body through cuts or wounds.

DIPHTHERIA causes a thick covering in the back of the throat.
- It can lead to breathing problems, paralysis, heart failure, and even death.

TETANUS (Lockjaw) causes painful tightening of the muscles, usually all over the body.
- It can lead to "locking" of the jaw so the victim cannot open his mouth or swallow. Tetanus leads to death in up to 2 out of 10 cases.

PERTUSSIS (Whooping Cough) causes coughing spells so bad that it is hard for infants to eat, drink, or breathe. These spells can last for weeks.
- It can lead to pneumonia, seizures (jerking and staring spells), brain damage, and death.

Diphtheria, tetanus, and pertussis vaccine (DTaP) can help prevent these diseases. Most children who are vaccinated with DTaP will be protected throughout childhood. Many more children would get these diseases if we stopped vaccinating.

DTaP is a safer version of an older vaccine called DTP. DTP is no longer used in the United States.

2 Who should get DTaP vaccine and when?

Children should get 5 doses of DTaP vaccine, one dose at each of the following ages:

✓ 2 months ✓ 4 months ✓ 6 months
✓ 15-18 months ✓ 4-6 years

DTaP may be given at the same time as other vaccines.

3 Some children should not get DTaP vaccine or should wait

- Children with minor illnesses, such as a cold, may be vaccinated. But children who are moderately or severely ill should usually wait until they recover before getting DTaP vaccine.
- Any child who had a life-threatening allergic reaction after a dose of DTaP should not get another dose.
- Any child who suffered a brain or nervous system disease within 7 days after a dose of DTaP should not get another dose.
- Talk with your doctor if your child:
  - had a seizure or collapsed after a dose of DTaP,
  - cried non-stop for 3 hours or more after adose of DTaP,
  - had a fever over 105°F after a dose of DTaP.

Ask your health care provider for more information. Some of these children should not get another dose of pertussis vaccine, but may get a vaccine without pertussis, called **DT**.

4 Older children and adults

DTaP is not licensed for adolescents, adults, or children 7 years of age and older.

But older people still need protection. A vaccine called **Tdap** is similar to DTaP. A single dose of Tdap is recommended for people 11 through 64 years of age. Another vaccine, called **Td**, protects against tetanus and diphtheria, but not pertussis. It is recommended every 10 years. There are separate Vaccine Information Statements for these vaccines.

Diphtheria/Tetanus/Pertussis	5/17/2007

FIGURE 30.6 Federal law mandates the use of Vaccine Information Statements (VIS). These should be given to the parent or primary caregiver for each vaccine the child receives.

5 What are the risks from DTaP vaccine?

Getting diphtheria, tetanus, or pertussis disease is much riskier than getting DTaP vaccine.

However, a vaccine, like any medicine, is capable of causing serious problems, such as severe allergic reactions. The risk of DTaP vaccine causing serious harm, or death, is extremely small.

Mild Problems (Common)

- Fever (up to about 1 child in 4)
- Redness or swelling where the shot was given (up to about 1 child in 4)
- Soreness or tenderness where the shot was given (up to about 1 child in 4)

These problems occur more often after the 4th and 5th doses of the DTaP series than after earlier doses. Sometimes the 4th or 5th dose of DTaP vaccine is followed by swelling of the entire arm or leg in which the shot was given, lasting 1-7 days (up to about 1 child in 30).

Other mild problems include:

- Fussiness (up to about 1 child in 3)
- Tiredness or poor appetite (up to about 1 child in 10)
- Vomiting (up to about 1 child in 50)

These problems generally occur 1-3 days after the shot.

Moderate Problems (Uncommon)

- Seizure (jerking or staring) (about 1 child out of 14,000)
- Non-stop crying, for 3 hours or more (up to about 1 child out of 1,000)
- High fever, over 105°F (about 1 child out of 16,000)

Severe Problems (Very Rare)

- Serious allergic reaction (less than 1 out of a million doses)
- Several other severe problems have been reported after DTaP vaccine. These include:
  - Long-term seizures, coma, or lowered consciousness
  - Permanent brain damage.

  These are so rare it is hard to tell if they are caused by the vaccine.

Controlling fever is especially important for children who have had seizures, for any reason. It is also important if another family member has had seizures. You can reduce fever and pain by giving your child an *aspirin-free* pain reliever when the shot is given, and for the next 24 hours, following the package instructions.

6 What if there is a moderate or severe reaction?

What should I look for?

Any unusual conditions, such as a serious allergic reaction, high fever or unusual behavior. Serious allergic reactions are extremely rare with any vaccine. If one were to occur, it would most likely be within a few minutes to a few hours after the shot. Signs can include difficulty breathing, hoarseness or wheezing, hives, paleness, weakness, a fast heart beat or dizziness. If a high fever or seizure were to occur, it would usually be within a week after the shot.

What should I do?

- **Call** a doctor, or get the person to a doctor right away.
- **Tell** your doctor what happened, the date and time it happened, and when the vaccination was given.
- **Ask** your doctor, nurse, or health department toreport the reaction by filing a Vaccine Adverse Event Reporting System (VAERS) form.

  Or you can file this report through the VAERS web site at **www.vaers.hhs.gov**, or by calling **1-800-822-7967**. *VAERS does not provide medical advice*

7 The National Vaccine Injury Compensation Program

In the rare event that you or your child has a serious reaction to a vaccine, a federal program has been created to help pay for the care of those who have been harmed.

For details about the National Vaccine Injury Compensation Program, call **1-800-338-2382** or visit the program's website at **www.hrsa.gov/vaccinecompensation.**

8 How can I learn more?

- Ask your health care provider. They can give you the vaccine package insert or suggest other sources of information.
- Call your local or state health department's immunization program.
- Contact the Centers for Disease Control and Prevention (CDC):
  - Call **1-800-232-4636 (1-800-CDC-INFO)**
  - Visit the National Immunization Program's website at **www.cdc.gov/nip**

FIGURE 30.6 (continued)

EVIDENCE-BASED PRACTICE 30.1
Which Intramuscular Thigh Vaccination Technique Results in the Fewest Adverse Reactions in Infants and Toddlers?

● Study
The incidence of vaccine-preventable diseases is decreasing, yet concern remains about adverse reactions following intramuscular immunizations. This single-center study, comprising 375 subjects age 2, 4, 6, or 18 months, used a blinded randomized controlled design to evaluate three techniques of intramuscular thigh injection: (1) the World Health Organization (WHO) recommendation—a 25-gauge, 16-mm (⅝-inch) needle inserted at a 90-degree angle to the long axis of the femur with the skin compressed between the thumb and index finger; (2) the Australian method—a 23-gauge, 25-mm (1-inch) needle inserted at the junction of the upper and middle thirds of the vastus lateralis at a 45- to 60-degree angle, pointing towards the knee; and (3) the U.S. technique—a 23-gauge, 25-mm (1-inch) needle inserted into the upper lateral quadrant at a 45-degree angle to the long axis of the femur and posterior at a 45-degree angle to the table top, with the thigh muscle bunched and the baby supine.

▲ Findings
Overall, the WHO technique resulted in less irritability and bruising than the other two techniques.

■ Nursing Implications
Parents often have concerns about adverse reactions associated with immunization. The 90-degree WHO technique is easier than the angled injection recommended in the Australian and U.S. techniques and reduces the risk of hitting bone with the longer needle. The amount of muscle varies with the size of the infant and toddler, so the nurse must ensure that the needle is long enough to place the medication intramuscularly. If a 1-inch-long needle is deemed necessary, the 90-degree angle technique may still be used to decrease the incidence of adverse reactions.

Diggle, L. (2006). The WHO technique for intramuscular thigh vaccination in infants and toddlers had fewer adverse reactions than two other techniques. *Evidence-Based Nursing, 9,* 9.

that increase the risk of an adverse reaction or may impair the child's ability to acquire immunity from the vaccine. On an individualized basis, providers must weigh the benefits of immunization against the likelihood of an adverse event. A summary of precautions and contraindications is presented in Table 30.9.

Diphtheria, Tetanus, and Pertussis Vaccines
Immunization against diphtheria, tetanus, and pertussis diseases is given via a combination vaccine. The vaccine currently used for children under age 7 is diphtheria, tetanus, acellular pertussis (DTaP). It contains diphtheria and tetanus toxoids and pertussis cell wall proteins. The older version of this vaccine—diphtheria, tetanus, pertussis (DPT)—contained killed whole cells of pertussis bacteria and caused more frequent and severe adverse reactions than DTaP. Diphtheria and tetanus (DT) vaccine is used for children under age 7 who have contraindications to pertussis immunization. Full-strength diphtheria toxoid causes significant adverse reactions in people over the age of 7 years. For this group, the TdaP adolescent preparation vaccine is used: it contains tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine. The lowercase "d" is used to designate the lower dose of diphtheria toxoid. The ACIP recommends that TdaP be used for all tetanus boosters in older children (11 to 12 years) and adolescents, because TdaP provides a boost to diphtheria and pertussis immunization.

▶ *Take* NOTE!

Pertussis cases have steadily risen since the 1970s, with 34% of cases occurring in adolescents. This increase prompted the AAP's recommendation to change the tetanus booster for older children and adolescents from Td to TdaP beginning in 2006, to provide continuing protection against pertussis infection.

Haemophilus influenzae Type B Vaccines
Haemophilus influenzae type B is a bacterium that causes several life-threatening illnesses in children under 5 years of age. These infections include meningitis, epiglottitis, and septic arthritis. *Haemophilus influenzae* type B conjugate vaccines (Hib) have been extremely effective in cutting the rates of these diseases in children. There are several different types of Hib conjugate vaccines. HibTITER (HbOC) and ActHib (PRP-T) require three doses for the primary infant series, while PedvaxHIB and Comvax (PRP-OMP) require two doses. These vaccines are interchangeable, but if different brands are administered to a child, then a total of three doses is necessary to complete the primary series in infants. Hib vaccine is not given to children 5 years of age or older.

Vaccine Administration Record for Children and Teens

Patient name: _____

Birthdate: _____

Chart number: _____

Vaccine	Type of Vaccine[1] (generic abbreviation)	Date given (mo/day/yr)	Source (F,S,P)[2]	Site[3]	Vaccine		Vaccine Information Statement		Signature/ initials of vaccinator
					Lot #	Mfr.	Date on VIS[4]	Date given[4]	
Hepatitis B[5] (e.g., HepB, Hib-HepB, DTaP-HepB-IPV) Give IM.									
Diphtheria, Tetanus, Pertussis[5] (e.g., DTaP, DTaP-Hib, DTaP-HepB-IPV, DT, Tdap, Td) Give IM.									
***Haemophilus influenzae* type b**[5] (e.g., Hib, Hib-HepB, DTaP-Hib) Give IM.									
Polio[5] (e.g., IPV, DTaP-HepB-IPV) Give IPV SC or IM. Give DTaP-HepB-IPV IM.									
Pneumococcal (e.g., PCV, conjugate; PPV, polysaccharide) Give PCV IM. Give PPV SC or IM.									
Rotavirus (Rv) Give oral (po).									
Measles, Mumps, Rubella[5] (e.g., MMR, MMRV) Give SC.									
Varicella[5] (e.g., Var, MMRV) Give SC.									
Hepatitis A (HepA) Give IM.									
Meningococcal (e.g., MCV4; MPSV4) Give MCV4 IM and MPSV4 SC.									
Human papillomavirus (e.g., HPV) Give IM.									
Influenza[5] (e.g., TIV, inactivated; LAIV, live attenuated) Give TIV IM. Give LAIV IN.									
Other									

1. Record the generic abbreviation for the type of vaccine given (e.g., DTaP-Hib, PCV), *not* the trade name.
2. Record the source of the vaccine given as either F (Federally-supported), S (State-supported), or P (supported by Private insurance or other Private funds).
3. Record the site where vaccine was administered as either RA (Right Arm), LA (Left Arm), RT (Right Thigh), LT (Left Thigh), IN (Intranasal), or O (Oral).
4. Record the publication date of each VIS as well as the date it is given to the patient.
5. For combination vaccines, fill in a row for each separate antigen in the combination.

Technical content reviewed by the Centers for Disease Control and Prevention, Nov. 2006.

FIGURE 30.7 Sample of a vaccine administration record.

TABLE 30.9 Contraindications and Precautions for Commonly Used Vaccines

Vaccine	Contraindications	Precautions
Hepatitis A (HepA)	• Standard contraindications* • Infants <12 months of age	Moderate or severe illness
Hepatitis B (HepB)	Standard contraindications*	• Moderate or severe illness with or without acute fever • Infants <2,000 g if mother is HBsAg negative
Diphtheria, tetanus, acellular pertussis (DTaP) Tetanus, diphtheria, acellular pertussis (TdaP)	• Standard contraindications* • Previous encephalopathy within 7 days after diphtheria, tetanus, pertussis (DTP) vaccine or DTaP	• Temperature 105° F (40.5° C) within 48 hours after previous dose • Continuous crying lasting 3 hours within 48 hours after previous dose • Previous convulsion within 3 days after immunization • Pale or limp episode or collapse within 48 hours after previous dose • Unstable progressive neurologic problem • History of Guillain-Barré syndrome within 6 weeks
Diphtheria, tetanus (DT)	Standard contraindications*	
Measles, mumps, rubella (MMR)	• Standard contraindications*† • Pregnancy or possibility of pregnancy within 4 weeks • Blood products within the past 5 months • Immunocompromised status • If not given same day as varicella and/or yellow fever, hold until spaced 28 days apart	Thrombocytopenia or history of thrombocytopenic purpura
Varicella	• Standard contraindications*† • Pregnancy or possibility of pregnancy within 4 weeks • Blood products received within the past 5 months • Immunocompromised status • If not given same day as MMR and/or yellow fever, hold until spaced 28 days apart	• Do not give within 24 hours of antiviral medications. • Family history of congenital or hereditary immunodeficiency
Inactivated poliovirus (IPV)	Standard contraindications*‡	• Moderate or severe acute illness • Pregnancy
Haemophilus influenzae type B (Hib)	Standard contraindications*	• Moderate or severe acute illness
Trivalent inactivated influenza vaccine (TIV)	Standard contraindications*	• History of Guillain-Barré syndrome within 6 weeks
Live attenuated influenza vaccine (LAIV)	• Standard contraindications* • Client <5 years old • Client 5 or more years old with chronic illnesses • Client with close contact with severely immunosuppressed persons	Do not give within 48 hours of antiviral medications.
Pneumococcal conjugate vaccine (PCV7)	Standard contraindications*	Moderate or severe acute illness
Pneumococcal polysaccharide vaccine (PPV23)		

*1. Do not administer if client has had an anaphylactic reaction to prior dose of vaccine or any of its components. 2. Do not administer if client has a moderate to severe acute illness. Minor illnesses are not a reason to postpone immunization.

†Inquire about neomycin or gelatin allergies.

‡Inquire about neomycin, streptomycin, or polymyxin B allergies.

Polio Vaccine

Inactivated polio vaccine (IPV) is the only polio vaccine currently recommended in the United States. It is a killed virus vaccine that poses no risk for vaccine-acquired disease. Oral polio vaccine (OPV), a live attenuated virus vaccine, was the preferred polio vaccine until 2000. At that time it became apparent that the only victims of poliomyelitis were people who had acquired it from OPV. The ACIP determined that in this country the risks of OPV outweighed the benefits and withdrew its recommendation of OPV.

Measles, Mumps, and Rubella Vaccines

Measles, mumps, and rubella (MMR) is a live attenuated virus combination vaccine. It is the one most commonly used in childhood immunizations. MMR can be given the same day as other live attenuated virus vaccines such as varicella vaccine. However, if not given on the same day, the immunizations should be spaced at least 28 days apart. Anaphylactic reactions are believed to be associated with the neomycin or gelatin components of the vaccine rather than the egg component. The vaccine is not prepared from the allergenic albumen portion of the egg, so egg allergy is no longer a contraindication for measles vaccine. Pregnancy in a child's mother is not a contraindication to the vaccination of the child. Individual measles, mumps, and rubella vaccines are available if needed.

Hepatitis A Vaccine

Hepatitis A vaccine (HepA) is an inactivated whole virus vaccine. The vaccine has been demonstrated to be about 94% effective in preventing hepatitis A infection. Hepatitis A is spread through close physical contact and by eating or drinking contaminated food or water. It is one of the most frequently reported vaccine-preventable diseases in the United States. Young children are particularly susceptible to hepatitis A because of their close contact with other children, inadequate hygiene practices, and their tendency to place everything in their mouth. Hepatitis A vaccine is recommended to be given to all children at age 12 months, followed by a repeat dose in 6 to 12 months.

Hepatitis B Vaccine

Hepatitis B vaccine (HepB) is a recombinant vaccine. The vaccine is 80% to 90% effective in preventing hepatitis B infection. For infants, the mother's HBsAg status determines when immunization for hepatitis B begins. If the mother's status is positive or unknown, the neonate is immunized within the first 12 hours of life, at 1 to 2 months of age, and at 6 months of age. This is vital, because up to 90% of infected neonates develop chronic carrier status and will be predisposed to cirrhosis and hepatic cancer. If the mother's status is negative, immunizations are given routinely at 2, 4, and 6 months of age. Because hepatitis B is a sexually transmitted infection, it is important to verify the immunization status of all adolescents.

Varicella Vaccine

Varicella vaccine (Var) is a live attenuated virus vaccine. All children age 12 to 15 months who have not had varicella (chickenpox) should be immunized. A second dose is recommended at age 4 to 6 years. The vaccine provides effective postexposure prophylaxis if administered within 3 to 5 days after exposure. Varicella vaccine may be given the same day as other live attenuated virus vaccines. However, if not given on the same day, the immunizations should be spaced at least 28 days apart. Pregnancy in a child's mother is not a contraindication to the vaccination of the child.

Pneumococcal Vaccines

Streptococcus pneumoniae (pneumococcus) is the most common cause of pneumonia, sepsis, and meningitis in children under 2 years of age. The two available pneumococcal vaccines are pneumococcal conjugate vaccine (PCV) and pneumococcal polysaccharide vaccine (PPV). PCV contains seven strains of *Streptococcus pneumoniae.* It stimulates an immune response in infants and is given at 2 months of age as part of the initial immunization series. PPV contains 23 strains of *Streptococcus pneumoniae.* It does not provoke an immune response in children under 2 years of age. PPV is given to children over 2 years old who are at high risk for pneumococcal sepsis. This group includes children with anatomic/functional asplenia; sickle cell disease; chronic cardiac, pulmonary, or renal disease; diabetes mellitus; HIV infection; or immunosuppression.

Influenza Vaccines

Influenza immunization is recommended yearly for children between the ages of 6 and 59 months. Children 2 years old or older should be vaccinated if they have chronic health problems. Caregivers and household contacts of these children should also be immunized. The vaccine can also be given to anyone wishing to have immunity.

There are two influenza vaccines available, the trivalent inactivated influenza vaccine (TIV) and the live attenuated influenza vaccine (LAIV). LAIV is given intranasally and is indicated for healthy persons between the ages of 5 and 49 years. The virus in LAIV can replicate, and a person who has received LAIV can shed virus for a week. LAIV should not be given to anyone who will be in contact with an immunosuppressed person requiring a protected environment. TIV is suitable for any eligible person age 6 months or older. TIV is not capable of causing disease and is given by intramuscular injection.

Rotavirus Vaccine

Rotavirus is the most common cause of severe gastroenteritis among young children. The virus is shed in the stool and easily spreads via the fecal–oral route. Rotavirus accounts for about 50% of annual hospitalizations for gastroenteritis in children. Severe, watery, crampy diarrhea quickly leads to dehydration in the infected child. The most severe disease occurs in children ages 3 to 35 months.

The rotavirus vaccine is a live vaccine targeting five strains of rotavirus and is given via the oral route to infants less than 32 weeks of age.

Human Papillomavirus Vaccine

Human papillomavirus (HPV) is a DNA tumor virus transmitted through direct skin-to-skin contact. HPV is contracted most often during vaginal or anal penetrative sexual acts. HPV infection is most common in adolescents and young adults aged 15 to 24 years who are sexually active. HPV causes genital warts and is responsible for the development of cervical cancer. For these reasons, the ACIP and AAP have recommended that HPV vaccination occur in preadolescent girls. The three-vaccine series should begin at age 11 to 12 years. The vaccine is anticipated to prevent most cases of genital warts and cervical cancer.

Meningococcal Vaccine

Meningococcal disease may manifest as meningitis or as a deadly blood infection (meningococcemia). It is caused by the bacterium *Neisseria meningitiditis,* which is spread through direct contact or by air droplets. Since the 1990s, the incidence of meningococcal disease among adolescents and young adults has increased about 60%. About 10% to 12% of infected persons die; of the remaining victims, about 20% suffer severe long-term consequences (National Meningitis Association, 2007). For these reasons, the meningococcal vaccine is now recommended for all previously unvaccinated children at age 11 to 12 years. These children should receive the meningococcal conjugated vaccine (MCV4). Certain high-risk groups may be vaccinated at 2 years of age (through age 10) with the meningococcal polysaccharide vaccine (MPSV4).

Recall the Randall children, introduced at the beginning of the chapter. What immunizations would be appropriate for them to receive? Explain how you would administer the injections, and discuss any contraindications or precautions.

Barriers to Immunization

A fully immunized child is protected from the discomforts and complications of many infectious diseases. Disease prevention spares the family the emotional and financial burdens that serious illnesses can cause. Immunization programs prevent devastating epidemics in a community. Health care dollars not spent treating preventable diseases can be used for other urgent issues. Despite the numerous advantages of immunization, many children in this country are not fully immunized.

Many factors lead to children not being fully immunized. Parental concerns about vaccine safety are a significant cause of inadequate immunization. Misconceptions of what constitutes a contraindication to vaccination and having more than one health care provider are major contributors to inadequate immunization status. The more children in a family, the less likely the children are to be fully vaccinated. The costs for vaccines can also deter families from obtaining immunizations. Parents may want to postpone some of the scheduled immunizations because they are concerned about the effects of multiple injections on their child. Postponing a portion of the immunizations puts the child at risk for contracting disease. Disrupting the optimal spacing of the immunizations can decrease the efficacy of vaccine, further putting the child at risk.

Overcoming Barriers to Immunization

The AAP recommends the use of a manufacturer-produced combination vaccine whenever it will reduce the number of injections at a visit. These combination vaccines have been studied and approved by the U.S. Food and Drug Administration (FDA). The nurse should never mix separate vaccines in the same syringe unless expressly permitted in the product insert for all vaccines involved. Examples of combination vaccines are:

- DTaP: diphtheria, tetanus, acellular pertussis
- MMR: measles, mumps, rubella
- HepB-Hib: hepatitis B virus and *Haemophilus influenzae* type B

The Vaccines for Children (VFC) program was implemented in 1994. Prior to this program, free vaccines were available only through public health agencies. By providing free vaccines to low-income and uninsured families through their private health care providers, immunization rates have increased tremendously. Additional information on the VFC program is available at http://www.cdc.gov/vaccines/programs/vfc/default.htm.

Establishing a medical home for every child will alleviate many of the factors associated with lack of immunization. Parents who have a long-term, trusting relationship with a health care provider are more likely to have their concerns about vaccine safety discussed and removed. Missed opportunities for immunizations can be reduced by:

- Maintaining a centralized immunization record
- Verifying immunization status at every visit, not just health supervision visits
- Verifying the status of siblings accompanying the child to the appointment
- Providing parents with up-to-date information on vaccines geared to their concerns and needs

Two excellent resources for vaccination recommendations in the United States are the CDC's Vaccines and Immunizations website (http://www.cdc.gov/vaccines/default.htm) and the National Immunization Hotline (800-235-2522).

Discuss potential barriers to the Randall children being fully immunized. As a nurse, how can you help overcome these barriers?

Health Promotion

Health promotion focuses on maintaining or enhancing the physical and mental health of clients. The principal components of health promotion are identifying risk factors for a disease, facilitating lifestyle changes to eliminate or reduce those risk factors, and empowering clients at the individual and community level to develop resources to optimize their health. The nurse implements health promotion through education and anticipatory guidance.

Partnership development is the key strategy for success when implementing a health promotion activity. Identifying key stakeholders from the community allows problems to be solved and provides additional venues for disseminating information. Health promotion messages can be reinforced at schools, daycare centers, community agencies, and churches. If families have difficulty getting to health care facilities, the community arenas may be the primary source of health promotion.

Providing Anticipatory Guidance

Anticipatory guidance is primary prevention. The nurse partners with the parents to create a "road map" to optimal health for the child. *Healthy People 2010* provides a framework for determining health promotion goals. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* (Green & Palfrey, 2002) is another valuable resource.

The "skeleton" of the guidance provided involves common childhood health problems. The nurse fleshes out that information using the results of risk assessments and screening tests, health concerns unique to the child, and the interests and concerns of the parents. Age-related anticipatory guidance information is provided in Chapters 4 through 8.

Provide appropriate anticipatory guidance for 3-year-old Maya and 9-month-old Evan.

Promoting Oral Health Care

Effective oral health practices are essential to the overall health of children and adolescents. Dental care is the most prevalent unmet health need among children in the United States. Poor oral health can have significant negative effects on systemic health. Children who suffer from dental caries have an increased incidence of pain, a decreased appetite, and sleep pattern disturbances. They are at increased risk for abscesses and systemic infections.

Optimal oral health is not limited to the prevention and treatment of dental caries. It includes anticipatory guidance about non-nutritive sucking habits, injury prevention, oral cancer prevention, and tongue and lip piercing. Preventing and treating malocclusion can have a significant benefit for children. Comprehensive health care is not possible if oral health is not a priority in the health delivery system.

Optimizing oral health can benefit the community as well as the individual client. There has been a 60% reduction in early childhood caries over the past 50 years since community water supplies were fluoridated at optimal levels. The cost of pediatric oral health care could be reduced 50% with the proper use of fluoride treatments coupled with other preventive measures. These health care dollar savings will enhance community resources.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth.	• Teach children and adolescents appropriate toothbrushing and flossing techniques. • Encourage use of fluoride-containing toothpastes. • Encourage routine dental visits.

Source: USDHHS, 2007.

Having a dental home enhances the likelihood that the child will obtain appropriate preventive and routine care. The American Academy of Pediatric Dentistry (AAPD) adopted the policy of the dental home in 2001. It is modeled on the AAP medical home policy. The dental home provides the same benefits to the child as the medical home. Characteristics of a dental home are listed in Box 30.9. The AAPD recommends that the dental home be established by the infant's first birthday.

Promoting Healthy Weight

Childhood obesity is a growing problem. The number of overweight children has doubled since 1980; the rate for teens has tripled. The principal causes of this increase in obesity are unhealthy eating habits and decreased physical activity. Research has demonstrated that weight is best managed with a combination of diet and exercise. Nurses can have the maximum effect in promoting healthy weight in children by encouraging activities that address both healthy eating patterns and physical fitness. Children, parents, and communities are all targets for healthy weight promotion by nurses.

The focus of healthy weight promotion should be health-centered, not weight-centered. Emphasizing the

BOX 30.9 Characteristics of the Dental Home

- Preventive health program based on risk assessment
- Anticipatory guidance on oral health developmental issues
- Plans for emergency dental trauma
- Anticipatory guidance on oral hygiene
- Comprehensive dental care
- Referral to specialists for care not available at the dental home

benefits of health through an active lifestyle and nutritious eating creates a nurturing environment for the child. This allows the child to maintain his or her self-esteem. Linking success to numbers on a scale increases the possibility of developing eating disorders, nutritional deficiencies, and body hatred. A health-centered orientation also allows the family to develop a lifestyle that incorporates its cultural food patterns and traditions.

The nurse can stress the benefits of the mother's healthy nutritional habits on the fetus at prenatal visits. Parents who have a healthy eating pattern are likely to maintain and encourage those patterns in their children. The nurse provides parents with anticipatory guidance about age-related eating patterns during each health supervision visit. Parents with toddlers and preschoolers may need training in ways to cope with the child's growing autonomy while providing a variety of nutritious options.

The nurse can begin directly advising children on healthy foods starting at age 3. Information and teaching modalities need to be age-appropriate. With colorful posters and games, the nurse can teach the preschool child the difference between healthy and unhealthy food choices. As children enter school, group and peer-led activities can be very effective. The nurse must gear material toward the teen's growing autonomy in making self-care decisions.

Before providing education to school-age and teenage children, it is important to obtain nutritional histories directly from them because increasingly they are eating meals away from the family table. As they spend more time away from their parents, they need to develop the ability to make nutritious choices. The goal is to help older children develop strategies for making healthy choices as part of their increasingly independent lifestyle. Detailed anticipatory guidance is provided in Teaching Guidelines 30.1 and in Chapters 28 through 32.

TEACHING GUIDELINES 30.1

Healthy Eating

Breakfast

1. Don't skip breakfast. You will not have enough energy to play well later in the day. Skipping breakfast can also lower your grades in school.
2. Avoid eating high-sugar foods at breakfast. They will make you sleepy during the day.
3. Start your breakfast with some fruit. A small glass of juice, berries on your cereal, or a banana is a good choice.
4. Protein is important at breakfast. Milk, either in a glass or on cereal, is a good source of protein; so is yogurt or peanut butter.

Lunch

1. Check the quality of school-provided lunches. If they are high in fat or sugar, bring your lunch. Many schools publish their daily menus in advance. Check the newspaper or ask the school for a copy.
2. Add a variety of healthy alternatives to your lunches.
   a. Try different types of breads. Pitas, wraps, bagels, and taco shells can be a good change of pace in the sandwich routine.
   b. Freeze fruits before putting them in the lunch box. This will keep the lunch items cool and the fruit fresh-tasting. Canned pineapple and grapes freeze well; so do bananas.
   c. Try alternatives to high-fat chips. Dried fruits, baked pretzels, and animal crackers are a few examples of tasty, healthy treats.
   d. Low-fat chocolate milk is more nutritious than prepackaged juice boxes, which have high sugar concentrations.

Snacks

1. Limit snacks to after school and bedtime. Light snacks such as yogurt or fruit provide good hunger management. A very hungry child will tend to overeat at meals.
2. Children need to learn to eat only when they are hungry. Children often eat out of boredom. Discourage nonstop grazing by planning activities to occupy the child.

Dinner

1. Plan your menu a week ahead. Planning ahead reduces the likelihood of eating out or getting take-out food. Restaurant foods are more likely to be high in fats and carbohydrates.
2. Prepare homemade healthy versions of take-out favorites. Top prepared pizza crust with cooked chicken, vegetables, mushrooms, and cheese. Serve the pizza with a salad for a complete and healthy meal. "Make your own tacos" nights, using lean hamburger and low-fat sour cream, can be a lot of fun for children.
3. Don't turn dinner into a battle zone. Forcing children to eat foods they do not like will only deepen their dislike of them. Give them the healthy foods they do enjoy and eventually they will explore more options.
4. Lead by example. Children eventually adopt the eating patterns of their parents. If they see their parents eat vegetables, they will eventually try them.

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children and adolescents who are overweight or obese.	• Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age. • Provide accurate diet counseling. • Encourage daily physical activity. • Counsel parents to limit television/computer time daily.

Source: USDHHS, 2007.

HEALTHY PEOPLE 2010

Objective	Significance
Increase the proportion of adolescents who engage in moderate physical activity for at least 30 minutes on 5 or more of previous 7 days.	• For the nonexercising teen, advise him or her to start slowly by walking. • Work with the teen to identify physical activities that interest him or her. • Praise efforts to participate in a routine exercise plan. • Identify an athletic individual with whom the teen identifies, and encourage similar activities in the teen.

Source: USDHHS, 2007.

Healthy physical activity can take many forms. During the preschool years, nurses should encourage parents to provide a wide variety of physical activities. This exposure to multiple types of exercise allows the child to find the one that is most enjoyable and increases the chances that he or she will maintain an active lifestyle. The focus should be on noncompetitive, fun activities. When the child enters school, the lure of television and computers can significantly diminish the amount of time spent in physical activity. Parents can encourage their children to stay physically active in several ways. They can limit the amount of time spent in sedentary activities and actively encourage the child to pursue any exercise that he or she enjoys. In addition to verbal encouragement, parents can promote exercise by participating in exercise with the child. A simple family walk can increase physical fitness while providing time for interaction between parent and child. Teaching Guidelines 30.2 gives additional suggestions for promoting physical activity.

TEACHING GUIDELINES 30.2

Healthy Activity

1. Plan physical activities that your family can do as a group.
2. Write exercise activities on your family's daily schedule.
3. Look for activities that appeal to your child's interest, such as dance, team sports, or swimming.
4. Place value on noncompetitive as well as competitive activities.
5. Show your child you believe exercise is important. Exercise daily yourself.
6. Encourage the community to develop safe areas for spontaneous games and activities.

Promoting Personal Hygiene

Handwashing is the first personal hygiene topic that needs to be introduced to children. Handwashing prevents disease by limiting a child's exposure to pathogens. The nurse can introduce the topic to preschool children using cartoons and games. Have the child sing "Twinkle, Twinkle Little Star" while washing his or her hands; this encourages adequate cleansing time. Use soap containers and towels with colorful characters to make the experience more fun. The school-age child can understand the concepts of germs and disease. Slogans such as "Let's drown a germ" can serve as a reminder of the importance of handwashing. The "Glo Germ" program (www.glogerm.com) is very effective in this age group. A nontoxic substance that shines under a black light is placed on the children's hands. The children can follow how germs travel from object to object. After washing their hands, the children can see if they did a good job.

In response to peer pressure, teenagers are usually stringent about personal hygiene. Young teens may need guidance in dealing with pubescent body changes such as body odor, fungal infections such as tinea pedis (athlete's foot), and acne.

Promoting Safe Sun Exposure

Skin cancer is a significant health problem in the United States. Blistering sunburns in children substantially increase the risk of melanoma and other skin cancers. People with fair skin are at highest risk for skin cancers, but anyone can become sunburned and develop skin cancer. When teaching clients about safe sun exposure, remind them that harmful ultraviolet (UV) rays can reflect off water, snow, sand, and concrete, so being in the shade or under an awning does not guarantee protection. Adequate sun protection requires using sunscreen, avoiding peak sun hours, and wearing proper clothing. Teaching Guidelines 30.3 gives more detailed instruc-

TEACHING GUIDELINES 30.3

Safe Sun Exposure

Sunscreen

1. Use sunscreen lotions every day. Harmful ultraviolet (UV) rays penetrate clouds and cause damaging sunburns.
2. Use sunscreens with a sun protection factor (SPF) of 15 or higher. An adequate amount for an average-sized child is half an ounce.
3. Apply sunscreens half an hour before sun exposure.
4. Reapply every hour if the child is perspiring heavily.
5. Reapply immediately after swimming.
6. Infants 6 months old or younger should not use sunscreens. Take steps to avoid sun exposure completely with this age group.

Clothing

1. Wear hats. The brim of the hat should be 4 inches or more and should shade the ears. Straw hats need to have a sunproof liner to be effective. Children introduced to hats as infants usually accept hats as part of the "outfit."
2. Wear UV-blocking sunglasses. The eye is the second most common site for melanoma.
3. Wear long, loose, and lightweight clothing for maximum sun protection.

Lifestyle

1. Avoid sun exposure between 10 a.m. and 4 p.m. This is when UV rays are strongest.
2. Ask your health care provider if your medication will increase your sensitivity to UV rays. If the answer is yes, take extra precautions to reduce sun exposure.
3. Avoid tanning parlors. The devices emit UV rays just like the sun and can cause damage.
4. Check the UV index before going out. The higher the index, the more precautions you should take. UV index figures are available in newspapers, TV, and radio weather reports and on the Internet.
5. Advocate for safe-sun scheduling of recreational activities. Talk to others about scheduling outdoor activities before 10 a.m., after 4 p.m., or in the shade.
6. Consider UV-blocking plastic film for your house and car windows.

tions. With proper sun protection starting in infancy, 80% of skin cancers could be prevented.

▶ ***Take*** *NOTE!*

Give children the following physical reference when doing health promotion on safe sun exposure. Tell the child, "Play outside only when your shadow is taller than you are." The child's shadow will be "taller" before 10 a.m. and after 2 p.m. The nurse can demonstrate this concept by placing a ruler on end and shining a bright light over it. As the nurse moves the light, the child will see the ruler's shadow lengthen.

Key Concepts

- Health supervision for children is a dynamic process. Optimal wellness for the child can only occur if the nurse forms meaningful partnerships with the child, the family, and the community. These partnerships allow for free exchange of information and the establishment of mutually agreed upon goals. The medical home exists when there is a single primary care provider for the child. The medical home establishes a trusting long-term relationship with the child and family. This relationship leads to comprehensive, coordinated, and cost-effective care for the child.
- Health supervision has three components: developmental surveillance and screening; injury and disease prevention; and health promotion.
- Developmental surveillance is an ongoing process requiring a skilled observer and interviewer. To be effective, the nurse must understand normal growth and development expectations and be proficient at developmental screening procedures and techniques. Caregivers are most likely to reveal risk factors or warning signs for developmental delay when the nurse has a long-term and trusting relationship with the family.
- Screening tests are part of injury and disease prevention. They are modalities that identify treatable disease in an early or asymptomatic state and allow for cure or lessening of the disease's injury.
- Vision and hearing screening are functional testing modalities that the nurse must be proficient in administering in order for the child's results to be valid.
- Immunizations are a cornerstone of pediatric disease prevention. The nurse increases the effectiveness of immunization by understanding the principles of immunization and applying them to the client's individ-

ual circumstances. Adhering to good immunization management practices, as outlined by the ACIP and the AAP, enhances the benefits and reduces the risks of immunization.

- Barriers to full immunization include fragmentation of health care, concerns about vaccine safety, financial constraints, and lack of knowledge. The nurse can be pivotal in assuring that children and adolescents are fully immunized by serving as client educator and advocate.
- Children with chronic illnesses have a critical need for comprehensive and coordinated health supervision. Children with chronic illnesses require more frequent health supervision assessments. These children must have a medical home. The location of that medical home may be with a knowledgeable primary health care provider or at a multidisciplinary specialty facility. The location is determined by the child's needs and the family's preferences.
- The nurse incorporates frequent assessments of the many psychosocial stressors faced by families of children with chronic illnesses when establishing health care plans for them.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. During the health interview, the mother of a 4-month-old says, "I'm not sure my baby is doing what he should be." What is the nurse's best response?
   a. "I'll be able to tell you more after I do his physical."
   b. "Fill out this developmental screening questionnaire and then I can let you know."
   c. "Tell me more about your concerns."
   d. "All mothers worry about their babies. I'm sure he's doing well."
2. An infant boy is at your facility for his initial health supervision visit. He is 2 weeks old and responds to a bell during his examination. You review all his birth records and find no documentation that a newborn hearing screening was performed. What is the best action by the nurse?
   a. Do nothing; responding to the bell proves the infant does not have a hearing deficit.
   b. Schedule the infant immediately for newborn hearing screening.
   c. Ask the mother to observe for signs that the infant is not hearing well.
   d. Screen again with the bell at the infant's 2-month health supervision visit.
3. A 15-month-old girl is having her first health supervision visit at your facility. Her mother has not brought a copy of the child's immunization record but believes she is fully immunized: "She had immunizations 3 months ago at the local health department." Which would be the best action by the nurse?
   a. Ask the mother to bring the records to the 18-month health supervision visit.
   b. Start the "catch-up" schedule because there are no immunization records.
   c. Keep the child at the facility while the mother returns home for the records.
   d. Call the local health department and verify the child's immunization status.
4. A 4-year-old child is having a vision screening performed. Which screening chart would be best for determining the child's visual acuity?
   a. Snellen
   b. Ishihara
   c. Allen figures
   d. CVTME
5. Which facility fulfills the characteristics of a medical home?
   a. An urgent care center
   b. A primary care pediatric practice
   c. A mobile outreach immunization program
   d. A dermatology practice
6. When should the child's first examination by a dentist occur?
   a. By the first birthday
   b. By the second birthday
   c. By entry into kindergarten
   d. By entry into first grade

CRITICAL THINKING EXERCISES

1. During a health supervision visit for a 5-year-old boy, the mother tells you she is worried about his hearing. Your facility has been his medical home since birth. He was the product of a normal pregnancy and delivery. He has had frequent ear infections since the age of 8 months. Six months ago he had a ruptured appendix. He was treated with an aminoglycoside. He has been fully recovered for 4 months.
   a. During the health interview, what information should the nurse elicit from the mother?
   b. What information should the nurse verify from the permanent medical record?
   c. What risk factors for hearing loss does this child have?
   d. What is the best course of action at this time?
2. The nurse is examining a 4-year-old to determine his readiness for school. Describe the developmental, vision, and hearing screening tools that will help the nurse to identify any problems.

STUDY ACTIVITIES

1. Develop an immunization plan for the following well children: a 2-month-old, an 18-month-old who has never been immunized, and a 5-year-old who was current with all immunizations at age 2.
2. This is the first health supervision visit, since arriving in this country 1 week ago, for a 3-year-old international adoptee from Russia. Develop a plan for this visit.
3. Develop a healthy weight program for the following: a preschool class, a family in which the parents and the two school-age children are mildly overweight, and a teenage girl who is of normal weight but fears "getting fat."

CHAPTER 31

Health Assessment of Children

Elliot Simmons, 3 years old, is brought to the clinic for his annual examination. His mother states that he is very fearful and anxious about this visit.

KEY TERMS

accommodation
acrocyanosis
auscultation
body mass index (BMI)
cerumen
chief complaint
fontanel
inspection
lanugo
obligate nose breathing
palpation
PERRLA
point of maximal impulse (PMI)
stadiometer
Tanner stages
tympanometer

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Demonstrate an understanding of the appropriate health history to obtain from the child and the parent or primary caregiver.
2. Individualize elements of the health history depending upon the age of the child.
3. Discuss important concepts related to health assessment in children.
4. Describe the appropriate sequence of the physical examination in the context of the child's developmental stage.
5. Perform a health assessment using approaches that relate to the age and developmental stage of the child.
6. Distinguish normal variations in the physical examination from differences that may indicate serious alterations in health status.
7. Determine the sexual maturity of females and males based upon evaluation of the secondary sex characteristics.

Wow

Growth and development is a journey, on which many children venture without a map.

Assessment of the child's health status involves many components: the health interview and history; observation of the parent–child interaction; physical examination; and the child's emotional, physiological, cognitive, and social development. The nurse's skills are vital to the success of the assessment process. The nurse must (Mandleco, 2005):

- Establish rapport and trust
- Demonstrate respect for the child and the parent or caregiver
- Communicate effectively by actively listening, demonstrating empathy, and providing feedback
- Observe systematically
- Obtain accurate data
- Validate and interpret data accurately

The focus of the assessment process depends on the purpose of the visit and the needs of the patient. Assessment is an ongoing process and is repeated to varying degrees at every encounter. Expert nurses are constantly evaluating all of those in their care, whether directly or indirectly as part of conversation and play. Indeed, some of the subtlest developmental signs may express themselves only during relaxed and casual interaction with a child. You can observe gait while watching a child run down the hall; assess fine motor skills and social adaptation while playing a board game; or observe balance and coordination when bouncing a ball. Playful activities such as tickling a child can give the nurse feedback related to upper body strength when the child attempts to push the nurse's arms away. Nurses must also learn to perform a comprehensive and thorough examination of a child in an efficient manner.

A thorough and thoughtful assessment of a child is the foundation upon which a nurse determines the needs of and plan of care for the patient. Nothing can replace it for giving the nurse a snapshot of the life and health of the child. A comprehensive history, a thorough examination, and developmental or cognitive testing as appropriate will provide practical information about the health of a child and guide the nurse's plan of care. The history and physical examination also provide a time for health education, teaching about expected growth and development, and discussing healthy lifestyle choices. The nurse uses critical thinking skills to analyze the data and establish priorities for nursing intervention or follow-up.

The health assessment may be documented using a number of formats. The information should be easily retrievable and available to all members of the child's health care team.

Health History

The health history provides the nurse with an overall picture of what the child has experienced, highlighting areas of concern such as recurrent upper respiratory infections or headaches. This not only helps the nurse to assess those specific areas more comprehensively but also provides the opportunity to ask focused questions and identify areas where education may be needed. The time used to obtain the health history also gives the nurse an opportunity to interact with the child in a nonthreatening manner, while the child watches the interactions between the nurse and the primary caregiver.

PREPARING FOR THE HEALTH HISTORY

Appropriate materials and a suitable environment are needed when performing a thorough health history. Take into account family roles and values. Consider the age and developmental stage of the child so that you can approach the child appropriately and possibly involve him or her in the health history. Observe the child–parent interaction. Determine the extent of the health history that is needed in a given situation. Being well organized and staying flexible will help ensure success.

Gathering Materials and Preparing Yourself for the Health History

Before you begin, make sure you have materials to record your history data (either a computer or chart paper and a pen), a private space with adequate lighting, chairs for adults and the nurse, and a bed or examination table for the child. The space should be safe for your patient's developmental stage and allow you uninterrupted time for your examination. Sit down for as much of the history taking as possible to demonstrate a relaxed and welcoming manner.

Approaching the Parent or Caregiver

Greet the parent or caregiver by name. While interviewing the parent, provide toys or books to occupy the child, allowing the parent to concentrate on your questions. Use open-ended questions and avoid making judgmental comments. Show respect by remaining approachable. Remember that the structure of the family and its roles and dynamics will affect how the family communicates and how they make decisions about health care. Demonstrate patience and help the parent stay on track when there are several children in the family. Throughout the interview, refer to the child by name and use the correct gen-

der when referring to the child, demonstrating interest and competence.

▶ *Take* NOTE!

Illness can cause great stress in families and individuals, so nurses must remember to protect themselves from potentially threatening behavior on the part of the family. Sit close to the door, and if you are uncomfortable with a family member, ask for assistance. You may need to keep the door open or have another nurse or security personnel present.

Approaching the Child

Show a professional demeanor while still being warm and friendly to the caregivers and child. A white examination coat or all-white uniform may be frightening to children, who may associate the uniform with painful experiences or find it too unfamiliar. The nurse can wear a variety of professional-looking outfits, whether colorful uniform tops, aprons, or smocks worn over white uniforms, or everyday clothing, depending on the setting of the nurse's practice. Make eye contact if possible and address the child by name. Use slow deliberate gestures rather than very quick or grand ones, which may be frightening to shy children.

Some young children will warm up when given time to be invisible in the room, such as hiding behind a parent before they tentatively appear. Make physical contact with the child in a nonthreatening way at first. Briefly cuddling a newborn before returning it to the caregiver, warmly shaking the hand of older children and teens, and laying your hand on the head or arm of toddlers and preschoolers will convey a gentle demeanor. A joke, a puppet, a silly story, or even a simple magic trick may coax the child into warming up. Being at the same eye level as the child can also be more reassuring than standing over the child. This may require having extra seating for the nurse at the same level as the child and parent/caregiver. Aim to be seen as a trustworthy adult who is the child's partner in feeling better and staying healthy.

Elicit the child's cooperation by allowing him or her control over the pace, the order, or anything else that the child can control while still allowing you to obtain the information you need. All of this establishes a personal relationship with the child and helps gain his or her cooperation.

Communicating With the Child During the Health History

The child should be given opportunities to actively participate in the health history and assessment process. For young children, such as toddlers and preschoolers, ask them to point to where it hurts and allow them to answer questions. Validation of the information by the parent/caregiver is essential because of the limited comprehension and language use of children at these ages. The school-aged child can be more accurate because of his or her increased language skills and maturity level.

Initially, address the child and obtain as much information from him or her as possible. School-aged children should be able to answer questions about interactions with friends and siblings and school and activities they enjoy or are involved in. Ask the parent/caregiver if any additional information or observations should be included.

Adolescents may not feel comfortable addressing health issues, answering questions, or being examined in the presence of the parent/caregiver. The nurse must establish a trusting relationship with the adolescent to provide him or her with optimal health care. Ask adolescents whether they would be more comfortable answering questions alone in the examination area or whether they prefer for their parents to be present. Either way, the parent/caregiver will have an opportunity to talk with the nurse after the health history and assessment are completed.

Demonstrate an interest in the teen by asking questions about school, work, hobbies or activities, and friendships. Begin with these topics to make the teen feel comfortable in communicating with you. Communicate honestly with the adolescent and explain the rationale for various aspects of the health history. Teens are very sensitive to nonverbal communication, so be very aware of your gestures and expressions. Once a rapport has been established, move on to more emotionally charged questions that relate to sexuality, substance use, depression, and suicide.

Always assure the teen that complete confidentiality will be maintained to the extent possible. Current state law will determine the types of information that may be withheld from parents. If the information that the nurse receives indicates that the teen may be in danger, then the nurse must inform the teen that the information will be shared with other providers and/or the parents.

▶ *Take* NOTE!

Do not try to become the adolescent's peer. Remain in the role of the health care provider while demonstrating respect and acceptance toward the teen. Clarify the meaning of jargon or slang that the teen uses, but do not use these words yourself, as the teen will simply not accept you as a peer.

Observing the Parent–Child Interaction

Observation of the parent–child interaction begins during the focused conversation of the health interview and continues throughout the physical examination. Explore the family dynamics, not only through questions but also by observing the family for behavioral clues. Does the parent make eye contact with the infant? Does the parent anticipate and respond to the infant's needs? Are the parents ineffective when dealing with a toddler's temper tantrum? The plan of care may need to be adjusted to teach appropriate responses to the infant's needs or toddler's behavior. Do the parents' comments increase the school-age child's sense of self-worth? Behavioral observations are crucial to proper assessment of the family's needs.

Does the parent seem to be coping with the health issue or does he or she appear overwhelmed? Is the parent's/caregiver's behavior appropriate? Does the child look at the parent/caregiver before answering? Does the child seem relaxed and happy with the parent/caregiver, or is the child tense? The infant will appear calm and relaxed if his or her needs are generally met. Crying may occur when the baby is ill or frightened but may also indicate discomfort with the parent or caregiver. Use a calm and comforting voice with the infant. Infants respond well to higher-pitched and soothing voices.

When observing the relationship between the adolescent and the parent/caregiver, does the parent/caregiver allow the adolescent to speak, or does he or she frequently interrupt? Does the parent/caregiver contradict what is being said? Observe the body language of the adolescent. Does the adolescent seem relaxed or tense? Since adolescents are between childhood and adulthood, they have unique needs. They are in a time of multiple physical and emotional changes, many of which they cannot control. They need to know that the nurse is interested in what they have to say. The use of open-ended questions allows the adolescent to talk. "Tell me about your. . . ." or "What have you noticed about. . . ." are comfortable phrases to use to elicit the information needed.

Be aware of your reactions to the adolescent's questions or behaviors, such as your nonverbal and facial expressions. Talk with the adolescent using accurate language that is developmentally and age-appropriate.

Determining the Type of History Needed

The purpose of the examination will determine how comprehensive the history must be. If the health care provider rarely sees the child or if the child is critically ill, a complete and detailed history is in order, no matter what the setting. The child who has received routine health care and presents with a mild illness may need only a problem-focused history. In critical situations, some of the history taking must be delayed until after the child's condition is stabilized. Evaluate the situation to determine the best timing and the extent of the history. Also, be sensitive to repetitive interviews in hospital situations, and collaborate with physicians or other members of the health care team to ensure that a family already under stress does not need to undergo prolonged or repetitive questioning.

Remember Elliot, the 3-year-old being seen for his annual examination? When you enter the room, he is hiding behind his mother's legs. Considering his age and developmental level, how will you proceed with obtaining a health history?

PERFORMING A HEALTH HISTORY

The health interview is the foundation of an accurate health assessment. Information about the child's health will come not only from a physical examination, but also from a careful conversation or interview with the child and/or the caregiver. Depending on the intent of the health assessment, many of the questions will be direct, and many will require the caregiver or child to answer simply "yes" or "no." In other than emergency situations, though, asking open-ended questions offers an excellent opportunity to learn more about the patient's life. For example, "Are you happy at school?" may elicit a brief nod of the head, whereas "Tell me what it's like on your school playground" may result in a story about the child's friends, the kind of activities they enjoy, any bullying that goes on, and so forth. These stories will provide the nurse with clues to the child's stage of physical, emotional, and moral development as well as his or her functional status.

Establish a therapeutic relationship with the child and family. Without the trust that comes from this therapeutic relationship, the family may not reveal vital information due to fear, embarrassment, or mistrust. Use therapeutic communication techniques such as active listening, open-ended questions, and eliminating barriers to communication. Establishing a "medical home" where ongoing health supervision occurs encourages the formation of trust through continuity of care and the family's continuing relationships with health care providers (see Chapter 30).

Components of the Health Interview

The structure of the health interview is determined by the nature of the visit. At an initial visit, large amounts of historical data are collected. Having the family fill out a questionnaire can save time, but a questionnaire is not a substitute for the health interview. The questionnaire may serve as a springboard to begin structured conversations between the family and the nurse. At subsequent visits the health interview can focus on the pertinent issues of that visit as well as any health issues that are being monitored.

The health history includes demographics, chief complaint and history of present illness, past health history, review of systems, family health history, developmental history, functional history, and family composition, resources, and home environment.

▶ **Take** NOTE!

Any questionnaires used in the health care setting must be appropriate to the reading level and primary language of the person filling them out.

Demographics

Questions should start with simple and nonintrusive ones; once a rapport between the nurse and patient has started, sensitive questions can be asked. First obtain data such as the child's name, nickname, birth date, and gender. Determine the child's race or ethnicity, the language the child understands, and the language the child speaks. Record the child's address and home telephone number and the parent's or caregiver's work telephone number. Identify who the historian is (the child or the parent or caregiver), and note how reliable you consider this source of information to be. Do not assume that an adult with the child is the child's parent. Establish the relationship of the adult to the child, and ask who cares for the child if that person does not. Determine the composition of the household, including other children and other family members or other persons who live there.

Chief Complaint and History of Present Illness

Next, ask about the **chief complaint** (reason for the visit). The reason may not always be apparent to you. A question such as, "What can I help you with today?" or "What did you notice in your baby/child that you wanted to have checked today?" is very welcoming. The response from the child or parent may be a functional problem, a developmental concern, or a disease.

Record the chief complaint in the child's or parent's own words.

Next address the history related to the present illness. For each concern, determine its onset, duration, characteristics and course (location, signs, symptoms, exposures, and so on), previous episodes in patient or family, previous testing or therapies, what makes it better and what makes it worse, and what the concern means to the child and family. Inquire about any exposure to infectious agents.

Past Health History

Ask about the prenatal history (any problems with pregnancy), perinatal history (any problems with labor and delivery), past illnesses, or any other health or developmental problems. Document the child's prior history of illnesses (recurrent, chronic, or serious) and any accidents or injuries in the past. Inquire about any operations or hospitalizations the child has had. Document the child's diet. Note the child's allergies to foods, medications, animals, environmental or contact agents, or latex products. Determine the child's reaction to the allergen as well as its severity. Determine the child's immunization status (refer to Chapter 30 for further information on immunizations). Record any medications the child is taking, the dosage and schedule, as well as when the last dose was given. In preadolescent and adolescent females, determine menstrual history.

Family Health History

Obtaining information about the family's health is a key part of a health interview. Perform a three-generation family health history. This information may be documented in a genogram (Fig. 31.1). Asking about the age and health status of mother, father, siblings, and other family members helps to identify trends and specific health issues. For example, do the grandparents have early-onset coronary artery disease? If they do, the child may benefit from additional health screening. Siblings may exhibit a genetic disease or carry a trait for the disease. This family health information helps to guide future health planning.

Review of Systems

Inquire about current or past history of problems related to:

- Growth and development
- Skin

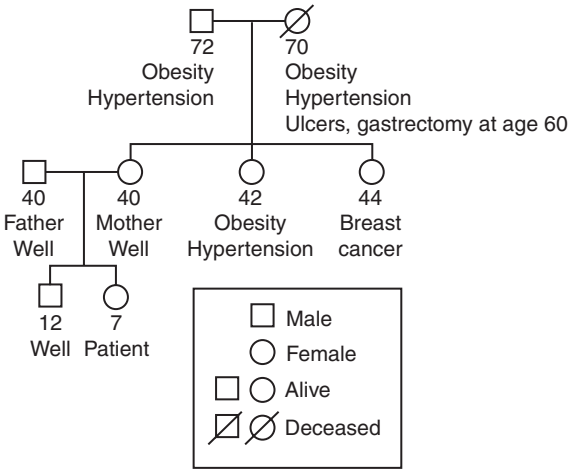

FIGURE 31.1 Genogram.

- Head and neck
- Eyes and vision
- Ears and hearing
- Mouth, teeth, and throat
- Respiratory system and breasts
- Cardiovascular system
- Gastrointestinal system
- Genitourinary system
- Musculoskeletal system
- Neurologic system
- Endocrine system
- Hematologic system

Table 31.1 provides specific questions related to each of these systems.

Developmental History

Determine the age when landmarks in gross motor control were achieved, such as sitting, standing, walking, pedaling, and so on. Ask whether the child has attained fine motor skills such as grasping, releasing, pincer grasp, crayon or utensil use, and handwriting skills. Note the child's age and extent of language acquisition. Document speech problems such as a lisp or stuttering. The rate of developmental skill acquisition may vary from child to child, but the sequence of skill attainment should remain the same. Inquire about self-care ability (e.g., tying shoes, dressing, brushing teeth) and, in the younger child, how toilet training is progressing. Assess feeding skills, including how well the child drinks from a cup and uses utensils or whether the

TABLE 31.1 QUESTIONS FOR THE REVIEW OF SYSTEMS

Systems	Has the Child Experienced:
Growth and development	Weight loss or gain, appropriate energy and activity levels, fatigue, behavioral changes such as irritability, nervousness, anger, or increased crying
Skin	Easy bruising or bleeding, rash, lesion, skin disease, pruritus, birthmarks, or change in mole, pigment, hair, or nails
Head and neck	Head injury, headache, dizziness, syncope
Eyes and vision	Pain, redness, discharge, diplopia, strabismus, cataracts, vision changes, reading difficulties, need to sit close to the board at school or close to the TV at home
Ears and hearing	Earache, recurrent ear infection, tubes in eardrums, discharge, difficulty hearing, ringing, excess cerumen
Mouth, teeth, and throat	Swollen gums, pain with teething, caries, tooth loss, toothache, sores, difficulty with chewing or swallowing, hoarseness, sore throat, mouth breathing, change in voice
Respiratory system and breasts	Nasal congestion or discharge, cough, wheeze, noisy breathing, snoring, shortness of breath or other difficulty breathing, problems with or changes in breasts
Cardiovascular system	Murmur, color change (cyanosis), exertional dyspnea, activity intolerance, palpitations, extremity coldness, high blood pressure, high cholesterol
Gastrointestinal system	Nausea, vomiting, abdominal pain, cramping, diarrhea, constipation, stool-holding, anal pain or itching
Genitourinary system	Dysuria; polyuria; oliguria; narrow urine stream; dark, cloudy, or discolored urine; difficulty with toilet training; bedwetting *Boys:* undescended testicles, pain in penis or scrotum, sores or lesions, discharge, scrotal swelling when crying, changes in scrotum or penis size, addition of pubic hair *Girls:* vaginal discharge, itching rash, problems with menstruation or menstrual cycle, development of pubic hair
Musculoskeletal system	Joint or bone pain, stiffness, swelling, injury (e.g., broken bones or sprains), movement limitation, decreased strength, altered gait, changes in coordination, back pain, posture changes or spinal curvature
Neurologic system	Numbness, tingling, difficulty learning, altered mood or ability to stay alert, tremors, tics, seizures
Endocrine system	Increased thirst, excessive appetite, delayed or early pubertal changes, problems with growth
Hematologic system	Swelling of lymph nodes, pale color, excessive bruising

Data from Burns, C., Dunn, A., Brady, M., Starr, N., & Blosser, C. (2004). *Pediatric primary care: A handbook for nurse practitioners.* Philadelphia: W. B. Saunders; Jarvis, C. (2008). *Physical examination and health assessment* (5th ed.). St. Louis: Saunders; Weber, J., & Kelley, J. (2005). *Health assessment in nursing* (3rd ed.). Philadelphia: Lippincott Williams & Wilkins.

child has any special requirements. Inquire about social skills and comfort articles (e.g., blankets, stuffed animals). Note whether the child has a habit of thumb or finger sucking or using a pacifier. Document daycare attendance and preschool or school adjustment and achievements.

Functional History

The functional history should contain information about the child's daily routine. Inquire about:

- Safety measures (e.g., car seats and their placement, use of seat belts, smoke detectors, bike helmets)
- Routine health care and dental care (including dates of dental care and what was done)
- Nutrition, including a 24-hour dietary recall or week-long food diary, use of supplements and vitamins, feeding pattern and satisfaction with diet, amount of "junk food" consumed, food likes and dislikes, and the parent's perception of the child's nutrition (refer to Chapters 25 through 29 for nutritional needs at various ages)
- Physical activity and organized sports, play, and recreation
- Television and computer habits
- Sleep behavior and bedtime
- Elimination patterns and any concerns
- Hearing or vision problems (dates of last screenings and results)
- Relationships with other family members and friends, coping and temperament, discipline strategies, attention or school behavior problems
- Religious involvement and other spiritual practices
- Use of adaptive and assistive devices such as eyeglasses or contact lenses, hearing aids, walker, braces, wheelchair
- Sexual practices

Family Composition, Resources, and Home Environment

Determine the marital status of the parents. Does the child live with the parents, a stepparent, or other family member? Is the child adopted or in foster care? Are the parents the primary caretakers for the child? If not, the primary caretaker should be included in the interview process if possible. Parents may not know some of the child's routines if the child spends much of the time being cared for by someone else. Working parents may learn about a health or behavior issue only after being alerted by the child's daycare center or babysitter. It may be helpful to expand the family history to include the grandparents and their interaction with the child.

Determine the employment status of the parents and their occupations, as this could affect the child's overall well-being; for example, the parents' work schedule may not allow them to spend much time with the child. Assess family income and financial resources, including health insurance and food stamps or other governmental supplemental income. Major family changes can also affect how the parents and child interact, so evaluate for relationship problems or changes.

Ask about the family's home and its age and the home environment. Is there a safe outdoor play area? If there is a pool, are safety features in place? Determine whether the home has electricity and an indoor water supply. Also determine whether the home has heating, air conditioning, and refrigeration. What pets does the family have? How are they housed? Are there infestations of insects or rodents in the home?

Take NOTE!

Homes or apartments built prior to 1978 may contain lead-based paint, and children who live there are at an increased risk for the development of lead poisoning.

Performing a Physical Examination

After the history comes the physical examination. It should focus on the chief complaint or any of the systems that engaged the nurse's critical thinking while taking the history. The examination will reflect the nurse's general practice style, the developmental stage and age of the child, the temperament of the child and caregiver, and the health status of the child. A very ill child will not waste energy protesting the examination, so the nurse can move quickly in that situation. A healthy child, however, will express his or her normal developmental stage and will show varying degrees of resistance to the examination.

PREPARING FOR THE PHYSICAL EXAMINATION

When performing the physical examination, being prepared and organized ensures that you will obtain the needed information. The appropriate methods to use and ways to approach the child depend on the child's developmental stage.

Gathering Materials and Preparing for the Examination

The examination area should include an exam table or the child's hospital crib or bed. Appropriate lighting is necessary for adequate observation and inspection. Gather the equipment necessary for the examination such as clean gloves, stethoscope, thermometer, sphygmomanom-

eter, tape measure, reflex hammer, penlight, otoscope/ophthalmoscope, tongue depressor, and cotton ball. An infant or adult scale is needed, as well as a **stadiometer** for children capable of standing independently. Young children may be frightened by seeing a large amount of equipment, so take out one piece of equipment at a time. Some children can be very resistant to what they see as a threat or an invasion of their privacy, so it may help to have washable toys in the examination area to use as distractions during the assessment.

Children and their parents may be able to sense any frustration or anxiety on the part of the examiner, so display a confident and matter-of-fact approach. If the child is not cooperative, do not become discouraged; more time and explanation will usually do the trick.

Regardless of the child's age, if the examination room is cold, the child will be uncomfortable and possibly less cooperative. Provide appropriate covers to ensure the child's comfort, or have the child remain dressed until the time of the examination.

Approaching the Child

Approach the child according to his or her developmental age and stage. Table 31.2 outlines a general approach to the physical examination in each broad developmental category.

If several children are to be seen at the same time, begin with the child who will be most cooperative. If the other children do not see anything scary and realize that their sibling was examined without a problem, it sets the stage for better cooperation from the younger ones.

Newborns and Infants

If the infant is asleep, auscultate the heart, lungs, and abdomen first while the baby is quiet. Count the heart rate and respiratory rate before undressing the baby. Completely undress newborns and infants down to their diaper, removing it just at the end to examine the genitalia, anus, spine, and hips. It is best to examine the infant 1 to 2 hours before a feeding. Having the parent or caregiver hold the child during the examination can help to alleviate fears and anxieties (Fig. 31.2). Allow the parent or caregiver to be a nurturer rather than assisting with painful procedures, unless there are no other choices available.

Perform the assessment in a head-to-toe manner, leaving the most traumatic procedures, such as examination of the ears, nose, mouth, and throat, until last. Also delay eliciting the Moro reflex until the end of the examination, as the startling sensation may make the infant cry. Use firm, gentle handling while examining the infant. Make sure your hands and the stethoscope are warm. Perform the assessment as quickly and completely as possible. Use a soft and crooning voice, smile, and engage the infant in eye contact. If the baby is crying, a pacifier may be useful and brightly colored objects may help distract him or her.

▶ ***Take*** NOTE!

Many older infants demonstrate stranger anxiety as a normal part of development. If the infant is not being held by the parent, make sure the parent is within the infant's view; this will increase the baby's comfort and cooperation.

Toddlers and Preschoolers

Toddlers and preschoolers usually prefer to remove their clothing one item at a time as needed for the examination. After one area is examined, the child may feel more comfortable replacing that item of clothing before removing another one. An examination gown is usually not necessary before school age. Again, make certain the room temperature is comfortable.

When the nurse enters the room, a child of this age is often sitting or standing by the parent. Incorporate play as appropriate during the health assessment. Remember your own facial expressions and tone. Use little touch at the beginning of the encounter with the child and the caregiver.

Introduce the equipment to be used slowly, explaining briefly what is going to happen. Let the child touch and hold the equipment whenever possible, even taking a parent's temperature or putting the blood pressure cuff on a teddy bear (Fig. 31.3). The toddler will prefer to sit on the caregiver's lap. When the toddler must be supine for the abdominal examination, sit in your chair knee-to-knee with the caregiver so the toddler may lie back on the caregiver's and your laps.

Praise the child for being cooperative during the examination. "You did such a good job holding still while I listened to your chest" and similar phrases give positive feedback to the child.

If the child is uncooperative, assess as thoroughly as possible and move on to the next area to be assessed. The caregiver may need to place an arm around the toddler's body to provide restraint for invasive procedures. Use short phrases to tell the toddler what you are going to do, rather than asking if it is OK.

▶ ***Take*** NOTE!

Toddlers are egocentric. Telling a toddler how well another child behaved probably will not be helpful in gaining the young child's cooperation.

The preschooler may fear body invasion and mutilation and will withdraw from any procedure or assessment that is viewed as intrusive. Otherwise, the sense of initiative often leads the preschooler to be cooperative. The

TABLE 31.2 DEVELOPMENTAL CONSIDERATIONS FOR EXAMINATION

	Newborn	Infant	Toddler	Preschool	School-age	Early Teen	Late Teen
Place to perform examination	May lie on examination table or in caregiver's lap.	In caregiver's lap or on exam table with caregiver right beside infant.	Allow some freedom of movement where possible; child may stand between sitting caregiver's legs or sit on the lap.	Some may be willing to sit on exam table with caregiver standing close by with hand on the leg.	Sitting on examination table where they still have eye contact with caregiver.	Some may be willing to have their caregiver wait outside the exam room.	Explain to the caregiver that the teen needs privacy and that he or she should wait outside the exam room.
Examination direction	Keep up a running dialog with the caregiver, explaining each step as you do it.	Continue to explain each step to the caregiver; address child by name. Perform most invasive parts last.	Introduce yourself to caregiver and child; explain most steps to the child and all steps to caregiver; allow child to handle instruments. Perform most invasive parts last.	Allow child to decide the order of the examination; explain what the instruments do and let the child try them; speak to the caregiver before and after the examination.	Include the child in all parts of the examination; use head-to-toe approach with genital exam last. Speak to the caregiver before and after the examination.	Speak to the child using mature language; appeal to his or her desire for self-care. Use a head-to-toe approach, with genital exam last.	Explain confidentiality to caregiver and teen; allow time talking with them together and separately. Use a head-to-toe approach, with genital exam last.

FIGURE 31.2 The infant or toddler may feel more comfortable and secure being examined while sitting in the parent or caregiver's lap.

preschooler may be willing to undress completely, leaving just the underpants on. Use simple explanations to inform the child about each step of the examination, offering reassurance as appropriate. Allow him or her to "help" by holding the stethoscope or penlight. If choices are available, offer them to the child. Again, always compliment the child on his or her cooperation.

▶ ***Take*** NOTE!

Preschoolers like to play games. To encourage deep breathing during lung auscultation, hold up a finger or a lit penlight and instruct the child to "blow it out."

FIGURE 31.3 The preschooler enjoys listening to her mother's heart first.

School-Age Children

The school-age child's thinking is still very concrete, but he or she can be objective and realistic. Avoid using medical jargon and words that may have a double meaning to a young child. Instead of "take your temperature," "take your blood pressure," "hit your knee," or "test," say, "Let's see how warm you are," "I want to listen to you breathe," and other phrases that describe, in words the child can understand, what you are preparing to do. The school-age child may be very interested in how things work and why certain things need to be done and will be responsive to truthful and simple explanations. Instruments that are colorful or look like toys are very helpful until adolescence, when teens are put off by childish things.

Always respect a child's desire to avoid pain and insult. Allow children to wear their underpants under the examination gown to provide a sense of security until the genitalia need to be examined. Allow the child to replace his or her clothing as soon as possible. Privacy and respect for the child's feelings are important to children of this age.

▶ ***Take*** NOTE!

Describing and commenting on your findings during the physical examination is interesting to the school-age child, as children of this age like to learn about how the body works.

Adolescents

Provide privacy while the adolescent is undressing and putting on a gown. Demonstrate an attitude of respect. Perform the assessment in a head-to-toe manner, exposing only the area to be examined. Provide information about physical changes in a matter-of-fact way, such as, "the hair on your legs is what is expected at this time." This provides information related to sensitive areas that the teen may be reluctant to ask about. It also provides the adolescent with information about the sexual development that is normal and expected. Allow opportunities for the teen to ask questions without the caregiver being present. Assure the adolescent that there are no "dumb questions" about the changes being experienced. Teenage girls should remove their bra so that you can do a breast examination, teach breast self-examination, and check for scoliosis. If the nurse is a male and the patient is an adolescent female, it is appropriate for a female staff member to be present during the breast and genital examination.

Steps of the Physical Examination

The physical examination of children, just as for adults, begins with a systematic **inspection**: checking color, warmth, characteristics, and texture visually and smelling for any odor. **Palpation** follows inspection to validate your obser-

vations. Percussion is a useful tool for determining the location, size, and density of organs or masses. Tapping with the reflex hammer elicits deep tendon reflexes. The stethoscope is used to auscultate the heart, lungs, and abdomen.

Performing a Physical Examination

A complete examination includes assessment of the general appearance, vital signs, body measurements, pain assessment, as well as examination of the head, neck, eyes, ears, nose, mouth and throat, skin, thorax and lungs, breasts, heart and peripheral perfusion, abdomen, genitalia and rectum, musculoskeletal system, and neurologic system. The nurse in most settings will not be assessing the breasts, genitalia, or eyes or ears in detail. Be aware of the role of the nurse in different settings and how the nurse can facilitate the assessment process.

General Appearance

Never discount first impressions. As you become more comfortable performing physical examinations, you will develop an ability to describe what you see and hear. Does the child give an impression of being ill or well? What is the child's expression and energy level? Note lethargy, listlessness, excessive activity, or inappropriate attention span for the child's age. Observe the child's state of alertness and whether he or she is responding appropriately to the stress of the situation. Note the child's posture and positioning:

- The newborn's posture is flexed, with arms and legs tucked in.
- The older infant should have improving head and then trunk control.
- The toddler demonstrates lordosis (swayback) and bowlegs, with a relatively large head and protuberant belly.
- The preschooler is more slender and upright in appearance.
- The school-age child and adolescent should demonstrate an upright, straight, and well-balanced posture.

Note whether the child's development appears appropriate. Observing the child initially may yield a wealth of information about the child's development. Is the child active, moving about the room? Does the child's speech seem appropriate for his or her age? Notice whether the family interacts appropriately with one another and the child. Does the child appear clean and well cared for? Does the child appear well nourished or small for age or obese? Do you smell tobacco or alcohol on the family's clothing? Does the child have a toy or transitional object? Is there a baby bottle or pacifier nearby? Do the siblings appear equally well cared for? Is there tension in the room between adults or adolescents? This initial quick assessment of general appearance will serve the nurse well if it is objective; delay your interpretation of what you have assessed until you gather more data.

Measurement of Vital Signs

Measure, document, and interpret the vital signs of children using age-appropriate equipment and approaches. The child's age and size, as well as knowledge of underlying health conditions, will affect your analysis of the vital signs. Vital signs are the temperature, pulse rate, respiratory rate, and blood pressure. In terms of vital signs, there is greater fluctuation in what is considered normal in children compared to adults. Therefore, count the heart rate and respiratory rate for a full minute (this will require comforting an infant or distracting a young child). If possible, perform these measurements when the child is quiet; if the child is crying or otherwise active during the assessment, document this. Many acute care settings require continuous measurement of vital signs using specific monitoring equipment. Also assess the child's pain level when assessing the vital signs.

Temperature

Temperature is measured as it is in adults. Thermometers are available in glass, electronic, and digital types. Use the same type of equipment consistently to allow reliable comparisons to be made and to permit tracking of temperatures during the course of illness. No matter which type of thermometer is used, ensure accuracy by carefully following the manufacturer's instructions.

The routes for taking the child's temperature are tympanic, temporal, oral, axillary, and rectal. Evidence is conflicting as to which method actually correlates best with the child's core, bladder, or arterial temperature, but recent studies support the use of a tympanic temperature as the most accurate, if it is appropriately obtained (El Radhi & Patel, 2006; Nimah et al., 2006). Take the child's temperature using the least invasive method that is best accepted by the child, parent, and health care provider.

▶ **Take** NOTE!

Glass thermometers are rarely used today due to the federal safety recommendations related to glass and mercury.

Choosing a method of measuring temperature depends on what is available at the facility and the child's age and physical condition. Tympanic thermometers measure the temperature within seconds, so this route is ideal for most children. Tympanic temperature reflects the pulmonary artery temperature. Tympanic thermometers are now available with smaller speculums, more appropriate for the infant or young child's ear canal. The accuracy of a

tympanic temperature reading depends on the user's technique (Nursing Procedure 31.1). The tympanic method is not affected by the presence of ear wax, but it may be affected by vernix in the newborn's ear.

Temporal scanning is a newer method of temperature measurement that uses infrared scanning on the skin over the temporal artery combined with a mathematical computation to determine the child's arterial temperature. The arterial temperature is considered the most accurate reflection of body temperature. Measure temperature on the exposed side of the head (not the side that has been lying on a pillow or covered by a hat). Slide the sensor tip externally in a horizontal line across the child's forehead, midway between the eyebrows and hairline and ending at the temporal artery (Fig. 31.4). Hold it there until the device registers the temperature reading, which usually requires 1 second. Accuracy may be affected by excessive sweating.

FIGURE 31.4 Temporal artery thermometers are noninvasive and well tolerated by young children. For an accurate reading, move hair to expose forehead and hairline.

Oral temperature is highly reliable if the child can cooperate. By 4 years of age, the child can hold an electronic oral thermometer in the mouth well enough to obtain a reading. Place the probe under the tongue. The child's mouth remains closed until the device registers the temperature. Have the child sit or lie quietly while the temperature is being taken. Electronic devices provide a temperature reading in as little as 4 seconds, but again the length of time varies with manufacturer. Oral intake, oxygen administration, and nebulized medications or treatments may affect oral temperature.

The axillary method works well for children who are uncooperative, neurologically impaired, or immunosuppressed or have injuries or surgery to the oral cavity. Place the tip of the electronic or digital thermometer in the axilla to obtain the reading. Make sure the tip is indeed in the axilla and not just between the arm and the child's side. Hold the thermometer parallel rather than perpendicular to the child's side to obtain the most accurate reading. Keep the child's arm pressed down to the side until the thermometer registers, which will be as little as 10 seconds with certain electronic models but 2 or 3 minutes with digital models commonly used at home.

Though long considered to reflect core temperature, the rectal route is invasive, not well accepted by children or parents, and probably unnecessary with the modern alternative methods now available. In addition to its intrusiveness, obtaining the rectal temperature runs the risks of damaging the rectal mucosa and inducing bradycardia in young infants. To take the rectal temper-

Nursing Procedure 31.1

TYMPANIC TEMPERATURE

1. Note age of child. If younger than 3 years, pull the earlobe back and down.
2. Insert the tympanic thermometer gently into the ear canal with the infrared sensor beam directed toward the center of the tympanic membrane rather than the sides of the ear canal.
3. Push the button to take the temperature and hold until a reading is obtained. The length of time required for the temperature to register varies per manufacturer but is only a few seconds at most.

ature, position the young infant supine with legs flexed. The older infant or child should be prone or side-lying. Small children may lie across the parent's lap for additional comfort. Apply a water-soluble jelly to the covered probe, insert the thermometer past the anal sphincter no more than 1 inch (2.5 cm), and hold it there until the temperature registers (as little as 15 seconds with certain electronic models but longer with digital models). See Evidence-Based Practice 31.1.

▶ ***Take*** NOTE!

Avoid the rectal route of temperature measurement in the neonate and the immunosuppressed child, as well as the child who has diarrhea, a bleeding disorder, or a history of rectal surgery.

Pulse

Assess the heart rate while the child is resting or sleeping. The heart rate in infants is much faster than in adults. It also varies in infants and children who are anxious, fearful, or crying. As the child grows, the heart rate slows and the range of normal values narrows. Table 31.3 lists heart rate ranges according to the child's age. The radial pulse is difficult to palpate accurately in children less than 2 years of age because the blood vessels lie close to the skin surface and are easily obliterated. For children younger than 2 years of age, auscultate the apical pulse with the stethoscope for a full minute. The **point of maximum intensity (PMI)**, the point on the chest wall where the heartbeat is heard most distinctly, is just above and outside the left nipple of the infant at the third or fourth intercostal space. The PMI moves to a more medial and slightly lower area until 7 years of age, when it is heard best at the fourth or fifth interspace at the midclavicular line (see the section below on chest examination for more information). Apical pulse rate should also be taken if the child has a cardiac problem such as an irregular heart rate or a congenital heart defect, as well as before administration of certain medications such as digoxin. During this procedure with children, allow the young child to examine or handle the stethoscope to become familiar with the equipment. In older children, palpate the radial pulse for a full minute (Fig. 31.5). Note any irregularities in strength or rhythm.

Finally, document the method used to obtain pulse measurement as well as any activity of the child during the assessment and any action taken.

▶ ***Take*** NOTE!

In the infant and young child, the heart rate is often quite elevated due to fear or anxiety when the stethoscope is placed on the chest initially. For an accurate heart rate, wait several seconds until the rate slows, then count for 1 full minute.

EVIDENCE-BASED PRACTICE 31.1
Pacifier Thermometers

● Study

Nurses and parents are concerned with being able to measure temperature accurately with the least invasive method possible. Research trials on pacifier thermometry in the past have been limited. The researchers utilized a convenience sample of children aged 7 days to 24 months in a prospective, cross-sectional study. Subjects were limited to those without gastrointestinal illness or contraindication to either the sublingual or rectal method of temperature measurement. Each child underwent pacifier temperature measurement with recordings at 3 and 6 minutes. The result was adjusted upward .5° F. as recommended by the thermometer manufacturer. Rectal temperature was then taken.

▲ Findings

Analysis of the pairs of recorded temperatures for each subject revealed close agreement between the rectal temperature and the adjusted 6-minute pacifier temperatures. Differences between the two were not statistically significant. Variations between measurements are certain to occur when temperature is measured at different sites, so the researcher does not recommend replacing rectal thermometers with pacifier thermometers when a rectal temperature is indicated. Rather, it is the researcher's recommendation to use the pacifier thermometer as a screening tool.

■ Nursing Implications

Pacifier thermometers are an acceptable tool for temperature screening in children 7 days to 24 months of age. Nurses must use the thermometer properly, as well as instruct parents in its appropriate use if it is to be used at home. Consistent use of one particular method is important for tracking trends in temperature management over time. The mathematical upward adjustment of .5° F. must be included in the reporting of temperatures measured by pacifier thermometry.

Braun, C. A. (2006). Accuracy of pacifier thermometers in young children. *Pediatric Nursing, 32*(5), 413–418.

TABLE 31.3 HEART RATE AND RESPIRATORY RATE RANGES BY AGE GROUP

	Infant	Toddler	Preschooler	School-age	Adolescent
Heart rate	80–150	80–140	80–130	75–120	70–100
Respiratory rate	20–40	20–40	20–30	16–22	15–20

Respiratory Rate

Assess respirations when the child is resting or sitting quietly, since respiratory rate often changes when infants or young children cry, feed, or become more active. They also tend to breathe faster when they are anxious or scared. The most accurate respiratory rate is obtained before disturbing the infant or child. This can often be done easily when the parent/caregiver is holding the child before any clothing is removed. Count the respiratory rate for a full minute to ensure accuracy. Infants' respirations are primarily diaphragmatic, so count the abdominal movements. After 1 year of age, count the thoracic movements. Table 31.3 lists ranges of respiratory rate according to the child's age. Document the rate, activity of the child, any deviations from normal, and any action taken.

▶ *Take* NOTE!

Infants normally display an uneven or irregular breathing pattern, with short pauses between some breaths. This may be accentuated when they are ill.

Measuring Oxygen Saturation

Since the incidence of respiratory dysfunction is high in children who are ill, pulse oximetry is often routinely included in the vital signs assessment. This method is reliable and noninvasive. Pulse oximetry determines the oxygen saturation (SaO_2) in blood by using a sensor that measures the absorption of light waves as they pass through highly perfused areas of the body. The pulse rate on the oximeter should coincide with the apical pulse rate to ensure that the oxygen saturation reading is accurate. Nursing Procedure 31.2 details how to use the pulse oximeter. Identify whether pulse oximetry monitoring will be continuous or intermittent (as with vital signs).

A few guidelines to follow when using pulse oximetry are as follows:

- The probe may be placed on the finger, toe, ear, or foot. Avoid placing the probe on the same extremity with a blood pressure cuff or an intravenous or other type of line.
- Use the physician's orders or health care agency guidelines to set parameters for high and low pulse rate as well as high and low oxygen saturation. Never turn off the alarm settings.
- Ensure that the probe is not applied too tightly, as this will prevent venous flow and cause inaccurate readings.

Potential sources of errors in pulse oximeter readings include abnormal hemoglobin value, hypotension, hypothermia, ambient light interference, motion artifact, and skin breakdown. Falsely low readings may be associated with a nonsecure connection (movement of child's foot or hand), cold extremities/hypothermia, and hypovolemia. Falsely high readings may be associated with carbon monoxide poisoning and anemia.

FIGURE 31.5 Assessing the radial pulse of a young child.

Blood Pressure

The National Heart, Lung, and Blood Institute (NHLBI) recommends that children over 3 years of age have their blood pressure measured at least once during every health care episode. Children under 3 years old should have blood pressure measured if they have one of the following risk factors:

- History of prematurity, very low birthweight, or other neonatal intensive care complication
- Congenital heart disease
- Recurrent urinary tract infections, hematuria, proteinuria, known renal disease or urologic malformations, family history of congenital renal disease

Nursing Procedure 31.2

PULSE OXIMETRY MONITORING

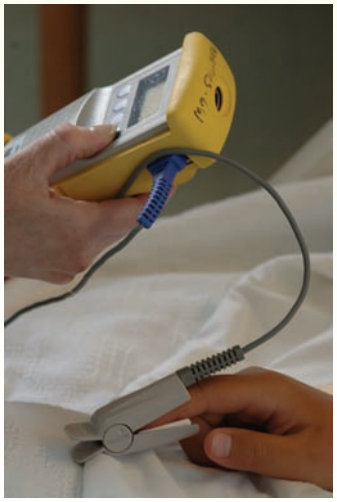
1. Explain the procedure to the child and family (use a penlight to show how the sensor "looks through the skin").
2. Attach the probe to the child and connect to the monitor.
3. Set the parameters for the alarm if monitoring pulse oximetry continuously.
4. Observe and record pulse rate and oxygen saturation.
5. Record the activity level of the child and the percentage of oxygen in use.
6. Check skin condition and rotate sensor position every few hours.

Types of probes

a. infant continuous

b. finger continuous

c. finger intermittent



- Malignancy, bone marrow transplant or solid organ transplant
- Treatment with medications that raise BP
- Systemic illnesses associated with hypertension such as neurofibromatosis and tuberous sclerosis
- Increased intracranial pressure (NHLBI, 2005)

In the hospital or outpatient setting when a child is ill or undergoing surgery or a procedure, the frequency of blood pressure measurement will depend on the child's physical status. Measurement of blood pressure can be frightening to a young child, so include an age-appropriate explanation and perform the procedure after obtaining the pulse rate and respirations (Fig. 31.6). Accuracy of blood pressure measurement depends on the cuff size, as well as the operator's skill and accurate calibration of an electronic

FIGURE 31.6 Allowing children to handle the equipment gives them some control over the situation.

device. The National Heart, Lung, and Blood Institute (NHLBI) recommends that the cuff bladder width be at least 40% of the circumference of the upper arm at its midpoint. The cuff bladder length should cover 80% to 100% of the circumference of the upper arm. Various pediatric and infant cuffs are available, as well as larger thigh cuffs that may be used on an arm in an obese adolescent.

▶ **Take** NOTE!

Using an accurate cuff size is important: a wider cuff yields a lower reading and a narrower cuff yields a higher reading.

Measure blood pressure in the upper arm, lower arm, thigh, or calf/ankle. The size of the cuff should match the extremity used. The measurement should be taken in the same limb, at the same place, and in the same position with each subsequent measurement to ensure consistency in tracking the blood pressure. To measure blood pressure using the upper arm, place the limb at the level of the heart, place the cuff around the upper arm, and auscultate at the brachial artery. When obtaining blood pressure in the lower arm, again, position the limb at the level of the heart, place the cuff above the wrist, and auscultate the radial artery. For measurement in the thigh, place the cuff above the knee and auscultate the popliteal artery. To obtain blood pressure on the calf or ankle, place the cuff above the malleoli or at the midcalf and auscultate the posterior tibial or dorsal pedal artery. Figure 31.7 shows appropriate cuff placement and auscultation points for the various sites.

The NHLBI recommends auscultation as the preferred method of obtaining blood pressure readings in children (Fig. 31.8). Systolic pressure in children is read at the moment the first Korotkoff sound is heard as the manometer pressure is lowered. The point at which the sound disappears is the diastolic pressure. The systolic blood pressure sometimes can be heard to a measurement of zero, so document the reading as systolic pressure over "P" for pulse.

Due to the small arm vessels in infants and young children, it may be very difficult to hear the Korotkoff sounds by auscultation. Alternative methods for obtaining blood pressure measurements in children include the use of Doppler or oscillometric (Dinamap) devices. The Doppler ultrasound method uses high-frequency sound waves that bounce off body parts to obtain blood pressure. Apply the gel to the Doppler end and listen with the Doppler device where you would ordinarily auscultate.

With either the Doppler method or auscultation, inflate the cuff 20 mm Hg past the point where the distal pulse disappears. Oscillometric equipment measures the mean arterial pulse and then calculates the systolic and diastolic readings. The accuracy of this method depends heavily on ongoing validation and calibration. Also, the cuff inflates to a preset value often far higher than the infant or child's blood pressure, resulting in a tight, uncomfortable cuff being in place for a longer period of time.

▶ **Take** NOTE!

If the oscillometric device yields a blood pressure greater than the 90th percentile for gender and height, repeat the reading using auscultation.

In children older than 1 year, the systolic pressure in the thigh tends to be 10 to 40 mm Hg higher than in the arm; the diastolic pressure remains the same. Refer to Appendix I for the NHLBI blood pressure levels based on gender and height. Systolic blood pressure increases

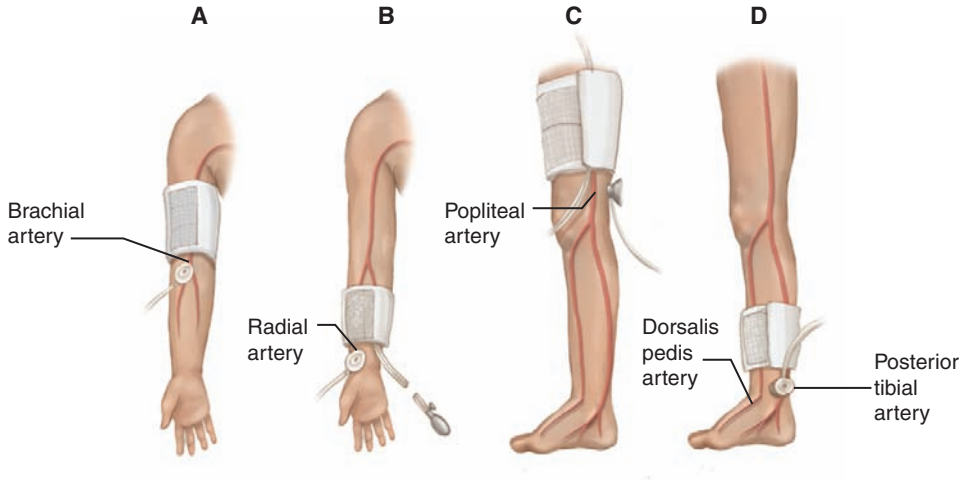


FIGURE 31.7 Various positions of cuff placement and auscultation area for obtaining blood pressure. (**A**) Upper arm. (**B**) Lower arm. (**C**) Thigh. (**D**) Calf/ankle.

FIGURE 31.8 Auscultation is the preferred method for measuring blood pressure in children.

if the child is crying or anxious, so measure the blood pressure with the child quiet and relaxed. If the reading is lower in the leg than in the arm, always consider coarctation of the aorta or interference with circulation to the lower extremities. Also pay attention to the pulse pressure (the difference between the systolic and diastolic readings): unusually wide (more than 50 mm Hg) or narrow (less than 10 mm Hg) pulse pressure readings suggest a congenital heart defect.

Infants and children presenting with cardiac complaints should have blood pressures assessed in all four extremities and also in the sitting, lying, and standing positions.

Document the method and site used, the activity of the child, any changes that may have occurred, and any actions or interventions performed.

Pain Assessment

Pain is considered to be the "fifth vital sign." Use the FLACC pain scale to measure pain in children who are too young to verbally or conceptually quantify their pain, or when there is a language barrier. The FLACC pain scale consists of a possible 10 points, with 0, 1, or 2 points given for each of five clinical signs (see Table 35.7 in Chapter 35).

Children who are older and can express that pain is worsening or improving should use the Pain Faces Scale (see Fig. 35.3 in Chapter 35). Explain that each face represents a person who is happy or sad, depending on how much or how little pain he has: 0 is for a person who is "very happy because he doesn't hurt at all"; 1 means "it hurts just a little bit"; 2, "it hurts a little more"; 3, "it hurts even more"; 4, "it hurts a whole lot"; and 5, "it hurts as much as you can imagine—but you don't have to be crying to feel this bad." Then ask the child to point to the face that best describes the amount of pain being felt.

For additional information related to pain assessment, refer to Chapter 35.

Body Measurements

Appropriate growth in children is usually an indicator of good health. A child who is not growing well may be in poor health, have inappropriate or inadequate dietary intake, or have a chronic disease. Accurate assessment of growth is a critical skill for the pediatric nurse and one that is rarely needed when caring for adults.

Determine the child's height or length, weight, and weight for length or **body mass index (BMI)**. Measure the head circumference for healthy children under age 3. Plot these measurements on a graph so they can be compared with earlier measurements and those of the child's peers. Additional anthropometric measurements used in children may include the chest circumference, mid-upper arm circumference, and skinfold measurement at the triceps, abdomen, or subscapular regions, but these are not performed routinely and are usually used only when a nutritionist consultation is necessary.

The growth chart is a screening tool for nutritional problems as well as a useful screen for chronic illness. Record each measurement in ink with a small dot at the correct location for the child's age and the date of the measurement written above it. Then use a plastic straightedge to connect the previous measurement to the most current one. Children grow at variable rates; in infancy and pre-puberty, the growth velocity is normally more rapid. The growth chart allows the nurse to compare the patient to other children of the same age and gender while allowing for normal genetic variation. When measurements fall close to the same percentiles over time, growth is normal for that child. Children whose measurements fall within the 5th and 95th percentiles are generally considered within the normal growth range.

Sudden or sustained changes in percentile may indicate a chronic disorder, emotional difficulty, or nutritional intake problem. These findings require further assessment of the physical status of the child as well as other types of evaluations such as dietary intake or serum laboratory measurements.

Appendix F provides growth charts for boys and girls, ages birth to 36 months and 2 to 20 years. Special growth charts are available for children with Down syndrome, Turner syndrome, and ethnic groups that are typically smaller in stature as adults. Children may be as much as 10% above or below the predicted measurement and still be normal. Look for a trend over time of healthy growth that is neither too fast nor too slow.

▶ *Take* NOTE!

The most valid and reliable growth charts are those supplied by epidemiologists at the Centers for Disease Control and Prevention.

Length or Height

Calculate the length of the infant and toddler in a lying position until the age of 24 months. Use a measuring board (Fig. 31.9) or a cloth or paper measuring tape. Stretch out the legs to get a full extension of the body. Marking the examination paper at the child's head and extended foot is an option. Make sure that the growth chart where the measurement is plotted is marked for length and not height, as the two measurements differ. Document the length in centimeters and inches.

Once the child can cooperate and stand independently, begin measuring the standing height. Using a stadiometer is best (Fig. 31.10), but a cloth or paper tape can be used. Ask the child to remove his or her shoes and check that the back, shoulders, buttocks, and heels are against the wall, with the pelvis tucked as much as possible to correct for lordosis. The chin should be parallel to the floor. Plot this measurement on a growth chart marked for height rather than length. Record the height in centimeters as well as feet and inches.

▶ ***Take*** *NOTE!*

Cloth and paper measuring tapes may stretch over time. Periodically replace or recalibrate all measuring tools.

Weight

Measure weight on a scale that is calibrated between every measurement. Just before placing the child on the electronic scale, press the "zero" or "tare" button and make sure the reading is 0. Calibrate the balance-type scale by setting the weight at zero, observing the beam balance, and making adjustments as necessary. Infants and toddlers should be weighed on a platform-type electronic or balance scale, with examination paper placed between the child and the scale surface. Calibrate the scale with the examination paper in place. Remove the infant's diaper immediately before placing him or her on the scale. Toddlers may sit on the scale with the nurse or caregiver nearby to avoid falls (Fig. 31.11). Weigh older children and adolescents on a standing scale (Fig. 31.12). They may keep their underpants on and wear a lightweight examination gown.

FIGURE 31.9 The recumbent measuring board is the most accurate method for obtaining a length measurement in infants and very young children.

FIGURE 31.10 Standing height is most accurately measured with the stadiometer.

An alternate method for obtaining weight, though much less accurate, is to weigh the caregiver initially and then weigh the caregiver holding the child. The difference between the two weights is the child's weight.

Regardless of the method used, weigh the infant to the nearest 10 g (or half-ounce) and the toddler and older child to the nearest 100 g (or quarter-pound). Record the weight in kilograms and in pounds.

Weight for Length

For children between the ages of newborn and 36 months, plot weight on the growth chart in comparison to the child's length. This allows the nurse to determine whether the child is a healthy weight for how long he or she is. Children placing less than the 5th percentile on the weight-for-length chart are considered underweight. Those placing greater than the 95th percentile are considered to be overweight.

Body Mass Index

With the recent increase in obesity in children, BMI is becoming an important measurement. BMI is a measure of

FIGURE 31.11 A nurse or caregiver should remain nearby while weighing the infant or toddler.

FIGURE 31.12 Children who can stand independently can be weighed on a regular standing balance scale.

body fat and is determined by comparing the child's height and weight. Calculate the BMI using the child's weight and height by either the English or metric method. Box 31.1 provides BMI calculation formulas. BMI is included on the charts for children ages 2 to 20 years. Plot the BMI on the growth chart according to the child's age. A child whose BMI for age plots at less than the 5th percentile is considered to be underweight. BMI between the 85th and 95th percentiles indicates risk for overweight. BMI greater than the 95th percentile indicates the child is overweight.

The growth chart can indicate when a child is not growing adequately and can also be used to predict the development of overweight and obesity.

Head Circumference

Measure head circumference at well-child visits and upon hospital admission until the third birthday. Then measure it at the annual well-child visit until 6 years old if there are problems such as microcephaly or macrocephaly present at age 3. Measure the largest point across the skull, not including the ears, with a non-stretching cloth or paper tape. Begin at the forehead just above the eyebrows and bring the tape around the head in a taut circle just above the occipital prominence at the back of the head (Fig. 31.13). Plot this measurement in relation to the child's age on the appropriate standardized growth chart (usual growth charts include head circumference only up to age 3 years).

Monitoring Equipment

Sometimes children in acute care settings require continuous monitoring of vital signs. This monitoring could be via an apnea monitor or a cardiopulmonary monitor. The apnea monitor measures abnormal or irregular breathing in infants. The cardiopulmonary monitor generally measures heart rate and respiratory rate. Additional equipment on this monitor also allows for blood pressure and temperature monitoring. Set high and low alarm limits according to the health care facility's policies. Figure 31.14 indicates the placement of electrodes for the apnea and cardiopulmonary monitors. Assess the skin where the electrodes are placed to ensure there is no skin breakdown. If the

BOX 31.1 Calculation of Body Mass Index (BMI)

English Formula:

$$\frac{\text{weight in pounds}}{(\text{height in inches}) \times (\text{height in inches})} \times 703$$

Metric Formula:

$$\frac{\text{weight in kilograms}}{(\text{height in meters}) \times (\text{height in meters})} \times 10{,}000$$

HEALTHY PEOPLE 2010

Objective	Significance
Reduce the proportion of children and adolescents who are overweight or obese.	• Screen for overweight in all children by plotting weight for length of children less than 36 months and BMI for age for children age 2–20 years. • Assess dietary intake and activity level in all children at risk for or overweight. • Provide diet and activity recommendations to attain a healthy weight or BMI. • Refer significantly overweight children to a pediatric endocrinologist.

alarm sounds, immediately check the child to ensure the leads are not disconnected or the child is not in distress.

Skin

The skin is the body's largest organ and reveals information about a child's nutrition, respiratory, cardiac, endocrine, and hydration status all at a glance. A careful skin examination provides an invaluable understanding of a child's health.

Inspection

Inspect the color of the skin. The color should be appropriate to the child's racial or ethnic background, with the nail beds, conjunctivae, soles of the feet, and palms of the hands appearing pink. Normal variations include the following:

- Blueness of the hands and feet, known as **acrocyanosis**, is normal in babies up to several days of age and results from an immature circulatory system completing the switch from fetal to extrauterine life (see Fig. 25.3 in Chapter 25).
- Cooling or warming the newborn and young infant may produce a vasomotor response that causes a mottling of the skin over the trunk and extremities (see Fig. 25.3).
- Babies of darkly pigmented Native American, African, and Asian parents will be paler than their parents for many months until the melanocytes in the epidermis begin production.
- Dark-skinned infants commonly have hyperpigmented areolas, genitals, and linea nigra.

FIGURE 31.13 Measure occipito-frontal head circumference at the largest point.

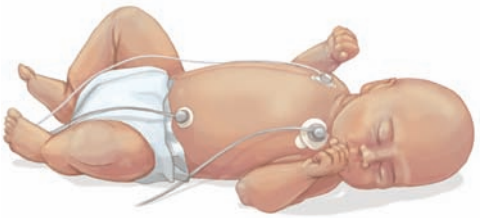

FIGURE 31.14 Placement of cardiac apnea monitor leads: white on the right upper chest, black on the left upper chest, red on the abdomen (not over bone).

Other variations related to skin color are discussed in Box 31.2.

Inspect the skin for the presence of **lanugo**. All infants display some degree of lanugo (soft, downy hair on the body, particularly the face and back). Lanugo is more

BOX 31.2 Variations in Skin Color and Their Causes

- **Pallor** (defined as decreased pinkness in light-skinned patients, ashy-gray in dark-skinned) is caused by anemia, shock, fever, or syncope.
- **Peripheral cyanosis** (blue discoloration) occurs in nails, soles, and palms and may be caused by anxiety or cold; also associated with central cyanosis.
- **Central cyanosis** (blueness of the lips, tongue, oral mucosa, trunk) is caused by hypoxia or circulatory collapse.
- Overall yellow color (**jaundice**) may be physiologic in the newborn or related to liver or hematopoietic disease in any age child.
- **Yellowing** of nose, palms, and soles may result from excess intake of yellow vegetables.
- **Redness** of the skin results from blushing, exposure to cold, hyperthermia, inflammation (localized), or alcohol ingestion.
- **Lack of color** in skin, hair, and eyes is related to albinism.

abundant in infants of Hispanic descent and in premature infants and recedes over the first few weeks of life.

Inspect the entire body for nevi and vascular and other lesions. Note their location, size, distribution, characteristics, and color. Pigmented nevi (also termed birthmarks) are indicated by a darker patch of skin and generally do not fade over time. Note the presence of hyperpigmented nevi (formerly called Mongolian spots), which appear as blue or gray, variably and irregularly shaped macules (Fig. 31.15). These are a common finding in dark-skinned infants. These nevi fade over months to years as the child's skin pigment darkens. Do not mistake hyperpigmented nevi for bruises. Inspect the skin for vascular lesions. Table 31.4 describes vascular lesions and their significance.

Rashes are common in children and are often associated with communicable diseases. Describe the rash in detail, noting types of lesions, distribution, drying, scabbing, and any drainage. The newborn and young infant may display milia (small white papules) on the forehead, chin, nose, and cheeks. These recede spontaneously. In adolescents the skin examination may reveal open or closed comedones (pimples or blackheads) across the face, chest, and back. Teens may sport tattoos, brandings, or various body piercings; inspect these areas for signs of infection such as erythema or drainage (Fig. 31.16).

Document the presence of any lacerations, abrasions, or burns. Note the distribution of the injury and whether it seems consistent with the mechanism described in the health history. Be alert to the possibility of child abuse if the type or number of burns, lacerations, or bruises seems unusual for the situation.

FIGURE 31.15 Transient hyperpigmentation most often occurs in darker-skinned infants.

▶ *Take* NOTE!

Petechiae or ecchymosis may be found over areas traumatized by the birth process; these may take a few weeks to resolve. Certain cultures use "cupping" or "coining" when a child is ill, and these practices may yield bruises or mild burns.

Palpation

Palpate the skin for temperature, moisture, texture, turgor, and edema. Use the back of your hand to assess the skin's temperature, comparing the right side of the body to the left and the upper body to the lower. The skin should feel uniformly warm. Cool extremities are associated with environmentally cool temperatures as well as impending circulatory collapse and shock. Warm skin may be associated with fever or sunburn, or locally a burn or infectious process. The skin should feel fairly dry, occasionally moister in the creases. Dry, flaking skin may occur in the young infant, particularly if born postmaturely. Overall skin dryness in the well-hydrated child may occur with excess sun exposure, poor nutrition, or

TABLE 31.4 VASCULAR LESIONS AND THEIR SIGNIFICANCE

Description	Significance
Salmon nevi: light pink macule usually on eyelids, nasal bridge, back of neck ("stork bite")	Usually fade over time, but may never go away completely. No complications.
Strawberry nevus: raised reddish papule made of blood vessels (hemangiomas)	Present at or develop after birth; recede over time, usually by age 9 years. Usually no complications.
Nevus flammeus: dark purple-red flat patch, grows with the child ("port-wine stain")	May be associated with Sturge-Weber syndrome. May be disfiguring; may be removed with laser therapy.
Ecchymosis: purplish discoloration, changing to blue, brown, black (bruise)	Common on lower extremities in young children. Should correlate with the injury.
Petechiae: pinpoint reddish purple macules that do not blanch when pressed	Broken tiny blood vessels; occur with coughing, bleeding disorders, meningococcemia
Purpura: larger purple macules	Bleeding under the skin; occur with bleeding disorders, meningococcemia

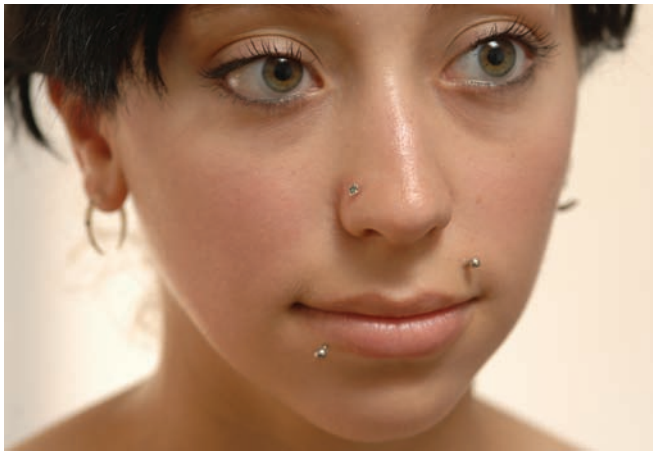

FIGURE 31.16 Adolescent with multiple piercings.

overbathing. Moist skin occurs with perspiration, fever resolution, and shock. The infant's and young child's skin is very soft ordinarily. Older children should continue to have a smooth and even skin texture. The preadolescent and adolescent may have oily-feeling skin on the face, shoulders, or back.

Assess skin turgor by elevating the skin on the abdomen in the infant or on the back of hand in the older child or teen. The "pinched-up" skin should quickly return to place. Skin that remains tented is strongly suggestive of moderate to severe dehydration. When edema is present, palpate the edematous area to determine its extent. Palpate any lumps or protrusions to determine firmness or tenderness. Palpate lesions or rashes with a gloved hand to document the size and extent of the lesions.

Hair and Nails

Inspect the hair and scalp, noting distribution of hair as well as color, texture, amount, and quality. The young infant's hair may be absent entirely or quite thick; it will be replaced by hair that is of a texture and color closer to what the child will have throughout childhood. Coarse, dry hair at any age may indicate a thyroid disorder or nutritional deficiency. Inspect the scalp thoroughly; it should be free from lesions and infestations. Note the presence of a greasy, scaly plaque on the scalp of infants; termed seborrheic dermatitis or cradle cap, it is benign and easily treated.

Inspect the nails for color, shape, and condition. Full-term infants may have long, papery fingernails that can scratch their skin if not trimmed. Children should have healthy nails. Dry, brittle nails may indicate a nutritional deficiency. Inspect the skin around the nails to ensure that it is intact and without signs of infection. Many children (especially school-age children) have a nervous habit of nail biting or hangnail biting or pulling.

Inspect the school-age child's or adolescent's toenails to ensure they are trimmed in a horizontal fashion. Self-trimming of toenails either too low or in a curved fashion places the child at risk for the development of ingrown nails. Clubbing of the nails indicates chronic hypoxemia related to respiratory or cardiac disease. Nails that curve inward or outward may be hereditary or linked with injury, infection, or iron deficiency anemia.

Head

Examining the head is critical in the newborn and infant periods but should not be overlooked in older children as an opportunity to check for diseases of the scalp and functional and developmental problems that are reflected in poor hygiene of the head and scalp. Note hair distribution and any bald or thinning areas. Use of gloves may be indicated, depending on the overall scalp cleanliness and chance of infestation by head lice (seen as small grayish specks near the base of hair shafts).

Inspection

Examine the head and face for shape and symmetry. In newborns, the head may be temporarily misshapen from uterine positioning or a long vaginal delivery. Some infants have a slight flattening of the back of the head since the recommended sleeping position is supine. Note any irregularities or asymmetry. Observe the infant's head shape by looking down on it from above. Observe whether the head appears centered on the neck or tilts to one side. After 4 months of age, the infant should have achieved enough head control to hold the head erect and in midline when placed in a vertical position. Pull the infant from the supine position into sitting to determine the extent of head lag. To determine the extent of head control in older infants and children, ask the child to turn the head in different directions, either by simple commands or by following a colorful object.

Observe the infant's face when crying, smiling, or babbling for symmetry of muscle movement. In children who are old enough to follow directions, a game of "Simon Says" is a playful way to determine facial symmetry and strength; ask them to puff out their cheeks, make kisses, look surprised, stick out their tongue, and so on (effectively testing function of cranial nerve VII [facial]).

▶ *Take* NOTE!

When you note a flattened occiput in an infant, encourage the parent or caregiver to allow the infant "tummy time" while awake and observed and to change the infant's head position frequently when upright in an infant seat.

Palpation

Gently palpate the anterior and posterior **fontanels** (Fig. 31.17), which remain open in infancy to allow for rapid brain growth in the first months of life. Note the size of the fontanels. The anterior fontanel is about the

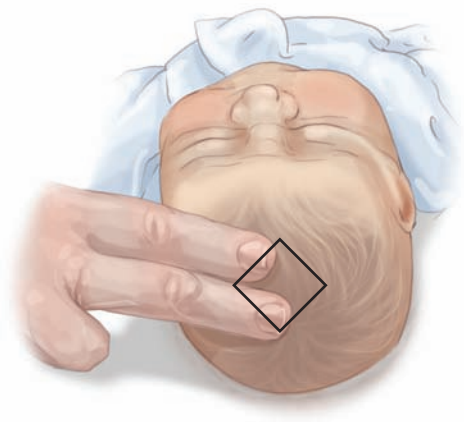

FIGURE 31.17 Note location and size of the fontanels. The anterior fontanel is diamond-shaped and closes between the ages of 9 and 18 months.

size of a quarter at birth and slowly gets smaller until it can no longer be felt when it is closed by the age of 9 to 18 months. The posterior fontanel is much smaller and may close any time between shortly after birth and approximately 2 months of age. The fontanel should be neither depressed nor taut and bulging, though it is not uncommon to see it pulsate or briefly bulge if the baby cries. In an acutely ill infant, assess the fontanels while obtaining the vital signs. Dehydration can cause the fontanels to be sunken; increased intracranial pressure and overhydration can cause them to bulge. Palpate the skull for asymmetry, overriding or open sutures, and lumps or other deformities. Palpate the jaw joints as the child bites down to assess cranial nerve V (trigeminal). Use the fingertips to palpate for occipital, postauricular, preauricular, submental, and submandibular lymph nodes, noting their size, mobility, and consistency (Fig. 31.18).

▶ **Take** NOTE!

Large fontanels may be associated with Down syndrome or congenital hypothyroidism. A fontanel that becomes larger over time rather than smaller may indicate the development of hydrocephalus, especially if accompanied by an accelerated increase in head circumference.

Neck

Inspect the neck for symmetry. The infant's neck is short, but by 4 years of age the child's neck should be similar in appearance to the adult's. Webbing or excessive neck skin folds may be associated with Turner syndrome, and lax neck skin may occur with Down syndrome. Assess the flexibility of the neck through a full range of motion. Take younger children through a passive range of motion. Older

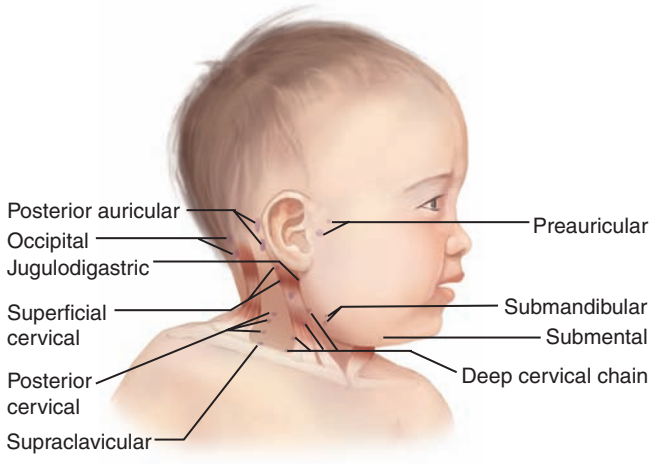

FIGURE 31.18 Location of lymph nodes.

children will be able to look in all directions on command and stretch their chins to the chests themselves. Test cranial nerve XI (accessory) in the older child by having the child attempt to turn the head against resistance. Assessment of neck mobility is particularly important when infections of the central nervous system are suspected. Pain or resistance to range of motion may indicate meningeal irritation. Do not assess neck mobility in the trauma victim.

Palpate the neck for masses and lymph nodes. Palpate the cervical and clavicular lymph nodes with the distal part of the fingers using gentle but firm pressure in a circular motion. Tilt the child's head upward slightly to allow better access. Assess the lymph nodes for swelling, mobility, temperature, and tenderness. In healthy infants and adolescents, the cervical lymph nodes are usually not palpable, whereas they are often found to be small, nontender, and mobile in healthy children from the ages of 1 year through 11 years (see Fig. 31.18 for locations of lymph nodes). Enlarged cervical lymph nodes frequently occur in association with upper respiratory infections and otitis media. Significant enlargement should be reported to the physician or nurse practitioner. Palpate the trachea; the thyroid is usually palpable only in older children.

▶ **Take** NOTE!

The infant or child who has experienced trauma should have the cervical spine maintained completely immobile until a radiologist has determined that the spinal cord is not damaged.

Eyes

Assessment of the eyes includes evaluation of the external and internal structures as well as screening for visual acuity. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal

structures will also be covered below but is usually performed only by the advanced practitioner. Refer to Chapter 30 for information on vision screening. Determination of visual acuity tests the function of cranial nerve II (optic).

External Structures

Observe the eyes for symmetry and spacing, even distribution of eyelashes and eyelids, and presence of epicanthal folds. Note the child's ability to blink, reporting inability to do so. The eyes should look symmetrical and both should be facing forward in the midline when the child is looking directly ahead. The iris should be perfectly round and the sclerae should be clear. The cornea should be uniformly transparent. Inspect the corners of the eye (medial and lateral canthus) and the conjunctiva (lining of the eyelids). They should be free of discharge, inflammation, or swelling. Epicanthal folds may be present in children of Asian descent, children with genetic abnormalities, or those with fetal alcohol spectrum disorder. Using a small penlight or ophthalmoscope, inspect the function and clarity of the pupil by putting your non-dominant hand on the child's forehead and moving the light toward and away from each eye. This will elicit the blink reflex. Next observe whether the pupil contracts with the light and expands when the light is removed. Make the same motion with a small toy or object and direct the child to look at it. The eyes demonstrate **accommodation**, or focusing at different distances, if the pupil constricts as the object moves closer. If normal findings are present, report **PERRLA** (pupils are equal, round, reactive to light and accommodation) (Fig. 31.19). This is a particularly important assessment in head and eye injuries, as well as when other neurologic concerns are present. Absence of pupillary reflexive action after age 3 weeks may indicate blindness.

▶ ***Take*** *NOTE!*

The normal infant may exhibit intermittent strabismus (crossing of the eyes) until about 3 months of age. However, persistent strabismus at any age or intermittent strabismus after 3 months of age should be evaluated by a pediatric ophthalmologist.

Check extraocular muscle motility and function of cranial nerves III and IV (oculomotor and abducens) by instructing the child to follow the light through the six cardinal positions of gaze. Infants and very young children will follow an interesting object. This tests cranial nerve III (oculomotor). Instruct the older child to look downward and inward (testing cranial nerve IV [trochlear]). Assess eye muscle strength using two tests. Using the Hirschberg test, bring the penlight to the middle of your face and direct the child to look at it. The small dot of reflected light seen in the iris should be symmetrically placed in each eye

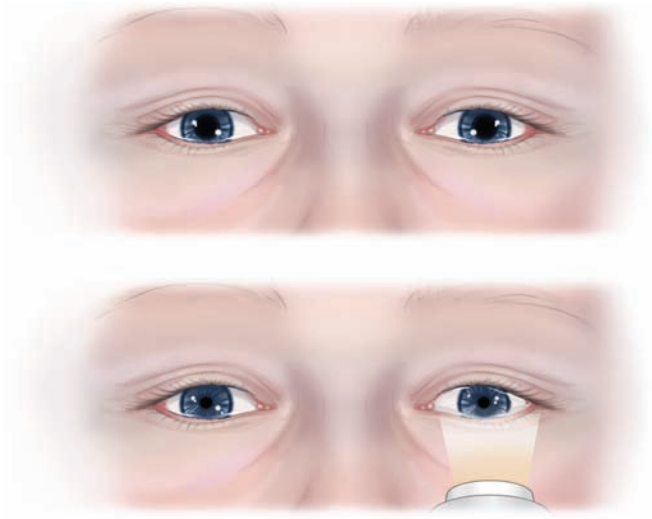

FIGURE 31.19 The pupils should be equal, round and reactive to light and accommodation (PERRLA).

(Fig. 31.20). The cover test also assesses eye muscle strength. Cover one of the child's eyes and instruct the child to focus on an interesting object. The eye should not waver. While the child is still focusing with the first eye, remove the cover from the second. Observe the uncovered eye for movement. Report any movement or drift.

To test peripheral vision, have the child focus on a specific point or object directly in front. Bring a finger or a small object from beyond the range of vision into the area of the peripheral vision. When the child sees the ob-

FIGURE 31.20 Note reflected light falling symmetrically on each pupil with the Hirschberg test.

ject from the side, while still focusing on the object or point in front, the child should say "stop." This also tests cranial nerve II (optic).

Internal Structures

Assessment of the internal structures of the eye is best accomplished by an advanced practitioner with experience in this type of assessment. An adequate assessment requires that the child cooperate. Restraint for eye examination does not usually prove fruitful, as movement and tearing of the eyes interfere with the accuracy of the examination. Use the ophthalmoscope to inspect the internal eye structures. Observe the glow of the pupil, which appears red (creamy-colored in children with very dark eye color). Inspect the optic disk, macula, fovea, and blood vessels. Refer any child with blurring or bulging of the optic disk or hemorrhage of vessels to a pediatric ophthalmologist for further evaluation.

▶ *Take* NOTE!

Immediately report absence of the red reflex in one or both eyes, as this may indicate the presence of cataracts.

Ears

Assessment of the ears includes evaluation of the external and internal structures as well as screening for hearing. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal structures will also be covered below but is usually performed only by the advanced practitioner. Refer to Chapter 30 for information on hearing screening. Testing of hearing also tests the function of cranial nerve VIII (acoustic).

External Structures

Assess the placement of the external ears on the head. They should be symmetrical and placed no lower than the eyes. The pinna should deviate no more than 10 degrees from an imaginary line that is perpendicular to a line drawn between the outer canthus of the eye and the top of the ear. Low-set ears may be associated with genetic abnormalities or syndromes (Fig. 31.21). Note protrusion or flattening of the ears, which may be normal for that child or may indicate inflammation (protrusion) or persistent side-lying (flattening). Note the presence of pits or skin tags in the preauricular area. Observe the exterior ear canal. A waxy **cerumen** that is soft and an orangish-brown color is normally found lubricating and protecting the external ear canal and should be left in place or washed gently away when bathing. Note drainage from the ear canal, which is always considered abnormal. Pull on the auricle and palpate the mastoid process, neither of which should result in pain in the healthy child.

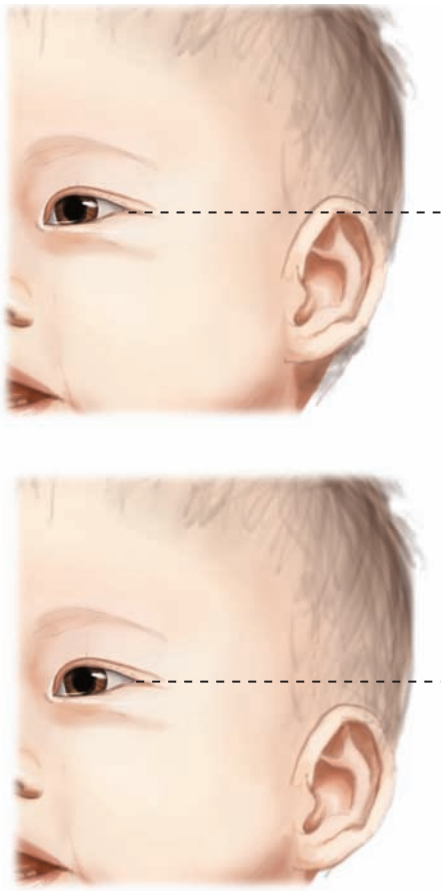

FIGURE 31.21 Low-set ears may be associated with chromosomal or other genetic anomalies.

▶ *Take* NOTE!

Impacted and dry cerumen can be softened with a few drops of mineral or cooking oil and then gently irrigated from the canal with an ear syringe and warm water.

Internal Structures

Use a **tympanometer** to assess the mobility of the eardrum (tympanic membrane). Gently pull down on the earlobe of infants and toddlers and up on the outer edge of the pinna in older children to straighten the ear canal, and press the tip of the tympanometer over the external canal. A reading of air pressure is recorded by the instrument, and this is useful to assess middle ear disease. Many tympanometers record a wave pattern that may be printed to include in the child's chart.

A nurse practitioner or physician generally performs inspection of the ear canal and tympanic membrane with an otoscope (Fig. 31.22). The otoscopic examina-

FIGURE 31.22 Otoscopic examination allows visualization of the internal structures of the ear.

tion is usually performed near the end of the physical assessment for infants and young children, as they are often quite resistant to this intrusive procedure. The infant or toddler may require restraint in the parent's lap for the otoscopic evaluation. The preschooler may cooperate if the nurse uses a game such as looking for pretend puppies or potatoes in the child's ear. As with the tympanometer, gently pull down on the earlobe of the infant or toddler and up on the outer edge of the pinna in older children to straighten the ear canal. Use an otoscopic speculum appropriate to the size of the child's ear canal. Insert the speculum into the ear canal to visualize the canal and the tympanic membrane. The canal should be pink, should have tiny hairs, and should be free from scratches, drainage, foreign bodies, and edema. The tympanic membrane should appear pearly pink or gray and should be translucent, allowing visualization of the bony landmarks. It may be red if the child has been crying recently. Compress the pneumatic insufflator bulb to provide a puff of air; this causes motion of the tympanic membrane when the middle ear is healthy. Note abnormalities such as a fluid level, bubble or pus behind the tympanic membrane, tympanic membrane immobility, holes or perforations in the tympanic membrane, and the presence of tympanostomy tubes, scarring, or vesicles.

▶ ***Take*** NOTE!

Never attempt to flush a foreign object out with water until it has been identified, because small pieces of sponge, clay, or vegetative material like peas or beans swell with water, further obstructing the ear canal.

Nose and Sinuses

The nose, as with all facial features in a child, should be symmetrical, but it can be displaced temporarily by birth trauma in newborns. Children of Asian or African descent often display a flattened nasal bridge as a normal variation. Ensure that the nares provide unobstructed airflow by alternately occluding one nostril at a time and observing for air movement through the other nostril. If the child is breathing comfortably, there should be little nostril movement visible. Adolescents may have pierced their nose or nasal septum; ensure that the site is free from infection or loose jewelry that could migrate into the sinuses. Ideally the nose should not be draining, though clear mucus may be present if the child has been crying. Assess the amount, color, thickness, and presence of any odor if drainage is present. Inspect the interior of the nose by tilting the child's head backward and pushing the tip of the nose upward. Direct the beam of a penlight in the nostril. The nasal mucosa should be uniformly firm, pink, and free from edema, excoriation, or masses. Test the older child's sense of smell by having the child close the eyes and identify a familiar scent such as peppermint or coffee (cranial nerve I [olfactory]). Palpate the sinuses for tenderness.

▶ ***Take*** NOTE!

Infants up to 3 to 6 months of age have traditionally been thought to be ***obligate nose breathers*** *because of their long soft palate and relatively large tongue, which allows for swallowing without aspiration during breast or artificial nipple feeding. This lessens with age and as the infant becomes better able to breathe through the mouth when necessary.*

Mouth and Throat

Wear a powder-free glove to examine the mouth, teeth, and throat. Inspection of the exterior of the mouth may be done at any point in the examination. Infants and young children may find assessment of the mouth and particularly the pharynx and uvula to be quite intrusive, so delay that part of the assessment until the end of the examination, after otoscopic evaluation. Assess the character and quality of the child's voice and the infant's cry. It should be neither too hoarse nor too shrill.

Inspection of the Mouth

Observe the lips for color, symmetry, and absence of inflammation or edema. Salivation in infants begins at about 3 months of age; drooling occurs because the infant does not learn to swallow saliva until several months later. Next, inspect the interior of the mouth. The mouth

is the first part of the digestive system, and a pink, moist, healthy mucosal lining is indicative of a healthy gastrointestinal tract. In infants, the tongue should lie within the mouth at rest and should be capable of extending over the lower gum line to help the baby feed. The tongue extrusion reflex is normal in infants up until the age of 6 months and allows the infant to suckle easily from birth. Observe movement of the tongue when the infant or young child babbles or cries. Ask the older child to touch the tongue to the roof of the mouth and then stick out the tongue and move it from side to side (testing cranial nerve XII [hypoglossal]). Full movement should be present and the tongue should be free from lesions or exudate. Visualize the hard and soft palate (which should be intact) or palpate with the gloved finger.

Most infants have no teeth before the fifth to sixth month. When the teeth begin to erupt, they usually erupt symmetrically at the rate of about one a month, until toddlers have 20 teeth by 30 months of age. The infant may drool for several months before teething. During teething the gums will be swollen at the location of the impending tooth. In older children, the secondary teeth replace the primary teeth much more slowly and with little discomfort from the 5th to the 20th year. Figure 31.23 shows the usual permanent tooth eruption pattern.

Look for dental caries or alignment problems and inspect the gums for signs of infection. Test cranial nerve IX (glossopharyngeal) by having the child identify taste with the posterior portion of the tongue.

Take NOTE!

Natal (present at birth) or neonatal (erupting by 30 days of age) teeth should be evaluated by a pediatric dentist for potential extraction, as they may pose an aspiration risk.

Inspection of the Throat

Inspect the tonsils, uvula, and oropharynx. Assess the infant's throat during a yawn or cry, as any forcible attempt to depress the tongue with a tongue depressor produces a strong reflex elevation of the base of the tongue that completely blocks the view of the pharynx. The young child will require restraint so that the nurse can depress the tongue and visualize the back of the mouth without injuring the child (Fig. 31.24). Asking the older child to open wide, stick out the tongue, and say "aaaah" simultaneously will allow for a quick look at the tonsils and pharynx without the need to use a tongue depressor, but the nurse must be very quick because the tongue rises rapidly after those maneuvers are performed.

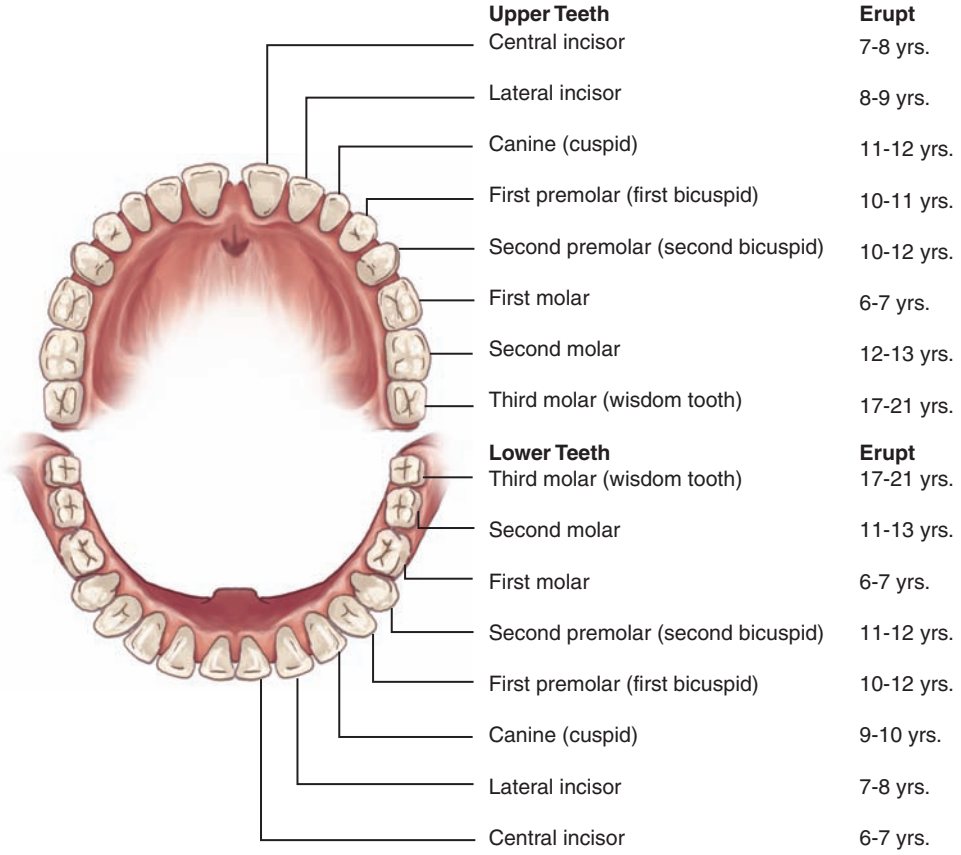

FIGURE 31.23 Usual sequence of permanent tooth eruption.

FIGURE 31.24 The young child may need to be restrained so that the throat examination can be done safely.

Tonsils usually cannot be seen in the infant. As the child becomes a toddler, the tonsils become dramatically larger and then begin to decrease in size again by the ninth year. The tonsils should be pink and often have crypts on their surfaces, which are sometimes filled with debris. Is the uvula at midline? Does it rise if the gag reflex is elicited (cranial nerve X [vagus])? Inspect the oropharynx, which should be pink and free from exudate.

▶ ***Take*** NOTE!

If a gag reflex is inadvertently elicited in the very ill child, the airway may become compromised. Therefore, the pharynx should be examined by asking the child to say "aaah" rather than by depressing the tongue with a tongue depressor.

Thorax and Lungs

Assessment of the thorax and lungs begins by observing the shape and contour of the thorax and determining work of breathing. Accurate auscultation of the lungs is essential, since children often have respiratory infections and disorders and may exhibit alterations in respiratory effort and breath sounds. Note the child's color, which should be pink; cyanosis indicates hypoxia. Listen for audible stridor (inspiratory high-pitched sound), expiratory grunting or snoring, audible wheezing (heard with the naked ear), or cough. Document type and extent of cough. Observe the nail beds for clubbing, which occurs with diseases inducing chronic hypoxic states.

Thorax

Examine the chest with the head in a midline position to determine size and shape as well as symmetry, movement, and bony landmarks. The newborn's chest should be smooth and round, with the transverse diameter nearly equal to the anterior-posterior diameter. The shape of the chest progresses to that of the adult by age 5 to 6 years. At that time the anterior-posterior diameter is about half the transverse diameter (Fig. 31.25). At the point where the xiphoid process and the right and left costal margins meet, the costal angle should measure 90 degrees or less. Inspect for structural deformity such as pectus excavatum (depressed sternum) or pectus carinatum (protuberant sternum) (Fig. 31.26). Note symmetric movement of the chest wall with respiration. Infants and younger children are primarily diaphragmatic breathers, so the abdomen and chest will rise and fall together. Older children, particularly adolescent females, demonstrate thoracic breathing, yet the abdomen and chest should continue to rise and fall together. Asymmetry of chest wall movement is an abnormal finding.

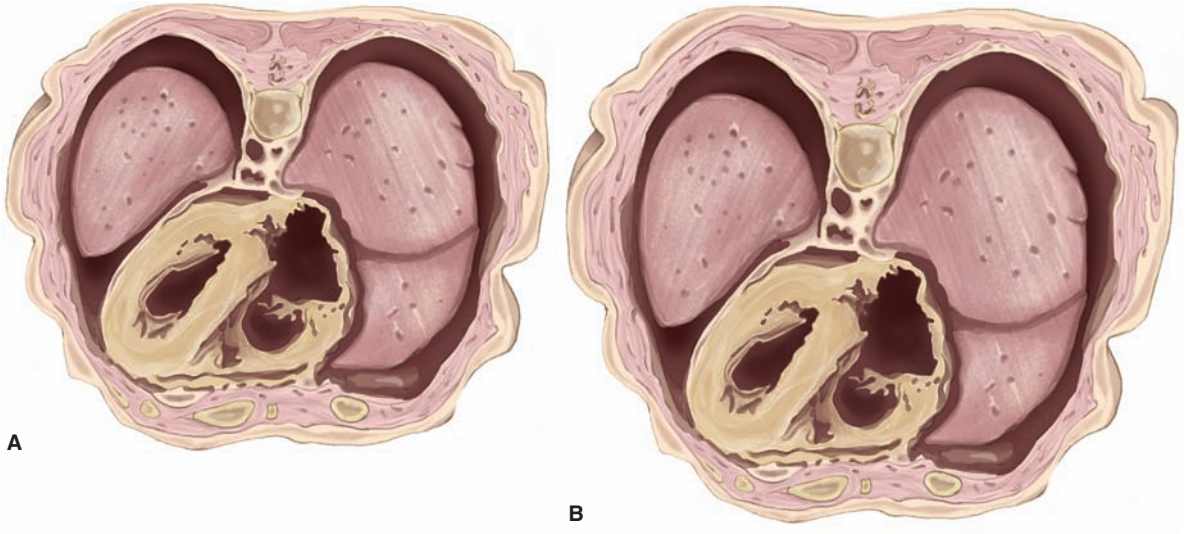

FIGURE 31.25 (**A**) The newborn's chest is round. (**B**) The adult chest has an anterior-posterior diameter about twice the transverse diameter.

FIGURE 31.26 Pectus excavatum: note depression in xiphoid area.

Observe the depth and regularity of respirations, noting the length of the inspiratory and expiratory phases in relation to each other. The newborn and young infant demonstrate an irregular respiratory pattern. Older infants and children should have a more regular respiratory pattern.

Assess the child's respiratory effort by first observing for nasal flaring, which indicates labored breathing. Observe the chest wall and shoulders for accessory muscle use, which normally is not present. If retractions are present, note their location and severity. Typical locations for retraction include the intercostal, subcostal, substernal, suprasternal, and clavicular regions (Fig. 31.27). Pay attention to the position the child naturally assumes to breathe comfortably: children in respiratory distress often sit forward and are uncomfortable lying down or talking.

Lungs

Experienced examiners may palpate and percuss the lungs before using **auscultation** to evaluate the breath sounds. Palpate for symmetric respiratory excursion by placing the thumbs and fingers together along the costal margin on the chest or back. Movement should be symmetric with each breath. Palpate for the normal presence of tactile fremitus with the palms or fingertips while the infant is crying or the older child says "99." Indirectly percuss the lungs of older children, noting resonance over lung fields. Hyperresonance may be present in conditions resulting in hyperaeration of the lungs, such as asthma.

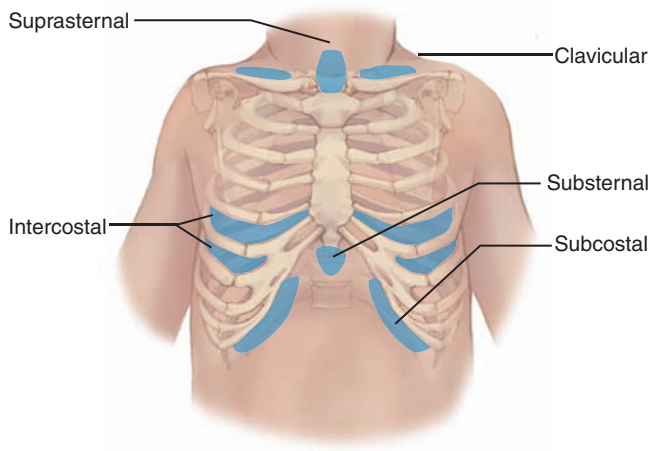

FIGURE 31.27 Location of retractions.

Auscultation

Use the bell of the stethoscope or switch to a small diaphragm to auscultate lung sounds in the infant or child. The adult-sized diaphragm may be used for the adolescent. Auscultate the lung fields with the infant or child in a sitting position, even if that requires propping the infant in a parent's lap. Infants and young children have loud breath sounds because of their thin chest walls. Breath sounds should be clear with adequate aeration throughout all lung fields. Listen to a full inspiration and expiration at the apices of the lungs as well as symmetrically across the entire lung field, systematically comparing the right to the left side. Listen on the anterior chest, posterior chest, and in the axillary regions.

Playing games may encourage younger children to cooperate with deep breathing during lung assessment. The child can blow a cotton ball up in the air, blow a pinwheel, or "blow out" the light of the penlight. Older children are capable of deep breathing when instructed to do so.

The child who has a respiratory disorder or who is experiencing respiratory distress may exhibit diminished breath sounds, most often in the lung bases. Diminished breath sounds are softer and quieter than lung sounds demonstrating adequate aeration. In the healthy infant or child, no adventitious sounds should be heard. If noisy breath sounds are heard in the infant or young child, particularly over all lung fields, compare the sound to the noises heard over the trachea or within the nose. Infants and young children with secretions in the nasopharyngeal area may have those sounds transmitted over the lung fields. These sounds usually clear with coughing or airway suctioning; they are not true adventitious sounds. Note adventitious breath sounds such as wheezes or crackles, documenting their location and whether they are present on inspiration, expiration, or both. It is most important to describe the abnormal breath sounds being heard rather than attempting to classify the sounds. Adventitious lung sounds are associated with a variety of disorders, and extensive experience is required to appropriately classify lung sounds. Adventitious breath sounds should be reported for further evaluation.

Breasts

Assess the breasts of children of all ages and both genders. Note the size of the breasts in relation to the age of the child. Palpate the axillary lymph nodes during the breast assessment.

Inspection

Observe the breasts for position, shape, size, symmetry, and color. Newborns of both genders may have swollen nipples from the influence of maternal estrogen, but by several weeks of age the nipples should be flat and should continue to be so in all prepubertal children. In children the nipples are located lateral to the midclavicular line, usually between the fourth and fifth rib. The areola becomes darker in color as the child approaches puberty. Overweight children may appear to have enlarged breasts due to adipose tissue. Note the location of additional (supernumerary) nipples if present (usually located along the mammary ridge); they may appear as darkly pigmented elevated or nipple-like spots. These are usually of no concern as they do not change over time, but they may be associated with renal disorders.

Inspect the breasts for the current stage of development: widening of the areola, elevation of the nipple, and increase in breast size. Female breast development may begin as early as age 8 but starts by age 13 in most girls. Breast development then continues in a characteristic pattern but usually is asymmetric, with one breast larger than the other throughout the lifespan. The sexual maturity rating scale developed by Tanner in 1962 is used to describe breast development (**Tanner stages**; Fig. 31.28). Adolescent boys may develop gynecomastia (enlargement of the breast tissue) due to hormonal pubertal changes. When the hormone levels stabilize, male adolescents then have flat nipples. Occasionally gynecomastia is caused by marijuana use, anabolic steroids, or hormonal dysfunction.

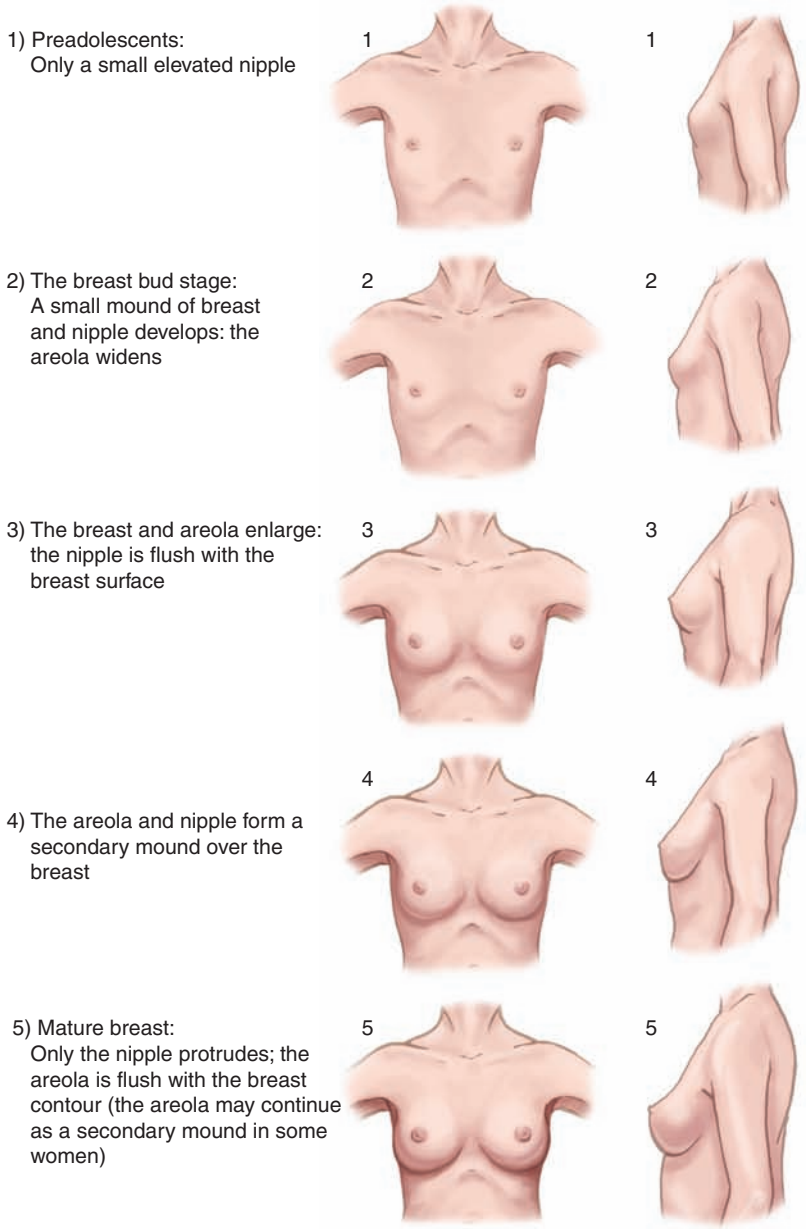

FIGURE 31.28 Tanner sexual maturity rating for breast development.

Palpation

Palpate the breasts in a systematic fashion. A tender nodule palpated just under the nipple confirms pubertal changes. This change may be difficult to assess in girls with excessive adipose tissue. Normal breast tissue should feel smooth, firm, and elastic. Note masses or nodules if present. Palpate for axillary lymph nodes with the child's arms relaxed at the side but slightly abducted. Note size and texture of nodes if present.

Heart and Peripheral Perfusion

The examination of the heart in children is identical to that of adults except for the focus of the examiner's attention. Congenital heart defects are the most common cause of heart problems in children, and children with these defects present differently than adults with heart disease.

▶ ***Take*** *NOTE!*

The younger the child, the more responsive the heart rate is to activity changes. It increases with fever, fear, crying, or anxiety and decreases with sleep, sedation, or vagal stimulation.

Inspection

Observe the child's posture. Note the presence of pallor, cyanosis, mottling, or edema, which may indicate a cardiovascular problem. Inspect the anterior chest from the side or at an angle, noting symmetry in shape as well as movement. Observe for the apical impulse, which is visible in about half of children. It occurs at the PMI, which is located at the fourth intercostal space just medial of the child's left midclavicular line until age 4 years, at the fourth intercostal space at the left midclavicular line in children ages 4 to 6 years, and then lateral to the left midclavicular line at the fifth intercostal space in children ages 7 years and older (Fig. 31.29). Note clubbing of the fingertips or distention of neck veins, both of which may be associated with congenital heart disease.

FIGURE 31.30 It is important to assess brachial and femoral pulses simultaneously to determine equality or differences in strength and intensity.

Palpation

Using the fingertips, palpate the chest for lifts and heaves or thrills, which are not normal. Palpate the apical pulse in the area of the PMI (see Fig. 31.29). Check the pulses and compare the upper body to lower body pulses, as well as left versus right, noting strength and quality (Fig. 31.30). The pedal, brachial, and femoral pulses are usually easily palpated. The radial pulse is very difficult to palpate in children less than 2 years of age. Note warmth of the distal extremities. To assess capillary refill time, place slight pressure on the nail beds and quickly release it. Observe the length of time required for refill and return to original color. Compare capillary refill time of the fingers to the toes. A capillary refill time of less than 3 seconds indicates adequacy of perfusion.

Auscultation

Perform auscultation of the heart with the child in two different positions, upright and reclined (Fig. 31.31).

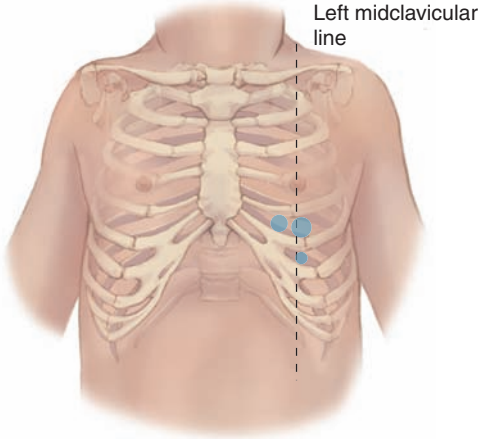

FIGURE 31.29 The point of maximal intensity (PMI) or apical impulse.

FIGURE 31.31 Auscultating the child's heart.

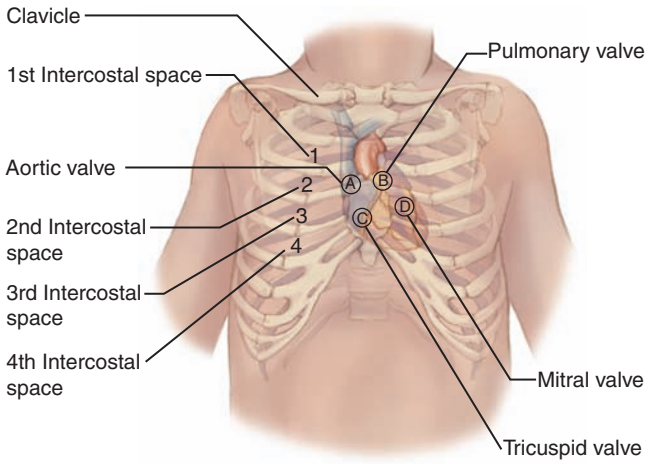

FIGURE 31.32 Areas where the sounds of heart valves radiate. A: Aortic valve—second intercostal space, just right of sternum. P: Pulmonic valve—second intercostal space, just left of sternum. T: Tricuspid valve—fourth intercostal space, just right of sternum. M: Mitral valve—fourth intercostal space at left midclavicular line.

Auscultate the heart rate in the area of the PMI (see Fig. 31.29). As you begin auscultation, listen first for respirations and note their timing so as not to confuse the heart sounds with the lung sounds. A crying infant may help by briefly holding his or her breath between cries. Once you are confident that you are listening to the heart, be sure to listen for 1 to 3 minutes because of the irregularity of rhythms in some children. Count the heart rate, which should be consistent with the palpated pulse (either radial or brachial).

Develop a systematic approach to auscultation of the heart. Listen over all four valvular areas anteriorly (Fig. 31.32). In the infant or younger child, also auscultate the heart in the axillary region and posteriorly (certain murmurs radiate to these areas). Note S1, S2, extra heart sounds, or murmurs. S1 is usually loudest at the mitral and tricuspid areas and increases in intensity with fever, exercise, and anemia. S2 is usually most intense at the aortic and pulmonic areas. A split S2 heard at the apex occurs in many infants and young children. S3 may be heard in many healthy children and is considered normal, though the child with a chronic cardiac condition may develop an S3 when congestive heart failure is present. S4 is usually considered abnormal, most often occurring with cardiac disease.

Sinus arrhythmia is a common and normal finding in children and adolescents. It results in an irregular heart rhythm: the heart rate increases with inhalation and decreases with exhalation. If the child holds his or her breath, the rhythm becomes regular.

▶ ***Take*** NOTE!

S1 should not vary in intensity at a particular point. If it does, this may indicate a cardiac arrhythmia and the child should be referred for further evaluation.

Auscultate for murmurs. Note the location (where it is heard best or loudest) and timing of the murmur. A systolic murmur occurs in association with S1 (closure of the atrioventricular valves), a diastolic murmur in association with S2 (closure of the semilunar valves). Also note the duration of murmur. Does it occur early or late in diastole or systole? Does it occur all the way across systole (holosystolic)? Note the intensity of the murmur. Table 31.5 discusses grading of murmur intensity.

Innocent murmurs occur frequently in children because of the child's more dynamic circulation, thin chest wall, and angulated vessels. An innocent murmur is most often heard at the second or fourth intercostal space, and its timing is systolic. The innocent murmur is usually medium-pitched and musical. Often an innocent murmur disappears when the child changes position. A venous hum that is heard in the supraclavicular area and possibly radiating down the chest is considered an innocent murmur. Refer any child with a murmur to an experienced practitioner for further evaluation.

TABLE 31.5 GRADING HEART MURMURS IN CHILDREN

Grade	Sound
1	Barely audible; sometimes heard, sometimes not. Usually heard only with intense concentration
2	Quiet, soft; heard each time the chest is auscultated
3	Audible, intermediate intensity
4	Audible, with a palpable thrill
5	Loud, audible with edge of the stethoscope lifted off the chest
6	Very loud, audible with the stethoscope placed near but not touching the chest

Abdomen

The abdomen contains organs related to the genitourinary and lymphatic systems, in addition to the gastrointestinal system. These structures lie within the abdomen in approximately the same location as they do in adults. Dividing the abdomen into quadrants simplifies the description of normal organ location and the reporting of abnormalities. Draw an imaginary vertical line from the xiphoid process to the symphysis pubis. Cross this with an imaginary perpendicular line through the umbilicus. The sequence of physical examination is altered for the abdominal assessment: auscultation is done before percussion and palpation because manipulation of the lower abdomen may affect the bowel sounds.

Inspection

Inspect the abdomen for size, shape, and symmetry. The abdomen in the infant and toddler is rounded and protuberant until the abdominal musculature becomes well developed. Though rounded, the abdomen should not be distended (at any age). By adolescence, the stature is more erect and the abdomen begins to appear flat when standing and concave when supine. The thin skin of a young child may allow the visualization of superficial venous circulation across the abdomen. Inspect the abdomen for movement. At eye level with the abdomen, note abdomen and thorax movement occurring simultaneously. Visible peristaltic waves are abnormal and should be reported immediately.

Inspect the newborn's umbilicus for color, bleeding, odor, and drainage. The umbilical stump should slowly dry, become black and hard, and fall away from the cutaneous navel by the end of the second week of life. Note drainage or granulation at the umbilical site indicating delayed drying of the umbilical stump. Inspect the umbilicus in older infants and young children for the presence of umbilical hernia. Because the umbilicus divides the rectus abdominis muscle, it is not uncommon to see an umbilical hernia protrude through and become larger when the infant or toddler strains or cries. This is a benign finding and will usually disappear as the abdomen becomes stronger. Adolescents may have jewelry piercing the umbilicus.

Auscultation

Auscultate the abdomen using the diaphragm or the bell of the stethoscope pressed firmly against the abdomen. Count the bowel sounds in each of the four quadrants for a full minute. Bowel sounds should be present by a few hours after birth and should remain active throughout life. Note whether bowel sounds are normally active, hyperactive, hypoactive, or absent. Normal bowel sounds can be described as growls, gurgles and clicking sounds. Hypoactive bowel sounds may occur postoperatively. Hyperactive bowels sounds are common with diarrhea. Classify bowel sounds as absent after listening for 5 full minutes in each area. Absent bowel sounds may indicate ileus or peritonitis.

Percussion

Indirectly percuss all areas of the abdomen. Normal findings include dullness along the costal margins and tympany over the remainder of the abdomen. A full bladder may yield dullness to percussion.

Palpation

Palpate the abdomen with the child in a supine position. If the child's legs are small enough, the knees may be brought up with the nondominant hand to flex the hips and relax the abdomen. Palpate all four quadrants of the abdomen in a systematic fashion, first lightly and then deeply. Apply light pressure with the fingertips to perform light palpation, assessing for tenderness and muscle tone (Fig. 31.33). Note skin turgor by gently elevating a piece of skin and allowing it to fall back into place. Perform deep palpation to assess the organs and any masses. Place one hand on top of the other and palpate from the lower quadrants to the upper (see Fig. 31.33). The edge of the liver may be felt at the right costal margin, and the tip of the spleen can be felt at the left costal margin. The descending colon may be felt in the left lower quadrant as a small column and the blad-

FIGURE 31.33 (**A**) Light and (**B**) deep palpation of the abdomen.

der as a soft balloon below the umbilicus. The kidneys are rarely palpable. The abdomen should be soft and nontender to palpation. Report firmness, tenderness, or masses. Palpate the inguinal area for the presence of hernia or enlarged lymph nodes.

▶ **Take** NOTE!

To decrease ticklishness with abdominal palpation, place a flat, warm, still hand on the abdomen while distracting the child before palpation begins. An alternate technique is to first palpate with the child's hand under the examiner's hand.

Genitalia and Anus

Examination of the genitals should immediately follow the abdominal assessment in the younger child and should be reserved for the end of the assessment in the adolescent. Though the anus is part of the gastrointestinal tract, it is best assessed during the genital examination. Ensure privacy for the older child and adolescent. Keep the child covered as much as possible. Use a casual, matter-of-fact approach to place the child or teen at ease. During the genital examination, teach the child or adolescent about normal variations and changes with puberty, as well as issues related to health promotion.

Male

Inspect the penis and scrotum for size, color, skin integrity, and obvious masses. The obese boy's penis may appear small because of additional skin folds. Penis size should correlate with pubertal stage (Fig. 31.34). The penis may have a foreskin that covers the glans, protecting and lubricating it. If present, do not forcibly retract the foreskin. In circumcised males the urinary meatus is exposed and should be at the tip of the glans. Assess the meatus for absence of discharge. If possible, observe the stream of urine for strength of flow and patency of the urethral orifice. Skin lesions may indicate sexually transmitted infection. A foreskin that cannot be retracted in a boy over 3 years of age may indicate phimosis. Report abnormal findings.

▶ **Take** NOTE!

When you first remove a male infant's diaper, this is the ideal time to assess the force of the urine stream and the erection reflex, as the cool air may make the infant void and briefly experience an erection.

FIGURE 31.34 Tanner male sexual maturity rating for genitalia and pubic hair.

Assess the presence and distribution of pubic hair. Inspect the scrotum for size, slight asymmetry, color, and absence of edema. The scrotum may initially be swollen from birth trauma or maternal hormones, but this swelling should decrease in the first few days of life. The scrotum is ordinarily more deeply pigmented than the rest of the boy's skin. Figure 31.34 illustrates scrotal changes that occur with puberty. Assess the testicles by placing one finger over the inguinal canal and palpating the scrotum with the other. This prevents the retractile testes in a young child from slipping back up the inguinal canal. The testicles should be smooth, of similar sizes, and freely move-

FIGURE 31.35 Placing a digit over the inguinal canal during testicular palpation prevents retraction of the testis into the canal.

able. The infant's testicles may be palpated in the scrotum or in the inguinal canal, where they can be easily moved into the scrotum with gentle pressure from the examiner's nondominant hand (Fig. 31.35). Beyond infancy, allow the boy to sit cross-legged to reduce the cremasteric reflex that retracts the testicles during palpation. An adolescent boy may need to stand for the nurse to fully palpate the scrotum. Document the presence of both testicles in the scrotal sac, if they are retractile, or if they are absent. Report undescended testicle or other abnormal findings.

Female

In most cases, the female genitalia examination is limited to assessment of the external genitalia. Internal examination is not routinely performed before maturity unless the adolescent anticipates becoming or is sexually active or requests birth control or if pathology is suspected. If an internal examination is needed, refer the child or adolescent to the appropriate advanced practitioner or physician.

Position the infant in the parent's lap or on the examination table or crib. The toddler or preschooler should be examined in the parent's lap, in a frog-legged position. The school-age or adolescent girl should lie on the examination table or bed. Provide for privacy by keeping the genital area covered until it is time for the examination.

Perform the assessment of the external genitalia in a systematic fashion. First, determine the presence and distribution of pubic hair. Infants and young girls (particular those of dark-skinned races) may have a small amount of downy pubic hair. Otherwise, the appearance of pubic hair indicates the onset of pubertal changes, sometimes prior to breast changes. Pubic hair generally begins to appear by age 11 years, with age 13 being the latest. Figure 31.36 illustrates the development of pubic hair through puberty in girls.

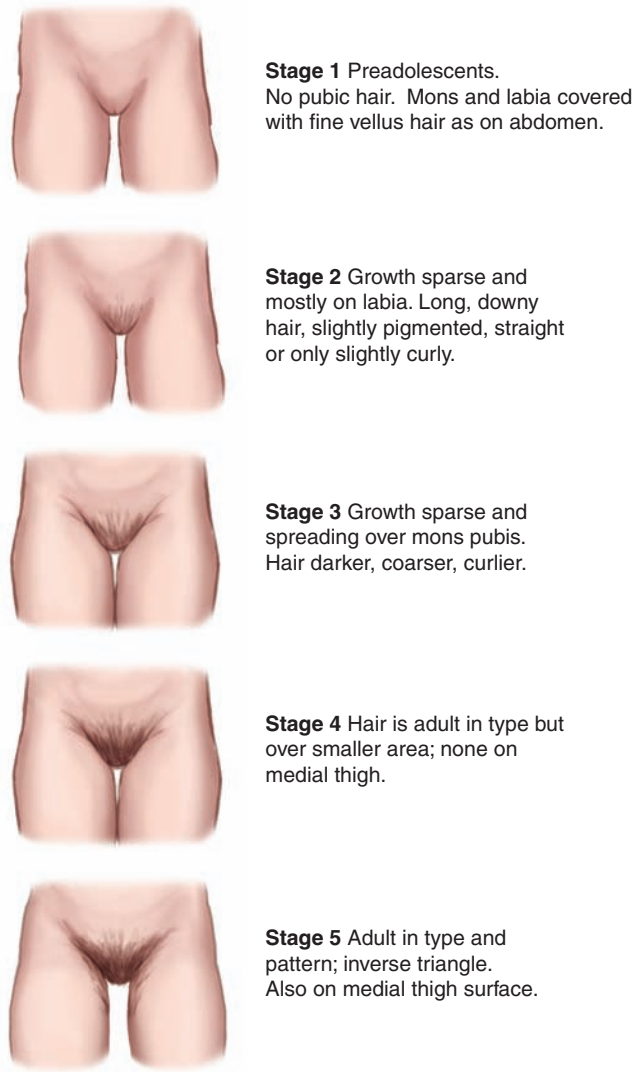

FIGURE 31.36 Tanner female sexual maturity rating for pubic hair.

Inspect the labia majora and minora for size, color, and skin integrity. The newborn's labia minora are swollen from the effects of maternal estrogen but will decrease in size and be hidden by the labia majora within the first weeks of life. Redness or swelling of the labia may occur with infection, sexual abuse, or masturbation. Lesions on the external genitalia may indicate sexually transmitted infection. Gently spread the labia to inspect the clitoris, urethral meatus, and vaginal opening. Some girls may prefer to spread the labia themselves. The urinary meatus and vaginal orifice should be visible and not occluded by the hymen. It is not uncommon to see a hymenal tag. Note clitoral size. Inspect the urinary meatus and vaginal opening for edema or redness, which should not be present. Observe for any vaginal discharge. A small amount of blood-tinged or mucoid discharge may be noted in the first few weeks of life as a result of maternal hormone exposure. A small amount of clear mucus-like dis-

charge is normal in all females. If present, document labial adhesion or other abnormal findings.

Anus

Inspect the anal area for fissures, rash, hemorrhoids, prolapse, or skin tags. Examine the infant's anal area while examining the genitalia. The younger child may lie back in the parent's lap and flex the knees to the chest. The older child or adolescent may be prone or in a side-lying position. If the adolescent boy is already standing for the scrotal assessment, have him bend forward so that you can assess the anal area. The anus should appear moist and hairless. Gently stroke the anal area to elicit the anal reflex (quick contraction). If indicated, inspect anal sphincter tone by inserting a gloved finger lubricated with water-soluble jelly just inside the anal sphincter.

Musculoskeletal

Assessment of the musculoskeletal system includes examination of the clavicles and shoulders, spine, extremities, joints, and hips. Determining the child's ability to move all extremities through the full range of motion is also important.

Clavicles and Shoulders

Palpate the clavicles. In the newborn, tenderness or crepitus reveals a fracture sustained at birth. In the older infant or child, a bump indicates callus formation with clavicle fracture. Test shoulder strength and the function of cranial nerve XI in the older child by requesting that the child shrug the shoulders while you apply downward pressure.

Spine

Observe the child's resting posture and alignment of the trunk. The newborn's position will look like the position the baby preferred *in utero* and is one of general flexion. The older infant moves more and can sit unassisted in the second half of the first year. Toddlers stand with a wide-based gait, a slightly swayed back, and the abdomen slightly protruding. The posture straightens in the preschool and school-age years. Adolescents often demonstrate kyphosis as the skeleton and muscles are both growing rapidly (Fig. 31.37).

Inspect the child's spine. The newborn's spine has a single C-shaped curve and remains rounded for the first 3 months of life. The cervical curve begins to develop around 3 to 4 months of age as the baby gains head control. By 12 to 18 months of age, the lumbar curve develops, which corresponds to the onset of walking. The S-shaped spine in older children and adolescents is similar to that of the adult's. The spine should be flexible, with good muscle tone and no rigidity. Assess the back, and hip and shoulder heights for symmetry.

Examine the preadolescent and adolescent for the development of scoliosis. Refer to Chapter 44 for information about scoliosis screening. Scoliosis screening is generally performed during well-child examinations by the physician or nurse practitioner or by the middle or high school nurse on a particular day of the school year.

FIGURE 31.37 The teen's posture often demonstrates kyphosis.

Note mobility of the vertebral column by having the child bend forward and side to side. Flex the neck and move it from side to side. No resistance or pain should occur. Inspect the back for discoloration, tufts of hair, or dimples. A normal pilonidal dimple is sometimes seen at the base of the spine, but there should be no tuft of hair or nevi along the spine. Document and report abnormal findings.

Extremities

All children, even newborns, should be able to move all extremities spontaneously. Screen the infant younger than 6 months of age for developmental dysplasia of the hip by performing the Ortolani and Barlow maneuvers (refer to Chapter 44 for additional information). These maneuvers are usually best performed by a proficient examiner. Inspect and palpate the child's upper and lower extremities. Assess for symmetry in size, contour, movement, warmth, and color of the extremities. The infant's feet and legs appear bowed secondary to *in utero* positioning but can be straightened through passive range of motion. Observe the child in a standing position. Bowing of the lower legs (internal tibial torsion) lessens as the toddler begins to bear weight and usually resolves in the second or third year of life as the strength of the muscles and bones increases. When it persists past that time, it is termed genu varum (bow legs). Genu valgum (knock knee) is usually present until the child is 7 years old. Observe the child walking, noting any difficulty with leg position or balance.

If the child is reluctant to walk, use play as a way to elicit the behavior. The school-age child should have gait and leg appearance similar to that of the adult.

Note the normal flat foot in the toddler and young child. The arch develops as the child grows and the muscles become less lax, though some children may continue with flexible flat feet; this is considered a normal variation.

Perform passive range of motion of the young infant's extremities. Inability to straighten the foot to midline may indicate clubfoot. Count the fingers and toes, noting abnormalities such as polydactyly (increased number of digits) or syndactyly (webbing of the digits). Palpate the joints for warmth or tenderness. Check the mobility of the joints of the upper and lower extremities by performing range of motion. Determine lower extremity muscle strength by having the child push against the examiner's hands with the soles of the forefoot. Assess upper extremity strength by having the child squeeze the examiner's crossed fingers and/or push up or down against the examiner's outstretched hands.

▶ ***Take*** *NOTE!*

Slight tremors may be noticed in the infant's extremities in the first month of life.

Neurologic

The neurologic examination should include level of consciousness, balance and coordination, sensory function, and reflexes. Motor function is assessed within the musculoskeletal section. Cranial nerve function is generally tested within other portions of the physical assessment as it applies to that section.

Level of Consciousness

Note the state of alertness and attentiveness to parents and the environment in the newborn and infant. Older infants become interactive with other people, as do toddlers and preschoolers. Younger children demonstrate orientation by positive interaction with family members and by crying or fussing when they feel threatened. By school age, the child should be oriented to name and place and a few years later should be able to state the date as well (even if only the day of the week).

Balance and Coordination

Balance and coordination are controlled by the cerebellum. Observe the child's gait to assess balance and coordination. Observe toddlers and older children rising and walking from a seated and supine position. They should be able to stand and balance without straining or holding on to objects. Continue to test cerebellar function by having the younger child skip or hop and requesting that the older child or adolescent walk heel to toe. Further tests of cerebellar function responsible for balance and coordination are discussed in Box 31.3. Demonstrate each test and make sure the child understands your instructions.

Sensory Testing

Portions of sensory testing related to most of the cranial nerves, vision, hearing, taste, and smell have already been incorporated into other sections as appropriate within the physical assessment. Test cranial nerve V (trigeminal) by lightly touching the child's cheek with a cotton ball. The young infant will root toward the side that is touched. With the child's eyes closed, ask the child to identify other locations where he or she is lightly touched (several different ones) to assess sensation. Ask the child to tell you when he or she is touched. Make a game of this activity to encourage cooperation in younger children. In the older child who knows the definition of sharp and dull, test for these sensations with the child's eyes closed. Use the rounded end of a tongue blade for dull and the broken edge of a tongue blade for the sharp sensation. The child should be able to discriminate the sensations of sharp and dull.

BOX 31.3 Cerebellar Function Testing

- **Romberg:** Ask the school-age or older child to stand still with eyes closed and arms down by the sides. Observe the child for leaning (stand close in case this does occur). This is considered a positive Romberg test, indicating cerebellar dysfunction.

For the following tests, the child should demonstrate accuracy and smoothness:

- **Heel-to-shin:** Have the child lie in a supine position, place one heel on the opposite knee, and run it down the shin.
- **Rapid alternating movements:** The child pats the thighs with the hands, lifts them, turns them over, pats the thighs with the back of the hands, and repeats the process multiple times. An alternate test is for the child to touch the thumb to each finger of the same hand starting at the index finger, then reverse the direction and repeat.
- **Finger-to-finger:** The child's eyes are open. The child touches the examiner's outstretched finger with the index finger, then touches his or her own nose. The examiner moves the finger to a different spot and the child repeats this process several times.
- **Finger-to-nose:** The child's eyes are closed. The child stretches the arm with the index finger extended, then touches his or her nose with that finger, keeping the eyes closed.

Reflexes

Assess the infant's primitive and protective reflexes. The primitive reflexes involve a whole-body response and are subcortical in nature. Selected primitive reflexes present at birth include Moro, root, suck, asymmetric tonic neck, plantar and palmar grasp, step, and Babinski. Most of the primitive reflexes diminish over the first few months of life, giving way to protective or postural reflexes. Protective reflexes are motor responses related to maintenance of equilibrium. They are necessary for appropriate motor development and remain throughout life once they are established. The protective reflexes include the righting and parachute reactions.

Place one finger in each of the infant's hands to elicit the palmar grasp reflex (usually disappears by age 3 to 4 months). Touch the thumb to the ball of the infant's foot to elicit the plantar grasp reflex. The infant's toes will curl down (this reflex disappears by 8 to 10 months). Refer to Table 25.2 and Figures 25.1 through 25.6 in Chapter 25 for additional explanation of the other reflexes. Appropriate presence and disappearance of primitive reflexes, as well as development of protective reflexes, is indicative of a healthy neurologic system. Primitive reflexes that persist beyond the usual age of disappearance may indicate an abnormality of the neurologic system and should be further investigated.

Assess deep tendon reflexes in all infants and children. Appropriate responses indicate that the reflex arc is intact. Use the reflex hammer in all ages or the curved tips of the two first fingers to elicit the responses in infants. The limb must be relaxed and the muscle partly stretched. Use a snapping motion of the wrist to tap with the fingertips or the reflex hammer. Test the biceps, triceps, patellar, and Achilles reflexes as you would in the adult. It may help to place a finger under the infant's knee to encourage relaxation. Young children who tense up when their reflexes are being tested may relax the area if you have them focus on another area, so have the child clasp the hands while testing the Achilles and patellar reflexes. As the child focuses on the hands, the lower extremities relax. Distraction may also be helpful.

Grade the strength of the response using the standard scale from 0 to 4+:

- 0: no response
- 1+: diminished or sluggish
- 2+: average
- 3+: brisker than average
- 4+: very brisk, may involve clonus

The newborn's deep tendon reflexes are normally brisk (3+). They decrease to average (2+), usually by 4 months of age. Healthy children should have reflexes of 2+ if the reflex has been elicited properly. Absent, sluggish, or hyperreactive responses usually indicate disease.

Refer back to Elliot, the 3-year-old from the beginning of the chapter. What are some important considerations when performing his physical examination?

Key Concepts

- The health history in children includes more than just the chief complaint, history of present illness, and past medical history; it is important to include the perinatal history and developmental milestones.
- Allow the chief complaint to determine which parts of the history require more in-depth investigation.
- The developmental history will warrant more attention in the younger child, while school performance and adjustment will be more important in the school-age child and adolescent.
- Though the parent will provide most of the health history for the infant and young child, allow the young verbal child to answer questions during the health history as appropriate.
- Direct health history questions to the school-age child and adolescent, seeking clarification from the parents as needed.
- Provide confidentiality and privacy for the adolescent during the health history.
- Weight and length or height should be assessed at each well-child visit to determine adequacy of growth.
- Measure head circumference until age 3 years to monitor brain growth.
- Perform hearing and vision screenings for children of all ages.
- BMI can be used to identify children who are overweight or at risk for being overweight.
- The normal range of vital signs varies based on the child's age.
- The sequence of the physical examination in children should be based on the child's developmental age, his or her level of cooperation, and the severity of the illness.
- Obtain heart rate and respiratory rate and auscultate the heart and lungs while the infant or young child is quiet.
- Perform intrusive procedures such as examination of the ears, mouth, and throat last in the infant or young child.
- Perform the health assessment in a head-to-toe fashion in the school-age child or adolescent, reserving the genitalia and anus examination for last.
- Plan the health assessment in such a way as to minimize trauma to the child or adolescent.
- Use age-appropriate measurement tools to assess pain in children.
- Allow the infant or young child to remain in the parent's lap for as much of the assessment as possible so that the child feels secure.

- Use age-appropriate games during the health assessment to gain cooperation in the younger child.
- Having the young boy sit cross-legged for a testicular examination may reduce the cremasteric reflex.
- The newborn may exhibit a wide variety of normal skin variations.
- The infant's fontanels should be soft and flat; report a bulging fontanel immediately.
- Jaundice (outside of the newborn period), pallor, cyanosis, and poor skin turgor indicate illness and may need immediate intervention.
- Heart murmurs should be assessed for intensity, location, and duration. They may be innocent or may indicate a congenital heart defect.
- The infant's chest wall is relatively thin, allowing upper airway sounds to be transmitted throughout the lung fields.
- Substernal or xiphoid retractions indicate that the child is laboring to breathe, whereas a fixed, depressed sternum (pectus excavatum) is a structural abnormality.
- The Tanner stages of sexual maturity provide a basis for assessing pubertal development in boys and girls. Use the breast and pubic hair charts for girls and the pubic hair and penis and scrotum size chart for boys.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

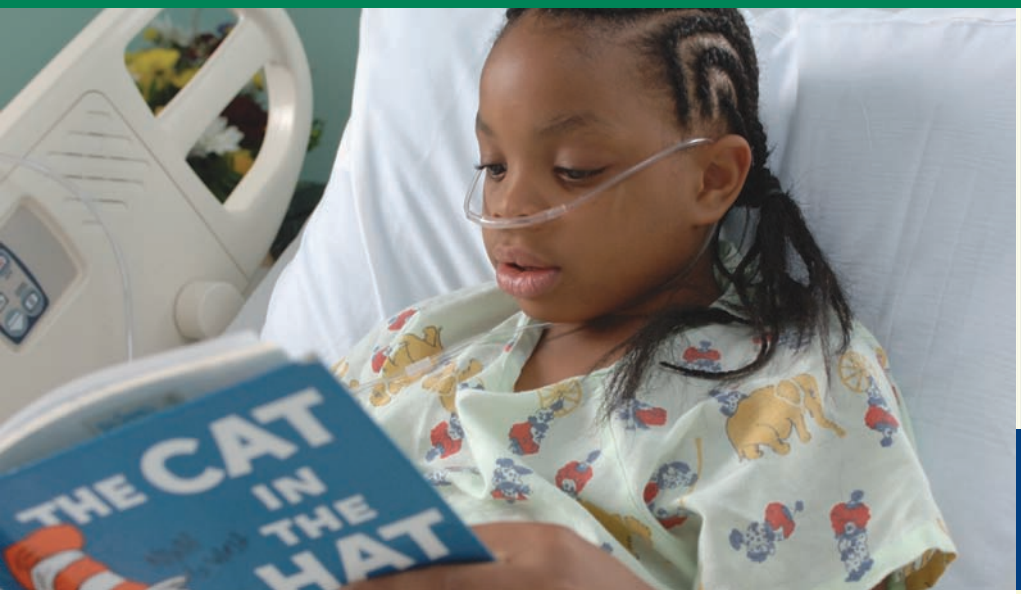
1. A 5-year-old boy visits the physician's office with an upper respiratory infection. Which approach would give the nurse the most information about the child's developmental level?
   a. Playing a game with the child.
   b. Talking with the child about the teddy bear next to him.
   c. Using a screening tool during a follow-up office visit.
   d. Asking the 10-year-old sibling about the child.
2. Which statement indicates the best sequence for the nurse to conduct an assessment in a non-emergency situation?
   a. Introduce yourself, ask about any problems, take a history, do the physical examination.
   b. Perform the physical examination and then ask the family if there are any problems in the child's life.
   c. Do the physical examination while at the same time asking about the child's previous illnesses; then talk about the family's concerns.
   d. Get a complete history of the family's health beliefs and practices, then assess the child.
3. What approach by the nurse would most likely encourage a child to cooperate with an assessment of physical and developmental health?
   a. Explain to the child what's going to happen when the child asks questions.
   b. Explain what is going to happen in words the child can understand.
   c. Force them to cooperate by having a parent hold them down.
   d. Give the child a sticker before beginning the examination.
4. A sleeping 5-month-old girl is being held by the mother when the nurse comes in to do a physical examination. What assessment should be done initially?
   a. Listening to the bowel sounds.
   b. Counting the heart rate.
   c. Checking the temperature.
   d. Looking in the ears.
5. Which assessment finding is considered normal in children?
   a. Irregular respiratory rate and rhythm.
   b. Split S2 and sinus arrhythmia.
   c. Decreased heart rate with crying.
   d. Genu varum past the age of 5 years.

CRITICAL THINKING EXERCISES

1. A soft and muffled heart murmur is heard in a 4-year-old patient. The mother states that she has never heard that the child has a murmur. What should the nurse do?
2. A nurse is helping a new mother breastfeed her 4-day-old baby. The mother notices that the baby has a bluish cast to the skin on his hands and that sometimes the infant has a tremor. She asks the nurse if the baby is cold, though the baby is swaddled and comfortably resting against the mother's skin. How might the nurse help teach this mother?
3. Devise a plan for encouraging cooperation of the toddler or preschooler during various parts of the physical examination.

STUDY ACTIVITIES

1. In the clinical setting, obtain a health history on an infant, child, or adolescent.
2. In the clinical setting, compare the approach you use for the physical examination of a toddler versus a school-aged child or adolescent.
3. No matter how thoughtfully and appropriately you plan your assessment, odds are good that you will have difficulty assessing a 2-year-old. Discuss with your classmates the strategies that you have used for success and brainstorm with them about their ideas for assessing a crying or resistant young child.



CHAPTER 32

Nursing Care of Children During Illness and Hospitalization

KEY TERMS

child life specialist
denial
magical thinking
regression
sensory deprivation
sensory overload
separation anxiety
therapeutic hugging
therapeutic play

LEARNING OBJECTIVES

Upon completion of the chapter, the learner will be able to:

1. Identify the major impact and stressors of illness and hospitalization for children in the various developmental stages.
2. Identify the reactions and responses of children and their families during illness and hospitalization.
3. Explain the factors that influence the reactions and responses of children and their families during illness and hospitalization
4. Describe the nursing care that minimizes stressors for children who are ill or hospitalized.
5. Discuss the major components of admission for children to the hospital.
6. Outline the nursing interventions required for children in specific units or situations in the hospital.
7. Discuss appropriate safety measures to use when caring for children of all ages.
8. Describe basic care procedures for children in various health care settings.
9. Review the major components and nursing responsibilities related to client education and discharge from the hospital.

Jake Jorgenson, 8 years old, was brought to the clinic with a history of headaches, vomiting not related to feeding, and changes in his gait. Initial testing leads to a suspected brain tumor. Jake is to be admitted to the neurologic service at a pediatric hospital for further testing and treatment. Up until this point he has been a healthy child with no previous hospitalizations. He lives at home with his parents and two siblings, Jenny, age 11, and Joshua, age 5. As a nurse on this unit, how can you help prepare Jake and his family for this hospitalization?

Wow

Sick children need love, hope, faith, and most of all a positive attitude from their nurse.

Illness, with the occasional consequence of hospitalization, affects children and their families in a variety of ways. Hospitalization is often confusing, complex, and overwhelming for children and their families. Reactions and responses to illness and hospitalization depend on a number of factors, including the child's developmental stage. Nursing strategies are needed to prepare children and their families for this experience while minimizing negative effects. These strategies include identifying the needs of children and families through astute assessment of nonverbal and verbal behaviors, then validating the information with accurate interpretation and providing appropriate responses and interventions.

Although the nurse implements these strategies throughout the interaction with the child and family, a critical time to ensure the best outcome for the child and family is during the admission process. The nurse assesses the learning needs and abilities of the child and family. For the interventions to be successful, the nurse must communicate and teach in the most effective method for the individual child and family. The nurse also evaluates the child's and family's competence in performing specific activities prior to discharge.

Hospitalization in Childhood

In today's health care environment, children receive much of their care for illnesses in community health settings such as physician's offices, urgent care settings, or day surgery centers. As a result of this trend, fewer children may actually be admitted to a hospital unit, and those who are hospitalized are generally acutely ill. In addition, hospital stays are often shorter due to economic trends in the health care environment, such as the delivery system of managed care and other factors that attempt to control costs. Acute conditions, trauma, or chronic diseases or illnesses requiring surgical intervention lead to hospitalization for children.

According to Child Health USA 2005, diseases of the respiratory system account for the majority of hospitalizations in children under 5 years of age, while diseases of the respiratory system, mental health problems, injuries, and gastrointestinal disorders lead to more hospitalizations in older children. Adolescents between 15 and 19 years of age are often hospitalized because of problems related to pregnancy, childbearing, and mental health (U.S. Department of Health and Human Services, 2005).

Other health problems begin before birth or immediately following birth, such as congenital heart disease or gastrointestinal atresia. Just when they are getting used to the idea of having a new child, the family must also deal with illness and possibly extended hospitalizations. Specific genetic or environmental factors also predispose the child to disease and injury, such as the genetic disorder of hemophilia or the environmental situation of homelessness. Many of these factors or situations put the child and family at greater risk for chronic health conditions and long periods of illness, hospitalization, and even death.

Children's Reactions to Hospitalization

In general, children are more vulnerable to the effects of illness and hospitalization because this is a change from their usual state of health and routine. They also have limited understanding and coping mechanisms to assist them in resolving the stressors that might occur during this time. Hospitalization creates a series of traumatic and stressful events in a climate of uncertainty for children and their families, whether it is an elective procedure that is planned in advance or an emergency situation resulting from trauma. The stressors that children experience in relation to hospitalization may result in various reactions. Children react to the stresses of hospitalization before admission, during hospitalization, and after discharge.

Besides the physiologic effects of the health problem, the effects of illness and hospitalization on a child include anxiety and fear related to the overall process and the potential for bodily injury, physical harm, and pain. In addition, children are separated from their homes, families, friends, and what is familiar to them, which may result in **separation anxiety** (distress related to removal from family and familiar surroundings). There is a general loss of control over their lives and sometimes their emotions and behaviors. The result may be feeling of anger and guilt, **regression** (return to a previous stage of development), acting out, and other types of defense mechanisms to cope with these effects. Children's typical coping strategies are tested during this experience.

Fear and Anxiety

For many children entering the hospital is like entering a foreign world. The result is fear and anxiety. Often anxiety stems from the rapid onset of the illness or injury, particularly when the child has limited experiences with disease or injury. The child becomes distressed about the unfamiliar environment, procedures, and situations, such as the strange words being used, ominous-looking equipment, strangers in unusual attire (e.g., surgical caps, masks, gowns), unfamiliar and frightening noises and smells, or the sounds of other children crying. Overall, hospitalization is a difficult experience for children.

Normal fears of childhood include the fear of separation, loss of control, and bodily injury, mutilation, or harm. Children's fears are similar to adult fears of the unknown, including fear of unfamiliar environments and losing control. In the hospital, children may be exposed to people, situations, and procedures that may be new to them and cause them pain (Fig. 32.1).

FIGURE 32.1 The presence of familiar objects and home routines normalizes the environment and helps the child cope with hospitalization. Reading a favorite bedtime story can be comforting.

▶ ***Take*** NOTE!

Wollin et al. (2004) interviewed 120 children between the ages of 5 and 12 and their parents to assess preoperative anxiety and fear. Needles, postoperative pain, the unknown, and the presence of many unrecognizable people in the room increased anxiety for children.

Separation Anxiety

Separation anxiety is a major stressor for children of certain ages. It occurs most frequently in children from middle infancy throughout the preschool years, with the peak incidence occurring between the ages of 6 and 30 months.

Separation anxiety consists of three stages. The first phase, protest, occurs when the child is separated from the parents or primary caretaker. This phase may last from a few hours to several days. The child reacts aggressively to this separation and exhibits great distress by crying, expressing agitation, and rejecting others who attempt to offer comfort. The child may also display anger and inconsolable grief.

If the parents do not return within a short time, the child exhibits the second phase, despair. The child displays hopelessness by withdrawing from others, becoming quiet without crying, and exhibiting apathy, depression, lack of interest in play and food, and overall feelings of sadness.

Detachment (also known as **denial**) is the third and final phase of separation anxiety. During this phase the child forms coping mechanisms to protect against further emotional pain. This occurs more often in long-term separations. During this stage, the child shows interest in the environment, starts to play again, and forms superficial relationships with the nurses and other children. If the parents return, the child ignores them. A child in this phase of separation anxiety exhibits resignation, not contentment. It is more difficult to reverse this stage, and developmental delays may occur.

Today, health care providers primarily observe the first and second stages because of the shorter hospital stays and the more common use of a family-centered approach to care.

Loss of Control

When hospitalized, children experience a significant loss of control. This loss of control increases the perception of threat and affects their coping skills. They lose control over routine self-care and their usual tasks and play as well as decisions related to the care of their own bodies. In the hospital, the child's usual routine is disrupted. He or she cannot choose what to do and at what time. The child can no longer accomplish simple tasks independently as he or she does at home or school. Confinement to the bed or crib worsens this loss of control. For example, if connected to tubes or intravenous lines, the child may not even be able to visit the bathroom alone.

Hospitalization also affects the child's control over decisions related to his or her own body. Many of the procedures and treatments that occur in the hospital are invasive or are at least disturbing to children, and much of the time they do not have the option to refuse to undergo them. Adults are presumed to be competent to make health care decisions, but generally children are not. Though the parents and nurses of hospitalized children have the children's best interest in mind, children often feel powerless when in the hospital, not having their feelings and wishes respected and having minimal control over events.

▶ ***Take*** NOTE!

When advocating for a child, make sure to include the child's voice. Do not assume what his or her wishes may be; ask about them directly.

Reactions Based on Developmental Level

Children's responses to the stressors of fear, separation anxiety, and loss of control vary depending on their age and developmental level. Although children are increasingly able to adapt as they grow older, lack of understanding about the need for hospitalization can make adaptation difficult. Moreover, hospitals threaten the sense of control that children are striving for as they develop (Romino et al., 2005).

Infants

Newborns and infants are adapting to life outside the womb with rapid growth and development and establish-

ment of a healthy attachment to parents or primary caregivers. They are dependent on others for nurturance and protection. They gain a sense of trust in the world through rhythmic and reciprocal patterns of contact and feeding, resulting in bonding to the primary caregiver. They need a secure pattern of restful sleep, satisfaction of oral and nutritional needs, relaxation of body systems, and spontaneous response to communication and gentle stimuli. The caregiver–infant attachment is critical for psychological health, especially during periods of illness and hospitalization.

Unfortunately, during illness and hospitalization, these critical patterns of feeding, contact, comfort, sleeping, elimination, and stimulation are disrupted, resulting in fear, separation anxiety, and loss of control. By 5 to 6 months of age, infants have developed an awareness of self as separate from mother. As a result, infants of this age are acutely aware of the absence of their primary caregiver and become fearful of unfamiliar persons. Infants may be separated from their parents when hospitalized if the parents cannot room-in because of hospital policy or if they must work or care for other children. This results in separation anxiety.

The infant's oral needs, the basic source of infant satisfaction, are often not met in the hospital due to the condition of the child or the procedures that must be performed. The infant is accustomed to having his or her basic needs met by the parent when he or she cries or gestures. The constraints of hospitalization result in loss of control over the environment, leading to additional anxiety in the infant.

Toddlers

Toddlers are more aware of self and can communicate their desires. Because their autonomy is developing, toddlers need to master accomplishments to minimize the development of shame and doubt. Control becomes an issue for toddlers. Toddlers also need opportunities to explore, and they need consistent routines. In addition, toddlers are aware of the need for care and protection from others, so they need familiarity and closeness to the primary caregiver. When the toddler is hospitalized, disruption occurs in this development of autonomy.

Toddlers are often fearful of strangers and can recall traumatic events. Simply walking toward the treatment room where a traumatic procedure previously occurred may upset the toddler. Ordinarily a resurgence in separation anxiety occurs during the toddler years. When the toddler is separated from his or her parents or caregivers in an unfamiliar environment, separation anxiety is compounded. In response to this anxiety, toddlers may demonstrate behaviors such as pleading for the parents to stay, physically trying to go after the parents, throwing temper tantrums, and refusing to comply with usual routines. Restrictions related to mobility and new skill acquisition result in loss of control. Disruption in usual routines also contributes to loss of control, and the toddler feels insecure. As a result, regression in toilet training and refusal to eat are common reactions in toddlers.

Preschoolers

The preschooler has better verbal and developmental skills to adapt to various situations, but illness and hospitalization can still be stressful. Preschoolers may understand that they are in the hospital because they are sick, but they may not understand the cause of their illness. Preschoolers fear mutilation and are afraid of intrusive procedures since they do not understand the body's integrity. They interpret words literally and have an active imagination. Therefore, when the nurse says, "I need to take some blood," preschoolers' fantasies may run wild. They may not understand the concept of blood and may think everything will come out of their body. They may think that blood is "taken" the same way a child picks up a toy to take it out of the room. Preschoolers' thinking is egocentric; they believe that some personal deed or thought caused their illness, which can lead to guilt and shame. These feelings may be internalized. Overall, preschoolers' concrete, egocentric, and **magical thinking** (type of thinking that allows for fantasies and creativity) limits their ability to understand, so communication and interventions must be on their level.

Separation anxiety may not be as much of an issue as it is for toddlers since preschoolers may already be spending time away from parents in preschool. They are, however, still acutely aware of the comfort and security that their family provides for them, so disruptions in these relationships lead to challenges. The preschooler may constantly ask for his or her parents or ask to call the parents. He or she may quietly cry, refuse to eat or take medication, or generally be uncooperative.

In addition, the hospitalized preschooler loses control over the environment. The preschooler is naturally curious about his or her surroundings and learns best by observing and working with objects. This might be limited during hospitalization. Because the preschooler cannot participate in typical activities and explore the environment as usual, the child's normal creative, curious nature may give rise to a variety of fantasies that may present challenges.

School-Age

School-age children generally are hospitalized because of long-term illnesses or trauma. The general task of their development stage, to develop confidence through a sense of industry, can be disrupted during hospitalization. Even at this time, they generally want to continue to learn and maintain their skills and abilities. The stress of illness or anxiety related to diagnostic tests and therapeutic interventions may lead to inward or outward expressions of distress. If they have learned various coping skills, this distress may be minimized. After 11 years of age there is an increased awareness of physiologic, psychological, and behavioral causes of illness and injury. Typically, the school-age child

has a more realistic understanding of the reasons for the illness and can better comprehend explanations. School-age children are concerned about disability and death, and they fear injury and pain. They want to know why procedures and tests are being performed. They can understand cause and effect and how it relates to their illness. They are uncomfortable with any type of sexual examination.

Separation anxiety is not as much of an issue for school-age children. They are accustomed to periods of separation and may already be experiencing some separation anxiety related to being in school. At the same time, they may be missing school and friends as they try to adjust to the unfamiliar environment. They may feel that friends will forget them if they remain in the hospital for a long time. Some school-age children may regress and become needy, demanding their parents' attention or playing with special "comfort toys" they used at a younger age.

Since school-age children are accustomed to controlling self-care and typically are highly social, they like being involved. They are used to making choices about meals and activities. Hospitalization presents loss of control by limiting their activities, making them feel helpless and dependent. This may result in feelings of loneliness, boredom, isolation, and depression. The key is to give them opportunities to maintain independence, retain a sense of control, enhance self-esteem, and continue to work toward achieving a sense of industry.

Adolescents

Adolescents fear injury and pain. Since appearance is important to them, they are concerned with how the illness or injury will affect their body image. Anything that changes their perceptions of themselves has a major impact on their response. Typically, adolescents do not like to be different; they like "being cool," which means being in control and not showing how afraid they really are. They also may feel ambivalent about wanting their parents. Adolescents typically do not experience separation anxiety from being away from their parents; instead, their anxiety comes from being separated from friends.

Loss of control is a key factor affecting the behavior of adolescents who are hospitalized. Anger, withdrawal, or general lack of cooperation may occur due to the feelings of loss of control. In addition, their desire to appear confident may led them to question everything that is being done or that they are asked to do. Their feelings of invincibility may cause them to take risks and be noncompliant with treatment. Overall, adolescents strive for independence, self-assertion, and liberation while developing their identity.

Factors Affecting Children's Reaction to Hospitalization

Various factors have a great impact on the ability of children to handle illness and hospitalization. These factors may increase or diminish the fears of the child who is ill and hospitalized. Each child responds differently and will perceive the hospital experience differently. Box 32.1 lists the various factors affecting a child's response to illness and hospitalization.

Developmental Abilities and Perceptions

The child's age, cognitive level, and developmental level will affect his or her perceptions of actual events, and this in turn will affect his or her reaction to illness and hospitalization. Younger children, with their limited life experience and immature intellectual capacities, have a more difficult time comprehending what is happening to them. This can be particularly true for toddlers and preschoolers, who perceive the intactness of their bodies to be exposed during physical intrusions. In addition, they frequently interpret illness as punishment for wrongdoing or hospital procedures as hostile, mutilating acts. Thus, children younger than 5 are more vulnerable to emotional distress from hospitalization.

Previous Experiences

In general, children's lack of understanding and experience of illness, hospitalization, and hospital procedures contributes to their anxiety level. However, previous experience with hospitalization and other health-related experiences can either facilitate preparation or impair it if the experiences were perceived as negative. For example, the child who associates the hospital with the birth of a sibling may view this experience as positive. However, the child who associates the hospital with the serious illness or death of a relative or close friend will probably view the experience as negative.

BOX 32.1 Factors Affecting a Child's Response to Illness and Hospitalization

- Amount of separation from parent/caregiver
- Age
- Developmental level
- Cognitive level
- Previous experience with illness and hospitalization
- Recent life stresses and changes
- Type and amount of preparation
- Temperament
- Innate and acquired coping skills
